- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.

- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.25 Mailbox Import Export Role

Mailbox Import Export Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Mailbox Import Export` management role enables administrators to import and export mailbox content and to purge unwanted content from a mailbox.

For information about how to assign this role to a role group, see Managing Mailbox Import and Export Requests.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more

information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-**

ManagementRoleAssignment cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:
The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.26 Mailbox Search Role

Mailbox Search Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Mailbox Search` management role enables administrators to search the content of one or more mailboxes in an organization.

This management role is one of several built-in roles in the Role Based Access Control

(RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.

- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Discovery Management	X		Organization	Organization	None	None
Organization Management		X	Organization	Organization	None	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group

- Remove a Role from a User or USG

4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.27 Message Tracking Role

Message Tracking Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Message Tracking` management role enables administrators to track messages in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't

be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment

- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Records Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

Migration Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Migration` management role enables administrators to migrate mailboxes and mailbox content into or out of a server.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role

assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a

role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.29 Monitoring Role

Monitoring Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Monitoring management role enables administrators to monitor Exchange services and component availability in an organization. This role can also be used with service accounts used by monitoring applications to collect information about the state of servers running Exchange.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
View-Only Organization Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following

topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.30 Move Mailboxes Role

Move Mailboxes Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Move Mailboxes` management role enables administrators to move mailboxes between servers in an organization and between servers in the local organization and another organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

In addition to recipient scopes, the **New-MoveRequest** cmdlet, which is included with this role, is also scoped using database configuration scopes. Database configuration scopes control which databases the cmdlet can move mailboxes to. The database where you want to move a mailbox must be within the database scope. This condition applies when you specify a database using the *TargetDatabase* parameter on the **New-MoveRequest** cmdlet or if you allow automatic mailbox distribution to select the database for you. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Automatic Mailbox Distribution

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

MyAddressInformation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyAddressInformation` management role enables individual users to view and modify their street address and work telephone and fax numbers. This is a custom role created from the MyContactInformation Role parent role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role.

This role is a specific type of role called a custom role. A custom role is one that's created, or derived, from a parent role. It contains a subset of management role entries that exist on the parent role. This role is provided to enable you to control, with a greater level of granularity, the information you allow end users to modify on their own mailboxes. Unlike other built-in roles, custom roles, including this one, can be deleted. If you won't use this role, it can be deleted.

For more information about built-in and custom management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, its parent role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role doesn't have any default role assignments. It's provided in case you want control, at a more granular level, of what end-user information you allow your users to modify. For more information about assigning this role to a role assignment policy, see the "Adding or Removing Role Assignments" section.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets,

and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.32 MyBaseOptions Role

MyBaseOptions Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyBaseOptions` management role enables individual users to view and modify the basic configuration of their own mailbox and associated settings.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Default role assignment policy. For more	X		Self	Self	OrganizationConfig	OrganizationConfig

information, see Understanding Management Role Assignment Policies.						
Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.33 MyContactInformation Role

MyContactInformation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyContactInformation` management role enables individual users to modify their contact information, including address and phone numbers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:
You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee

the ability to assign this role to role groups, users, or USGs.

- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default role assignment policy. For more information, see Understanding Management Role Assignment Policies.	X		Self	Self	OrganizationConfig	OrganizationConfig
Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.34 MyDiagnostics Role

MyDiagnostics Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyDiagnostics` management role enables individual users to perform basic diagnostics on their mailbox such as retrieving calendar diagnostic information.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC

components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.35 MyDisplayName Role

MyDisplayName Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyDisplayName` management role enables individual users to view and modify their display name. This is a custom role created from the MyProfileInformation Role parent role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are

included on a role, that cmdlet or script and its parameters can be run by those assigned the role.

This role is a specific type of role called a custom role. A custom role is one that's created, or derived, from a parent role. It contains a subset of management role entries that exist on the parent role. This role is provided to enable you to control, with a greater level of granularity, the information you allow end users to modify on their own mailboxes. Unlike other built-in roles, custom roles, including this one, can be deleted. If you won't use this role, it can be deleted.

For more information about built-in and custom management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, its parent role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the

"Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role doesn't have any default role assignments. It's provided in case you want control, at a more granular level, of what end-user information you allow your users to modify. For more information about assigning this role to a role assignment policy, see the "Adding or Removing Role Assignments" section.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:

- Change a Role Entry
- Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.36 MyDistributionGroupMembership Role

MyDistributionGroupMembership Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyDistributionGroupMembership` management role enables individual users to view and modify their membership in distribution groups in an organization, provided that those distribution groups allow manipulation of group membership.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Default role assignment policy. For more information, see Understanding Management Role Assignment Policies.	X		MyGAL	MyGAL	None	None
Organization Management		X	MyGAL	MyGAL	None	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features.

By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.37 MyDistributionGroups Role

MyDistributionGroups Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyDistributionGroups` management role enables individual users to create, modify, and view distribution groups, and to modify, view, remove, and add members to distribution groups they own.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope

Organization Management		X	MyGAL	MyDistributionGroups	OrganizationConfig	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.38 MyMobileInformation Role

MyMobileInformation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyMobileInformation` management role enables individual users to view and modify their mobile telephone and pager numbers. This is a custom role created from the MyContactInformation Role parent role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role.

This role is a specific type of role called a custom role. A custom role is one that's created, or derived, from a parent role. It contains a subset of management role entries that exist on the parent role. This role is provided to enable you to control, with a greater level of granularity, the information you allow end users to modify on their own mailboxes. Unlike other built-in roles, custom roles, including this one, can be deleted. If you won't use this role, it can be deleted.

For more information about built-in and custom management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't

add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, its parent role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role doesn't have any default role assignments. It's provided in case you want control, at a more granular level, of what end-user information you allow your users to modify. For more information about assigning this role to a role assignment policy, see the "Adding or Removing Role Assignments" section.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.39 MyName Role

MyName Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The MyName management role enables individual users to view and modify their full name and their notes field. This is a custom role created from the MyProfileInformation Role parent role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role.

This role is a specific type of role called a custom role. A custom role is one that's created, or derived, from a parent role. It contains a subset of management role entries that exist on the parent role. This role is provided to enable you to control, with a greater level of granularity, the information you allow end users to modify on their own mailboxes. Unlike other built-in roles, custom roles, including this one, can be deleted. If you won't use this role, it can be deleted.

For more information about built-in and custom management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, its parent role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role doesn't have any default role assignments. It's provided in case you want control, at a more granular level, of what end-user information you allow your users to modify. For more information about assigning this role to a role assignment policy, see the "Adding or Removing Role Assignments" section.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.40 MyPersonalInformation Role

MyPersonalInformation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyPersonalInformation` management role enables individual users to view and modify their Web site address and home telephone number. This is a custom role created from the MyContactInformation Role parent role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role.

This role is a specific type of role called a custom role. A custom role is one that's created, or derived, from a parent role. It contains a subset of management role entries that exist on the parent role. This role is provided to enable you to control, with a greater level of granularity, the information you allow end users to modify on their own mailboxes. Unlike other built-in roles, custom roles, including this one, can be deleted. If you won't use this role, it can be deleted.

For more information about built-in and custom management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role

assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, its parent role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role doesn't have any default role assignments. It's provided in case you want control, at a more granular level, of what end-user information you allow your users to modify. For more information about assigning this role to a role assignment policy, see the "Adding or Removing Role Assignments" section.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions.

Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.41 MyProfileInformation Role

MyProfileInformation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyProfileInformation` management role enables individual users to modify their name.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which

are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at

least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a

complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.42 MyRetentionPolicies Role

MyRetentionPolicies Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyRetentionPolicies` management role enables individual users to view their retention tags, and to view and modify their retention tag settings and defaults.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment

policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group or assignment policy	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

MyTextMessaging Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyTextMessaging` management role enables individual users to create, view, and modify their text messaging settings.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:

You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in

Active Directory.

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry

- Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.44 MyVoiceMail Role

MyVoiceMail Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `MyVoiceMail` management role enables individual users to view and modify their voice mail settings.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, such as a role assignment policy. This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

Note:
You can also assign this management role to a role group, USG, or directly to a user. However user-focused roles are most effective when used with role assignment policies.

This user-focused role has implicit scopes that can't be modified. Therefore, you shouldn't add custom scopes to role assignments that assign this role to role assignment policies, role groups, USGs, or users.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role may be assigned to one or more role assignment policies by default. For more information, see the "Default Management Role Assignments" section.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role assignment policies, or you can create role assignment policies and assign this role to them.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from the default role assignment policy, role assignment policies and role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Organization Management		X	Self	Self	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:
The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.45 Organization Client Access Role

Organization Client Access Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Organization Client Access` management role enables administrators to manage Client Access server settings in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of

Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:
There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in

Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the

role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.46 Organization Configuration Role

Organization Configuration Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Organization Configuration` management role enables administrators to manage organization-wide settings. Organization configuration that can be controlled with this role includes the following and more:

- Whether MailTips are enabled or disabled for the organization
- URL for the managed folder home page
- Microsoft Exchange recipient SMTP address and alternate e-mail addresses
- Resource mailbox property schema configuration
- Help URLs for the Exchange Management Console and Outlook Web App

This role type doesn't include the permissions included in the `Organization Client Access` or `Organization Transport Settings` roles.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions

granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope

- Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about

customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.47 Organization Transport Settings Role

Organization Transport Settings Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Organization Transport Settings` management role enables administrators to manage organization-wide transport settings, such as system messages, site

configuration, and other organization-wide transport settings.

This role doesn't enable you to create or manage transport Receive or Send connectors, queues, hygiene, agents, remote and accepted domains, or rules. To create or manage each of the transport features, you must be assigned one or more of the following roles:

- Receive Connectors Role
- Send Connectors Role
- Transport Queues Role
- Transport Hygiene Role
- Transport Agents Role
- Remote and Accepted Domains Role
- Transport Rules Role

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role

assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.

2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.48 POP3 and IMAP4 Protocols Role

POP3 and IMAP4 Protocols Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `POP3 and IMAP4 Protocols` management role enables administrators to manage POP3 and IMAP4 configuration, such as authentication and connection settings, on individual servers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organizatio	X	X	Organizat	Organizat	Organizat	Organizat

n Management			ion	ion	ionConfig	ionConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.49 Public Folder Replication Role

Public Folder Replication Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Public Folder Replication` management role enables administrators to start and stop public folder replication in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment

should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.50 Public Folders Role

Public Folders Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Public Folders` management role enables administrators to manage public folders in an organization.

This role doesn't enable you to manage whether public folders are mail-enabled or to manage public folder replication. To mail-enable or disable a public folder, you must be assigned a role associated with the `Mail Enabled Public Folders` role. To configure public folder replication, you must be assigned a role associated with the `Public Folder Replication` role. For more information, see:

- Mail Enabled Public Folders Role
- Public Folder Replication Role

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment

policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between

this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from

Active Directory.

- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Public Folder Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-**

ManagementRoleAssignment cmdlet. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.51 Receive Connectors Role

Receive Connectors Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Receive Connectors` management role enables administrators to manage transport Receive connector configuration, such as size limits on an individual server.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Hygiene Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of

this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.52 Recipient Policies Role

Recipient Policies Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Recipient Policies` management role enables administrators to manage recipient policies, such as provisioning policies, in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee

the ability to assign this role to role groups, users, or USGs.

- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

> **Important:**
> If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.53 Remote and Accepted Domains Role

Remote and Accepted Domains Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Remote and Accepted Domains` management role enables administrators to manage remote and accepted domains in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or

built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features.

By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.54 Retention Management Role

Retention Management Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Retention Management` management role enables administrators to manage retention policies in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a

member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.

- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Records Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove

any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:

- Remove a Role from a Role Group
- Remove a Role from a User or USG

4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.55 Role Management Role

Role Management Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Role Management` management role enables administrators to manage management role groups; role assignment policies and management roles; and role entries, assignments, and scopes in an organization.

Users assigned this role can override the role group managed by property, configure any role group, and add or remove members to or from any role group.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the

combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what

objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets,

and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.56 Security Group Creation and Membership Role

Security Group Creation and Membership Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Security Group Creation and Membership` management role enables administrators to create and manage universal security groups (USGs) and their memberships in an organization.

If your organization maintains a Role Based Access Control (RBAC) split permissions model where USG creation and management is performed by a different group other than those who manage servers running Exchange, assign this role to that group.

If your organization has enabled Active Directory split permissions, all non-delegating management role assignments to this management role were removed. When Active Directory split permissions is enabled, only Active Directory administrators using Active Directory management tools can create new security principals such as users and security groups.

For more information, see Understanding Split Permissions.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the

associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a

role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.57 Send Connectors Role

Send Connectors Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Send Connectors management role enables administrators to manage transport Send connectors in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organizatio	X	X	Organizat	Organizat	Organizat	Organizat

n Managemen t			ion	ion	ionConfig	ionConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.58 Support Diagnostics Role

Support Diagnostics Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Support Diagnostics` management role enables administrators to perform advanced diagnostics under the direction of Microsoft Customer Service and Support in an organization.

Caution:
This role grants permissions to cmdlets and scripts that should only be used under the direction of Customer Service and Support.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the

associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a

role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.59 Transport Agents Role

Transport Agents Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Transport Agents` management role enables administrators to manage transport agents in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Hygiene	X		Organizat	Organizat	Organizat	Organizat

Management			ion	ion	ionConfig	ionConfig
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.60 Transport Hygiene Role

Transport Hygiene Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Transport Hygiene` management role enables administrators to manage antivirus and anti-spam features in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment

should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Hygiene Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions.

Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.61 Transport Queues Role

Transport Queues Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Transport Queues` management role enables administrators to manage transport queues on an individual server.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned

the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role

group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.62 Transport Rules Role

Transport Rules Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Transport Rules` management role enables administrators to manage transport rules in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet.

For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Records Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a

role as a child of this role, and customize the new role.

Caution:
The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.63 UM Mailboxes Role

UM Mailboxes Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `UM Mailboxes` role enables administrators to manage the Unified Messaging configuration of mailboxes and other recipients in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment

policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between

this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from

Active Directory.

- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
UM Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-**

ManagementRoleAssignment cmdlet. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.64 UM Prompts Role

UM Prompts Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `UM Prompts` management role enables administrators to create and manage custom Unified Messaging voice prompts in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
UM Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about

customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.65 Unified Messaging Role

Unified Messaging Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Unified Messaging` role enables administrators to manage Unified Messaging (UM) servers in an organization.

This role doesn't enable you to manage UM-specific mailbox configuration or UM prompts. To manage UM-specific mailbox configuration, use roles associated with the `UM Mailboxes` role. To manage UM prompts, use the roles associated with the `UM Prompts` role. For more information, see:

- UM Mailboxes Role
- UM Prompts Role

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to

them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
UM Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the

following topics:
- Change a Role Entry
- Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.66 Unscoped Role Management Role

Unscoped Role Management Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Unscoped Role Management` management role enables administrators to create and manage unscoped top-level management roles in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the

combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what

objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management		X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets,

and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.67 User Options Role

User Options Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `User Options` management role enables administrators to view the Outlook Web App options of a user in an organization. This role can be used to help diagnose configuration problems.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly

increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.

- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Help Desk	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.68 View-Only Audit Logs Role

View-Only Audit Logs Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Audit Logs` management role enables administrators and specialist users to search the administrator audit logs in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or

built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features.

By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.69 View-Only Configuration Role

View-Only Configuration Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The View-Only Configuration management role enables administrators to view all the non-recipient Exchange configuration settings in an organization. Examples of configuration that are viewable are server configuration, transport configuration, database configuration, and organization-wide configuration.

This role can be combined with roles associated with the View-Only Recipients role to create a role group that can view every object in an organization. For more information, see View-Only Recipients Role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign

this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each

column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Delegated Setup	X		Organization	None	OrganizationConfig	None
Hygiene Management	X		Organization	None	OrganizationConfig	None
Organization Management	X	X	Organization	None	OrganizationConfig	None
View-Only Organization Management	X		Organization	None	OrganizationConfig	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a

built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.70 View-Only Recipients Role

View-Only Recipients Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `View-Only Recipients` management role enables administrators to view the configuration of recipients, such as mailboxes, mail users, mail contacts, distribution groups, and dynamic distribution groups.

This role can be combined with roles associated with the `View-Only Configuration` role to create a role group that can view every object in the organization. For more information, see View-Only Configuration Role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of

Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:
There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in

Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Help Desk	X		Organization	None	OrganizationConfig	None
Hygiene Management	X		Organization	None	OrganizationConfig	None
Organization Management	X	X	Organization	None	OrganizationConfig	None
View-Only Organization Management	X		Organization	None	OrganizationConfig	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-**

ManagementRoleAssignment cmdlet. For more information, see the following topics:

- Remove a Role from a Role Group
- Remove a Role from a User or USG

4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

> **Important:**
> If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.2 Understanding Split Permissions

Understanding Split Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-24*

Organizations that separate the management of Microsoft Exchange Server 2010 objects and Active Directory objects use what's called a *split permissions* model. Split permissions enable organizations to assign specific permissions and related tasks to specific groups within the organization. This separation of work helps to maintain standards and workflows, and helps to control change in the organization.

The highest level of split permissions is the separation of Exchange management and Active Directory management. Many organizations have two groups: administrators that manage the organization's Exchange infrastructure, including servers and recipients, and administrators that manage the Active Directory infrastructure. This is an important separation for many organizations because the Active Directory infrastructure often spans many locations, domains, services, applications, and even Active Directory forests. Active Directory administrators must ensure that changes made to Active Directory don't negatively impact any other services. As a result, typically only a small group of administrators is allowed to manage that infrastructure.

At the same time, the infrastructure for Exchange, including servers and recipients, can also be complex and require specialized knowledge. Additionally, Exchange stores extremely confidential information about the business of the organization. Exchange administrators can potentially access this information. By limiting the number of Exchange administrators, the organization limits who can make changes to Exchange configuration and who can access sensitive information.

Split permissions typically make a distinction between the creation of security principals in Active Directory, such as users and security groups, and the subsequent configuration of those objects. This helps to reduce the chance of unauthorized access to the network by controlling who can create objects that grant access to it. Most often only Active Directory administrators can create security principals while other administrators, such as Exchange administrators, can manage specific attributes on existing Active Directory objects.

To support the varying needs to separate the management of Exchange and Active Directory, Exchange 2010 lets you choose whether you want a shared permissions model or a split permissions model. Microsoft Exchange Server 2010 Service Pack 1 (SP1) offers two types of split permissions models: RBAC and Active Directory. Exchange 2010 SP1 defaults to a shared permissions model.

Contents

Explanation of Role Based Access Control and Active Directory

To understand split permissions, you need to understand how the Role Based Access Control (RBAC) permissions model in Exchange 2010 works with Active Directory. The RBAC model controls who can perform what actions, and on which objects those actions can be performed. For more information about the various components of RBAC that are discussed in this topic, see Understanding Role Based Access Control.

In Exchange 2010, all tasks that are performed on Exchange objects must be done through the Exchange Management Console, the Exchange Management Shell, or the Exchange Web administrative interface. Each of these management tools uses RBAC to authorize all tasks that are performed.

RBAC is a component that exists on every server running Exchange 2010, with the exception of Edge Transport servers. RBAC checks whether the user performing an action is authorized to do so:

- If the user isn't authorized to perform the action, RBAC doesn't allow the action to proceed.
- If the user is authorized to perform the action, RBAC checks whether the user is authorized to perform the action against the specific object being requested:
  - If the user is authorized, RBAC allows the action to proceed.
  - If the user isn't authorized, RBAC doesn't allow the action to proceed.

If RBAC allows an action to proceed, the action is performed in the context of the Exchange Trusted Subsystem and not the user's context. The Exchange Trusted Subsystem is a highly privileged universal security group (USG) that has read/write access to every Exchange-related object in the Exchange organization. It's also a member of the Administrators local security group and the Exchange Windows Permissions USG, which enables Exchange to create and manage Active Directory objects.

Caution:

Don't make any manual changes to the membership of the Exchange Trusted Subsystem security group. Also, don't add it to or remove it from object access control lists (ACLs). By making changes to the Exchange Trusted Subsystem USG yourself, you could cause irreparable damage to your Exchange organization.

It's important to understand that it doesn't matter what Active Directory permissions a user has when using the Exchange management tools. If the user is authorized, via RBAC, to perform an action in the Exchange management tools, the user can perform the action regardless of his or her Active Directory permissions. Conversely, if a user is an Enterprise Admin in Active Directory but isn't authorized to perform an action, such as creating a mailbox, in the Exchange management tools, the action won't succeed because the user doesn't have the required permissions according to RBAC.

Important:
Although the RBAC permissions model doesn't apply to the Active Directory Users and Computers management tool, Active Directory Users and Computers can't manage the Exchange configuration. So although a user may have access to modify some attributes on Active Directory objects, such as the display name of a user, the user must use the Exchange management tools, and therefore must be authorized by RBAC, to manage Exchange attributes.

Return to top

Shared Permissions

The shared permissions model is the default model for Exchange 2010. You don't need to change anything if this is the permissions model you want to use. This model doesn't separate the management of Exchange and Active Directory objects from within the Exchange management tools. It allows administrators using the Exchange management tools to create security principals in Active Directory.

The following table shows the roles that enable the creation of security principals in Exchange and the management role groups they're assigned to by default.

Security principal management roles

Management role	Role group
Mail Recipient Creation Role	Organization Management Recipient Management
Security Group Creation and Membership Role	Organization Management

Only role groups, users, or USGs that are assigned the Mail Recipient Creation role can create security principals such as Active Directory users. By default, the Organization Management and Recipient Management role groups are assigned this role. Therefore members of these role groups can create security principals.

Only role groups, users, or USGs that are assigned the Security Group Creation and Membership role can create security groups or manage their memberships. By default, only the Organization Management role group is assigned this role. Therefore only members of the Organization Management role group can create or manage the membership of security groups.

You can assign the Mail Recipient Creation role and the Security Group Creation and Membership role to other role groups, users, or USGs if you want other users to be able to create security principals.

To enable the management of existing security principals in Exchange 2010, the Mail Recipients role is assigned to the Organization Management and Recipient Management role groups by default. Only role groups, users, or USGs that are assigned the Mail Recipients role can manage existing security principals. If you want other role groups,

users, or USGs to be able to manage existing security principals, you must assign the Mail Recipients role to them.

For more information about how to add roles to role groups, users, or USGs, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

If you switched to a split permissions model and want to change back to a shared permissions model, see Configure Exchange 2010 for Shared Permissions.

Return to top

Split Permissions

If your organization separates Exchange management and Active Directory management, you need to configure Exchange to support the split permissions model. When configured correctly, only the administrators who you want to create security principals, such as Active Directory administrators, will be able to do so and only Exchange administrators will be able to modify the Exchange attributes on existing security principals. This splitting of permissions also falls roughly along the lines of the domain and configuration partitions in Active Directory. Partitions are also called naming contexts. The domain partition stores the users, groups, and other objects for a specific domain. The configuration partition stores the forest-wide configuration information for the services that used Active Directory, such as Exchange. Data that's stored in the domain partition is typically managed by Active Directory administrators, although objects may contain Exchange-specific attributes that can be managed by Exchange administrators. Data that's stored in the configuration partition is managed by the administrators for each respective service that stores data in this partition. For Exchange, this is typically Exchange administrators.

Exchange 2010 SP1 supports the two following types of split permissions:

- **RBAC split permissions** Permissions to create security principals in the Active Directory domain partition are controlled by RBAC. Only Exchange servers, services, and those who are members of the appropriate role groups can create security principals.
- **Active Directory split permissions** Permissions to create security principals in the Active Directory domain partition are completely removed from any Exchange user, service, or server. No option is provided in RBAC to create security principals. Creation of security principals in Active Directory must be performed using Active Directory management tools.

Important:

Although Active Directory split permissions can only be enabled or disabled by running Setup on a computer that has Exchange 2010 SP1 installed, Active Directory split permissions configuration applies to both Exchange 2010 release to manufacturing (RTM) and Exchange 2010 SP1 servers. It doesn't, however, have any impact on Microsoft Exchange Server 2003 or Microsoft Exchange Server 2007 servers.

If your organization chooses to use a split permissions model instead of shared permissions, we recommend that you use the RBAC split permissions model. The RBAC split permissions model provides significantly more flexibility while providing the nearly same administration separation as Active Directory split permissions, with the exception that Exchange servers and services can create security principals in the RBAC split permissions model.

You're asked whether you want to enable Active Directory split permissions during Setup. If you choose to enable Active Directory split permissions, you can only change to shared

permissions or RBAC split permissions by rerunning Setup and disabling Active Directory split permissions. This choice applies to the entire Exchange 2010 organization.

The following sections describe RBAC and Active Directory split permissions in more detail.

Return to top

RBAC Split Permissions

The RBAC security model modifies the default management role assignments to separate who can create security principals in the Active Directory domain partition from those who administer the Exchange organization data in the Active Directory configuration partition. Security principals, such as users with mailboxes and distribution groups, can be created by administrators who are members of the Mail Recipient Creation and Security Group Creation and Membership roles. These permissions remain separate from the permissions required to create security principals outside of the Exchange management tools. Exchange administrators who aren't assigned the Mail Recipient Creation or Security Group Creation and Membership roles can still modify Exchange-related attributes on security principals. Active Directory administrators also have the option of using the Exchange management tools to create Active Directory security principals.

Exchange servers and the Exchange Trusted Subsystem also have permissions to create security principals in Active Directory on behalf of users and third-party programs that integrate with RBAC.

RBAC split permissions is a good choice for your organization if the following are true:

- Your organization doesn't require that security principal creation be performed using only Active Directory management tools and only by users who are assigned specific Active Directory permissions.
- Your organization allows services, such as Exchange servers, to create security principals.
- You want to simplify the process required to create mailboxes, mail-enabled users, distribution groups, and role groups by allowing their creation from within the Exchange management tools.
- You want to manage the membership of distribution groups and role groups within the Exchange management tools.
- You have third-party programs that require that Exchange servers be able to create security principals on their behalf.

If your organization requires a complete separation of Exchange and Active Directory administration where no Active Directory administration can be performed using Exchange management tools or by Exchange services, see the Active Directory Split Permissions section later in this topic.

Switching from shared permissions to RBAC split permissions is a manual process where you remove the permissions required to create security principals from the role groups that are granted them by default. The following table shows the roles that enable the creation of security principals in Exchange and the management role groups they're assigned to by default.

Security principal management roles

Management role	Role group
Mail Recipient Creation Role	Organization Management Recipient Management
Security Group Creation and Membership Role	Organization Management

By default, members of the Organization Management and Recipient Management role groups can create security principals. You must transfer the ability to create security principals from the built-in role groups to a new role group that you create.

To configure RBAC split permissions, you must do the following:

1. Disable Active Directory split permissions if it's enabled.
2. Create a role group, which will contain the Active Directory administrators that will be able to create security principals.
3. Create regular and delegating role assignments between the Mail Recipient Creation role and the new role group.
4. Create regular and delegating role assignments between the Security Group Creation and Membership role and the new role group.
5. Remove the regular and delegating management role assignments between the Mail Recipient Creation role and the Organization Management and Recipient Management role groups.
6. Remove the regular and delegating role assignments between the Security Group Creation and Membership role and the Organization Management role group.

After doing this, only members of the new role group that you create will be able to create security principals, such as mailboxes. The new group will only be able to create the objects. It won't be able to configure the Exchange attributes on the new object. An Active Directory administrator, who is a member of the new group, will need to create the object, and then an Exchange administrator will need to configure the Exchange attributes on the object. Exchange administrators won't be able to use the following cmdlets:

- **New-Mailbox**
- **New-MailContact**
- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**

Exchange administrators will, however, be able to create and manage Exchange-specific objects, such as transport rules, distribution groups, and so on and manage Exchange-related attributes on any object.

Additionally, the associated features in the Exchange Management Console and Exchange Control Panel, such as the New Mailbox Wizard, will also no longer be available or will generate an error if you try to use them.

If you want the new role group to also be able to manage the Exchange attributes on the new object, the Mail Recipients role also needs to be assigned to the new role group.

For more information about configuring a split permissions model, see Configure Exchange 2010 for Split Permissions.

Return to top

Active Directory Split Permissions

With Active Directory split permissions, the creation of security principals in the Active Directory domain partition, such as mailboxes and distribution groups, must be performed using Active Directory management tools. Several changes are made to the permissions granted to the Exchange Trusted Subsystem and Exchange servers to limit what Exchange administrators and servers can do. The following changes in functionality occur when you enable Active Directory split permissions:

- Creation of mailboxes, mail-enabled users, distribution groups, and other

security principals is removed from the Exchange management tools.
- Adding and removing distribution group members can't be done from the Exchange management tools.
- All permissions granted to the Exchange Trusted Subsystem and Exchange servers to create security principals are removed.
- Exchange servers and the Exchange management tools can only modify the Exchange attributes of existing security principals in Active Directory.

For example, to create a mailbox with Active Directory split permissions enabled, a user must first be created using Active Directory tools by a user with the required Active Directory permissions. Then, the user can be mailbox-enabled using the Exchange management tools. Only the Exchange-related attributes of the mailbox can be modified by Exchange administrators using the Exchange management tools.

Active Directory split permissions is a good choice for your organization if the following are true:

- Your organization requires that security principals be created using only the Active Directory management tools or only by users who are granted specific permissions in Active Directory.
- You want to completely separate the ability to create security principals from those who manage the Exchange organization.
- You want to perform all distribution group management, including creation of distribution groups and adding and removing members of those groups, using Active Directory management tools.
- You don't want Exchange servers, or third-party programs that use Exchange on their behalf, to create security principals.

Important:

Switching to Active Directory split permissions is a choice that you can make when you install Exchange 2010 SP1 either by using the Setup wizard or by using the *ActiveDirectorySplitPermissions* parameter while running `setup.com` from the command line. You can also enable or disable Active Directory split permissions after you've installed Exchange 2010 by rerunning `setup.com` from the command line. To enable Active Directory split permissions, set the *ActiveDirectorySplitPermissions* parameter to `true`. To disable it, set it to `false`. You must always specify the *PrepareAD* switch along with the *ActiveDirectorySplitPermissions* parameter.
If you have multiple domains within the same forest, you must also either specify the *PrepareAllDomains* switch when you apply Active Directory split permissions or run setup with the *PrepareDomain* switch in each domain. If you choose to run setup with the *PrepareDomain* switch in each domain rather than use the *PrepareAllDomains* switch, you must prepare every domain that contains Exchange servers, mail-enabled objects, or global catalog servers that could be accessed by an Exchange server.

Important:

You can't enable Active Directory split permissions if you've installed Exchange 2010 on a domain controller.
After you enable or disable Active Directory split permissions, we recommend that you restart the Exchange 2010 servers in your organization to force them to pick up the new Active Directory access token with the updated permissions.

Exchange 2010 SP1 achieves Active Directory split permissions by removing permissions and membership from the Exchange Windows Permissions security group. This security group, in shared permissions and RBAC split permissions, is given permissions to many non-Exchange objects and attributes throughout Active Directory. By removing the permissions and membership to this security group, Exchange administrators and services are prevented from creating or modifying those non-Exchange Active Directory objects.

For a list of changes that occur to the Exchange Windows Permissions security group and other Exchange components when you enable or disable Active Directory split permissions, see the following table.

Note:
Role assignments to role groups that enable Exchange administrators to create security principals are removed when Active Directory split permissions is enabled. This is done to remove access to cmdlets that would otherwise generate an error when they're run because they don't have permissions to create the associated Active Directory object.

Active Directory split permissions changes

Action	Changes made by Exchange

Enable Active Directory split permissions during first Exchange 2010 SP1 server installation	The following happens when you enable Active Directory split permissions either through the Setup wizard or by running `setup.com` with the `/PrepareAD` and `/ActiveDirectorySplitPermissions:true` parameters:
	• An organizational unit (OU) called **Microsoft Exchange Protected Groups** is created.
	• The **Exchange Windows Permissions** security group is created in the **Microsoft Exchange Protected Groups** OU.
	• The **Exchange Trusted Subsystem** security group isn't added to the **Exchange Windows Permissions** security group.
	• Creation of non-delegating management role assignments to management roles with the following management role types is skipped:
	  • `MailRecipientCreation`
	  • `SecurityGroupCreationandMembership`
	• Access control entries (ACEs) that would have been assigned to the **Exchange Windows Permissions** security group aren't added to the Active Directory domain object.
	
	If you run setup with the *PrepareAllDomains* or *PrepareDomain* switch, the following happens in each child domain that's prepared:
	• All ACEs assigned to the **Exchange Windows Permissions** security group are removed from the domain object.
	• ACEs are set in each domain as defined in Exchange 2010 Deployment Permissions Reference with the exception of any ACEs assigned to the **Exchange Windows Permissions** security group.

Switch from shared permissions or RBAC split permissions to Active Directory split permissions	The following happens when you run the `setup.com` command with the `/PrepareAD` and `/ActiveDirectorySplitPermissions:true` parameters: • An OU called **Microsoft Exchange Protected Groups** is created. • The **Exchange Windows Permissions** security group is moved to the **Microsoft Exchange Protected** Groups OU.

	• The **Exchange Trusted Subsystem** security group is removed from the **Exchange Windows Permissions** security group.
	• Any non-delegating role assignments to management roles with the following role types are removed:
	  • `MailRecipientCreation`
	  • `SecurityGroupCreationandMembership`
	• All ACEs assigned to the **Exchange Windows Permissions** security group are removed from the domain object.
	
	If you run setup with either the *PrepareAllDomains* or *PrepareDomain* switch, the following happens in each child domain that's prepared:
	• All ACEs assigned to the **Exchange Windows Permissions** security group are removed from the domain object.
	• ACEs are set in each domain as defined in Exchange 2010 Deployment Permissions Reference with the exception of any ACEs assigned to the **Exchange Windows Permissions** security group.

Switch from Active Directory split permissions to shared permissions or RBAC split permissions	The following happens when you run the `setup.com` command with the `/PrepareAD` and `/ActiveDirectorySplitPermissions:false` parameters: • The **Exchange Windows Permissions** security group is moved to the **Microsoft Exchange Security Groups** OU. • The **Microsoft Exchange Protected Groups** OU is removed. • The **Exchange Trusted Subsystems** security group is added to the **Exchange Windows Permissions** security group. • ACEs are added to the domain object for the **Exchange Windows Permissions** security group. If you run setup with either the *PrepareAllDomains* or *PrepareDomain* switch, the following happens in each child domain that's prepared: • ACEs are added to the domain object for the **Exchange Windows Permissions** security group. • ACEs are set in each domain as defined in Exchange 2010 Deployment Permissions Reference including ACEs assigned to the **Exchange Windows Permissions** security group. Role assignments to the Mail Recipient Creation and Security Group Creation and Membership roles aren't automatically created when switching from Active Directory split to shared permissions. If

	delegating role assignments were customized prior to Active Directory split permissions being enabled, those customizations are left intact. To create role assignments between these roles and the Organization Management role group, see Configure Exchange 2010 for Shared Permissions.

After you enable Active Directory split permissions, the following cmdlets are no longer available:

- **New-Mailbox**
- **New-MailContact**
- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**

After you enable Active Directory split permissions, the following cmdlets are accessible but you can't use them to create distribution groups or modify distribution group membership:

- **Add-DistributionGroupMember**
- **New-DistributionGroup**
- **Remove-DistributionGroup**
- **Remove-DistributionGroupMember**
- **Update-DistributionGroupMember**

Some cmdlets, although still available, may offer only limited functionality when used with Active Directory split permissions. This is because they may allow you to configure recipient objects that are in the domain Active Directory partition and Exchange configuration objects that are in the configuration Active Directory partition. They may also allow you to configure Exchange-related attributes on objects stored in the domain partition. Attempts to use the cmdlets to create objects, or modify non-Exchange-related attributes on objects, in the domain partition will result in an error. For example, the **Add-ADPermission** cmdlet will return an error if you attempt to add permissions to a mailbox. However, the **Add-ADPermission** cmdlet will succeed if you configure permissions on a Receive connector. This is because a mailbox is stored in the domain partition while Receive connectors are stored in the configuration partition.

Additionally, the associated features in the Exchange Management Console and Exchange Control Panel, such as the New Mailbox wizard, will also no longer be available or will generate an error if you try to use them.

Exchange administrators will, however, be able to create and manage Exchange-specific objects, such as transport rules, and so on.

For more information about configuring an Active Directory split permissions model, see Configure Exchange 2010 for Split Permissions.

Return to top

1.3.1.3 Understanding Permissions Coexistence with Exchange 2003

Understanding Permissions Coexistence with Exchange 2003

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Permissions in Microsoft Exchange Server 2010 and Exchange Server 2003 are completely separate. This is because the permissions models used by Exchange 2010 and Exchange 2003 are different. You must take steps to grant existing Exchange 2003 administrators permissions to your Exchange 2010 servers, and vice versa. Additionally, management of Exchange 2010 and Exchange 2003 is performed separately using the management tools provided by each version. You can grant permissions to your administrators so that they can manage your combined Exchange 2010 and Exchange 2003 organization.

For more information about planning coexistence between Exchange 2010 and Exchange 2003, see Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

Exchange 2010 Permissions

Exchange 2010 uses the Role Based Access Control (RBAC) permissions model. This model consists of management role groups that are assigned one of a number of management roles. Management roles contain permissions that enable administrators to perform tasks in the Exchange organization. Administrators are added as members of the role groups and are granted all the permissions the roles provide. The following table provides an example of the role groups, some of the roles that they're assigned, and a description of the type of user who might be a member of the role group.

Examples of role groups and roles in Exchange 2010

Management role group	Management roles	Members of this role group
Organization Management	The following are some of the roles assigned to this role group: • Address Lists • Exchange Servers • Journaling • Mail Recipients • Public Folders	Users who need to manage the entire Exchange 2010 organization should be members of this role group. With some exceptions, members of this role group can manage nearly any aspect of the Exchange 2010 organization. By default, the user account used to prepare Active Directory for Exchange 2010 is a member of this role group. For more information about this role group, and for a complete list of roles assigned to this role group, see Organization

		Management.
View Only Organization Management	The following are the roles assigned to this role group: • Monitoring • View-Only Configuration • View-Only Recipients	Users who need to view the configuration of the entire Exchange 2010 organization should be members of this role group. These users need to be able to view server configuration, recipient information, and be able to perform monitoring functions without the ability to change organization or recipient configuration. For more information about this role group, see View-Only Organization Management.
Recipient Management	The following are the roles assigned to this role group: • Distribution Groups • Mail Enabled Public Folders • Mail Recipient Creation • Mail Recipients • Message Tracking • Migration • Move Mailboxes • Recipient Policies	Users who need to manage recipients, such as mailboxes, contacts, and distribution groups in the Exchange 2010 organization, should be members of this role group. These users can create recipients, modify or delete existing recipients, or move mailboxes. For more information about this role group, and for a complete list of roles assigned to this role group, see Recipient Management.
Server Management	The following are some of the roles assigned to this role group: • Databases • Exchange Connectors • Exchange Servers • Receive Connectors • Transport Queues	Users who need to manage Exchange server configuration, such as Receive connectors, certificates, databases, and virtual directories, should be members of this role group. These users can modify Exchange server configuration, create databases, and restart and manipulate transport queues. For more information

		about this role group, and for a complete list of roles assigned to this role group, see Server Management.
Discovery Management	The following are the roles assigned to this role group: • Legal Hold • Mailbox Search	Users who need to perform searches of mailboxes to support legal proceedings or configure legal holds should be members of this role group. This is an example of a role group that might contain non-Exchange administrators, such as personnel in your legal department. This allows legal personnel to perform their tasks without intervention from Exchange administrators. For more information about this role group, and for a complete list of roles assigned to this role group, see Discovery Management.

As shown in the previous table, Exchange 2010 provides a granular level of control over the permissions you grant to your administrators. You can choose from 11 role groups in Exchange 2010. For a complete list of role groups and the permissions they provide, see Built-in Role Groups.

Because of the number of role groups Exchange 2010 provides, and because further customization is possible by creating role groups with different role combinations, manipulating access control lists (ACLs) on Active Directory objects is no longer necessary and won't have any effect. ACLs are no longer used to apply permissions to individual administrators or groups in Exchange 2010. All tasks, such as an administrator creating a mailbox or a user accessing a mailbox, are managed by RBAC. RBAC authorizes the task and if it's allowed, Exchange performs the task on behalf of the user in the Exchange Trusted Subsystem universal security group (USG). With some exceptions, all of the ACLs on objects in Active Directory that Exchange 2010 needs to access are granted to the Exchange Trusted Subsystem USG. This is a fundamental change from how permissions are handled in Exchange 2003.

The permissions granted to a user in Active Directory are separate from the permissions granted to the user by RBAC when that user is using the Exchange 2010 management tools.

For more information about RBAC, see Understanding Role Based Access Control.

Exchange 2003 Permissions

Exchange 2003 has the following administrative roles:

- **Exchange View Only** This role grants permissions to view Exchange 2003 server and recipient information to an Exchange 2003 administrator.
- **Exchange Administrator** This role grants all permissions to Exchange 2003 servers and recipients except for the ability to take ownership, change permissions, or open user mailboxes, to Exchange 2003 administrators. If the administrator will need to add objects or modify object properties, but won't be required to delegate permissions on the objects, this role is assigned.
- **Exchange Full Administrator** This role grants all permissions to Exchange 2003 servers and recipients, including the ability to change permissions, to an Exchange 2003 administrator. This role is assigned to administrators who are required to delegate permissions to objects.

Exchange 2003 enables you to segment your administrators into one of these roles. The permissions are assigned directly to either the user or to the USG the user is a member of. Any actions performed by the user are performed in the context of that user's Active Directory account.

If you need to assign permissions at a more granular level, you must modify the ACLs on individual Exchange 2003 objects, such as address lists and databases. As with the administrative roles, the user, or the security group the user is a member of, is added to the ACL directly, and the actions are performed in the context of the user.

For more information about Exchange 2003 administrative groups, see Microsoft Knowledge Base article 823018, Overview of Exchange administrative role permissions in Exchange 2003.

Permissions in Exchange 2010 and Exchange 2003 Coexistence

As describe earlier in this topic, the permissions models for Exchange 2010 and Exchange 2003 are different. Exchange 2010 uses role groups to grant permissions, while Exchange 2003 uses a combination of administrative groups and ACLs to grant permissions. Exchange 2010 and Exchange 2003 permissions are completely separate, even though both versions exist in the same forest. This means that by default and without any additional configuration, Exchange 2003 administrators don't have permissions to manage Exchange 2010 servers and Exchange 2010 administrators don't have permissions to manage Exchange 2003 servers. This situation creates questions that you need to consider:

- Do you want to grant Exchange 2010 administrators access to administer Exchange 2003 servers and vice versa?
- Do you want to customize Exchange 2010 permissions so that they match the customizations you made to Exchange 2003?

Grant Exchange 2010 Permissions to Exchange 2003 Administrators

If you want Exchange 2003 administrators to administer Exchange 2010 servers, your Exchange 2003 administrators must be added as members to one or more Exchange 2010 role groups. You can add either users or USGs to role groups. The permissions granted to the role groups will then be applied to the users or USGs you add as members.

Important:

If you use domain local or global Active Directory security groups, you must change them to USGs if you want to add them as members of an Exchange 2010 role group. Exchange

2010 supports only USGs.

The following table provides a mapping between Exchange 2003 administrative roles and Exchange 2010 role groups.

Exchange 2003 administrative roles and Exchange 2010 role groups

Exchange 2003 administrative role	Exchange 2010 role group
Exchange Full Administrator	Organization Management
Exchange Administrator	There is no equivalent role group included with Exchange 2010. A custom role group that's based on the Organization Management role group, but without any delegating role assignments, must be created in Exchange 2010 to have a role group equivalent to the Exchange Administrator role group. For more information about creating custom role groups, see Create a Role Group.
Exchange View Only	View Only Organization Management

If all your Exchange 2003 administrators are members of one of the three Exchange 2003 administrative roles, you need to add the members of each of the administrative groups to their equivalent Exchange 2010 role group. For more information about adding users and USGs to role groups, see Add Members to a Role Group.

If you've modified ACLs on Exchange 2003 objects to grant more granular permissions to Exchange 2003 administrators, and want to assign similar permissions to Exchange 2010 servers to those administrators, you must do the following:

1. Inventory the ACL customization you've done on your Exchange 2003 objects, and identify the administrators granted permissions to each.
2. Classify each Exchange 2003 object, for example, whether it's a database, server, or recipient object.
3. Map the objects to the corresponding Exchange 2010 role group. For a list of built-in role groups, see Built-in Role Groups.
4. Add the USGs or users for each type of object to the corresponding Exchange 2010 role groups. For more information about adding users and USGs to role groups, see Add Members to a Role Group.

When you're done, your Exchange 2003 administrators should be members of the role group that maps to the Exchange 2010 objects they need to administer. They can now use the Exchange 2010 management tools to manage the Exchange 2010 servers and recipients.

Important:

In general, Exchange 2003 servers and recipients must be managed by Exchange 2003 management tools, and Exchange 2010 servers and recipients must be managed by Exchange 2010 management tools. For more information, see Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

If the built-in role groups don't give you the specific set of permissions you want to grant to some administrators, you can create custom role groups. When you create a custom role group, you can choose which roles you want to add to it. This enables you to define the specific features you want members of the role group to manage. For example, if you only want administrators to manage distribution groups, you can create a custom role group and choose just the Distribution Groups role. Members of that custom role group

will only be able to manage distribution groups. For more information about how to create custom role groups, see Create a Role Group.

If you've given selective permissions to certain Exchange 2003 objects, such as allowing administrators to administer only specific databases, and you want to apply the same configuration to your Exchange 2010 servers, see "Re-Create Exchange 2003 ACL Customization Using Management Scopes in Exchange 2010" later in this topic.

Grant Exchange 2003 Permissions to Exchange 2010 Administrators

If you want Exchange 2010 administrators to administer Exchange 2003 servers, you need to add your Exchange 2010 administrators to one of the three Exchange 2003 administrative groups or add them to the appropriate ACLs if you've customized your Exchange 2003 permissions. You can add either users or USGs to Exchange 2003 administrative groups. Role groups are USGs so they can be added directly to Exchange 2003 administrative groups. This topic discusses adding Exchange 2010 administrators to the built-in Exchange 2003 administrative groups.

The same mapping between Exchange 2010 role groups and Exchange 2003 administrative roles that's shown in the "Exchange 2003 administrative roles and Exchange 2010 role groups" table earlier in this topic applies. If you want your Exchange 2010 organization administrators to have full access to your Exchange 2003 administrative roles, add the Organization Management role group to the Exchange Full Administrators administrative group. Do the same with the View Only Organization Management role group and the Exchange View Only administrative group.

When you're done, your Exchange 2010 administrators should be members of the administrative group that maps to the role group they're in. They can now use the Exchange 2003 management tools to manage the Exchange 2003 servers and recipients.

Important:

In general, Exchange 2003 servers and recipients must be managed by Exchange 2003 management tools and Exchange 2010 servers and recipients must be managed by Exchange 2010 management tools. For more information, see Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

For more information about adding users or USGs to Exchange 2003 administrative groups, see Knowledge Base article 823018, Overview of Exchange administrative role permissions in Exchange 2003.

Re-Create Exchange 2003 ACL Customization Using Management Scopes in Exchange 2010

In Exchange 2003, if you want to restrict who can administer a specific mailbox store, administer specific users, or control which mailbox store mailboxes are created on, you need to modify the ACLs on the objects you want to restrict. Exchange 2010 provides the same capabilities, but without having to modify any ACLs. It does this by making use of management scopes, which are a component of RBAC.

Management scopes provide the ability to use built-in scopes and custom scopes to define what objects administrators can manage. By applying management scopes, you can define which recipients can be administered, which mailbox databases mailboxes can be created on, and which recipients or servers should be administered by a small group of administrators and no one else.

The following types of management scopes can be created:

- **Predefined relative** Predefined relative scopes are included with Exchange 2010. You can control what a user sees and is able to modify. For example, predefined relative scopes can control whether users see only information about themselves or information about the whole organization.

- **Recipient** Recipient scopes control which recipients an administrator can create, modify, or delete. These can be based on an organizational unit (OU), a recipient filter, or both. Recipient filters specify the criteria that a recipient must match to be included in the scope. For example, you might create a recipient filter scope that includes all users in a certain location or in a specific department. You can even combine OUs and recipient filters to match only users who are within a specific OU and only report to a specific manager.
- **Server** Server scopes control which servers an administrator can manage. You can specify either server lists or server filters. With server lists, you define a static list of servers that can be managed. Server filters work the same way as recipient filters, where you can specify criteria that needs to be matched. For example, you might create a server scope that matches all servers within a particular Active Directory site.
- **Database** Database scopes control which databases an administrator can manage. They can also control which databases mailboxes can be created on or moved to. Like server scopes, they can be defined as lists or as filters. For example, you might want to create a list or filter that allows administrators to create or move mailboxes on specific mailbox databases managed by a particular subsidiary.
- **Exclusive** With the exception of predefined relative scopes, any of the preceding scopes can also be created as exclusive scopes. Exclusive scopes work like deny access control entries (ACEs) in ACLs. If anything matches an exclusive scope, only the administrators assigned an exclusive scope can manage that object, even if another scope that's not exclusive, matches the same object. This is especially useful for executives, where you might want only a few highly trusted individuals to be able to manage their mailboxes. Even if another, broader, regular recipient scope includes the executive's mailbox in their scope, the administrators assigned the broader, regular recipient scope won't be able to manage that executive's mailbox unless they are also assigned the exclusive scope.

Management scopes are used with management roles, management role assignments, and management role groups to control who can manage what objects, and where. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Exclusive Scopes
- Understanding Management Role Assignments
- Understanding Management Role Groups
- Understanding Management Roles

To create the same permissions model in Exchange 2010 using management scopes that you might have defined in Exchange 2003 using customized ACLs, you need to inventory the ACLs you've customized and create management scopes that match them. You can use the filterable properties available on recipient, server, and database objects, to create management scopes that include the objects you want each management scope to control access to. For more information about the properties you can use with management scope filters, see Understanding Management Role Scope Filters.

For more information about creating management scopes, see Create a Regular or Exclusive Scope.

1.3.1.4 Understanding Permissions Coexistence with Exchange 2007

Understanding Permissions Coexistence with Exchange 2007

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The permissions model in Microsoft Exchange Server 2010 is improved from the models used in earlier versions of Exchange. Exchange 2010 includes Role Based Access Control (RBAC) permissions that replace the Active Directory access control entry (ACE)-based authorization model used in Microsoft Exchange Server 2007. RBAC is the authorization mechanism used for most of the management of Exchange 2010. This mechanism includes the following management areas:

- Exchange Management Shell
- Exchange Control Panel
- Exchange Management Console (EMC)
- Exchange Web Services
- MAPI on the middle-tier component

For more information about how to plan coexistence between Exchange 2010 and earlier versions of Exchange, see Understanding Upgrade to Exchange 2010.

Looking for management tasks related to permissions? Check out Managing Permissions.

Exchange 2010 Permissions

The Exchange 2010 RBAC permissions model consists of management role groups assigned one of several management roles. Management roles contain permissions that enable administrators to perform tasks in the Exchange organization. Administrators are added as members of the role groups and are granted all the permissions that the roles provide. The following table provides an example of the role groups, some of the roles assigned to role groups, and a description of the kind of user who might be a member of the role group.

Examples of role groups and roles in Exchange 2010

Management role group	Management roles	Members of this role group
Organization Management	The following roles are some of the roles assigned to this role group: • Address Lists • Exchange Servers • Journaling • Mail Recipients • Public Folders	Users who manage the entire Exchange 2010 organization should be members of this role group. With some exceptions, members of this role group can manage nearly any aspect of the Exchange 2010 organization. By default, the user account used to prepare Active Directory for Exchange 2010 is a member of this role group. For more information about this role group and for a complete list of roles assigned to this role group, see Organization Management.

View Only Organization Management	The following roles are assigned to this role group: • Monitoring • View-Only Configuration • View-Only Recipients	Users who view the configuration of the entire Exchange 2010 organization should be members of this role group. These users must be able to view server configuration and recipient information, and perform monitoring functions without the ability to change organization or recipient configuration. For more information about this role group, see View-Only Organization Management.
Recipient Management	The following roles are assigned to this role group: • Distribution Groups • Mail Enabled Public Folders • Mail Recipient Creation • Mail Recipients • Message Tracking • Migration • Move Mailboxes • Recipient Policies	Users who manage recipients such as mailboxes, contacts, and distribution groups in the Exchange 2010 organization should be members of this role group. These users can create recipients, modify or delete existing recipients, or move mailboxes. For more information about this role group and for a complete list of roles assigned to this role group, see Recipient Management.
Server Management	The following roles are some of the roles assigned to this role group: • Databases • Exchange Connectors • Exchange Servers • Receive Connectors • Transport Queues	Users who manage Exchange server configuration such as Receive connectors, certificates, databases, and virtual directories should be members of this role group. These users can modify Exchange server configuration, create databases, and restart and manipulate transport queues. For more information about this role group and for a complete list of roles assigned to this

		role group, see Server Management.
Discovery Management	The following roles are assigned to this role group: • Legal Hold • Mailbox Search	Users who perform searches of mailboxes to support legal proceedings or to configure legal holds should be members of this role group. This is an example of a role group that might contain non-Exchange administrators, such as personnel in the legal department. Legal personnel can perform their tasks without intervention from Exchange administrators. For more information about this role group and for a complete list of roles assigned to this role group, see Discovery Management.

This table shows that Exchange 2010 provides a granular level of control over the permissions that you grant to your administrators. You can choose among 11 role groups in Exchange 2010. For a complete list of role groups and the permissions that they provide, see Built-in Role Groups.

Because Exchange 2010 provides many role groups and because further customization is possible by creating role groups that have different role combinations, the manipulation of access control lists (ACLs) on Active Directory objects is no longer necessary and has no effect. ACLs are no longer used to apply permissions to individual administrators or groups in Exchange 2010. All tasks, such as an administrator creating a mailbox or a user accessing a mailbox, are managed by RBAC. RBAC authorizes the task, and then Exchange performs the task on behalf of the user if allowed. Exchange performs the task in the Exchange Trusted Subsystem universal security group (USG). With some exceptions, all the ACLs on objects in Active Directory that Exchange 2010 has to access are granted to the Exchange Trusted Subsystem USG. This is a fundamental change from how permissions are handled in Exchange 2007.

The permissions granted to a user in Active Directory are separate from the permissions granted to the user by RBAC when that user is using the Exchange 2010 management tools.

For more information about RBAC, see Understanding Role Based Access Control.

Exchange 2007 Permissions

The Exchange 2007 administrative model leverages Active Directory forests to define security boundaries. There is no isolation of security permissions within a particular forest.

Forest owners and enterprise administrators can always gain access to all resources in any domain. In Exchange 2007, you may have to grant enterprise administrator rights and top-level domain administrator rights on a temporary basis only.

Exchange 2007 provides the following predefined administrator roles:

- **Exchange Organization Administrator role** This role grants permissions to control all aspects of the Exchange 2007 organization. Additionally, an administrator who has this role can grant permissions to other Exchange administrators. This role is granted to the account that you use to install Exchange 2007.
- **Exchange View-Only Administrator role** This role grants permissions to view Exchange configuration. However, an administrator who has this role can't modify objects in the Exchange 2007 organization.
- **Exchange Recipient Administrator role** This role grants permissions to manage e-mail recipients. An administrator who has this role can modify Exchange-related items for users, groups, contacts, and distribution groups.
- **Exchange Server Administrator role** This role grants permissions to manage a specific server. However, this role doesn't grant permissions to perform actions that have a global impact on the Exchange 2007 organization.
- **Exchange Public Folder Administrator role** This role was added in Exchange 2007 Service Pack 1**.** This role grants permissions to manage public folders in the Exchange 2007 organization.

This permissions model uses USGs for all roles except for the Exchange Server Administrator role. When you run the Exchange 2007 **Setup /PrepareAD** command, the Setup program creates the USGs in the root domain and gives a forest-wide scope to the USGs. The USGs are assigned ACLs to manage Exchange objects throughout Active Directory.

In Exchange 2007, you can separate administrators by assigning them various roles. The permissions are assigned directly either to the user or to the USG of which the user is a member. Any actions performed by the user are performed in the context of that user's Active Directory account. The following table lists the Exchange 2007 administrator roles together with their Exchange-related permissions.

Exchange 2007 administrator roles

Administrator role	Members	Member of	Exchange permissions
Exchange Organization Administrator	The Administrator account or the account used to install the first Exchange 2007 server	Exchange Recipient Administrator Administrators local group of *<server name>*	Full control of the Microsoft Exchange container in Active Directory
Exchange View-Only Administrator	Exchange Recipient Administrators Exchange Server Administrators (*<server name>*)	Exchange Recipient Administrators Exchange Server Administrators	Read access to the Microsoft Exchange container in Active Directory Read access to all the Windows domains that have Exchange recipients
Exchange Recipient Administrator	Exchange Organization Administrators	Exchange View-Only Administrators	Full control of Exchange properties on Active Directory user objects

Exchange Server Administrator	Exchange Organization Administrators	Exchange View-Only Administrators Administrators local group of *<server name>*	Full control of Exchange *<server name>*
Exchange Server	Each Exchange 2007 computer account	Exchange View-Only Administrators	Special
Exchange Public Folder Administrator	Exchange Organization Administrators	Exchange View-Only Administrators	Full control to manage all public folders (granted the Create top level public folder extended right)

If you need to make more granular permission assignments, you can modify the ACLs on individual Exchange 2007 objects, such as address lists or databases. You must add the user or security group of which the user is a member directly to the ACL. Then, the actions are performed in the context of the particular user.

For more information about how to manage permissions in Exchange 2007, see Configuring Permissions in Exchange Server 2007.

Exchange 2010 and Exchange 2007 Coexistence Permissions

Because the permissions models for Exchange 2010 and for Exchange 2007 differ, Exchange 2010 permission assignments are separate from Exchange 2007 permission assignments. This is true even if both versions of Exchange are installed in the same forest. Without additional configuration, Exchange 2010 administrators don't have the required permissions to manage Exchange 2007-based servers, and Exchange 2007 administrators don't have the required permissions to manage Exchange 2010-based servers. You should consider the following questions:

- Do you want to grant Exchange 2010 administrators access to manage Exchange 2007 servers?
- Do you want to grant Exchange 2007 administrators access to manage Exchange 2010 servers?
- Do you want to customize Exchange 2010 permissions so that they match any customizations that have been made to Exchange 2007 ACLs?

Granting Exchange 2010 Permissions to Exchange 2007 Administrators

If you want Exchange 2007 administrators to administer Exchange 2010 servers, the Exchange 2007 administrators must be added as members of one or more Exchange 2010 role groups. You can add either users or USGs to role groups. The permissions granted to the role groups are then applied to the users or the USGs that you add as members.

Important:

If you use domain local or global Active Directory security groups, you must change them to USGs if you want to add them as members of an Exchange 2010 role group. Exchange 2010 supports only USGs.

The following table describes the mapping between Exchange 2007 administrator roles and Exchange 2010 role groups.

Exchange 2007 administrator roles and Exchange 2010 role groups

Exchange 2007 administrator role	Exchange 2010 role group
Exchange Organization Administrator	Organization Management
Exchange Recipient Administrator	Recipient Management
Exchange Server Administrator	Server Management
Exchange View-Only Administrator	View Only Organization Management
Exchange Server	No equivalent role group in Exchange 2010 (For more information about how to create custom role groups, see Create a Role Group.)
Exchange Public Folder Administrator	Public Folder Management

If all your Exchange 2007 administrators are members of one of the Exchange 2007 administrative roles, you can add the members of each of the administrative groups to their equivalent Exchange 2010 role group. For example, if you want to give all Exchange 2007 organization administrators full access to Exchange 2010 objects, add the Exchange Organization Administrators USG to the Organization Management role group.

For more information about how to add users and USGs to role groups, see Add Members to a Role Group.

If you modify ACLs on Exchange 2007 objects to grant more granular permissions to Exchange 2007 administrators, and if you want to assign similar permissions to Exchange 2010 servers to those administrators, follow these steps:

1. Review the ACL customizations that have been made to the Exchange 2007 objects, and locate the administrators who have been granted permissions to each object.
2. Categorize each Exchange 2007 object. For example, determine whether the object is a database, server, or recipient object.
3. Map the objects to the corresponding Exchange 2010 role group. For a list of built-in role groups, see Built-in Role Groups.
4. Add the USGs or users for each kind of object to the corresponding Exchange 2010 role groups. For more information about how to add users and USGs to role groups, see Add Members to a Role Group.

After you complete these steps, the Exchange 2007 administrators will be members of the specific role group that's mapped to the appropriate Exchange 2010 objects. The Exchange 2007 administrators can use the Exchange 2010 management tools to manage the Exchange 2010 servers and recipients.

Important:

In general, Exchange 2007 servers and recipients must be managed by using Exchange 2007 management tools, and Exchange 2010 servers and recipients must be managed by using Exchange 2010 management tools.

If the built-in role groups don't provide the specific set of permissions that you want to grant to some administrators, you can create custom role groups. When you create a custom role group, you can select which roles to add to it. You can define the specific features you want members of the role group to manage. For example, if you want administrators to manage only distribution groups, you can create a custom role group, and then select only the Distribution Groups role. After you do this, members of that custom role group can manage only distribution groups. For more information about how to create custom role groups, see Create a Role Group.

If you assign selective permissions to certain Exchange 2007 objects (for example, you allow administrators to administer only specific databases), and if you want to apply the same configuration to your Exchange 2010 servers, see "Re-Creating Exchange 2007 ACL Customization Using Management Scopes in Exchange 2010" later in this topic.

Granting Exchange 2007 Permissions to Exchange 2010 Administrators

If you want Exchange 2010 administrators to administer Exchange 2007 servers, add the Exchange 2010 administrators to the USGs or the security group that corresponds to the particular Exchange 2007 administrator role. Alternatively, if you have customized ACL settings, add the administrators to the appropriate ACLs. Role groups are USGs, so role groups can be added directly to Exchange 2007 administrator role USGs.

After you finish, the Exchange 2010 administrators will be members of the appropriate Exchange 2007 administrator role or roles. The Exchange 2010 administrators can use the Exchange 2007 management tools to manage Exchange 2007 servers and recipients.

Re-Creating Exchange 2007 ACL Customization Using Management Scopes in Exchange 2010

In Exchange 2007, when you want to restrict who can administer a specific mailbox store, administer specific users, or control which mailbox store mailboxes are created on, you must modify the ACLs on the objects you want to restrict. Exchange 2010 provides the same capabilities, but without having to modify any ACLs. It does this by using management scopes, which are a component of RBAC.

Management scopes provide built-in scopes and custom scopes to define the objects that administrators can manage. By applying management scopes, you can define which recipients can be administered, which mailbox databases mailboxes can be created on, and which recipients or servers should be administered by a small group of administrators and by no one else.

You can create the following types of management scopes:

- **Predefined relative** Predefined relative scopes are included in Exchange 2010. You can control what a user sees and what a user modifies. For example, predefined relative scopes can control whether users see only information about themselves or information about the entire organization.
- **Recipient** Recipient scopes control which recipients an administrator can create, modify, or delete. These selections can be based on an organizational unit (OU), a recipient filter, or both. Recipient filters specify the criteria that a recipient must match to be included in the scope. For example, you might create a recipient filter scope that includes all users in a certain location or in a specific department. You can even combine OUs and recipient filters to match only users who are within a specific OU and who report to a specific manager.
- **Server** Server scopes control which servers an administrator can manage. You can specify either server lists or server filters. For server lists, you define a static list of servers that can be managed. Server filters work in the same manner as recipient filters in that you can specify the criteria that has to be matched. For example, you might create a server scope that matches all servers within a particular Active Directory site.
- **Database** Database scopes control which databases an administrator can manage. They can also control which databases mailboxes can be created on or which databases mailboxes can be moved to. Like server scopes, they can be defined as lists or as filters. For example, you might create a list or filter that allows administrators to create mailboxes on or move mailboxes to specific mailbox databases managed by a specific subsidiary.
- **Exclusive** Recipient, server, and database scopes can also be created as exclusive scopes. Exclusive scopes work in the same manner as deny access ACEs in ACLs. If anything matches an exclusive scope, only the administrators

assigned an exclusive scope can manage that object. This is true even if another scope that isn't exclusive matches the same object. This is especially useful when you might want only a few, highly trusted individuals to be able to manage an executive's mailbox. Even if another regular recipient scope is broader and includes the executive's mailbox in the scope, the administrators assigned the broader, regular recipient scope won't be able to manage that executive's mailbox unless they are also assigned the exclusive scope.

Management scopes are used with management roles, management role assignments, and management role groups to control who can manage what objects and in what manner they can manage those objects. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Exclusive Scopes
- Understanding Management Role Assignments
- Understanding Management Role Groups
- Understanding Management Roles

To create the same permissions model in Exchange 2010 using management scopes that you might have defined using customized ACLs, you must inventory the ACLs that you've customized, and then create management scopes that match them. You can use the filterable properties available on recipient, server, and database objects to create management scopes that include the objects to which you want each management scope to control access. For more information about the properties that you can use with management scope filters, see Understanding Management Role Scope Filters.

For more information about how to create management scopes, see Create a Regular or Exclusive Scope.

1.3.1.5 Understanding Multiple-Forest Permissions

Understanding Multiple-Forest Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-06*

Many organizations deploy multiple forests to create security boundaries within their organizations. Using multiple forests helps administrators to define these security boundaries to better match their requirements, whether that's ensuring the fewest number of people have access to resources, or segmenting divisions within an organization.

Microsoft Exchange Server 2010 supports two types of multiple forest topologies:

- **Cross-forest** Cross-forest topologies can have multiple forests, each with their own installation of Exchange.
- **Resource forest** Resource forest topologies have an Exchange forest and one or more accounts forests.

For the purposes of this topic, the forest that contains the universal security groups (USGs) and users outside of the forest where Exchange 2010 is installed, whether it's an accounts forest or other resource forest, is called a foreign forest.

Configuration of permissions in a multiple forest topology relies on the correct configuration of forest trusts and global address list (GAL) synchronization for the creation of linked mailboxes. The Exchange 2010 forest must trust the foreign forest that contains the USGs associated with linked role groups and users associated with linked mailboxes.

For more information about multiple forest topologies, see Deploy Multiple Forest Topologies.

Exchange 2010 uses a Role Based Access Control (RBAC) permissions model. The management role groups that administrators are members of, and the management role assignment policies that end users are assigned, determine what each administrator and end user can do. To understand multiple-forest permissions, you need to be familiar with RBAC. For more information about RBAC, role groups, and role assignment policies, see the following topics:

- Understanding Role Based Access Control
- Understanding Management Role Groups
- Understanding Management Role Assignment Policies

Looking for management tasks related to managing permissions? See Managing Permissions.

Contents

Permissions in a Multiple Forest Topology

RBAC applies permissions to all Exchange objects within a single forest and the RBAC configuration in each forest is configured independently of all other forests. When you create a role group in one forest, that role group doesn't exist in any other forest and the permissions granted by that role group apply only to the forest in which it was created. For example, a member of a role group that grants permissions to create a mailbox can create a mailbox only in the forest that contains that role group.

If you have multiple Exchange forests and want to configure permissions identically within each forest, you must apply the same configuration explicitly in each forest. For example, if you have two Exchange 2010 forests and want to create a Compliance Management role group to manage permissions for your legal department, you must do the following:

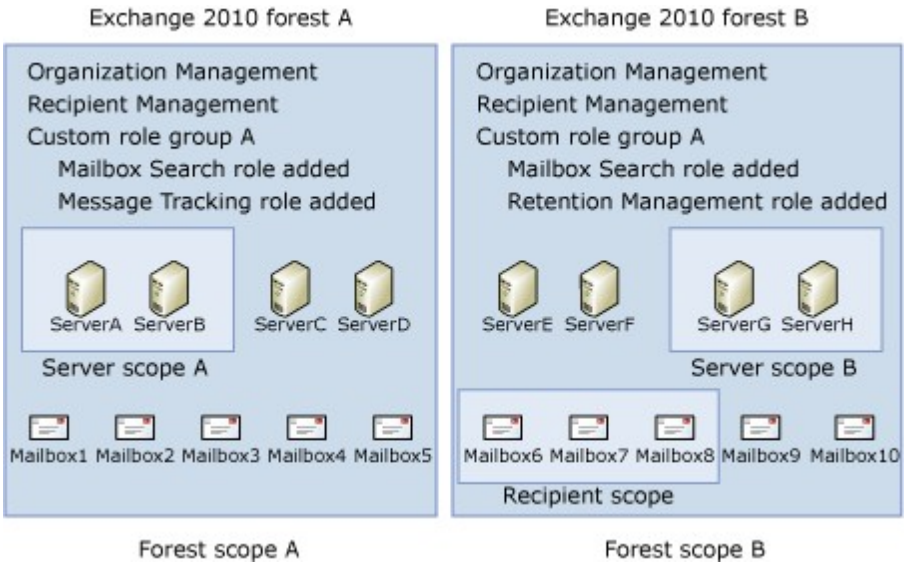
- In each forest, create a role group named Compliance Management. If your administrators are in a separate foreign forest from either Exchange forest, create both role groups as linked role groups. For more information about role groups, see the Cross-Boundary Permissions section.
- In each forest, create role assignments between the new role groups and the roles that you want to use.
- As part of the new role assignments, optionally add management scopes that encompass the server and recipient objects within each forest.
- If you created the role groups as linked role groups, add members to the associated USG in the foreign forest.

The following figure shows how the role groups configured within Exchange 2010 forests are bound to their respective forests. The Organization Management role group in Exchange 2010 forest A grants permissions only to manage the mailboxes and servers that are within that forest. Likewise, the role groups in Exchange 2010 forest B grant permissions only to the mailboxes and servers within that forest.

The figure also shows that the Custom role group A is created in each forest. Even though they were created with the same name, each is its own separate entity. In fact, as the

figure shows, each can be assigned different management roles in their respective forests. Custom role group A in Exchange 2010 forest A is assigned the Mailbox Search and Message Tracking roles while Custom role group A in Exchange 2010 forest B is assigned the Mailbox Search and Retention Management roles.

Finally, management scopes created in each forest are also bound by the forest. Server scopes created in each forest can only contain the servers that are members of that forest. Server scope A can contain only servers within Exchange 2010 forest A while Server scope B can contain only servers that are within Exchange 2010 forest B. Similarly, the recipient scope in Exchange 2010 forest B can only contain mailboxes that are within Exchange 2010 forest B.



Return to top

Cross-Boundary Permissions

The permissions granted by RBAC only allow users to view or modify Exchange objects within a specific forest. However, you can grant permissions to view and modify Exchange objects in a forest to users outside of that forest. By using cross-boundary permissions, you can centralize Exchange management accounts in a single forest rather than having to authenticate against each individual forest to perform tasks.

Note:

The permissions that are granted to a user outside of an Exchange forest still apply only to that specific Exchange forest. For example, if a user in a foreign forest is a member of the Organization Management linked role group that's located in ForestA, the user can manage only the Exchange objects contained within ForestA. A user must be made a member of linked role groups in each Exchange forest to be granted permissions to manage each forest.

Cross-boundary permissions also enable you to apply role assignment policies to the mailboxes of users who have mailboxes in an Exchange forest, but have user accounts that reside in an accounts forest. Exchange 2010 supports cross-boundary permission using linked role groups and linked mailboxes, which are discussed in the following sections.

Administrative Permissions

Administrative permissions are granted cross forest boundaries by the use of linked role

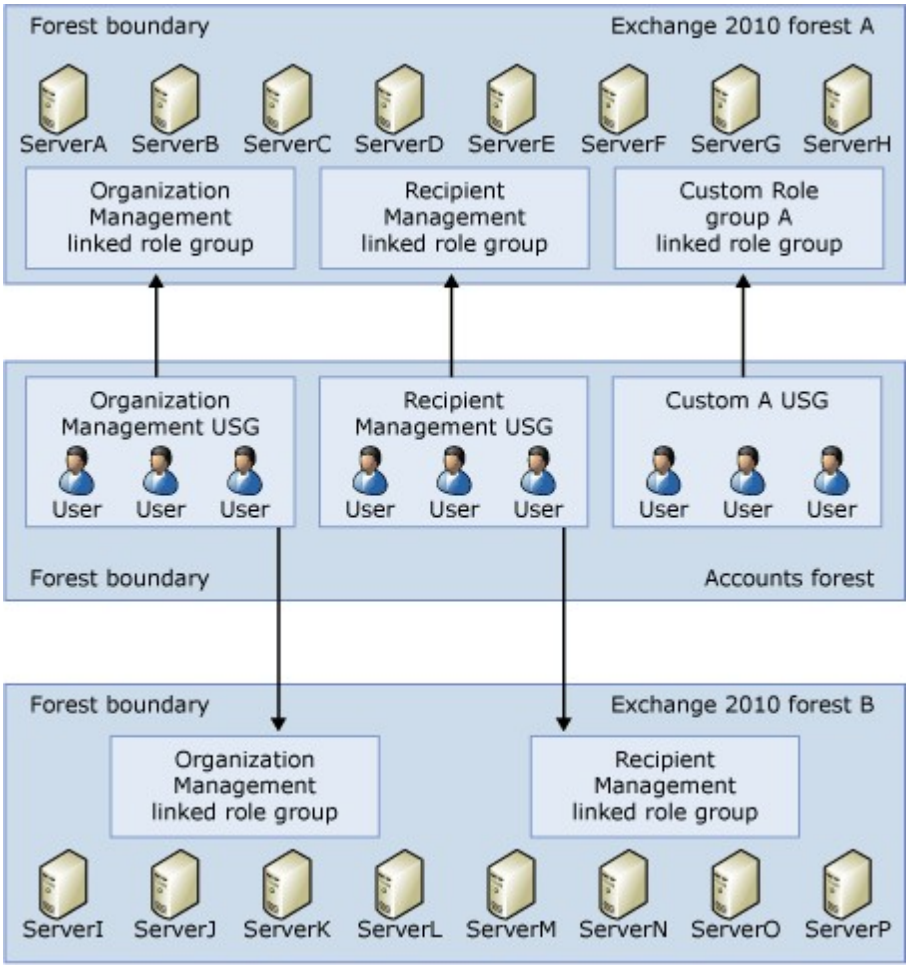
groups and linked mailboxes.

A linked role group is created in the Exchange 2010 organization and is linked to a USG across the forest boundary in the foreign forest. The USG the linked role group is linked to can be any of the following:

- A dedicated USG for the specific use of the linked role group
- A USG that's linked to by linked role groups in multiple Exchange 2010 forests
- A role group USG in another Exchange 2010 forest
- A USG associated with an Exchange Server 2007 administrative role
- A USG that's used to grant permissions to manage an Exchange Server 2003 organization

The USG that a linked role group is linked to must be in another forest. You can't link a linked role group to a USG in the same forest.

The following figure shows that USGs in an accounts forest can be associated with role groups in one or more Exchange 2010 resource forests. The members of the USGs in the accounts forest effectively become members of the role groups through the USGs.



When you create a linked role group, you assign roles to the linked role group in the Exchange 2010 forest. The assignments that associate the roles to the linked role group can include management scopes, if necessary. These scopes are confined to the forest in which the linked role group is created.

Membership of the linked role group is managed by adding and removing members to and

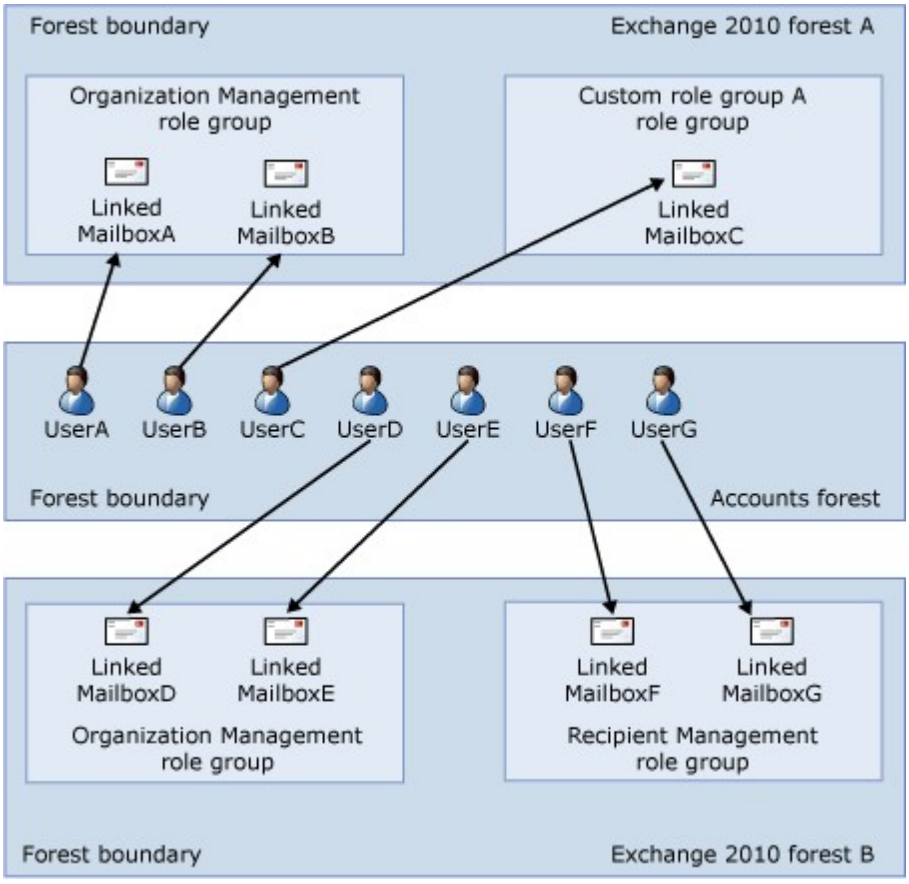
from the USG in the foreign forest. When you add members to this USG, they are granted the permissions assigned to the linked role group in the Exchange 2010 forest. If you've linked multiple linked role groups with the same USG, the members of that USG are granted the permissions assigned to each linked role group in each Exchange 2010 forest.

You can't manage the membership of a linked role group from the Exchange 2010 forest.

A second method to assign administrative permissions across forest boundaries is through the use of linked mailboxes. For users in an accounts forest to use an Exchange 2010 deployment in a separate Exchange 2010 resource forest, you must configure linked mailboxes for each user. Linked mailboxes can be added as members to role groups within the Exchange 2010 forest. When a linked mailbox becomes a member of a role group, that linked mailbox, and in turn the user in the accounts forest associated with the linked mailbox, is granted the permissions provided by the role group.

For more information about linked mailboxes, see Understanding Recipients.

The following figure shows the relationship between users in an accounts forest, the linked mailboxes associated with them, and the role groups in which they're members.



Linked role groups and linked mailboxes both have advantages and disadvantages when used to assign administrative permission across forest boundaries. The following table describes some of them.

Linked role group and linked mailbox advantages and disadvantages

Linked role groups or linked	Advantage	Disadvantage

mailboxes		
Linked role groups	You can associate multiple linked role groups from multiple Exchange 2010 forests to a single USG in an accounts forest or other Exchange resource forest. This enables you to administer complex Exchange forest topologies through a small set of USGs in a single forest.	A regular role group can't be converted to a linked role group. You must manually create linked role groups to replace each regular role group that has the permissions you want to grant across a forest boundary. For more information, see Configure cross-boundary permissions.
Linked mailboxes	Linked mailboxes allow you to use the existing role groups within the Exchange forest. Linked mailboxes are added as members to the existing role groups just like regular mailboxes, USGs, and users in the same Exchange forest.	If you grant permissions in multiple Exchange 2010 forests using linked mailboxes linked to a single user in an accounts forest, you must modify the role group membership in each Exchange 2010 forest if you want to modify the permissions granted to the user.

We recommend that you use linked role groups to grant permission across forest boundaries if you plan on having multiple Exchange resource forests.

End-User Permissions

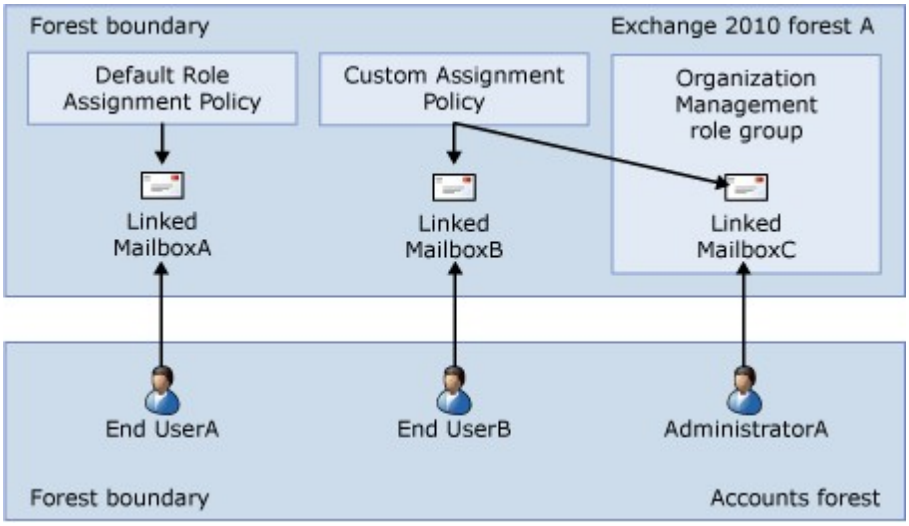
End-user permissions are assigned to individual mailboxes using role assignment policies. When Exchange 2010 is installed in a resource forest, linked mailboxes are created in the resource forest and are associated with user accounts in the accounts forest.

For more information about linked mailboxes, see Understanding Recipients.

When a linked mailbox is created, it's assigned to a default role assignment policy just like a regular mailbox. The role assignment policy determines which end-user permissions are granted to the mailbox. These permissions enable users to view and modify settings related to the following, and other, features:

- End-user profile information
- End-user voicemail
- End-user distribution membership and ownership

When a role assignment policy is assigned to a linked mailbox, the user in the accounts forest associated with the linked mailbox is granted permissions to manage the features available to that user. The permissions apply to only the resources in the Exchange forest where the linked mailbox is located. The following figure shows the relationship between the end user in the accounts forest, its associated linked mailbox, and the role assignment policy assigned to the linked mailbox. Additionally, a linked mailbox associated with an administrative user in the accounts forest can be associated with multiple role groups in addition to a role assignment policy.



For more information about linked mailboxes, see Understanding Recipients.

Return to top

Configure Cross-Boundary Permissions

To configure cross-boundary permissions in a multiple-forest topology, you must create linked role groups for each of the role groups you want to link to USGs in a foreign forest. This means that you must create a linked role group for each built-in role group. You need to:

1. Create a USG in the foreign forest for each linked role group to be created. Add members to this USG that you want to grant permissions to.
2. Create a linked role group for each built-in role group. The following happens when the linked role group is created:
   - The same roles that are assigned to the built-in role group are assigned to the new linked role group.
   - The linked role group is associated with the USG in the foreign forest.
3. Create linked role groups for any custom role groups you created.
4. Optionally assign custom scopes to the new linked role groups.

For detailed information about how to perform these steps, see the following topics:

- Create Linked Role Groups that Mirror Built-in Role Groups
- Create a Linked Role Group
- Change the Scope of Role Assignments to a Role Group

If you need to change the USG that a linked role group is associated with, see Change a Linked Foreign USG on a Linked Role Group.

When a linked mailbox is created, it's automatically assigned to a role assignment policy. You can change the role assignment policy that's assigned to the linked mailbox or change the role assignment policy that's assigned to mailboxes by default when they're created. For more information, see the following topics:

- Change the Assignment Policy on a Mailbox
- Change the Default Assignment Policy

1.3.2 Feature Permissions

Feature Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-12*

Permissions in Microsoft Exchange Server 2010 are managed using the Role Based Access Control (RBAC) permissions model. The following topics identify the management role groups required to administer the features associated with each functional area in Exchange 2010. For more information about RBAC, see Understanding Role Based Access Control.

- Mailbox Permissions
- Client Access Permissions
- Transport Permissions
- Unified Messaging Permissions
- Exchange and Shell Infrastructure Permissions
- Role Management Permissions
- High Availability Permissions
- Messaging Policy and Compliance Permissions

1.3.2.1 Mailbox Permissions

Mailbox Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-12-11*

The permissions required to perform tasks on the Mailbox server role vary depending on the procedure being performed or the cmdlet you want to run. For more information about mailbox features, see Mailbox. For a list of permissions related to high availability, see High Availability Permissions.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:

You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Mailbox Server Permissions

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Calendar repair, server configuration	Organization Management Server Management
Delegating Mailbox servers	Organization Management
E-mail address policies	Organization Management Server Management
Exchange Search	Organization Management View-Only Organization Management Server Management
Get unsearchable items	Organization Management View-Only Organization Management Support Diagnostics role **Note:** The Support Diagnostics role isn't assigned to a role group. For more information, see Add a Role to a User or USG.
Group metrics	Organization Management Server Management
Import Export	Mailbox Import Export role **Note:** The Mailbox Import Export role isn't assigned to a role group. For more information, see Add the Mailbox Import Export Role to a Role Group.
Mailbox Assistants	Organization Management Server Management
Mailbox moves	Organization Management Recipient Management

Mailbox recovery	Organization Management
Mailbox repair request	Organization Management Server Management Recipient Management
Mailbox restore request	Organization Management
Mailbox server configuration	Organization Management Server Management
Manage Exchange Search Indexer service on a Mailbox server	Local Administrator on the Mailbox server
MAPI connectivity	Organization Management Server Management
OAB virtual directories	Organization Management Server Management
Remove store mailbox	Organization Management Server Management

Calendar and Sharing Permissions

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Calendar configuration	Organization Management Recipient Management
Calendar diagnostics	Organization Management Retention Management Role Help Desk
Calendar processing	Organization Management Recipient Management Help Desk
Notifications	Organization Management Recipient Management
Organization relationships	Organization Management
Sharing policies	Organization Management

Resource Mailbox Configuration Permissions

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Booking policies	Organization Management Recipient Management Help Desk
Delegation	Organization Management Recipient Management
Resource mailbox schema configuration	Organization Management

Address List Permissions

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Address book policies	Organization Management
Address list paging	Organization Management
Address lists	Organization Management
Details templates	Organization Management
File distribution service	Organization Management
Global address lists	Organization Management
Offline address books	Organization Management

Mailbox Database Permissions

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Mailbox databases	Organization Management Server Management

Public Folder Permissions

Users who are assigned the View-Only Management role group can view the configuration

of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Mail-enabled public folders	Organization Management Recipient Management Public Folder Management
Public folder administrative permissions	Organization Management Public Folder Management
Public folder client permissions	Organization Management Public Folder Management
Public folder database repair request	Organization Management Recipient Management Server Management
Public folder databases	Organization Management Server Management
Public folder replication	Organization Management Public Folder Management
Public folders	Organization Management Public Folder Management

Recipient Provisioning Permissions

This table contains the various permissions that are required to manage recipients.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Address list, GAL	Organization Management
Anti-spam	Organization Management Recipient Management
Applying sharing policies	Organization Management Recipient Management
Arbitration	Organization Management
Archive connectivity	Organization Management View-Only Organization Management

	Server Management
Assigning offline address books	Organization Management Recipient Management

1.3.2.2 Client Access Permissions

Client Access Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The permissions required to perform tasks on the Client Access server vary depending on the procedure being performed or the cmdlet you want to run. For more information about Client Access features, see Client Access.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:
You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Note:
Some features may require that you have local administrator permissions on the server you want to manage. To manage these features, you must be a member of the Local Administrators group on that server.

Client Access Server Permissions

You can configure any of the following for the Client Access server role.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Client Access server settings	Server Management
Client Access server security settings	Server Management

Client Access server management settings	Server Management
Client Access server user settings	Server Management
Client Access server array settings	Organization Management Server Management
Client Access user settings	Server Management
RPC Client Access settings	Organization Management Server Management View-Only Organization Management
Client Access service e-mail channel settings	Organization Management Server Management
Reset Client Access virtual directories	Organization Management Server Management

Exchange ActiveSync Permissions

You can configure any of the following for Exchange ActiveSync.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Exchange ActiveSync settings	Organization Management Server Management
Exchange ActiveSync virtual directory settings	Organization Management Server Management
Exchange ActiveSync mailbox policy settings	Organization Management Server Management
Exchange ActiveSync user settings	Recipient Management
Exchange ActiveSync server settings	Organization Management Server Management
Exchange ActiveSync security settings	Organization Management Server Management
Exchange ActiveSync device settings	Recipient Management

Autodiscover Permissions

You can configure the following for the Autodiscover service.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Autodiscover virtual directory settings	Organization Management Server Management View-Only Organization Management Delegated Setup Hygiene Management
Test Autodiscover service connectivity	Organization Management Server Management View-Only Organization Management
Autodiscover service configuration settings	Organization Management Server Management View-Only Organization Management Delegated Setup Hygiene Management
Autodiscover service site affinity	Organization Management Server Management

Availability Service Permissions

You can configure the following for the Availability service.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Availability service address space settings	Organization Management View-Only Organization Management
Availability service configuration settings	Organization Management Server Management View-Only Organization Management

Client Throttling Permissions

You can configure the following for client throttling.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Client throttling settings	Organization Management View-Only Organization Management

Exchange Control Panel Permissions

You can configure the following for Exchange Control Panel (ECP).

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Exchange Control Panel virtual directory settings	Organization Management View-Only Organization Management
Test ECP	Organization Management
User reporting	Organization Management
User options	Organization Management

Exchange Web Services Permissions

You can configure the following for Web Services virtual directories.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Exchange Web Services virtual directory settings	Organization Management
Test Exchange Web Services	Organization Management Server Management
Test Outlook Web Services	Organization Management

Outlook Anywhere Permissions

You can configure and manage the following settings for Outlook Anywhere.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required

SSL for Outlook Anywhere	ISA Server Enterprise Administrator
SSL offloading for Outlook Anywhere	Organization Management Server Management
Authentication for Outlook Anywhere	Organization Management Server Management
Outlook Anywhere configuration (enable, disable, change, view)	Organization Management Server Management View-Only Organization Management Delegated Setup Hygiene Management
RPC over HTTP Proxy component	Local Server Administrator
Test Outlook Anywhere connectivity	Organization Management View-Only Organization Management Server Management

Outlook Web App Permissions

You can use the following features to view Outlook Web App settings, control security and user access to Outlook Web App, and test Outlook Web App connectivity.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Outlook Web App virtual directories	Organization Management Server Management
Outlook Web App mailbox policies	Organization Management Recipient Management
View Outlook Web App virtual directories	Organization Management Server Management View-Only Organization Management Delegated Setup Hygiene Management
View Outlook Web App mailbox policies	Organization Management Recipient Management

	View-Only Organization Management Delegated Setup Hygiene Management
Test Outlook Web App connectivity	Organization Management Server Management View-Only Organization Management
IIS Manager	Local Server Administrator
Registry Editor	Local Server Administrator
Text editor	Local Server Administrator
Graphics editor	Local Server Administrator
ISA Server 2006	ISA Server Enterprise Administrator

POP3 and IMAP4 Permissions

You can configure the following for POP3 and IMAP4.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
POP3 settings	Organization Management View-Only Organization Management
IMAP4 settings	Organization Management View-Only Organization Management
Test POP3 settings	Organization Management
Test IMAP4 settings	Organization Management

Windows PowerShell Virtual Directory Permissions

You can configure the following for Windows PowerShell.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
PowerShell settings	Organization Management
Test PowerShell	Organization Management

Text Messaging Permissions

You can configure the following for Text Messaging.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Text messaging settings	Recipient Management
Text messaging user settings	Recipient Management
Text messaging notification settings	Recipient Management

1.3.2.3 Transport Permissions

Transport Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-30*

The permissions required to perform tasks on the Edge Transport and Hub Transport server roles vary depending on the procedure being performed or the cmdlet you want to run. For more information about transport features, see Transport.

This topic lists the permissions required to manage the Transport features in Microsoft Exchange Server 2010.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:

You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Note:
Some features that you want to manage might exist on Edge Transport servers. To manage features on Edge Transport servers, you need to become a member of the Local Administrators group on the Edge Transport server you want to manage. Edge Transport servers don't use Role Based Access Control (RBAC). Features that can be managed on Edge Transport servers have Edge Transport Local Administrator in the "Permissions required" column in the table below. For more information about Edge Transport permissions, see Setting Administrator Permissions for the Edge Transport Server Role.

Note:
Some features may require that you have local administrator permissions on the server you want to manage. To manage these features, you must be a member of the Local Administrators group on that server.

Transport Permissions

You can use the features in the following table to configure settings on Hub Transport and Edge Transport servers. The permissions that are required to configure each feature are listed.

Users who are assigned the View Only Management role group can view the configuration of the features shown in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Accepted domains	Organization Management
Accepted domains - Edge Transport	Edge Transport Local Administrator
Active Directory site and site link management	Organization Management
Address Rewriting agent	Edge Transport Local Administrator
Anti-spam features	Organization Management Hygiene Management
Anti-spam features - Edge Transport	Edge Transport Local Administrator
Anti-spam updates	Organization Management Hygiene Management
Anti-spam updates - Edge Transport	Edge Transport Local Administrator
Certificate management	Organization Management

1.3.2.4 Unified Messaging Permissions

Unified Messaging Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The permissions required to perform tasks on the Unified Messaging (UM) server role vary depending on the procedure being performed or the cmdlet you want to run. For more information about Unified Messaging features, see Unified Messaging.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:

You must be assigned the Role Management management role to run the

Get-ManagementRoleAssignment cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

UM Component Permissions

You can configure settings for the Unified Messaging components and features in the following table.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
UM auto attendants	Organization Management UM Management
UM call data and summary reports	Organization Management UM Management
UM dial plans	Organization Management UM Management
UM hunt groups	Organization Management UM Management
UM IP gateways	Organization Management UM Management
UM mailbox policies	Organization Management UM Management
UM mailboxes	Organization Management UM Management
UM prompts	Organization Management UM Management
UM server	Organization Management Server Management

1.3.2.5 Exchange and Shell Infrastructure Permissions

Exchange and Shell Infrastructure Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The permissions required to perform tasks to configure various components of Microsoft Exchange Server 2010 depend on the procedure being performed or the cmdlet you want to run. See each of the sections in this topic for more information about their respective features.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:
You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Note:
Some features may require that you have local administrator permissions on the server you want to manage. To manage these features, you must be a member of the Local Administrators group on that server.

Exchange Infrastructure Permissions

The following table lists the permissions required to perform tasks that configure general Exchange 2010 settings. For more information, see the following topics:

- Overview of Administrator Audit Logging
- Exchange Management Console
- Enter Product Key
- Opt-in or Opt-out of the Customer Experience Improvement Program
- Set-ExchangeAssistanceConfig
- Get-MessageCategory
- Test-SystemHealth

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Administrator audit logging	Organization Management Records Management
Exchange Help settings	Organization Management
Exchange Management Console configuration settings	View-Only Organization Management
Exchange server configuration settings	Organization Management Server Management
Message categories	Organization Management Hygiene Management Recipient Management Help Desk
Test system health	Organization Management Server Management
Product key	Organization Management
View-only administrator audit logging	Organization Management Records Management **Note:** You can also manually assign the View-Only Audit Logs management role to a management role group. For more information, see View-Only Audit Logs Role.
Write to audit log	Users that are members of any role group or assigned any management role can write to the administrator audit log.

Shell Infrastructure Permissions

The following table lists the permissions required to perform tasks that configure features that control how the Exchange Management Shell runs. For more information about each of the features listed in this topic, see the following topics:

- Overview of Exchange Management Shell
- Understanding Cmdlet Extension Agents
- Overview of Administrator Audit Logging

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Active Directory Domain Services server settings	Organization Management Server Management

	Recipient Management UM Management
Cmdlet extension agents	Organization Management
PowerShell virtual directories	Organization Management Server Management
Remote Shell	Organization Management
PowerShell and WinRM installation	Local Server Administrator

Federation and Certificates Permissions

The following table lists permissions required for performing tasks related to federation trusts, certificate management, and hybrid configuration.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Federation trusts	Organization Management
Test federation trusts	Organization Management View-Only Organization Management Server Management
Certificate management	Organization Management Server Management
Hybrid configuration	Organization Management

1.3.2.6 Role Management Permissions

Role Management Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The permissions required to perform tasks to configure management roles vary depending on the procedure being performed or the cmdlet you want to run. For more information about management roles, see Understanding Management Roles.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.

2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:

You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Role Management Permissions

You can use the features in the following table to manage the management role groups, roles, assignment policies, assignments, scopes that define the permissions you can apply to administrators, and end users. Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Management roles	Organization Management
Unscoped management roles	Unscoped Role Management Role management role
Role groups	Organization Management
Assignment policies	Organization Management
Role assignments	Organization Management
Management scopes	Organization Management
Management role entries	Organization Management
Legacy permissions	Organization Management
Active Directory split permissions	Organization Management **Important:** To run the `setup.com` command with the *PrepareAD* and *ActiveDirectorySplitPermissions* parameters, the account you use must be a member of the Schema Admins and Enterprise Administrators groups.

1.3.2.7 High Availability Permissions

High Availability Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The permissions required to configure high availability vary depending on the procedure being performed or the cmdlet you want to run. For more information about high availability, see High Availability and Site Resilience.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:

You must be assigned the Role Management management role to run the **Get-ManagementRoleAssignment** cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Database Availability Group Permissions

You can use the features in the following table to add, remove, and configure settings for database availability groups (DAGs).

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Database availability group membership	Organization Management Database Availability Groups Role
Database availability group properties	Organization Management Database Availability Groups Role
Database availability groups	Organization Management Database Availability Groups Role

Database availability networks	Organization Management Database Availability Groups Role

Mailbox Database Copy Permissions

You can use the features in the following table to add, remove, and update, and activate mailbox database copies.

Feature	Permissions required
Database switchover	Organization Management Database Copies Role
Mailbox database copies	Organization Management Database Copies Role
Server switchover	Organization Management Database Copies Role
Update a mailbox database copy	Organization Management Database Copies Role

1.3.2.8 Messaging Policy and Compliance Permissions

Messaging Policy and Compliance Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-27*

The permissions required to configure messaging policy and compliance vary depending on the procedure being performed or the cmdlet you want to run. For more information about messaging policy and compliance, see Messaging Policy and Compliance.

To find out what permissions you need to perform the procedure or run the cmdlet, do the following:

1. In the table below, find the feature that is most related to the procedure you want to perform or the cmdlet you want to run.
2. Next, look at the permissions required for the feature. You must be assigned one of those role groups, an equivalent custom role group, or an equivalent management role. You can also click on a role group to see its management roles. If a feature lists more than one role group, you only need to be assigned one of the role groups to use the feature. For more information about role groups and management roles, see Understanding Role Based Access Control.
3. Now, run the Get-ManagementRoleAssignment cmdlet to look at the role groups or management roles assigned to you to see if you have the permissions that are necessary to manage the feature.

Note:
You must be assigned the Role Management management role to run the

Get-ManagementRoleAssignment cmdlet. If you don't have permissions to run the **Get-ManagementRoleAssignment** cmdlet, ask your Exchange administrator to retrieve the role groups or management roles assigned to you.

If you want to delegate the ability to manage a feature to another user, see Delegate Role Assignments.

Note:
Some features that you want to manage might exist on Edge Transport servers. To manage features on Edge Transport servers, you need to become a member of the Local Administrators group on the Edge Transport server you want to manage. Edge Transport servers don't use Role Based Access Control (RBAC). Features that can be managed on Edge Transport servers have Edge Transport Local Administrator in the "Permissions required" column in the table below. For more information about Edge Transport permissions, see Setting Administrator Permissions for the Edge Transport Server Role.

Messaging Policy and Compliance Permissions

You can use the features in the following table to configure messaging policy and compliance features. The role groups that are required to configure each feature are listed.

Users who are assigned the View-Only Management role group can view the configuration of the features in the following table. For more information, see View-Only Organization Management.

Feature	Permissions required
Applying retention policies	Organization Management Recipient Management Records Management
Creating discovery mailboxes	Organization Management Recipient Management
Delete mailbox content (using the Search-Mailbox cmdlet with the *DeleteContent* switch)	Mailbox Import Export role. **Note:** By default, the Mailbox Import Export role isn't assigned to any role group. For more information, see Add a Role to a User or USG.
Journaling	Organization Management Records Management
Litigation hold	Discovery Management Organization Management Records Management
Mailbox audit logging	Organization Management

	Records Management
Message classifications	Organization Management
Messaging records management	Organization Management Records Management
Multi-Mailbox Search	Discovery Management **Note:** By default, the Discovery Management role group doesn't have any members. No users, including administrators, have the required permissions to search mailboxes.
Personal archive	Organization Management Recipient Management
Rights protection	Organization Management
Transport rules	Organization Management Records Management

1.3.3 Managing Permissions

Managing Permissions

Exchange Server 2010 > Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-09*

1.3.3.1 Managing Administrator and Specialist Users

Managing Administrator and Specialist Users

Exchange Server 2010 > Permissions > Managing Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-06*

1.3.3.1.1 Add Members to a Role Group

Add Members to a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

To give a user the permissions that are granted by a management role group, you need to add the user, or a universal security group (USG), or another role group that the user is a member of, as a member of the role group. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to add members to a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to add members to and, then click **Details**.
6. In the **Members** section, click **Add**.
7. Select the users, USGs, or other role groups you want to add to the role group, and then click **OK**.
8. Click **Save** to save the changes to the role group.

Use the Shell to add a mailbox as a member of a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To add a mailbox as a member of a role group, use the following syntax.

```
Add-RoleGroupMember <role group name> -Member <member>
```

This example adds the mailbox Robert to the Seattle Administrators role group.

```
Add-RoleGroupMember "Seattle Administrators" -Member Robert
```

For detailed syntax and parameter information, see Add-RoleGroupMember.

Use the Shell to use a filter to add a group of similar users as members of a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can use the **Get-User** cmdlet to add members to a role group if the mailboxes match the criteria you specify in a filter. The **Add-RoleGroupMembers** cmdlet doesn't accept the object type provided by the **Get-User** cmdlet, so you need to pass the data through the **ForEach** statement first.

This procedure makes use of pipelining, variables, recipient filters, and the **ForEach** statement. For more information about these concepts, see the following topics:

- Pipelining
- User-Defined Variables
- Creating Filters in Recipient Commands

To add mailboxes that meet the criteria you specify as members of a role group, do the following.

1. Collect the mailboxes that match the criteria you specify using the **Get-User** command with the *Filter* parameter and store the mailboxes in a variable.

```
$Mailboxes = Get-User -Filter { RecipientType -Eq "UserMailbox" -and <
```

2. This is an optional step. View the list of mailboxes stored in the $Mailboxes variable.

```
$Mailboxes
```

3. Pass the mailboxes stored in the $Mailbox variable to the **Add-RoleGroupMember** cmdlet that's running in a **ForEach** statement.

```
$Mailboxes | ForEach { Add-RoleGroupMember <role group name> -Member $
```

This example adds all the mailboxes that are in the Sales IT Staff department to the Sales Help Desk role group.

```
$Mailboxes = Get-User -Filter { RecipientType -Eq "UserMailbox" -and Department -
$Mailboxes | ForEach { Add-RoleGroupMember "Sales Help Desk" -Member $_.Name }
```

For detailed syntax and parameter information, see Add-RoleGroupMember.

Other Tasks

After you add a member to a role group, you may also want to:

- View the Members of a Role Group
- Remove Members from a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group

1.3.3.1.2 Remove Members from a Role Group

Remove Members from a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

To remove the permissions granted by a management role group from a user, you need to remove the user, or the universal security group (USG) the user is a member of, from the role group's membership. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to remove members from a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the Exchange Managdment Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an

account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to remove members from, and then click **Details**.
6. In the **Members** section, select one or more members to remove, and then click **Remove**.
7. Click **Save** to save the changes to the role group.

Use the Shell to remove a mailbox as a member of a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To remove a mailbox as a member of a role group, use the following syntax.

```
Remove-RoleGroupMember <role group name> -Member <member>
```

This example removes the mailbox Robert from the Seattle Administrators role group.

```
Remove-RoleGroupMember "Seattle Administrators" -Member Robert
```

For detailed syntax and parameter information, see Remove-RoleGroupMember.

Other Tasks

After you remove a member from a role group, you may also want to:

- View the Members of a Role Group
- Add Members to a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group

1.3.3.1.3 View the Members of a Role Group

View the Members of a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The members of a management role group are granted the permissions provided by the management roles assigned to the role group. You can view the members of a role group to see which users, universal security groups (USG), or other role groups are granted permissions by the role group you specify. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to view the members of a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To view the members of a role group, do the following:

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. To view the members of a role group, select the role group you want to view. The members of the role group are displayed in the details pane.

Use the Shell to view the members of a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To view the members of a role group, you must specify the name of the role group with the **Get-RoleGroupMember** cmdlet.

1. To find the names of the role groups in your organization, use the following command:

```
Get-RoleGroup
```

2. Find the name of the role group whose members you want to list.
3. To list the members of the role group, use the following syntax:

```
Get-RoleGroupMember <role group name>
```

For example, to list all of the members of the "Organization Management" role group, use the following command:

```
Get-RoleGroupMember "Organization Management"
```

Note:

A maximum of 1,000 role group members are displayed by default. If you want to display more than 1,000 members, you must use the *ResultSize* parameter to override the maximum number of members to return. You can type in either an integer value or the value `unlimited`. The value `unlimited` returns all members of the role group.

Other Tasks

After you view a list of role group members, you may also want to:

- Add Members to a Role Group
- Remove Members from a Role Group

1.3.3.1.4 Create a Role Group

Create a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you want to customize the permissions that you can assign to a group of users, create a new custom management role group. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Prerequisites

To create a new role group, you need to know the management roles you want to assign to it.

If you're using the Exchange Management Shell to create a new role group, all other properties on a role group are optional and can be added after the role is created. For a role to be functional, you must add at least one management role and at least one member.

For a list of built-in roles, see Built-in Management Roles.

Use the ECP to create a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Click **New** under **Role Groups**.
6. In the **Name** field, enter the name of the new role group.
7. In the **Description** field, provide a short description of the purpose for the role group.
8. Select one of the two following **Write scope** options:
   - A write scope from the drop-down box. In this box, you can select either the default write scope or a custom write scope.
   - **Organizational unit** Select this option and provide an organizational unit (OU) if you want to scope this role group to an OU.
9. In the **Roles** section, do the following:
   - To add one or more management roles to the role group, click **Add** and select the roles you want to add. You can select multiple roles at one time. Then click **OK**.
   - To remove one or more roles from the role group, select the roles you want to remove, and click **Remove**.
10. In the **Members** section, do the following:
    - To add one or more members to the role group, click **Add** and select the

mailboxes, role groups or universal security groups (USGs) you want to add. You can select multiple items at one time. Then click **OK**.
- To remove one or more members, select the members you want to remove, and click **Remove**.

11. When you're done, click **Save** to create the new role group.

Use the Shell to create a role group with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To create a role group, add members to the role group and also specify the users who can delegate the role group to other users, use the following syntax.

```
New-RoleGroup -Name <role group name> -Roles <roles to assign> -Members <member1,
```

This example creates a role group that's assigned to the Transport Rules and Journaling management roles, is assigned to Joe, John, and David, and can be delegated by David and Chris.

```
New-RoleGroup -Name "Compliance Role Group" -Roles "Transport Rules", "Journaling
```

For detailed syntax and parameter information, see New-RoleGroup.

Use the Shell to create a role group with a custom recipient scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can create role groups with custom recipient management scopes, custom configuration management scopes, or both. To create a new role group that uses a custom management scope that you created, use the following syntax.

```
New-RoleGroup -Name <role group name> -Roles <roles to assign> -CustomRecipientWr
```

This example creates a new role group that's assigned the Transport Rules and Journaling management roles and uses the Seattle Recipients recipient scope.

```
New-RoleGroup -Name "Seattle Compliance Group" -Roles "Transport Rules", "Journal
```

You can also add members to the role group when you create it by using the *Members* parameter as shown in Use the Shell to create a role group with no scope earlier in this topic. For more information about management scopes, see Understanding Management Role Scopes.

For detailed syntax and parameter information, see New-RoleGroup.

Use the Shell to create a role group with an OU scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions

topic.

To create a role group that's scoped to a specific OU, use the following syntax.

```
New-RoleGroup -Name <role group name> -Roles <roles to assign> -RecipientOrganiza
```

This example creates a role group that allows management only of recipients in the Vancouver Office OU.

```
New-RoleGroup -Name "Vancouver Office Recipients Group" -Roles "Mail Recipients"
```

You can also add members to the role group when you create it by using the *Members* parameter as shown in Use the Shell to create a role group with no scope earlier in this topic. For more information about management scopes, see Understanding Management Role Scopes.

For detailed syntax and parameter information, see New-RoleGroup.

Other Tasks

After you create a new role group, you may also want to:

- View a List of Role Groups
- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group
- Change the Scope of Role Assignments to a Role Group
- Add or Remove a Role Group Delegate
- View the Members of a Role Group
- Change a Linked Foreign USG on a Linked Role Group

1.3.3.1.5 Copy a Role Group

Copy a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you have a management role group that contains the permissions you want to grant to users, but you want to apply a different management scope, or remove or add one or two management roles without having to add all the other roles manually, you can copy the existing role group. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to copy a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions

topic.

Important:

You can't use the Exchange Control Panel (ECP) to copy a role group if you've used the Exchange Management Shell to configure multiple management role scopes or exclusive scopes on the role group. If you've configured multiple scopes or exclusive scopes on the role group, you must use the Shell procedures later in this topic to copy the role group. For more information about management role scopes, see Understanding Management Role Scopes.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to copy, and then click **Copy**.
6. In the **Name** field, enter the name of the new role group.
7. In the **Description** field, provide a short description of the purpose for the role group.
8. Select one of the two following **Write scope** options:
   - A write scope from the drop-down box. In this box, you can select either the default write scope or a custom write scope.
   - **Organizational unit** Select this option and provide an organizational unit (OU) if you want to scope this role group to an OU.
9. In the **Roles** section, do the following:
   - To add one or more management roles to the role group, click **Add** and select the roles you want to add. You can select multiple roles at one time. Then click **OK**.
   - To remove one or more roles from the role group, select the roles you want to remove, and click **Remove**.
10. In the **Members** section, do the following:
    - To add one or more members to the role group, click **Add** and select the mailboxes, role groups or universal security groups (USGs) you want to add. You can select multiple items at one time. Then click **OK**.
    - To remove one or more members, select the members you want to remove, and click **Remove**.
11. When you're done, click **Save** to create the new role group.

Use the Shell to copy a role group with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. Store the role group that you want to copy in a variable using the following syntax:

```
$RoleGroup = Get-RoleGroup <name of role group to copy>
```

2. Create the new role group, and also add members to the role group and specify who can delegate the new role group to other users, using the following syntax:

```
New-RoleGroup <name of new role group> -Roles $RoleGroup.Roles -Member
```

For example, the following commands copy the Organization Management role group, and name the new role group "Limited Organization Management". It adds the members Isabelle, Carter, and Lukas and can be delegated by Jenny and Katie.

```
$RoleGroup = Get-RoleGroup "Organization Management"
New-RoleGroup "Limited Organization Management" -Roles $RoleGroup.Roles -Members
```

After the new role group is created, you can add or remove roles, change the scope of role assignments on the role, and more. For more information, see the Other Tasks section later in this topic.

For detailed syntax and parameter information, see Get-RoleGroup and New-RoleGroup.

Use the Shell to copy a role group with a custom scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To copy a role group and add a custom scope to the new role group, do the following:

1. Store the role group that you want to copy in a variable using the following syntax:

   ```
   $RoleGroup = Get-RoleGroup <name of role group to copy>
   ```

2. Create the new role group with a custom scope using the following syntax:

   ```
   New-RoleGroup <name of new role group> -Roles $RoleGroup.Roles -Custom
   ```

For example, the following commands copy the Organization Management role group and create a new role group called Vancouver Organization Management with the Vancouver Users recipient scope and Vancouver Servers configuration scope.

```
$RoleGroup = Get-RoleGroup "Organization Management"
New-RoleGroup "Vancouver Organization Management" -Roles $RoleGroup.Roles -Custom
```

You can also add members to the role group when you create it by using the *Members* parameter as shown in Use the Shell to copy a role group with no scope earlier in this topic. For more information about management scopes, see Understanding Management Role Scopes.

After the new role group is created, you can add or remove roles, change the scope of role assignments on the role, and perform other tasks. For more information, see the Other Tasks section later in this topic.

For detailed syntax and parameter information, see Get-RoleGroup and New-RoleGroup.

Use the Shell to copy a role group with an OU scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. Store the role group that you want to copy in a variable using the following syntax:

   ```
   $RoleGroup = Get-RoleGroup <name of role group to copy>
   ```

2. Create the new role group with a custom scope using the following syntax:

   ```
   New-RoleGroup <name of new role group> -Roles $RoleGroup.Roles -Recipi
   ```

For example, the following commands copy the Recipient Management role group and create a new role group called Toronto Recipient Management that allows management of only users in the Toronto Users OU.

```
$RoleGroup = Get-RoleGroup "Recipient Management"
New-RoleGroup "Toronto Recipient Management" -Roles $RoleGroup.Roles -RecipientOr
```

You can also add members to the role group when you create it by using the *Members* parameter as shown in Use the Shell to copy a role group with no scope earlier in this topic. For more information about management scopes, see Understanding Management Role Scopes.

After the new role group is created, you can add or remove roles, change the scope of role assignments on the role, and more. For more information, see the Other Tasks section later in this topic.

For detailed syntax and parameter information, see Get-RoleGroup and New-RoleGroup.

Other Tasks

After you copy a role group, you may also want to:

- View a List of Role Groups
- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group
- Change the Scope of Role Assignments to a Role Group
- Add or Remove a Role Group Delegate
- View the Members of a Role Group
- Change a Linked Foreign USG on a Linked Role Group

1.3.3.1.6 Remove a Role Group

Remove a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you no longer need a role group you created, you can remove it. When you remove a role group, the management role assignments between the role group and the management roles are deleted. The management roles aren't deleted. If a user depended on the role group for access to a feature, the user will no longer have access to the feature. You can't remove built-in role groups. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to remove a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select one or more role groups you want to remove, and then click ✕.

Important:
You can't remove built-in role groups or any role group that is assigned the last delegating role assignment to a role.

Use the Shell to remove a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

To remove a role group, use the following syntax.

```
Remove-RoleGroup <role group name>
```

This example removes the Seattle Recipients Group role group.

```
Remove-RoleGroup "Seattle Recipients Group"
```

For detailed syntax and parameter information, see Remove-RoleGroup.

1.3.3.1.7 Add a Role to a Role Group

Add a Role to a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Adding a management role to a management role group is the best and simplest way to grant permissions to a group of administrators or specialist users in Microsoft Exchange Server 2010. If you want to give users that are members of a role group the ability to manage a feature, you add the management role that manages the feature to the role group. After the role is added, the members of the role group are granted the permissions provided by the role.

For more information about role groups, in Exchange 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to add a management role to

a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Important:

You can't use the Exchange Control Panel (ECP) to add roles to a role group if you've used the Exchange Management Shell to configure multiple management role scopes or exclusive scopes on the role group. If you've configured multiple scopes or exclusive scopes on the role group, you must use the Shell procedures later in this topic to add roles to the role group. For more information about management role scopes, see Understanding Management Role Scopes.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to add one or more roles to, and then click **Details**.
6. In the **Roles** section, click **Add**.
7. Select one or more roles to add to the role group, and then click **OK**.
8. Click **Save** to save the changes to the role group.

Use the Shell to create a role assignment with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can create a role assignment with no scope between a role and a role group. When you do this, the implicit read and implicit write scopes of the role apply.

Use the following syntax to assign a role without any scope to a role group. A role assignment name is created automatically if you don't specify one.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name>
```

This example assigns the Transport Rules management role to the Seattle Compliance role group.

```
New-ManagementRoleAssignment -SecurityGroup "Seattle Compliance" -Role "Transport
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Use the Shell to create a role assignment with a predefined scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

If a predefined scope meets your business requirements, you can apply that scope to the

role assignment rather than create a new one. For a list of predefined scopes and their descriptions, see Understanding Management Role Scopes.

For more information about role assignments, see Understanding Management Role Assignments.

Use the following syntax to assign a role to a role group with a predefined scope. A role assignment name is created automatically if you don't specify one.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name> -
```

This example assigns the Message Tracking role to the Enterprise Support role group and applies the Organization predefined scope.

```
New-ManagementRoleAssignment -SecurityGroup "Enterprise Support" -Role "Message T
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Use the Shell to create a role assignment with a recipient filter-based scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

If you created a recipient filter-based scope, you need to include the scope in the command used to assign the role to a role group by using the *CustomRecipientWriteScope* parameter.

You can also include a configuration write scope when you create a role assignment that has a recipient write scope.

For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Use the following syntax to assign a role to a role group with a recipient filter-based scope. A role assignment name is created automatically if you don't specify one.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name> -
```

This example assigns the Message Tracking role to the Seattle Recipient Admins role group and applies the Seattle Recipients scope.

```
New-ManagementRoleAssignment -SecurityGroup "Seattle Recipient Admins" -Role "Mes
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Use the Shell to create a role assignment with a configuration scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

If you created a server or database configuration filter or list-based scope, you need to

include the scope in the command used to assign the role to a role group by using the *CustomConfigWriteScope* parameter.

You can also include a recipient write scope when you create a role assignment that has a configuration write scope.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Use the following syntax to assign a role to a role group with a configuration scope. A role assignment name is created automatically if you don't specify one.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name> -
```

This example assigns the Databases role to the Seattle Server Admins role group and applies the Seattle Servers scope.

```
New-ManagementRoleAssignment -SecurityGroup "Seattle Server Admins" -Role "Databa
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Use the Shell to create a role assignment with an OU scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

If you want to scope a role's write scope to an OU, you can specify the OU in the *RecipientOrganizationalUnitScope* parameter directly.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Use the following command to assign a role to a role group and restrict the write scope of a role to a specific OU. A role assignment name is created automatically if you don't specify one.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name> -
```

This example assigns the Mail Recipients role to the Seattle Recipient Admins role group and scopes the assignment to the Sales\Users OU in the Contoso.com domain.

```
New-ManagementRoleAssignment -SecurityGroup "Seattle Recipient Admins" -Role "Mai
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Other Tasks

After you add a role to a role group, you may also want to:

- View a List of Roles on a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group

- View the Members of a Role Group
- Add or Remove a Role Group Delegate
- Change the Scope of Role Assignments to a Role Group

1.3.3.1.8 Remove a Role from a Role Group

Remove a Role from a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Removing a management role from a management role group is the best and simplest way to revoke permissions granted to a group of administrators or specialist users in Microsoft Exchange Server 2010. If you don't want administrators or specialist users to have permissions to manage a feature, you remove the management role from the management role group that manages the permissions. After the role is removed, the members of the role group will no longer have permissions to manage the feature.

For more information about role groups in Exchange 2010, see Understanding Management Role Groups.

Note:

Some role groups, such as the Organization Management role group, restrict what roles can be removed from a role group. For more information, see Understanding Management Role Groups.
If an administrator is a member of another role group that contains management roles that grants permissions to manage the feature, you need to either remove the administrator from the other role groups, or remove the role that grants permissions to manage the feature from the other role groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to remove a management role from a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Important:

You can't use the Exchange Control Panel (ECP) to remove roles from a role group if you've used the Exchange Management Shell to configure multiple scopes or exclusive scopes on the role group. If you've configured multiple scopes or exclusive scopes on the role group, you must use the Shell procedures later in this topic to remove roles from the role group. For more information about management role scopes, see Understanding Management Role Scopes.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an

account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to remove roles from, and then click **Details**.
6. In the **Roles** section, select one or more roles that you want to remove, and then click **Remove**.
7. Click **Save** to save changes to the role group.

Use the Shell to remove a role from a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can remove roles from role groups by retrieving the associated management role assignment using the **Get-ManagementRoleAssignment** cmdlet and then piping the role assignment returned to the **Remove-ManagementRoleAssignment** cmdlet. Unless you want to remove both delegating and regular role assignments at the same time, specify the Delegating parameter to specify whether you want to remove regular or delegating role assignments.

For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

This procedure uses pipelining. For more information about pipelining, see Pipelining.

To remove a role from a role group, use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <role group name> -Role <role name> -D
```

This example removes the Distribution Groups role, which enables administrators to manage distribution groups, from the Seattle Recipient Administrators role group. Because we want to remove the role assignment that provides permissions to manage distribution groups, the *Delegating* parameter is set to `$False`, which returns only regular role assignments.

```
Get-ManagementRoleAssignment -RoleAssignee "Seattle Recipient Administrators" -Ro
```

For detailed syntax and parameter information, see Remove-ManagementRoleAssignment.

Other Tasks

After you remove a role from a role group, you may also want to:

- Add a Role to a Role Group
- View a List of Roles on a Role Group

1.3.3.1.9 View a List of Role Groups

View a List of Role Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view either a list of management role groups or the detailed information about a specific role group that exists in your organization. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to view a list of role groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. To view the details of a specific role group, select the role group you want to view. The role group description, its members and the roles assigned to it are displayed in the details pane.

Use the Shell to view a list of role groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

This procedure makes use of pipelining and the **Format-Table** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

You can view a list of all the role groups in your organization by not specifying any role groups when you run the **Get-RoleGroup** cmdlet.

This example returns a list of all role groups in your organization.

```
Get-RoleGroup
```

To return a list of specific properties for all the role groups in your organization, you can pipe the results of the **Format-Table** cmdlet and specify the properties you want in the list of results. Use the following syntax.

```
Get-RoleGroup | Format-Table <property 1>, <property 2...>
```

This example returns a list of all the role groups in your organization and includes the **Name** and **Roles** properties.

```
Get-RoleGroup | Format-Table Name, Roles
```

For detailed syntax and parameter information, see Get-RoleGroup.

Use the Shell to view the details of a

single role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

This procedure makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

You can view the details of a specific role group by using the **Get-RoleGroup** cmdlet and piping the output to the **Format-List** cmdlet.

To view the details of a specific role group, use the following syntax.

```
Get-RoleGroup <role group name> | Format-List
```

This example gets the details about the Organization Management role group.

```
Get-RoleGroup "Organization Management" | Format-List
```

For detailed syntax and parameter information, see Get-RoleGroup.

Other Tasks

After you view a list of role groups, you may also want to:

- View the Members of a Role Group

1.3.3.1.10 View a List of Roles on a Role Group

View a List of Roles on a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The management roles assigned to a management role group determine what tasks can be performed by the members of the role group. You can view the roles on a role group to see what the members of the role group can do. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Use the ECP to view a list of roles on a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions

topic.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. To view the list of roles on a role group, select the role group you want to view. The roles assigned to the role group are displayed in the details pane.

Use the Shell to view a basic list of roles assigned to a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can use the **Get-RoleGroup** cmdlet to view a basic list of roles assigned to a role group. If you want to view more detailed information about the role assignments that assign a role to a role group, such as what management scopes are associated with the assignments, see "View a more detailed list of roles assigned to a role group" later in this topic.

1. To find the names of the role groups in your organization, use the following command.

```
Get-RoleGroup
```

2. Find the name of the role group whose roles you want to list.
3. To list the roles on a role group, use the following syntax.

```
(Get-RoleGroup <role group name>).Roles
```

This example lists all of the roles assigned to the Organization Management role group.

```
(Get-RoleGroup "Organization Management").Roles
```

For detailed syntax and parameter information, see Get-RoleGroup.

Use the Shell to view a more detailed list of roles assigned to a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

You can use the **Get-ManagementRoleAssignment** cmdlet to view more detailed information about the role assignments that assign a role to a role group. If you want to view only a basic list of roles assigned to a role group, see "View a basic list of roles assigned to a role group" earlier in this topic.

1. To find the names of the role groups in your organization, use the following command.

```
Get-RoleGroup
```

2. Find the name of the role group whose roles you want to list.
3. To list the roles on a role group, use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <role group name>
```

This example lists all of the roles assigned to the Organization Management role group.

```
Get-ManagementRoleAssignment -RoleAssignee "Organization Management"
```

This command displays the default information about the role assignment between the role group and the roles assigned to it. If you want to view other, more advanced, information about the role assignments on a role group, such as which role assignments are delegating or exclusive, see View Role Assignments.

For detailed syntax and parameter information, see Get-RoleGroup or Get-ManagementRoleAssignment.

Other Tasks

After you view the list of roles on a role group, you may also want to:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Change the Scope of Role Assignments to a Role Group
- View the Members of a Role Group

1.3.3.1.11 Add or Remove a Role Group Delegate

Add or Remove a Role Group Delegate

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role group delegates are users or universal security groups (USGs) that can add or remove members from a role group or change the properties of a role group. By adding or removing role group delegates, you can control who is allowed to manage a role group. For more information about role groups in Microsoft Exchange Server 2010, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Important:

After you add a delegate to a role group, the role group can only be managed by the delegates on the role group, or by users who are assigned, either directly or indirectly, the Role Management management role.
If a user is assigned, either directly or indirectly, the Role Management role and isn't added as a delegate of the role group, the user must use the *BypassSecurityGroupManagerCheck* switch on the **Add-RoleGroupMember**, **Remove-RoleGroupMember**, **Update-RoleGroupMember**, and **Set-RoleGroup** cmdlets to manage a role group.

Use the Shell to add a delegate to a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to add a delegate to a role group.

To change the list of delegates on a role group, you use the *ManagedBy* parameter on the **Set-RoleGroup** cmdlet. The *ManagedBy* parameter overwrites the entire delegate list on the role group. If you want to add delegates to the role group rather than replace the entire list of delegates, use the following steps:

1. Store the role group in a variable using the following command.

```
$RoleGroup = Get-RoleGroup <role group name>
```

2. Add the delegate to the role group stored in the variable using the following command.

```
$RoleGroup.ManagedBy += (Get-User <user to add>).Identity
```

Note:
Use the **Get-Group** cmdlet if you want to add a USG.

3. Repeat Step 2 for each delegate you want to add.
4. Apply the new list of delegates to the actual role group using the following command.

```
Set-RoleGroup <role group name> -ManagedBy $RoleGroup.ManagedBy
```

This example adds the user David Strome as a delegate on the Organization Management role group.

```
$RoleGroup = Get-RoleGroup "Organization Management"
$RoleGroup.ManagedBy += (Get-User "David Strome").Identity
Set-RoleGroup "Organization Management" -ManagedBy $RoleGroup.ManagedBy
```

For detailed syntax and parameter information, see Set-RoleGroup.

Use the Shell to remove a delegate from a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to remove a delegate from a role group.

To change the list of delegates on a role group, you use the *ManagedBy* parameter on the **Set-RoleGroup** cmdlet. The *ManagedBy* parameter overwrites the entire delegate list on the role group. If you want to remove delegates from the role group rather than replace the entire list of delegates, use the following steps:

1. Store the role group in a variable using the following command.

```
$RoleGroup = Get-RoleGroup <role group name>
```

2. Remove the delegate from the role group stored in the variable using the following command.

```
$RoleGroup.ManagedBy -= (Get-User <user to remove>).Identity
```

Note:
Use the **Get-Group** cmdlet if you want to remove a USG.

3. Repeat Step 2 for each delegate you want to remove.
4. Apply the new list of delegates to the actual role group using the following command.

```
Set-RoleGroup <role group name> -ManagedBy $RoleGroup.ManagedBy
```

This example removes the user David Strome as a delegate on the Organization Management role group.

```
$RoleGroup = Get-RoleGroup "Organization Management"
$RoleGroup.ManagedBy -= (Get-User "David Strome").Identity
Set-RoleGroup "Organization Management" -ManagedBy $RoleGroup.ManagedBy
```

For detailed syntax and parameter information, see Set-RoleGroup.

Other Tasks

After you add a delegate to a role group, you may also want to:

- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group

1.3.3.1.12 Change the Scope of Role Assignments to a Role Group

Change the Scope of Role Assignments to a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role groups are assigned management roles. The management role assignments between a role group and a role contain management scopes, which determine what objects are made available to members of that role group. By changing the write scope on a role group, you can change what objects are made available to role group members to create, change, or remove. You can't change the read scope on a role group.

Microsoft Exchange Server 2010 includes scopes that are applied by default to role assignments when no custom scopes are created. If you want to use a custom scope with a role assignment on a role group, you must create one first. For more information about creating custom scopes, which is an advanced task, see Create a Regular or Exclusive Scope.

For more information about management role scopes and assignments in Exchange 2010, see the following topics:

- Understanding Management Role Scopes
- Understanding Management Role Assignments

Looking for other management tasks related to role groups? Check out Managing Administrator and Specialist Users.

Use the ECP to change the scope on a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

When you use the Exchange Control Panel (ECP) to change the scope on a role group, you're actually changing the scope on all the role assignments between the role group and each of the management roles assigned to the role group. If you want to change the scope on specific role assignments, you must use the Exchange Management Shell procedures later in this topic.

Important:

You can't use the ECP to manage scopes on role assignments between roles and a role group if you've used the Shell to configure multiple scopes or exclusive scopes on those role assignments. If you've configured multiple scopes or exclusive scopes on those role assignments, you must use the Shell procedures later in this topic to manage scopes. For more information about management role scopes, see Understanding Management Role Scopes.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **Administrator Roles** tab.
5. Select the role group you want to change the scope on, and then click **Details**.
6. Select one of the two following **Write scope** options:
   - A write scope from the drop-down box. In this box, you can select either the default write scope or a custom write scope.
   - **Organizational unit** Select this option and provide an organizational unit (OU) if you want to scope this role group to an OU.
7. Click **Save** to save the changes to the role group.

Use the Shell to change the scope of all role assignments on a role group at the same time

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Role assignments between the role group and the roles assigned to it can use the implicit scope obtained from the roles themselves, the same custom scope, or different custom scopes. For more information about role assignments, see Understanding Management Role Assignments.

The scopes on the role assignments are managed using the **Set-ManagementRoleAssignment** cmdlet. You can't manage scopes using the **Set-RoleGroup** cmdlet.

To change the scope of all the role assignments between a role group and a set of management roles at the same time, you need to first retrieve the role assignments on

the role group, and then set the new scope on each of the assignments. You can do this by using the **Get-ManagementRoleAssignment** cmdlet to retrieve the role assignments, and then pipe them to the **Set-ManagementRoleAssignment** cmdlet.

This procedure uses the concepts of pipelining and the *WhatIf* switch. For more information, see the following topics:

- Pipelining
- WhatIf, Confirm, and ValidateOnly Switches

To set the scope on all of the role assignments on a role group at the same time, use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <name of role group> | Set-ManagementR
```

You use only the parameters you need to configure the scope you want to use. For example, if you want to change the recipient scope for all role assignments on the Sales Recipient Management role group to Direct Sales Employees, use the following command.

```
Get-ManagementRoleAssignment -RoleAssignee "Sales Recipient Management" | Set-Man
```

Note:

You can use the *WhatIf* switch to verify that only the role assignments you want to change are changed. Run the preceding command with the *WhatIf* switch to verify the results, and then remove the *WhatIf* switch to apply the changes.

For more information about changing management role assignments, see Change a Role Assignment.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Use the Shell to change the scope of individual role assignments on a role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Role assignments between the role group and the roles assigned to it can use the implicit scope obtained from the roles themselves, the same custom scope, or different custom scopes. For more information about role assignments, see Understanding Management Role Assignments.

The scopes on the role assignments are managed using the **Set-ManagementRoleAssignment** cmdlet. You can't manage scopes using the **Set-RoleGroup** cmdlet.

This procedure uses the concepts of pipelining and the **Format-List** cmdlet. For more information, see the following topics:

- Pipelining
- Working with Command Output

To change the scope on a role assignment between a role group and a management role, you first find the name of the role assignment, and then set the scope on the role assignment.

1. To find the names of all the role assignments on a role group, use the

following command. By piping the management role assignments to the **Format-List** cmdlet, you can view the full name of the assignment.

```
Get-ManagementRoleAssignment -RoleAssignee <role group name> | Format-
```

2. Find the name of the role assignment you want to change. Use the name of the assignment in the next step.
3. To set the scope on an individual assignment, use the following syntax.

```
Set-ManagementRoleAssignment <role assignment name> -CustomRecipientWr
```

You use only the parameters you need to configure the scope you want to use. For example, if you want to change the recipient scope for the Mail Recipients_Sales Recipient Management role assignment to All Sales Employees, use the following command.

```
Set-ManagementRoleAssignment "Mail Recipients_Sales Recipient Management" -Custom
```

For more information about changing management role assignments, see Change a Role Assignment.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Other Tasks

After you change the scope of role assignments on a role group, you may also want to:

- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group

1.3.3.1.13 Create a Linked Role Group

Create a Linked Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A linked management role group can be used to enable members of a universal security group (USG) in a foreign Active Directory forest to manage a Microsoft Exchange Server 2010 organization in a resource Active Directory forest. By associating a USG in a foreign forest with a linked role group, the members of that USG are granted the permissions provided by the management roles assigned to the linked role group. For more information about linked role groups, see Understanding Management Role Groups.

Important:

To add or remove users on a linked role group, you must add or remove members in the USG in the foreign Active Directory forest. You can't use the **Add-RoleGroupMember**, **Remove-RoleGroupMember**, or **Update-RoleGroupMember** cmdlets to change the membership of a linked role group.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Prerequisites

- Configuring a linked role group requires that, at a minimum, a one-way trust is established between the resource Active Directory forest in which the linked role group will reside, and the foreign Active Directory forest where the users or USGs reside. The resource forest must trust the foreign forest.
- You must have the following information about the foreign Active Directory forest:
  - **Credentials** You must have a user name and password that can access the foreign Active Directory forest. This information is used with the *LinkedCredential* parameter on the **New-RoleGroup** cmdlet.
  - **Domain controller** You must have the fully qualified domain name (FQDN) of an Active Directory domain controller in the foreign Active Directory forest. This information is used with the *LinkedDomainController* parameter on the **New-RoleGroup** cmdlet.
  - **Foreign USG** You must have the full name of a USG in the foreign Active Directory forest that contains the members you want to associate with the linked role group. This information is used with the *LinkedForeignGroup* parameter on the **New-RoleGroup** cmdlet.

Use the Shell to create a linked role group with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a linked role group with no scope.

To create a linked role group and assign management roles to the linked role group, do the following:

1. Store the foreign Active Directory forest credentials in a variable.

```
$ForeignCredential = Get-Credential
```

2. Create the linked role group using the following syntax.

```
New-RoleGroup <role group name> -LinkedForeignGroup <name of foreign U
```

3. Add or remove members to or from the foreign USG using Active Directory Users and Computers on a computer in the foreign Active Directory forest.

This example does the following:

- Retrieves the credentials for the users.contoso.com foreign Active Directory forest. These credentials are used to connect to the DC01.users.contoso.com domain controller in the foreign forest.
- Creates a linked role group called Compliance Role Group in the resource forest where Exchange 2010 is installed.
- Links the new role group to the Compliance Administrators USG in the users.contoso.com foreign Active Directory forest.
- Assigns the Transport Rules and Journaling management roles to the new linked role group.

```
$ForeignCredential = Get-Credential
New-RoleGroup "Compliance Role Group" -LinkedForeignGroup "Compliance Administrat
```

For detailed syntax and parameter information, see New-RoleGroup.

Use the Shell to create a linked role group with a custom management scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a linked role group with a custom management scope.

You can create linked role groups with custom recipient management scopes, custom configuration management scopes, or both. To create a linked role group and assign management roles with custom scopes to it, do the following:

1. Store the foreign Active Directory forest credentials in a variable.

```
$ForeignCredential = Get-Credential
```

2. Create the linked role group using the following syntax.

```
New-RoleGroup <role group name> -LinkedForeignGroup <name of foreign U
```

3. Add or remove members to or from the foreign USG using Active Directory Users and Computers on a computer in the foreign Active Directory forest.

This example does the following:

- Retrieves the credentials for the users.contoso.com foreign Active Directory forest. These credentials are used to connect to the DC01.users.contoso.com domain controller in the foreign forest.
- Creates a linked role group called Seattle Compliance Role Group in the resource forest where Exchange 2010 is installed.
- Links the new role group to the Seattle Compliance Administrators USG in the users.contoso.com foreign Active Directory forest.
- Assigns the Transport Rules and Journaling management roles to the new linked role group with the Seattle Recipients custom recipient scope.

```
$ForeignCredential = Get-Credential
New-RoleGroup "Seattle Compliance Role Group" -LinkedForeignGroup "Seattle Compli
```

For more information about management scopes, see Understanding Management Role Scopes.

For detailed syntax and parameter information, see New-RoleGroup.

Use the Shell to create a linked role group with an OU scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a linked role group with an organizational unit (OU) scope.

You can create linked role groups that use an OU recipient scope. To create a linked role group and assign management roles to it with an OU scope, do the following:

1. Store the foreign Active Directory forest credentials in a variable.

```
$ForeignCredential = Get-Credential
```

2. Create the linked role group using the following syntax.

```
New-RoleGroup <role group name> -LinkedForeignGroup <name of foreign U
```

3. Add or remove members to or from the foreign USG using Active Directory Users and Computers on a computer in the foreign Active Directory forest.

This example does the following:

- Retrieves the credentials for the users.contoso.com foreign Active Directory forest. These credentials are used to connect to the DC01.users.contoso.com domain controller in the foreign forest.
- Creates a linked role group called Executives Compliance Role Group in the resource forest where Exchange 2010 is installed.
- Links the new role group to the Executives Compliance Administrators USG in the users.contoso.com foreign Active Directory forest.
- Assigns the Transport Rules and Journaling management roles to the new linked role group with the OU recipient scope Executives OU.

```
$ForeignCredential = Get-Credential
New-RoleGroup "Executives Compliance Role Group" -LinkedForeignGroup "Executives
```

For more information about management scopes, see Understanding Management Role Scopes.

For detailed syntax and parameter information, see New-RoleGroup.

Other Tasks

After you create a linked role group, you may also want to:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Change the Scope of Role Assignments to a Role Group

1.3.3.1.14 Change a Linked Foreign USG on a Linked Role Group

Change a Linked Foreign USG on a Linked Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can change the universal security group (USG), which is located in a foreign Active Directory forest associated with a linked management role group. This can be useful if the original foreign USG is being removed, and you need to transition to a new USG. For more information about linked role groups, see Understanding Management Role Groups.

Looking for other management tasks related to administrators and specialist users? Check out Managing Administrator and Specialist Users.

Prerequisites

- **Credentials** You must have a user name and password that can access the foreign Active Directory forest. This information is used with the *LinkedCredential* parameter on the **Set-RoleGroup** cmdlet.

- **Domain controller** You must have the fully qualified domain name (FQDN) of an Active Directory domain controller in the foreign Active Directory forest. This information is used with the *LinkedDomainController* parameter on the **Set-RoleGroup** cmdlet.
- **Foreign USG** You must have the full name of a USG in the foreign Active Directory forest that contains the members you want to associate with the linked role group. This information is used with the *LinkedForeignGroup* parameter on the **Set-RoleGroup** cmdlet.

Use the Shell to change the foreign USG on a linked role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the foreign USG on a linked role group.

To change the foreign USG associated with a linked role group, do the following:

1. Store the foreign Active Directory forest credentials in a variable.

```
$ForeignCredential = Get-Credential
```

2. Create the new linked role group using the following syntax.

```
Set-RoleGroup <role group name> -LinkedForeignGroup <name of foreign U
```

This example does the following:

- Retrieves the credentials for the users.contoso.com foreign Active Directory forest. These credentials are used to connect to the DC01.users.contoso.com domain controller in the foreign forest.
- Changes the foreign USG on the Compliance Role Group role group to Regulatory Compliance Officers.

```
$ForeignCredential = Get-Credential
Set-RoleGroup "Compliance Role Group" -LinkedForeignGroup "Regulatory Compliance
```

For detailed syntax and parameter information, see Set-RoleGroup.

Other Tasks

After you change the foreign USG on a linked role group, you may also want to:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Change the Scope of Role Assignments to a Role Group

1.3.3.1.15 Create Linked Role Groups that Mirror Built-in Role Groups

Create Linked Role Groups that Mirror Built-in Role Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Using linked management role groups in Microsoft Exchange Server 2010, you can link a role group in an Exchange 2010 resource forest with a universal security group (USG) in a foreign user forest. This is useful when you want administrators with accounts in the user forest to manage the servers running Exchange in the resource forest. For more information about linked role groups, see Understanding Management Role Groups.

By default, Exchange 2010 includes a number of built-in role groups that provide you with permissions to manage a variety of features and job functions. Each role group is tailored to provide specific permissions for each feature and job function. However, these role groups can't be linked to USGs in a foreign forest. They can only contain users and USGs from the local resource forest. Fortunately, it's possible to replicate these built-in role groups using linked role groups.

You can re-create each built-in role group as a linked role group. All of the management roles and management scopes assigned to each role group are added to the new linked role group. For more information about management roles and scopes, see the following topics:

- Understanding Management Roles
- Understanding Management Role Scopes

Looking for other management tasks related to role groups? Check out Managing Administrator and Specialist Users.

Prerequisites

- Configuring a linked role group requires a one-way trust between the resource Active Directory forest in which the linked role group will reside, and the foreign Active Directory forest where the users or USGs reside. The resource forest must trust the foreign forest.
- You must have the following information about the foreign Active Directory forest:
  - **Credentials** You must have a user name and password that can access the foreign Active Directory forest. This information is used with the *LinkedCredential* parameter on the **New-RoleGroup** cmdlet. This information is obtained by running the **Get-Credential** cmdlet. The format of the user name is *domain**username*.
  - **Domain controller** You must have the fully qualified domain name (FQDN) of an Active Directory domain controller in the foreign Active Directory forest. This information is used with the *LinkedDomainController* parameter on the **New-RoleGroup** cmdlet.
  - **Foreign USG** You must have the full name of a USG in the foreign Active Directory forest that contains the members you want to associate with the linked role group. This information is used with the *LinkedForeignGroup* parameter on the **New-RoleGroup** cmdlet.

Use the Shell to create linked role groups that replicate built-in role groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to create linked role groups that replicate built-in role groups.

Each of the following sections shows you how to re-create each role group as a linked role group. Complete the procedures in each section to re-create all of the built-in role groups as linked role groups.

Create the Organization Management linked role group

To re-create the Organization Management role group as a linked role group, you perform a procedure that's different than the procedure used to re-create other built-in role groups. This is because the Organization Management role group has delegating role assignments between it and all of the management roles. Re-creating the delegating role assignments requires an additional step.

1. Create a USG in the foreign forest that will be linked to the Organization Management role group.
2. Store the foreign Active Directory forest credentials in a variable.

```
$ForeignCredential = Get-Credential
```

3. Store all of the roles assigned to the Organization Management role group in a variable.

```
$OrgMgmt  = Get-RoleGroup "Organization Management"
```

4. Create the Organization Management linked role group and add the roles assigned to the built-in Organization Management role group.

```
New-RoleGroup "Organization Management - Linked" -LinkedForeignGroup <
```

5. Remove all of the regular assignments between the new Organization Management linked role group and the My* end-user roles.

```
Get-ManagementRoleAssignment -RoleAssignee "Organization Management -
```

6. Add delegating role assignments between the new Organization Management linked role group and all management roles.

```
Get-ManagementRole | New-ManagementRoleAssignment -SecurityGroup "Orga
```

This example assumes the following values are used for each parameter:

- **LinkedForeignGroup** `Organization Management Administrators`
- **LinkedDomainController** `DC01.users.contoso.com`

Using the preceding values, this example re-creates the Organization Management role group as a linked role group.

```
$ForeignCredential = Get-Credential
$OrgMgmt  = Get-RoleGroup "Organization Management"
New-RoleGroup "Organization Management - Linked" -LinkedForeignGroup "Organizatio
Get-ManagementRoleAssignment -RoleAssignee "Organization Management - Linked" -Ro
Get-ManagementRole | New-ManagementRoleAssignment -SecurityGroup "Organization Ma
```

Create all other linked role groups

To re-create the built-in role groups (other than the Organization Management role group) as linked role groups, use the following procedure for each group.

1. Create a USG in the foreign forest for each role group that will be linked to each new role group.
2. Store the foreign Active Directory forest credentials in a variable. You only need to do this once.

```
$ForeignCredential = Get-Credential
```

3. Retrieve a list of role groups using the following cmdlet.

```
Get-RoleGroup
```

4. For each role group, other than the Organization Management role group, do the following.

```
$RoleGroup = Get-RoleGroup <name of role group to re-create>
New-RoleGroup "<role group name> - Linked" -LinkedForeignGroup <name o
```

5. Repeat the preceding step for each built-in role group you want to re-create

as a linked role group.

This example assumes the following values are used for each parameter:

- **LinkedDomainController** `DC01.users.contoso.com`
- **Built-in role groups to be re-created as linked role groups** `Recipient Management, Server Management`
- **Foreign group for Recipient Management linked role group** `Recipient Management Administrators`
- **Foreign group for Server Management linked role group** `Server Management Administrators`

Using the preceding values, this example re-creates the Recipient Management and Server Management role groups as linked role groups.

```
$ForeignCredential = Get-Credential
Get-RoleGroup
$RoleGroup = Get-RoleGroup "Recipient Management"
New-RoleGroup "Recipient Management - Linked" -LinkedForeignGroup "Recipient Mana
$RoleGroup = Get-RoleGroup "Server Management"
New-RoleGroup "Server Management - Linked" -LinkedForeignGroup "Server Management
```

Other Tasks

After you create linked role groups, you may also want to:

- Add members to the foreign USGs using Active Directory Users and Computers in the foreign forest.
- Remove members of built-in role groups. For more information, see Remove Members from a Role Group.
- Add additional roles to the new linked role groups. For more information, see Add a Role to a Role Group.
- Remove roles from the new linked role groups. For more information, see Remove a Role from a Role Group.
- Change the scopes of role assignments between the new linked role groups and management roles. For more information, see Change the Scope of Role Assignments to a Role Group.
- Create additional linked role groups. For more information, see Create a Linked Role Group.

1.3.3.2 Managing End Users

Managing End Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-06-04*

Add an Assignment Policy

Remove an Assignment Policy

View a List of Assignment Policies

Change the Assignment Policy on a Mailbox

Change the Default Assignment Policy

Add a Role to an Assignment Policy

Remove a Role from an Assignment Policy

View a List of Roles on an Assignment Policy

1.3.3.2.1 Add an Assignment Policy

Add an Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you want to customize the permissions that you assign to a group of end users, create a new custom management role assignment policy. The assignment policy you create can be customized to suit your end user's specific requirements. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

After you've created the new assignment policy, you assign users to it. For more information, see Change the Assignment Policy on a Mailbox.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the ECP to create a new assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

Note:

You can only create explicit assignment policies using the Exchange Control Panel (ECP). If you want to create a new default assignment policy, you must use the Exchange Management Shell. For more information, see the "Use the Shell to create a default assignment policy" section later in this topic.

1. In the EMC, navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. Click New under Role Assignment Policies.
6. In the **Name** field, enter the name of the new assignment policy.
7. In the **Description** field, provide a short description of the purpose for the assignment policy.
8. Select the check box next to the role or roles you want to add to the assignment policy. You can select multiple roles, including end-user roles you've added. If you select a role that has child roles, the child roles are

automatically selected.

9. Click **Save** to save the changes to the assignment policy.

Use the Shell to create an explicit assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

To create an explicit assignment policy that can be manually assigned to mailboxes, use the following syntax.

```
New-RoleAssignmentPolicy <assignment policy name> -Roles <roles to assign>
```

This example creates the explicit assignment policy Limited Mailbox Configuration and assigns the `MyBaseOptions`, `MyAddressInformation`, and `MyDisplayName` roles to it.

```
New-RoleAssignmentPolicy "Limited Mailbox Configuration" -Roles MyBaseOptions, My
```

For detailed syntax and parameter information, see New-RoleAssignmentPolicy.

Use the Shell to create a default assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

To create a default assignment policy assigned to new mailboxes, use the following syntax.

```
New-RoleAssignmentPolicy <assignment policy name> -Roles <roles to assign> -IsDef
```

This example creates the default assignment policy Limited Mailbox Configuration and assigns the `MyBaseOptions`, `MyAddressInformation`, and `MyDisplayName` roles to it.

```
New-RoleAssignmentPolicy "Limited Mailbox Configuration" -Roles MyBaseOptions, My
```

For detailed syntax and parameter information, see New-RoleAssignmentPolicy.

Other Tasks

After you create a new assignment policy, you may also want to:

- Change the Assignment Policy on a Mailbox
- Add a Role to an Assignment Policy
- Remove a Role from an Assignment Policy
- View a List of Assignment Policies
- Change the Default Assignment Policy

1.3.3.2.2 Remove an Assignment Policy

Remove an Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you no longer need a management role assignment policy, you can remove it. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Prerequisites

- All users assigned the assignment policy must be changed to another assignment policy. For more information about how to change an assignment policy on a mailbox, see Change the Assignment Policy on a Mailbox.
- All the management role assignments between the assignment policy and the assigned management roles must be removed. For more information about how to remove a role assignment from an assignment policy, see Remove a Role from an Assignment Policy.
- If you want to remove a default assignment policy, it must be the last assignment policy in the Exchange 2010 organization.

Use the ECP to remove an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. Select the assignment policy you want to remove, and then click  .

Use the Shell to remove an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

To remove an assignment policy, use the following syntax.

```
Remove-RoleAssignmentPolicy <role assignment policy>
```

This example removes the New York Temporary Users assignment policy.

```
Remove-RoleAssignmentPolicy "New York Temporary Users"
```

For detailed syntax and parameter information, see Remove-RoleAssignmentPolicy.

Other Tasks

After you remove an assignment policy, you may also want to:

- Add an Assignment Policy
- View a List of Assignment Policies

1.3.3.2.3 View a List of Assignment Policies

View a List of Assignment Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view management role assignment policies in a variety of ways, depending on the information you want and whether you're using the Exchange Control Panel (ECP) or the Exchange Management Shell.

In the ECP, you can view the list of assignment policies and the roles assigned to them. In the Shell, you can view all the assignment policies in your organization, list the mailboxes assigned a specific policy, and more.

For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the ECP to view a list of assignment policies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. To view the details of a specific assignment policy, select the assignment policy you want to view. The description and the roles assigned to the assignment policy are displayed in the details pane.

Use the Shell to view a list of assignment policies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can view a list of all the assignment policies in your organization by not specifying any assignment policies when you run the **Get-RoleAssignmentPolicy** cmdlet.

This procedure makes use of pipelining and the **Format-Table** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

To return a list of all assignment policies in your organization, use the following command.

```
Get-RoleAssignmentPolicy
```

To return a list of specific properties for all the assignment policies in your organization, you can pipe the results to the **Format-Table** cmdlet and specify the properties you want in the list of results. Use the following syntax.

```
Get-RoleAssignmentPolicy | Format-Table <property 1>, <property 2...>
```

This example returns a list of all the assignment policies in your organization and includes the **Name** and **IsDefault** properties.

```
Get-RoleAssignmentPolicy | Format-Table Name, IsDefault
```

For detailed syntax and parameter information, see Get-Mailbox or Get-RoleAssignmentPolicy.

Use the Shell to view the details of a single assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can view the details of a specific assignment policy by using the **Get-RoleAssignmentPolicy** cmdlet and piping the output to the **Format-List** cmdlet.

This procedure makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

To view the details of a specific assignment policy, use the following syntax.

```
Get-RoleAssignmentPolicy <assignment policy name> | Format-List
```

This example views the details about the Redmond Users - no Text Messaging assignment policy.

```
Get-RoleAssignmentPolicy "Redmond Users - no Text Messaging" | Format-List
```

For detailed syntax and parameter information, see Get-Mailbox or Get-RoleAssignmentPolicy.

Use the Shell to find the default assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can find the default assignment policy by piping the output of the **Get-RoleAssignmentPolicy** cmdlet to the **Where** cmdlet. With the **Where** cmdlet, filter the data returned to display only the assignment policy that has its *IsDefault* property set to `$True`.

This procedure makes use of pipelining and the **Where** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

This example returns the default assignment policy.

```
Get-RoleAssignmentPolicy | Where { $_.IsDefault -eq $True }
```

For detailed syntax and parameter information, see Get-Mailbox or Get-RoleAssignmentPolicy.

Use the Shell to view mailboxes that are assigned a specific policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can find all of the mailboxes assigned a specific assignment policy by piping the output of the **Get-Mailbox** cmdlet to the **Where** cmdlet. With the **Where** cmdlet, filter the data returned to display only the mailboxes that have their *RoleAssignmentPolicy* property set to the assignment policy name you specify.

This procedure makes use of pipelining and the **Where** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

Use the following syntax.

```
Get-Mailbox | Where { $_.RoleAssignmentPolicy -Eq "<role assignment policy>" }
```

This example finds all the mailboxes assigned the policy Vancouver End Users.

```
Get-Mailbox | Where { $_.RoleAssignmentPolicy -Eq "Vancouver End Users" }
```

For detailed syntax and parameter information, see Get-Mailbox or Get-RoleAssignmentPolicy.

Other Tasks

After you view a list of assignment policies, you may also want to:

- Change the Assignment Policy on a Mailbox

1.3.3.2.4 Change the Assignment Policy on a Mailbox

Change the Assignment Policy on a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can change the management role assignment policy assigned to a mailbox. When you change a mailbox's assignment policy, the change takes effect as soon as the user refreshes the connection, such as the next time they log into their mailbox or open your mailbox options page. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the EMC to change the assignment policy on a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the user or resource mailbox you want to change the assignment policy on.
3. In the action pane, click **Properties**.
4. Select the **Mailbox Settings** tab.
5. Click **Role Assignment Policy**, and then click **Properties**.
6. Click **Browse** next to the **Apply role assignment policy** text box to see a list of available assignment policies. Select the role assignment you want to configure on this user or resource mailbox, and then click **OK**.

Use the Shell to change the assignment policy on a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

To change the assignment policy that's assigned to a mailbox, use the following syntax.

```
Set-Mailbox <mailbox alias or name> -RoleAssignmentPolicy <assignment policy>
```

This example sets the assignment policy to Unified Messaging Users on the mailbox Brian.

```
Set-Mailbox Brian -RoleAssignmentPolicy "Unified Messaging Users"
```

Use the Shell to change the assignment policy on a group of mailboxes assigned a specific assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

Note:
You can't use the Exchange Management Console (EMC) to change the assignment policy on a group of mailboxes all at once.

This procedure makes use of pipelining, the **Where** cmdlet, and the *WhatIf* parameter. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output
- WhatIf, Confirm, and ValidateOnly Switches

If you want to change the assignment policy for a group of mailboxes that are assigned a specific policy, use the following syntax.

```
Get-Mailbox | Where { $_.RoleAssignmentPolicy -Eq "<assignment policy to find>" }
```

This example finds all the mailboxes assigned to the Redmond Users - No Voicemail assignment policy and changes the assignment policy to Redmond Users - Voicemail Enabled.

```
Get-Mailbox | Where { $_.RoleAssignmentPolicy -Eq "Redmond Users - No Voicemail"
```

This example includes the *WhatIf* parameter so that you can see all the mailboxes that would be changed without committing any changes.

```
Get-Mailbox | Where { $_.RoleAssignmentPolicy -Eq "Redmond Users - No Voicemail"
```

For detailed syntax and parameter information, see Get-Mailbox or Set-Mailbox.

Other Tasks

After you change the assignment policy on a mailbox, you may also want to:

- Add a Role to an Assignment Policy
- Remove a Role from an Assignment Policy
- Add an Assignment Policy
- View a List of Assignment Policies

Change the Default Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can change the management role assignment policy assigned to new mailboxes that are created. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the Shell to change the default assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the default assignment policy.

To change the default assignment policy, use the following syntax.

```
Set-RoleAssignmentPolicy <assignment policy name> -IsDefault
```

This example sets the Vancouver End Users assignment policy as the default assignment policy.

```
Set-RoleAssignmentPolicy "Vancouver End Users" -IsDefault
```

Important:
New mailboxes are assigned the default assignment policy even if the policy hasn't been assigned management roles. Mailboxes assigned assignment policies with no assigned management roles can't access any mailbox configuration features in the Exchange 2010 Web interface. For more information about assigning management roles, see Other Tasks later in this topic.

For detailed syntax and parameter information, see Set-RoleAssignmentPolicy.

Other Tasks

After you change the default assignment policy, you may also want to:

- Add a Role to an Assignment Policy
- Remove a Role from an Assignment Policy
- Change the Assignment Policy on a Mailbox
- View a List of Assignment Policies

Add a Role to an Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you want to enable users to manage a feature on their mailboxes, you can add a management role to the management role assignment policy they're assigned to. If more than one user is assigned an assignment policy, all the users gain the ability to manage that feature. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the ECP to add a role to an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. Select the assignment policy you want to add one or more roles to, and then click **Details**.
6. Select the check box next to the role or roles you want to add to the assignment policy. You can select multiple roles, including end-user roles you've added. If you select a role that has child roles, the child roles are automatically selected.
7. Click **Save** to save the changes to the assignment policy.

Use the Shell to add a role to an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

To create a management role assignment between a role and an assignment policy, use the following syntax.

```
New-ManagementRoleAssignment -Name <role assignment name> -Role <role name> -Poli
```

This example creates the role assignment Seattle Users - Voicemail between the MyVoicemail role and the Seattle Users assignment policy.

```
New-ManagementRoleAssignment -Name "Seattle Users - Voicemail" -Role MyVoicemail
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Other Tasks

After you add a role to an assignment policy, you may also want to:

- Change the Assignment Policy on a Mailbox
- Change the Default Assignment Policy
- View a List of Roles on an Assignment Policy

1.3.3.2.7 Remove a Role from an Assignment Policy

Remove a Role from an Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you don't want end users to have permissions to manage certain features of their mailbox or distribution group, you can remove the management role that grants the permissions from the management role assignment policy the user is assigned. If other users are assigned the same assignment policy, they also lose the ability to manage that feature. For more information about assignment policies in Microsoft Exchange Server 2010, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the ECP to remove a role from an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. Select the assignment policy you want to remove one or more roles from, and then click **Details**.
6. Clear the check box next to the role or roles you want to remove from the assignment policy. If you clear the check box for a role that has child roles, the check boxes for the child roles are also cleared.
7. Click **Save** to save the changes to the assignment policy.

Use the Shell to remove a role from an

assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can remove roles from assignment policies by retrieving the associated management role assignment using the **Get-ManagementRoleAssignment** cmdlet and then piping the role assignment returned to the **Remove-ManagementRoleAssignment** cmdlet.

For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

This procedure uses pipelining. For more information about pipelining, see Pipelining.

To remove a role from an assignment policy, use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <assignment policy name> -Role <role n
```

This example removes the MyVoicemail management role, which enables users to manage their voice mail options, from the Seattle Users assignment policy.

```
Get-ManagementRoleAssignment -RoleAssignee "Seattle Users" -Role MyVoicemail | Re
```

For detailed syntax and parameter information, see Remove-ManagementRoleAssignment.

Other Tasks

After you remove a role from an assignment policy, you may also want to:

- Add a Role to an Assignment Policy
- View a List of Roles on an Assignment Policy

1.3.3.2.8 View a List of Roles on an Assignment Policy

View a List of Roles on an Assignment Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The management roles assigned to an assignment policy determine what actions the end users who are assigned the assignment policy can perform. By viewing the list of roles assigned to an assignment policy, you can see what actions the users assigned that assignment policy can perform. For more information about role assignment policies, see Understanding Management Role Assignment Policies.

Looking for other management tasks related to end users? Check out Managing End Users.

Use the ECP to view a list of roles on an

assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the Exchange Management Console (EMC), navigate to **Toolbox** in the console tree.
2. In the work pane, double-click **Role Based Access Control (RBAC) User Editor** to open the user editor in the Exchange Control Panel (ECP).
3. Provide credentials in the **Domain\user name** and **Password** fields for an account that has the permissions needed to open the user editor in the ECP. Click **Sign in**.
4. Click the **User Roles** tab.
5. To view the list of roles on an assignment policy, select the assignment policy you want to view. The roles assigned to the assignment policy are displayed in the details pane.

Use the Shell to view a list of roles on an assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Assignment policies" entry in the Role Management Permissions topic.

You can use the **Get-ManagementRoleAssignment** cmdlet to view the list of roles assigned to an assignment policy.

1. To find the names of the assignment policies in your organization, use the following command.

```
Get-RoleAssignmentPolicy
```

2. Find the name of the assignment policy whose roles you want to list.
3. To list the roles on an assignment policy, use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <assignment policy name>
```

This example lists all of the roles assigned to the Default Role Assignment Policy assignment policy.

```
Get-ManagementRoleAssignment -RoleAssignee "Default Role Assignment Policy"
```

For detailed syntax and parameter information, see Get-RoleAssignmentPolicy or Get-ManagementRoleAssignment.

Other Tasks

After you view the list of roles assigned to an assignment policy, you may also want to:

- Add a Role to an Assignment Policy
- Remove a Role from an Assignment Policy
- Add an Assignment Policy
- Change the Assignment Policy on a Mailbox

1.3.3.3 View Effective Permissions

View Effective Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Permissions in Microsoft Exchange Server 2010 are granted using management roles that are assigned to management role groups, management role assignment policies, universal security groups (USGs), or directly to users. Users are granted the permissions if they're members of the role groups or USGs, or are assigned role assignment policies.

Most permissions are granted based on role group membership or the assignment of assignment policies to end users. Although using role groups and assignment policies makes it easy to grant permissions to large numbers of users, you may not be aware of who is a member of a role group, or who has been assigned an assignment policy. This is where the *GetEffectiveUsers* switch on the **Get-ManagementRoleAssignment** cmdlet is useful. It shows you what users are granted the permissions given by a management role through the role groups, assignment policies, and USGs that are assigned to them.

The *GetEffectiveUsers* switch is used with the **Get-ManagementRoleAssignment** cmdlet when the *Role* parameter is used. By specifying this switch with a particular role, the **Get-ManagementRoleAssignment** cmdlet examines all of the role assignees assigned to the role, such as role groups, assignment policies, and USGs, and lists the members of each.

Note:

The *GetEffectiveUser* switch doesn't list users that are members of a linked foreign role group. Instead of a list of users, if a linked role group is found, **All Linked Group Members** is displayed. For more information about permissions in multiple forests, see Understanding Multiple-Forest Permissions.

For more information about management roles, role groups, and assignment policies, see Understanding Role Based Access Control.

For more information about management role assignments, see Understanding Management Role Assignments.

Looking for other management tasks related to managing permissions? Check out Managing Permissions.

Use the Shell to list all effective users

Note:

You can't use the EMC to list all effective users.

To list all of the users that are granted the permissions provided by a management role, use the following syntax.

```
Get-ManagementRoleAssignment -Role <role name> -GetEffectiveUsers
```

This example lists all the users that are granted permissions provided by the Mail Recipients role.

```
Get-ManagementRoleAssignment -Role "Mail Recipients" -GetEffectiveUsers
```

If you want to change what properties are returned in the list or export the list to a

comma-separated value (CSV) file, see Customize output and display it later in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Use the Shell to find a specific user on a role

Note:
You can't use the EMC to find a specific user on a role.

To find a specific user that's been granted permissions by a management role, you must use the **Get-ManagementRoleAssignment** cmdlet to retrieve a list of all effective users, and then pipe the output of the cmdlet to the **Where** cmdlet. The **Where** cmdlet filters the output and returns only the user you specified. Use the following syntax.

```
Get-ManagementRoleAssignment -Role <role name> -GetEffectiveUsers | Where { $_.Ef
```

This example finds the user David Strome on the Journaling role.

```
Get-ManagementRoleAssignment -Role Journaling -GetEffectiveUsers | Where { $_.Eff
```

If you want to change what properties are returned in the list or export the list to a CSV file, see Customize output and display it later in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Use the Shell to find a specific user on all roles

Note:
You can't use the EMC to find a specific user on all roles.

To know every role that a user receives permissions from, you must use the **Get-ManagementRoleAssignment** cmdlet to retrieve all effective users on all management roles and then pipe the output of the cmdlet to the **Where** cmdlet. The **Where** cmdlet filters the output and returns only the role assignments that grant the user permissions.

```
Get-ManagementRoleAssignment -GetEffectiveUsers | Where { $_.EffectiveUserName -E
```

This example finds all the role assignments that grant permissions to the user Kim Akers.

```
Get-ManagementRoleAssignment -GetEffectiveUsers | Where { $_.EffectiveUserName -E
```

If you want to change what properties are returned in the list or export the list to a CSV file, see Customize output and display it later in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Use the Shell to customize output and display it

Note:
You can't use the EMC to customize output and display it.

The default output of the **Get-ManagementRoleAssignment** cmdlet might not have the information you want. The output of the cmdlet contains many more properties that you can access. The following are some of the properties that could be useful:

- **EffectiveUserName** This is the name of the user.
- **Role** This indicates the role that's granting the permissions.
- **RoleAssigneeName** This is the role group, assignment policy, or USG that's assigned to the role and contains the user in the `EffectiveUserName` property.
- **RoleAssigneeType** This indicates whether the role assignment is to a role group, assignment policy, USG, or user.
- **AssignmentMethod** This indicates whether the assignment between the role and the role assignee is direct or indirect.
- **CustomRecipientWriteScope** This indicates the custom recipient write scope, if any, that was applied to the role assignment when it was created. The scope specified in this property overrides the implicit recipient write scope specified in the `RecipientWriteScope` property.
- **CustomConfigWriteScope** This indicates the custom configuration write scope, if any, that was applied to the role assignment when it was created. The scope specified in this property overrides the implicit configuration write scope specified in the `ConfigWriteScope` property.
- **RecipientReadScope** This indicates the implicit recipient read scope that's applied to the role.
- **RecipientWriteScope** This indicates the implicit recipient write scope that's applied to the role.
- **ConfigReadScope** This indicates the implicit configuration read scope that's applied to the role.
- **ConfigWriteScope** This indicates the implicit configuration write scope that's applied to the role.

To select the properties you want to display in your list, you use nearly the same commands that are used in the Use the Shell to list all effective users, Use the Shell to find a specific user on a role, and Use the Shell to find a specific user on all roles sections. The difference is that you pipe the results of those commands to the **Format-Table** or **Select-Object** cmdlets. The **Format-Table** cmdlet is useful to output the list of results to your screen. The **Select-Object** cmdlet is useful to output the list of your results to a CSV file.

Both cmdlets let you specify the properties you want to see and in the order you want to see them. The **Format-Table** cmdlet gives you more options when you list results to a screen while **Select-Object** doesn't modify the output in any way, which is useful when piping the list to a CSV file.

For more information about the **Format-Table** and **Select-Object** cmdlets, see Working with Command Output.

Output a customized list to your screen

First, choose the information you want to see and find the associated command from one of the following procedures:

- Use the Shell to list all effective users
- Use the Shell to find a specific user a role
- Use the Shell to find a specific user on all roles

Then, choose the properties you want to see in your list. Finally, use the following syntax to view the list.

```
<command to retrieve list > | Format-Table <property 1>, <property 2>, <property
```

This example finds the user David Strome on all roles, and displays the `EffectiveUserName`, `Role`, `CustomRecipientWriteScope`, and `CustomConfigWriteScope` properties.

```
Get-ManagementRoleAssignment -GetEffectiveUsers | Where { $_.EffectiveUserName -E
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

Output a customized list to a CSV file

To export a list to a CSV file, you need to pipe the results of the **Get-ManagementRoleAssignment** command from the appropriate procedure listed previously to the **Select-Object** cmdlet. The output of the **Select-Object** cmdlet is then piped to the **Export-CSV** cmdlet, which saves the CSV output to a file name you specify.

First, choose the information you want to see and find the associated command from one of the following procedures:

- Use the Shell to list all effective users
- Use the Shell to find a specific user a role
- Use the Shell to find a specific user on all roles

Then, choose the properties you want to see in your list. Finally, use the following syntax to export the list to a CSV file.

```
<command to retrieve list > | Select-Object <property 1>, <property 2>, <property
```

This example finds the user David Strome on all roles, and displays the `EffectiveUserName`, `Role`, `CustomRecipientWriteScope`, and `CustomConfigWriteScope` properties.

```
Get-ManagementRoleAssignment -GetEffectiveUsers | Where { $_.EffectiveUserName -E
```

You can now view the CSV file in a viewer of your choice.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

1.3.3.4 Setting Administrator Permissions for the Edge Transport Server Role

Setting Administrator Permissions for the Edge Transport Server Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-19*

This topic provides an overview of the permissions that a user must have to administer a computer that has the Microsoft Exchange Server 2010 Edge Transport server role installed.

Edge Transport Server Role Permissions

The Edge Transport server role is deployed in an organization's perimeter network, which is also known as the boundary network or screened subnet. The Edge Transport server can be deployed as a stand-alone server or as a member of a perimeter Active Directory domain.

When the Exchange 2010 Edge Transport server role is installed, no Exchange-specific groups are created. The Administrators local group is granted full control of the Edge Transport server. The Administrators local group control includes the instance of Active Directory Lightweight Directory Services (AD LDS) on the Edge Transport server. When you log on by using an account that has Administrators local group membership, you can modify the server configuration, the status of queues and messages in transit, the security configuration of the server, and AD LDS data.

You perform remote administration of Edge Transport servers by using Microsoft Windows Terminal Services. The Administrators local group is automatically granted remote logon permissions. Other user accounts must have membership in the Remote Desktop Users local group to log on to the server by using a remote desktop connection. We recommend that you create a specific user account for each user who administers an Edge Transport server. You must add these user accounts to the Administrators local group to make sure that the correct access level is granted.

Permissions That Are Required to Administer the Edge Transport Server

The following table lists the common administrative tasks that are performed on the Edge Transport server and the group memberships that are required to complete each task successfully. You can use this information to delegate server administration.

Administrative tasks and group membership requirements

Task	Required group membership
Backup and restore	Backup Operators
Enable and disable agents	Administrators
Configure connectors	Administrators
Configure anti-spam policies	Administrators
Configure IP Block lists and IP Allow lists	Administrators
View queues and messages	Users
Manage queues and messages	Administrators
Create an Edge Subscription file	Administrators

1.3.3.5 Managing Advanced Permissions

Managing Advanced Permissions

Exchange Server 2010 > Permissions > Managing Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-21*

The procedures in the following sections enable you to configure advanced permissions models for your organization. You should have an in-depth knowledge of Role Based Access Control (RBAC) before performing advanced customization of your permissions model.

Management Roles and Role Entries

Management Role Scopes

Management Role Assignments

Managing Split Permissions

We recommend you manage your permissions using management role groups and management role assignment policies. For more information, see the following topics:

Managing Administrator and Specialist Users

Managing End Users

For more information about RBAC, see Understanding Role Based Access Control.

1.3.3.5.1 Management Roles and Role Entries

Management Roles and Role Entries

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-11*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Create a Role

View a Role

Remove a Role

Add a Role Entry to a Role

Change a Role Entry

View Role Entries

Remove a Role Entry from a Role

Create an Unscoped Role

Change a Role Entry on an Unscoped Top-Level Role

Add a Role Entry to an Unscoped Top-Level Role

For more information about managing role groups and role assignment policies, see the following topics:

Managing Administrator and Specialist Users

Managing End Users

Create a Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can create a management role, change the management role entries, add a scope if needed, and then assign the role to a role assignee. You should rarely need to perform this procedure. We recommend that you check whether a built-in management role can be used instead of creating a management role. For a list of built-in management roles, see Built-in Management Roles.

For more information about management roles in Microsoft Exchange Server 2010, see Understanding Management Roles.

You must use the Shell to create management roles.

Note:
This topic doesn't discuss how to create an unscoped management role. For information about how to create an unscoped management role, see Create an Unscoped Role.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Steps

Here are the basic steps needed to create a management role. Each of these steps includes links to more detailed procedures:

Step 1: Use the Shell to create the management role.

Step 2: Use the Shell to change the new role's management role entries.

Step 3: Use the Shell to create a custom management role scope, if required.

Step 4: Use the Shell to assign the new management role.

Note:
You can't use the EMC to create a management role.

Step 1: Create the management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

New management roles are based on existing roles. When you create a role, an existing role and its management role entries are copied to the new role. The existing role becomes the parent to the new child role. You must always choose a role that contains all the cmdlets and parameters you need to use, and then remove the ones you don't want. Child roles can't have management role entries that don’t exist in the parent role.

Use the following syntax to create the new role.

```
New-ManagementRole -Parent <existing role to copy> -Name <name of new role>
```

This example copies the Mail Recipients role and its management role entries to the Seattle Mail Recipients role.

```
New-ManagementRole -Parent "Mail Recipients" -Name "Seattle Mail Recipients"
```

For detailed syntax and parameter information, see New-ManagementRole.

Step 2: Change the new role's management role entries

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

After you create your role, you need to change the role's entries. You can remove an entire role entry, which removes access to the associated cmdlet completely. Or, you can remove parameters from a role entry to remove access to those specific parameters on the associated cmdlet.

You can't add new role entries or parameters on role entries unless they exist in the parent role. Because you just created a role from a parent role in Step 1, you can't add any additional role entries or parameters on role entries because they don't exist in the parent role.

When you change a role entry on a role, you can do one of the following:

- Remove a single, entire role entry.
- Remove multiple, entire role entries.
- Remove parameters from a role entry.

To remove role entries from your new role, see Remove a Role Entry from a Role.

Step 3: Create a custom management role scope, if required

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Management role scopes determine the objects made available to a user to view or change using the role entries configured in Step 2. New management roles inherit the read and write management role scopes of their parent role. These are called *implicit scopes*. However, there may be cases where you want to change the write scope of the new role to match your business needs. When you create a custom scope, you override the implicit write scope of the role. The implicit read scope of the role doesn't change. For more information about management role scopes, see Understanding Management Role Scopes.

You can create a custom scope, create an exclusive scope, use a predefined scope, or scope an assignment to an organizational unit (OU). The new scope must be within the implicit read scope of the role. To use a predefined scope or to specify an organizational unit, skip to Step 4.

To add a custom scope to your new role, see Create a Regular or Exclusive Scope.

Step 4: Assign the new management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

The final step when you create and configure a role is to assign it to a role assignee.

When you create a role assignment, you can choose to do one of the following:

- Create the role assignment with no scope.
- Create the role assignment with a predefined scope.
- Create the role assignment with an OU without a domain restriction filter.
- Create the role assignment with the custom or exclusive scope you created in Step 3.

Note:
You can't specify a scope when you create an assignment between a role and a management role assignment policy.

You can assign the new role to a role group, a role assignment policy, a user, or a universal security group (USG). For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to an Assignment Policy
- Add a Role to a User or USG

1.3.3.5.1.2 View a Role

View a Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management roles can be listed in a variety of ways, depending on the information you want. For example, you can choose to return only roles of a specific role type, roles that contain only specific cmdlets and parameters, or view the details of a specific management role. For more information about management roles in Microsoft Exchange Server 2010, see Understanding Management Roles.

If you want to view a list of all management role entries on a role, see View Role Entries.

You must use the Shell to view management roles.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

This topic makes use of pipelining and the **Format-List** and **Format-Table** cmdlets. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

What Do You Want To Do?

- View a specific management role
- List all management roles
- List management roles that contain a specific cmdlet
- List management roles that contain a specific parameter
- List management roles of a specific role type
- List the immediate child roles of a parent role
- List all child roles below a parent role

Note:
You can't use the EMC to view roles.

View a specific management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can view the details of a specific role by retrieving a specific role using the **Get-ManagementRole** cmdlet and piping the output to the **Format-List** cmdlet.

To view the details of a specific role, use the following syntax.

```
Get-ManagementRole <role name> | Format-List
```

This example retrieves the details about the Mail Recipients management role.

```
Get-ManagementRole "Mail Recipients" | Format-List
```

For detailed syntax and parameter information, see Get-ManagementRole.

List all management roles

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can view a list of all the management roles in your organization by not specifying any roles when you run the **Get-ManagementRole** cmdlet. By default, the role name and role type of each role are included in the results.

This example returns a list of all roles in your organization.

```
Get-ManagementRole
```

To return a list of specific properties for all the roles in your organization, you can pipe the results of the **Format-Table** cmdlet and specify the properties you want in the list of results. Use the following syntax.

```
Get-ManagementRole | Format-Table <property 1>, <property 2...>
```

This example returns a list of all the roles in your organization and includes the **Name** property and any property with the word **Implicit** at the beginning of the property name.

```
Get-ManagementRole | Format-Table Name, Implicit*
```

For detailed syntax and parameter information, see Get-ManagementRole.

List management roles that contain a specific cmdlet

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can return a list of roles that contain a cmdlet that you specify by using the *Cmdlet* parameter on the **Get-ManagementRole** cmdlet.

To return a list of roles that contain the cmdlet you specify, use the following syntax.

```
Get-ManagementRole -Cmdlet <cmdlet>
```

This example returns a list of roles that contain the **New-Mailbox** cmdlet.

```
Get-ManagementRole -Cmdlet New-Mailbox
```

For detailed syntax and parameter information, see Get-ManagementRole.

List management roles that contain a specific parameter

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can return a list of roles that contain one or more specified parameters by using the *CmdletParameters* parameter on the **Get-ManagementRole** cmdlet. Only roles that contain all the parameters you specify are returned.

When you use the *CmdletParameters* parameter, you can choose to include the *Cmdlet* parameter. If you include the *Cmdlet* parameter, only roles that contain the parameters you specify on the cmdlet you specify are returned. If you don't include the *Cmdlet* parameter, roles that contain the parameters you specify, regardless of the cmdlet they're on, are returned.

To return a list of roles that contain the parameters you specify, use the following syntax.

```
Get-ManagementRole [-Cmdlet <cmdlet>] -CmdletParameters <parameter 1>, <parameter
```

This example returns a list of roles that contain the *Database* and *Server* parameters, regardless of the cmdlets they exist on.

```
Get-ManagementRole -CmdletParameters Database, Server
```

This example returns a list of roles where the *EmailAddresses* parameter exists only on the **Set-Mailbox** cmdlet.

```
Get-ManagementRole -Cmdlet Set-Mailbox -CmdletParameters EmailAddresses
```

You can also use the wildcard character (*) with either the *Cmdlet* or *CmdletParameters* parameters to match partial cmdlet or parameter names.

For detailed syntax and parameter information, see Get-ManagementRole.

List management roles of a specific role type

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can return a list of roles based on a specified role type by using the *RoleType* parameter on the **Get-ManagementRole** cmdlet.

To return a list of roles that match the role type you specify, use the following syntax.

```
Get-ManagementRole -RoleType <roletype>
```

This example returns a list of roles based on the `UmMailboxes` role type.

```
Get-ManagementRole -RoleType UmMailboxes
```

For detailed syntax and parameter information, see Get-ManagementRole.

List the immediate child roles of a parent role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can return a list of roles that are the immediate children of the specified parent role by using the *GetChildren* parameter on the **Get-ManagementRole** cmdlet. Only roles that contain the role you specify as the parent role are returned.

To return a list of the immediate children roles of a parent role, use the following syntax.

```
Get-ManagementRole <parent role name> -GetChildren
```

This example returns a list of immediate children of the Disaster Recovery role.

```
Get-ManagementRole "Disaster Recovery" -GetChildren
```

For detailed syntax and parameter information, see Get-ManagementRole.

List all child roles below a parent role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

You can return a list of the entire chain of roles from a specified parent role to the last child role by using the *Recurse* parameter on the **Get-ManagementRole** cmdlet. The *Recurse* parameter tells the **Get-ManagementRole** cmdlet to recurse down through every parent and child relationship it finds until it reaches the last child role. The parent role is included in the list that's returned.

This example returns a list of all the child roles of a parent role.

```
Get-ManagementRole <parent role name> -Recurse
```

This example returns all the child roles of the Mail Recipients role.

```
Get-ManagementRole "Mail Recipients" -Recurse
```

For detailed syntax and parameter information, see Get-ManagementRole.

1.3.3.5.1.3 Remove a Role

Remove a Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management roles that are no longer required can be removed from your organization. You can only remove management roles that you created. Built-in management roles can't be removed. For more information about management roles in Microsoft Exchange Server 2010, see Understanding Management Roles.

You must use the Shell to remove management roles.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

Before you can remove a management role, you must remove all its management role assignments. For more information about how to remove a role assignment, see Remove a Role from a User or USG.

What Do You Want to Do?

- Use the Shell to remove a management role with no child roles
- Use the Shell to remove a management role with child roles
- Use the Shell to remove an unscoped management role

Note:
You can't use the EMC to remove a management role.

Remove a management role with no child roles

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

To remove a role with no child roles, use the following syntax.

```
Remove-ManagementRole <role name>
```

This example removes the Seattle Server Administrators role.

```
Remove-ManagementRole "Seattle Server Administrators"
```

For detailed syntax and parameter information, see Remove-ManagementRole.

Remove a management role with child roles

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

If a role that you want to remove has child roles, you must remove all the child roles also. You receive an error message if you try to remove a role that has child roles unless you use the *Recurse* switch. If you use the *Recurse* switch when you remove a role, the role you specify and all its child roles are removed.

Caution:

If you use the *Recurse* switch, all child roles of the specified role you want to remove are also removed. Make sure that you're aware of what roles will be removed before you run this command.

To make sure that you remove only the roles that you want to remove, use the *WhatIf* switch with your command to verify that it's correct. Use the following syntax.

```
Remove-ManagementRole <role name> -Recurse -WhatIf
```

The *WhatIf* switch performs the command without committing any changes and reports which roles it would have removed. For more information about the *WhatIf* switch, see WhatIf, Confirm, and ValidateOnly Switches.

After you confirm that only the roles you want to remove will be removed, run the same command without the *WhatIf* switch. This example removes the London Administrators role and all its child roles.

```
Remove-ManagementRole "London Administrators" -Recurse
```

For detailed syntax and parameter information, see Remove-ManagementRole.

Remove an unscoped management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

To remove an unscoped role, the same procedures provided in Remove a management role with no child roles and Remove a management role with child roles earlier in this topic can be used. The only difference is that when you remove an unscoped role, you must specify the *UnScopedTopLevel* switch when you run the command. This example removes an unscoped role and all its child roles.

```
Remove-ManagementRole "Custom IT Scripts" -Recurse -UnScopedTopLevel
```

As with removing other roles, you should use the *WhatIf* switch to verify that you're removing the correct roles.

For detailed syntax and parameter information, see Remove-ManagementRole.

Add a Role Entry to a Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

If you want to grant access to a cmdlet, you need to add the associated management role entry to a management role. After you add the role entry to a role, the users assigned the role will be able to access that cmdlet. For more information about management role entries in Microsoft Exchange Server 2010, see Understanding Management Roles.

You can't add role entries to built-in roles. If you want to customize roles, you must create a new role. For more information about how to create a new role, see Create a Role.

You must use the Shell to add role entries to a role.

Note:
This topic doesn't discuss how to add unscoped management role entries to an unscoped management role. For more information about how to add unscoped role entries, see Add a Role Entry to an Unscoped Top-Level Role.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

- A role entry that you want to add to a management role must exist in that role's immediate parent management role.
- This topic makes use of pipelining. For more information about pipelining, see Pipelining.

What Do You Want to Do?

- Use the Shell to add a single role entry from a parent role
- Use the Shell to add a single role entry from a parent role and include only specific parameters
- Use the Shell to add multiple role entries from a parent role

Note:
You can't use the EMC to add a role entry to a role.

Add a single role entry from a parent role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

You can add a role entry to a role exactly as it appears on the parent role by using the following syntax.

```
Add-ManagementRoleEntry <child role name>\<cmdlet>
```

This example adds the **Set-Mailbox** cmdlet to the Recipient Administrators role.

```
Add-ManagementRoleEntry "Recipient Administrators\Set-Mailbox"
```

This command checks the parent role, and if the role entry exists, adds it to the child role. If the role entry already exists on the child role, you can include the *Overwrite* parameter to overwrite the existing role entry.

For detailed syntax and parameter information, see Add-ManagementRoleEntry.

Add a single role entry from a parent role and include only specific parameters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

If you want to add a role entry from a parent role, but you want to include only specific parameters in the role entry on the child role, use the following syntax.

```
Add-ManagementRoleEntry <child role name>\<cmdlet> -Parameters <parameter 1>, <pa
```

This example adds the **Set-Mailbox** cmdlet to the Help Desk role, but includes only the *DisplayName* and *EmailAddresses* parameters in the entry on the child role.

```
Add-ManagementRoleEntry "Help Desk\Set-Mailbox" -Parameters DisplayName, EmailAdd
```

This command checks the parent role, and if the role entry exists, adds it to the child role. If the role entry already exists on the child role, you can include the *Overwrite* parameter to overwrite the existing role entry.

For detailed syntax and parameter information, see Add-ManagementRoleEntry.

Add multiple role entries from a parent role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

If you want to add more than one role entry to a role, you need to retrieve a list of role entries that exist on the parent role that you want to add to the child role, and then add them to the child role. To do this, you retrieve the list of role entries on a parent role by using the **Get-ManagementRoleEntry** cmdlet. Then you pipe the output of the **Get-ManagementRoleEntry** cmdlet to the **Add-ManagementRoleEntry** cmdlet. To retrieve multiple role entries, you need to use the wildcard character (*).

To add multiple entries from a parent role to a child role, use the following syntax.

```
Get-ManagementRoleEntry <parent role name>\*<partial cmdlet name>* | Add-Manageme
```

This example adds all the role entries that contain the string `Mailbox` in the cmdlet name on the Mail Recipients parent role to the Seattle Mail Recipients child role.

```
Get-ManagementRoleEntry "Mail Recipients\*Mailbox*" | Add-ManagementRoleEntry -Ro
```

If the role entries already exist on the child role, you can include the *Overwrite* parameter to overwrite the existing role entries.

For more information about retrieving a list of management role entries, see View Role Entries.

For detailed syntax and parameter information, see Get-ManagementRoleEntry and Add-ManagementRoleEntry.

1.3.3.5.1.5 Change a Role Entry

Change a Role Entry

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Each management role entry on a management role represents a single cmdlet. By adding parameters to or removing parameters from a role entry, which is then added to a management role, you control whether those parameters are available on that cmdlet. For more information about management role entries in Microsoft Exchange Server 2010, see Understanding Management Roles.

You can't modify the role entries on built-in management roles.

You must use the Shell to add or remove parameters from a role entry.

Note:
This topic doesn't discuss how to modify unscoped management role entries on an unscoped management role. For more information about how to modify unscoped role entries, see Create a Role.

Caution:
To add or remove parameters from a role entry, you must use the *AddParameter* or *RemoveParameter* parameters. If you omit the *AddParameter* or *RemoveParameter* parameter when you run the **Set-ManagementRoleEntry** cmdlet, only the parameters you specify using the *Parameters* parameter will be included in the role entry. All other parameters on the role entry will be removed.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

- If you want to add parameters to a role entry, the parameters you add must exist in the role entry in the parent role.
- The parameters must also exist on the cmdlet you specify.
- If you want to remove parameters from a role entry, the parameters you remove can't exist in the role entries of any child roles. You must remove the parameters from the role entries of the child roles. Use the "Use the Shell to remove one or more parameters from a role entry" procedure later in this topic to remove the parameters from the role entries of all child roles.

What Do You Want to Do?

- Use the Shell to add one or more parameters to a role entry
- Use the Shell to remove one or more parameters from a role entry

- Use the Shell to remove all parameters from a role entry
- Use the Shell to apply a specific set of parameters

Note:
You can't use the EMC to change a role entry.

Use the Shell to add one or more parameters to a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

To add parameters to a role entry, you need to specify the parameters you want to add using the *Parameters* parameter. You then need to specify the *AddParameter* parameter to indicate that you want to perform an add operation.

To add parameters to a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters <parameter 1>, <paramete
```

This example adds the *EmailAddresses* and *Type* parameters to the **Set-Mailbox** cmdlet on the Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\Set-Mailbox" -Parameters EmailA
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove one or more parameters from a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

To remove parameters from a role entry, you need to specify the parameters you want to remove using the *Parameters* parameter. You then need to specify the *RemoveParameter* parameter to indicate that you want to perform a remove operation.

To remove parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters <parameter 1>, <paramete
```

This example removes the *Port*, *ProtocolLoggingLevel*, and *SmartHostAuthMechanism* parameters from the **Set-SendConnector** cmdlet on the Tier 1 Server Administrators role.

```
Set-ManagementRoleEntry "Tier 1 Server Administrators\Set-SendConnector" -Paramet
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove all parameters from a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

To remove all the parameters from a role entry, you need to specify the value $Null on the *Parameters* parameter. You don't need to include the *RemoveParameters* parameter.

Removing all the parameters from a role entry is most useful when you want to make only a few parameters available on a cmdlet and exclude all of the other parameters. If you don't want the role to have access to a cmdlet, remove the associated role entry from the role completely instead of just removing the parameters. For more information about how to remove a role entry from a role, see Remove a Role Entry from a Role.

Caution:
You can't undo remove operations. If you mistakenly remove all the parameters from a role entry, you must add them again manually.

To remove all the parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters $Null
```

This example removes all the parameters from the **Set-CasMailbox** cmdlet on the Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\Set-CasMailbox" -Parameters $Nu
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to apply a specific set of parameters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

If you want only a specific set of parameters to be included on a role entry, specify the *Parameters* parameter only. Don't include the *AddParameter* or *RemoveParameter* parameters. When you specify only the *Parameters* parameter, only the parameters you specify in the command are included on the role entry. All other parameters are removed.

To specify a specific set of parameters, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<cmdlet> -Parameters <parameter 1>, <paramete
```

This example includes only the *Identity*, *DisplayName*, *MissedCallNotificationEnabled*, and *PersonalAuthAttendantEnabled* parameters on the **Set-UMMailbox** cmdlet on the Seattle Mail Recipients role.

```
Set-ManagementRoleEntry "Seattle Mail Recipients\Set-UMMailbox" -Parameters Ident
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

1.3.3.5.1.6 View Role Entries

View Role Entries

Managing Permissions > Managing Advanced Permissions > Management Roles and Role Entries >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Each management role entry represents a single cmdlet or script. The parameters included on a role entry determine what parameters on the cmdlet or script a user can access.

The identity of role entries consists of the management role name that the role entry is associated with, and the cmdlet or script that the role entry refers to. For more information about role entries in Microsoft Exchange Server 2010, see Understanding Management Roles.

You must use the Shell to view role entries.

Looking for other management tasks related to role entries? Check out Managing Advanced Permissions.

Prerequisites

This topic makes use of pipelining, the **Format-List** cmdlet, objects, and properties. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output
- Structured Data

What Do You Want To Do?

- View a list of role entries
  - View a list of all role entries on a role
  - View a list of roles that contain a specific role entry
  - View a targeted list of roles that contain similar role entries
- View a single role entry
- View the parameters on a single role entry

View a list of role entries

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

You can use the **Get-ManagementRoleEntry** cmdlet to retrieve a list of role entries. When you use the **Get-ManagementRoleEntry** cmdlet, you must specify a value that contains both the role name that contains the role entries you want to list and also the cmdlet name of the role entry you want to list. By combining the role name and cmdlet name with the wildcard character (*), you can return specific or broad lists of role entries.

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a list of all role entries on a role

To view a list of role entries on a specific role, use the following syntax.

```
Get-ManagementRoleEntry <role name>\*
```

This examples retrieves all the role entries on the `Recipient Administrators` role.

```
Get-ManagementRole "Recipient Administrators\*"
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a list of roles that contain a specific role entry

To view a list of all the roles that contain a specific role entry, use the following syntax.

```
Get-ManagementRoleEntry *\<cmdlet name>
```

This example retrieves all the roles that contain the **Set-Mailbox** role entry.

```
Get-ManagementRoleEntry *\Set-Mailbox
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a targeted list of roles that contain similar role entries

To view a list of targeted roles that contain cmdlets with similar names, use the following syntax.

```
Get-ManagementRoleEntry *<partial role name>*\*<partial cmdlet name>*
```

This example returns a list of role entries that contain the string `Mailbox` that are on roles that contain the string `Tier 1` in their names.

```
Get-ManagementRoleEntry "*Tier 1*\*Mailbox*"
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View a single role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

To view the details of a single role entry, use the following syntax.

```
Get-ManagementRoleEntry <role name>\<cmdlet name> | Format-List
```

This example retrieves the details of the **Set-Mailbox** role entry on the `Recipient Administrators` role.

```
Get-ManagementRoleEntry "Recipient Administrators\Set-Mailbox" | Format-List
```

If the role entry you view has too many parameters to list using the **Format-List** cmdlet, see "View the parameters on a single role entry" later in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

View the parameters on a single role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

Some role entries have more parameters than can be viewed by piping the results of the **Get-ManagementRoleEntry** cmdlet to the **Format-List** cmdlet. If you need to view all the parameters on a role entry, you need to directly access the **Parameters** property of the role entry object.

To view parameters stored in the **Parameters** property of a role entry object, use the following syntax.

```
(Get-ManagementRoleEntry <role name>\<cmdlet name>).Parameters
```

This example retrieves the parameters on the **Set-Mailbox** role entry on the Mail Recipients role.

```
(Get-ManagementRoleEntry "Mail Recipients\Set-Mailbox").Parameters
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry.

1.3.3.5.1.7 Remove a Role Entry from a Role

Remove a Role Entry from a Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management role entries on a management role determine what cmdlets and parameters are available on a management role. By removing role entries or parameters on a role entry, you can restrict what users assigned the management role can perform. For more information about management role entries in Microsoft Exchange Server 2010, see Understanding Management Roles.

You must use the Shell to remove role entries from a role.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

What Do You Want to Do?

- Use the Shell to remove a single entire role entry from a role
- Use the Shell to remove multiple entire role entries from a role
- Use the Shell to remove parameters from a role entry on a role

Note:
You can't use the EMC to remove a role entry from a role.

Remove a single entire role entry from a role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

When you remove a role entry from a role, you remove the ability for users assigned that role to access the associated cmdlet or script.

Use the following syntax to remove an entire management role entry from a role.

```
Remove-ManagementRoleEntry <management role>\<management role entry>
```

This example removes the **Enable-MailUser** cmdlet from the Seattle Server Administrators role.

```
Remove-ManagementRoleEntry "Seattle Server Administrators\Enable-MailUser"
```

For detailed syntax and parameter information, see Remove-ManagementRoleEntry.

Remove multiple entire role entries from a role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

When you remove multiple role entries from a role, you remove the ability for users assigned that role to access the associated cmdlets or scripts.

To remove multiple role entries from a role, you need to retrieve the list of role entries to remove using the **Get-ManagementRoleEntry** cmdlet. Then you need to pipe the output to the **Remove-ManagementRoleEntry** cmdlet. You can use wildcard characters with the **Get-ManagementRoleEntry** cmdlet to match multiple role entries. It's a good idea to use the *WhatIf* switch to verify that you're removing the correct role entries. Use the following syntax.

```
Get-ManagementRoleEntry <management role>\<role entry with wildcard character> |
```

This example removes all the role entries that contain the word journal from the Seattle Server Administrators role.

```
Get-ManagementRoleEntry "Seattle Server Administrators\*Journal*" | Remove-Manage
```

When you run the command with the *WhatIf* switch, the cmdlet returns a list of all the role entries that would be removed. If the list looks correct, run the command again without the *WhatIf* switch to remove the role entries.

```
Get-ManagementRoleEntry "Seattle Server Administrators\*Journal*" | Remove-Manage
```

For detailed syntax and parameter information, see Get-ManagementRoleEntry and Remove-ManagementRoleEntry.

Remove parameters from a role entry on a role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management role entries" entry in the Role Management Permissions topic.

When you remove parameters from a role entry on a role, those parameters are no longer available to users assigned the role.

Use the following syntax to remove parameters from a role entry.

```
Set-ManagementRoleEntry <management role>\<role entry> -Parameters <parameter 1>,
```

This example removes the *MaxSafeSenders*, *MaxSendSize*, *SecondaryAddress*, and *UseDatabaseQuotaDefaults* parameters from the **Set-Mailbox** role entry on the Seattle Server Administrators role.

```
Set-ManagementRoleEntry "Seattle Server Adminstrators\Set-Mailbox" -Parameters Ma
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

1.3.3.5.1.8 Create an Unscoped Role

Create an Unscoped Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

An unscoped management role can be used to provide administrators and specialist users access to Windows PowerShell scripts and non-Exchange cmdlets. You can either create an unscoped top-level role and add scripts or non-Exchange cmdlets to that role, or create a role that's based on an existing, unscoped top-level role. After an unscoped role has been created and customized, the role can be assigned to management role groups, users, and universal security groups (USGs). Unscoped roles can't be assigned to management role assignment policies. For more information about unscoped roles, see Understanding Management Roles.

Caution:
Unscoped roles can be powerful because, as their name implies, no management scopes are applied to them. This means that the scripts and non-Exchange cmdlets that they contain can be run against any object in your Exchange organization. Consider this when adding scripts or non-Exchange cmdlets to an unscoped role and when assigning the unscoped role.

Note:
If you want to create a role that contains Exchange cmdlets, you must create a role that's based on an existing management role. For more information about creating roles with Exchange cmdlets, see Create a Role.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

The ability to create unscoped roles isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a USG or role group of which the user is a member, before the user is able to create a role group. For more information about adding a role to a user, USG, or role group, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

What Do You Want to Do?

- Create an unscoped top-level management role
- Create an unscoped role based on another unscoped role

Create an unscoped top-level management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

If you want to make scripts or non-Exchange cmdlets available to administrators or specialists in your organization, you need to create an unscoped top-level role. Scripts and non-Exchange cmdlets can only be added to an unscoped role that's created as a top-level role, because the initial unscoped role doesn't inherit from other roles. The new, unscoped top-level role can then be a parent to other unscoped roles that can also use the added scripts and non-Exchange cmdlets.

Here are the steps to create an unscoped top-level role:

- Step 1: Create the unscoped top-level role
- Step 2a: Add script management role entries
- Step 2b: Add non-Exchange cmdlet role entries
- Step 3: Assign the management role

Step 1: Create the unscoped top-level role

Unscoped top-level roles don't have a parent role. You need to specify the *UnscopedTopLevel* switch to create a role without a parent. Use the following syntax to create the new role.

```
New-ManagementRole <name of new role> -UnscopedTopLevel
```

This example creates the IT Scripts unscoped top-level role.

```
New-ManagementRole "IT Scripts" -UnscopedTopLevel
```

After it's created, the role is empty until you add scripts or non-Exchange cmdlets to it.

For detailed syntax and parameter information, see New-ManagementRole.

Step 2a: Add script management role entries

If you want to add a script to the new unscoped role, use this step. If you want to add a non-Exchange cmdlet to the new unscoped role, use Step 2b.

To add a Windows PowerShell script to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the script's name and the parameters on the script that you want to make available to the role.

The script must reside in the Scripts directory in the Microsoft Exchange Server 2010 installation path on every server running Exchange 2010 where users might connect to run the script. If a user has access to run a script, but the script isn't located on the Exchange 2010 server the user is connected to, an error occurs. By default, the path to the Scripts directory is C:\Program Files\Microsoft\Exchange Server\V14\Scripts.

After you copy the script to the appropriate Exchange 2010 servers and you decide what script parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>\<script filename> -Paramet
```

This example adds the BulkProvisionUsers.ps1 script to the IT Scripts role with the *Name* and *Location* parameters.

```
Add-ManagementRoleEntry "IT Scripts\BulkProvisionUsers.ps1" -Parameters Name, Loc
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the script. However, no further validation is done after the role entry is added. If parameters are later added or removed, you must manually update the role entries that contain the script.

Step 2b: Add non-Exchange cmdlet role entries

If you want to add a non-Exchange cmdlet to the new unscoped role, use this step. If you want to add a script to the new unscoped role, use Step 2a.

To add a non-Exchange cmdlet to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the cmdlet snap-in, cmdlet name, and the parameters on the cmdlet that you want to make available to the role.

If you add non-Exchange cmdlets to the new role, the cmdlets must be installed on every Exchange 2010 server where users might connect to run the cmdlets. To learn how to properly install and register the Windows PowerShell snap-ins that contain the cmdlets you want to use, refer to the documentation for your product.

After you install the Windows PowerShell snap-in that contains the cmdlets on the appropriate Exchange 2010 servers and you decide what cmdlet parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>\<cmdlet name> -PSSnapinNam
```

This example adds the **Set-WidgetConfiguration** cmdlet in the Contoso.Admin.Cmdlets snap-in to the Widget Cmdlets role with the *Database* and *Size* parameters.

```
Add-ManagementRoleEntry "Widget Cmdlets\Set-WidgetConfiguration" -PSSnapinName Co
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the cmdlet. However, no further validation is done after the role entry is added. If the cmdlet is later changed, and parameters are added or removed, you must manually update the role entries that contain the cmdlet.

Step 3: Assign the management role

The final step when you create and configure a role is to assign it to a role assignee.

Important:

Management scopes can't be configured on role assignments that assign an unscoped role. Whether you choose to create a role assignment for a role group, user, or USG, you must choose the option to create a role assignment without a management scope.

You can assign the new role to a role group, user, or USG. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Create an unscoped role based on another unscoped role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

If you have an existing, unscoped top-level role or other unscoped roles that you want to base new unscoped roles on, you can create child unscoped roles. The child unscoped roles can contain a subset of the scripts and cmdlets that exist on the parent unscoped roles. This is useful, for example, if you want to give only a subset of the scripts or cmdlets available on a parent unscoped role to a less experienced administrator.

Here are the steps to create an unscoped child role:

- Step 1: Create the unscoped child role
- Step 2: Change the role's management role entries
- Step 3: Assign the management role

Step 1: Create the unscoped child role

New, unscoped child roles can be based on existing unscoped roles. When you create a role, an existing role and its management role entries are copied to the new role. The existing role becomes the parent to the new child role. If you create an unscoped role that's based on another unscoped role, you must choose a role that contains all the cmdlets and parameters you need to use, and then remove the ones you don't want. Child unscoped roles can't have management role entries that don't exist in the parent role.

Note:

If you need to create an unscoped role that contains scripts or non-Exchange cmdlets that don't exist in any other unscoped role, create an unscoped top-level role. For more information, see Create an unscoped top-level management role earlier in this topic.

Use the following syntax to create the new role.

```
New-ManagementRole -Parent <existing unscoped role to copy> -Name <name of new un
```

This example copies the IT Global Scripts role and its management role entries to the Diagnostic IT Scripts role.

```
New-ManagementRole -Parent "IT Global Scripts" -Name "Diagnostic IT Scripts"
```

For detailed syntax and parameter information, see New-ManagementRole.

Step 2: Change the role's management role entries

After you create your role, you need to change the role's entries. You can remove an entire role entry, which removes access to the associated script or non-Exchange cmdlet completely. Or, you can remove parameters from a role entry to remove access to those specific parameters on the associated script or non-Exchange cmdlet.

You can't add role entries or parameters on role entries unless they exist in the parent role. Because you just created a role from a parent role in Step 1, you can't add any additional role entries or parameters on role entries because they don't exist in the parent role.

When you change a role entry on a role, you can do one of the following:

- Remove a single, entire role entry.
- Remove multiple, entire role entries.
- Remove parameters from a role entry.

To remove role entries from your new role, see Remove a Role Entry from a Role.

Step 3: Assign the management role

The final step when you create and configure a role is to assign it to a role assignee.

Important:

Management scopes can't be configured on role assignments that assign an unscoped role. Whether you choose to create a role assignment for a role group, user, or USG, you must choose the option to create a role assignment without a management scope.

You can assign the new role to a role group, user, or USG. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

1.3.3.5.1.9 Change a Role Entry on an Unscoped Top-Level Role

Change a Role Entry on an Unscoped Top-Level Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role entries on unscoped top-level management roles refer to the scripts and non-Exchange cmdlets, and their parameters, that you want to make available to those assigned the role. By changing the parameters available on a role entry, you control what those assigned the role can do with the script or non-Exchange cmdlet. For more information about unscoped role entries, see Understanding Management Roles.

Note:
If you want to change a role entry on a management role that contains Exchange cmdlets, see Change a Role Entry.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

The ability to change a role entry on an unscoped top-level role isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a universal security group (USG) or role group of which the user is a member, before the user is able to add or change an unscoped top-level role entry. For more information about adding a role to a user, USG, or role group, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Note:
You can't use the EMC to change a role entry.

Use the Shell to add one or more parameters to a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

To add parameters to an unscoped top-level role entry, you need to do the following:

- Specify the parameters you want to add using the *Parameters* parameter.
- Specify the *AddParameter* parameter to indicate that you want to perform an add operation.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

To add parameters to a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters <
```

This example adds the *EmailAddress* and *City* parameters to the **CreateUsers.ps1** script on the Recipient Administrators unscoped role.

```
Set-ManagementRoleEntry "Recipient Administrators\CreateUsers.ps1" -Parameters Em
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove one or more parameters from a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

To remove parameters from a role entry, you need to do the following:

- Specify the parameters you want to remove using the *Parameters* parameter.
- Specify the *RemoveParameter* parameter to indicate that you want to perform a remove operation.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

Caution:

You can't undo remove operations. If you mistakenly remove a parameter from a role entry, you must add it again manually.

To remove parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters <
```

This example removes the *Delay*, *Force*, and *Credential* parameters from the **Start-Widget** non-Exchange cmdlet on the Tier 1 Server Administrators role.

```
Set-ManagementRoleEntry "Tier 1 Server Administrators\Start-Widget" -Parameters D
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to remove all parameters from a role entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

To remove all of the parameters from a role entry, you need to do the following:

- Specify the value `$Null` on the *Parameters* parameter. You don't need to include the *RemoveParameter* parameter.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped top-level role. If you don't specify this parameter when you change a role entry on an unscoped role, an error occurs.

Removing all the parameters from a role entry is most useful when you want to make only a few parameters available on a script or non-Exchange cmdlet and exclude all of the

other parameters.

If you don't want the role to have access to a script or non-Exchange cmdlet, remove the associated role entry from the role completely instead of just removing the parameters. For more information about how to remove a role entry from a role, see Remove a Role Entry from a Role.

Caution:
You can't undo remove operations. If you mistakenly remove all the parameters from a role entry, you must add them again manually.

To remove all the parameters from a role entry, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters $
```

This example removes all the parameters from the FindMailboxesOverQuota.ps1 script on the Recipient Administrators role.

```
Set-ManagementRoleEntry "Recipient Administrators\FindMailboxesOverQuota.ps1" -Pa
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Use the Shell to apply a specific set of parameters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

If you want only a specific set of parameters to be included on a role entry, you need to do the following:

- Specify the *Parameters* parameter only. Don't include the *AddParameter* or *RemoveParameter* parameters.
- Specify the *UnscopedTopLevel* parameter to indicate that you're changing a role entry on an unscoped role. If you don't specify this parameter when you change a role entry on an unscoped top-level role, an error occurs.

Caution:
When you specify only the *Parameters* parameter, only the parameters you specify in the command are included on the role entry. All other parameters are removed.

To specify a specific set of parameters, use the following syntax.

```
Set-ManagementRoleEntry <role name>\<script or non-Exchange cmdlet> -Parameters <
```

This example includes only the *Alias*, *DisplayName*, *WidgetConfig*, and *Enabled* parameters on the **Set-Widget** cmdlet on the Seattle Mail Recipient Admins role.

```
Set-ManagementRoleEntry "Seattle Mail Recipient Admins\Set-UMMailbox" -Parameters
```

For detailed syntax and parameter information, see Set-ManagementRoleEntry.

Other Tasks

After you change a role entry on an unscoped top-level role, you may also want to:

- Add a Role Entry to a Role

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

1.3.3.5.1.10 Add a Role Entry to an Unscoped Top-Level Role

Add a Role Entry to an Unscoped Top-Level Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can add scripts and non-Exchange cmdlets to unscoped top-level management roles if you want to make new scripts or non-Exchange cmdlets available to existing unscoped roles. These scripts and non-Exchange cmdlets are added as management role entries to unscoped top-level management roles. They can then be used by those unscoped top-level role entries or any unscoped roles derived from the top-level roles. For more information about unscoped role entries, see Understanding Management Roles.

Note:
If you want to change a role entry on a management role that contains Exchange cmdlets, see Change a Role Entry.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

The ability to add a role entry on an unscoped top-level role isn't included in any management role group by default. You must first assign the Unscoped Role Management role to a user, or to a universal security group (USG) or role group of which the user is a member, before the user is able to add an unscoped top-level role entry. For more information about adding a role to a role group, user, or USG, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Add a script role entry to an unscoped top-level role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

If you want to add a script to an existing unscoped role, use this procedure. If you want to add a non-Exchange cmdlet to an existing unscoped role, see "Add a non-Exchange cmdlet role entry to an unscoped top-level role" later in this topic.

To add a Windows PowerShell script to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the script's name and the

parameters on the script that you want to make available to the role.

The script must reside in the Scripts directory in the Microsoft Exchange Server 2010 installation path on every server running Exchange 2010 where users might connect to run the script. If a user has access to run a script, but the script isn't located on the Exchange 2010 server the user is connected to, an error occurs. By default, the path to the Scripts directory is C:\Program Files\Microsoft\Exchange Server\V14\Scripts.

After you copy the script to the appropriate Exchange 2010 servers and you decide what script parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>\<script filename> -Paramet
```

This example adds the BulkProvisionUsers.ps1 script to the IT Scripts role with the *Name* and *Location* parameters.

```
Add-ManagementRoleEntry "IT Scripts\BulkProvisionUsers.ps1" -Parameters Name, Loc
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the script. However, no further validation is done after the role entry is added. If parameters are later added or removed, you must manually update the role entries that contain the script.

Add a non-Exchange cmdlet role entry to an unscoped top-level role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Unscoped management roles" entry in the Role Management Permissions topic.

If you want to add a non-Exchange cmdlet to an existing unscoped role, use this procedure. If you want to add a script cmdlet to an existing unscoped role, see "Add a script role entry to an unscoped top-level role" earlier in this topic.

To add a non-Exchange cmdlet to an unscoped top-level role, you must add a management role entry to the role. The role entry contains the cmdlet snap-in, cmdlet name, and the parameters on the cmdlet that you want to make available to the role.

If you add non-Exchange cmdlets to the new role, the cmdlets must be installed on every Exchange 2010 server where users might connect to run the cmdlets. To learn how to properly install and register the Windows PowerShell snap-ins that contain the cmdlets you want to use, refer to the documentation for your product.

After you install the Windows PowerShell snap-in that contains the cmdlets on the appropriate the Exchange 2010 servers and you decide what cmdlet parameters should be used, create the role entry using the following syntax.

```
Add-ManagementRoleEntry <unscoped top-level role name>\<cmdlet name> -PSSnapinNam
```

This example adds the **Set-WidgetConfiguration** cmdlet in the Contoso.Admin.Cmdlets snap-in to the Widget Cmdlets role with the *Database* and *Size* parameters.

```
Add-ManagementRoleEntry "Widget Cmdlets\Set-WidgetConfiguration" -PSSnapinName Co
```

Note:

The **Add-ManagementRoleEntry** cmdlet performs basic validation to make sure that you add only the parameters that exist in the cmdlet. However, no further validation is done after the role entry is added. If the cmdlet is later changed, and parameters are added or

removed, you must manually update the role entries that contain the cmdlet.

Other Tasks

After you add a role entry or an unscoped top-level role, you may also want to:

- Add a Role Entry to a Role
- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

1.3.3.5.2 Management Role Scopes

Management Role Scopes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-05*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Create a Regular or Exclusive Scope

Change a Role Scope

View Role Scopes

Remove a Role Scope

Control Automatic Mailbox Distribution Using Database Scopes

For more information about managing role groups and role assignment policies, see the following topics:

Managing Administrator and Specialist Users

Managing End Users

1.3.3.5.2.1 Create a Regular or Exclusive Scope

Create a Regular or Exclusive Scope

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. By adding a management scope, you can configure management role assignments so users can administer specific servers, databases, recipients, and other objects in your organization while being restricted from changing other objects.

Important:
When you create a regular or exclusive scope, you override the write scope that's defined on the management role you're assigning. You can't override the read scope that's configured on the management role.

You can create a custom management scope and add or change a management role assignment. If you want to create a management role assignment with a prebuilt or organizational unit (OU) management scope, see Add a Role to a User or USG.

For more information about management role scopes and assignments in Microsoft Exchange Server 2010, see the following topics:

- Understanding Management Role Scopes
- Understanding Management Role Assignments

Looking for other management tasks related to scopes? Check out Managing Advanced Permissions.

Step 1: Create a custom scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a custom scope.

To create a custom scope, choose one of the following types of scopes.

Recipient filter scope

Recipient filter-based scopes are created by using the *RecipientRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. When you create a recipient filter, in addition to the recipient properties to filter, you can specify the OU in which the filter query runs. When you specify a base OU, you further restrict the write scope of the role.

For more information about management scope filters, see Understanding Management Role Scope Filters.

Use the following syntax to create a domain restriction filter scope with a base OU.

```
New-ManagementScope -Name <scope name> -RecipientRestrictionFilter <filter query>
```

This example creates a scope that includes all mailboxes within the contoso.com/Sales OU.

```
New-ManagementScope -Name "Mailboxes in Sales OU" -RecipientRestrictionFilter { R
```

Note:
You can omit the *RecipientRoot* parameter if you want the filter to apply to the entire implicit read scope of the management role and not just within a specific OU.

For detailed syntax and parameter information, see New-ManagementScope.

Server filter configuration scope

Server filter-based configuration scopes are created by using the *ServerRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. A server filter enables you to create a scope that applies only to the servers that match the filter you specify.

For more information about management scope filters and for a list of filterable server properties, see Understanding Management Role Scope Filters.

Use the following syntax to create a server filter scope.

```
New-ManagementScope -Name <scope name> -ServerRestrictionFilter <filter query>
```

This example creates a scope that includes all the servers within the 'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com' AD (Active Directory) site.

```
New-ManagementScope -Name "Servers in Seattle AD site" -ServerRestrictionFilter {
```

For detailed syntax and parameter information, see New-ManagementScope.

Server list configuration scope

Server list-based configuration scopes are created by using the *ServerList* parameter on the **New-ManagementScope** cmdlet. A server list scope enables you to create a scope that applies only to the servers you specify in a list.

Use the following syntax to create a server list scope.

```
New-ManagementScope -Name <scope name> -ServerList <server 1>, <server 2...>
```

This example creates a scope that applies only to MBX1, MBX3, and MBX5.

```
New-ManagementScope -Name "Mailbox servers" -ServerList MBX1,MBX3,MBX5
```

For detailed syntax and parameter information, see New-ManagementScope.

Database filter configuration scope

Database filter-based configuration scopes are created by using the *DatabaseRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. A database filter enables you to create a scope that applies only to the databases that match the filter you specify.

Important:

Role assignments associated with database scopes are applied only to users who connect to servers running Microsoft Exchange Server 2010 Service Pack 1 (SP1). If a user assigned a role assignment associated with a database scope connects to a release to manufacturing (RTM) version of Exchange 2010, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

For more information about management scope filters and for a list of filterable database properties, see Understanding Management Role Scope Filters.

Use the following syntax to create a database restriction filter.

```
New-ManagementScope -Name <scope name> -DatabaseRestrictionFilter <filter query>
```

This example creates a scope that includes all the databases that contain the string "Executive" in the **Name** property of the database.

```
New-ManagementScope -Name "Executive Databases" -DatabaseRestrictionFilter { Name
```

For detailed syntax and parameter information, see New-ManagementScope.

Database list configuration scope

Database list-based configuration scopes are created by using the *DatabaseList* parameter on the **New-ManagementScope** cmdlet. A database list scope enables you to create a scope that applies only to the databases you specify in a list.

Important:

Role assignments associated with database scopes are applied only to users who connect to servers running Microsoft Exchange Server 2010 Service Pack 1 (SP1). If a user assigned a role assignment associated with a database scope connects to a release to manufacturing (RTM) version of Exchange 2010, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

Use the following syntax to create a database list scope.

```
New-ManagementScope -Name <scope name> -DatabaseList <database 1>, <database 2...
```

This example creates a scope that applies only to the databases Database 1, Database 2, and Database 3.

```
New-ManagementScope -Name "Primary databases" -DatabaseList "Database 1", "Databa
```

For detailed syntax and parameter information, see New-ManagementScope.

Exclusive scope

Any scope that you create with the **New-ManagementScope** cmdlet can be designated as an exclusive scope. To create an exclusive scope, you use the same commands in one of the preceding sections to create a recipient filter-based scope, server filter-based scope, server list-based scope, database filter-based scope, or database list-based scope, and then add the *Exclusive* switch to the command.

Caution:

When you create exclusive management scopes, only the role assignees assigned exclusive scopes that contain objects to be modified can access those objects. Only those administrators assigned a role with the exclusive scope can access these exclusive, or protected, objects.

This example creates an exclusive recipient filter-based scope that matches any user in the Executives department.

```
New-ManagementScope "Executive Users Exclusive Scope" -RecipientRestrictionFilter
```

By default, when an exclusive scope is created, you're required to acknowledge that you created an exclusive scope and that you're aware of the impact that an exclusive scope has on existing role assignments that aren't exclusive. If you want to suppress the warning, you can use the *Force* switch. This example creates the same scope as the previous example, but without a warning.

```
New-ManagementScope "Executive Users Exclusive Scope" -RecipientRestrictionFilter
```

For detailed syntax and parameter information, see New-ManagementScope.

Step 2: Add or change a management role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to add or change a management role assignment.

After you create the scope, you must add it to a new or existing management role assignment.

If you create a management scope and want to add it to a new management role assignment that you're going to create, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

If you create a management role scope and want to add it to an existing management role assignment, see the following topics:

- Change the Scope of Role Assignments to a Role Group
- Change a Role Assignment

1.3.3.5.2.2 Change a Role Scope

Change a Role Scope

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. By changing a scope, you can change what objects are made available to users to create, change, or remove.

You can change a custom management scope. You can change either exclusive or regular scopes. If you change an exclusive scope, the new scope takes effect immediately. If you want to change a management role assignment with a predefined or organizational unit (OU) management scope, see Change a Role Assignment.

For more information about management role scopes and assignments in Microsoft Exchange Server 2010, see the following topics:

- Understanding Management Role Scopes
- Understanding Management Role Assignments

You must use the Shell to change scopes.

Looking for other management tasks related to role scopes? Check out Managing Advanced Permissions.

Change the name of a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the name of a scope.

To change the name of a scope, use the following syntax.

```
Set-ManagementScope <current scope name> -Name <new scope name>
```

This example changes the Seattle Servers scope to Seattle Exchange Servers.

```
Set-ManagementScope "Seattle Servers" -Name "Seattle Exchange Servers"
```

For detailed syntax and parameter information, see Set-ManagementScope.

Change a recipient filter on a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a recipient filter on a scope.

To change the recipient filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -RecipientRestrictionFilter { <new recipient fil
```

This example changes the recipient filter to match all the recipient objects where the **Company** property is set to contoso.

```
Set-ManagementScope "Company Scope" -RecipientRestrictionFilter { Company -eq 'co
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about recipient filters and to see a list of filterable recipient properties, see Understanding Management Role Scope Filters.

Change the organizational unit root on a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the organizational unit root on a scope.

To change the OU root on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -RecipientRoot <OU>
```

This example changes the OU root to the North America/Sales Sales Users OU under the contoso.com domain.

```
Set-ManagementScope "Sales Users" -RecipientRoot "contoso.com/North America/Sales
```

For detailed syntax and parameter information, see Set-ManagementScope.

Change a server filter on a scope

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a server filter on a scope.

To change the server filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -ServerRestrictionFilter { <new server filter> }
```

This example changes the server filter to match all the server objects where the **ServerSite** property is set to 'CN=Redmond,CN=Sites,CN=Configuration,DC=contoso,DC=com'.

```
Set-ManagementScope "Company Scope" -ServerRestrictionFilter { ServerSite -eq 'CN
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about server filters and to see a list of filterable server properties, see Understanding Management Role Scope Filters.

Change the server list on a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

You can't change the list of servers on a scope. If you need to change the server list, you need to do the following:

1. If needed, retrieve the current server list in the scope to be replaced by using the "View a specific scope" procedure in the View Role Scopes topic.
2. Create a scope with the new server list by using the "Step 1: Create a custom scope" procedure in the Create a Regular or Exclusive Scope topic.
3. Change all the management role assignments that use the old scope to use the new scope by using the "Use the Shell to change the server filter or list-based scope on a role assignment" procedure in the Change a Role Assignment topic.
4. Remove the old scope by using the procedure in the Remove a Role Scope topic.

Change a database filter on a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a database filter on a scope.

To change the database filter on a scope, use the following syntax.

```
Set-ManagementScope <scope name> -DatabaseRestrictionFilter { <new database filte
```

This example changes the database filter to match all the database objects where the **Name** property contains the string "Executive".

```
Set-ManagementScope "Database Executive Scope" -DatabaseRestrictionFilter { Name
```

For detailed syntax and parameter information, see Set-ManagementScope.

For more information about database filters and to see a list of filterable database properties, see Understanding Management Role Scope Filters.

Change the database list on a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

You can't change the list of databases on a scope. If you need to change the database list, you need to do the following:

1. If needed, retrieve the current database list in the scope to be replaced by using the "View a specific scope" procedure in the View Role Scopes topic.
2. Create a scope with the new database list by using the "Step 1: Create a custom scope" procedure in the Create a Regular or Exclusive Scope topic.
3. Change all the management role assignments that use the old scope to use the new scope by using the "Use the Shell to change the database filter or list-based scope on a role assignment" procedure in the Change a Role Assignment topic.
4. Remove the old scope by using the procedure in the Remove a Role Scope topic.

1.3.3.5.2.3 View Role Scopes

View Role Scopes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role scopes determine what objects are made available to a user so that the objects can be changed using the cmdlets and parameters assigned to them. You can view scopes to determine what scopes have been added to your organization, the configuration of a specific scope, or what scopes are orphans.

For more information about management role scopes in Microsoft Exchange Server 2010, see Understanding Management Role Scopes.

You must use the Shell to view scopes; you can't use the EMC to view role scopes.

Looking for other management tasks related to role scopes? Check out Managing Advanced Permissions.

Prerequisites

This topic makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

View a specific scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

You can view the details of a scope by piping the output of the **Get-ManagementScope** cmdlet to the **Format-List** cmdlet.

To view the details of a specific scope, use the following syntax.

```
Get-ManagementScope <scope name> | Format-List
```

This example retrieves the details of the Seattle Servers scope.

```
Get-ManagementScope "Seattle Servers" | Format-List
```

For detailed syntax and parameter information, see Get-ManagementScope.

List all scopes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

This example retrieves a list of scopes in your organization.

```
Get-ManagementScope
```

This cmdlet retrieves both exclusive and regular scopes. If you only want to return exclusive scopes or regular scopes, see "List all exclusive or regular scopes only" later in this topic.

For detailed syntax and parameter information, see Get-ManagementScope.

List all orphaned scopes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Orphaned scopes are scopes that haven't been associated with any management role assignments.

This examples retrieves a list of orphaned scopes.

```
Get-ManagementScope -Orphan
```

For detailed syntax and parameter information, see Get-ManagementScope.

List all exclusive or regular scopes only

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

By default, the **Get-ManagementScope** cmdlet returns a list of scopes that contains both

exclusive and regular scopes. If you want to return only exclusive scopes or only regular scopes use the following syntax.

```
Get-ManagementScope -Exclusive < $true | $false >
```

This example returns only exclusive scopes.

```
Get-ManagementScope -Exclusive $true
```

This example returns a list of regular scopes only.

```
Get-ManagementScope -Exclusive $false
```

For detailed syntax and parameter information, see Get-ManagementScope.

1.3.3.5.2.4 Remove a Role Scope

Remove a Role Scope

Managing Permissions > Managing Advanced Permissions > Management Role Scopes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management role scopes determine what objects are made available to a user who can then change the objects using the cmdlets and parameters assigned to the user. If you're no longer using a scope, it can be removed. For more information about management role scopes in Microsoft Exchange Server 2010, see Understanding Management Role Scopes.

You must use the Shell to remove scopes.

Prerequisites

Before you can remove a scope, you must remove the scope from any management role assignments that might be using it. For more information about how to remove a scope from a role assignment, see Change a Role Assignment.

Use the Shell to remove a scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topics.

To remove a scope, use the following syntax:

```
Remove-ManagementScope <scope name>
```

For example, to remove the "Dublin Servers" scope, use the following command:

```
Remove-ManagementScope "Dublin Servers"
```

Control Automatic Mailbox Distribution Using Database Scopes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Automatic mailbox distribution is a feature in Microsoft Exchange Server 2010 that randomly selects a mailbox database to store a new or moved mailbox when you don't specify a database explicitly. This feature can be helpful when you want to allow junior administrators or help desk staff to create mailboxes without needing to know which mailbox databases mailboxes should be created on.

You can use database management scopes to control which mailbox databases can be selected by automatic mailbox distribution. When you apply database scopes to an administrator, only the databases that match the defined database scope are available to the administrator. Because automatic mailbox distribution uses the context of the current user, it's also constrained by the database scopes applied to the administrator.

For more information about automatic mailbox distribution, database scopes, and role assignments, see the following topics:

- Understanding Automatic Mailbox Distribution
- Understanding Management Role Scopes
- Understanding Management Role Assignments

Looking for other management tasks related to scopes? Check out Managing Advanced Permissions.

Step 1: Create a database scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management scopes" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to create a database scope.

In this step, decide which databases you want to include in the database scope. Also, decide whether you want to specify a static list of databases, or whether you want to create a database filter that includes only the databases that match the criteria you specify.

Important:

Role assignments associated with database scopes are applied only to users who connect to servers running Exchange 2010 Service Pack 1 (SP1). If a user assigned a role assignment associated with a database scope connects to a release to manufacturing (RTM) version of Exchange 2010, the role assignment isn't applied to the user, and the user won't be granted any permissions provided by the role assignment.

Use a database list scope

Use a database list if you want to define a static list of mailbox databases that should be included in this scope. Use the following syntax to create a database list scope.

```
New-ManagementScope -Name <scope name> -DatabaseList <database 1>, <database 2...
```

This example creates a scope that applies only to the databases Database 1, Database 2, and Database 3.

```
New-ManagementScope -Name "Accounting databases" -DatabaseList "Database 1", "Dat
```

For detailed syntax and parameter information, see New-ManagementScope.

Use a database filter scope

Use a database filter if you want to create a dynamic database scope that includes only the databases that match the criteria you specify. This can be useful if you don't want to manage the database scope after it's created and you've defined standard values for your organization that can identify specific sets of mailbox databases.

For a list of filterable database properties, see Understanding Management Role Scope Filters.

Use the following syntax to create a database filter scope.

```
New-ManagementScope -Name <scope name> -DatabaseRestrictionFilter <filter query>
```

This example creates a scope that includes all the databases that contain the string "ACCT" in the **Name** property of the database.

```
New-ManagementScope -Name "Accounting Databases" -DatabaseRestrictionFilter { Nam
```

For detailed syntax and parameter information, see New-ManagementScope.

Step 2: Add the database scope to a management role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to add the database scope to a management role assignment.

After you create the scope, you must add it to a new or existing management role assignment. We recommend that you use management role groups to control administrative permissions, so the examples in this step use an example role group called Accounting Administrators. For more information about how to create a role group, see Create a Role Group.

After you assign the role to a role group with the database scope, the members of the role group will only be able to create mailboxes on, and move mailboxes to, the databases included in the scope.

For a list of built-in roles that you can assign to role groups, see Built-in Management Roles.

Add a new role assignment

Use this procedure if you've just created a role group and you need to add roles to it.

Use the following syntax to create a role assignment between the management role you want to assign and the new role group, with the new database scope.

```
New-ManagementRoleAssignment -SecurityGroup <role group name> -Role <role name> -
```

This example creates a role assignment between the Mail Recipients and Mail Recipient Creation roles and the Accounting Administrators role group, using the Accounting Databases database scope.

```
New-ManagementRoleAssignment -SecurityGroup "Accounting Administrators" -Role "Ma
New-ManagementRoleAssignment -SecurityGroup "Accounting Administrators" -Role "Ma
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Modify an existing role assignment

Use this procedure if you have an existing role group that already has role assignments between it and the roles you want to apply the new database scope to.

This procedure uses pipelining. For more information, see Pipelining.

Use the following syntax to modify a role assignment between the management role that you want to apply the database scope to, and an existing role group.

```
Get-ManagementRoleAssignment -RoleAssignee <role group name> -Role <role name> |
```

This example adds the Accounting Databases database scope to the Mail Recipients and Mail Recipient Creation roles assigned to the Accounting Administrators role group.

```
Get-ManagementRoleAssignment -RoleAssignee "Accounting Administrators" -Role "Mai
Get-ManagementRoleAssignment -RoleAssignee "Accounting Administrators" -Role "Mai
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment or Set-ManagementRoleAssignment.

Step 3: Add members to a role group (if applicable)

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to add members to a role group.

If you want to add members to a role group, see Add Members to a Role Group.

Important:

If you add members to this role group to restrict what databases they can create users on, or move mailboxes to, make sure they aren't members of other role groups that could grant extra permissions.

Step 4: Remove members from a role group (if applicable)

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to remove members from a role group.

If you've added members to a new role group that restricts what databases they can create mailbox on, or move mailboxes to, and they're members of another role group that has additional permissions, remove them from the old role group. For more information, see Remove Members from a Role Group.

1.3.3.5.3 Management Role Assignments

Management Role Assignments

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-06-09*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Add a Role to a User or USG

Change a Role Assignment

View Role Assignments

Remove a Role from a User or USG

Delegate Role Assignments

For more information about managing role groups and role assignment policies, see the following topics:

Managing Administrator and Specialist Users

Managing End Users

1.3.3.5.3.1 Add a Role to a User or USG

Add a Role to a User or USG

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role assignments can assign a management role to a user or universal security group (USG). By assigning a role to a user or USG, you enable those users to perform tasks dependent on cmdlets or scripts and their parameters defined on the management role.

Although you can assign roles directly to users and USGs, the recommended method of granting permissions to administrators and end users is to use management role groups and management role assignment policies. When you use role groups and assignment policies, you simplify your permissions model.

If you want to assign roles to a management role group or a management role assignment policy, see the following topics:

- Add a Role to a Role Group
- Add a Role to an Assignment Policy

If you want to add members to a role group or assign a role assignment policy to an end user, see the following topics:

- Add Members to a Role Group
- Change the Assignment Policy on a Mailbox

For more information, see Understanding Role Based Access Control.

Note:
Role assignments are additive. This means that all the roles are added together when they are evaluated. If two roles are assigned to a user and one role contains a cmdlet but the other doesn't, the cmdlet will still be available to the user.
By default, role assignments don't grant the ability to assign roles to other users. To enable a user to assign roles to other users or USGs, see Delegate Role Assignments.

You must use the Shell to add a role assignment.

If you create an assignment with a scope, the scope overrides the role's implicit write scope. However, the role's implicit read scope still applies. The new scope can't return objects outside of the role's implicit read scope. For more information, see Understanding Management Role Scopes.

All the procedures in this topic use the *SecurityGroup* parameter to assign roles to a USG. If you want to assign the role to a specific user, use the *User* parameter instead of the *SecurityGroup* parameter. All other syntax for each command is the same.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Create a role assignment with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with no scope.

You can create a role assignment with no scope. When you do this, the implicit read and implicit write scopes of the role apply.

Use the following syntax to assign a role to a USG without any scope.

```
New-ManagementRoleAssignment -Name <assignment name> -SecurityGroup <USG> -Role <
```

This example assigns the Exchange Servers role to the SeattleAdmins USG.

```
New-ManagementRoleAssignment -Name "Exchange Servers_SeattleAdmins" -SecurityGrou
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a predefined relative scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with a predefined relative scope.

If a predefined relative scope meets your business requirements, you can apply that scope to the role assignment rather than create a custom scope. For a list of predefined scopes and their descriptions, see Understanding Management Role Scopes.

Use the following syntax to assign a role to a USG with a predefined scope.

```
New-ManagementRoleAssignment -Name <assignment name> -SecurityGroup < USG> -Role
```

This example assigns the Exchange Servers role to the SeattleAdmins USG and applies the Organization predefined scope.

```
New-ManagementRoleAssignment -Name "Exchange Servers_SeattleAdmins" -SecurityGrou
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a recipient filter-based scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with a recipient filter-based scope.

If you created a recipient filter-based scope and want to use it with a role assignment, you need to include the scope in the command used to assign the role to a USG by using the *CustomRecipientWriteScope* parameter. If you use the *CustomRecipientWriteScope* parameter, you can't use the *RecipientOrganizationalUnitScope* parameter.

Before you can add a scope to a role assignment, you need to create one. For more information, see Create a Regular or Exclusive Scope.

Use the following syntax to assign a role to a USG with a recipient filter-based scope.

```
New-ManagementRoleAssignment -Name <assignment name> -SecurityGroup < USG> -Role
```

This example assigns the Mail Recipients role to the Seattle Recipient Admins USG and applies the Seattle Recipients scope.

```
New-ManagementRoleAssignment -Name "Mail Recipients_Seattle Recipient Admins" -Se
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with a server or database filter or list-based configuration scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with a server or database filter or list-based configuration scope.

If you created a server or database filter or list-based configuration scope and want to use it with a role assignment, you need to include the scope in the command used to assign the role to a USG by using the *CustomConfigWriteScope* parameter.

Before you can add a scope to a role assignment, you need to create one. For more information, see Create a Regular or Exclusive Scope.

Use the following syntax to assign a role to a USG with a configuration scope.

```
New-ManagementRoleAssignment -Name <assignment name> -SecurityGroup <USG> -Role <
```

This example assigns the Exchange Servers role to the MailboxAdmins USG and applies the Mailbox Servers scope.

```
New-ManagementRoleAssignment -Name "Exchange Servers_MailboxAdmins" -SecurityGrou
```

The preceding example shows you how to add a role assignment with a server configuration scope. The syntax to add a database configuration scope is the same. You specify the name of a database scope instead of a server scope.

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with an OU scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with an organization unit (OU) scope.

If you want to scope a role's write scope to an OU, you can specify the OU in the *RecipientOrganizationalUnitScope* parameter directly. If you use the *RecipientOrganizationalUnitScope* parameter, you can't use the *CustomRecipientWriteScope* parameter.

Use the following syntax to assign a role to a USG and restrict the write scope of a role to a specific OU.

```
New-ManagementRoleAssignment -Name <assignment name> -SecurityGroup <USG> -Role <
```

This example assigns the Mail Recipients role to the SalesRecipientAdmins USG and scopes the assignment to the sales/users OU in the contoso.com domain.

```
New-ManagementRoleAssignment -Name "Mail Recipients_SalesRecipientAdmins" -Securi
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Create a role assignment with an exclusive recipient or configuration scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment with an exclusive recipient or configuration scope.

To create an exclusive role assignment with an exclusive recipient or configuration scope, the same procedures provided in the Create a role assignment with a recipient filter-based scope and Create a role assignment with a server or database filter or list-based configuration scope sections can be used. The only difference is that when you create a role assignment with an exclusive scope, you must specify the following exclusive parameters depending on whether you're using an exclusive recipient scope or an exclusive configuration scope:

- **Exclusive recipient scopes** Use the *ExclusiveRecipientWriteScope* parameter instead of the *CustomRecipientWriteScope* parameter.
- **Exclusive configuration scopes** Use the *ExclusiveConfigWriteScope* parameter instead of the *CustomConfigWriteScope* parameter.

When you perform this procedure, the role assignees assigned the role can perform actions against the objects included in the exclusive scope. For more information about exclusive scopes, see Understanding Exclusive Scopes.

You can't create a role assignment with both exclusive and regular scopes.

This example assigns the Mail Recipients role to the Protected User Admins USG and applies the Protected Users exclusive scope.

```
New-ManagementRoleAssignment -Name "Mail Recipients_Protected User Admins" -Secur
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

1.3.3.5.3.2 Change a Role Assignment

Change a Role Assignment

Managing Permissions > Managing Advanced Permissions > Management Role Assignments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role assignments assign a management role to a role assignee. By changing the role assignment, you can control what objects role assignees assigned a role can change. Management role scopes applied to role assignments override the role's implicit write scope. However, the role's implicit read scope still applies. Scopes that you apply can't return objects outside of the role's implicit read scope.

For more information about management role scopes and assignments in Microsoft Exchange Server 2010, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

You must use the Shell to change role assignments. Looking for other management tasks related to role assignments? Check out Managing Advanced Permissions.

Use the Shell to enable or disable a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to enable or disable a role assignment.

Role assignments are enabled by default, meaning that the associated role is applied to the role assignee to which the role is assigned. If a role assignment is disabled, the associated role isn't applied to the role assignee.

To enable a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <role assignment> -Enabled $true
```

To disable a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <role assignment> -Enabled $false
```

This example disables the Help Desk Assignment role assignment.

```
Set-ManagementRoleAssignment "Help Desk Assignment" -Enabled $false
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change a management role or role assignee on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a management role or role assignee on a role assignment.

You can't change the management role or role assignee specified on a role assignment. If you want a role assignment to be associated with another role or role assignee, you must create a new role assignment, and then delete the old role assignment. For more information about how to add and remove role assignments, see the following topics:

- Add a Role to a User or USG
- Remove a Role from a User or USG

If you've created assignments directly to a user or universal security group (USG), we recommend that you consider using management role groups and management role assignment policies. Role groups and assignment policies enable you to simplify your permissions model and reduce the number of role assignments you need to manage. For more information, see Understanding Role Based Access Control.

Use the Shell to change a predefined

relative scope on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a predefined relative scope on a role assignment.

You can change or add a predefined relative scope on a role assignment. If you add or change a predefined scope, any previously specified recipient scopes are removed from the role assignment. For a list of predefined scopes and their descriptions, see Understanding Management Role Scopes.

To change or add a predefined scope on a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -RecipientRelativeWriteScope < MyD
```

This example changes the predefined scope on the John's Assignment role assignment to MyDistributionGroups.

```
Set-ManagementRoleAssignment "John's Assignment" - RecipientRelativeWriteScope My
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change a recipient filter scope on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change a recipient filter scope on a role assignment.

You can either specify a new recipient filter-based scope or change the recipient filter-based scope that's already applied to the role assignment. If you add a recipient filter scope, any previously defined recipient scopes are removed from the role assignment.

To specify a new recipient filter-based scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -CustomRecipientWriteScope <role s
```

This example adds or changes the recipient filter-based scope to Redmond Recipients.

```
Set-ManagementRoleAssignment "Redmond Recipient Administrators Assignment" -Custo
```

If you want to keep the same recipient filter-based scope that's applied to the role assignment but change the recipient filter used to match recipient objects, you need to change the recipient filter on the scope itself. For more information about how to change scopes, see Change a Role Scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the server filter or

list-based configuration scope on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the server filter or list-based configuration scope on a role assignment.

You can either specify a new server filter or list-based configuration scope, or change the scope that's already applied to the role assignment. If you add or change the configuration scope, any previously specified configuration scopes are removed from the role assignment.

To specify a new configuration scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -CustomConfigWriteScope <role scop
```

This example adds or changes the configuration scope to Redmond Servers.

```
Set-ManagementRoleAssignment "Redmond Administrators Assignment" -CustomConfigWri
```

If you want to keep the same configuration scope that's applied to the role assignment but change the server filter or server list on the scope, you need to change the configuration scope itself. For more information about how to change scopes, see Change a Role Scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the database filter or list-based configuration scope on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the database filter or list-based configuration scope on a role assignment.

You can either specify a new database filter or list-based configuration scope, or change the scope that's already applied to the role assignment. If you add or change the configuration scope, any previously specified configuration scopes are removed from the role assignment.

To specify a new configuration scope or replace an existing one, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -CustomConfigWriteScope <role scop
```

This example adds or changes the configuration scope to Redmond Databases.

```
Set-ManagementRoleAssignment "Redmond Database Admins" -CustomConfigWriteScope "R
```

If you want to keep the same configuration scope that's applied to the role assignment but change the database filter or database list on the scope, you need to change the configuration scope itself. For more information about how to change scopes, see Change a Role Scope.

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change the organizational unit on a role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change the organizational unit (OU) on a role assignment.

You can either add a new OU or change an OU that's already applied to the role assignment. If you specify a new OU, any previously specified recipient scopes are removed from the role assignment.

To change or add a new OU on a role assignment, use the following syntax.

```
Set-ManagementRoleAssignment <assignment name> -RecipientOrganizationalUnitScope
```

This example adds the Engineering\Users OU in the contoso.com domain to the Engineering Help Desk role assignment.

```
Set-ManagementRoleAssignment "Engineering Help Desk" -RecipientOrganizationalUnit
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

Use the Shell to change an exclusive recipient or configuration scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to change an exclusive recipient or configuration scope.

To change exclusive recipient or exclusive configuration scopes, you can use the procedures provided in the "Use the Shell to change a recipient filter scope on a role assignment," "Use the Shell to change the server filter or list-based configuration scope on a role assignment," and "Use the Shell to change the database filter or list-based configuration scope on a role assignment" sections earlier in this topic. The only difference is that when you change an exclusive scope, you must specify the following exclusive parameters depending on whether you're changing an exclusive recipient scope or an exclusive configuration scope:

- **Exclusive recipient scopes** Use the *ExclusiveRecipientWriteScope* parameter instead of the *CustomRecipientWriteScope* parameter.
- **Exclusive server and database configuration scopes** Use the *ExclusiveConfigWriteScope* parameter instead of the *CustomConfigWriteScope* parameter.

As with regular recipient and configuration scopes, if you add or change an exclusive scope, any previously defined recipient or configuration scopes are replaced.

This example changes an exclusive recipient write scope.

```
Set-ManagementRoleAssignment "Exclusive Executive Users" -ExclusiveRecipientWrite
```

For detailed syntax and parameter information, see Set-ManagementRoleAssignment.

1.3.3.5.3.3 View Role Assignments

View Role Assignments

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role assignments assign a management role to a role assignee. For more information about management role assignments in Microsoft Exchange Server 2010, see Understanding Management Role Assignments.

You must use the Shell to view role assignments.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Prerequisites

This topic makes use of pipelining and the **Format-List** cmdlet. For more information about these concepts, see the following topics:

- Pipelining
- Working with Command Output

Note:
You can't use the EMC to view role assignments.

View a list of all role assignments

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

You can view a list of all role assignments configured in your organization by running the **Get-ManagementRoleAssignment** cmdlet. If you want to retrieve a list of role assignments that match a partial string that you specify, use wildcard characters (*). This example retrieves a list of all the role assignments that start with the string "Tier 1".

```
Get-ManagementRoleAssignment "Tier 1*"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the details of a specific role

assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

You can view the details of a role assignment by piping the results of the **Get-ManagementRoleAssignment** cmdlet to the **Format-List** cmdlet. Use the following syntax.

```
Get-ManagementRoleAssignment <assignment name> | Format-List
```

This example retrieves the details of the Help Desk Assignment role assignment.

```
Get-ManagementRoleAssignment "Help Desk Assignment" | Format-List
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the list of role assignments assigned to a specific role assignee

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments associated with a management role group, role, or role assignment policy, or associated with a user or universal security group (USG), use the following syntax.

```
Get-ManagementRoleAssignment -RoleAssignee <role assignee name>
```

This example retrieves all of the role assignments associated with the Server Management role group.

```
Get-ManagementRoleAssignment -RoleAssignee "Server Management"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the role assignments associated with a specific role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

Each role can have multiple role assignments. You can use the **Get-ManagementRoleAssigment** cmdlet to view a list of role assignments associated with a specified role.

To view a list of role assignments associated with a specified role, use the following syntax.

```
Get-ManagementRoleAssignment -Role <role name>
```

This example retrieves all of the role assignments associated with the Mail Recipients role.

```
Get-ManagementRoleAssignment -Role "Mail Recipients"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that use a specific predefined scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments that use a specific predefined scope, use the following syntax.

```
Get-ManagementRoleAssignment -RecipientWriteScope < MyGAL | MyDistributionGroups
```

This example retrieves all of the role assignments that use the Organization predefined scope.

```
Get-ManagementRoleAssignment -RecipientWriteScope Organization
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that have been scoped to a specific OU

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments that have been scoped to a specific organizational unit (OU), use the following syntax.

```
Get-ManagementRoleAssignment -RecipientOrganizationalUnitScope <OU>
```

This example retrieves all of the role assignments that have been scoped to the North America\Engineering\Users OU in the contoso.com domain.

```
Get-ManagementRoleAssignment -RecipientOrganizationalUnitScope "contoso.com/North
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of assignments that use a specific custom scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments that use a specific custom scope, you need to first determine whether the scope is a recipient scope, configuration scope, exclusive recipient scope, or exclusive configuration scope. Each type of scope uses a different parameter on the **Get-ManagementRoleAssignment** cmdlet. The following lists each scope and its associated parameter:

- **Recipient scopes** *CustomRecipientWriteScope*
- **Configuration scopes** *CustomConfigWriteScope*

- **Exclusive recipient scopes** *ExclusiveRecipientWriteScope*
- **Exclusive configuration scopes** *ExclusiveConfigWriteScope*

The syntax for each parameter is the same. Specify the name of the scope with the parameter that matches the type of scope it is.

This example retrieves all of the role assignments that use the Vancouver Recipients recipient scope.

```
Get-ManagementRoleAssignment -CustomRecipientWriteScope "Vancouver Recipients"
```

This example retrieves all of the role assignments that use the Seattle AD Site exclusive configuration scope.

```
Get-ManagementRoleAssignment -ExclusiveConfigWriteScope "Seattle AD Site"
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of exclusive or regular scopes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of exclusive or regular role assignments, use the following syntax.

```
Get-ManagementRoleAssignment -Exclusive < $True | $False >
```

For example, to view a list of exclusive scopes, run the following command:

```
Get-ManagementRoleAssignment -Exclusive $True
```

This example retrieves a list of regular scopes without any exclusive scopes.

```
Get-ManagementRoleAssignment -Exclusive $False
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View who can modify a specific recipient or server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments that can modify a specific recipient or server, use the *WritableRecipient* and *WritableServer* parameters. Specify the name of the recipient with the *WritableRecipient* parameter, and the name of the server with the *WritableServer* parameter.

This example retrieves a list of role assignments that can modify the recipient Brian.

```
Get-ManagementRoleAssignment -WritableRecipient "Brian"
```

You can combine the *WritableRecipient* and *WritableServer* parameters with other parameters, such as the *RoleAssignee* parameter and the *GetEffectiveUsers* switch to refine your query and expand any role groups or USGs. This example retrieves all of the users who can modify the server EX02 and who are assigned the Server Management role group.

```
Get-ManagementRoleAssignment -WritableServer EX02 -RoleAssignee "Server Managemen
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View the users who receive permissions from an assignment via a role group or USG

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of users that receive permissions from a role assignment, use the following syntax.

```
Get-ManagementRoleAssignment <assignment name> -GetEffectiveUsers
```

This example retrieves a list of users in the Help Desk Assignment role assigment.

```
Get-ManagementRoleAssignment "Help Desk Assignment" -GetEffectiveUsers
```

You can also combine the *GetEffectiveUsers* switch with several other parameters on the **Get-ManagementRoleAssignment** cmdlet to expand the role groups and USGs that the role assignments are assigned to. For an example of how the *GetEffectiveUsers* switch is used with other parameters, see "View who can modify a specific recipient or server" earlier in this topic.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

View a list of role assignments that are enabled or disabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

To view a list of role assignments that are enabled or disabled, use the following syntax.

```
Get-ManagementRoleAssignment -Enabled < $True | $False >
```

This example retrieves a list of role assignments that are disabled.

```
Get-ManagementRoleAssignment -Enabled $False
```

For detailed syntax and parameter information, see Get-ManagementRoleAssignment.

1.3.3.5.3.4 Remove a Role from a User or USG

Remove a Role from a User or USG

Managing Permissions > Managing Advanced Permissions > Management Role Assignments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management role assignments assign a management role to a user or universal security group (USG). If you remove a role assignment, the users assigned the role will no longer have access to the cmdlets available on that role. For more information about management role assignments in Microsoft Exchange Server 2010, see Understanding Management Role Assignments.

You must use the Shell to remove role assignments.

Looking for other management tasks related to roles? Check out Managing Advanced Permissions.

Remove a management role assignment

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role assignments" entry in the Role Management Permissions topic.

If you know the name of the role assignment you want to remove, use the following syntax:

```
Remove-ManagementRoleAssignment <assignment name>
```

For example, to remove the "Tier 2 Help Desk Assignment" role assignment, use the following command:

```
Remove-ManagementRoleAssignment "Tier 2 Help Desk Assignment"
```

If you don't know the name of the role assignment, you can use the following syntax:

```
Get-ManagementRoleAssignment -RoleAssignee <user or USG> -Role <role name> -Deleg
```

For example, if you want to remove the Mail Recipients regular role assignment from the user davids, use the following command:

```
Get-ManagementRoleAssignment -RoleAssignee davids -Role "Mail Recipients" -Delega
```

1.3.3.5.3.5 Delegate Role Assignments

Delegate Role Assignments

Managing Permissions > Managing Advanced Permissions > Management Role Assignments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Management role delegation enables role assignees to assign a specified management role to other management role groups, management role assignment policies, users, or universal security groups (USG). By default, only members of the Organization Management management role group can delegate role assignments. When a new installation of Microsoft Exchange Server 2010 is deployed, only the user account that installed Exchange 2010 is a member of the Organization Management role group.

If you assign a delegating role assignment to a role group, any member of the role group can delegate the associated management role to other role assignees.

Important:

Delegating role assignments doesn't give the role assignee the permissions granted by the role, only the ability to assign the role to others. If you want to also give the permissions granted by the role to the role assignee, you must also create a regular role assignment. To create a regular role assignment, see the following topics:
Add a Role to a Role Group
Add a Role to an Assignment Policy
Add a Role to a User or USG

Note:
This topic discusses management role assignment delegation. If you want to delegate who can add members to or remove members from role groups, which is the recommended method of delegation, see Add or Remove a Role Group Delegate.

For more information about regular role assignments and delegating management role assignments, see Understanding Management Role Assignments.

Looking for other management tasks related to managing permissions? Check out Managing Advanced Permissions.

Use the Shell to delegate a management role

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Management roles" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to delegate a role assignment.

You can create delegating role assignments using the same predefined scopes, recipient filter or server-filter-based scopes, server list-based scopes, and organizational unit (OU) scopes that can be used to create regular or exclusive scopes. The only difference between creating a regular role assignment and a delegating role assignment is the addition of the *Delegating* switch to the command. For more information about how to create role assignments, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Note:
You can't create a delegating role assignment to a management role assignment policy.

This example creates a delegating role assignment to enable members of the Senior Admins role group to assign the Mail Recipients role to any role assignee in the Exchange organization.

```
New-ManagementRoleAssignment -Role "Mail Recipients" -SecurityGroup "Senior Admin
```

This example creates a delegating role assignment to enable members of the Senior Admins role group to assign the Mail Recipients role only to users in the Sales/Users OU in the contoso.com domain.

```
New-ManagementRoleAssignment -Role "Mail Recipients" -SecurityGroup "Senior Admin
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

1.3.3.5.4 Managing Split Permissions

Managing Split Permissions

Permissions > Managing Permissions > Managing Advanced Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-25*

The following procedures enable you to perform advanced permissions management. You should only use these procedures if management role groups and management role assignment policies don't meet the needs of your organization.

Configure Exchange 2010 for Split Permissions

Configure Exchange 2010 for Shared Permissions

For more information about managing role groups and role assignment policies, see the following topics:

Managing Administrator and Specialist Users

Managing End Users

1.3.3.5.4.1 Configure Exchange 2010 for Split Permissions

Configure Exchange 2010 for Split Permissions

Managing Permissions > Managing Advanced Permissions > Managing Split Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Split permissions enable two separate groups, such as Active Directory administrators and Microsoft Exchange Server 2010 administrators, to manage their respective services, objects, and attributes. Active Directory administrators manage security principals, such as users, that provide permissions to access an Active Directory forest. Exchange administrators manage the Exchange-related attributes on Active Directory objects and Exchange-specific object creation and management.

Microsoft Exchange Server 2010 Service Pack 1 (SP1) offers the following types of split permissions models:

- **RBAC split permissions** Permissions to create security principals in the Active Directory domain partition are controlled by Role Based Access Control (RBAC). Only those who are members of the appropriate role groups can create security principals.
- **Active Directory split permissions** Permissions to create security principals in the Active Directory domain partition are completely removed from any Exchange user, service, or server. No option is provided in RBAC to create security principals. Creation of security principals in Active Directory must be performed using Active Directory management tools.

Note:

Active Directory split permissions are available beginning with Exchange 2010 SP1.

The model that you choose depends on the structure and needs of your organization. Choose the procedure that follows that's applicable to the model you want to configure. We recommend that you use the RBAC split permissions model. The RBAC split permissions model provides significantly more flexibility while providing the same administration separation as Active Directory split permissions.

For more information about shared and split permissions, see Understanding Split Permissions.

For more information about management role groups, management roles, and regular and delegating management role assignments, see the following topics:

- Understanding Role Based Access Control
- Understanding Management Role Groups
- Understanding Management Roles
- Understanding Management Role Assignments

Looking for other management tasks related to permissions? Check out Managing Advanced Permissions.

Switch to RBAC split permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory split permissions" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to switch to RBAC split permissions.

You can configure your Exchange 2010 organization for RBAC split permissions. When you are done, only Active Directory administrators will be able to create Active Directory security principals. This means that Exchange administrators won't be able to use the following cmdlets:

- **New-Mailbox**
- **New-MailContact**
- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**

Exchange administrators will only be able to manage the Exchange attributes on existing Active Directory security principals. However, They will be able to create and manage Exchange-specific objects, such as transport rules and distribution groups. For more information, see the "RBAC Split Permissions" section in Understanding Split Permissions.

To configure Exchange 2010 for split permissions, you must assign the Mail Recipient Creation role and the Security Group Creation and Membership role to a role group that contains members that are Active Directory administrators. You must then remove the assignments between those roles and any role group or universal security group (USG) that contains Exchange administrators.

To configure RBAC split permissions, do the following:

1. If your organization is currently configured for Active Directory split permissions, do the following from a Windows command shell prompt:
   1.a. Disable Active Directory split permissions by running the following command from the Exchange 2010 SP1 installation media.

```
setup.com /PrepareAD /ActiveDirectorySplitPermissions:false
```

1.b.Restart the Exchange 2010 servers in your organization or wait for the Active Directory access token to replicate to all of your Exchange 2010 servers.

2. Do the following from the Exchange Management Shell:

2.a.Create a role group for the Active Directory administrators. In addition to creating the role group, the command creates regular role assignments between the new role group and the Mail Recipient Creation role and the Security Group Creation and Membership role.

```
New-RoleGroup "Active Directory Administrators" -Roles "Mai
```

Note:

If you want members of this role group to be able to create role assignments, include the Role Management role. You don't have to add this role now. However, if you ever want to assign either the Mail Recipient Creation role or Security Group Creation and Membership role to other role assignees, the Role Management role must be assigned to this new role group. The steps that follow configure the Active Directory Administrators role group as the only role group that can delegate these roles.

2.b.Create delegating role assignments between the new role group and the Mail Recipient Creation role and Security Group Creation and Membership role using the following commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient Creation
New-ManagementRoleAssignment -Role "Security Group Creation
```

2.c.Add members to the new role group using the following command.

```
Add-RoleGroupMember "Active Directory Administrators" -Memb
```

2.d.Replace the delegate list on the new role group so that only members of the role group can add or remove members.

```
Set-RoleGroup "Active Directory Administrators" -ManagedBy
```

Important:

Members of the Organization Management role group, or those who are assigned the Role Management role, either directly or through another role group or USG, can bypass this delegate security check. If you want to prevent any Exchange administrator from adding himself or herself to the new role group, you must remove the role assignment between the Role Management role and any Exchange administrator and assign it to another role group.

2.e.Find all of the regular and delegating role assignments to the Mail Recipient Creation role using the following command. The command displays only the **Name**, **Role**, and **RoleAssigneeName** properties.

```
Get-ManagementRoleAssignment -Role "Mail Recipient Creation
```

2.f.Remove all of the regular and delegating role assignments to the Mail Recipient Creation role that aren't associated with the new role group or any other role groups, USGs, or direct assignments you want to keep using the following command.

```
Remove-ManagementRoleAssignment <Mail Recipient Creation rc
```

Note:
If you want to remove all of the regular and delegating role assignments to the Mail Recipient Creation role on any role assignee other than the Active Directory Administrators role group, use the following command. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch and run the command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Mail Recipient Creation
```

2.g.Find all of the regular and delegating role assignments to the Security Group Creation and Membership role using the following command. The command displays only the **Name**, **Role**, and **RoleAssigneeName** properties.

```
Get-ManagementRoleAssignment -Role "Security Group Creation
```

2.h.Remove all of the regular and delegating role assignments to the Security Group Creation and Membership role that aren't associated with the new role group or any other role groups, USGs, or direct assignments you want to keep using the following command.

```
Remove-ManagementRoleAssignment <Security Group Creation ar
```

Note:
You can use the same command in the preceding Note to remove all of the regular and delegating role assignments to the Security Group Creation and Membership role on any role assignee other than the Active Directory Administrators role group, as shown in this example.

```
Get-ManagementRoleAssignment -Role "Security Group Creation
```

For detailed syntax and parameter information, see the following topics:

- New-RoleGroup
- New-ManagementRoleAssignment
- Add-RoleGroupMember
- Set-RoleGroup
- Get-ManagementRoleAssignment
- Remove-ManagementRoleAssignment

Switch to Active Directory split permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory split permissions" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to switch to Active Directory split permissions.

You can configure your Exchange 2010 organization for Active Directory split permissions.

Active Directory split permissions completely remove the permissions that allow Exchange administrators and servers from creating security principals in Active Directory or modifying non-Exchange attributes on those objects. When you are done, only Active Directory administrators will be able to create Active Directory security principals. This means that Exchange administrators won't be able to use the following cmdlets:

- **Add-DistributionGroupMember**
- **New-DistributionGroup**
- **New-Mailbox**
- **New-MailContact**
- **New-MailUser**
- **New-RemoteMailbox**
- **Remove-DistributionGroup**
- **Remove-DistributionGroupMember**
- **Remove-Mailbox**
- **Remove-MailContact**
- **Remove-MailUser**
- **Remove-RemoteMailbox**
- **Update-DistributionGroupMember**

Exchange administrators and servers will only be able to manage the Exchange attributes on existing Active Directory security principals. They will, however, be able to create and manage Exchange-specific objects, such as transport rules and Unified Messaging dial plans.

Caution:

After you enable Active Directory split permissions, Exchange administrators and servers will no longer be able to create security principals in Active Directory, and they won't be able to manage distribution group membership. These tasks must be performed using Active Directory management tools with the required Active Directory permissions. Before you make this change, you should understand the impact it will have on your administration processes and third-party applications that integrate with Exchange 2010 and the RBAC permissions model.
For more information, see the "Active Directory Split Permissions" section in Understanding Split Permissions.

To switch from shared or RBAC split permissions to Active Directory split permissions, do the following:

1. From a Windows command shell, run the following command from the Exchange 2010 SP1 installation media to enable Active Directory split permissions.

```
setup.com /PrepareAD /ActiveDirectorySplitPermissions:true
```

2. Restart the Exchange 2010 servers in your organization or wait for the Active Directory access token to replicate to all of you Exchange 2010 servers.

1.3.3.5.4.2 Configure Exchange 2010 for Shared Permissions

Configure Exchange 2010 for Shared Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Shared permissions enable you, as an administrator of Microsoft Exchange Server 2010, to create Active Directory security principals, such as users, and then configure them as Exchange recipients. Unlike split permissions, which separate management tasks between groups of Exchange administrators and Active Directory administrators, there's no separation of tasks with shared permissions.

For more information about shared and split permissions, see Understanding Split Permissions.

You can configure your Exchange 2010 organization for shared permissions if you've previously set your organization for split permissions. The procedure to switch to shared permissions is different depending on whether you're currently using Role Based Access Control (RBAC) split permissions or Active Directory split permissions. Choose the procedure that follows that's applicable to your current configuration. If the following are true, your organization is using Active Directory split permissions:

- The Microsoft Exchange Protected Groups organizational unit (OU) exists.
- The Exchange Windows Permissions security group is located in the Microsoft Exchange Protected Groups OU.
- The Exchange Trusted Subsystem security group is a member of the Exchange Windows Permissions security group.
- There are no regular management role assignments to the Mail Recipient Creation role or Security Group Creation and Membership role.

If you've never configured your organization for split permissions, you don't need to perform this procedure. Exchange 2010 is configured for shared permissions by default.

For more information about management role groups, management roles, and regular and delegating management role assignments, see the following topics:

- Understanding Role Based Access Control
- Understanding Management Role Groups
- Understanding Management Roles
- Understanding Management Role Assignments

Looking for other management tasks related to permissions? Check out Managing Advanced Permissions.

Prerequisites

- The Exchange 2010 organization must currently be configured for RBAC or Active Directory split permissions.
- You must have permissions to delegate the Mail Recipient Creation management role and the Security Group Creation and Membership management role to the Organization Management management role group or another role group that's assigned the Mail Recipients role.

Switch from RBAC split permissions to shared permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to switch from RBAC split permissions to shared permissions.

To switch from RBAC split permissions to Exchange 2010 shared permissions, you must assign the Mail Recipient Creation role and the Security Group Creation and Membership

role to a role group that's also assigned the Mail Recipients role and has Exchange 2010 administrators as members. In the default shared permissions configuration, the Organization Management role group contains each of these roles. Because of this, the Organization Management role group is in this procedure.

Configure shared permissions

To configure shared permissions on the Organization Management role group, do the following using an account that has permissions to delegate role assignments for the Mail Recipient Creation role and the Security Group Creation and Membership role:

1. Add delegating role assignments for the Mail Recipient Creation role and Security Group Creation and Membership role to the Organization Management role group using the following commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient Creation" -Security
New-ManagementRoleAssignment -Role "Security Group Creation and Member
```

Note:

The role group (in this procedure, the Active Directory Administrators role group) that has delegating role assignments for the Mail Recipient Creation role and Security Group Creation and Membership role must be assigned the Role Management role to run the **New-ManagementRoleAssignment** cmdlet. The role assignee that can delegate the Role Management role must assign that role to the Active Directory Administrators role group.

2. Add regular role assignments for the Mail Recipient Creation role to the Organization Management and Recipient Management role groups using the following commands.

```
New-ManagementRoleAssignment -Role "Mail Recipient Creation" -Security
New-ManagementRoleAssignment -Role "Security Group Creation and Member
```

3. Add a regular role assignment for the Security Group Creation and Membership role to the Organization Management role group using the following command.

```
New-ManagementRoleAssignment -Role "Security Group Creation and Member
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Remove permissions from Active Directory administrators (Optional)

You can optionally remove the permissions granted to Active Directory administrators if you no longer want them to be able to create or manage Active Directory objects using the Exchange management tools. If you want to remove permissions from Active Directory administrators, perform this procedure.

Note:

Although you can remove permissions for Active Directory administrators to manage Active Directory objects using the Exchange management tools, Active Directory administrators can continue to manage Active Directory objects using Active Directory management tools, if their Active Directory permissions allow it. They won't, however, be able to manage Exchange-specific attributes on Active Directory objects. For more information, see Understanding Split Permissions.

To remove Exchange-related split permissions from Active Directory administrators, do the following:

1. Remove the regular and delegating role assignments that assign the Mail Recipient Creation role to the role group or universal security group (USG) that contains the Active Directory administrators as members using the following command. This command uses the Active Directory Administrators role group as an example. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch, and run the

command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Mail Recipient Creation" | Where {
```

2. Remove the regular and delegating role assignments that assign the Security Group Creation and Membership role to the role group or USG that contains the Active Directory administrators as members using the following command. This command uses the Active Directory Administrators role group as an example. The *WhatIf* switch lets you see what role assignments will be removed. Remove the *WhatIf* switch, and run the command again to remove the role assignments.

```
Get-ManagementRoleAssignment -Role "Security Group Creation and Member
```

3. Optional. If you want to remove all Exchange permissions from the Active Directory administrators, you can remove the role group or USG in which they're members. For more information about how to remove a role group, see Remove a Role Group.

For detailed syntax and parameter information, see Get-ManagementRoleAssignment or Remove-ManagementRoleAssignment.

Switch from Active Directory split permissions to shared permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory split permissions" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to switch from Active Directory split permissions to shared permissions.

To switch from Active Directory split permissions to Exchange 2010 shared permissions, you must rerun Exchange Setup to disable Active Directory split permissions in the Exchange organization, and then create role assignments between a role group and the Mail Recipient Creation role and Security Group Creation and Membership role. In the default shared permissions configuration, the Organization Management role group contains each of these roles. Because of this, the Organization Management role group is in this procedure.

Important:

The setup.com command in this procedure makes changes to Active Directory. You must use an account that has the permissions required to make these changes. This account might not be the same account that has permissions to create role assignments using the **New-ManagementRoleAssignment** cmdlet. Use the account, or accounts, with the permissions necessary to successfully complete each step in this procedure.

To switch from Active Directory split permissions to shared permissions, do the following:

1. From a Windows command shell, run the following command from the Exchange 2010 SP1 installation media to disable Active Directory split permissions.

```
setup.com /PrepareAD /ActiveDirectorySplitPermissions:false
```

2. From the Exchange Management Shell, run the following commands to add regular role assignments between the Mail Recipient Creation role and Security Group Creation and Management role and the Organization Management and Recipient Management role groups.

```
New-ManagementRoleAssignment "Mail Recipient Creation_Organization Man
New-ManagementRoleAssignment "Security Group Creation and Membership_O
New-ManagementRoleAssignment "Mail Recipient Creation_Recipient Manage
```

3.Restart the Exchange 2010 servers in your organization.

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

1.4 Exchange Management Console

Exchange Management Console

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

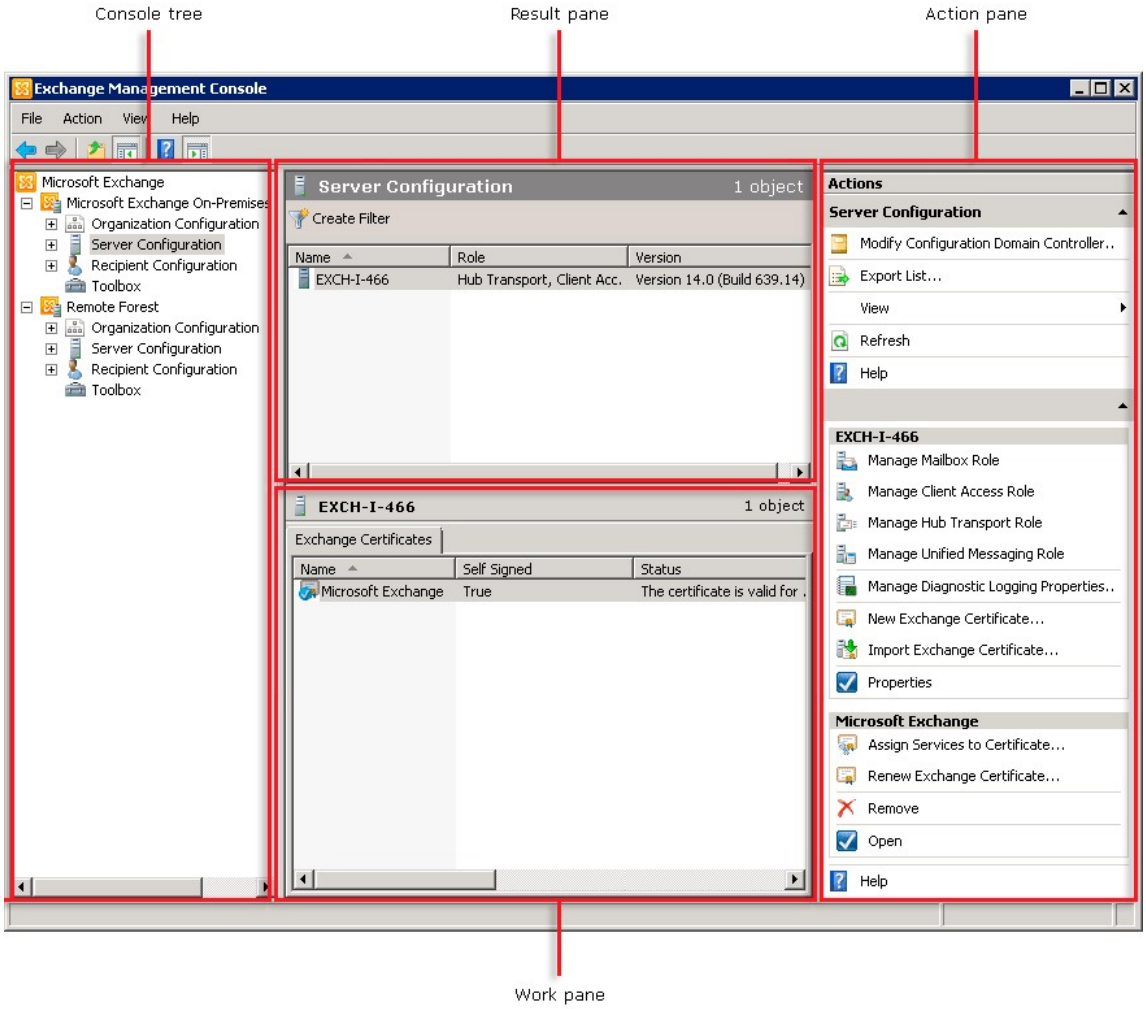
Topic Last Modified: *2011-04-28*

The Exchange Management Console (EMC) is a Microsoft Management Console (MMC) 3.0-based tool that provides Exchange administrators with a graphical user interface (GUI) to manage the configuration of Exchange organizations. You can also add the EMC snap-in to custom MMC-based tools.

For more information about improvements to the EMC, see New Administrative Functionality in the Exchange Management Console.

Common User Interface Elements in the Exchange Management Console

This section describes the user interface elements that are common across the EMC.



Console Tree

The console tree is located on the left side of the console and is organized by nodes that are based on the server roles you've installed. These server role-based nodes are described in greater detail later in this topic.

Result Pane

The result pane is located in the center of the console. This pane displays objects based on the node that's selected in the console tree. In addition, you can filter the information in the result pane. For more information, see Filter the Result Pane.

Work Pane

The work pane is located at the bottom of the result pane. This pane displays objects based on the server role that's selected in the **Server Configuration** node.

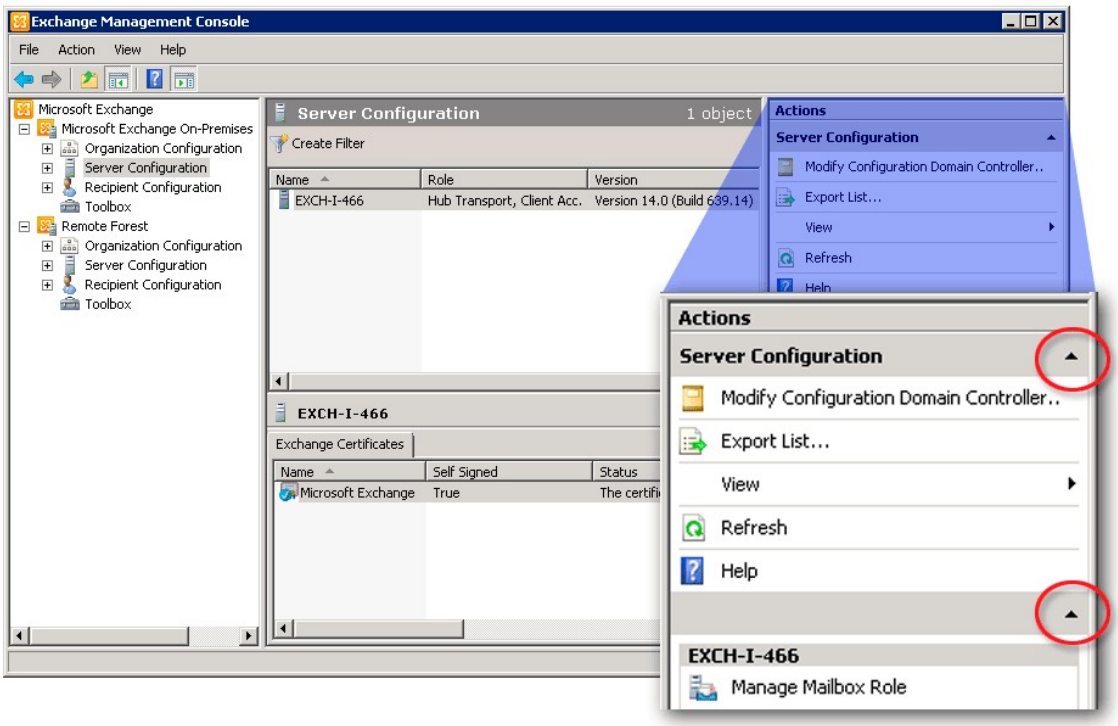
Note:

The work pane is available only when you select objects under the **Server Configuration** node, such as **Mailbox** or **Client Access**.

Action Pane

The action pane is located on the right side of the console. This pane lists the actions based on the object that's selected in the console tree, result pane, or work pane. The action pane is an extension of the shortcut menu, which is the menu that appears when you right-click an item. However, the shortcut menu is still available. To show or hide the

action pane, click the **Show/Hide Action Pane** arrow.



The following table lists common action pane options.

Action pane option	Description
Export List	Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.
View	Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree: • **View Exchange Management Shell Command Log** Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC. • **Add/Remove Columns** Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the

	order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console. • **Visual Effects** Click **Visual Effects** to set the visual effects to be never on or automatic. Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off. • **Save Current Filter as Default** Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane. • **Customize** Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.
Refresh	Click **Refresh** to refresh the information displayed in the result pane.
Help	Click **Help** to read the context-sensitive Help for the node or object selected.
Properties	Click **Properties** to view or edit the current configuration for the object selected in the result pane or work pane. **Note:** This option may not be available for all objects.
Remove	Click **Remove** to delete the selected object from the work pane. **Note:** This option may not be available for all objects. **Important:** When you remove a mailbox, not only is the Exchange data deleted, but the associated user account in Active Directory is deleted as well.
Enable or **Disable**	Click **Enable** or **Disable** to enable or disable the object selected in the result pane or work pane. Disabling an object doesn't delete it. **Note:**

	These options may not be available for all objects.

1.4.1 Microsoft Exchange On-Premises

Microsoft Exchange On-Premises

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-13*

The **Microsoft Exchange** On-Premises node in the Exchange Management Console allows you to manage your on-premises deployments of Exchange. When you select this node, the result pane displays these tabs:

- **Organizational Health** The Organizational Health report gives you a quick view of your organization and its operating characteristics. The service provides an organizational summary that includes health and licensing information plus a summary of the Exchange servers and recipients.

  Important:
  This report provides you with a quick overview of your Exchange organization that's representative of conditions only at the time the information was collected. In addition, this information may not be accurate because of errors that may have occurred while information was being collected.

  Exchange doesn't display the organizational information by default. To enable the report, you must use the Collect Organizational Health Data wizard to configure how frequently you want to collect data. For more information, see Collect Organizational Health Data.
- **Customer Feedback** The **Customer Feedback Options** section on this tab allows you to run the Customer Experience Improvement Program wizard, in which you can opt-in or out of CEIP. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.
  The **Help and Feedback** section provides you with a link to the Exchange TechCenter and also allows you to submit feedback or report bugs directly to the Exchange team.

1.4.2 Organization Configuration Node

Organization Configuration Node

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Organization Configuration** node to manage federations and organization relationships. You can also modify the configuration domain controller from this node.

To focus on a set of items in the result pane that have specific attributes, you can use a variety of expressions to filter the list. For more information about filters, see Filter the

Result Pane.

The **Organization Configuration** node contains the following sub-nodes:

- **Mailbox** Use this node to manage Mailbox server role settings that apply to your entire organization. You can maintain existing or create new address lists, managed custom folders, messaging records management (MRM) mailbox policies, and offline address books (OABs).
- **Client Access** Use this node to manage Client Access server role settings that apply to your entire organization. You can maintain existing or create new Exchange ActiveSync mailbox policies and Outlook Web App mailbox policies.
- **Hub Transport** Use this node to manage Hub Transport server role settings that apply to your entire organization. You can maintain existing or create new remote domains, accepted domains, e-mail address policies, transport rules, journal rules, Send connectors, global settings, and Edge subscriptions.
- **Unified Messaging** Use this node to manage Unified Messaging (UM) server role settings that apply to your entire organization. You can maintain existing or create new UM dial plans, UM IP gateways, UM mailbox policies, and UM Auto Attendants.

When you select the **Organization Configuration** node, the following actions are available either by right-clicking **Organization Configuration** or by using the action pane.

Term	Definition
Modify Configuration Domain Controller	Click **Modify Configuration Domain Controller** to select the domain controller that you want to use for server and organization configuration. For more information, see Using the Configuration Domain Controller.
New Federation Trust	Use the **New Federation Trust** wizard to create a new federation trust. A federation trust establishes trust with Windows Live as a prerequisite for enabling sharing of calendar free/ busy information and contacts between two Exchange organizations, or allowing users to share with external recipients. For more information, see Create a Federation Trust.
Manage Federation	Use the **Manage Federation** wizard to configure the federation trust and federated organization identifier. The federated organization identifier specifies the accepted domains in an Exchange Server organization that are available for federation. Only users that have e-mail addresses with domains configured with the federated organization identifier can participate in federated sharing. The first domain specified with the organization identifier is called the *account namespace*. Additional domains can subsequently be added to the organization identifier. **Note:** This action is only available when a federation trust is selected in the result pane. For more information, see Manage Federation.

New Organization Relationship	Use the **New Organization Relationship** wizard to define a partnership for federated sharing with an external Exchange organization. The partnership is defined by specifying the domains configured for federated sharing in the external Exchange organization. Features can be enabled for an organization relationship, allowing you to control the information that is shared with the external organization.
Export List	Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.
View	Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree: • **View Exchange Management Shell Command Log** Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC. • **Add/Remove Columns** Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console. • **Visual Effects** Click **Visual Effects** to set the visual effects to be never on or automatic. Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off. • **Save Current Filter as Default**

	Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane. • **Customize** Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.
Refresh	Click **Refresh** to refresh the information displayed in the result pane.

1.4.3 Server Configuration Node

Server Configuration Node

Exchange Server 2010 > Exchange Management Console >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the **Server Configuration** node to view a list of all the servers in your Exchange organization and perform server role-specific tasks, such as viewing the Exchange certificates in the work pane.

To focus on a set of items in the result pane that have specific attributes, you can use a variety of expressions to filter the list. For more information about filters, see Filter the Result Pane.

The nodes that appear under **Server Configuration** show only the Microsoft Exchange servers that have a specific server role installed. The **Server Configuration** node contains the following sub-nodes:

- **Mailbox** Use this node to manage the features of Mailbox servers, including viewing the properties of database copies.
- **Client Access** Use this node to manage the features of Client Access servers, including POP3 and IMAP4, Exchange ActiveSync, Outlook Web App, the Exchange Control Panel, and offline address book (OAB) distribution.
- **Hub Transport** Use this node to manage the features of Hub Transport server and receive connectors.
- **Unified Messaging** Use this node to manage the features of Unified Messaging (UM) servers, including enabling and disabling UM.

When you select the **Server Configuration** node, the following actions are available either by right-clicking **Server Configuration** or by using the action pane.

Modify Configuration Domain Controller

Click **Modify Configuration Domain Controller** to select the domain controller that you want to use for server and organization configuration.

Export List

Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.

View

Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree:

- **View Exchange Management Shell Command Log**
  Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC.
- **Add/Remove Columns**
  Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console.
- **Visual Effects**
  Click **Visual Effects** to set the visual effects to be never on or automatic. Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off.
- **Save Current Filter as Default**
  Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane.
- **Customize**
  Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.

Refresh

Click **Refresh** to refresh the information displayed in the result pane.

1.4.4 Recipient Configuration Node

Recipient Configuration Node

Exchange Server 2010 > Exchange Management Console >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the **Recipient Configuration** node for several recipient management tasks. Specifically, you can view the recipients in your Microsoft Exchange Server 2010 organization, create new recipients, and manage existing mailboxes, mail contacts, mail users, and distribution groups.

To focus on a set of items in the result pane that have specific attributes, you can use a variety of expressions to filter the list. For more information about filters, see Filter the Result Pane.

The **Recipient Configuration** node contains the following sub-nodes:

- **Mailbox** Use this node to manage mailboxes, users, and resource mailboxes (resource mailboxes include room and equipment mailboxes). You can create new mailboxes and remove, disable, or move existing mailboxes. You can also

configure mailbox properties, enable and disable Unified Messaging (UM), and manage mobile devices.

- **Distribution Group** Use this node to manage mail-enabled distribution groups (which include security groups) and dynamic distribution groups. You can create new distribution groups, and remove, disable, or configure existing distribution groups.
- **Mail Contact** Use this node to manage mail contacts and mail users. You can create, delete, or configure mail contacts and mail users.
- **Disconnected Mailbox** Use this node to view and connect disconnected mailboxes.

Note:
Disconnected mailboxes are retained based on the configured mailbox database limits. You see only the mailboxes that have been disconnected within the retention period that is specified for the mailbox database.

- **Move Request** Use this node to manage mailbox move requests. For more information, see Understanding Move Requests.

When you select the **Recipient Configuration** node, the following actions are available either by right-clicking **Recipient Configuration** or by using the action pane.

Modify Recipient Scope

Click **Modify Recipient Scope** to open the **Recipient Scope** dialog box box.

- Changing the recipient scope changes the number of recipients that are displayed in the result pane. The recipient-specific dialog boxes within various wizards and property pages also work within the same scope.
- You can set the scope to include all recipients in the forest or limit it to all recipients in a specific organizational unit (OU). The recipient scope allows administrators to focus on all recipients that are in a specific location in Active Directory Domain Services (AD DS). Selecting a limited recipient scope reduces the number of recipients that are returned, and consequently improves the performance of the Exchange Management Console.

For more information, see Modify the Maximum Number of Recipients to Display in the Result Pane.

Modify the Maximum Number of Recipients to Display

Click **Modify Maximum Number of Recipients to Display** to open the **Maximum Number of Recipients to Display** dialog box. You can use this dialog box to set the maximum number of recipients to display in the result pane.

By default, a maximum of 1,000 recipients is displayed. Increasing this value can be beneficial in large environments. However, increasing the value also increases the time it takes to display the results. Depending on the size of your organization, it may also have a performance impact on the domain controller to which you are connected.

For more information, see Modify the Maximum Number of Recipients to Display in the Result Pane.

Find

Click **Find** to open the **Find** dialog box. You can use the **Find** dialog to search for recipients in your organization. For more information, see Using the Find Dialog Box.

New Mailbox

Click **New Mailbox** to open the New Mailbox wizard. This wizard helps you create a new user, room, equipment, or linked mailbox. For more information, see Managing User Mailboxes.

New Mail Contact

Click **New Mail Contact** to open the New Mail Contact wizard. Mail contacts are mail-enabled Active Directory objects that contain information about people or

organizations that exist outside your Exchange organization. For more information, see Managing Mail Contacts and Mail Users

New Mail User

Click **New Mail User** to open the New Mail User wizard. Mail users are mail-enabled Active Directory users that don't have a mailbox in your Exchange organization.

New Remote Mailbox

Click **New Remote Mailbox** to open the New Remote Mailbox wizard. Use this wizard to create a mail-enabled user in your Exchange 2010 on-premises organization with an associated mailbox in the cloud-based service.

For more information, see Create a Remote Mailbox.

New Distribution Group

Click **New Distribution Group** to open the New Distribution Group wizard. This wizard helps you create both distribution and security groups. Distribution groups are mail-enabled Active Directory objects that contain information about people within an Exchange organization. All distribution groups can be used for e-mail distribution. Security groups can also be used to assign permissions to shared resources. For more information, see Managing Distribution Groups.

New Dynamic Distribution Group

Click **New Dynamic Distribution Group** to open the New Dynamic Distribution Group wizard. This wizard helps you create a new dynamic distribution group.

In Exchange Server 2003, dynamic distribution groups were called query-based distribution groups. Dynamic distribution groups provide the same functionality as mail-enabled distribution groups. However, instead of containing a static group of recipients, the membership list for dynamic distribution groups is calculated based on their configuration each time they are used. When a message is sent to a dynamic distribution group, it's delivered to all recipients in the organization that match the criteria defined for that dynamic distribution group. For more information, see Managing Distribution Groups.

Export List

Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.

View

Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree:

- **View Exchange Management Shell Command Log**
  Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC.
- **Add/Remove Columns**
  Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console.
- **Visual Effects**
  Click **Visual Effects** to set the visual effects to be never on or automatic.

Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off.

- **Save Current Filter as Default**
  Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane.
- **Customize**
  Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.

Refresh

Click **Refresh** to refresh the information displayed in the result pane.

1.4.5 View Local Forest Properties

View Local Forest Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Console to view the properties of a forest in Microsoft Exchange Server 2010.

Note:
You can't perform this procedure in the Exchange Management Shell.

Use the EMC to view the properties of an Exchange forest

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the console tree, right-click, select the forest in which you're interested, and then select **Properties**.
2. The **General** tab displays the following information about the forest:
   - **Administrator identity** The identity of the administrator of the forest. For example, Contoso\Adminstrator.
   - **Select a server to connect to for remote PowerShell** Select the server to connect to for remote PowerShell. Remote PowerShell is required to open the Exchange Management Shell or the Exchange Management Console on Mailbox, Hub Transport, Unified Messaging, and Client Access servers. You can choose to connect automatically to the selected server, or you can specify a server to connect to.

For More Information

Add an Exchange Forest

1.4.6 View Remote Exchange Forest

View Remote Exchange Forest

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Console to view the properties of a forest in Microsoft Exchange Server 2010.

Note:
You can't perform this procedure in the Exchange Management Shell.

Use the EMC to view the properties of an Exchange forest

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the console tree, select the remote Exchange forest in which you're interested, right-click, and then select **Properties**.
2. The **General** tab displays the following information about the forest:
   - **Administrator identity** The identity of the administrator of the source forest. For example, Contoso\Adminstrator.
   - **Remote PowerShell URL** The URL for the source forest's remote PowerShell connection. For example, https://server1.contoso.com/PowerShell/.

For More Information

Add an Exchange Forest

1.4.7 Microsoft Exchange Edge Transport Server

Microsoft Exchange Edge Transport Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-05-28*

The **Microsoft Exchange** node in the EMC is the starting point for managing Exchange. When you select this node, the result pane displays the following tabs:

- **Post-Installation Tasks** Use this tab to complete a variety of tasks that help you complete the deployment of the Edge Transport server role. The following post-installation tasks are available:
  - **Finalize Deployment Tasks** Required tasks that complete the deployment of your Edge Transport server. Examples of finalize deployment tasks are entering the product key, configuring Internet mail flow (either using the edge synchronization process or manual configuration) or configuring an external postmaster address.
  - **End-to-End Scenario Tasks** Recommended optional tasks that provide

end-to-end solutions. Examples of end-to-end scenarios are setting up monitoring options for your Edge Transport server or configuring anti-spam updates.

- **Additional Post-Installation Tasks** Optional tasks that you may want to perform depending on the needs of your organization. Examples are configuring administrator permissions or verifying your Microsoft Exchange Server 2010 installation.

- **Community and Feedback** This tab provides you with links to Exchange-related topics on Microsoft TechNet and new postings from the Exchange team blog. In addition, you can launch the Customer Experience Improvement Program (CEIP) wizard. For more information about CEIP, see Opt-in or Opt-out of the Customer Experience Improvement Program.

1.4.8 Managing Exchange Management Console Features

Managing Exchange Management Console Features

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Using the Find Dialog Box

1.4.8.1 Add an Exchange Forest

Add an Exchange Forest

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Add Exchange Forest** dialog box to add an Exchange forest. When you add an Exchange forest, you can administer recipients in multiple forests from the Exchange Management Console (EMC). You can add up to 10 forests.

Note:
You can't perform this procedure in the Exchange Management Shell.

Prerequisites

You must establish a federated trust or an Active Directory trust to the target forest before you can add an Exchange forest. For more information, see the following topics:

- Deploy Exchange 2010 in a Cross-Forest Topology
- "Understanding Multiple Forest Administration" in Deploy Multiple Forest Topologies
- Configure Cross-Forest Connectors
- Federation

Use the EMC to add an Exchange forest

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

1. In the console tree, click the **Microsoft Exchange** node. This is the top-most node in the tree.
2. In the action pane, click **Add Exchange Forest**.
3. In the **Add Exchange Forest** dialog box, complete the following fields:
   - **Specify a friendly name for this Exchange forest** Type the name of the Exchange forest. This name will display in the console tree.
   - **Specify the FQDN or URL of the server running the Remote PowerShell instance** Type the FQDN or URL for the source forest's remote PowerShell connection. For example, https://server1.contoso.com/PowerShell/ for the URL connection. For an Online organization, select **Exchange Online**.
   - **Logon with default credential** If you select this check box, the default logged-on administrator password is used.

For More Information

View Local Forest Properties

View Remote Exchange Forest

Understanding Federation

What's New in Exchange 2010 SP1

1.4.8.2 Add or Remove Columns in the Exchange Management Console

Add or Remove Columns in the Exchange Management Console

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-21*

By default, the result pane or work pane in the EMC displays only a subset of the columns available. You can add or remove columns based on the type of information that you want to see.

The Microsoft Management Console (MMC) saves any changes you make to a snap-in as preferences in your user profile on the administrator computer. As a result, the next time you start the EMC on the same computer, any changes you've made to the columns will remain. However, if you use another computer or a different user account to run the EMC, you'll need to add or remove columns again. For more information about the MMC, see Microsoft Management Console.

Add or Remove Columns in the Results Pane or Work Pane

1. In the EMC, select an item in either the result pane or the work pane.
2. In the action pane or from the toolbar, navigate to **View** > **Add/Remove Columns**. You can perform the following tasks:
   - To add columns to your current view, select the column name in the **Available columns** box, and then click **Add**.
   - To remove columns from your current view, select the column name from the **Displayed columns** box, and then click **Remove**.
   - To change the position in which the columns display, select a column name from the **Displayed columns** box, and then click **Move Up** or **Move Down**.
   - To restore the EMC to its original configuration, click **Restore Defaults**.
3. Click **OK** to apply your changes and close the dialog box.

1.4.8.3 Collect Organizational Health Data

Collect Organizational Health Data

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-04*

The Collect Organizational Health Data wizard collects the information that is displayed on the **Organizational Health** tab in the EMC.

Use the EMC to gather organizational

health data

1. In the console tree, navigate to the appropriate forest.
2. In the action pane, click **Collect Organizational Health Data**.

3. On the **Introduction** page, select one of the following schedule settings:
   - **Immediately** Select this option to collect organizational health information immediately.
   - **At the following time** Select this option, and then use the corresponding drop-down lists to apply a date and time.
   - **Cancel tasks that are still running after (hours)** Select this check box, and then use the corresponding text box to specify how long the wizard will run. The default is 8 hours.

     Click **Next**.

4. On the **Collect Organizational Health Data** page, review your settings. Click **Collect** to collect the data or click **Back** to make configuration changes.

5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

1.4.8.4 Connect to the Disconnected Mailbox Server

Connect to the Disconnected Mailbox Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Exchange Management Console (EMC) allows you to manage disconnected mailboxes on one server at a time. Use the **Connect to Server** dialog box to specify the Exchange server in your organization that you want to manage disconnected mailboxes.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailbox" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Disconnected Mailbox**.
2. In the action pane, click **Connect to Server**.
3. In **Connect to Server**, click **Browse** to open the **Select Exchange Server** dialog box. Use this dialog box to select the server from which you want to manage disconnected mailboxes.
4. Click **OK**.
5. In **Connect to Server**, you can set this server as the default server by selecting the **Set as default server** check box.
6. Click **OK** to close the dialog box and to save your settings.

For More Information

Connect or Restore a Disabled Mailbox

Understanding Disconnected Mailboxes

1.4.8.5 Customize the Exchange Management Console

Customize the Exchange Management Console

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-26*

You can customize the way the Exchange Management Console (EMC) looks.

The Microsoft Management Console (MMC) saves any changes you make to a snap-in as preferences in your user profile on the administrator computer. As a result, the next time you start the EMC on the same computer, the default any changes you've made to the columns will remain. However, if you use another computer or a different user account to run the EMC, you'll need to add or remove columns again. For more information about the MMC, see Microsoft Management Console.

Looking for other management tasks related to the EMC? Check out Exchange Management Console.

What Do You Want to Do?

- Turn visual effects on or off
- Show or hide console items

Turn visual effects on or off

Visual effects settings configure the way the Exchange wizards appear. By default, the visual effects are turned on. If you notice that your connection is slow when using wizards, you may want to turn off these effects.

In the action pane or from the toolbar, navigate to **View** > **Visual Effects**. Select from the following options:

- **Never** The wizards will display in a low-resolution mode.
- **Automatic** Based on your network connection, Exchange will decide whether to turn the effects on or off.

Show or hide console items

You can modify the EMC to show only the console items that you want to see.

1. In the action pane or from the toolbar, navigate to **View** > **Customize**.
2. In **Customize View**, select or clear the check boxes to show or hide items in the console window. Your changes will take effect immediately upon selecting or clearing the check boxes.
3. Click **OK**.

1.4.8.6 Export Lists from the Exchange Management Console

Export Lists from the Exchange Management Console

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the EMC, Public Folder Management Console, Details Templates Editor, or Queue Viewer to export lists from the result pane and the work pane.

You can export lists to the following file formats:

- Text (tab delimited)
- Text (comma delimited)
- Unicode text (tab delimited)
- Unicode text (comma delimited)

Note:
The result pane displays only the first 1,000 objects. For more information about how to filter results, see Filter the Result Pane.

Looking for other management tasks related to the EMC? Check out Managing Exchange Management Console Features.

Use the EMC to export a list from the result pane

Note:
You can't use the Shell to export a list from the result pane.

1. In the console tree, select the node or folder for which you want to display results. The list in the result pane is refreshed.

   Note:
   If the result pane doesn't refresh, in the action pane, click **Refresh**. Long lists may take several minutes to refresh.

2. In the action pane, click **Export List**. The **Export List** dialog box appears.
3. In **Export List**, type the name of the file in the **File name** box, and then select the file format from the **Save as type** list.
4. Click **Save**.

Use the EMC to export a list from the work pane

Note:
You can't use the Shell to export a list from the work pane.

1. In the console tree, expand **Server Configuration**, and then click **Mailbox**,

Client Access, or **Hub Transport**.
2. In the work pane, for any of the tabs displayed, right-click any empty space, and then click **Export List**. The **Export List** dialog box appears.
3. In **Export List**, type the name of the file in the **File name** box, and then select the file format from the **Save as type** list.
4. Click **Save**.

1.4.8.7 Filter the Result Pane

Filter the Result Pane

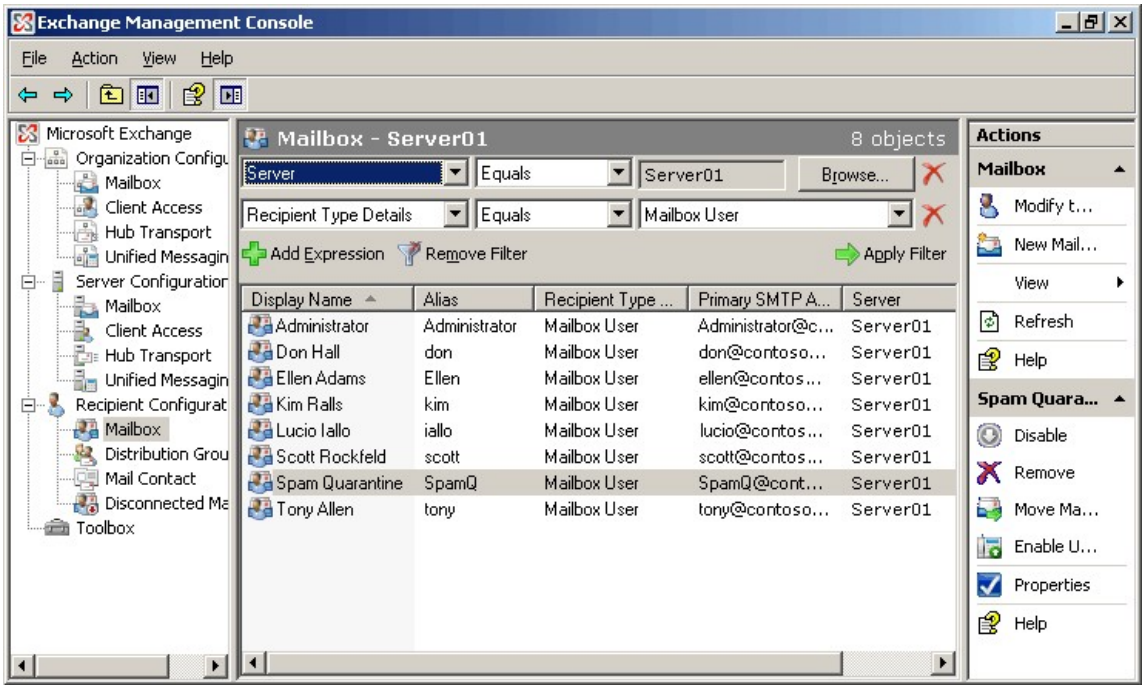
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-19*

In addition to filtering the result pane for the EMC, you can create filters for the Queue Viewer, Details Templates Editor, and the Public Folder Management Console.

You can create filters for the result pane of the **Organization Configuration** node, **Server Configuration** node, **Recipient Configuration** node, and **Edge Transport** node.

The following figure illustrates a filter for the **Mailbox** node under **Recipient Configuration**. This filter displays all mailbox users for the server Server01.



Caution:

The result pane displays up to one thousand objects. We recommend that you create a default filter to allow the objects to display more quickly. For more information about how to set a default filter, see Step 6 of this procedure.

Looking for other management tasks related to the EMC? Check out Managing Exchange Management Console Features.

Prerequisites

- A filter contains one or more expressions. Each expression consists of an attribute, an operator, and a value. The attributes vary depending on the items for which you are creating the filter. For example, you can filter mailboxes based on attributes such as **Alias** and **Display Name**.
- The list of operators that are available is based on the attribute you select. For example, when you're filtering recipients, the **Display Name** attribute can have **Starts With** as an operator.
- The list of acceptable values is also based on the attribute you select. Acceptable values are selected from a drop-down list, such as the **Role** attribute for servers. In addition, you can type the values for some attributes in the **Value** field, such as the **Display Name** attribute.
- When you are building expressions for a filter, you can't specify what is an **AND** or an **OR** expression. However, the default behavior of the filter is as follows:
  - Multiple expressions that use the same attribute are considered an **OR** expression.
  - Expressions that use different attributes are considered an **AND** expression.

Use the EMC to filter the result pane

Note:
You can't use the Shell to filter the result pane.

1. In the result pane, click **Create Filter** to start defining your filter.
2. Using the drop-down list boxes, create the first filter expression.
3. To create a filter with more than one expression, click **Add Expression**. Additional expressions make the filter more restrictive, which allows you to focus more on the list of items. You can add up to 10 expressions.

   Note:
   You can modify any expression as you're creating it. You can also remove any expression from your filter definition by clicking  .
4. To view only the items that match the criteria defined by the expressions you created, click **Apply Filter**.
5. To remove all expressions and close the filter, click **Remove Filter**. The result pane then displays the full list of items in the Exchange organization.
6. To save the filter as the default filter, click **View** on the menu bar, and then click **Save Current Filter as Default**.

1.4.8.8 Manage Diagnostic Logging Levels

Manage Diagnostic Logging Levels

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Modifying logging levels may help you troubleshoot issues that may occur in an Exchange Server 2010 environment. This topic explains how to use the Exchange Management Console and the Exchange Management Shell to change the diagnostic logging level for processes used by Exchange 2010.

The logging level for each Exchange process determines which events are written to the Application event log in Event Viewer. Changing the process logging level for a given process may not yield additional events in the event log. Many variables affect whether a change to the process logging level setting will increase the number of events. These variables include, but are not limited to, the actions being performed by the process and the number of events implemented in the source code for the logging level selected.

You can use the information in the following table to configure settings for any of the Exchange server roles in your organization. The default logging level is 0 (Lowest). It's recommended that you return the logging level to the default setting after completing your troubleshooting activities.

Logging level	Description
Lowest	Only critical events, error events, and events with a logging level of zero (0) are logged. **Note:** This is the default level for all services on Exchange servers.
Low	Events with a logging level of 1 or lower are logged.
Medium	Events with a logging level of 3 or lower are logged.
High	Events with a logging level of 5 or lower are logged.
Expert	Events with a logging level of 7 or lower are logged.

What Do You Want to Do?

- Use the EMC to set logging levels
- Use the Shell to set logging levels

Use the EMC to set logging levels

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shell infrastructure permissions" section in the Exchange and Shell Infrastructure Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Mailbox**.
2. In the Actions pane, select **Manage Diagnostic Logging Properties**.
3. On the **Manage Diagnostic Logging Properties** wizard page, click the Exchange service for which you want to change the logging level.
4. Select the logging level, and then click **Configure**.

   Note:
   You can return to the default logging levels by selecting **Reset all services to default logging levels** and then clicking **Configure**.

5. On the **Completion** page, confirm whether the process completed

successfully. A status of **Completed** indicates that the wizard completed the task successfully. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

6. Click **Finish** to complete the Manage Diagnostic Logging Level wizard.

Use the Shell to set logging levels

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shell infrastructure permissions" section in the Exchange and Shell Infrastructure Permissions topic.

This example identifies all processes and their current logging level.

```
Get-EventLogLevel
```

This example changes the MSExchangeAl\Account Management logging level to High.

```
Set-EventLogLevel -Identity "MSExchangeAl\AccountManagement" -Level High
```

For more information on setting or viewing your logging levels, see the following:

- Set-EventLogLevel
- Get-EventLogLevel

1.4.8.9 Opt-in or Opt-out of the Customer Experience Improvement Program

Opt-in or Opt-out of the Customer Experience Improvement Program

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

The Customer Experience Improvement Program (CEIP) collects anonymous information about how you use Microsoft Exchange 2010 and the problems that you might encounter. You can choose a level of participation. For example, you can choose to opt-out either your entire organization or just specific servers. If you decide not to participate in the CEIP, the servers are opted-out automatically.

You can join the CEIP during installation of Exchange 2010, or you join and specify your participating servers after you've set up your organization. For more information about the program, see Microsoft Customer Experience Program FAQ.

What Do You Want to Do?

- Use EMC to opt-in or opt-out of CEIP
- Use the Shell to opt-in or opt-out of CEIP

Use the EMC to opt-in or opt-out of the CEIP

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange server configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In the console tree, navigate to the **Microsoft Exchange On-Premises** node.
2. In the result pane, navigate to **Customer Feedback Options** > **Customer Experience Improvement Program**.
3. On the **Customer Experience Improvement Program** page, read the information about the CEIP and then complete the following settings:
   - **The industry that best represents your organization** Use the corresponding drop-down box to select the industry that best represents your organization.
   - **Join the Exchange Customer Experience Improvement Program** Select this option to join CEIP. If you select this option, select the participating servers later in this procedure.
   - **I don't want to join the program at this time** If you select this option, your organization will not participate in the program and the **Servers Opted in for the CEIP Program** list box will be disabled.
   - **Servers Opted in for the CEIP Program** Click **Add** to add servers to the program, or select servers from the list box and then click Remove (**X**) to remove servers from the program.
4. When you click **Add**, the **Select Exchange Server** dialog appears. Highlight each server that you want to add to the program, and then click **OK** for each server.
5. Click **Apply** on the **Customer Experience Improvement Program** page.
6. On the **Completion** page, the **Summary** states whether the operation was successful. The summary also displays the Exchange Management Shell command that was used to perform this procedure.
7. Click **Finish**.

Use the Shell to opt-in or opt-out of the CEIP

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange server configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

This example joins your organization to the CEIP and identifies the industry that is relevant for your organization. In this example, the industry used is `Hospitality`.

```
Set-OrganizationConfig -Industry 'Hospitality' -CustomerFeedbackEnabled $true
```

This example opts-out your entire organization from the CEIP.

```
Set-OrganizationConfig -CustomerFeedbackEnabled $false
```

This example opts-in an Exchange server to the CEIP. In this example, the server name is SERVER01.

Note:
The organization must be joined to the CEIP before you can opt-in any servers.

```
Set-ExchangeServer -Identity 'SERVER01' -CustomerFeedbackEnabled $true
```

This example opts-out an Exchange server from the CEIP. In this example, the server name is SERVER01.

```
Set-ExchangeServer -Identity 'SERVER01' -CustomerFeedbackEnabled $false
```

For detailed syntax and parameter reference, see the following topics:

- Set-OrganizationConfig
- Set-ExchangeServer

1.4.8.10 Command Exposure in Exchange Management Console Property Pages

Command Exposure in Exchange Management Console Property Pages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

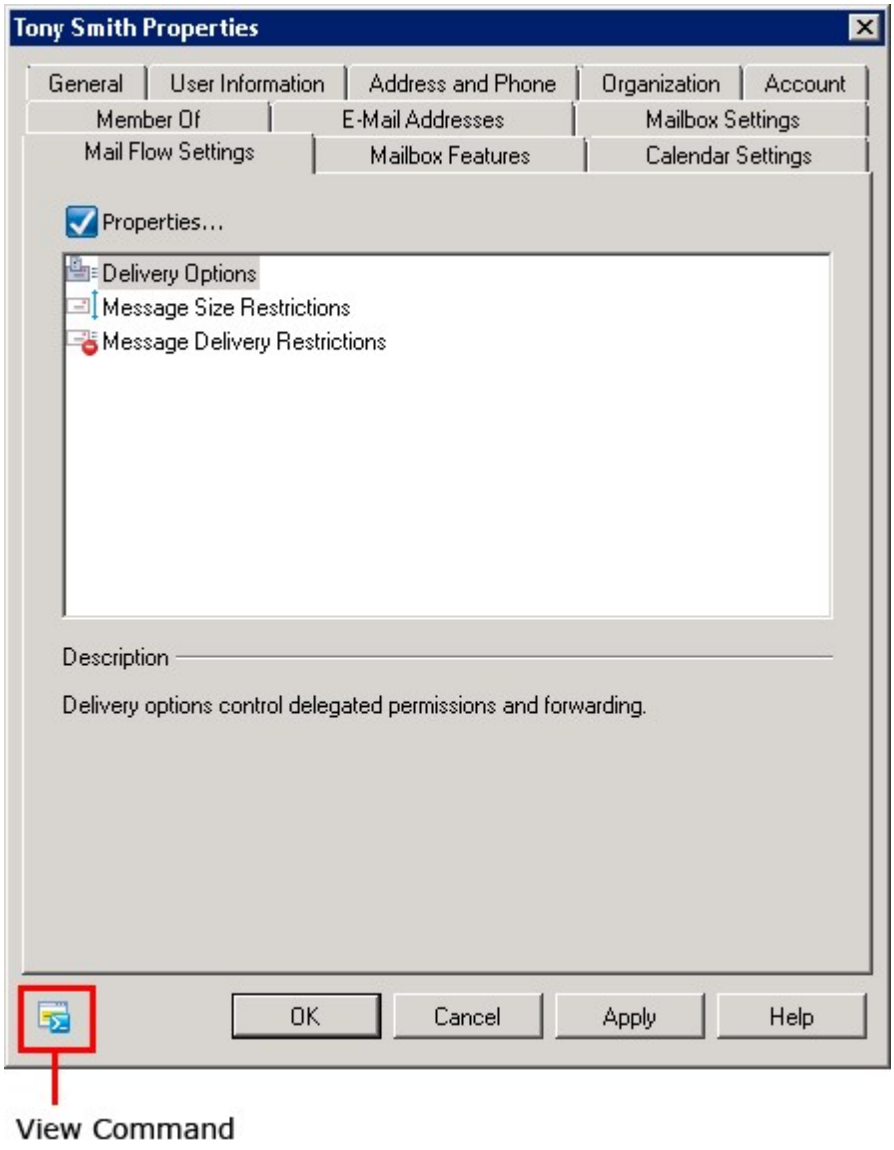
Topic Last Modified: *2009-10-21*

Command exposure in property pages is a new feature that allows you to view the Exchange Management Shell commands that are executed when you make changes to an object's properties.

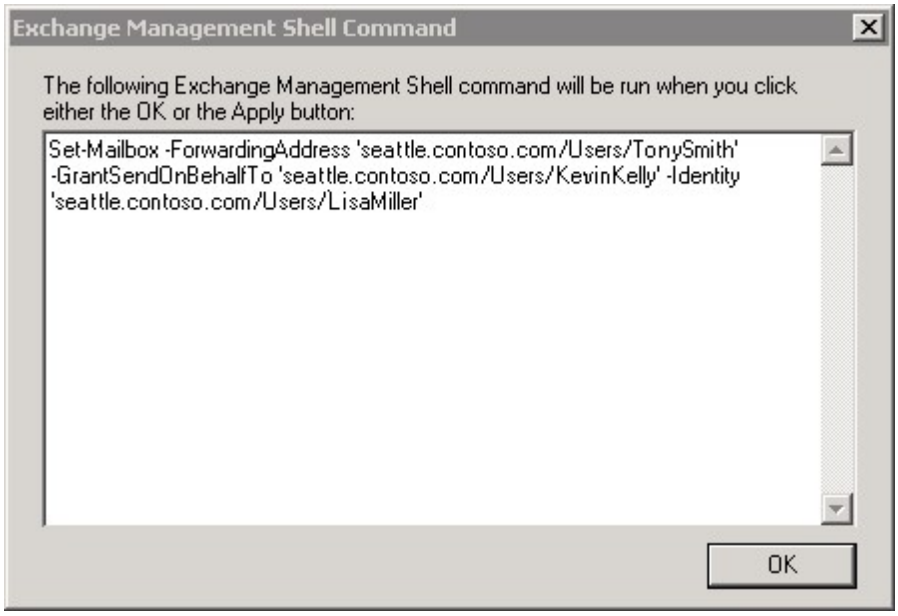
For example, the following figure shows the property page for the user mailbox Tony Smith. To view the Shell command that corresponds to any property changes, click the command-line icon that's located in the lower-left corner.

Note:

The icon is unavailable until you make a change to one of the settings.



When you click the command-line icon, the Exchange Management Shell Command dialog box displays the corresponding Shell command.



To copy the Shell command, highlight all of the text in the dialog box and press CTRL+C. You can then paste the command into a script or into the Shell.

1.4.8.11 Using the Configuration Domain Controller

Using the Configuration Domain Controller

Exchange Server 2010 > Exchange Management Console > Managing Exchange Management Console Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the **Configuration Domain Controller** dialog box to specify a domain controller to use to read and write to Active Directory if you modify any server or organization configuration.

To change the configuration domain controller click **Organization Configuration**, and then, in the action pane, click **Modify Configuration Domain Controller**.

Use a default domain controller

Click this button to use the default domain controller. The default domain controller is the domain controller to which the computer is currently connected.

Domain

If you want to specify a domain controller instead of using a default one, click **Browse** to open the **Select Domain** dialog box. Use this dialog box to select a domain in your Active Directory forest. You must select a domain before you can select a domain controller.

Configuration domain controller

This field isn't made available until you've specified a domain.

Click **Browse** to open the **Select Domain Controller** dialog box. Use this dialog box to select the domain controller you want to use when modifying server or organization

configuration.

1.4.8.12 Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC

Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Exchange Management Shell Command Log records the Shell commands that you run in the EMC. In addition, after you start command logging, you can view detailed information about the commands that have run by selecting an item in the result pane. The command that was run displays in the command display box.

Looking for other management tasks related to the EMC? Check out Exchange Management Console.

What Do You Want to Do?

- Turn on command logging
- Turn off command logging
- Export the command log
- Copy the command log to the Clipboard
- Modify the number of commands to log
- Clear the command log

Turn on command logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In the EMC, select **View** > **View Exchange Management Shell Command Log**.

   Note:

   You can't perform this action from the **Microsoft Exchange** node.

2. Select **Action** > **Start Command Logging**.
3. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all commands.

Turn off command logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

After you start command logging, the command log will run until you turn it off. Even if you close the program, the application will run in the background.

1. If the Exchange Management Shell Command Log is running in the background, in the EMC select **View** > **View Exchange Management Shell Command Log**.

2. In the Windows PowerShell Command Log, select **Action** > **Stop Command Logging**.

   Note:
   After you close the command log, all logged commands are cleared. The log will not be cleared until you close the EMC.

3. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all the commands.

Export the command log

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

The command log doesn't save the log of the current EMC session. If you want to save the log, you can export it to a file.

1. If the Exchange Management Shell Command Log is running in the background, in the EMC select **View** > **View Exchange Management Shell Command Log**.
2. Select **Action** > **Export List**. You can save the file in the following formats:
   - Text (Tab Delimited) (*.txt)
   - Text (Comma Delimited) (*.csv)
   - Unicode Text (Tab Delimited) (*.txt)
   - Unicode Text (Comma Delimited) (*.csv)
3. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all the commands.

Copy the command log to the Clipboard

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

The command log doesn't save the log of the current EMC session. If you want to save specific log entries, you can select them and then copy them to the Clipboard.

1. If the Exchange Management Shell Command Log is running in the background, in the EMC select **View** > **View Exchange Management Shell Command Log**.
2. Select an item or multiple items in the result pane, and then select **Action** | **Copy Commands**.
3. You can paste the command into a file, such as Notepad, by pressing CTRL+V.
4. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all the commands.

Modify the number of commands to log

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

By default, the Exchange Management Shell Command Log tracks up to 2,048 entries.

1. If the Exchange Management Shell Command Log is running in the background, in the EMC select **View** > **View Exchange Management Shell Command Log**.
2. Select **Action** > **Modify the Maximum Number of Windows PowerShell Commands to log**.
3. Enter a number between 1 and 32767.
4. Click **OK** to save your changes and close the dialog box.

5. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all the commands.

Clear the command log

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Management Console configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

Clearing the command log is a permanent action. After you clear it, you can't retrieve the log.

1. If the Exchange Management Shell Command Log is running in the background, in the EMC select **View** > **View Exchange Management Shell Command Log**.
2. Select **Action** > **Clear Log**.
3. A dialog box displays asking you to confirm that you want to clear the log. Click **Yes**.
4. Select **File** > **Close** to close the Exchange Management Shell Command Log. The log will run in the background and continue to record all the commands.

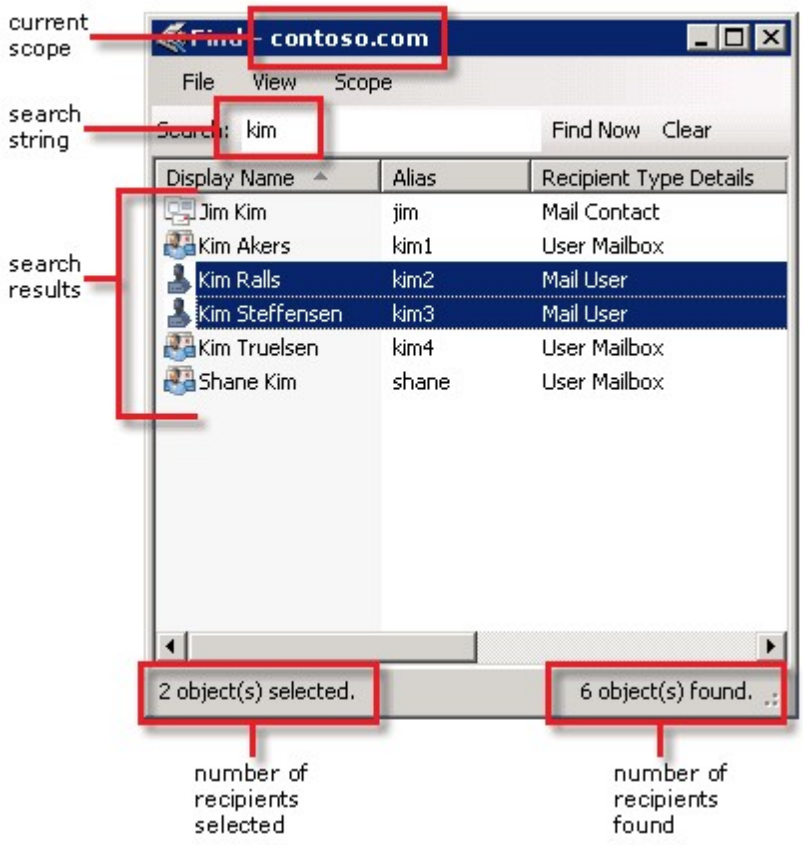
1.4.8.13 Using the Find Dialog Box

Using the Find Dialog Box

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Use the **Find** dialog box (a search feature) to help search for specific recipients by name. The following figure illustrates the components within the **Find** dialog box.



The **Find** dialog box is available in the **Recipient Configuration** node of the Exchange Management Console (EMC). To open the **Find** dialog box, click the **Recipient Configuration** node (or the **Mailbox**, **Distribution Group**, or **Mail Contact** sub-nodes), and then click **Find** in the action pane. Alternatively, you can right-click any blank area of the result pane, and then click **Find**.

Important:

While the **Find** dialog box is open, you can't perform other tasks in the EMC. Any wizard or property pages that are open will be inaccessible. To return to the EMC, you must close all dialog boxes and property pages that are associated with the **Find** dialog box, including the dialog box itself.

Components of the Find Dialog Box

The **Find** dialog box consists of the following four components:

- Menu bar
- Search toolbar
- Result pane
- Status bar

Expand the following sections to learn more about each of these components.

Menu Bar

The menu bar of the **Find** dialog box contains the following items.

File

- **Close** Click this menu item to close the **Find** dialog box.

View

- **Add/Remove Columns** Click this menu item to open the **Add/Remove Columns** dialog box. You can use the **Add**, **Remove**, and **Add All** buttons to change the columns that are displayed in the result pane. You can also use the **Move Up** and **Move Down** buttons to change the order of the columns. Click **OK** to return to the **Find** dialog box.
- **Modify the Maximum Number of Recipients to Display** Click this menu item to open the **Maximum Number of Recipients to Display** dialog box. You can use this dialog box to change the number of recipients that are displayed in the result pane when a search completes.

Note:
This setting applies only to the **Find** dialog box. It is independent of the **Maximum Number of Recipients to Display** setting in the **Recipient Configuration** node. The setting is preserved while the EMC is running. If you restart the EMC, the setting reverts to the default value of 1,000.

Scope

- **Modify Recipient Scope** Click this menu item to open the **Find Scope** dialog box. You can use this dialog box to change the scope of your search. You can view all recipients in the forest or in a specific organizational unit (OU).

Note:
This setting applies only to the **Find** dialog box. It is independent of the **Recipient Scope** setting in the **Recipient Configuration** node. The setting is preserved while the EMC is running. If you restart the EMC, the setting reverts to the default value, which is the domain of the computer that is running the EMC.

Search Toolbar

The search toolbar is directly below the menu bar. The search toolbar contains the following items.

Search

Use this text box to type the search string to use to find recipients.

Important:
The search string that you provide must be at least three characters long. Leading or trailing spaces are not included in the total.

Note:
You cannot use wildcard characters in the search string.

Find Now

Click this button to start the search. The search returns all recipients whose first name, last name, display name, user principal name (UPN), alias, or e-mail address begins with the specified search string. For example, if you search for the string **ter**, the search results include the recipient Terry Adams, but not Adam Carter.

The **Find Now** button is unavailable while a search is in progress. After the search completes or is cancelled, it is made available again.

Clear or **Stop**

Click **Clear** to clear the search results and the information that is displayed on the status bar.

Click **Stop** to stop the search that is in progress. Partial results may be displayed if matching recipients were found while the search was in progress.

Note:
While a search is in progress, the **Clear** button changes to **Stop**. If you stop the search, or the search completes, the button changes back to **Clear**.

Result Pane

The result pane is directly below the search toolbar. When a search completes, the

recipient objects that match your criteria are displayed in the result pane. If you double-click a recipient in the result pane, the property page for that recipient is displayed. If you right-click a recipient, the shortcut menu displays the actions you can perform for that recipient type.

Status Bar

The status bar, located directly below the result pane, displays the following information:

- While a search is in progress, a progress indicator is displayed on the right side of the status bar.
- After a search is complete or is stopped, the number of recipient objects found is displayed on the right side of the status bar. If the search is stopped before completion, the status bar displays the text **The query was cancelled** after the number of objects found.
- After a search is complete or is stopped, the number of recipient objects that are selected is displayed on the left side of the status bar.

1.4.9 Managing Tools in the Toolbox

Managing Tools in the Toolbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-30*

The Toolbox is a collection of diagnostic, troubleshooting, and recovery tools installed with Microsoft Exchange. The tools available in the Toolbox work center are divided into two categories:

- **Dedicated Microsoft Management Console (MMC) 3.0 tools** Some tools, such as Queue Viewer, are self-hosted in an MMC console. The Exchange Management Console (EMC) doesn't have to be running to use the MMC tools.
- **Independent tools** Independent tools, such as the Exchange Best Practices Analyzer, aren't integrated with the EMC and function as separate executable files when run from the Toolbox. These tools have their own Help file content. For more information about how to use the tools, refer to the Help file for each tool.

When you click the **Toolbox** node from the **Microsoft Exchange On-Premises** node, all the tools discussed in this topic are displayed in the result pane. You can open the tool by double-clicking the tool name, by clicking **Open Tool** from the action pane, or from the right-click menu.

When you click the **Toolbox** node from a remote forest node, only the following tools are displayed:

- Role Based Access Control (RBAC) User Editor
- Message Tracking
- Call Statistics
- User Call Logs

Configuration Management Tools

The following configuration management tools are available in the Toolbox:

- **Best Practices Analyzer** The Exchange Best Practices Analyzer automatically

examines an Exchange deployment and determines whether the configuration is in line with Microsoft best practices. We recommend running the Exchange Best Practices Analyzer after you install a new Exchange server, upgrade an existing Exchange server, or make configuration changes. For more information, see Microsoft Exchange Analyzers.

- **Details Templates Editor** The Details Templates Editor controls the appearance of the object properties accessed by using address lists in MAPI 32-bit client applications, such as Microsoft Outlook. For example, when a user opens an address list in Outlook, the properties of the recipients in that address list are displayed in accordance with the details template that exists in your Exchange organization. For more information, see Managing Details Templates.
- **Public Folder Management Console** The Public Folder Management Console is an MMC 3.0-based interface that provides you with a graphical user interface (GUI) for creating, configuring, and managing public folders. For more information, see Using the Public Folder Management Console.
- **Remote Connectivity Analyzer** The Exchange Remote Connectivity Analyzer is a Web-based tool that helps you troubleshoot connectivity issues. The tool simulates several client logon and mail flow scenarios. When a test fails, many of the errors have troubleshooting tips to assist you in correcting the problem. For more information, see Exchange Remote Connectivity Analyzer Tool.
- **Role Based Access Control (RBAC) User Editor** The RBAC User Editor allows you to add users to management role groups. When you open this tool, you need to sign in to Microsoft Office Outlook Web App as a user who has permission to perform this task. After you sign in, you are directed to the **Administrator Roles** tab. For more information, see Understanding Role Based Access Control.

Mail Flow Tools

The following mail flow tools are available in the Toolbox:

- **Mail Flow Troubleshooter** The Mail Flow Troubleshooter assists you in troubleshooting common mail flow problems. You can diagnose a problem by selecting the symptoms observed. Based on the symptoms, the tool walks you through the correct troubleshooting path. It shows an analysis of possible root causes and provides suggestions for corrective actions.
- **Message Tracking** The Message Tracking tool helps you access and configure delivery reports. When you open this tool, you need to sign in to Outlook Web App as a user who has permission to perform this task. After you sign in, you are directed to the **Delivery Reports** tab. For more information, see Understanding Message Tracking.
- **Queue Viewer** Queue Viewer helps you monitor mail flow, and inspect queues and messages. You can also perform actions to the queuing databases such as suspending or resuming a queue, or removing messages. For more information, see Using Queue Viewer.
- **Routing Log Viewer** Routing Log Viewer is a tool you can use to open a routing log file that contains information about the routing topology. You can also open a second routing log and compare it to the first log opened. The tool consists of a parser and a public user interface.
  To use the Routing Log Viewer to view logs of routing table configuration changes, you must connect to an Exchange server that has the Hub Transport server role or the Edge Transport server role installed. For more information, see Using the Routing Log Viewer.
- **Tracking Log Explorer** Tracking Log Explorer provides a detailed log of all message activity as messages are transferred to and from an Exchange server that has the Hub Transport server role, the Mailbox server role, or the Edge Transport server role installed. Exchange servers that have the Client Access server role or Unified Messaging (UM) server role installed don't have message tracking logs. Message tracking logs can be used for message forensics, mail

flow analysis, reporting, and troubleshooting.

Performance Tools

The following performance tools are available in the Toolbox:

- **Performance Monitor** Performance Monitor is a tool you can configure to collect information about the performance of your messaging system. Specifically, you can use it to monitor, create graphs, and log performance metrics for core system functions. You can also use Performance Monitor to monitor Exchange-specific parameters, such as the number of inbound or outbound messages per hour or the number of directory lookups performed by Exchange. Performance Monitor is commonly used to view key parameters while troubleshooting performance problems. It's also used to gather baseline performance data to perform historical trend analysis and measure the impact of changes to your Exchange environment.
- **Performance Troubleshooter** Performance Troubleshooter helps you to locate and identify performance-related issues that could affect an Exchange server. You can diagnose a problem by selecting the symptoms observed. Based on the symptoms, the tool walks you through the correct troubleshooting path. Performance Troubleshooter identifies possible bottlenecks and suggests corrective actions.

Unified Messaging Tools

The following Unified Messaging tools are available in the Toolbox:

- **Call Statistics** The Call Statistics tool provides aggregated statistical information about calls forwarded to or placed by Unified Messaging servers. This information can be used if you're interested in overall statistics for the Exchange 2010 Unified Messaging servers in your organization. When you open this tool, you need to sign in to Outlook Web App as a user who has permission to perform this task. After you sign in, you are directed to the **Call Statistics** page. For more information, see the following topics:
  - Review the UM Calls for Your Organization
  - Using Unified Messaging Tools
- **User Call Logs** The User Call Logs tool displays the call data records for a selected UM-enabled user. These logs are useful in Help desk situations where the Help desk employee must gather information about specific calls for a UM-enabled user to assist them in diagnosing and fixing issues. When you open this tool, you need to sign in to Outlook Web App as a user who has permission to perform this task. After you sign in, you are directed to the **User Call Logs** page. For more information, see the following topics:
  - Review the UM Calls for a User
  - Using Unified Messaging Tools

1.4.9.1 Using the Routing Log Viewer

Using the Routing Log Viewer

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Routing Log Viewer tool works on a server running Microsoft Exchange Server 2010

that has the Hub Transport or the Edge Transport server role installed. It is started from the Exchange Management Console (EMC).

In earlier versions of Exchange, you could connect to the Microsoft Exchange Routing Engine service on port 691 by using the WinRoute tool. In Exchange 2010, there's no routing engine, but you can use the Routing Log Viewer to open a routing log file that contains information about how the routing topology appears to the server. You can also open a second routing log, and then determine the changes that have occurred within the routing topology between two time periods. This is helpful when routing problems resolve themselves before troubleshooting begins, or for determining what changes have occurred in the topology over time. In these cases, if problems occurred because of changes in the routing topology, the tool can be used to compare the changes and help resolve any mail routing problems.

The Routing Log Viewer tool consists of a parser and a public graphical user interface to the parsing component.

There are four tabs in the Routing Log Viewer that present server information:

- Active Directory Sites & Routing Groups
- Servers
- Send Connectors
- Address Spaces

These tabs are described in the following sections.

Active Directory Sites & Routing Groups Tab

The **Active Directory Sites & Routing Groups** tab provides a listing of Active Directory sites and routing groups in the Exchange organization. For Active Directory sites, only those sites that have Exchange servers are listed.

If the site is enabled as a hub site, it can be verified on this tab. The local site where the routing table log was generated is also noted. All servers in each site are listed as is the total cost to deliver mail to the site from the local site, and the **Backoff path** that should be used if there are problems with delivering messages.

Note:

If the site is a hub site, all sites beyond it will have the **Next hop site** property pointing to the hub site. This indicates where the mail stops before it's relayed to the target site.

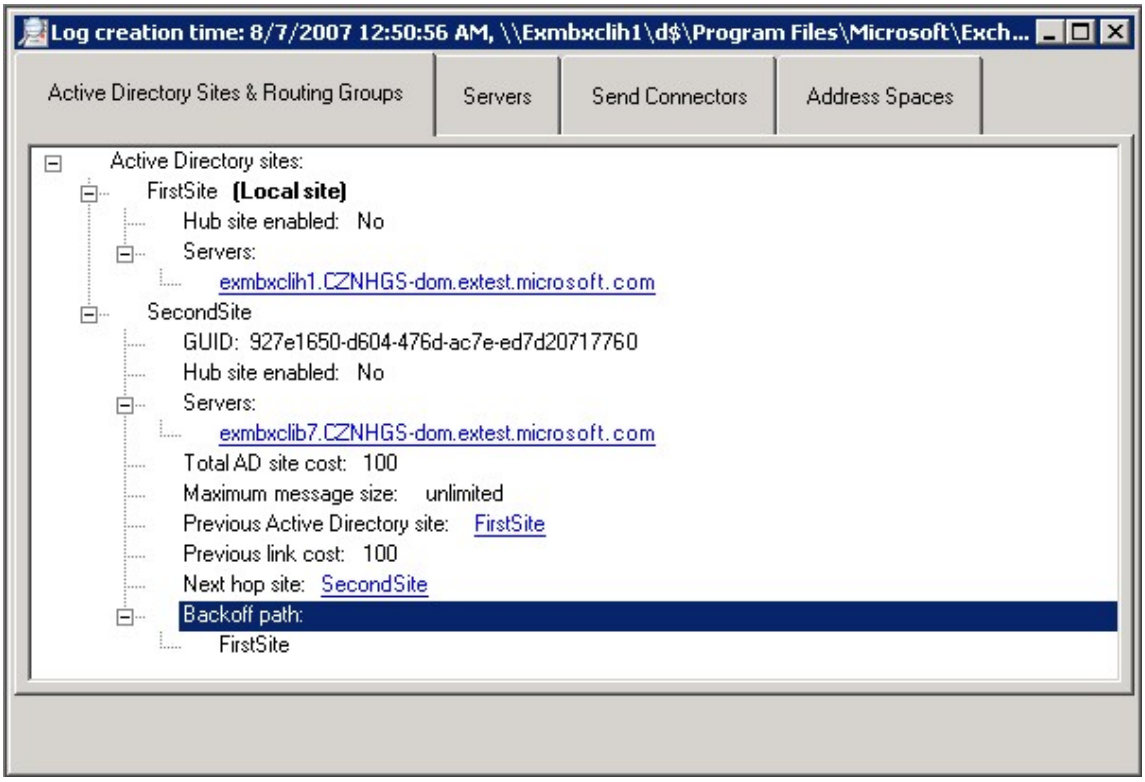
Note:

The **Backoff path** property refers to the full backoff path, instead of the binary backoff path. Routing will use the binary backoff path if the number of segments in the backoff path is greater than four.

For routing groups, although all Exchange 2010 servers are installed in their own routing group, only Exchange Server 2003 routing groups are listed. Exchange 2010 servers are listed under the Active Directory sites. Each server in each routing group is listed together with the first hop routing group connector used to reach that routing group.

All servers and connectors displayed on this page have hyperlinks that link to the appropriate object with either the **Servers** or **Send Connectors** tabs.

The following figure is an example of what is displayed when you double-click the **Active Directory Sites & Routing Groups** tab.



Servers Tab

The **Servers** tab contains a list of all Exchange servers in the Exchange organization. The local server where the routing logs were generated is indicated at the top level. The following information is generated when you use the **Servers** tab:

- Distinguished name (DN) of the server
- Proximity to the local server
- Active Directory site or routing group that the server belongs to
- Server roles installed such as Mailbox or Hub Transport
- Total cost
- Message databases (MDBs) available
- Legacy DN
- Whether you are using Exchange 2007 or a later version

Some properties have hyperlinks that link to their counterpart in related tabs. For example, Active Directory sites and routing groups have hyperlinks that link to their counterpart on the **Active Directory Sites & Routing Groups** tab. Routing group connectors have hyperlinks to the appropriate connector on the **Send Connectors** tab.

Send Connectors Tab

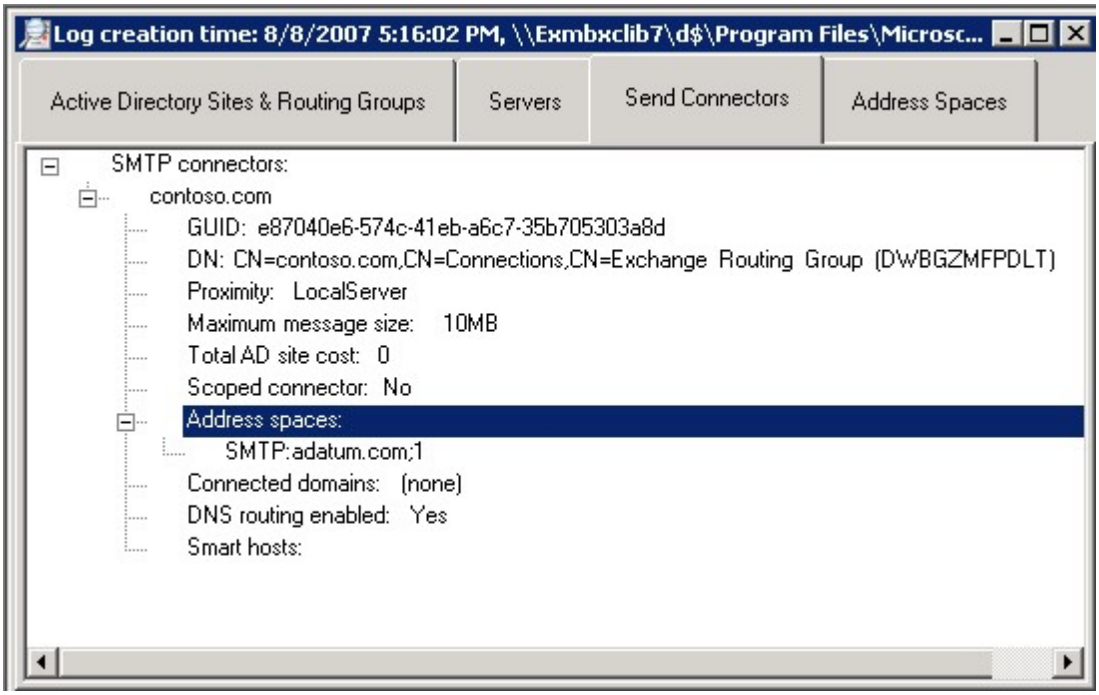
The **Send Connectors** tab provides a list of all SMTP connectors, foreign connectors, and routing group connectors available in the Exchange organization. Legacy gateway connectors homed on legacy servers are also listed.

Information for each connector type includes the following:

- Name
- GUID
- DN

- Proximity to the local server
- Maximum message size of a message that passes through a connector (default is unlimited)
- Total site cost to reach the connector
- Whether this is scoped connector
- Address spaces
- Whether DNS routing is enabled
- What smart hosts are defined

The following figure shows an example of the **Send Connectors** tab for SMTP connectors.



If the connector uses connected routing groups, that information is available on the **Connected domains** property. For **Foreign connectors**, the value specified by the drop directory is also provided.

Routing group connectors identify the targeted routing group and list all targeted Exchange servers except routing group connectors that target Exchange 2010. These connectors have a blank **Target routing group** property.

Address Spaces Tab

The **Address Spaces** tab provides a list of all address spaces in the Exchange organization, separated by the address type, such as SMTP. Each address space lists all the associated connectors with their cost. The list of connectors is ordered based on the connector selection algorithm for using that particular address space. Therefore, the first connector in the list is the connector that Exchange 2010 uses for delivery to that address space.

Note:
If the first connector can't meet the message size, one of the other connectors for that address space, or a less specific address space, can be used.

The connectors displayed on the **Address Spaces** tab have hyperlinks that link to their

properties on the **Send Connectors** tab.

Examples of How Routing Table Log Data Can Be Used

The following are examples of how you can use the Routing Log Viewer tool to examine the routing data.

Finding the Lowest Cost Path to a Site

After a routing log XML file is opened and parsed, the Routing Log Viewer displays all the information about each Active Directory site in the **Active Directory Sites & Routing Groups** tab on the **Routing Log Viewer** screen. To find the lowest cost path from the local site to another site, locate the destination site, expand it, find the **Previous Active Directory** site, and follow the chain until you reach the local site.

Finding the Preferred Connector for a Specific Address

After a routing log file is opened and parsed, the Routing Log Viewer displays all the information about each address space that can be routed by the local server. For a specific address space, all connectors that have the address space configured are listed in the priority order using the address selection algorithm used by Exchange 2010 routing. Unless the preferred connector has size restrictions, the preferred connector is listed first, is bold, and is always the connector used to route to the address space that it's listed under. If the preferred connector has size restrictions, the next best connector in the list that meets size restrictions, or a connector with a less specific address space match, is chosen.

1.4.9.1.1 Open a Log File by Using the Routing Log Viewer

Open a Log File by Using the Routing Log Viewer

Exchange Management Console > Managing Tools in the Toolbox > Using the Routing Log Viewer >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can open a log file by using the Routing Log Viewer. There are no logs available when the Routing Log Viewer first opens. You can either specify the name of a transport server, or you can browse through the files on a local server.

Important:

When you are using the Edge Transport server role, you must use the **Browse local files** button on the Edge Transport server. The **Browse server files** option from the **Open Routing Table Log File** dialog box doesn't work for browsing on the Edge Transport server role.

You can specify alternative credentials with which to access the remote routing table logs. The **Run As** dialog box enables you to provide credentials with which to access files from the remote servers. If all fields are blank in this dialog box, the Routing Log Viewer uses the local user's credentials for all file access operations.

Use the Routing Log Viewer to open a log

file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport logs" entry in the Transport Permissions topic.

1. In the EMC, click **Toolbox** > **Routing Log Viewer** > **Open Tool**.
2. On the **Routing Log Viewer** menu, click **File**, and then click **Open log file**.
3. In the **Name of transport server** box, enter the name of the transport server you want, or click **Browse server files** and then click the server that you want to use and click **Open**. On an Exchange Hub Transport server, you can leave the server name field blank to browse through the local server's log files.

   Note:
   When you click **Browse server files**, the Routing Log Viewer connects to Active Directory. The tool reads the Exchange server object, determines where the routing logs are stored, and then tries to open the directory.

4. Or, you can click **Browse local files** and then select the file of interest and click **Open**.
5. If you are browsing the files on a remote server, you need to supply administrator permissions to access the share on the remote server. To supply alternative credentials, click **Run As** to do remote browsing. Complete the following, and then click **OK**:
   - **Use Run As for remote browsing** This is selected by default.
   - **User name** Type the alternative user name.
   - **Domain** Type the domain for the alternative user name.
   - **Password** Type the password.

Use the Routing Log Viewer to change credentials to browse through files on a remote server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport logs" entry in the Transport Permissions topic.

1. In the EMC, click **Toolbox** > **Routing Log Viewer** > **Open Tool**.
2. On the **Routing Log Viewer** menu, click **Settings**, and then click **Run As**. Or, on the **Routing Log Viewer** menu, click **File**, and then click **Open log file**.
3. From **Open Routing Table Log File**, click **Run As**. In the **Run As** dialog box, complete the following, and then click **OK**:
   - **Use Run As for remote browsing** Click this check box to use the alternative credentials you provide in this dialog box when browsing through logs on remote computers. This is selected by default.
   - **User name** Type the alternative user name.
   - **Domain** Type the domain for the alternative user name.
   - **Password** Type the password.

Note:
Local administrator permissions are required on the remote server to access the administrative share used to access the log file directory. This is why you would want to change credentials to browse through files on remote servers.

1.4.9.1.2 Compare Routing Log Files

Compare Routing Log Files

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

With the Routing Log Viewer tool, you can load two routing table logs and then view the differences between them. This approach can help you discover changes that have occurred in the routing topology between different sets of logs. The log with the most recent timestamp is the log labeled with the change status Added, Removed, or Modified. As long as the timestamp is different, it's not important which log you open first. If the timestamps are the same, the comparison is performed from the perspective of the first log opened.

Looking for other management tasks related to tools? Check out Managing Tools in the Toolbox.

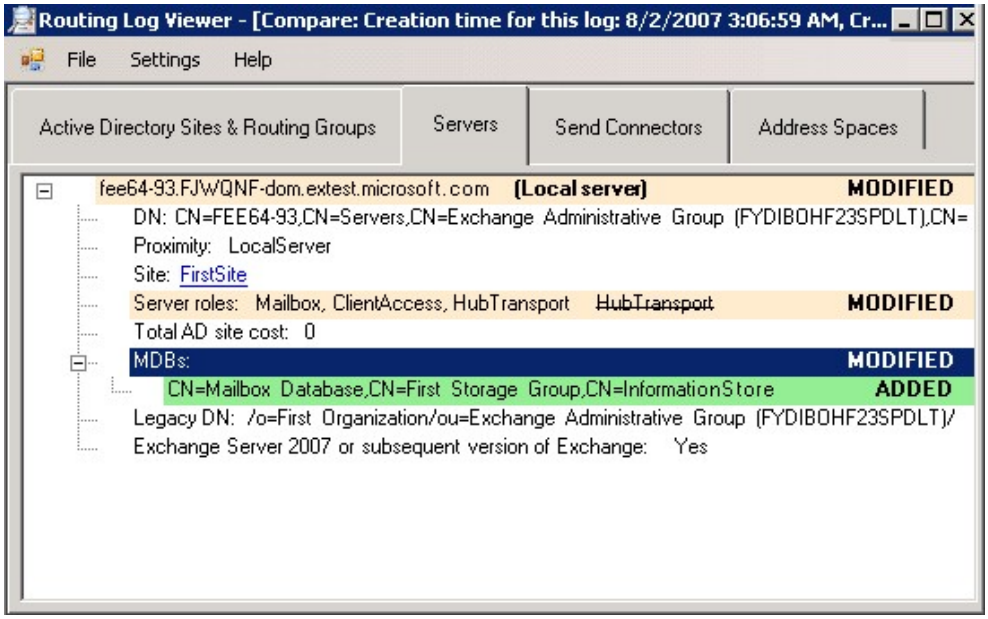
Use the Routing Log Viewer tool to compare log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport logs" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Routing Log Viewer**.
3. In the action pane, click **Open Tool**.
4. Open the first log by following the procedure in the topic Open a Log File by Using the Routing Log Viewer.
5. On the **File** menu, click **Compare log file**.

   Note:
   The **Compare log files** option on the **File** menu is available only when the window of a previously parsed log file has been left open.

6. Open a second log file by entering the applicable information in the **Open Routing Table Log file** dialog box.
7. An example of the report is shown in the following figure. Any changes that have been made to the topology are highlighted to indicate whether the item was **Added**, **Removed**, or **Modified**. If a value was modified, both the original value and the changed values are shown. In the following example, the report shows an addition and three modifications. The information is being displayed from the **Servers** tab.



1.4.9.2 Using the Public Folder Management Console

Using the Public Folder Management Console

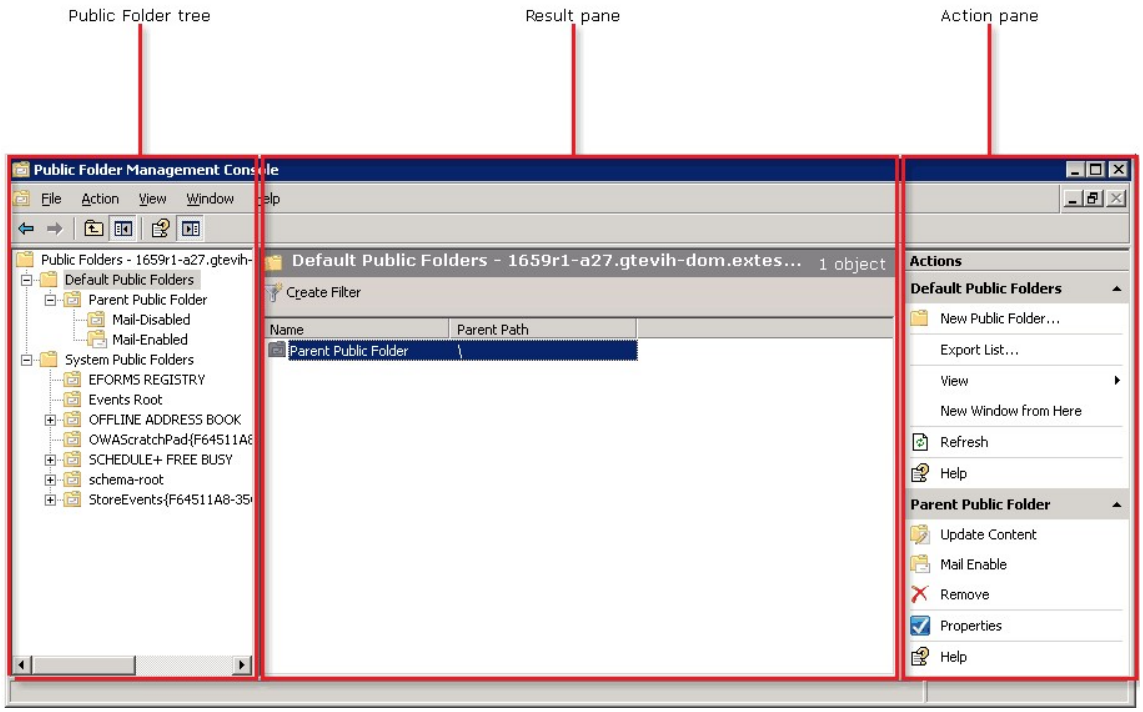
Exchange Server 2010 > Exchange Management Console > Managing Tools in the Toolbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Public Folder Management Console is a Microsoft Management Console (MMC) 3.0-based interface that provides you with a graphical user interface (GUI) to create, configure, and maintain public folders. You can access the Public Folder Management Console from the Toolbox in the Exchange Management Console (EMC). For more information about the Toolbox, see Managing Tools in the Toolbox.

Similar to the EMC, the Public Folder Management Console is organized into three panes. In the Public Folder Management Console, these panes are called the public folder tree, the result pane, and the action pane.



Mail-enabled public folders are represented in the user interface by this icon: 

System public folders and public folders that are not mail-enabled are represented in the user interface by this icon: 

Expand the following sections to learn more about each pane

Public Folder Tree

The public folder tree is located on the left side of the console and is organized by nodes that are based upon the public folder hierarchy. Exchange Server 2003 supports the use of a non-MAPI folder tree, otherwise known as an *Application* folder tree or *General Purpose* folder tree. Exchange 2007 and Exchange 2010 support only the default MAPI folder tree.

The MAPI folder tree is divided into the following subtrees:

- **Default Public Folders (also known as the IPM_Subtree)** Users can access these folders directly by using client applications such as Outlook.
- **System Public Folders (also known as the Non IPM_Subtree)** Users cannot access these folders directly by using conventional methods. Client applications such as Outlook use these folders to store information such as free and busy data, offline address books (OABs), and organizational forms. Other system folders contain configuration information that is used by custom applications or by Exchange itself. The public folder tree contains additional system folders, such as the EFORMS REGISTRY folder, that do not exist in general-purpose public folder trees. System folders include the following:
  - **EFORMS REGISTRY** By default, one content replica of each of these folders resides in the default public folder database on the first server that is installed in the first administrative group. This is the location where organizational forms are stored for legacy Outlook clients (clients that use an Outlook version earlier than Office Outlook 2007).

- **Offline Address Book** and **Schedule+ Free Busy** The Offline Address Book folder and the Schedule+ Free Busy folders automatically contain a subfolder for each administrative group (or site) in your topology. By default, a content replica of a specific administrative group folder resides on the first server that is installed in the administrative group. These folders are used to store legacy free and busy information and OAB data for legacy Outlook clients. Legacy Outlook clients do not support the Exchange Server 2007 or later features that manage free and busy information and OAB data. (These features include the Availability service, the Autodiscover service, and OAB distribution on Client Access servers).

Result Pane

The result pane is located in the center of the console. This pane displays public folders based upon the public folder that is selected in the public folder tree.

To focus on a set of items in the result pane that have specific attributes, you can use a variety of expressions to filter the list. For more information about filters, see Filter the Result Pane.

The following columns are displayed by default:

- **Name** This column lists the name of the public folder.
- **Parent Path** This column lists the public folder path to the parent public folder. If a backslash (****) is displayed, the parent public folder is the top-level public folder for that tree.

The following columns are hidden by default:

- **Mail Enabled** This column lists the mail-enabled status of the public folder.
- **Age Limit in Days** This column lists the age limit (in days) of the public folder.
- **Local Replica Age Limit in Days** This column lists the local replica age limit (in days) of the public folder.
- **Hidden From Address List** This column lists the true or false status of whether the public folder is hidden from address lists in your organization.
- **Replicas** This column lists the server name on which this public folder is replicated.

Action Pane

The action pane is located on the right side of the console. The action pane lists the actions based upon the object that is selected in the public folder tree or the result pane. The action pane is an extension of the shortcut menu, which is the menu that appears when you right-click an item.

Public Folder Node Actions

When you select the **Public Folders** node in the public folder tree, the following actions are available in the action pane.

Properties

Click **Properties** to view or configure the settings of the server that Remote Power Shell uses to perform the specified tasks in the Public Folder Management Console.

For more information, see View or Configure Remote PowerShell Connectivity.

Connect to Server

Click this button to connect the Public Folder Management Console to a Mailbox server on which a public folder database resides.

For more information, see Connect to Public Folder Server.

Update Hierarchy

Click this button to synchronize the public folder hierarchy from one server to the other servers on which public folder replicas exist.

For more information, see Update a Public Folder Hierarchy.

View

Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree:

- **View Exchange Management Shell Command Log**
  Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC.
- **Add/Remove Columns**
  Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console.
- **Visual Effects**
  Click **Visual Effects** to set the visual effects to be never on or automatic. Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off.
- **Save Current Filter as Default**
  Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane.
- **Customize**
  Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.

Refresh

Click **Refresh** to refresh the information displayed in the result pane.

Export List

Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.

Public Folder Tree Actions

When you select a public folder in the public folder tree, the following actions are available in the action pane.

New Public Folder

Click New Public Folder to create a public folder child under the public folder that is selected in the public folder tree. For more information, see Create a Public Folder.

Export List

Click **Export List** to open the **Export List** dialog box. You can use this dialog box to save the list of recipients in the result pane to a text file. For instructions about how to use the Export List feature, see Export Lists from the Exchange Management Console.

View

Click **View** in the action pane to modify how objects are displayed in the console and to record and view the Exchange Management Shell commands that run in the console. The following options may vary depending on your location in the console tree:

- **View Exchange Management Shell Command Log**
  Click **View Exchange Management Shell Command Log** to view the Shell Command Log dialog box. The Command Log allows you to view all the Shell commands that have been executed in the console. For more information, see Using the Exchange Management Shell Command Log to

Track Tasks Performed in the EMC.

- **Add/Remove Columns**
  Click **Add/Remove Columns** to select which columns you want to display in the result pane and to change the order. The available columns depend on the node that you select. The MMC automatically saves your settings. To revert to the default column view, click **Restore Defaults** in the **Add/Remove Columns** dialog box. For more information, see Add or Remove Columns in the Exchange Management Console.
- **Visual Effects**
  Click **Visual Effects** to set the visual effects to be never on or automatic. Use the visual effects setting to configure how Exchange wizards are displayed. If your connection is slow when running wizards, you can increase performance by turning off visual effects. Use the **Automatic** setting to have the console detect if your system should have visual effects turned on or off.
- **Save Current Filter as Default**
  Click **Save Current Filter as Default** to make the existing filter the default filter for the servers listed in the result pane.
- **Customize**
  Click **Customize** to select the console components and snap-ins to display or hide. These settings apply to the entire console. For more information, see Customize the Exchange Management Console.

Refresh

Click **Refresh** to refresh the information displayed in the result pane.

Public Folder Actions

When you select a public folder in the result pane, the following actions are available for that public folder in the action pane:

Update Content

Click this button to synchronize the public folder content from one server to the other servers on which public folder replicas exist.

For more information, see Update Public Folders.

Mail Enable or Mail Disable

Click these buttons to mail-enable or mail-disable a public folder. For more information, see the following topics:

- Mail-Enable a Public Folder
- Mail-Disable a Public Folder

Remove

Click this button to remove a public folder. For more information, see Remove Public Folders.

Manage Settings

Click this button to open the Manage Public Folder Settings wizard. Use this wizard to manage client permissions for the current public folder and its subfolders.

For more information, see Use the Public Folder Management Console to Manage Public Folder Settings.

Manage Send As Permission

This button is available only for mail-enabled public folders.

Click this button to use the Manage Send As Permission wizard to grant Send As permissions to users or groups for the selected public folder. You can also use this wizard to remove Send As permissions from users or groups

For more information, see Manage Send As Permissions for Mail-Enabled Public Folders.

1.4.9.3 Connect to Public Folder Server

Connect to Public Folder Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Public Folder Management Console allows you to manage public folders on one server at a time. Use the **Connect to Server** dialog box to connect the Public Folder Management Console to a Mailbox server on which a public folder database resides.

Connect to a public folder server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the EMC console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console.**
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In console tree of the Public Folder Management Console, click the top-level node.
5. In the action pane, click **Connect to Server**.
6. In **Connect to server**, click **Browse** to view a list of the available Mailbox servers that contain a public folder database.
7. In **Select Public Folder Servers**, select a Mailbox server. To search for a Mailbox server to which to connect, perform one of the following steps:
   - In the **Search** box, type the exact name of the server (or the first few letters of the name), click **Find Now**, and then select a server from the result pane.
   - From the **View** menu, click **Show Filter**. In the **Name**, **Site**, or **Role** boxes, type the filter criteria, and then select a server from the result pane.
8. Click **OK** to close **Select Public Folder Servers**.
9. (Optional) After you select a server, in the **Connect to Server** dialog box, you can select the **Set as Default Server** check box to set the server you selected as the default Exchange server for managing public folders. By default, this is the server to which the Public Folder Management Console connects each time you open the console.

   Note:

   This setting is saved for the user on the computer that is running the Public Folder Management Console. If you open the Public Folder Management Console from another computer or by using a different user account, the default server may be different.

10. Click **Connect**.

1.4.9.4 View or Configure Remote PowerShell Connectivity

View or Configure Remote PowerShell Connectivity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-10-19*

Use the Remote PowerShell Connectivity dialog box to view or configure the server to which remote Windows PowerShell connects.

Note:

Although the name of this dialog box appears in the user interface as **<Management Console Name> Properties**, it's more commonly referred to as the Remote PowerShell Connectivity dialog box.

This dialog box is available in the following management consoles:

- Exchange Management Console (EMC)
- Public Folder Management Console
- Queue Viewer
- Details Templates Editor

When you change the server to which remote Windows PowerShell connects, you're changing it only for that management console. Changing the remote Windows PowerShell server in one management console doesn't change it for other management consoles.

1. To open the Remote PowerShell Connectivity dialog box, perform one of the following steps:
   From the EMC
   1.a. In the console tree, click **Microsoft Exchange On-Premises**.
   1.b. In the action pane, click **Properties**.
   From the Public Folder Management Console, Queue Viewer, or Details Templates Editor
   1.c. To open the appropriate management console, in the EMC, click **Toolbox**, and then click the console you want.
   1.d. In the action pane, click **Open Tool**.
   1.e. In the action pane of the Public Folder Management Console, Queue Viewer, or Details Templates Editor, click **Properties**.
2. View or configure the following settings:
   2.a. **Administrator identity** This read-only field displays the administrator credentials of the selected Exchange forest.
   2.b. **Connect to the automatically selected server** Click this button if you want to connect to the default server.
   2.c. **Specify a server to connect to** Click this button if you want to use a different server to run remote Windows PowerShell. Click **Browse** to select a server.
3. Click **OK**.

1.4.9.5 Using Unified Messaging Tools

Using Unified Messaging Tools

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-24*

The new Unified Messaging (UM) reporting tools added in Microsoft Exchange Server 2010 Service Pack 1 (SP1) can be used to gather usage statistics for UM servers and call statistics for UM-enabled users in your organization. You can access Unified Messaging server statistic reports by using the **Call Statistics** tool and access call logs for UM-

enabled users by using the **User Call Logs** tool.

Both tools are found in the **Toolbox** node of the Exchange Management Console. These reports are displayed in the Exchange Control Panel.

Overview

The reports generated by the new tools in Exchange 2010 SP1 provide aggregated statistical information about calls for UM servers and calls for UM-enabled users in your organization. With the new tools, reports:

- Are more scalable than the reports available in Exchange Server 2007.
- Give tenant administrators, cross-premises administrators, and on-premises administrators the ability to gather statistics about the UM servers and UM-enabled users in their organizations.
- Provide summaries from the data that's gathered. This data can be stored for 90 days and to be archived for up to 2 years to meet retention requirements.

Administrators can use the new reports to:

- Verify how UM servers deployed in the organization are used over a given period of time.
- Plan for UM server capacity for their on-premises organization.
- Easily verify the availability of the voice mail system and UM servers in the organization for a given period of time.
- Verify the overall audio quality for incoming calls to UM servers that are deployed.

To support the UM reporting tools in the EMC, the following cmdlets have been added for SP1:

- **Get-UMCallSummaryReport**
- **Get-UMCallDataRecord**

In Exchange 2007, 3 reports related to the Unified Messaging server role were available to administrators who used System Center Operations Manager. These Unified Messaging reports were based on the values of performance counters on each UM server that was deployed in an organization. However, generating reports using performance counters on each UM server had limitations. When System Center and UM performance counters were used to create reports based on aggregated data from all the UM servers in an organization and a user's call data, the results weren't scalable and couldn't be used in cross-premises organizations.

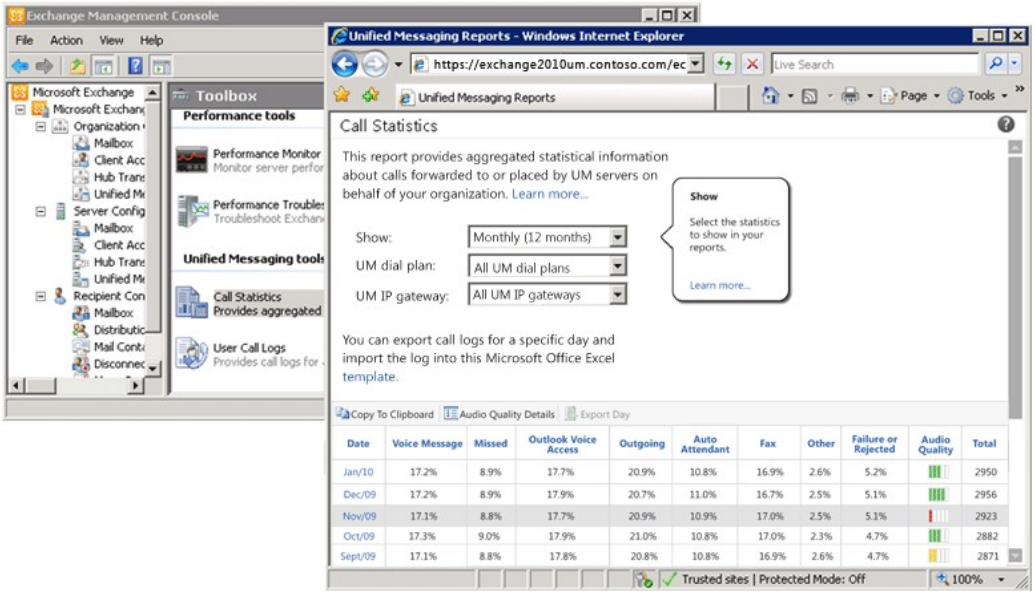
Without the ability to generate scalable reports or reports that could be used cross-premises, the administrator of an organization wouldn't be able to:

- Verify how UM servers deployed in the organization were used over a given period of time. This was a critical issue for a tenant administrator or an administrator in a cross-premises deployment, because no information, including performance counters from the UM server, would be available to them.
- Plan for UM server capacity for their on-premises organization.
- Easily verify the availability of the voice mail system and UM servers in the organization for a given period of time.
- Verify the overall audio quality of the UM servers that were deployed.

Call Statistics

The **Call Statistics** tool provides aggregated statistical information about calls forwarded to or placed by UM servers and can be used by administrators who are interested in overall statistics for the Exchange 2010 Unified Messaging servers in their organization.

Call statistics reports that you initiate in the EMC are displayed in the Exchange Control Panel user interface.



Reports can be filtered to show call statistics by month or by day for the past 90 days or since UM was deployed in your organization. You can then filter these results by UM dial plan and UM IP gateway within your organization.

Call statistics reports display:

- The total number of calls organized by type of call (for example, missed calls, Outlook Voice Access calls, or fax calls).
- Whether the call was accepted or rejected.
- The average audio quality.
- The day or the month covered in the report, or all calls.

You can export the call logs to a Microsoft Office Excel template, or copy the call statistics information to the Clipboard so that it can be pasted into another application. You can use the **Audio Quality Details** button to display more specific information about the call, including the information in the following table.

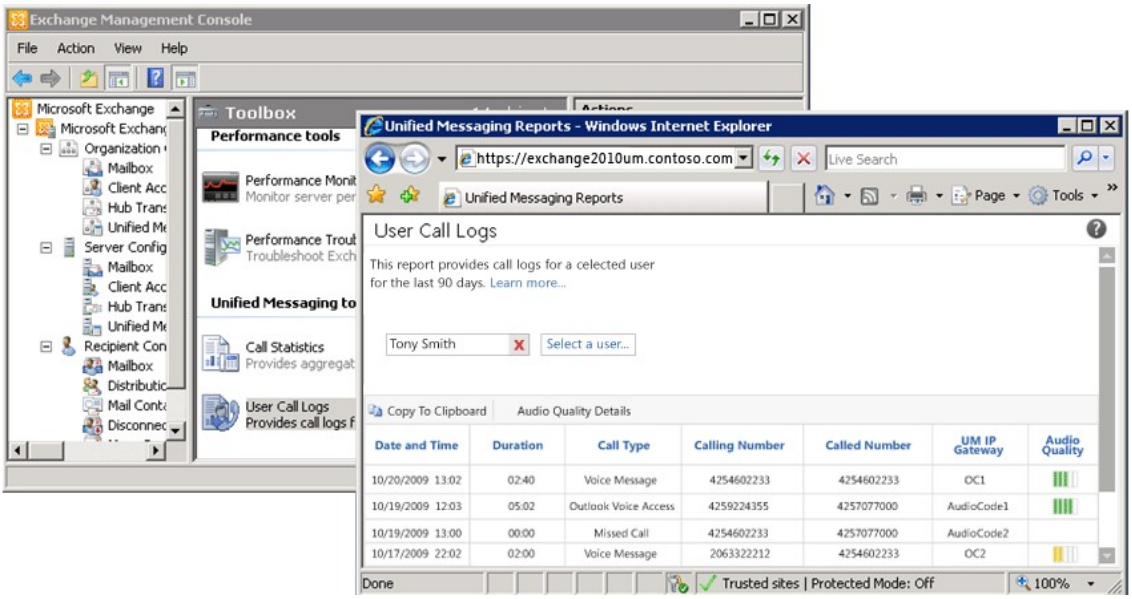
Data	Description
Date	The date and time of the incoming or outgoing call.
UM dial plan	The name of the UM dial plan that's associated with the UM IP gateway used for handling the incoming or outgoing call.
UM IP gateway	The name of the UM IP gateway used for the incoming or outgoing call.
Type of audio codec	The audio codec that's used when sending RTP or SRTP data across a network. The audio codec can be RTAudio (Wide band), RTAudio (Narrow band), G.711, or G.723.1, depending on the audio codec that's configured on the IP gateway or IP PBX or whether Microsoft Office Communications Server 2007 R2 or a later version is used.
NMOS	The mean opinion score for the audio across the network. The UM audio quality indicator will be

	calculated based on the Network MOS (NMOS) that's gathered from the RTP (and SRTP). "Mean opinion score" (MOS) is a number on a scale from 1 to 5 (5 being excellent) that indicates the audio quality of the call. MOS metrics are directly linked to the audio codec that's used. This means that users will get a different audio quality if they use different audio codecs. The following is the NMOS maximum for the audio codecs that are supported: • RTAudio (Wide band): 4.10 • RTAudio (Narrow band): 2.95 • G.711 a/u: 3.61 • G.723.1: 2.63
NMOS degradation	Total NMOS degradation is how far the reported NMOS value is from the top value for the audio codec that was used for the call.
Jitter	The average Jitter for the incoming or outgoing call. In data networks, the term jitter is used as a measure of the packet latency across a network. A network with constant latency has no variation (or jitter). Jitter is sometimes expressed as the average deviation from the network mean latency.
Pack loss	The average percentage of network packet loss during the call.
Round trip time	For the selected call, this is the time, in milliseconds, for a round trip (between the UM IP gateway and the UM server) of the audio packets that carried the voice data over the network.
Burst Loss Duration	The average duration of packet loss during burst losses for the incoming call.

User Call Logs

You can use the **User Call Logs** tool to display the call statistics for a selected UM-enabled user. The report is displayed in the Exchange Control Panel and is useful in helpdesk-type situations where you have to gather information about specific calls for a UM-enabled user to assist them in diagnosing and fixing issues. After you click the **Select a user** button and specify the user, the following information will be displayed for calls of the user you selected:

- Date and time
- Duration of the call
- Type of call
- The calling number
- The called number
- The UM IP gateway
- Audio quality



You can copy the user's call statistics to the Clipboard and then paste them into another application. You can use the **Audio Quality Details** button to display more specific information about the call, including the information in the following table.

Data	Description
Date	The date and time of the incoming or outgoing call.
UM dial plan	The name of the UM dial plan that's associated with the UM IP gateway used for handling the incoming or outgoing call.
UM IP gateway	The name of the UM IP gateway that was used for the incoming or outgoing call.
Type of audio codec	The audio codec that's used when sending RTP or SRTP data across a network. The audio codec can be RTAudio (Wide band), RTAudio (Narrow band), G.711, or G.723.1, depending on the audio codec that's configured on the IP gateway or IP PBX or whether Office Communications Server R2 or a later version is used.
NMOS	The mean opinion score for the audio across the network. The UM audio quality indicator will be calculated based on the Network MOS (NMOS) that's gathered from the RTP (and SRTP). "Mean opinion score" (MOS) is a number on a scale from 1 to 5 (5 being excellent) that indicates the audio quality of the call. MOS metrics are directly linked to the audio codec that's used. This means that users will get a different audio quality if they use different audio codecs. The following is the NMOS maximum for the audio codecs that are supported: • RTAudio (Wide band): 4.10 • RTAudio (Narrow band): 2.95 • G.711 a/u: 3.61

	• G.723.1: 2.63
NMOS degradation	Total NMOS degradation is how far the reported NMOS value is from the top value for the audio codec that was used for the call.
Jitter	The average Jitter for the incoming or outgoing call. In data networks, the term jitter is used as a measure of the packet latency across a network. A network with constant latency has no variation (or jitter). Jitter is sometimes expressed as the average deviation from the network mean latency.
Pack loss	The average percentage of network packet loss during the call.
Round trip time	For the calls within the selected time range, this is the average time, in milliseconds, for a round trip (between the UM IP gateway and the UM server) of the audio packets that carried the voice data over the network.
Burst Loss Duration	The average duration of packet loss during burst losses for the incoming call.
Number of calls sampled	This is the total number of incoming calls that were sampled to determine the audio quality for the call.

For detailed information about other tools in the EMC Toolbox, see Managing Tools in the Toolbox.

1.4.10 Troubleshooting the Exchange Management Console

Troubleshooting the Exchange Management Console

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

While using the Exchange Management Console (EMC), you may encounter problems. Most of these problems will be those associated with the remote Exchange Management Shell. For more information, see "Connection Issues" in Troubleshooting the Exchange Management Shell.

The EMC now checks a user's permissions before loading, so it may take several minutes to load. Use the progress bar located in the lower-left corner of the EMC to view the status of the EMC initialization or to troubleshoot connection issues.

1.5 Exchange Management Shell

Exchange Management Shell

1.5.1 Overview of Exchange Management Shell

Overview of Exchange Management Shell

Exchange Server 2010 > Exchange Management Shell >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

The Exchange Management Shell, built on Windows PowerShell technology, provides a powerful command-line interface for Microsoft Exchange Server 2010 that enables automation of administrative tasks. With the Shell, you can manage every aspect of Exchange. You can enable new e-mail accounts, configure SMTP connectors, store database properties, store transport agents, and more. The Shell can perform every task that can be performed by the Exchange Management Console and the Exchange Web interface in addition to tasks that can't be performed in those interfaces. In fact, when a task is performed in the console and the Web interface, those interfaces use the Shell to perform the task.

The Shell also provides a robust and flexible scripting platform that can reduce the

complexity of current Microsoft Visual Basic scripts. Tasks that previously required many lines in Visual Basic scripts can now be done by using as little as one line of code in the Shell. The Shell provides this flexibility because it doesn't use text as the basis for interaction with the system, but uses an object model based on the Microsoft .NET platform. This object model enables the Shell cmdlets to apply the output from one command to subsequent commands when they are run.

If you want to start using the Shell immediately, see Exchange Management Shell Basics. Otherwise, read this topic for more information about the Shell in Exchange 2010.

Local Shell and Remote Shell

The Shell in Exchange 2010 uses two methods, local Shell and remote Shell, to connect to servers running Exchange 2010. The following sections describe each of the concepts.

Local Shell

In Microsoft Exchange Server 2007, the Shell consists of a Windows PowerShell host; a Windows PowerShell snap-in, which contains all of the Exchange cmdlets; and some additional custom scripts. Loading all three components enables you to run Exchange cmdlets on the Exchange server you opened the Shell on.

When you open Windows PowerShell on a computer, you create a local session. In simple terms, a session is an environment in which Windows PowerShell runs. Cmdlets, variables, and other Windows PowerShell components within the same session can share data with each other. In Exchange 2007, cmdlets are always run in the local session on the local Exchange 2007 server. Even if you change an object that resides on a different server, the cmdlet is always run on the local Exchange server.

Except for the Edge Transport server role, Exchange 2010 doesn't use the local Shell. Instead, it uses a new concept called remote Shell, which is explained in the next section.

Remote Shell

With Exchange 2010, you can connect to a remote session on a remote Exchange 2010 computer to perform commands on that remote computer. Whether you use the Shell to administer a server you are physically connected to or administer a server across the country, remote Shell is used to perform the operation in Exchange 2010. Only the Edge Transport server role doesn't use remote Shell.

Remote Shell performs almost like the Shell in Exchange 2007. Other than feature changes that occurred between versions, you're likely to continue using the Shell as you did in Exchange 2007. If the Exchange management tools are installed and you want to use the Shell, follow the procedure in the Open the Shell topic.

In Exchange 2010, when you click the Shell shortcut, Windows PowerShell opens. Unlike in Exchange 2007, a Windows PowerShell snap-in for Exchange isn't loaded. Instead, Windows PowerShell connects to the closest Exchange 2010 server using a new required component called Windows Remote Management 2.0, performs authentication checks, and then creates a remote session for you to use. When the remote session is created, you're given access only to the cmdlets and the parameters associated with the management roles you've been assigned. For more information about management roles, see Understanding Role Based Access Control.

A benefit of remote Shell is that you don't need to install Exchange-specific tools on your computer. With just Windows PowerShell and Windows Remote Management installed on any client computer running the Windows Vista operating system with Service Pack 1 (SP1) or Windows Server 2008, you can connect to a remote Exchange 2010 computer to administer it. However, while it's possible to manage an Exchange 2010 server with just Windows PowerShell and Windows Remote Management, we recommend that you install the Exchange management tools on any computer that you use to manage Exchange

2010. Without the Exchange management tools installed, you need to connect to the remote Exchange 2010 server manually, and you don't have access to the additional capabilities that the Exchange management tools provide.

For more information about connecting to Exchange 2010 servers without the Exchange management tools installed, see Create a Manual Remote Shell Connection.

Edge Transport Server Role

Exchange 2010 uses the local Shell only on the Edge Transport server role. This is because each computer that runs the Edge Transport server role is administered individually and because the Edge Transport server role doesn't use Active Directory Domain Services (AD DS). You can open the Shell on an Edge Transport server using the procedure in Open the Shell.

1.5.1.1 Understanding Importing and Exporting Files in the Exchange Management Shell

Understanding Importing and Exporting Files in the Exchange Management Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 uses Windows PowerShell command-line interface remoting to establish a connection between the server or workstation from which you're administering Exchange and the server running Exchange 2010 that you're administering. In Exchange 2010, this is called remote Exchange Management Shell, or remote Shell. Even if you're administering the local Exchange 2010 server, remote Shell is used to make the connection. For more information about local and remote Shell, see Overview of Exchange Management Shell.

How you import and export files to and from an Exchange server has changed in Exchange 2010 due to the implementation of remote Shell. This topic discusses why this new process is required and how to import and export files between a local server or workstation and a remote Exchange 2010 server.

Windows PowerShell Sessions

To understand why you need a special syntax to import and export files in remote Shell, you need to know how the Shell is implemented in Exchange 2010. The Shell uses Windows PowerShell sessions, which are the environments in which variables, cmdlets, and so on, can share information. Every time you open a new Shell window, you create a new session. The cmdlets that are run in each window can access variables and other information stored in that window, but can't access variables in other open Shell windows. This is because they're each contained within their own Windows PowerShell session. Windows PowerShell sessions can also be referred to as runspaces.

Remote Shell in Exchange 2010 has two sessions, the local session and the remote session. The local session is the Windows PowerShell session that's running on your local computer. This session contains all of the cmdlets that ship with Windows PowerShell. It also has access to your local file system.

The remote session is the Windows PowerShell session that's running on the remote Exchange server. This session is where all Exchange cmdlets are run. It has access to the Exchange server's file system.

When you connect to a remote Exchange server, a connection is made between your local session and the remote session on the Exchange server. This connection enables you to run Exchange cmdlets on the remote Exchange server in your local session even though your local computer doesn't have any Exchange cmdlets installed.

Important:

Even if you open the Shell on an Exchange 2010 server, the same connection process takes place and two sessions are created. This means that you must use the same new syntax to import and export files whether you're opening the Shell on an Exchange 2010 server or a remote client workstation.

The Exchange cmdlets that run in the remote session on the remote Exchange server don't have access to your local file system. This means that you can't use Exchange cmdlets, on their own, to import or export files from or to your local file system. Additional syntax needs to be used to transfer the files to and from your local file system so that the Exchange cmdlets running on the remote Exchange server can use the data. For more information about the required syntax, see "Importing and Exporting Files in Remote Shell" later in this topic.

Note:

Importing and exporting files on Edge Transport servers doesn't require any special syntax. For more information about the Edge Transport server role, see "Importing and Exporting Files on Edge Transport Servers" later in this topic.

Importing and Exporting Files in Remote Shell

Remote Shell is used on the Mailbox, Hub Transport, Unified Messaging, and Client Access server roles in Exchange 2010. Importing and exporting files require a specific syntax because they use remote Shell. The Edge Transport server role uses local Shell and uses a different syntax. For more information about the Edge Transport server role, see "Importing and Exporting Files on Edge Transport Servers" later in this topic.

Importing Files in Remote Shell

The syntax to import files in Exchange 2010 is used any time you want to send a file to a cmdlet running on an Exchange 2010 server from your local computer or server. Cmdlets that accept data from a file on your local computer will have a parameter called *FileData* (or something similar). To determine the correct parameter to use, see the Help information for the cmdlet you're using.

The Shell must know what file you want to send to the Exchange 2010 cmdlet, and what parameter will accept the data. To do so, use the following syntax.

```
<Cmdlet> -FileData ([Byte[]]$(Get-Content -Path <local path to file> -Encoding By
```

For example, the following command imports the file C:\MyData.dat into the *FileData* parameter on the **Import-SomeData** fictional cmdlet.

```
Import-SomeData -FileData (Byte[]]$(Get-Content -Path "C:\MyData.dat" -Encoding B
```

The following actions occur when the command is run:

1. The command is accepted by remote Shell.
2. Remote Shell evaluates the command and determines that there's an embedded command in the value being provided to the *FileData* parameter.
3. Remote Shell stops evaluating the **Import-SomeData** command and runs

the **Get-Content** command. The **Get-Content** command reads the data from the MyData.dat file.

4. Remote Shell temporarily stores the data from the **Get-Content** command as a `Byte[]` object so that it can be passed to the **Import-SomeData** cmdlet.
5. Execution of the **Import-SomeData** command resumes. Remote Shell sends the request to run the **Import-SomeData** cmdlet to the remote Exchange 2010 server, along with the object created by the **Get-Content** cmdlet.
6. On the remote Exchange 2010 server, the **Import-SomeData** cmdlet is run, and the data stored in the temporary object created by the **Get-Content** cmdlet is passed to the *FileData* parameter. The **Import-SomeData** cmdlet processes the input and performs whatever actions are required.

Some cmdlets use the following alternate syntax that accomplishes the same thing as the preceding syntax.

```
[Byte[]]$Data = Get-Content -Path <local path to file> -Encoding Byte -ReadCount
Import-SomeData -FileData $Data
```

The same process happens with this alternate syntax. The only difference is instead of performing the entire operation at once, the data retrieved from the local file is stored in a variable that can be referenced after it's created. The variable is then used in the import command to pass the contents of the local file to the **Import-SomeData** cmdlet. Using this two-step process is useful when you want to use the data from the local file in more than one command.

There are limitations that you must consider when importing files. For more information, see "Limitations on Importing Files" later in this topic.

For specific information about how to import data into Exchange 2010, see the Help topics for the feature you're managing.

Limitations on Importing Files

Limits must be set when importing data in remote Shell to preserve the integrity of the data that's being transferred. Transfers that are in progress can't be resumed if they're interrupted. Also, because data being transferred is stored in the remote server's memory, the server must be protected from memory exhaustion caused by excessively large amounts of data.

For these reasons, the amount of data that's transferred to a remote Exchange 2010 server from a local computer or server is limited to the following:

- 500 megabytes (MB) for each cmdlet that's run
- 75 MB for each object that's passed to a cmdlet

If you exceed either of the limits, the execution of the cmdlet and its associated pipeline will stop and you'll receive an error. Consider the examples in the following table to understand how these limits work.

Import data limit examples

Number of objects	Object size (MB)	Total size (MB)	Result of operation
10	40	400	The operation is successful because neither the size of the individual objects exceeds 75 MB nor the total amount of data passed to the cmdlet exceeds 500 MB.

5	80	400	The operation fails because, although the total amount of data passed to the cmdlet is only 400 MB, the size of each individual object exceeds the 75 MB limit.
120	5	600	The operation fails because, although each individual object is only 5 MB, the total amount of data passed to the cmdlet exceeds the 500 MB limit.

Due to the size limits that have been placed on the amount of data that can be transferred between a remote Exchange 2010 server and a local computer, not all cmdlets that once supported importing support this method of data transfer. To determine whether a specific cmdlet supports this method, see the Help information for the specific cmdlet.

These limits should accommodate the majority of typical operations that can be performed on an Exchange 2010 server. If the limits are lowered, you may find that some normal operations fail because they exceed the new limits. If the limits are raised, the data being transferred could take longer to transfer and become more at risk to transient conditions that interrupt the data transfer. Also, you may exhaust the memory on the remote server if you haven't installed enough memory to allow the server to store the entire block of data during transfer. Each possibility could result in data loss and therefore we recommend you don't change the default limits.

Exporting Files in Remote Shell

The syntax to export files in Exchange 2010 is used any time you want to accept data from a cmdlet running on a remote Exchange 2010 server and store the data on your local computer or server. Cmdlets that provide data that you can save to a local file will output an object that will contain the **FileData** property (or something similar). Depending on the cmdlet, the **FileData** property is only populated on the object that's output in specific situations. To determine the correct property to use and when it can be used, see the Help information for the cmdlet you're using.

The Shell must know that you want to save the data stored in the **FileData** property to your local computer. To do so, use the following syntax.

```
<cmdlet> | ForEach { $_.FileData | Add-Content <local path to file> -Encoding Byt
```

For example, the following command exports the data stored in the **FileData** property on the object created by the **Export-SomeData** fictional cmdlet. The exported data is stored in a file you specify on the local computer, in this case MyData.dat.

Note:

This procedure uses the **ForEach** cmdlet, objects, and pipelining. For more information about each, see:
Pipelining
Structured Data

```
Export-SomeData | ForEach { $_.FileData | Add-Content C:\MyData.dat -Encoding Byt
```

The following actions occur when the command is run:

1. The command is accepted by remote Shell.
2. Remote Shell calls the **Export-SomeData** cmdlet on the remote Exchange 2010 server.
3. The output object created by the **Export-SomeData** cmdlet is passed back to the local Shell session via the pipeline.
4. The output object is then piped to the **ForEach** cmdlet, which has a script block.
5. Within the script block, the **FileData** property on the current object in the pipeline is accessed. The data contained within the **FileData** property is piped to the **Add-Content** cmdlet.
6. The **Add-Content** cmdlet saves the data piped from the **FileData** property to the file MyData.dat on the local file system.

For specific information about how to export data from Exchange 2010, see the Help topics for the feature you're managing.

Importing and Exporting Files on Edge Transport Servers

The Edge Transport server role doesn't use remote Shell like the other Exchange 2010 server roles. It uses local Shell. This is because remote Shell requires Active Directory and Role Based Access Control (RBAC) to work. The Edge Transport server role uses Active Directory Lightweight Directory Services (AD LDS).

Because the Edge Transport server role doesn't use remote Shell, the new process for importing and exporting files doesn't apply to it. Cmdlets that are run on the Edge Transport server role can accept files directly without any additional syntax. To find the required syntax for importing and exporting files on Edge Transport servers, see the Help information for the cmdlet you're using.

Overview of Exchange Management Shell

Exchange 2010 Cmdlets

Create a Manual Remote Shell Connection

1.5.2.1 Open the Shell

Open the Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-21*

When you open the Exchange Management Shell, you can perform administrative tasks against servers that run Microsoft Exchange Server 2010.

Are you looking for information about how to connect to an Exchange 2010 server without installing the Exchange management tools? If so, check out Create a Manual Remote Shell Connection.

Prerequisites

- The Exchange management tools have been installed on the computer you want to use to administer Exchange servers. For detailed steps, see Install the Exchange 2010 Management Tools.
- To connect to any server role other than the Edge Transport server role, the user must be enabled to connect to the Shell remotely. For detailed steps, see Enable Remote Exchange Management Shell for a User.
- To connect to any server role other than the Edge Transport server role, the

user must be assigned at least one management role. For detailed steps, see Managing Permissions.

Open the Shell

1. Click **Start** > **All Programs**, and then **Microsoft Exchange Server 2010**.
2. Click **Exchange Management Shell**.

1.5.2.2 Getting Help

Getting Help

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-14*

In Microsoft Exchange Server 2010, the Exchange Management Shell provides many Help resources so that you can use it to its fullest potential. This topic provides the following sections, which describe Help resources and functionality:

- Exchange 2010 Help Exchange 2010 Help contains all the cmdlet Help topics in a role-based and task-based hierarchy. The cmdlet Help topics also link to procedural topics that tell you how to perform specific tasks.
- Help Cmdlets The Shell has several Help cmdlets that enable you to find the appropriate information to accomplish your task.
- Help Views Help in the Shell contains extensive information about the cmdlets available to you. Help views enable you to access the information that you need about a cmdlet.
- Tab Completion You can use tab completion on cmdlet names and parameter names to reduce the amount of typing at a command prompt.

Exchange 2010 Help

Exchange 2010 Help contains the same cmdlet Help information available on each cmdlet in the Shell. However, in Exchange 2010 Help, the Help topics for all the cmdlets are organized by server role and administration task so that you can easily find specific cmdlets associated with the task that you want to perform. Also, cmdlet topics in Exchange 2010 Help are linked to topics that introduce you to the features that they manage, show you how to use the cmdlets to manage that feature, and provide specific details about the feature or common scenarios.

For more information about the cmdlet Help topics available in Exchange 2010 Help, see Exchange 2010 Cmdlets.

Help Cmdlets

The following tables provide examples of how to use the **Get-Help** and **Get-Command** cmdlets to access the Help information available for each cmdlet in the Shell.

Important:
To view a list of Exchange cmdlets that match a string that you specify, use the **Get-ExCommand** cmdlet. For more information, see the "Examples of how to use miscellaneous Help commands" table later in this section.

The following table provides examples of how the **Get-Help** cmdlet is used.

Examples of how to use the Get-Help cmdlet

Examples	Description
`Get-Help`	When you use the **Get-Help** cmdlet by itself, it gives you basic instructions on how to use the Shell Help system.
`Get-Help <cmdlet>`	When you give the **Get-Help** cmdlet a cmdlet as an argument, it displays the Help information for that cmdlet. For example, to retrieve the Help information for the **Get-SystemMessage** cmdlet, use the following command. `Get-Help Get-SystemMessage`
`Get-Help About_*`	The **Get-Help About_*** command provides a list of all general Shell Help topics to help you better understand and use the Shell. If you want to learn more about a topic in the list displayed, run the **Get-Help About_<*feature*>** command. For example, if you want to learn more about wildcards, use the following command. `Get-Help About_wildcards.`
`Get-Help <cmdlet> -Detailed`	For a description, see the Help Views section later in this topic.
`Get-Help <cmdlet> -Full`	For a description, see the Help Views section later in this topic.
`Get-Help <cmdlet> -Examples`	For a description, see the Help Views section later in this topic.
`Get-Help <cmdlet> -Parameter <parameter name>`	For a description, see the Parameters Filter section later in this topic.
`Get-Help <cmdlet> -Online`	For a description, see the Online Help section later in this topic.

The following table provides examples of how the **Get-Command** cmdlet is used.

Examples of how to use the Get-Command cmdlet

Examples	Description
`Get-Command`	The **Get-Command** cmdlet provides a list of all the cmdlets available to the Shell. The **Get-Command** cmdlet allows for wildcard character expansion.
`Get-Command *<string>*`	When you enclose a string with wildcard characters (*), the **Get-Command** cmdlet returns a list of all cmdlets and functions that are available to you that contain that string. For example, to find all cmdlets or functions that contain the string "`mailbox`",

	use the command `Get-Command *mailbox*`. Exchange 2010 cmdlets are shown as functions in the output of the **Get-Command** cmdlet.
`Get-Command -Noun <CmdletNoun>`	The **Get-Command -Noun <***CmdletNoun***>** command lists all the cmdlets that exist with the specified noun. This command is useful when you want to view a list of all cmdlets associated with a particular feature. For example, the **Get-Command -Noun SystemMessage** command returns all the cmdlets available for the SystemMessage feature.
`Get-Command -Verb <CmdletVerb>`	The **Get-Command -Verb <***CmdletVerb***>** command lists all the cmdlets that exist with the specified verb. This command is useful when you want to view a list of all cmdlets associated with a particular action. For example, the **Get-Command -Verb Enable** command returns all cmdlets available that perform the enable action.

The following table provides examples of how to use miscellaneous Help commands.

Examples of how to use miscellaneous Help commands

Examples	Description
`Get-ExCommand`	The Get-ExCommand command returns a list of all Exchange cmdlets available to you.
`Get-ExCommand *<string>*`	When you enclose a string with wildcard characters (*), the **Get-ExCommand** command returns a list of all Exchange cmdlets that are available to you that contain that string. For example, to find all Exchange cmdlets that contain the string "mailbox", use the command `Get-ExCommand *mailbox*`. Exchange 2010 cmdlets are shown as functions in the output of the **Get-ExCommand** command.
`QuickRef`	The **QuickRef** command opens a link to a printable HTML chart that lists the most frequently used Shell cmdlets. This command works only if the Exchange management tools are installed. To open this chart directly, see Exchange Management Shell Quick Reference for Exchange 2010.
`<Cmdlet> -?`	Use the **<Cmdlet> -?** command together with any cmdlet to find the same Help

	information available when you use the **Get-Help** cmdlet. For example, type `Get-SystemMessage -?` to display detailed Help for the **Get-SystemMessage** cmdlet.
`Get-Tip`	The **Get-Tip** cmdlet generates a new Exchange Management Shell Tip of the Day. This cmdlet works only if the Exchange management tools are installed.
`Get-ExBlog`	The **Get-ExBlog** cmdlet opens your default browser to display the Exchange Team blog. This cmdlet works only if the Exchange management tools are installed.

Help Views

When a cmdlet is specified as a parameter of the **Get-Help** cmdlet, the Help information for the specified cmdlet is displayed. In some cases, the information returned can be extensive, and you may only want to see specific information. Help views enable you to view specific information about a cmdlet without having to sort through information that you may not need.

The Shell has four views that present different types of information. You can also retrieve a specific parameter or set of similar parameters.

The following table shows the sections displayed in each view.

Help views in the Exchange Management Shell

Help view	Default	Detailed	Full	Examples
Synopsis	X	X	X	X
Syntax	X	X	X	
Description	X	X	X	
Parameters without metadata		X		
Parameters with metadata			X	
Inputs			X	
Outputs			X	
Errors			X	
Examples		X	X	X
Related links	X		X	
Remarks	X	X		

The following table describes each view and provides an example of a command that calls each view.

Examples of Exchange Management Shell Help views

Help view	Examples	Description
Default	`Get-Help Set-Mailbox`	The Default view is displayed when you use the command `Get-Help` *<cmdlet>*.
`Detailed`	`Get-Help Set-Mailbox -Detailed`	The `Detailed` view is displayed when you use the command `Get-Help` *<cmdlet>* `-Detailed`. The parameters returned in the `Parameters` section don't include parameter metadata. For more information, see Parameters.
`Full`	`Get-Help Set-Mailbox - Full`	The `Full` view is displayed when you use the command `Get-Help` *<cmdlet>* `-Full`. The parameters returned in the `Parameters` section include the following parameter metadata: • `Required?` • `Position?` • `Default value` • `Accept pipeline input?` • `Accept wildcard characters?` For more information, see Parameters.
`Examples`	`Get-Help Set-Mailbox -Examples`	The `Examples` view is displayed when you use the command `Get-Help` *<cmdlet>* `-Examples`.

Parameters Filter

In addition to these four Help views, you can also access the description and metadata about a specific parameter or set of similar parameters. You can specify the parameter together with the `Get-Help` *<cmdlet>* command. The following example shows how you can display the description of the *ForwardingAddress* parameter on the **Set-Mailbox** cmdlet:

```
Get-Help Set-Mailbox -Parameter ForwardingAddress
```

You can also display a set of similar parameters that exist on a specific cmdlet if you specify the partial name of a parameter together with a wildcard character (*). The following example shows how you can display all the parameters on the **Set-Mailbox** cmdlet that contain the word Quota.

```
Get-Help Set-Mailbox -Parameter *Quota*
```

Note:

When you use the *Parameter* parameter with the **Get-Help** cmdlet to retrieve Help information for a cmdlet that has only one parameter, the **Get-Help** cmdlet doesn't return any results, even if you use the wildcard character (*). This is a known issue in Microsoft Windows PowerShell.

Online Help

If a cmdlet has many parameters, it may be difficult to read the Help information for that cmdlet in the Shell. With Exchange 2010, the *Online* switch has been made available. The *Online* switch tells the Shell to open your default Web browser and browse to the online Help topic for the cmdlet. The online Help topic is the same as the Help for the cmdlet in the Shell with the additional benefits of being able to view the topic in a larger window, to

search the topic for terms, or to click related links embedded within the topic. For example, to view online Help for the **Set-Mailbox** cmdlet, use the following command:

```
Get-Help Set-Mailbox -Online
```

Using the *Online* switch requires that your computer has a connection to the Internet.

Tab Completion

You can use tab completion to reduce typing when you use the Shell. After you type a partial cmdlet name, and then press the TAB key, the Shell completes the cmdlet name if a matching cmdlet is found. If multiple matching cmdlet names are found, each cmdlet name cycles through after you press the TAB key. When you use tab completion with cmdlet names, you must supply at least the verb and the hyphen (-). The following examples show how you can use tab completion when you enter a cmdlet name:

```
Get-Transport<Tab>
Enable-<Tab>
```

Each time you press the TAB key in the first example, the Shell cycles through all the cmdlet names that start with **Get-Transport**. In the second example, the Shell cycles through all cmdlets with the verb **Enable**.

As with cmdlet names, you can also use tab completion when you want the Shell to complete the partial parameter name that you entered. When you use tab completion with parameter names, you must specify the full cmdlet name either by typing it or by using tab completion. The following examples show how you can use tab completion when you enter a parameter name:

```
Set-Mailbox -Email<Tab>
New-TransportRule -Cond<Tab>
```

Each time you press the TAB key in the first example, the Shell cycles through all the parameter names that start with *Email* on the **Set-Mailbox** cmdlet. In the second example, when you press the TAB key, the Shell completes the *Conditions* parameter on the **New-TransportRule** cmdlet.

1.5.2.3 Cmdlets

Cmdlets

Exchange Server 2010 > Exchange Management Shell > Exchange Management Shell Basics >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-11*

A *cmdlet*, pronounced "command-let", is the smallest unit of functionality in the Exchange Management Shell. Cmdlets resemble built-in commands in other shells, for example, the `dir` command found in `cmd.exe`. Like these familiar commands, cmdlets can be called directly from the command line in the Shell and run under the context of the Shell, not as a separate process.

Note:

Since Microsoft Exchange Server 2007, there have been changes to how Exchange 2010 uses cmdlets internally due to the use of Windows PowerShell remoting functionality. These changes have little to no impact on how you need to use cmdlets, but they may offer additional flexibility in how you manage your Exchange servers.

Cmdlets are usually designed around repetitive administrative tasks, and, in the Shell, several hundred cmdlets are provided for Exchange-specific management tasks. These cmdlets are available in addition to the non-Exchange system cmdlets included in the basic Windows PowerShell shell design. For information about how to open the Exchange Management Shell, see Open the Shell.

All cmdlets in the Shell are presented in verb-noun pairs. The verb-noun pair is always separated by a hyphen (-) without spaces, and the cmdlet nouns are always singular. Verbs refer to the action that the cmdlet takes. Nouns refer to the object on which the cmdlet takes action. For example, in the **Get-SystemMessage** cmdlet, the verb is **Get**, and the noun is **SystemMessage**. All Shell cmdlets that manage a specific feature share the same noun. The following table provides examples of some verbs available in the Shell.

Note:

By default, if the verb is omitted, the Shell assumes the **Get** verb. For example, when you call **Mailbox**, you retrieve the same results as when you call **Get-Mailbox**.

Examples of verbs in the Exchange Management Shell

Verb	Description
Disable	**Disable** cmdlets set the `Enabled` status of the specified Exchange 2010 object to `$False`. This prevents the object from processing data even though the object exists.
Enable	**Enable** cmdlets set the Enabled status of the specified Exchange 2010 object to `$True`. This enables the object to process data.
Get	**Get** cmdlets retrieve information about a specific Exchange 2010 object. **Note:** Most **Get** cmdlets only return summary information when you run them. To tell the **Get** cmdlet to return verbose information when you run a command, pipe the command to the **Format-List** cmdlet. For more information about the **Format-List** command, see Working with Command Output. For more information about pipelining, see Pipelining.
Install	**Install** cmdlets install a new object or feature on an Exchange 2010 server.
Move	**Move** cmdlets relocate the specified Exchange 2010 object from one container or server to another.
New	**New** cmdlets create new Exchange 2010 object.
Remove	**Remove** cmdlets delete the specified Exchange 2010 object.
Set	**Set** cmdlets modify the properties of an existing Exchange 2010 object.
Test	**Test** cmdlets test specific Exchange 2010 components and provide log files that you

	can examine.
Uninstall	**Uninstall** cmdlets remove an object or feature from an Exchange 2010 server.

The following list of cmdlets is an example of a complete cmdlet set. This cmdlet set is used to manage the delivery status notification (DSN) message and mailbox quota message features of Exchange 2010:

- **Get-SystemMessage**
- **New-SystemMessage**
- **Remove-SystemMessage**
- **Set-SystemMessage**

Exchange Management Shell Basics

1.5.2.4 Parameters

Parameters

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-14*

Most cmdlets rely on parameters. Parameters are elements that provide information to the cmdlet, either identifying an object and its attributes to act upon, or controlling how the cmdlet performs its task. The name of the parameter is preceded by a hyphen (-) and followed by the value of the parameter as follows:

```
Verb-Noun -ParameterName <ParameterValue>
```

In this simple example, the hyphen in front of the parameter name tells the Exchange Management Shell that the word that immediately follows the hyphen is a parameter that is passed to the cmdlet and that the next separate word after the parameter is the value of the parameter.

This topic discusses the following parameters and their behavior in the Shell:

Positional Parameters

Boolean Parameters

Switch Parameters

Common Parameters

Positional Parameters

A positional parameter is a parameter that lets you specify the parameter's value without specifying the parameter's name. A parameter is a positional parameter if the `Parameter Position` attribute is an integer. This integer indicates the position on the command line where the cmdlet can find the parameter's value. For more information about the various attributes that make up a parameter, see the Parameter Details section later in this topic.

Most cmdlets only have one positional parameter, *Identity*. *Identity* is always in position 1 if it is available on a cmdlet. Some cmdlets have multiple positional parameters. With these cmdlets, you can specify the values for each positional parameter in the order specified by the `Parameter Position` attribute on each parameter. The values for each parameter must be in the correct position on the command line to work correctly.

If a parameter isn't a positional parameter, it's considered to be a `named` parameter. You must specify the parameter name and parameter value for `named` parameters.

The following two commands perform the same task of returning configuration information for a Receive connector that is named `"Contoso"`.

```
Get-ReceiveConnector -Identity "Contoso"
Get-ReceiveConnector "Contoso"
```

The following two commands perform the same task. The positional parameter values in the first command are placed in the exact order as required by the Parameter Position attribute on each parameter.

```
Set-ExampleCmdlet "Seattle Users" $True "Contoso.com"
Set-ExampleCmdlet -Name "Seattle Users" -Enabled $True -Domain "Contoso.com"
```

Parameter Details

Attributes, also called metadata, on each parameter are included in the PARAMETERS section of the Shell Help that is retrieved by the **Get-Help** cmdlet. The following example is from the **Get-Service** cmdlet.

```
PARAMETERS
    -ServiceName System.String[]
        Parameter required?           false
        Parameter position?           1
        Default value                 *
        Accept pipeline input?       true
        Accept wildcard characters?  True
```

This example from the **Get-Service** cmdlet includes some specific details about the value types that can be passed for the *ServiceName* parameter. Not all cmdlets include such details. However, most cmdlets do include some settings for each parameter as described in the following table.

Parameter settings

Setting	Description
Required?	Indicates whether the cmdlet will run if you don't supply the parameter. When *Required?* is set to `True`, the Shell prompts you for the value if the parameter isn't supplied on the command line.
Position?	Indicates whether you must put the parameter name in front of the parameter value. When *Position?* is set to `Named`, the parameter name is required. When *Position?* is set to an integer, the name isn't required, only the value.
Default value	Indicates the default value for this parameter if no other value is provided.

Accept pipeline input?	Indicates whether the parameter can receive its value as an input through a pipeline from another cmdlet.
Accept wildcard characters?	Indicates whether the parameter's value can contain wildcard characters and can be matched to multiple objects.

Boolean Parameters

Boolean parameters are used in the Shell to determine, among other things, whether a feature or option is enabled, `$True`, or disabled, `$False`. The value that you assign to a Boolean parameter is stored in the configuration of the object that you're modifying. When you supply a value to a Boolean parameter, you must use the values `$True` or `1`, or `$False` or `0`. The dollar sign ($) must be included with `$True` and `$False`. You may notice that some commands insert a colon (:) between the Boolean parameter name and Boolean value. On Boolean parameters, this colon is optional. The following example disables the Receive connector "Contoso.com":

```
Set-ReceiveConnector "Contoso.com" -Enabled $False
```

Switch Parameters

Switch parameters are commonly used to indicate whether the current command should proceed with additional prompting or to enable an alternate option for the command being run. This state isn't saved between commands. Switch parameters resemble Boolean parameters, but they serve different purposes and require different syntax. Switch parameters don't require a value. When you specify a switch parameter on a command line without a value, the parameter evaluates to `$True`.

On some cmdlets, the cmdlet may run as though the switch parameter was included on the command line, even if you didn't include it yourself. This behavior commonly occurs with the *Confirm* switch parameter on cmdlets that can cause data loss if they're inadvertently run. In the case of the *Confirm* switch parameter on such a cmdlet, the cmdlet will always prompt for confirmation before running unless you explicitly tell the cmdlet not to by overriding the switch parameter. You can override the switch parameter by including the *Confirm* switch parameter on the command line with a value of `:$False`. Unlike any other parameters, the colon character (`:`) is required between switch parameters and the value `$False`.

The first of the following examples instructs the **Start-EdgeSynchronization** cmdlet to display a confirmation prompt before it lets EdgeSync synchronization start. The second example instructs the **Remove-ReceiveConnector** cmdlet not to display a confirmation prompt before deleting the Receive connector "Contoso.com":

```
Start-EdgeSynchronization -Confirm
Remove-ReceiveConnector "Contoso.com" -Confirm:$False
```

Common Parameters

Common parameters are parameters that are automatically added to all commands by the Shell. These parameters perform functions that can be used with, or used by, the commands that they're run against. The following table lists all the common parameters that are available in the Shell. Three additional parameters, *WhatIf, Confirm*, and *ValidateOnly*, may also be added to cmdlets. For more information about these additional parameters, see WhatIf, Confirm, and ValidateOnly Switches.

Common parameters in the Exchange Management Shell

Parameter name	Required	Type	Description
Debug	Optional	System.Boolean	The *Debug* parameter instructs the command to provide programmer-level detail about the operation.
ErrorAction	Optional	System.Enum	The *ErrorAction* parameter controls the behavior of the command when an error occurs. Values are as follows: • `Continue`, which is the default value • `Stop` • `SilentContinue` • `Inquire`, which asks the user what to do
ErrorVariable	Optional	System.String	The *ErrorVariable* parameter specifies the name of the variable that the command uses to store errors that are encountered during processing. This variable is populated in addition to `$ERROR`.
OutVariable	Optional	System.String	The *OutVariable* parameter specifies the name of the variable that the command uses for objects that are output from this command. This is equivalent to piping the command to `Set-Variable <name> -Passthru:$true`
Verbose	Optional	System.Boolean	The *Verbose* parameter instructs the command to provide detailed information about the operation. **Note:** Most **Get** cmdlets only return summary information that contains the most commonly used properties when you run them. To tell the **Get** cmdlet to return all of the properties on an object, pipe the command to the **Format-List** cmdlet. For more information, see Pipelining and Working with Command Output.

For More Information

Exchange Management Shell Basics

1.5.2.5 Identity

Identity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-03*

The *Identity* parameter is a special parameter that you can use with most cmdlets. The *Identity* parameter gives you access to the unique identifiers that refer to a specific object in Microsoft Exchange Server 2010. This capability lets you perform actions on a specific Exchange 2010 object.

The following sections describe the Identity parameter and provide examples of how you can use it effectively:

Characteristics of the Identity Parameter

The primary unique identifier of an object in Exchange 2010 is always a GUID. A GUID is a 128-bit identifier, such as `63d64005-42c5-4f8f-b310-14f6cb125bf3`. This GUID never repeats and is therefore always unique. However, you don't want to type such GUIDs regularly. Therefore the *Identity* parameter typically also consists of the values of other parameters, or combined set of values from multiple parameters on a single object. These values are also guaranteed to be unique across that set of objects. You can specify the values of these other parameters, such as *Name* and *DistinguishedName*, or they can be system-generated. The additional parameters that are used, if any, and how they are populated, depend on the object you refer to.

The *Identity* parameter is also considered a positional parameter. The first argument on a cmdlet is assumed to be the *Identity* parameter when no parameter label is specified. This reduces the number of keystrokes when you type commands. For more information about positional parameters, see Parameters.

The following example shows the use of the *Identity* parameter by using the Receive connector's unique *Name* parameter value. This example also shows how you can omit the *Identity* parameter name because *Identity* is a positional parameter.

```
Get-ReceiveConnector -Identity "From the Internet"
Get-ReceiveConnector "From the Internet"
```

Like all objects in Exchange 2010, this Receive connector can also be referred to by its unique GUID. For example, if the Receive connector named `"From the Internet"` is also assigned the GUID `63d64005-42c5-4f8f-b310-14f6cb125bf3`, you can also retrieve the Receive connector by using the following command:

```
Get-ReceiveConnector 63d64005-42c5-4f8f-b310-14f6cb125bf3
```

Return to top

Wildcard Characters in Identity

Some **Get** cmdlets can accept a wildcard character (*) as part of the value you submit to *Identity* when you run the cmdlet. By using a wildcard with the *Identity* parameter, you can specify a partial name and retrieve a list of objects that match that partial name. You can place a wildcard character at the beginning or the end of the *Identity* value, but you can't place the character in the middle of a string. For example, the commands `Get-Mailbox David*` and `Get-Mailbox *anders*` are valid, but `Get-Mailbox Reb*ca` isn't a valid command.

Some **Get** cmdlets retrieve objects in Exchange 2010 that are organized in a hierarchical or parent and children relationship. That is, there may be a collection of parent objects that also contain their own child objects. Objects that have a parent and child relationship may have an *Identity* with the syntax of `<parent>\<child>`.

When an *Identity* parameter has a syntax of `<parent>\<child>`, some cmdlets enable you to use a wildcard character (*) to replace all or some of the parent or child names. For example, if you want to find all of the child objects named "Contoso" in all parent objects, you could use the syntax `"*\Contoso"`. Likewise, if you want to find all of the child objects with a partial name of "Auth" that exist under the `"ServerA"` parent object, you could use the syntax `"ServerA\Auth*"`.

Some, but not all, cmdlets allow you to specify just the child portion of the Identity parameter when you run a command. When you do this, the cmdlets default to the current parent object being accessed. For example, two receive connectors named "Contoso Receive Connector" exist on both MBX1 and MBX2. If you run the command `Get-ReceiveConnector "Contoso Receive Connector"` on MBX2, only the receive connector on the server MBX2 is returned.

The specific behavior of the Identity parameter and wildcard characters is dependent on the cmdlet that's being run. For more information about the cmdlet you're running, see the feature-specific content for that cmdlet.

Return to top

Examples of the Identity Parameter

The examples described in this topic illustrate how the *Identity* parameter can accept different unique values to refer to specific objects in the Exchange 2010 organization. These examples also illustrate how the *Identity* parameter label can be omitted to reduce the number of keystrokes when you type commands.

DSN Messages

The examples in this section refer to the delivery status notification (DSN) messages that can be configured in an Exchange 2010 organization. The first example shows how to retrieve DSN 5.4.1 by using the **Get-SystemMessage** cmdlet. In the **Get-SystemMessage** cmdlet, the *Identity* parameter consists of several pieces of data that are configured on each DSN message object. These pieces of data include the language that the DSN is written in, whether the DSN is internal or external in scope, and the DSN message code as in the following example:

```
Get-SystemMessage en\internal\5.4.1
```

You can also retrieve this DSN message by using its GUID as in the following example, because all objects in Exchange 2010 have a GUID:

```
Get-SystemMessage 82ca7bde-1c2d-4aa1-97e1-f298a6f10222
```

For more information about the makeup of the *Identity* parameter when it's used with the **SystemMessage** cmdlets, see DSN Message Identity.

Management Role Entries

The examples in this section refer to management role entries that make up management roles in Exchange 2010. Management roles are used to control the permissions that are granted to administrators and end users. Management role entries are made up of two parts: the management role they're associated with and a cmdlet. The Identity parameter is likewise made up of both the management role name and the cmdlet name. For example, the following is the role entry for the **Set-Mailbox** cmdlet on the `Mail Recipients` role:

```
Mail Recipients\Set-Mailbox
```

The `Mail Recipients\Set-Mailbox` role entry is one of several entries on the `Mail Recipients` role. To view all the role entries on the `Mail Recipients` role, you can use the following command:

```
Get-ManagementRoleEntry "Mail Recipients\*"
```

To view all the role entries on the `Mail Recipients` role that contain the string "`Mailbox`", use the following command:

```
Get-ManagementRoleEntry "Mail Recipients\*Mailbox*"
```

To view all the management roles where **Set-Mailbox** is one of the role entries, use the following command:

```
Get-ManagementRoleEntry *\Set-Mailbox
```

With role entries you can use the wildcard character in a variety of ways to query Exchange 2010 for the information you're interested in.

For more information about management roles, see Understanding Permissions.

Exchange Management Shell Basics

1.5.2.6 Syntax

Syntax

Exchange Server 2010 > Exchange Management Shell > Exchange Management Shell Basics >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-07-09*

This topic explains how to read the Exchange Management Shell parameter sets and examples in the Exchange Help documentation and how to format a command so that the Shell can process the command. In the Shell and the Microsoft Exchange Server 2010 Help, parameter sets are displayed in the Syntax section of a cmdlet Help topic. For more information about cmdlet help, see Getting Help.

See the following sections:

Command Conventions in the Exchange Management Shell

The Shell follows several command conventions that help you understand what information is required or optional when you run a command and how you must present the parameters and their values. See the "Parameter Sets" section later in this topic for examples of how parameter sets are presented in the Shell Help and Exchange 2010 Help.

The following table lists these command conventions.

Exchange Management Shell command conventions

Symbol	Description
-	A hyphen indicates that the next word on the command line is a parameter. The most common parameter is *Identity*. For more information, see Parameters.
< >	Angle brackets are used to enclose parameter values. These values can be choices or names. For example, in `-Parameter1 <1 | 2 | 3>`, the numbers represent specific value choices. In `-Parameter2 <ServerName>`, `ServerName` represents the actual value.
[ ]	Square brackets are used to enclose an optional parameter and its value. A parameter and its value that are not enclosed in square brackets are required.
|	When the pipe symbol is used in a parameter value list, such as `-Parameter1 <1 | 2 | 3>`, it indicates a choice between available values. This convention applies to `System.Enum` parameters and `System.Boolean` parameters.

These command conventions help you understand how a command should be constructed. Don't type these conventions when you enter the command on the command line.

Parameter Sets

In the Exchange Help documentation, all cmdlets display their associated parameters in parameter sets. Parameter sets are groupings of parameters that can be used with each other. Parameters that exist in one parameter set, but not in another parameter set, are mutually exclusive. They can't be used together.

Although all cmdlets have parameter sets, many only have one set of parameters. This means that all the parameters on that cmdlet can be used with each other. Other cmdlets may have several parameter sets. The following example displays the parameter sets that are available on the **New-SystemMessage** cmdlet:

```
New-SystemMessage -DsnCode <EnhancedStatusCode> -Internal <$true | $false>
-Language <CultureInfo> -Text <String> [-DomainController <String>] [-Templ
ateInstance <MshObject>]
New-SystemMessage -Language <CultureInfo> -QuotaMessageType <WarningMailbox
UnlimitedSize | WarningPublicFolderUnlimitedSize | WarningMailbox | Warning
PublicFolder | ProhibitSendMailbox | ProhibitPostPublicFolder | ProhibitSen
dReceiveMailBox> -Text <String> [-DomainController <String>] [-TemplateInst
ance <MshObject>]
```

The **New-SystemMessage** cmdlet has two parameter sets. The first parameter set contains the *DsnCode* parameter and *Internal* parameter, and the second parameter set contains the *QuotaMessageType* parameter. This means that the *DsnCode* parameter and *Internal* parameter can be used with each other. But, they can't be used with the *QuotaMessageType* parameter. The remaining parameters, *Language*, *Text*, *DomainController*, and *TemplateInstance*, are listed in both parameter sets. This means that they can be used with the *DsnCode* parameter and *Internal* parameter and with the *QuotaMessageType* parameter.

Parameter sets can indicate that a single cmdlet may have multiple uses. For example, you can use the **New-SystemMessage** cmdlet to configure customized delivery status notification (DSN) messages or configure customized mailbox quota limit messages. However, cmdlets typically have multiple parameter sets because one parameter may perform a function that is incompatible with another parameter. For example, the following example displays the parameter sets for the **New-AddressList** cmdlet:

```
New-AddressList -Name <String> [-ConditionalCompany <MultiValuedProperty>]
[-ConditionalCustomAttribute1 <MultiValuedProperty>] [-ConditionalCustomAtt
ribute10 <MultiValuedProperty>] [-ConditionalCustomAttribute11 <MultiValued
Property>] [-ConditionalCustomAttribute12 <MultiValuedProperty>] [-Conditio
nalCustomAttribute13 <MultiValuedProperty>] [-ConditionalCustomAttribute14
<MultiValuedProperty>] [-ConditionalCustomAttribute15 <MultiValuedProperty>
] [-ConditionalCustomAttribute2 <MultiValuedProperty>] [-ConditionalCustomA
ttribute3 <MultiValuedProperty>] [-ConditionalCustomAttribute4 <MultiValued
Property>] [-ConditionalCustomAttribute5 <MultiValuedProperty>] [-Condition
alCustomAttribute6 <MultiValuedProperty>] [-ConditionalCustomAttribute7 <Mu
ltiValuedProperty>] [-ConditionalCustomAttribute8 <MultiValuedProperty>] [-
ConditionalCustomAttribute9 <MultiValuedProperty>] [-ConditionalDepartment
<MultiValuedProperty>] [-ConditionalStateOrProvince <MultiValuedProperty>]
[-Confirm [<SwitchParameter>]] [-Container <AddressListIdParameter>] [-Disp
layName <String>] [-DomainController <Fqdn>] [-IncludedRecipients <Nullable
>] [-Organization <OrganizationIdParameter>] [-RecipientContainer <Organiza
tionalUnitIdParameter>] [-WhatIf [<SwitchParameter>]] [<CommonParameters>]
New-AddressList -Name <String> [-Confirm [<SwitchParameter>]] [-Container <
AddressListIdParameter>] [-DisplayName <String>] [-DomainController <Fqdn>]
 [-Organization <OrganizationIdParameter>] [-RecipientContainer <Organizati
onalUnitIdParameter>] [-RecipientFilter <String>] [-WhatIf [<SwitchParamete
r>]] [<CommonParameters>]
```

In the **New-AddressList** cmdlet, the first parameter set lists parameters that let you create a new address list based on values supplied to the *Company*, *Department*, *IncludedRecipients*, and *StateOrProvice* parameters. However, you can also create a new address list by using a custom filter that is specified with the *RecipientFilter* parameter. When you create a new address list, a custom filter that was specified by using the *RecipientFilter* parameter overrides anything that was configured by using the parameters

that exist in the first parameter set. Therefore, the *RecipientFilter* parameter is put in its own parameter set. Exchange 2010 doesn't let you specify both parameters on the same command line. As with the **New-SystemMessage** cmdlet, the remaining parameters that exist in both parameters sets in the **New-AddressList** cmdlet can be used in any combination.

Use of Quotation Marks

Double quotation marks (") are most commonly used to enclose a value that has spaces when you pass that value to a parameter. For example, if you want to pass `Contoso Receive Connector` to the *Name* parameter of the **Set-ReceiveConnector** cmdlet, you must enclose `Contoso Receive Connector` in quotation marks as in the following example:

```
Set-ReceiveConnector -Name "Contoso Receive Connector"
```

If you don't enclose the string in quotation marks, the Shell tries to interpret each word in the string as a new argument on the command line and displays an error.

In the Shell, double quotation marks and single quotation marks (') have different meanings. When you enclose a string in double quotation marks, the Shell replaces any variables with a matching value. For example, assume the value `ServerName` is assigned to the variable `$Server`. Then, assume the following command is entered on the command line:

```
"$Server Example"
```

The following output is displayed:

```
ServerName Example
```

The variable `$Server` is replaced by the value `ServerName` in the output.

When you enclose a string in single quotation marks, the Shell doesn't try to replace variables with a matching value. Assume the variable `$Server` is still assigned the value `ServerName`. Then assume the following command is entered on the command line:

```
'$Server-Example'
```

The following output is displayed:

```
$Server-Example
```

The variable `$Server` has not been replaced with a value because the Shell doesn't interpret variables that are included in text that is enclosed in single quotation marks.

For more information about variables, see User-Defined Variables and Shell Variables.

Escape Character

You may also want to display some characters, such as the dollar sign ($), double or single quotation marks, or back quotation mark (` ). These characters have special meanings when you use them in the Shell. To instruct the Shell not to interpret these characters and to display them when they are included in a string that is enclosed with double quotation marks, you must use the back quotation mark escape character ( `). For example, type the following text on the command line:

```
"The price is `$23."
```

The following output is displayed:

```
The price is $23.
```

Because we used the back quotation escape character with the dollar sign ($), the Shell doesn't interpret the $ as the beginning of a variable.

If you enclose a string in single quotation marks, you don't have to escape any character unless you want to display a single quotation mark in a string. If you want to display a single quotation mark in a string that is enclosed in single quotation marks, you must use two single quotation marks (''). For example, type the following on the command line:

```
'Don''t confuse two single quotation marks with a double quotation mark!'
```

The following output is displayed:

```
Don't confuse two single quotation marks with a double quotation mark!
```

Command Operators in the Exchange Management Shell

Use the operators in the following table when you type commands in the Shell. Some of the operators may match some of the previously mentioned command conventions. However, they don't have the same meaning when they are typed on the command line. The following table shows the valid operators that you can use in a command.

Exchange Management Shell command operators

Operator	Description
=	The equal sign is used as an assignment character. The value on the right side of the equal sign is assigned to the variable on the left side of the equal sign. The following characters are also assignment characters: • **+=** Add the value on the right side of the equal sign to the current value that is contained in the variable on the left side of the equal sign. • **-=** Subtract the value on the right side of the equal sign from the current value that is contained in the variable on the left side of the equal sign. • ***=** Multiply the current value of the variable on the left side of the equal sign by the value that is specified on the right side of the equal sign. • **/=** Divide the current value of the variable on the left side of the equal sign by the value that is specified on the right side of the equal sign. • **%=** Modify the current value of the variable on the left side of the equal sign by the value that is specified on the right side of the equal sign.
:	A colon can be used to separate a parameter's name and the parameter's value, as in the following example: `-Enabled:$True`. The use of a colon is optional with all parameter types except switch parameters. For more information about

	switch parameters, see Parameters.
!	The exclamation point is a logical **NOT** operator. When it is used with the equal (**=**) sign, the combined pair means "not equal to."
[ ]	Brackets are used to specify the index value of an array position. For example, `$Red[9]` refers to the tenth index position in the array, `$Red`. It refers to the tenth index position because array indexes start at zero (0). Brackets can also be used to assign a type to a variable, as in the following example: `$A=[XML] "<Test><A>value</A></Test>"`. The following types are valid: `Array`, `Bool`, `Byte`, `Char`, `Char[]`, `Decimal`, `Double`, `Float`, `Int`, `Int[]`, `Long`, `Long []`, `RegEx`, `Single`, `ScriptBlock`, `String`, `Type`, and `XML`.
{ }	Braces are used to include an expression in a command, as in the following example: `Get-Process | Where { $_.HandleCount -gt 400 }`
|	The pipe symbol is used when one cmdlet pipes a result to another cmdlet. For example, the following command pipes the results from the Get-Mailbox cmdlet to the Set-Mailbox cmdlet: `Get-Mailbox -Server SRV1 | Set-Mailbox -ProhibitSendQuota 2GB`
>	The right-angle bracket is used to send the output of a command to a file, as in the following example: `Get-TransportRulePredicate > c:\out.txt`. The destination file is overwritten.
>>	Double right-angle brackets are used to append the output of a command to a file, if the file exists. If the file doesn't exist, a new file is created. The following is an example of how to use double right-angle brackets: `Get-TransportRulePredicate >>c:\out.txt`
" "	Quotation marks are used to enclose a string that contains spaces.
$	A dollar sign indicates a variable. For example, `$Blue = 10` assigns the value 10 to the variable `$Blue`.
@	The @ symbol references an associative array. For more information, see Arrays.
$( )	A dollar sign ($) with parentheses indicates command substitution. You can use command substitution when you want to use the output of one command as an argument in another command, as in the following example: `Get-ChildItem $(Read-Host -Prompt "Enter`

	`FileName: ")`
..	Double-periods indicate a value range. For example, if an array contains several indexes, you can specify the following command to return the values of all indexes between the second and fifth indexes, as in the following example: `$Blue [2..5]`
+	The **+** operator adds two values together. For example, `6 + 6` equals 12.
-	The **-** operator subtracts one value from another value. For example, `12 - 6` equals 6. The **-** operator can also be used to represent a negative number, such as -6. For example, `-6 * 6` equals -36.
*****	A wildcard character has several meanings. You can use wildcard characters to match strings, to multiply numeric values, or, if strings and numeric values are used together, to repeat the string value the number of times that is specified by the numeric value, as in the following example: `"Test" * 3` equals `TestTestTest`.
/	The **/** operator divides one value by another. For example, `6 / 6` equals 1.
%	When used in a numerical evaluation, the **%** operator returns the remainder from a division operator. For example, `6 % 4` equals 2. When used in a pipeline, the percent character (`%`) is shorthand for the `ForEach` cmdlet. For example, instead of the command `Import-Csv c:\MyFile.csv | ForEach { Set-Mailbox $_.Identity -Name $_.Name }`, you can use `Import-Csv c:\MyFile.csv | % { Set-Mailbox $_.Identity -Name $_.Name }`. For more information, see Pipelining.
?	The question mark character (?) is shorthand for the **Where** cmdlet. For example, instead of `Get-Alias | Where {$_.Definition -eq "Clear-Host"}`, you can use `Get-Alias \| ? {$_.Definition -eq "Clear-Host"}`.

For More Information

Exchange Management Shell Basics

1.5.2.7 Pipelining

Pipelining

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-23*

Pipelining in the Exchange Management Shell is the act of one cmdlet using the output of another cmdlet when it performs an operation. Pipelining is accomplished by using the pipe "|" symbol. All verbs in the same noun-cmdlet set can use piped information from another command. Some noun-cmdlet sets also let you pass data through the pipeline to another noun cmdlet set.

See the following sections for information and examples of using pipelining in the Shell:

Using Pipelining to Perform Multiple Actions

The use of pipelining to string together the actions of two or more cmdlets gives the Shell the power of composition, which lets you take smaller components and convert them into something more powerful. For example, you can use one cmdlet to gather data, pass that data to a second cmdlet to filter the data to a subset, and then pass that data to a third cmdlet to act on the subset only.

For example, the following command uses pipelining to move all the mailboxes on `Server1` to the `Executives` database on `Server2` by using the **Move-Mailbox** cmdlet, based on output that is piped from the **Get-Mailbox** cmdlet:

```
Get-Mailbox -Server Server1 | Move-Mailbox -TargetDatabase Executives
```

Using Pipelining to Process Data from Another Cmdlet

You can also use pipelining to process data that is output by a cmdlet. For example, for a list of all processes where the `HandleCount` property of the process is larger than 400, you can run the following command:

```
Get-Process | Where { $_.HandleCount -gt 400 } | Format-List
```

In this example, the **Get-Process** cmdlet passes objects to the **Where-Object** cmdlet. The **Where-Object** cmdlet picks out the objects that have a property called `HandleCount` with a value larger than 400.

Note:

Where is an alias for the **Where-Object** cmdlet. For more information, see Aliases.

In this example, the `HandleCount` property is preceded by the `$_` variable. This variable is created automatically by the Shell to store the current pipeline object. The **Where-Object** cmdlet then sends these objects to the **Format-List** cmdlet to be displayed.

The use of structured objects, instead of text, is one of the most exciting capabilities of the Shell. The use of structured objects forms the basis of a powerful compositional model of administration. For more information about structured objects, see Structured Data.

Using Pipelining to Pipe Data between Dissimilar Nouns

Piping data between dissimilar nouns is useful in cases where you want to use the data from one cmdlet with another cmdlet, but the preceding cmdlet in the pipeline doesn't output an object that the next cmdlet can use to identify the object to act upon. This situation typically happens if you're trying to pipe an object from a cmdlet with a noun that's different than the cmdlet that's expecting the object. For more information about cmdlets, see Cmdlets.

To pass data between cmdlets that haven't been optimized to pass objects directly between each other, you need to pass the object through the **ForEach** cmdlet. When you use the **ForEach** cmdlet, you can access the object directly using the `$_` special variable and associate its properties with the parameters on the second cmdlet.

In the following example, the **Get-Mailbox** cmdlet and the **New-InboxRule** cmdlet aren't optimized to send objects directly between each other. For the **New-InboxRule** cmdlet to take action on objects provided by the **Get-Mailbox** cmdlet, we need to manually associate the correct property on the mailbox object to the correct parameter on the **New-InboxRule** cmdlet. To do this, we use the following command:

```
Get-Mailbox | ForEach { New-InboxRule -Name "Mark as Read" -Mailbox $_.Name -From
```

In this example, we know that the **New-InboxRule** cmdlet requires that you specify the mailbox on which to create the new inbox rule. We also know that the **Get-Mailbox** cmdlet outputs an object that contains the name of each mailbox being returned. By using the **ForEach** cmdlet, which contains the command to be run on each object it receives, we gain access to the `$_` special variable, which contains the current object in the pipeline. We can access the *Name* property of the current mailbox object using the syntax `$_.Name`. We provide `$_.Name` as an argument on the *Mailbox* parameter of the **New-InboxRule** cmdlet which provides the cmdlet with the information it needs to create the new inbox rule.

Note:

ForEach is an alias for the **ForEach-Object** cmdlet. For more information, see Aliases.

Using Pipelining to Report Errors

To report errors, you can use the error pipeline. The error pipeline lets you report errors while a command runs. You don't have to wait until the command has finished running or to put the error information in the standard result pipeline. The **Write-Error** cmdlet writes its arguments to the error pipeline.

For more information about pipelining, run the following command in the Shell:

```
Get-Help About_Pipeline
```

Exchange Management Shell Basics

1.5.2.8 WhatIf, Confirm, and ValidateOnly Switches

WhatIf, Confirm, and ValidateOnly Switches

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-20*

Both experienced administrators and script writers, and administrators who are new to Exchange and scripting, can benefit from using the *WhatIf*, *Confirm*, and *ValidateOnly* switches. These switches let you control how your commands run and indicate exactly what a command will do before it affects data. This functionality is quite valuable as you transition from your test environment into your production environment and as you roll out new scripts or commands.

The *WhatIf*, *Confirm*, and *ValidateOnly* switches are especially useful when you use them with commands that modify objects that are returned by using a filter or by using a **Get** command in a pipeline. This topic describes each switch and also provides an example command for each switch.

Important:

If you want to use the *WhatIf*, *Confirm*, and *ValidateOnly* switches with commands in a script, you must add the appropriate switch to each command in the script, and not on the command line that calls the script.

Note:

WhatIf, *Confirm*, and *ValidateOnly* are called switch parameters. For more information about switch parameters, see Parameters.

WhatIf Switch

The *WhatIf* switch instructs the command to which it is applied to run but only to display the objects that would be affected by running the command and what changes would be made to those objects. The switch does not actually change any of those objects. When you use the *WhatIf* switch, you can see whether the changes that would be made to those objects match your expectations, without the worry of modifying those objects.

When you run a command together with the *WhatIf* switch, you put the *WhatIf* switch at the end of the command, as in the following example:

```
New-AcceptedDomain -Name "Contoso Domain" -DomainName "contoso.com" -WhatIf
```

When you run this example command, the following text is returned by the Shell:

```
What if: Creating Accepted Domain "Contoso Domain" with domain name "contoso.com"
```

Confirm Switch

The *Confirm* switch instructs the command to which it is applied to stop processing before any changes are made. The command then prompts you to acknowledge each action before it continues. When you use the *Confirm* switch, you can step through changes to objects to make sure that changes are made only to the specific objects that you want to change. This functionality is useful when you apply changes to many objects and want precise control over the operation of the Shell. A confirmation prompt is displayed for each

object before the Shell modifies the object.

By default, the Shell automatically applies the *Confirm* switch to cmdlets that have the following verbs:

- **Clear**
- **Disable**
- **Dismount**
- **Move**
- **Remove**
- **Stop**
- **Suspend**
- **Uninstall**

When a cmdlet runs that has any of these verbs, the Shell automatically stops the command and waits for your acknowledgement before it continues to process.

If you want to manually apply the *Confirm* switch to a command, include the *Confirm* switch at the end of the command, as in the following example:

```
Get-JournalRule | Enable-JournalRule -Confirm
```

When you run this example command, the following confirmation prompt is returned by the Shell:

```
Confirm
Are you sure you want to perform this action?
Enabling journal rule "Litigation Journal Rule".
[Y] Yes  [A] Yes to All  [N] No  [L] No to All  [S] Suspend  [?] Help
(default is "Y"):
```

The confirmation prompt gives you the following choices:

- **[Y] Yes** Type **Y** to instruct the command to continue the operation. The next operation will present another confirmation prompt. `[Y] Yes` is the default choice.
- **[A] Yes to All** Type **A** to instruct the command to continue the operation and all subsequent operations. You will not receive additional confirmation prompts for the duration of this command.
- **[N] No** Type **N** to instruct the command to skip this operation and continue with the next operation. The next operation will present another confirmation prompt.
- **[L] No to All** Type **L** to instruct the command to skip this operation and all subsequent operations.
- **[S] Suspend** Type **S** to pause the current pipeline and return to the command line. Type **Exit** to resume the pipeline.
- **[?] Help** Type **?** to display confirmation prompt Help on the command line.

If you want to override the default behavior of the Shell and suppress the confirmation prompt for cmdlets on which it is automatically applied, you can include the *Confirm* switch with a value of `$False`, as in the following example:

```
Get-JournalRule | Disable-JournalRule -Confirm:$False
```

In this case, no confirmation prompt is displayed.

Caution:

The default value of the *Confirm* switch is `$True`. The default behavior of the Shell is to automatically display a confirmation prompt. If you suppress this default behavior, you instruct the command to suppress all confirmation prompts for the duration of that command. The command will process all objects that meet the criteria for the command without confirmation.

ValidateOnly Switch

The *ValidateOnly* switch instructs the command to which it is applied to evaluate all the conditions and requirements that are needed to perform the operation before you apply any changes. The *ValidateOnly* switch is available on cmdlets that may take a long time to run, have several dependencies on multiple systems, or affect critical data, such as mailboxes.

When you apply the *ValidateOnly* switch to a command, the command runs through the whole process. The command performs each action as it would without the *ValidateOnly* switch. But the command doesn't change any objects. When the command completes its process, it displays a summary with the results of the validation. If the validation indicates that the command was successful, you can run the command again without the *ValidateOnly* switch.

When you run a command together with the *ValidateOnly* switch, you put the *ValidateOnly* switch at the end of the command, as in the following example:

```
Get-Mailbox "Kim Akers" | Move-Mailbox -TargetDatabase "Executive Database" -Vali
```

When you run this example command, the following text is returned by the Shell:

```
Identity                          : contoso.com/Users/Kim Akers
DistinguishedName                 : CN=Kim Akers,CN=Users,DC=contoso,DC=com
DisplayName                       : Kim Akers

Exchange Management Shell Basics

1.5.2.9 Modifying Multivalued Properties

Modifying Multivalued Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Shell to add values to and remove values from a multivalued property on an object.

Multivalued Property Overview

A multivalued property is a property that can contain more than one value. For example, the **BlockedRecipients** property on the **RecipientFilterConfig** object can accept multiple recipient addresses as in the following examples:

- john@contoso.com
- kim@northwindtraders.com
- david@adatum.com

Because the **BlockedRecipients** property can accept more than one value, it's called a multivalued property.

For more information about objects, see Structured Data.

Modifying a Multivalued Property vs. Modifying a Property That Accepts Only a Single Value

How you modify a multivalued property is slightly different from how you modify a property that accepts only one value. When you modify a property that accepts only a single value, you can assign a value directly to it, as in the following command.

```
Set-TransportConfig -MaxSendSize 12MB
```

When you use this command to provide a new value to the **MaxSendSize** property, the stored value is overwritten. This isn't a problem with properties that accept only one value. However, it becomes a problem with multivalued properties. For example, assume that the **BlockedRecipients** property on the **RecipientFilterConfig** object is configured to have the three values that are listed in the previous section. When you run the command `Get-RecipientFilterConfig | Format-List BlockedRecipients`, the following is displayed.

```
BlockedRecipients : {david@adatum.com, kim@northwindtraders.com, john@contoso.com
```

Now assume that you've received a request to add a new SMTP address to the blocked recipients list. You run the following command to add the new SMTP address.

```
Set-RecipientFilterConfig -BlockedRecipients chris@contoso.com
```

When you run the `Get-RecipientFilterConfig | Format-List BlockedRecipients` command again, you will see the following.

```
BlockedRecipients : {chris@contoso.com}
```

This isn't what you expected. You wanted to add the new SMTP address to the existing list of blocked recipients, but instead the existing list of blocked recipients was overwritten by the new SMTP address. This unintended result exemplifies how modifying a multivalued property differs from modifying a property that accepts only a single value. When you modify a multivalued property, you must make sure that you append or remove values instead of overwriting the whole list of values. The following sections show you how to do exactly that.

Note:

Some cmdlets, such as **Set-TransportRule**, don't support modifying properties on objects in the manner described in this topic. For more information about how to add values to and remove values from the multivalued properties of these cmdlets, see the topics for those cmdlets, such as Set-TransportRule.

Modifying Multivalued Properties

Modifying multivalued properties is similar to modifying single-valued properties. You just need to add some additional syntax to tell the Shell that you want to add or remove values to or from the multivalued property rather than replace everything that's stored in the property. The syntax is included, along with the value or values to add or remove to or from the property, as a value on a parameter when you run a cmdlet. The following table shows the syntax that you need to add to a parameter on a cmdlet to modify multivalued properties.

Multivalue property syntax

Action	Syntax
Add one or more values to a multivalued property	`@{Add="<value1>", "<value2>", "<value3>"}`
Remove one or more values from a multivalued property	`@{Remove="<value1>", "<value2>", "<value3>"}`

The syntax that you choose from the Multivalue property syntax table is specified as a

parameter value on a cmdlet. For example, the following command adds multiple values to a multivalued property:

```
Set-ExampleCmdlet -Parameter @{Add="Red", "Blue", "Green"}
```

When you use this syntax, the values that you specify are added or removed from the list of values already present on the property. Taking the **BlockedRecipients** example earlier in this topic, we can now add chris@contoso.com without overwriting the rest of the values on this property by using the following command:

```
Set-RecipientFilterConfig -BlockedRecipients @{Add="chris@contoso.com"}
```

If you wanted to remove david@adatum.com from the list of values, you would use this command:

```
Set-RecipientFilterConfig -BlockedRecipients @{Remove="david@adatum.com"}
```

More complex combinations can be used, such as adding or removing values to and from a property at the same time. To do so, insert a semicolon (`;`) between `Add` and `Remove` actions. For example:

```
Set-RecipientFilterConfig -BlockedRecipients @{Add="carter@contoso.com", "sam@nor
```

If we use the `Get-RecipientFilterConfig | Format-List BlockedRecipients` command again, we can see that the email addresses for Carter, Sam, and Brian have been added while the address for John has been removed.

```
BlockedRecipients : {brian@adatum.com, sam@northwindtraders.com, carter@contoso.c
```

1.5.2.10 Working with Command Output

Working with Command Output

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

The Exchange Management Shell offers several methods that you can use to format command output. This topic discusses the following subjects:

- How to format data Control how the data that you see is formatted by using the **Format-List**, **Format-Table**, and **Format-Wide** cmdlets.
- How to output data Determine whether data is output to the Shell console window or to a file by using the **Out-Host** and **Out-File** cmdlets. Included in this topic is a sample script to output data to Microsoft Internet Explorer.
- How to filter data Filter data by using either of the following filtering methods:
  - Server-side filtering, available on certain cmdlets
  - Client-side filtering, available on all cmdlets by piping the results of a command to the **Where-Object** cmdlet

To use the functionality that is described in this topic, you must be familiar with the following concepts:

- Pipelining
- Shell Variables
- Comparison Operators

How to Format Data

If you call formatting cmdlets at the end of the pipeline, you can override the default formatting to control what data is displayed and how that data appears. The formatting cmdlets are **Format-List**, **Format-Table**, and **Format-Wide**. Each has its own distinct output style that differs from the other formatting cmdlets.

Format-List

The **Format-List** cmdlet takes input from the pipeline and outputs a vertical columned list of all the specified properties of each object. You can specify which properties you want to display by using the *Property* parameter. If the **Format-List** cmdlet is called without any parameters specified, all properties are output. The **Format-List** cmdlet wraps lines instead of truncating them. One of the best uses for the **Format-List** cmdlet is to override the default output of a cmdlet so that you can retrieve additional or more focused information.

For example, when you call the **Get-Mailbox** cmdlet, you only see a limited amount of information in table format. If you pipe the output of the **Get-Mailbox** cmdlet to the **Format-List** cmdlet and add parameters for the additional or more focused information that you want to view, you can retrieve the output that you want.

You can also specify a wildcard character "*" with a partial property name. If you include a wildcard character, you can match multiple properties without having to type each property name individually. For example, `Get-Mailbox | Format-List -Property Email*` returns all properties that begin with `Email`.

The following examples show the different ways that you can view the same data returned by the **Get-Mailbox** cmdlet.

```
Get-MailBox TestUser1
Name                    Alias                ServerName       ProhibitSendQuo
                                                              ta
----                    -----                ----------       ---------------
TestUser1               TestUser1            mbx              unlimited
```

In the first example, the **Get-Mailbox** cmdlet is called without specific formatting so the default output is in table format and contains a predetermined set of properties.

```
Get-Mailbox TestUser1 | Format-List -Property Name,Alias,EmailAddresses
Name           : TestUser1
Alias          : TestUser1
EmailAddresses : {SMTP:TestUser1@contoso.com}
```

In the second example, the output of the **Get-Mailbox** cmdlet is piped to the **Format-List** cmdlet, together with specific properties. As you can see, the format and content of the output is significantly different.

```
Get-Mailbox TestUser1 | Format-List -Property Name, Alias, Email*
Name                       : Test User
Alias                      : TestUser1
EmailAddresses             : {SMTP:TestUser1@contoso.com}
EmailAddressPolicyEnabled : True
```

In the last example, the output of the **Get-Mailbox** cmdlet is piped to the **Format-List** cmdlet as in the second example. However, in the last example, a wildcard character is used to match all properties that start with `Email`.

If more than one object is passed to the **Format-List** cmdlet, all specified properties for an object are displayed and grouped by object. The display order depends on the default parameter for the cmdlet. The default parameter is most frequently the *Name* parameter or the *Identity* parameter. For example, when the **Get-Childitem** cmdlet is called, the

default display order is file names in alphabetical order. To change this behavior, you must call the **Format-List** cmdlet, together with the *GroupBy* parameter, and the name of a property value by which you want to group the output. For example, the following command lists all files in a directory and then groups these files by extension.

```
Get-Childitem | Format-List Name,Length -GroupBy Extension
    Extension: .xml
Name   : Config_01.xml
Length : 5627
Name   : Config_02.xml
Length : 3901
    Extension: .bmp
Name   : Image_01.bmp
Length : 746550
Name   : Image_02.bmp
Length : 746550
    Extension: .txt
Name   : Text_01.txt
Length : 16822
Name   : Text_02.txt
Length : 9835
```

In this example, the **Format-List** cmdlet has grouped the items by the *Extension* property that is specified by the *GroupBy* parameter. You can use the *GroupBy* parameter with any valid property for the objects in the pipeline stream.

Format-Table

The **Format-Table** cmdlet lets you display items in a table format with label headers and columns of property data. By default, many cmdlets, such as the **Get-Process** and **Get-Service** cmdlets, use the table format for output. Parameters for the **Format-Table** cmdlet include the *Properties* and *GroupBy* parameters. These parameters work exactly as they do with **Format-List** cmdlet.

The **Format-Table** cmdlet also uses the *Wrap* parameter. This parameter enables long lines of property information to display completely instead of truncating at the end of a line. To see how the *Wrap* parameter is used to display returned information, compare the output of the **Get-Command** command in the following two examples.

In the first example, when the **Get-Command** cmdlet is used to display command information about the **Get-Process** cmdlet, the information for the *Definition* property is truncated.

```
Get-Command Get-Process | Format-Table Name,Definition
Name                                Definition
----                                ----------
get-process                         get-process [[-ProcessName] String[]...
```

In the second example, the *Wrap* parameter is added to the command to force the complete contents of the *Definition* property to display.

```
Get-Command Get-Process | Format-Table Name,Definition -Wrap
Get-Process                         Get-Process [[-Name] <String[]>] [-Comp
                                    uterName <String[]>] [-Module] [-FileVe
                                    rsionInfo] [-Verbose] [-Debug] [-ErrorA
                                    ction <ActionPreference>] [-WarningActi
                                    on <ActionPreference>] [-ErrorVariable
                                    <String>] [-WarningVariable <String>] [
                                    -OutVariable <String>] [-OutBuffer <Int
                                    32>]
                                    Get-Process -Id <Int32[]> [-ComputerNam
                                    e <String[]>] [-Module] [-FileVersionIn
                                    fo] [-Verbose] [-Debug] [-ErrorAction <
                                    ActionPreference>] [-WarningAction <Act
                                    ionPreference>] [-ErrorVariable <String
                                    >] [-WarningVariable <String>] [-OutVar
```

```
                                        iable <String>] [-OutBuffer <Int32>]
                                        Get-Process [-ComputerName <String[]>]
                                        [-Module] [-FileVersionInfo] -InputObje
                                        ct <Process[]> [-Verbose] [-Debug] [-Er
                                        rorAction <ActionPreference>] [-Warning
                                        Action <ActionPreference>] [-ErrorVaria
                                        ble <String>] [-WarningVariable <String
                                        >] [-OutVariable <String>] [-OutBuffer
                                        <Int32>]
```

As with the **Format-List** cmdlet, you can also specify a wildcard character "*" with a partial property name. By including a wildcard character, you can match multiple properties without typing each property name individually.

Format-Wide

The **Format-Wide** cmdlet provides a much simpler output control than the other format cmdlets. By default, the **Format-Wide** cmdlet tries to display as many columns of property values as possible on a line of output. By adding parameters, you can control the number of columns and how the output space is used.

In the most basic usage, calling the **Format-Wide** cmdlet without any parameters arranges the output in as many columns as will fit the page. For example, if you run the **Get-Childitem** cmdlet and pipe its output to the **Format-Wide** cmdlet, you will see the following display of information:

```
Get-ChildItem | Format-Wide
    Directory: FileSystem::C:\WorkingFolder
Config_01.xml                           Config_02.xml
Config_03.xml                           Config_04.xml
Config_05.xml                           Config_06.xml
Config_07.xml                           Config_08.xml
Config_09.xml                           Image_01.bmp
Image_02.bmp                            Image_03.bmp
Image_04.bmp                            Image_05.bmp
Image_06.bmp                            Text_01.txt
Text_02.txt                             Text_03.txt
Text_04.txt                             Text_05.txt
Text_06.txt                             Text_07.txt
Text_08.txt                             Text_09.txt
Text_10.txt                             Text_11.txt
Text_12.txt
```

Generally, calling the **Get-Childitem** cmdlet without any parameters displays the names of all files in the directory in a table of properties. In this example, by piping the output of the **Get-Childitem** cmdlet to the **Format-Wide** cmdlet, the output was displayed in two columns of names. Notice that only one property type can be displayed at a time, specified by a property name that follows the **Format-Wide** cmdlet. If you add the *Autosize* parameter, the output is changed from two columns to as many as can fit the screen width.

```
Get-ChildItem | Format-Wide -AutoSize
    Directory: FileSystem::C:\WorkingFolder
Config_01.xml   Config_02.xml   Config_03.xml   Config_04.xml   Config_05.xml
Config_06.xml   Config_07.xml   Config_08.xml   Config_09.xml   Image_01.bmp
Image_02.bmp    Image_03.bmp    Image_04.bmp    Image_05.bmp    Image_06.bmp
Text_01.txt     Text_02.txt     Text_03.txt     Text_04.txt     Text_05.txt
Text_06.txt     Text_07.txt     Text_08.txt     Text_09.txt     Text_10.txt
Text_11.txt     Text_12.txt
```

In this example, the table is arranged in five columns, instead of two columns. The *Column* parameter offers more control by letting you specify the maximum number of columns to display information as follows:

```
Get-ChildItem | Format-Wide -Column 4
    Directory: FileSystem::C:\WorkingFolder
```

```
Config_01.xml       Config_02.xml       Config_03.xml       Config_04.xml
Config_05.xml       Config_06.xml       Config_07.xml       Config_08.xml
Config_09.xml       Image_01.bmp        Image_02.bmp        Image_03.bmp
Image_04.bmp        Image_05.bmp        Image_06.bmp        Text_01.txt
Text_02.txt         Text_03.txt         Text_04.txt         Text_05.txt
Text_06.txt         Text_07.txt         Text_08.txt         Text_09.txt
Text_10.txt         Text_11.txt         Text_12.txt
```

In this example, the number of columns is forced to four by using the *Column* parameter.

How to Output Data

Out-Host and Out-File

The **Out-Host** cmdlet is an unseen default cmdlet at the end of the pipeline. After all formatting is applied, the **Out-Host** cmdlet sends the final output to the console window for display. You don't have to explicitly call the **Out-Host** cmdlet, because it is the default output. You can override sending the output to the console window by calling the **Out-File** cmdlet as the last cmdlet in the command. The **Out-File** cmdlet then writes the output to the file that you specify in the command as in the following example:

```
Get-ChildItem | Format-Wide -Column 4 | Out-File c:\OutputFile.txt
```

In this example, the **Out-File** cmdlet writes the information that is displayed in the **Get-ChildItem | Format-Wide -Column 4** command to a file that is named `OutputFile.txt`. You can also redirect pipeline output to a file by using the redirection operator, which is the right-angle bracket (>). To append pipeline output of a command to an existing file without replacing the original file, use the double right-angle brackets (>>), as in the following example:

```
Get-ChildItem | Format-Wide -Column 4 >> C:\OutputFile.txt
```

In this example, the output from the **Get-Childitem** cmdlet is piped to the **Format-Wide** cmdlet for formatting and then is written to the end of the `OutputFile.txt` file. Notice that if the `OutputFile.txt` file did not exist, use of the double right-angle brackets (>>) would create the file.

For more information about pipelines, see Pipelining.

For more information about the syntax used in the previous examples, see Syntax.

Viewing Data in Internet Explorer

Because of the flexibility and ease of scripting in the Exchange Management Shell, you can take the data that is returned by commands and format and output them in almost limitless ways.

The following example shows how you can use a simple script to output the data that is returned by a command and display it in Internet Explorer. This script takes the objects that are passed through the pipeline, opens an Internet Explorer window, and then displays the data in Internet Explorer:

```
$Ie = New-Object -Com InternetExplorer.Application
$Ie.Navigate("about:blank")
while ($Ie.Busy) { Sleep 1 }
$Ie.Visible = $True
$Ie.Document.Write("$Input")
# If the previous line doesn't work on your system, uncomment the line below.
# $Ie.Document.IHtmlDocument2_Write("$Input")
$Ie
```

To use this script, save it to the `C:\Program Files\Microsoft\Exchange Server`

\V14\Scripts directory on the computer where the script will be run. Name the file Out-Ie.ps1. After you save the file, you can then use the script as a regular cmdlet.

Note:
To run scripts in Exchange 2010, scripts must be added to an unscoped management role and you must be assigned the management role either directly or through a management role group. For more information, see Understanding Management Roles.

The Out-Ie script assumes that the data it receives is valid HTML. To convert the data that you want to view into HTML, you must pipe the results of your command to the **ConvertTo-Html** cmdlet. You can then pipe the results of that command to the Out-Ie script. The following example shows how to view a directory listing in an Internet Explorer window:

```
Get-ChildItem | Select Name,Length | ConvertTo-Html | Out-Ie
```

How to Filter Data

The Shell gives you access to a large quantity of information about your servers, mailboxes, Active Directory directory service, and other objects in your organization. Although access to this information helps you better understand your environment, this large quantity of information can be overwhelming. The Shell lets you control this information and return only the data that you want to see by using filtering. The following two types of filtering are available:

- **Server-side filtering** Server-side filtering takes the filter that you specify on the command line and submits it to the Exchange server that you query. That server processes the query and returns only the data that matches the filter that you specified.
  Server-side filtering is performed only on objects where tens or hundreds of thousands of results could be returned. Therefore, only the recipient management cmdlets, such as the **Get-Mailbox** cmdlet, and queue management cmdlets, such as the **Get-Queue** cmdlet, support server-side filtering. These cmdlets support the *Filter* parameter. This parameter takes the filter expression that you specify and submits it to the server for processing.
- **Client-side filtering** Client-side filtering is performed on the objects in the local console window in which you are currently working. When you use client-side filtering, the cmdlet retrieves all the objects that match the task that you are performing to the local console window. The Shell then takes all the returned results, applies the client-side filter to those results, and returns to you only the results that match your filter. All cmdlets support client-side filtering. This is invoked by piping the results of a command to the **Where-Object** cmdlet.

Server-Side Filtering

The implementation of server-side filtering is specific to the cmdlet on which it is supported. Server-side filtering is enabled only on specific properties on the objects that are returned.

For more information about how to manage recipients by using server-side filtering, see Creating Filters in Recipient Commands. For more information about how to manage queues by using server-side filtering, see Filter Queues.

Client-Side Filtering

Client-side filtering can be used with any cmdlet. This capability includes those cmdlets that also support server-side filtering. As described earlier in this topic, client-side filtering accepts all the data that is returned by a previous command in the pipeline, and in turn, returns only the results that match the filter that you specify. The **Where-Object** cmdlet performs this filtering. It can be shortened to **Where**.

As data passes through the pipeline, the **Where** cmdlet receives the data from the previous object and then filters the data before passing it on to the next object. The filtering is based on a script block that is defined in the **Where** command. The script block filters data based on the object's properties and values.

The **Clear-Host** cmdlet is used to clear the console window. In this example, you can find all the defined aliases for the **Clear-Host** cmdlet if you run the following command:

```
Get-Alias | Where {$_.Definition -eq "Clear-Host"}
CommandType     Name                            Definition
-----------     ----                            ----------
Alias           clear                           clear-host
Alias           cls                             clear-host
```

The **Get-Alias** cmdlet and the **Where** command work together to return the list of aliases that are defined for the **Clear-Host** cmdlet and no other cmdlets. The following table outlines each element of the **Where** command that is used in the example.

Elements of the Where command

Element	Description
`{ }`	Braces enclose the script block that defines the filter.
`$_`	This special variable automatically initiates and binds to the objects in the pipeline.
`Definition`	The `Definition` property is the property of the current pipeline objects that stores the name of the alias definition. When `Definition` is used with the `$_` variable, a period comes before the property name.
`-eq`	This comparison operator for "equal to" is used to specify that the results must exactly match the property value that is supplied in the expression.
"**Clear-Host**"	In this example, "**Clear-Host**" is the value for which the command is parsing.

In the example, the objects that are returned by the **Get-Alias** cmdlet represent all the defined aliases on the system. Even though you don't see them from the command line, the aliases are collected and passed to the **Where** cmdlet through the pipeline. The **Where** cmdlet uses the information in the script block to apply a filter to the alias objects.

The special variable $_represents the objects that are being passed. The $_variable is automatically initiated by the Shell and is bound to the current pipeline object. For more information about this special variable, see Shell Variables.

Using standard "dot" notation (object.property), the `Definition` property is added to define the exact property of the object to evaluate. The `-eq` comparison operator then compares the value of this property to `"Clear-Host"`. Only the objects that have the `Definition` property that match this criterion are passed to the console window for output. For more information about comparison operators, see Comparison Operators.

After the **Where** command has filtered the objects returned by the **Get-Alias** cmdlet, you can pipe the filtered objects to another command. The next command processes only the filtered objects returned by the Where command.

Exchange Management Shell Basics

1.5.2.11 Comparison Operators

Comparison Operators

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-27*

The Exchange Management Shell has a rich set of operators that enables comparisons of one object with another object or one object with a set of objects. For more information about comparison operators, run the following command in the Shell:

```
Get-Help About_Comparison_Operators
```

The following table lists the comparison operators that are available in the Shell. Some comparison operators are case-sensitive. If a comparison operator is case-sensitive, the case that is used in the strings that are being compared must match. For example, the string "Test" does not match "test" when you use a comparison operator that is case-sensitive.

Comparison operators that are available in the Exchange Management Shell

Operator	Definition
-eq	Equals (not case-sensitive)
-ieq	Equals (not case-sensitive)
-ceq	Equals (case-sensitive)
-ne	Not equal (not case-sensitive)
-ine	Not equal (not case-sensitive)
-cne	Not equal (case-sensitive)
-lt	Less than (not case-sensitive)
-ilt	Less than (not case-sensitive)
-clt	Less than (case-sensitive)
-gt	Greater than (not case-sensitive)
-igt	Greater than (not case-sensitive)
-cgt	Greater than (case-sensitive)
-le	Less than or equal to (not case-sensitive)
-ile	Less than or equal to (not case-sensitive)
-cle	Less than or equal to (case-sensitive)

-ge	Greater than or equal to (not case-sensitive)
-ige	Greater than or equal to (not case-sensitive)
-cge	Greater than or equal to (case-sensitive)
-contains	The elements in the left operand that is equal to the right operand (not case-sensitive)
-icontains	The elements in the left operand that is equal to the right operand (not case-sensitive)
-ccontains	The elements in the left operand that is equal to the right operand (case-sensitive)
-notcontains	The elements in the left operand that is equal to the right operand (not case-sensitive)
-inotcontains	The elements in the left operand that is equal to the right operand (not case-sensitive)
-cnotcontains	The elements in the left operand that is equal to the right operand (case-sensitive)
-band	Bitwise And
-bor	Bitwise Or
-bnot	Bitwise NOT
-and	Logical and
-or	Logical or
-not	Logical not
-match	Compare strings by using regular expressions (not case-sensitive)
-notmatch	Compare strings by using regular expressions (not case-sensitive)
-imatch	Compare strings by using regular expressions (not case-sensitive)
-inotmatch	Compare strings by using regular expressions (not case-sensitive)
-cmatch	Compare strings by using regular expressions (case-sensitive)
-cnotmatch	Compare strings by using regular expressions (case-sensitive)
-like	Compare strings by using wildcard rules
-notlike	Compare strings by using wildcard rules

-ilike	Compare strings by using wildcard rules (not case-sensitive)
-inotlike	Compare strings by using wildcard rules (not case-sensitive)
-clike	Compare strings by using wildcard rules (case-sensitive)
-cnotlike	Compare strings by using wildcard rules (case-sensitive)

For More Information

Exchange Management Shell Basics

1.5.2.12 Aliases

Aliases

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-19*

You can assign an Exchange Management Shell cmdlet or Cmd.exe command to an administrator-defined and easy-to-remember alias in Microsoft Exchange Server 2010. Such aliases can be handy when you frequently use certain cmdlets and want to reduce the typing that you must do.

When an alias is called from the command line, the rules that apply to the cmdlet that is represented by the alias are enforced exactly as when the cmdlet is called. You must supply any required parameters and their values exactly as if you had called the cmdlet name.

See the following sections for more information about using aliases in the Shell:

Built-in Aliases

Creating Custom Aliases

Removing an Alias

Importing and Exporting Aliases

Alias Persistence

Alias Limitations

Built-in Aliases

Many cmdlets that are used regularly have default, or built-in, aliases assigned to them. These built-in aliases help reduce the typing that you have to do when you administer Exchange 2010 by using the Shell.

For example, the **Get-ChildItem** cmdlet resembles the MS-DOS `Dir` command. Because you are familiar with the `Dir` command, you might want to use the `Dir` alias when you use the Shell instead of typing **Get-ChildItem** every time that you want to view the contents of a directory. The output from the **Get-ChildItem** cmdlet and the `Dir` alias is the same and can be used interchangeably.

The following table shows the built-in aliases and their full names.

Built-in aliases

Alias	Cmdlet	Alias	Cmdlet	Alias	Cmdlet
%	ForEach-Object	gdr	Get-PSDrive	popd	Pop-Location
?	Where-Object	ghy	Get-History	ps	Get-Process
ac	Add-Content	gi	Get-Item	pushd	Push-Location
asnp	Add-PSSnapIn	gjb	Get-Job	pwd	Get-Location
cat	Get-Content	gl	Get-Location	r	Invoke-History
cd	Set-Location	gm	Get-Member	rbp	Remove-PSBreakpoint
chdir	Set-Location	gmo	Get-Module	rcjb	Receive-Job
clc	Clear-Content	gp	Get-ItemProperty	rd	Remove-Item
clear	Clear-Host	gps	Get-Process	rdr	Remove-PSDrive
clhy	Clear-History	grid	Out-GridView	ren	Rename-Item
cli	Clear-Item	group	Group-Object	ri	Remove-Item
clp	Clear-ItemProperty	gsn	Get-PSSession	rjb	Remove-Job
cls	Clear-Host	gsnp	Get-PSSnapIn	rm	Remove-Item
clv	Clear-Variable	gsv	Get-Service	rmdir	Remove-Item
compare	Compare-Object	gu	Get-Unique	rni	Rename-Item
copy	Copy-Item	gv	Get-Variable	rnp	Rename-ItemProperty
cp	Copy-Item	gwmi	Get-WmiObject	rp	Remove-ItemProperty
cpi	Copy-Item	h	Get-History	rsn	Remove-PSSession
cpp	Copy-	history	Get-History	rsnp	Remove-

	ItemProperty				PSSnapin
cvpa	Convert-Path	icm	Invoke-Command	rv	Remove-Variable
dbp	Disable-PSBreakpoint	iex	Invoke-Expression	rvpa	Resolve-Path
del	Remove-Item	ihy	Invoke-History	rwmi	Remove-WMIObject
diff	Compare-Object	ii	Invoke-Item	sajb	Start-Job
dir	Get-ChildItem	imo	Import-Module	sal	Set-Alias
ebp	Enable-PSBreakpoint	ipal	Import-Alias	sasv	Start-Service
echo	Write-Output	ipcsv	Import-Csv	sbp	Set-PSBreakpoint
emm	Export-ModuleMember	IPSN	Import-PSSession	sc	Set-Content
epal	Export-Alias	iwmi	Invoke-WMIMethod	select	Select-Object
epcsv	Export-Csv	kill	Stop-Process	set	Set-Variable
EPSN	Export-PSSession	list	format-list	si	Set-Item
erase	Remove-Item	lp	Out-Printer	sl	Set-Location
ETSN	Enter-PSSession	ls	Get-ChildItem	sleep	Start-Sleep
EXSN	Exit-PSSession	man	help	sort	Sort-Object

ft	Format-Table	mount	New-PSDrive	spsv	Stop-Service
fw	Format-Wide	move	Move-Item	start	Start-Process
gal	Get-Alias	mp	Move-ItemProperty	sv	Set-Variable
gbp	Get-PSBreakpoint	mv	Move-Item	swmi	Set-WMIInstance
gc	Get-Content	nal	New-Alias	table	format-table

gci	**Get-ChildItem**	**ndr**	**New-PSDrive**	**tee**	**Tee-Object**
gcm	**Get-Command**	**ni**	**New-Item**	**type**	**Get-Content**
gcs	**Get-PSCallStack**	**nmo**	**New-Module**	**where**	**Where-Object**
nv	**New-Variable**	**nsn**	**New-PSSession**	**wjb**	**Wait-Job**
ogv	**Out-GridView**	**oh**	**Out-Host**	**write**	**Write-Output**

For more information about aliases, run the following command in the Shell:

```
Get-Help About_Alias
```

Return to top

Creating Custom Aliases

In addition to the default, or built-in, aliases, you can define and use custom aliases instead of the names of cmdlets that you frequently use. You can use the **Set-Alias** cmdlet to associate cmdlets to familiar command names that have the equivalent functionality in Cmd.exe. You can assign multiple aliases to a single command. However, each alias can only be assigned to a single command. For example, you can have three aliases `Alias1`, `Alias2`, and `Alias3` that are assigned to the **New-Mailbox** cmdlet. You could then use any of the three aliases to run the **New-Mailbox** cmdlet. However, each alias that you create can only be assigned to the **New-Mailbox** cmdlet. You can't, for example, assign `Alias1` to both the **New-Mailbox** cmdlet and the **Get-Mailbox** cmdlet.

To create a new alias-cmdlet pairing, run the **Set-Alias** cmdlet and supply the name of the alias, together with the name of the cmdlet that you want to call when the alias is entered.

The following table shows several examples of how to create a new alias.

Examples of custom aliases

Alias description	Alias command
Retrieve the contents of a file.	`Set-Alias Type Get-Content`
Retrieve the listing of a directory.	`Set-Alias Dir Get-ChildItem`
Remo	`Set-Alias Erase Remove-Item`

ve a file.	
Set **pad** as an alias for Microsoft Word Pad.	`Set-Alias Pad "${env:programfiles}\Windows NT\Accessories\wordpad.exe"`
Display the list of all defined aliases.	`Set-Alias Aliases Get-Alias`

Return to top

Removing an Alias

To remove an alias, delete the alias from the alias drive. For example, an administrator creates the `Ls` alias by using the following command:

```
Set-Alias Ls Get-ChildItem
```

Later the administrator decides that the `Ls` alias is no longer needed and uses the following command to remove the `Ls` alias:

```
Remove-Item Alias Ls
```

Importing and Exporting Aliases

The **Export-Alias** cmdlet writes the current alias list to a file in comma-separated values (CSV) format. You can include the name of the file and its path in the command line. If the path doesn't exist, the cmdlet will create the path for you.

The **Import-Alias** cmdlet reads a text file that has CSV values and brings the list into the Shell as an object. By using the **Export-Alias** cmdlet and **Import-Alias** cmdlet, you can export a list of aliases from the Shell on one computer and import them to the Shell on another computer. Because existing predefined aliases exist on both computers, all alias name conflicts will be ignored and not imported.

Alias Persistence

Aliases that are created from the command line by using the **Set-Alias** cmdlet during a Shell session can be used when the session is active. After the session is closed, the alias definition is lost. To make a user-defined alias persistent and available every time that a new Shell session is opened, you must add the alias definition to your Shell profile. You can modify your Shell profile by running the command `Notepad $Profile`. If the profile directory doesn't exist, you might have to create it first. To find out the path of your

profile, run the command `$Profile`.

Alias Limitations

Although aliases can be defined for cmdlets and used instead of cmdlet names, you can't include parameters in the definition of the aliases that you define. You must provide parameters as needed when the alias is called, exactly as you would if you called the cmdlet.

Exchange Management Shell Basics

1.5.2.13 User-Defined Variables

User-Defined Variables

Exchange Server 2010 > Exchange Management Shell > Exchange Management Shell Basics >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-27*

A variable is a location to store information. Unlike in many programming environments, in the Exchange Management Shell, you don't have to declare a variable before you use it.

You designate a variable by prepending a string with a dollar sign ($). You must enclose the string in braces ({ }) if the string contains spaces or other special characters. By using the array reference notation ([ ]), you can address the elements of an array or hash table variable. For more information, see Arrays.

See the following sections for more information about user-defined variables in the Shell:

Using Variables to Store Values

Storing the Output of a Command in a Variable

Storing the Output of the Dir Command in a Variable

Using Variables to Store Values

Variables are very useful if you want to store a value. You can assign values to variables by using an assignment operator. For more information about operators, see Syntax.

For example, to assign a value of 8 to the variable `$Example`, use the following command:

```
$Example = 8
```

This command assigns the integer 8 to the variable `$Example`. You can then call the `$Example` variable later in another command to recall the value. The values that are specified in a variable are treated exactly as if the value that it contains was typed in the location that the variable is specified. For example, the following two commands are equivalent if `$Example2` is assigned the value `"Hello"`:

```
Write-Host $Example2
Write-Host "Hello"
```

Storing the Output of a Command in a Variable

You can also store the output of commands in a variable for later use. When you assign a command to a variable, the command is evaluated at the time that command is run. The output of that command is assigned to the variable. For example, if you run `$CurrentDate = Get-Date` on the command line and then call `$CurrentDate` repeatedly over several seconds, the value that is reported is the same every time that the variable is called.

When you assign the output of a command to a variable, you can also access the properties and methods of the underlying object. For example, to view the properties and methods that are available when you assign `Get-Date` to `$CurrentDate`, you can use the `$CurrentDate | Get-Member` command. When you use the `$CurrentDate | Get-Member -MemberType Property` command, the following properties are returned in a list:

```
Name        MemberType Definition
----        ---------- ----------
Date        Property   System.DateTime Date {get;}
Day         Property   System.Int32 Day {get;}
DayOfWeek   Property   System.DayOfWeek DayOfWeek {get;}
DayOfYear   Property   System.Int32 DayOfYear {get;}
Hour        Property   System.Int32 Hour {get;}
Kind        Property   System.DateTimeKind Kind {get;}
Millisecond Property   System.Int32 Millisecond {get;}
Minute      Property   System.Int32 Minute {get;}
Month       Property   System.Int32 Month {get;}
Second      Property   System.Int32 Second {get;}
Ticks       Property   System.Int64 Ticks {get;}
TimeOfDay   Property   System.TimeSpan TimeOfDay {get;}
Year        Property   System.Int32 Year {get;}
```

You can then call any of these properties by typing the variable, a period (`.`), and then the property that you want to view. For example, to view the year that is stored on a variable, use the following command:

```
$CurrentDate.Year
```

By accessing the properties of a variable, you can easily manipulate and use each piece of information that is stored in the variable without the use of text parsing.

Storing the Output of the Dir Command in a Variable

You can also store the output of the `Dir` command in a variable. Because the `Dir` command returns multiple rows when it runs, each row that is returned is stored in a variable as a new array element. You can then access each file object that is stored in the newly created array. For more information about arrays, see Arrays.

The following command assigns the output of the `Dir` command to the `$DirOutput` variable:

```
$DirOutput = Dir
```

You can then select a specific file object by specifying the array index that you want to

view as follows:

```
$DirOutput[1].Name
```

Or you can create a simple loop that cycles through the whole array and displays the name and file size of each file that is stored in the array as follows:

```
0..$DirOutput.Length | ForEach { $DirOutput[$_].Name + " is " + $DirOutput[$_].Le
```

The following list examines this example:

- The `0..$DirOutput.Length` command instructs the Shell to output an integer from 0 to the maximum length of the array that is stored in the `$DirOutput` variable.
- The output of the `0..$DirOutput.Length` command is piped to the `ForEach` command that loops through each element of the array until it reaches the end of the array. The `ForEach` command runs the commands that are enclosed in the braces " { } ".
- The $_ variable stores the current object that is in the pipeline. In this case, the object in the pipeline is an integer that is produced by the `0..$DirOutput.Length` command as it counts from 0 to the maximum length of the array. This variable is used in the `$DirOutput[$_].Name` command and `$DirOutput[$_].Length` command to select the array element to access.
- For more information about the $_ variable, see Shell Variables.
- The plus " + " signs concatenate the output of the `$DirOutput[$_].Name` command and `$DirOutput[$_].Length` command, together with the strings supplied, to create output similar to the following:

```
abv_dg.dll is 416144 bytes long.
addxa.dll is 285056 bytes long.
ASDat.MSI is 5626880 bytes long.
ASEntDat.MSI is 5626880 bytes long.
ASEntIRS.MSI is 910336 bytes long.
ASEntSig.MSI is 45056 bytes long.
BPA.Common.dll is 211848 bytes long.
BPA.ConfigCollector.dll is 101272 bytes long.
BPA.NetworkCollector.dll is 52128 bytes long.
```

These examples show that you can use the `Length` property more than one time to display different information about the same variable. You can do this because more than one type of data is stored in the `$DirOutput` variable. The first type of data is the directory object itself, and the second type of data is the file objects. When you run the `$DirObject.Length` command, without specifying an array index, you're accessing the directory parent object types that are stored in the array. When you specify an array index, such as `$DirObject[5].Length`, you're accessing the file child objects that are stored in the directory object.

This behavior exists on many objects. You can typically access many levels of object data that are contained in a single variable. The ability to access this data makes the Shell quite flexible.

For More Information

Exchange Management Shell Basics

1.5.2.14 Shell Variables

Shell Variables

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-16*

Shell variables are a set of variables that are created and declared automatically by the Exchange Management Shell. The variables are maintained throughout your session as part of the system state and are available to all commands, scripts, and applications that run in that session.

The Shell supports two types of shell variables:

- Automatic variables provide a mechanism for passing information to and from commands, scripts, and applications.
- Policy variables store information about the state of the Shell.

You can use shell variables as you would use any other type of variable. For example, the `$PSHome` shell variable stores the name of the directory where the Shell is installed, and the `$_` shell variable stores the current pipeline object. You can use these variables in a command to specify the location of the file and to call a property of the `Get-ChildItem` object, as shown in the following example:

```
Get-ChildItem $PSHome | Sort {$_.Name}
```

This command retrieves all items from the Shell installation directory, and it uses the name property of the object that is stored in the `$_` variable to sort the data when it is displayed.

Common Shell Variables

The following table lists several common automatic variables that are available for your use in the Shell.

Common automatic variables

Automatic variable	Description
`$$`	Contains the last token of the last line that is received by the Shell.
`$?`	Contains the success or fail status of the last operation.
`$^`	Contains the first token of the last line that is received by the Shell.
`$_`	Contains the current pipeline object that is used in script blocks, filters, and the `Where` statement.
`$Error`	Contains objects for which an error occurred when they are processed in a cmdlet.
`$ExBin`	Displays the full path of the Exchange Server\bin directory. This variable is only available if the Exchange management tools are installed.

$ExScripts	Displays the full path of the Exchange scripts directory. This variable is only available if the Exchange management tools are installed.
$ForEach	Refers to the enumerator in a ForEach loop.
$Home	Specifies the user's root directory. It is the equivalent of %HomeDrive%%HomePath%.
$MaximumHistoryCount	Specifies the maximum number of entries that can be saved in the command history.
$PSHome	Specifies the directory where the Shell is installed.

1.5.2.15 Structured Data

Structured Data

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-05-02*

Each action that you take in the Exchange Management Shell must be done within the context of objects. The Shell uses structured collections of information called objects. These objects represent items in hierarchical data sources. When you call a cmdlet, one or more strongly typed structured objects are returned. Objects carry information about an item and about the object's structure. The object also acts as a proxy for the real item. For example, when you access a file from the Shell, you work with the object that represents that file, and not with the file itself.

Using objects gives the Shell an advantage over other traditional command shells. Traditional command shells have always supported the redirection of the output of one command to another in the form of a textual stream. This method has its disadvantages because parsing text has to be carefully controlled, usually by some kind of encoding to prevent unexpected behavior. By using objects, the Shell enables you to more easily choose the data you want to work with and use predefined methods to utilize and manipulate that data. You spend less time retrieving the data and more time using it.

The Exchange Management Shell uses this object model to pass information from one command to another by using pipelining. This avoids the problems caused by textual parsing in other command shells because the data that the Shell uses has a definite structure and is interpreted according to the object model.

For more information about pipelining, see Pipelining.

Structure of an Object

An object consists of three types of data: the object's type, its properties, and its methods.

Object Type

The data type of an object provides details about what kind of object it is. For example, an object that represents a mailbox is a **Mailbox** object. An object that represents a file is a **FileInfo** object. All objects have a distinct predefined type and namespace that the

Shell can process.

To see what object types are accepted and returned by cmdlets, see Cmdlet Input and Output Types.

Object Properties

A property is data associated with an object that specifies a particular state of that object. For example, a **Mailbox** object includes the property **EmailAddresses**. This object property represents the value of the actual attribute **ProxyAddresses** on mailbox-enabled Active Directory user accounts. This is the actual item represented by the **Mailbox** object.

The information about properties included with an object includes the current state and the definition of each property. This includes its name and the type of data that the property can take, such as Integer, Boolean, String, and so on.

Object Methods

A method is a set of instructions that defines a particular action that you can take on an object. Methods are defined based on the object type. For example, an object that is of type System.String, or String, has several methods that enable you to manipulate the string. Using the **ToUpper()** method on a string enables you to raise all of the characters within the string to uppercase. Some methods don't take arguments and some require arguments. It depends on the particular method you're using.

To call the methods available to an object, specify the method you want to use after the variable that the object is stored in. The variable and the method are separated by a period. The following example stores a string in the *$Example* variable and then calls the **ToUpper()** method to raise the string to uppercase.

```
$Example = "This is a string"
$Example.ToUpper()
THIS IS A STRING.
```

Notice that if you run `$Example` again, the string itself hasn't been modified.

```
$Example
This is a string.
```

To update the variable with the output of the method, you need to assign the output to the variable as shown in the following example.

```
$Example = "This is a string"
$Example = $Example.ToUpper()
```

Now when you run `$Example`, the string has been changed to uppercase in the variable.

```
$Example
THIS IS A STRING.
```

If an object has properties, the properties can also have their own methods. As with objects, the type of the property defines what methods are available. The property type doesn't necessarily match the object type. To call a method on an object property, you use similar syntax to when you call an object method, but you include the property along with the object. For example, a Send connector object has a property called **MaxMessageSize**, which is of type ByteQuantifiedSize. One of the methods for the type ByteQuantifiedSize is **ToMB()**. The following command displays the value stored in **MaxMessageSize**.

```
$Connector = Get-ReceiveConnector "From Internet"
$Connector.MaxMessageSize
10 MB (10,485,760 bytes)
```

If you now call the **ToMB()** method, the value stored in **MaxMessageSize** is displayed in

megabytes.

```
$Connector.MaxMessageSize.ToMB()
10
```

1.5.2.16 Arrays

Arrays

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-02-16*

An array provides a data structure that can be used to store a collection of data elements of the same type. The Exchange Management Shell supports all kinds of data elements. See the following sections for information about:

Creating Arrays

Reading Arrays

Manipulating Arrays

Associative Arrays

For detailed information about how to use arrays, run the following command in the Shell:

```
Get-Help About_Array
```

Creating Arrays

You can create and initialize arrays by assigning multiple values to a variable. The values that are stored in the array are delimited by using a comma and are separated from the variable name by the **=** assignment operator. For example, suppose you want to create an array that is named `$Example` that contains the following seven integer values: `22, 5, 10, 8, 12, 9, 80`. To create the array, enter the following command:

```
$Example = 22,5,10,8,12,9,80
```

In the array, the first data element is at index position 0, the second is at position 1, and so on.

Reading Arrays

You can reference an array by its variable name, such as `$Example`. You can reference a specific value within the array by using the index number of the position in the array where the value is stored. For example, to reference the first data element in the `$Example` array, enter the following command:

```
Write-Host $Example[0]
```

The Shell will return the value 22 because that is stored in the first array element.

Manipulating Arrays

To change the value of a single item in an array, specify the array name, the index you want to modify, the **=** assignment operator, and the new value that you want to use instead of the existing value. For example, to change the value of the second item in the `$Example` array, index position 1, to 10, enter the following command:

```
$Example[1] = 10
```

You can also use the **SetValue** method to change a value. The following example changes the second value, index position 1, of an array named `$Example` to 500:

```
$Example.SetValue(500,1)
```

You can append a value to the end of an existing array. For example, to add an additional integer, such as 200, to the `$Example` array, enter the following command:

```
$Example += 200
```

Associative Arrays

Associative arrays are the same as regular arrays. However, they enable the assignment of key-value pairs to a variable. For example, you may want to assign values to keys in an array to be called on when a command is being processed. The following example creates an associative array:

```
$Example = @{blue = 1; red = 2,3}
```

When you enter `$Example` on the command line, you see the following output:

```
Key                            Value
---                            -----
red                            {2, 3}
blue                           1
```

You can retrieve the information that is stored in the array by calling the array as follows:

```
$Example.blue
```

The previous example returns a value 1.

Because multiple values were assigned to the `red` key, those values make up a nested array. You can reference the values in this nested array by using their index value. You can retrieve the information that is stored in the key's nested array by calling the associative array, `$Example`, with the `red` key and the index of the nested array location that you want to retrieve 1, as follows:

```
$Example.red[1]
```

The previous example returns the value 3.

For more information about associative arrays, run the following command in the Shell:

```
Get-Help About_Associative_Array
```

1.5.2.17 Script Security

Script Security

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Script security in the Exchange Management Shell helps prevent harmful or otherwise unwanted scripts from running in your organization. Options are available to modify script security to meet the requirements of your organization.

You typically encounter scripts from several sources: yourself, another person in your organization, and script writers from outside your organization, such as the Internet. If you write a script, you trust the script to do what it's designed to do. If you share the script with other administrators in your organization, they too may trust the script because they trust you.

When scripts come from other sources, such as the Internet, script security is a concern. The only way that you can trust scripts from sources unknown to your organization is to inspect the script code directly and test it in an isolated lab environment. Although this process can be time consuming and tedious, we recommend this practice to prevent unintentional execution of malicious or destructive code.

The Shell supports the recommended use of digital signatures to make sure a script isn't altered after the script is created. For more information about digital signatures, see "Code-Signing Basics" later in this topic.

Script Execution Modes

Four modes of script execution in the Shell control how scripts are used, depending on how they are signed and if they are from known or unknown sources. The following table describes each script execution mode.

Important:
The remote Shell requires that the script execution mode be set to `RemotedSigned` or `Unrestricted`. For more information about the remote Shell, see Overview of Exchange Management Shell.

Script execution modes

Mode	Description
`Restricted` mode	No scripts will run, even if they are signed by a trusted publisher. This is the default script execution mode.
`AllSigned` mode	All scripts must be digitally signed by a trusted publisher before they will run.
`RemoteSigned` mode	All scripts locally created will run. Scripts downloaded from remote locations, such as the Internet, that can't be trusted, won't run.
`Unrestricted` mode	All scripts, regardless of whether they are digitally signed or trusted, will run. We don't recommend the `Unrestricted` mode unless you're running the script in a controlled test environment and not in a production

	environment.

To change the script execution mode from the default `Restricted` script execution mode, use the **Set-ExecutionPolicy** cmdlet in the Shell. This example changes the execution policy to `RemotedSigned` mode.

```
Set-ExecutionPolicy RemotedSigned
```

The Shell recognizes the change to the policy immediately.

Note:
If you have user access control enabled, you must open the Shell with elevated permissions to set the execution policy. To open the Shell with elevated permissions, right-click the Shell icon and select **Run as administrator**.

Large organizations that want to set a consistent script execution mode for all computers running the Shell should apply the script execution mode setting by using an Active Directory Group Policy. You configure the Active Directory Group Policy to set the `ExecutionPolicy` value located under the **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\PowerShell\1\ShellIds\Microsoft.PowerShell** registry key to the desired script execution mode.

Caution:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Code-Signing Basics

Digital signatures are created by using a public-key signature algorithm that uses two different cryptographic keys called a key pair: the public key and the private key. The private key is known only to its owner, and the public key is available to anyone. In digital signatures, the private key generates the signature, and the corresponding public key validates the signature.

A *certificate* is a digital document that's generally used for authentication and to help secure information on open networks. A certificate securely binds a public key to the entity that holds the corresponding private key. Certificates are digitally signed by the issuing certification authority (CA). By using a code-signing certificate, the author of the script adds a digital signature to the script file. During this process, a one-way hash of the script is created and encrypted by using the private key. The encrypted hash is a digital signature string that's added to the script file. This digital signature string is commented out so that it doesn't interfere with script functionality.

When this script is run in a Shell environment where code signing is required, a new one-way hash of the script file is produced. The one-way hash is compared to the encrypted hash included with the script file after it's decrypted by using the public key. If the script wasn't altered in any way after it was signed, the hashes will match. The computer then tries to verify that the signature is from a trusted publisher by building a certificate chain to a trusted CA. If the trust is verified, the script runs.

Whether a script is from a trusted source depends on the origin of the code-signing certificate used to digitally sign the script. There are generally two types of certificates:

- **Certificates issued by a trusted CA** The CA verifies the identity of the requestor before it issues a code-signing certificate. The issuing authority can be an external, public third party that sells certificates or an internal CA hosted by your organization. If you sign a script by using this kind of certificate, you can share the script with users on other computers that recognize and trust

the CA that issued the certificate.

- **Self-signed certificates** For this kind of certificate, your computer is the authority that creates the certificate. The benefit of a self-signed certificate is you can write, sign, and run scripts on your computer. But you can't share your script to run on other computers because your computer isn't recognized as a trusted CA. If your computer isn't trusted, your self-signed signature can't be validated, and the script won't run.

Cmdlets for Managing Code Signing

The Shell includes two cmdlets for managing code signing. The **Set-AuthenticodeSignature** cmdlet is used to add digital signatures to script files. The **Set-AuthenticodeSignature** cmdlet takes the name of the file to be signed as its first positional parameter. If the file isn't in the current working directory, you must provide the path of the file. The second input parameter for this cmdlet is the certificate used for signing. This certificate is stored in the local certificate store. You must provide this parameter in the form of a string that references the certificate. The certificate can be accessed through the Cert: drive.

The other cmdlet for managing code signing is the **Get-AuthenticodeSignature** cmdlet. Use the **Get-AuthenticodeSignature** cmdlet to check and confirm the current code-signing status for the file provided as a parameter input. If a problem occurs when you use a code-signed script, the output from the **Get-AuthenticodeSignature** cmdlet will provide useful troubleshooting information.

If you want to run scripts from outside sources, such as Microsoft, you must adapt the scripts according to the script execution mode of your environment. You can receive scripts as basic .txt files, rename them as .ps1 script files, and then after you apply any required signing, run these scripts as if you had written the scripts yourself.

For more information about digital signing and script execution policies, in the Shell, run the following command: `Get-Help About_Signing`. This command returns information that includes detailed instructions for digitally signing scripts.

1.5.2.18 Scripting with the Exchange Management Shell

Scripting with the Exchange Management Shell

Exchange Server 2010 > Exchange Management Shell > Exchange Management Shell Basics >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

For most general tasks, running cmdlets one at a time or together through pipelines is sufficient. However, sometimes you may want to automate tasks. The Exchange Management Shell supports a rich scripting language, based on the Microsoft .NET Framework, which resembles the scripting language in other shells. The Shell lets you create scripts, from simple to complex. Language constructs for looping, conditional, flow control, and variable assignment are all supported.

Every organization has tasks that are in some way unique to that organization. With a library of script files to perform these tasks, you can save time by running these scripts on any computer that has the Shell installed.

For more information about how to use scripts, see Scripting with Windows PowerShell. Because the Shell is built on Microsoft Windows PowerShell technology, the scripting guidance for Windows PowerShell applies to the Exchange Management Shell.

Running a Script Inside the Exchange Management Shell

Those familiar with the Cmd.exe environment know how to run command shell scripts. These scripts are simply text files that have the .bat file name extension. Like batch files, you can create the Shell script files by using a text editor, such as Notepad. You can also use the Windows PowerShell Integrated Scripting Environment (ISE) to write scripts. The Windows PowerShell ISE provides a rich editing experience with debugging support, syntax coloring, selective execution, and more. The Shell script files use the .ps1 file name extension.

The Shell uses a root directory for script files when they are called. By default, the root directory is the *<root drive>*:\Program Files\Microsoft\Exchange Server\V14\bin directory. You can also verify the current PSHome directory on any computer running the Shell by running `$PSHome` at a command prompt. Both of these directories are in the PATH environment variable.

If a script file is saved to the root directory, you can call it by using the script name. If the script file is located somewhere other than the current location, the path and script name must be used. If the script file is located in the current location, the script name must be prefixed by the period backslash (.\) characters.

These examples show the command syntax requirements for calling three different scripts. These examples all use the **Get-Date** cmdlet, from three different locations.

```
[PS] C:\>Get-Date-Script-A.ps1
Friday, January 20, 2006 3:13:01 PM
```

The script file Get-Date-Script-A.ps1 is located in the directory specified by `$PSHhome` and requires only the script name to run.

```
[PS] C:\>c:\workingfolder\Get-Date-Script-B.ps1
Friday, January 20, 2006 3:13:25 PM
```

The script file Get-Date-Script-B.ps1 is located in the C:\workingfolder directory so the full path must be supplied to run.

```
[PS] C:\>.\Get-Date-Script-C.ps1
Friday, January 20, 2006 3:13:40 PM
```

The script file Get-Date-Script-C.ps1 is located in the current location, C:\. Therefore, it must be prefixed with .\ to run.

```
[PS] C:\>Get-Date-Script-C.ps1
The term 'Get-Date-Script-C.ps1' is not recognized as the name of a cmdlet, funct
of the name, or if a path was included, verify that the path is correct and try a
At line:1 char:22
+ Get-Date-Script-C.ps1 <<<<
    + CategoryInfo          : ObjectNotFound: (Get-Date-Script-C.ps1:String) [],
    + FullyQualifiedErrorId : CommandNotFoundException
```

In the last example, when this same script, Get-Date-Script-C.ps1, is called without the prefix .\, the expected results are shown.

As a best practice, always give script files a descriptive name and include comments in the script to describe its purpose and to identify each point of interest. Some information about the author should also be included in case someone running the script has questions about its use. Use the number sign (#) to start comment lines inside the script body.

Running a Script from Cmd.exe

If you want to run a script on a scheduled basis using the Windows Task Scheduler service, you can call the Shell and include the script that you want to run as a parameter. If you want to use Exchange cmdlets with your script, you must direct Windows PowerShell to connect to a server running Exchange and load the Exchange cmdlets you have access to. The shortcut you use to open the Shell does this automatically. To do this when you want to run a script that contains Exchange cmdlets, you must direct Windows PowerShell to run the scripts that make this connection. This syntax is required to open Windows PowerShell, connect to an Exchange server, and run your script from the Cmd.exe command.

```
PowerShell.exe -command ". 'D:\Program Files\Microsoft\Exchange Server\V14\bin\Re
```

This example runs the script RetrieveMailboxes.ps1 from C:\My Scripts.

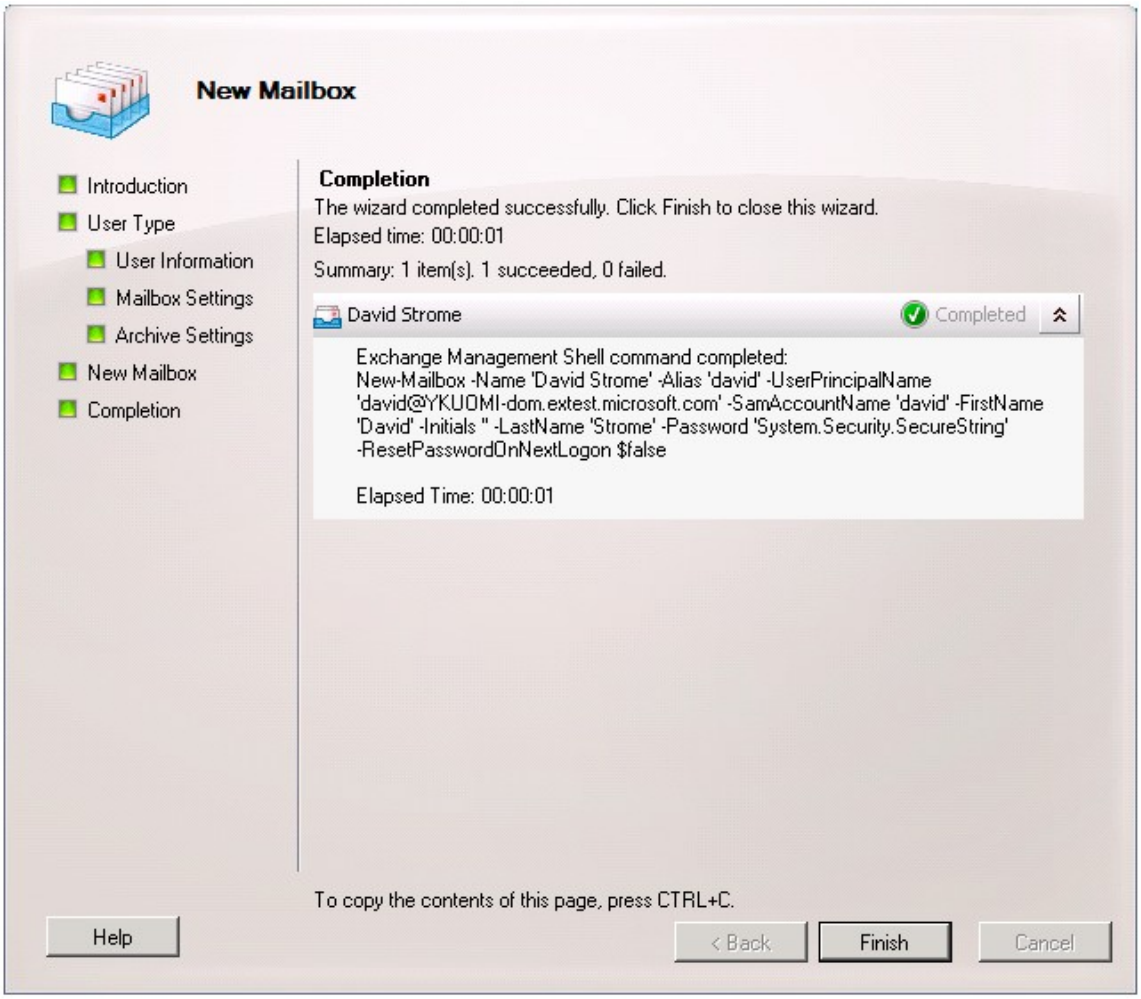
```
PowerShell.exe -command ". 'D:\Program Files\Microsoft\Exchange Server\V14\bin\Re
```

For additional options to use when you call the Shell from the Cmd.exe environment, type **PowerShell.exe /?**

Getting Hints from the Exchange Management Console

In Microsoft Exchange Server 2010, you can use the Exchange Management Console (EMC) to view detailed information about specific shell commands used to perform certain tasks. When you run a wizard in the EMC, the wizard takes the information that you entered and creates a shell command that is then run by the computer. You can copy and paste this command directly into the Shell or copy it into a text editor where you can modify it. If you examine how the EMC creates commands, you can obtain a better understanding of how to construct or modify those commands to suit your future needs.

For example, if you create a mailbox for the user David Strome, the following information is displayed on the **Completion** page of the New Mailbox wizard.



The information displayed on the **Completion** page gives you an idea of the information that you must have to make sure a similar command that you run in the Shell is completed successfully. On the **Completion** page, press CTRL+C to copy this information to the Clipboard. Then you can use a text editor to examine the command to determine what must be changed to add more mailboxes. You can also customize the command so that it can be used as part of a script that consumes a comma-separated values (CSV) file or another input source to automate creating many mailboxes.

In addition to the wizard **Completion** page, the EMC also provides the Exchange Management Shell Command Log, which when enabled, logs every command that the EMC runs. The output of this log can be saved so that you can study the commands the EMC uses as it retrieves and saves information. For more information, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC.

Testing Scripts

When you create scripts, you should always test them in a lab environment before you apply them in your production environment. As you test your scripts in your lab, and as you deploy them in your production environment, you can use the *WhatIf* parameter that's available on many cmdlets included in the Shell to verify that your script performs as expected. The *WhatIf* parameter instructs the command to which it is applied to run, but only to display which objects would be affected by running the command and what changes would be made to those objects, without actually changing any of those objects.

For more information about the *WhatIf* parameter, see WhatIf, Confirm, and ValidateOnly Switches.

Troubleshooting Scripts

Scripts may not work as expected for many reasons. It can be difficult to determine where the problem is and what's wrong. The Shell can help you locate general syntax errors by reporting the line and character at the point of failure. When the syntax of a script is correct but its behavior is unexpected, it can be much more difficult to diagnose the problem. The Shell includes simple debugging functionality to troubleshoot script files by examining each step that the script makes as it executes. This functionality is called *tracing*.

To enable tracing and examine each command step in a script, use the **Set-PSDebug** cmdlet with the *Trace* parameter set to a value of 1. To examine each step and each variable assignment as they are made, set the *Trace* parameter to a value of 2. To turn tracing off, set the value of the *Trace* parameter to 0 (zero).

To examine each command in a script line by line, use the **Set-PSDebug** cmdlet with the *Step* parameter. At each step, you will be prompted to continue the operation. The following choices are available in step mode.

```
[Y] Yes (continue to the next step)
[A] Yes to All (continue to the end of the script)
[N] No (stop this step)
[L] No to All (stop all remaining steps)
[S] Suspend (suspend at this point and drop to a prompt)
```

Suspend lets you exit to a prompt where you can run any command, for example, to check or set values on an object before the script can access it. When you are ready to resume script execution, type **Exit**, and control immediately returns to the point at which the script was suspended.

1.5.3 Managing Exchange Management Shell Connections

Managing Exchange Management Shell Connections

Exchange Server 2010 > Exchange Management Shell >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-21*

Enable Remote Exchange Management Shell for a User

Disable Remote Exchange Management Shell for a User

Create a Manual Remote Shell Connection

1.5.3.1 Enable Remote Exchange Management Shell for a User

Enable Remote Exchange Management Shell for a User

Exchange Server 2010 > Exchange Management Shell > Managing Exchange Management Shell

Connections >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Remote Shell in Microsoft Exchange Server 2010 enables you to manage your server running Exchange 2010 from a remote computer, either on your network or from the Internet. A user must be enabled for remote Shell before the user can use it. For more information about remote Shell, see Overview of Exchange Management Shell.

Looking for other management tasks related to remote Shell? Check out Managing Exchange Management Shell Connections.

Important:

To use remote Shell, users must be a member of a management role group or be directly assigned a management role that enables the user to run Exchange cmdlets. For more information about role groups and management roles, see Understanding Role Based Access Control.

Use the Shell to enable remote Shell for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote Shell" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

You can't use the EMC to enable remote Shell for a user.

To enable remote Shell for a user, set the *RemotePowerShellEnabled* parameter to `$True` on the **Set-User** cmdlet. This example enables remote Shell for the user David.

```
Set-User David -RemotePowerShellEnabled $True
```

For detailed syntax and parameter information, see Set-User.

Other Tasks

After you enable remote Shell for a user, you may also want to:

- Add Members to a Role Group
- Open the Shell

1.5.3.2 Disable Remote Exchange Management Shell for a User

Disable Remote Exchange Management Shell for a User

Exchange Server 2010 > Exchange Management Shell > Managing Exchange Management Shell Connections >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Remote Shell in Microsoft Exchange Server 2010 enables you to manage your server running Exchange 2010 from a remote computer, either on your network or from the Internet. If remote Shell is disabled for a user, it can't be used by the user. For more information about remote Shell, see Overview of Exchange Management Shell.

Looking for other management tasks related to remote Shell? Check out Managing Exchange Management Shell Connections.

Use the Shell to disable remote Shell for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote Shell" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to disable remote Shell for a user.

To disable remote Shell for a user, set the *RemotePowerShellEnabled* parameter to `$False` on the **Set-User** cmdlet. This example disables remote Shell for the user David.

```
Set-User David -RemotePowerShellEnabled $False
```

For detailed syntax and parameter information, see Set-User.

1.5.3.3 Create a Manual Remote Shell Connection

Create a Manual Remote Shell Connection

Exchange Server 2010 > Exchange Management Shell > Managing Exchange Management Shell Connections >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-12*

The Exchange Management Shell is the administrative interface that enables you to manage your Microsoft Exchange Server 2010 organization from the command line. If you don't have the Exchange management tools installed but you still want to connect to, and administer, a server running Exchange 2010, this topic explains how you can create a manual remote Shell to connect to an Exchange 2010 server.

Note:
For ease of management and to receive the benefits that come with them, we recommend that you install the Exchange management tools on any computer that's used to administer an Exchange 2010 server. For more information, see the following topics:
Install the Exchange 2010 Management Tools
Open the Shell

For more information about the Exchange Management Shell, see Overview of Exchange Management Shell.

Administer Exchange 2010 Using the

Remote Shell

To administer Exchange 2010 using the remote Shell without the Exchange management tools installed, you'll need the following:

- Windows Management Framework installed

  Note:
  Windows Management Framework includes Windows PowerShell V2 and Windows Remote Management (WinRM) 2.0.

- The fully qualified domain name (FQDN) of an Exchange 2010 server in your organization
- TCP port 80 open between your client computer and the remote Exchange 2010 server
- A user that's enabled for remote Shell

Before you can connect using remote Shell, you need to install the Windows Management Framework. If you have previous versions of Windows PowerShell or WinRM, you need to uninstall them before installing the Windows Management Framework. Choose the option that matches your operating system:

- **Windows 7 or Windows Server 2008 R2** The correct version of the Windows Management Framework is already installed. You can continue on to connect remote Shell to an Exchange server.
- **Windows Vista, Windows Server 2008, Windows Server 2003, or Windows XP** Perform the steps in the following topics to install the Windows Management Framework:
  - Uninstall Previous Versions of Windows PowerShell and Windows Remote Management
  - Install Windows Management Framework

After you've installed the Windows Management Framework, see the following topics:

- Connect Remote Exchange Management Shell to an Exchange Server
- Disconnect Remote Exchange Management Shell from an Exchange Server
- Troubleshooting the Exchange Management Shell

1.5.3.3.1 Uninstall Previous Versions of Windows PowerShell and Windows Remote Management

Uninstall Previous Versions of Windows PowerShell and Windows Remote Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You need to uninstall previous versions of Windows PowerShell and Windows Remote Management (WinRM) before you can install Windows Management Framework, which includes Windows PowerShell 2.0 and WinRM 2.0. This procedure should be performed on computers running Windows Vista, Windows Server 2008, Windows Server 2003, or Windows XP.

You don't need to perform this procedure on computers running Windows 7 or Windows Server 2008 R2. The current version of Windows Management Framework is already

installed on these operating systems.

Looking for other management tasks related to Windows PowerShell and Windows Remote Management? Check out Managing Exchange Management Shell Connections.

Note:
If you want to run remote Shell on a computer that already has Microsoft Exchange Server 2010 installed, you don't need to perform this procedure. Instead, for more information about how to open the Shell with the Exchange management tools installed, see Open the Shell.

What Do You Want To Do?

- Remove Windows PowerShell on Windows Vista
- Remove Windows PowerShell on Windows Server 2008 with the built-in version of Windows PowerShell installed
- Remove Windows PowerShell on Windows Server 2008 with a pre-release version of Windows PowerShell V2 installed
- Remove WinRM on Windows Vista and Windows Server 2008
- Remove Windows PowerShell on Windows Server 2003 and Windows XP
- Remove WinRM on Windows Server 2003 and Windows XP

Remove Windows PowerShell on Windows Vista

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "PowerShell and WinRM installation" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In **Control Panel**, in **Programs**, open **Programs and Features**.
2. Uninstall any instances of Windows PowerShell that appear in the installed programs list or the installed updates list. Previous versions may appear as **Windows PowerShell(TM) V2** if you have installed the Community Technology Preview (CTP) versions of Windows PowerShell v2. If Windows PowerShell v1 is installed, it might be listed as a Windows update with one of the following Knowledge Base article numbers:
   - KB928439
   - KB923569

   Note:
   You might need to click the **View installed updates** link in the Tasks sidebar to view currently installed updates.

Remove Windows PowerShell on Windows Server 2008 with the built-in version of Windows PowerShell installed

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "PowerShell and WinRM installation" entry in the Exchange and Shell Infrastructure Permissions topic.

1. Start **Server Manager** and navigate to **Features**.
2. Click **Uninstall Features**.
3. Select **Windows PowerShell** and follow the directions to uninstall.

Remove Windows PowerShell on Windows Server 2008 with a pre-release version of Windows PowerShell 2.0 installed

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "PowerShell and WinRM installation" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In **Control Panel**, in **Programs**, open **Programs and Features**.
2. Uninstall any instances of Windows PowerShell that appear in the installed programs list or the installed updates list.

Note:
You might need to click the **View installed updates** link in the Tasks sidebar to view currently installed updates.

Remove WinRM on Windows Vista and Windows Server 2008

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "PowerShell and WinRM installation" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In **Control Panel**, in **Programs**, open **Programs and Features**.
2. Uninstall any instances of Windows Remote Management that appear in the installed programs list or the installed updates list. WinRM might be listed as a Windows update with one of the following Knowledge Base articles numbers:
   - KB936059
   - KB950099

Note:
You might need to click the **View installed updates** link in the Tasks sidebar to view currently installed updates.

Remove Windows PowerShell on Windows Server 2003 and Windows XP

1. In **Control Panel**, open **Add or Remove Programs**.
2. Uninstall any instances of Windows PowerShell that appear in the installed programs list or the installed updates list. Windows PowerShell might be listed as a Windows update with the Knowledge Base article number KB926139.

Note:
You might need to select the **Show updates** box to view currently installed updates.

Remove WinRM on Windows Server 2003 and Windows XP

1. In **Control Panel**, open **Add or Remove Programs**.

2. Uninstall any instances of Windows Remote Management that appear in the installed programs list or the installed updates list. WinRM might be listed as a Windows update with the Knowledge Base article number KB936059.

Note:
You might need to select the **Show updates** box to view currently installed updates.

Other Tasks

After you uninstall all previously installed versions of Windows PowerShell and WinRM, you need to install Windows Management Framework. For more information, see Install Windows Management Framework.

1.5.3.3.2 Install Windows Management Framework

Install Windows Management Framework

Exchange Management Shell > Managing Exchange Management Shell Connections > Create a Manual Remote Shell Connection >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Windows Management Framework, which contains Windows PowerShell 2.0 and Windows Remote Management (WinRM) 2.0, is a required component that enables you to use the EMC and the Shell. You can install Windows Management Framework on computers running Windows Vista, Windows Server 2008, Windows Server 2003, or Windows XP.

You don't need to perform this procedure on computers running Windows 7 or Windows Server 2008 R2. Windows Management Framework is already installed on these operating systems.

Looking for other management tasks related to Windows Management Framework? Check out Managing Exchange Management Shell Connections.

Note:
If you want to run the EMC or the remote Shell on a computer that already has Microsoft Exchange Server 2010 installed, you don't need to perform this procedure. Instead, for more information about how to open the EMC or the Shell with the Exchange management tools installed, see the following topics:
Exchange Management Console
Open the Shell

Prerequisites

- Before you install Windows Management Framework, you must uninstall all previous versions of Windows PowerShell and WinRM from the computer you are using. For instructions about how to uninstall Windows PowerShell and WinRM, see Uninstall Previous Versions of Windows PowerShell and Windows Remote Management.
- You must be running one of the following operating systems to install Windows Management Framework:
  - Windows Vista Service Pack 1 (SP1)
  - Windows Vista SP2
  - Windows Server 2008 SP1

- Windows Server 2008 SP2
- Windows Server 2003 SP2
- Windows XP SP3

Install Windows Management Framework

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "PowerShell and WinRM installation" entry in the Exchange and Shell Infrastructure Permissions topic.

1. Download Windows Management Framework to your local computer. See Microsoft Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0). Choose the version that includes the Windows PowerShell and WinRM components, and applies to your operating system, system architecture, and language.

   Note:
   Before you install Windows Management Framework, verify that your computer meets all of the requirements listed on the download page for the package. For more information, see the installation instructions available from the Windows Management Framework download Web site.

2. Install Windows Management Framework. Follow the wizard to install the Windows PowerShell and WinRM components.
3. Set the Windows PowerShell script execution policy to allow unsigned scripts you created and signed scripts obtained from the Internet to run by doing the following:
   3.a. Click **Start**, point to **All Programs**, point to **Accessories**, point to **Windows PowerShell**, and then click **Windows PowerShell**.
   If you're running Windows Vista, Windows 7, or Windows Server 2008 R2 and you have User Account Control (UAC) enabled, right-click **Windows PowerShell**, and then select **Run as administrator**.
   If you receive a prompt stating Windows needs your permission to continue, click **Continue**.

   Note:
   This is the only time you should need to run Windows PowerShell as the administrator. When using Windows PowerShell to connect to an Exchange 2010 server, you don't need to select **Run as administrator**.

   3.b. In Windows PowerShell, type **Set-ExecutionPolicy RemoteSigned**, and then press Enter.
4. Close Windows PowerShell.

Other Tasks

After you install Windows Management Framework, you may want to connect to a remote Exchange 2010 server. For more information, see Connect Remote Exchange Management Shell to an Exchange Server.

If you want to use the EMC, see Exchange Management Console.

1.5.3.3.3 Connect Remote Exchange Management Shell to an Exchange Server

Connect Remote Exchange Management Shell to an Exchange Server

Exchange Management Shell > Managing Exchange Management Shell Connections > Create a

Manual Remote Shell Connection >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Using the remote Shell, you can connect to a remote server running Microsoft Exchange Server 2010 to perform administration without the need to have any Exchange administration tools installed on your local computer. The remote Shell uses Windows PowerShell 2.0 and Windows Remote Management (WinRM) 2.0 to enable you to connect to remote Exchange 2010 servers.

After you connect the remote Shell to an Exchange server, the Exchange 2010 cmdlets that you have access to are made available to you in your local PowerShell session. When you run a cmdlet on your computer, the requests are sent to the remote Exchange 2010 server. The remote Exchange 2010 server then returns the results, if any, to your computer. Use the **Get-Help** cmdlet to access Help for individual cmdlets.

For more information about the remote Shell, see Create a Manual Remote Shell Connection.

Looking for other management tasks related to the remote Shell? Check out Managing Exchange Management Shell Connections.

Note:

If you want to use the Shell on an Exchange server or on a computer that has Exchange management tools installed, see Open the Shell. Use the procedure in this topic only on computers that don't have the Exchange management tools installed.

Prerequisites

- **Install Windows Management Framework** Windows Management Framework contains Windows PowerShell and WinRM. For more information, see Install Windows Management Framework.
- **Join your computer to a Windows domain** If you want to use your current network credentials, the domain you're joined to must be trusted by the domain where the Exchange server resides. Your domain doesn't need to be trusted if you manually specify credentials that are valid in the remote domain.
- **Open TCP port 80** TCP port 80 must be open between your computer and the remote Exchange 2010 server, and the port must be allowed through Windows Firewall on the Exchange 2010 server.

Use your network logon account to connect to a remote Exchange 2010 server

To connect to a remote Exchange 2010 server using the remote Shell, the user you connect as must be enabled for the remote Shell. This is enabled by default for the account used to install the first Exchange 2010 server in your organization. For more information about how to enable the remote Shell for other users, see Enable Remote Exchange Management Shell for a User.

To perform administrative tasks on a remote Exchange 2010 server, the account you use must be assigned the management roles that allow that feature to be managed. To determine the required management roles, see the Help topic for each feature. For more information about permissions, assigning management roles and management role scopes, and the rights required to administer Exchange 2010, see Understanding

Permissions.

If you want to connect to a remote Exchange server using your current network logon account, use the following procedure. You don't need to specify your user name or password. This procedure can be used even if there are no Exchange 2010 management tools installed.

1. Click **Start**, point to **All Programs**, point to **Windows PowerShell**, and then click **Windows PowerShell** or **Windows PowerShell ISE**.

   Note:
   Windows PowerShell Integrated Scripting Environment (ISE) is the new Windows PowerShell graphical console and can be used instead of the traditional text-based PowerShell console.

2. Open the connection to Exchange 2010 by running the following command.

```
$Session = New-PSSession -ConfigurationName Microsoft.Exchange -Connec
```

3. Import the server-side PowerShell session into your client-side session by running the following command.

```
Import-PSSession $Session
```

After you perform this procedure, you can run Exchange cmdlets in the remote Shell.

Use a user account that you specify to connect to a remote Exchange 2010 server

To connect to a remote Exchange 2010 server using the remote Shell, the user you connect as must be enabled for the remote Shell. This is enabled by default for the account used to install the first Exchange 2010 server in your organization. For more information about how to enable the remote Shell for other users, see Enable Remote Exchange Management Shell for a User.

To perform administrative tasks on a remote Exchange 2010 server, the account you use must be assigned the management roles that allow that feature to be managed. To determine the required management roles, see the Help topic for each feature. For more information about permissions, assigning management roles and management role scopes, and the rights required to administer Exchange 2010, see Understanding Permissions.

When you connect to a remote Exchange 2010 server using a user name and password you specify, you direct the remote Shell to connect to the remote server using those credentials when it authenticates the session. The credentials can be different from your current user name and password. This is called *explicit authentication*. This procedure can be used even if there are no Exchange 2010 management tools installed.

1. Click **Start**, point to **All Programs**, point to **Windows PowerShell**, and then click **Windows PowerShell** or **Windows PowerShell ISE**.

   Note:
   Windows PowerShell Integrated Scripting Environment (ISE) is the new Windows PowerShell graphical console and can be used instead of the traditional text-based PowerShell console.

2. Enter your network credentials and store them in a variable by running the following command.

```
$UserCredential = Get-Credential
```

3. In the dialog box that opens, type the user name and password of the

administrator account that has access to administer the Exchange 2010 server you want to connect to, and then click **OK**.

4. Open the connection to Exchange 2010 by running the following command.

```
$Session = New-PSSession -ConfigurationName Microsoft.Exchange -Connec
```

5. Import the server-side PowerShell session into your client-side session by running the following command.

```
Import-PSSession $Session
```

After you perform this procedure, you can run Exchange cmdlets in the remote Shell.

Other Tasks

After you connect to a remove Exchange 2010 server, you may also want to:

Disconnect Remote Exchange Management Shell from an Exchange Server

Troubleshooting the Exchange Management Shell

1.5.3.3.4 Disconnect Remote Exchange Management Shell from an Exchange Server

Disconnect Remote Exchange Management Shell from an Exchange Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

You can disconnect from a remote server running Microsoft Exchange Server 2010 using the remote Shell.

Looking for other management tasks related to the remote Shell? Check out Managing Exchange Management Shell Connections.

Caution:

If you close the Windows PowerShell window without following this procedure, the session will have to time out, and the quota for the maximum number of concurrent connections may prevent you from connecting back to the service on a timely basis.

Use the Shell to disconnect from an Exchange 2010 server

Note:

You can't use the EMC to disconnect from a remote Exchange 2010 server.

This example disconnects from the Exchange 2010 server.

```
Remove-PSSession $Session
```

1.5.4 Cmdlet Extension Agent

Cmdlet Extension Agent

Topic Last Modified: *2009-09-11*

Understanding Cmdlet Extension Agents

Managing Cmdlet Extension Agents

Understanding the Scripting Agent

1.5.4.1 Understanding Cmdlet Extension Agents

Understanding Cmdlet Extension Agents

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-25*

Cmdlet extension agents are components in Microsoft Exchange Server 2010 called by Exchange 2010 cmdlets when the cmdlets run. As the name implies, cmdlet extension agents extend the capabilities of the cmdlets that call them by assisting in processing data or performing additional actions based on the requirements of the cmdlet. Cmdlet extension agents are available on any server role except the Edge Transport server role.

Agents can modify, replace, or extend functionality of Exchange Management Shell cmdlets. An agent can provide a value for a required parameter that isn't provided on a command, override a value provided by a user, perform other actions outside of the cmdlet workflow while a cmdlet runs, and more.

For example, the **New-Mailbox** cmdlet accepts the *Database* parameter that specifies the mailbox database in which to create a new mailbox. In Exchange Server 2007, if you don't specify the *Database* parameter when you run the **New-Mailbox** cmdlet, the command fails. With Exchange 2010, the **New-Mailbox** cmdlet calls the `Mailbox Resources Management` agent when the cmdlet runs. If the *Database* parameter isn't specified, the `Mailbox Resources Management` agent automatically determines a suitable mailbox database on which to create the new mailbox and inserts that value into the *Database* parameter.

Cmdlet extension agents can only be called by Exchange 2010 cmdlets. Exchange 2007 cmdlets and cmdlets provided by other Microsoft and third-party products can't call cmdlet extension agents. Scripts also can't call cmdlet extension agents directly. However, if scripts contain Exchange 2010 cmdlets, those cmdlets continue to call the cmdlet extension agents.

Looking for management tasks related to cmdlet extension agents? See Managing Cmdlet Extension Agents.

Agent Priority

The priority of an agent determines the order in which the agent is called while a cmdlet runs. An agent that has a higher priority, closer to 0, is called first. The priority of an agent becomes important when two or more agents attempt to set the value of the same property. The highest priority agent that attempts to set a property value succeeds, and all subsequent attempts to set the same property by lower priority agents are ignored. For example, if the **Name** property on an object is modified by an agent with a priority of 3 and another agent with a priority of 6 modifies the same object, the modification made by the agent with a priority of 6 is ignored.

If you want to use the `Scripting agent` to set the value of properties that might be set by other, higher priority agents, you have the following options:

- Disable the agent that currently sets the property.
- Set the `Scripting agent` to a priority higher than the existing agent you want to replace.
- Keep the priorities of the agents the same and make sure that the script that runs under the `Scripting agent` respects the value provided by the other agents.

Caution:

Changing the priority or replacing the functionality of a built-in agent is an advanced operation. Be sure that you completely understand the changes you're making.

For more information about changing the priority of an agent, see Change the Priority of a Cmdlet Extension Agent.

Built-in Agents

Exchange 2010 includes several agents that can be called when a cmdlet runs. The following table lists the agents, their order, and whether the agents are enabled by default. You can't add or remove agents to or from a server running Exchange 2010. You can, however, use the Scripting agent to run Microsoft Windows PowerShell scripts to extend the functionality of the cmdlets that use it. For more information about the Scripting agent, see Understanding the Scripting Agent.

You can enable or disable agents or change the priority of the agents if you want to replace the functionality of a particular agent with functionality you provide in a custom script that you call using the Scripting agent.

The configuration for agents is stored at the organization level. When you enable or disable an agent, or set its priority, you set that agent configuration across every server in the organization. The exception is adding scripts to the `Scripting agent`. You must update the scripts on each server individually. For more information about configuring scripts for use with the `Scripting agent`, see Understanding the Scripting Agent.

Caution:

Changing the priority of agents, or enabling or disabling agents, can cause unintended effects if you don't completely understand what each agent does and how they interact with Exchange cmdlets. Before you change the configuration of any agent, be sure you fully understand the changes and results you want and that you verify that your custom script will work as intended.

Exchange 2010 cmdlet extension agents

Agent name	Priority	Enabled by default
Admin Audit Log Agent	255	True
Scripting Agent	6	False

OAB Resources Management Agent	5	True
Provisioning Policy Agent	4	True
Mailbox Creation Time Agent	3	True
Mailbox Resources Management Agent	2	True
Rus Agent	1	True
Query Base DN Agent	0	True

1.5.4.1.1 Understanding the Scripting Agent

Understanding the Scripting Agent

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-20*

You can use the Scripting Agent cmdlet extension agent in Microsoft Exchange Server 2010 to insert your own scripting logic into the execution of Exchange cmdlets. Using the Scripting Agent, you can add conditions, override values, and set up reporting.

Caution:

When you enable the Scripting Agent cmdlet extension agent, the agent is called every time a cmdlet is run on a server running Exchange 2010. This includes not only cmdlets run directly by you in the Exchange Management Shell, but also cmdlets run by Exchange services, the Exchange Management Console (EMC), and the Exchange Control Panel (ECP). We strongly recommend that you test your scripts and any changes you make to the configuration file, before you copy your updated configuration file to your Exchange 2010 servers and enable the Scripting Agent cmdlet extension agent.

Every time an Exchange cmdlet is run, the cmdlet calls the Scripting Agent cmdlet extension agent. When this agent is called, the cmdlet checks whether any scripts are configured to be called by the cmdlet. If a script should be run for a cmdlet, the cmdlet tries to call any APIs defined in the script. The following APIs are available and are called in the following order:

1. **ProvisionDefaultProperties** This API can be used to set values of properties on objects when they're created. When you set a value, that value is returned to the cmdlet, and the cmdlet sets the value on the property. You can fill in values on properties if the user didn't specify a value, or you can override the value specified by the user. This API respects the values set by higher priority agents. The Scripting Agent cmdlet extension agent won't overwrite the values set by higher priority agents.
2. **UpdateAffectedIConfigurable** This API can be used to set values of properties on objects after all other processing has been completed, but the `Validate` API hasn't yet been called. This API respects the values set by higher priority agents. The Scripting Agent cmdlet extension agent won't overwrite the values set by higher priority agents.
3. **Validate** This API can be used to validate the values on an object's properties that are about to be set by the cmdlet. This API is called just before a cmdlet writes any data. You can configure validation checks that

allow a cmdlet to either succeed or fail. If a cmdlet passes the validation checks in this API, the cmdlet is allowed to write the data. If the cmdlet fails the validation checks, it returns any errors defined in this API.

4. **OnComplete** This API is used after all cmdlet processing is complete. It can be used to perform post-processing tasks, such as writing data to an external database.

Note:
The Scripting Agent cmdlet extension agent isn't called when cmdlets with the `Get` verb are run. Also, the agent doesn't run on Exchange servers running the Edge Transport server role because that server role doesn't support cmdlet extension agents.

The Scripting Agent is one of several cmdlet extension agents. For more information about cmdlet extension agents, see Understanding Cmdlet Extension Agents.

Contents

Scripting Agent Configuration File

The Scripting Agent configuration file contains all of the scripts that you want the Scripting Agent to run. Scripts in the configuration file are contained within XML tags that define the beginning and end of the script and various input parameters required to pass data to the script. Scripts are written using Windows PowerShell syntax. The configuration file is an XML file that uses the elements or attributes in the following table.

Element	Attribute	Description
`Configuration`	Not applicable	This element contains all of the scripts that the Scripting Agent cmdlet extension agent can run. The `Feature` tag is a child of this tag. There is only one `Configuration` tag in the configuration file.
`Feature`	Not applicable	This element contains a set of scripts that relate to a feature. Each script, defined in the `ApiCall` child tag, extends a specific part of the cmdlet execution pipeline. This tag contains the `Name` and `Cmdlets` attributes. There can be multiple `Feature` tags under the `Configuration` tag.
	`Name`	This attribute contains the name of the feature. Use this attribute to help identify which feature is extended by the scripts contained within the tag.
	`Cmdlets`	This attribute contains a list of the Exchange cmdlets that the set of scripts in this feature extension will be

		used by. You can specify multiple cmdlets by separating each cmdlet with a comma.
ApiCall	Not applicable	This element contains scripts that can extend a part of the cmdlet execution pipeline. Each script is defined by the API call name in the cmdlet execution pipeline it's extending. The following are the API names that can be extended: • ProvisionDefaultProperties • UpdateAffectedIConfigurable • Validate • OnComplete
	Name	This attribute includes the name of the API call that's extending the cmdlet execution pipeline.
Common	Not applicable	This element contains functions that can be used by any script in the configuration file.

Every Exchange 2010 server includes the file ScriptingAgentConfig.xml.sample in the *<installation path>*\V14\Bin\CmdletExtensionAgents folder. This file must be renamed to ScriptingAgentConfig.xml on every Exchange 2010 server if you enable the Scripting Agent cmdlet extension agent. The sample configuration file contains sample scripts that you can use to help you understand how to add scripts to the configuration file.

After you add a script to the configuration file, or if you make a change to the configuration file, you must update the file on every Exchange 2010 server in your organization. This must be done to make sure that each server contains an up-to-date version of the scripts that the Scripting Agent cmdlet extension agent runs.

Some characters typically used in scripts also have a special meaning in XML. To use these characters in your script, use escape sequences. For example, the following characters use an escape sequence:

- Instead of a greater than sign (>), use `>`
- Instead of a less than sign (<), use `$lt;`
- Instead of an ampersand (&), use `&`

Return to top

Enable the Scripting Agent

The Scripting Agent cmdlet extension agent is disabled by default. When you enable the Scripting Agent, the agent is enabled for the entire Exchange 2010 organization. Before you enable the Scripting Agent, verify that the Scripting Agent configuration file has been properly renamed and updated with your scripts on every Exchange 2010 server. You will receive an error message each time a cmdlet runs if you don't rename the configuration file correctly.

To enable the Scripting Agent, you must do the following:

1. Rename the ScriptingAgentConfig.xml.sample file in **<installation path>\V14\Bin\CmdletExtensionAgents** to ScriptingAgentConfig.xml on every

Exchange 2010 server in your organization.

Note:
You can copy the configuration file from one Exchange 2010 server to other Exchange 2010 servers. Be sure you update the configuration file you want to copy before you copy it.

2. Add your script to the renamed configuration file on every Exchange 2010 server in your organization.
3. Enable the Scripting Agent cmdlet extension agent. For more information about enabling cmdlet extension agents, see Enable a Cmdlet Extension Agent.

Return to top

Agent Priority

By default, the Scripting Agent cmdlet extension agent runs after every other agent, with the exception of the Admin Audit Log agent. If you want a script you created to replace an existing agent, you must either disable the other agent or change the priority of either agent so that the Scripting Agent cmdlet extension agent runs first. For more information about how to disable or change the priority of agents, see the following topics:

- Disable a Cmdlet Extension Agent
- Change the Priority of a Cmdlet Extension Agent

Change the Priority of a Cmdlet Extension Agent

Exchange Management Shell > Cmdlet Extension Agent > Managing Cmdlet Extension Agents >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The ability to change the priority of a cmdlet extension agent in Microsoft Exchange Server

2010 is useful when you want a certain agent to be called by a cmdlet before another agent. This is especially useful if you create a custom script that's run in the `Scripting Agent`, and you want that script to take precedence over a built-in agent. For more information about the `Scripting Agent`, see Understanding the Scripting Agent.

Caution:
Changing the priority or replacing the functionality of a built-in agent is an advanced operation. Be sure that you completely understand the changes you're making.

Looking for other management tasks related to managing cmdlet extension agents? Check out Managing Cmdlet Extension Agents.

Use the Shell to change the priority of a cmdlet extension agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Cmdlet extension agents" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to change the priority of a cmdlet extension agent.

Agents are ordered from 0 to the maximum number of agents. The closer to zero the agent is, the higher the priority of the agent. Agents with a higher priority are called first. For more information about agent priorities, see Understanding Cmdlet Extension Agents.

This example changes the priority of a cmdlet extension agent by using the **Set-CmdletExtensionAgent** cmdlet. In this example, the priority of the `Scripting Agent` is changed to 3.

```
Set-CmdletExtensionAgent "Scripting Agent" -Priority 3
```

For detailed syntax and parameter information, see Set-CmdletExtensionAgent.

Other Tasks

After you change the priority of a cmdlet extension agent, you may also want to:

- Disable a Cmdlet Extension Agent
- Enable a Cmdlet Extension Agent
- View Existing Cmdlet Extension Agents

1.5.4.2.2 View Existing Cmdlet Extension Agents

View Existing Cmdlet Extension Agents

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Viewing cmdlet extension agents enables you to see which agents are run first, and

which agents are enabled in a Microsoft Exchange Server 2010 organization. For more information about pipelining and the **Format-Table** cmdlet, see the following topics:

- Pipelining
- Working with Command Output

Looking for other management tasks related to managing cmdlet extension agents? Check out Managing Cmdlet Extension Agents.

What Do You Want to Do?

- Use the Shell to view the details of a cmdlet extension agent
- Use the Shell to view multiple cmdlet extension agents

Use the Shell to view the details of a cmdlet extension agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Cmdlet extension agents" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to view existing cmdlet extension agents.

This example gets the details of a specific cmdlet extension agent by using the **Get-CmdletExtensionAgent** cmdlet. In this example, the details of the `Mailbox Permissions Agent` are returned.

```
Get-CmdletExtensionAgent "Mailbox Permissions Agent"
```

Use the Shell to view multiple cmdlet extension agents

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Cmdlet extension agents" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You cannot use the EMC to view existing cmdlet extension agents.

This example gets multiple cmdlet extension agents by using the **Get-CmdetExtensionAgent** cmdlet, and then pipes the output to the **Format-Table** cmdlet. This example displays a list of all of the cmdlet extension agents in the organization, and by using the **Format-Table** cmdlet, the **Name**, **Enabled**, and **Priority** properties of each agent are displayed in a table.

```
Get-CmdletExtensionAgent | Format-Table Name, Enabled, Priority
```

For detailed syntax and parameter information, see Get-CmdletExtensionAgent.

Other Tasks

After you view existing cmdlet extension agents, you may also want to:

- Change the Priority of a Cmdlet Extension Agent
- Disable a Cmdlet Extension Agent
- Enable a Cmdlet Extension Agent

1.5.4.2.3 Disable a Cmdlet Extension Agent

Disable a Cmdlet Extension Agent

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you disable a cmdlet extension agent in Microsoft Exchange Server 2010, the agent is disabled on every server running Exchange 2010 in the organization. When an agent is disabled, it's not made available to cmdlets. Cmdlets can no longer use the agent to perform additional operations.

Caution:

Before you disable an agent, be sure that you're aware of how the agent works and what impact disabling the agent will have on your organization.

Looking for other management tasks related to managing cmdlet extension agents? Check out Managing Cmdlet Extension Agents.

Use the Shell to disable a cmdlet extension agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Cmdlet extension agents" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

You can't use the EMC to disable a cmdlet extension agent.

To disable a cmdlet extension agent, use the **Disable-CmdletExtensionAgent** cmdlet. Specify the name of the agent you want to disable when you run the cmdlet. This example disables the `Scripting Agent`.

```
Disable-CmdletExtensionAgent "Scripting Agent"
```

For detailed syntax and parameter information, see Disable-CmdletExtensionAgent.

Other Tasks

After you disable a cmdlet extension agent, you may also want to:

- Change the Priority of a Cmdlet Extension Agent
- Enable a Cmdlet Extension Agent
- View Existing Cmdlet Extension Agents

1.5.4.2.4 Enable a Cmdlet Extension Agent

Enable a Cmdlet Extension Agent

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you enable a cmdlet extension agent in Microsoft Exchange Server 2010, the agent is run on every server running Exchange 2010 in the organization. When an agent is enabled, it's made available to cmdlets, which can then use the agent to perform additional operations.

Caution:

Before you enable an agent, be sure that you're aware of how the agent works and what impact the agent will have on your organization.

Looking for other management tasks related to managing cmdlet extension agents? Check out Managing Cmdlet Extension Agents.

Prerequisites

Before you enable the `Scripting Agent`, you must verify that it's configured correctly. For more information about the `Scripting Agent`, see Understanding the Scripting Agent.

Use the Shell to enable a cmdlet extension agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Cmdlet extension agents" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

You can't use the EMC to enable a cmdlet extension agent.

This example enables a cmdlet extension agent by using the **Enable-CmdletExtensionAgent** cmdlet. You must specify the name of the agent you want to enable when you run the cmdlet. Before you enable the `Scripting Agent`, you need to make sure that you've deployed the `ScriptingAgentConfig.xml` configuration file to all of the servers in your organization. If you don't deploy the configuration file first and you enable the `Scripting Agent`, all non-**Get** cmdlets fail when they're run. This example enables the `Scripting Agent`.

```
Enable-CmdletExtensionAgent "Scripting Agent"
```

For detailed syntax and parameter information, see Enable-CmdletExtensionAgent.

Other Tasks

After you enable a cmdlet extension agent, you may also want to:

- Change the Priority of a Cmdlet Extension Agent
- Disable a Cmdlet Extension Agent
- View Existing Cmdlet Extension Agents

1.5.5 Administrator Audit Logging

Administrator Audit Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-24*

In Microsoft Exchange Server 2010, administrator audit logging enables you to log each time a cmdlet is run in the Exchange Management Shell, the Exchange Management Console, or the Exchange Web management interface. For more information, see the following topics:

- Overview of Administrator Audit Logging
- Configure Administrator Audit Logging
- Search the Administrator Audit Log
- Disable Administrator Audit Logging
- Enable Administrator Audit Logging
- View Administrator Audit Logging Settings

1.5.5.1 Overview of Administrator Audit Logging

Overview of Administrator Audit Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-30*

You can use administrator audit logging in Microsoft Exchange Server 2010 to record actions taken by a user or administrator that make changes in your organization. By keeping a log of the changes, you can trace a change to the person who made it. You can also augment your change logs with detailed records of the change as it was implemented, use the records to comply with regulatory requirements and requests for discovery, and so on.

By default, audit logging is enabled in new installations of Microsoft Exchange Server 2010 Service Pack 1 (SP1).

What Gets Audited

Cmdlets that are run directly in the Exchange Management Shell are audited. In addition, operations that are performed by using the Exchange Management Console (EMC) and the Exchange Web management interface are also logged because those operations run cmdlets in the background.

Regardless of where it's run, a cmdlet is audited if it's on the cmdlet auditing list and if

one or more parameters on that cmdlet are on the parameter auditing list. **Get-** and **Search-** cmdlets aren't logged. Audit logging is intended to show what actions have been taken to modify objects in an Exchange organization rather than what objects have been viewed.

Important:

A cmdlet might not be logged if an error occurs before the cmdlet calls the Admin Audit Log cmdlet extension agent. If an error occurs after the Admin Audit Log agent is called, the cmdlet is logged together with the associated error. For more information, see the Admin Audit Log Agent section later in this topic.
Changes that are made by using Microsoft Exchange Server 2007 management tools aren't logged.
Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer.

Audit Logging Configuration

By default, if audit logging is enabled, a log entry is created every time any cmdlet, other than a **Get-** or **Search-** cmdlet, is run. If you don't want to audit every cmdlet that's run, you can configure audit logging to audit only the cmdlets and parameters you're interested in. You configure audit logging with the **Set-AdminAuditLogConfig** cmdlet. The parameters referenced in the following sections are used with this cmdlet.

Important:

Changes to the administrator audit log configuration are always logged, regardless of whether the **Set-AdministratorAuditLog** cmdlet is included in the list of cmdlets being audited, or whether audit logging is enabled or disabled.

When a command is run, Exchange inspects the cmdlet that was used. If the cmdlet that was run matches any of the cmdlets provided with the *AdminAuditLogConfigCmdlets* parameter, Exchange then checks the parameters specified in the *AdminAuditLogConfigParameters* parameter. If at least one or more parameters from the parameters list are matched, Exchange logs the cmdlet that was run in the mailbox specified by using the *AdminAuditLogMailbox* parameter.

Note:

With Exchange 2010 release to manufacturing (RTM), you specify an administrator audit log mailbox. Administrator audit logging in Exchange 2010 SP1 uses a dedicated mailbox. This dedicated mailbox can't be changed or configured.

The following sections contain more information about each aspect of the audit logging configuration.

For more information about how to manage audit logging configuration, see Configure Administrator Audit Logging.

Cmdlets

You can control which cmdlets are audited by providing a list of cmdlets, and their parameters, that you want to log. When you configure audit logging, you can specify to audit every cmdlet, or you can specify the cmdlets you want to audit using the *AdminAuditLogConfigCmdlets* parameter. You can specify full cmdlet names, such as **New-Mailbox**, or you can specify partial cmdlet names and enclose those names in wildcard characters, such as an asterisk (*). For example, if you want to log when any cmdlet that contains the string `Transport` runs, you can specify a value of `*Transport*`. You can use a mix of full cmdlet names and partial cmdlet names at the same time to tailor the audit logging configuration to your needs.

Parameters

In addition to specifying which cmdlets you want to log, you can also indicate that cmdlets should only be logged if certain parameters on those cmdlets are used. Use the *AdminAuditLogConfigParameters* parameter to specify which parameters should be logged. As with cmdlets, you can specify full parameter names, such as `Database`, or partial parameter names enclosed in wildcard characters (*), such as `*Address*`, or a combination of both.

Audit Log Age Limit

By default, audit logging is configured to store audit log entries for 90 days. After 90 days, the audit log entry is deleted. You can change the audit log age limit using the *AdminAuditLogAgeLimit* parameter. You can specify the number of days, hours, minutes, and seconds that audit log entries should be kept. To specify a value, use the format `dd.hh:mm:ss` where the following applies:

- **dd** The number of days to keep the audit log entry.
- **hh** The number of hours to keep the audit log entry.
- **mm** The number of minutes to keep the audit log entry.
- **ss** The number of seconds to keep the audit log entry.

You must specify multiple years using the dd field. For example, 365 days equals one year; 730 days equals two years; 913 days equals two years and six months. For example, to set the audit log age limit to two years and six months, use the syntax `913.00:00:00`.

Caution:

You can set the audit log age limit to a value that's less than the current age limit. If you do this, any audit log entry whose age exceeds the new age limit is deleted.
If you set the age limit to 0, Exchange deletes all the entries in the audit log.
We recommend that you grant permissions to configure the audit log age limit only to highly trusted users.

Test Cmdlets

Cmdlets that begin with the verb **Test** aren't logged by default. You can indicate that **Test** cmdlets should be logged by setting the *TestCmdletLoggingEnabled* parameter to `$true`. Although you can enable logging of test cmdlets, we recommend that you do this only for short periods of time. This is because test cmdlets can produce a large amount of information.

Audit Logs

Each time that a cmdlet is logged, an audit log entry is created. Audit logs are stored in a hidden, dedicated arbitration mailbox that can be accessed only by using the Exchange Control Panel (ECP) **Auditing Reports** page or the **Search-AdminAuditLog** or **New-AdminAuditLogSearch** cmdlet. Audit logs can't be opened by using Microsoft Office Outlook Web App or Microsoft Outlook. The following sections provide information about the following:

- What's included in the logs
- Reports available on the ECP **Auditing Reports** page
- Audit log search cmdlets

Note:

With Exchange 2010 release to manufacturing (RTM), you specify an administrator audit log mailbox. Administrator audit logging in Exchange 2010 SP1 uses a dedicated mailbox. This dedicated mailbox can't be changed or configured.
The ECP **Auditing Reports** page, and the **Search-AdminAuditLog** and **New-AdminAuditLogSearch** cmdlets work only with Exchange 2010 SP1 administrator audit logs. To view the contents of an Exchange 2010 RTM audit log mailbox, you must open that mailbox using Outlook Web App or an e-mail client such as Outlook.

Audit Log Contents

Each audit log entry contains the information described in the following table. The audit log contains one or more audit log entries. The number of audit log entries is controlled by the audit log age limit that's specified by using the **Set-AdminAuditLog** cmdlet. Any audit log entry that exceeds the age limit is deleted.

Audit log entry fields

Field	Description
RunspaceId	This field is used internally by Exchange.
ObjectModified	This field contains the object that was modified by the cmdlet specified in the CmdletName field.
CmdletName	This field contains the name of the cmdlet that was run by the user in the Caller field.
CmdletParameters	This field contains the parameters that were specified when the cmdlet in the CmdletName field was run. Also stored in this field, but not visible in the default output, is the value specified with the parameter, if any. For more information about how to access the additional information in this field, see Search the Administrator Audit Log.
ModifiedProperties	This field contains the properties that were modified on the object in the ObjectModified field. Also stored in this field, but not visible in the default output, are the old value of the property and the new value that was stored. For more information about how to access the additional information in this field, see Search the Administrator Audit Log.
Caller	This field contains the user account of the user who ran the cmdlet in the CmdletName field.
Succeeded	This field specifies whether the cmdlet in the CmdletName field ran successfully. The value is either True or False.
Error	This field contains the error message generated if the cmdlet in the CmdletName field failed to complete successfully.
RunDate	This field contains the date and time when the cmdlet in the CmdletName field was run. The date and time are stored in Coordinated Universal Time (UTC) format.
Identity	This field is used internally by Exchange.
IsValid	This field is used internally by Exchange.

ECP Audit Reports

The **Auditing Reports** page in the ECP has several reports that provide information on

various types of compliance and administrative configuration changes. The following reports provide information on configuration changes in your organization:

- **Administrator Role Changes** This report enables you to search for changes to management role groups that you specify within a specified timeframe. The results that are returned include the role groups that have been changed, who changed them and when, and what changes were made. A maximum of 3,000 entries can be returned. If your search might return more than 3,000 entries, use the **Export Configuration Changes** report or the **Search-AdminAuditLog** cmdlet.
- **Export Configuration Changes** This report enables you to export the audit log entries recorded within a specified timeframe to a XML file and then email the file to a recipient you specify. For more information about the contents of the XML file, see Administrator Audit Log Structure.

For information about how to use these reports, see Search the Administrator Audit Log.

Reports for litigation hold, mailbox configuration changes, and non-owner mailbox access are also included on the **Auditing Reports** page. For more information about these reports, see:

- Understanding Litigation Hold
- Understanding Mailbox Audit Logging

Search-AdminAuditLog Cmdlet

When you run the **Search-AdminAuditLog** cmdlet, all the audit log entries that match the search criteria that you specify are returned. You can specify the following search criteria:

- **Cmdlets** Specifies the cmdlets you want to search for in the administrator audit log.
- **Parameters** Specifies the parameters you want to search for in the administrator audit log. You can only search for parameters if you specify a cmdlet to search for.
- **End date** Scopes the administrator audit log results to log entries that occurred on or before the specified date.
- **Start date** Scopes the administrator audit log results to log entries that occurred on or after the specified date.
- **Object IDs** Specifies that only administrator audit log entries that contain the specified changed objects should be returned
- **User IDs** Specifies that only the administrator audit log entries that contain the specified IDs of the user who ran the cmdlet should be returned.
- **Successful completion** Specifies whether only administrator audit log entries that indicated a success or failure should be returned.

Each audit log entry returned contains the information described in the table in Audit Log Contents. By default, only the first 1,000 log entries that match the criteria you specify are returned. However, you can override this default and return more or fewer entries using the *ResultSize* parameter. You can specify a value of `Unlimited` with the *ResultSize* parameter to return all log entries that match the specified criteria.

For information about how to use the **Search-AdminAuditLog** cmdlet, see Search the Administrator Audit Log.

New-AdminAuditLogSearch Cmdlet

The **New-AdminAuditLogSearch** cmdlet searches the audit log just like the **Search-AdminAuditLog** cmdlet. However, instead of displaying the results of the audit log search in the Shell, the **New-AdminAuditLogSearch** cmdlet performs the search and then sends the results of the search to a recipient you specify via e-mail. The results are included as an XML attachment to the e-mail message.

You can use the same search criteria with the **New-AdminAuditLogSearch** cmdlet that's used on the **Search-AdminAuditLog** cmdlet. For a list of the search criteria, see Search-AdminAuditLog Cmdlet.

After you run the **New-AdminAuditLogSearch** cmdlet, Exchange may take up to 15 minutes to deliver the report to the specified recipient. The XML file attached report can be a maximum of 10 megabytes (MB). The XML file contains the same information described in the table in Audit Log Contents. For more information about the structure of the XML file, see Administrator Audit Log Structure.

Note:

Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another e-mail client, such as Microsoft Office Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or Configure Outlook Web App Virtual Directories.

For information about how to use the **New-AdminAuditLogSearch** cmdlet, see Search the Administrator Audit Log.

Manual Audit Log Entries

In addition to logging Exchange cmdlets when they're run, Exchange 2010 SP1 enables you to manually write log entries to the audit log. Exchange 2010 SP1 supports this using the **Write-AdminAuditLog** cmdlet. Situations where you might want to add a manual log entry include the following:

- Custom script entry and exit
- Change control information
- Maintenance start and end times

With the **Write-AdminAuditLog** cmdlet, you specify a string of text to include in the audit log using the *Comment* parameter. The *Comment* parameter accepts an alphanumeric string up to 500 characters. Included in the manual audit log entry along with the comment string is all of the same information captured when an Exchange cmdlet is logged. For a description of each field included in the audit log, see the table in Audit Log Contents.

You can retrieve manual audit log entries the same way as any other log entry, using the ECP **Auditing Reports** page or using the **Search-AdminAuditLog** or **New-AdminAuditLogSearch** cmdlets.

To view the contents of the *Comment* parameter on the **Write-AdminAuditLog** cmdlet in a manual audit log entry, see Search the Administrator Audit Log.

Active Directory Replication

Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all servers running Exchange 2010 in your organization.

Admin Audit Log Agent

The Admin Audit Log built-in cmdlet extension agent performs administrator audit logging of cmdlet operations in Exchange 2010. This agent reads the audit log configuration, and then performs an evaluation of each cmdlet run in your organization. If the criteria you've specified in the audit log configuration matches the cmdlet that's being run, the agent generates an audit log.

The Admin Audit Log agent is enabled by default, which is required for audit logging to function. It can't be disabled, and its priority can't be changed. For more information about cmdlet extension agents, see Understanding Cmdlet Extension Agents.

How Admin Audit Logs May Cause Rapid Database Growth

By default, the admin audit log is enabled in Exchange Server 2010. The log results are stored in the arbitration mailbox in the AdminAuditLogs folder. If cmdlets are executed in the Exchange Management Shell frequently, multiple log entries are generated, and may cause the size of the database to grow quickly. This behavior may occur even if no user mailboxes exist.

To determine the size of the AdminAuditLogs folder, run the following cmdlet in the Exchange Management Shell: **Get-MailboxFolderstatistics** *"Guid of arbitration mailbox"* **-FolderScope RecoverableItems –IncludeAnalysis**. Next, view the item count and size of the AdminAuditLogs folder.

If the item count and the size of the AdminAuditLogs folder are high, run the following cmdlet to delete the items from the folder: **Search-Mailbox** *Guid of arbitration mailbox* **-Dumpsteronly -deletecontent**.

A cmdlet that is being executed frequently may be causing the database growth. Typically, the cmdlet is in a script that is scheduled to run periodically. Identify the cmdlet that is causing the admin audit log to grow. After you confirm that the cmdlet can be excluded from the admin audit log, run the following cmdlet in the Exchange Management Shell: **Set-AdminAuditLogConfig AdminAuditLogExcludedCmdlets** *cmdlet name*. For example, run the following cmdlet: **Set-AdminAuditLogConfig AdminAuditLogExcludedCmdlets Add-DistributionGroupMember**. After you run the cmdlet, you must wait for replication to be completed.

1.5.5.1.1 Administrator Audit Log Structure

Administrator Audit Log Structure

Exchange Management Shell > Administrator Audit Logging > Overview of Administrator Audit Logging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-24*

Administrator audit logs contain a record of all the cmdlets and parameters that have been run in the Exchange Management Shell and by the Exchange Management Console (EMC) and Exchange Control Panel (ECP). They're created on-demand when you run the Export Configuration Changes report in the ECP, or when you run the **New-AdminAuditLogSearch** cmdlet in the Shell. For more information about audit logs, see Overview of Administrator Audit Logging.

The audit logs are XML files and can contain multiple audit log entries. The following table describes each XML tag and its associated attributes.

Audit log XML tags and attributes

Element	Attribute	Description

<?xml version="1.0" encoding="utf-8"?>	N/A	This is the XML document declaration tag. It's included in every audit log XML file and contains the XML version number and the character encoding value.
SearchResults	N/A	This tag contains all the audit log entries in the XML file. The Event tag is a child of this tag. There is only one SearchResults tag per XML file.
Event		This tag contains the audit log entry for an individual cmdlet. This tag contains the Caller, Cmdlet, ObjectModified, RunDate, Succeeded, and Error attributes. The CmdletParameters and ModifiedProperties tags are children of this tag. There is one Event tag per audit log entry.
	Caller	This attribute contains the user account of the user who ran the cmdlet in the Cmdlet attribute.
	Cmdlet	This attribute contains the name of the cmdlet that was run by the user in the Caller attribute.
	ObjectModified	This attribute contains the object that was modified by the cmdlet specified in the Cmdlet attribute. The ModifiedProperties tag shows which properties were modified on this object.
	RunDate	This attribute contains the date and time when the cmdlet in the Cmdlet attribute was run. The date and time are stored in Coordinated Universal Time (UTC) format.
	Succeeded	This attribute specifies whether the cmdlet in the Cmdlet attribute ran successfully. The value is

		either `True` or `False`.
	`Error`	This attribute contains the error message generated if the cmdlet in the `Cmdlet` attribute failed to complete successfully. If no error was encountered, the value is set to `None`.
`CmdletParameters`	`N/A`	This tag contains all of the parameters specified when the cmdlet was run. The `Parameter` tag is a child of this tag. There is one `CmdletParameters` tag per `Event` tag.
`Parameter`		This tag contains an individual parameter that was specified when the cmdlet was run. This tag contains the `Name` and `Value` attributes. There can be multiple `Parameter` tags per `CmdletParameters` tag.
	`Name`	This attribute contains the name of the parameter that was specified on the cmdlet that was run.
	`Value`	This attribute contains the value that was provided on the parameter specified in the `Name` attribute.
`ModifiedProperties`	`N/A`	This tag contains all of the properties that were modified by the cmdlet that was run. The `Property` tag is a child of this tag. There is one `ModifiedProperties` tag per `Event` tag.
`Property`		This tag contains an individual property that was specified when the cmdlet was run. This tag contains the `Name`, `OldValue`, and `NewValue` attributes. There can be multiple

		Property tags per ModifiedProperties tag.
	Name	This attribute contains the name of the property that was modified when the cmdlet was run.
	OldValue	This attribute contains the value that was contained in the property specified in the Name attribute before it was changed.
	NewValue	This attribute contains the value that the property in the Name attribute was changed to.

Example audit log entry

The following is an example of a typical audit log entry. Based on the information in log entry, we know the following occurred:

- On 3/5/2010 at 11:59 P.M. UTC, the user Administrator ran the cmdlet **Set-Mailbox**.
- The two following parameters were provided when the **Set-Mailbox** cmdlet was run:
  - *Identity* with a value of david
  - *ProhibitSendReceiveQuota* with a value of 1.727 GB
- The two following properties on the object david were modified:
  - *ProhibitSendReceiveQuota* with a new value of 1.727 GB, which replaced the old value of 523.4 MB
  - *ObjectState* with a new value of Changed, which replaced the old value of Unchanged
- The operation completed successfully without any errors.

```
<?xml version="1.0" encoding="utf-8"?>
<SearchResults>
  <Event Caller="Wally14.extest.microsoft.com/Users/Administrator" Cmdlet="Set-Ma
    <CmdletParameters>
      <Parameter Name="Identity" Value="david" />
      <Parameter Name="ProhibitSendReceiveQuota" Value="1.727 GB (1,854,030,822 b
    </CmdletParameters>
    <ModifiedProperties>
      <Property Name="ProhibitSendReceiveQuota" OldValue=" 523.4 MB (548,845,001
      <Property Name="ObjectState" OldValue="Unchanged" NewValue="Changed" />
    </ModifiedProperties>
  </Event>
</SearchResults>
```

1.5.5.2 Configure Administrator Audit Logging

Configure Administrator Audit Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Administrator audit logging in Microsoft Exchange Server 2010 enables you to create a log entry each time a specified cmdlet is run. Log entries detail what cmdlet was run, which parameters were used, who ran the cmdlet, and what objects were affected. For more information about administrator audit logging, see Overview of Administrator Audit Logging.

You must use the Shell to configure administrator audit logging.

Important:

Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all Exchange 2010 servers in your organization.
Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer.

Specify the cmdlets to be audited

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

You can't use the EMC to specify the cmdlets to be audited.

By default, audit logging creates a log entry for every cmdlet that's run. If you're enabling audit logging for the first time and want this behavior, you don't have to change the cmdlet audit list. If you've previously specified cmdlets to audit and now want to audit all cmdlets, you can audit all cmdlets by specifying the asterisk (*) wildcard character with the *AdminAuditLogCmdlets* parameter on the **Set-AdminAuditLogConfig** cmdlet, as shown in the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogCmdlets *
```

You can specify which cmdlets to audit by providing a list of cmdlets using the *AdminAuditLogCmdlets* parameter. When you provide the list of cmdlets to audit, you can provide single cmdlets, cmdlets with the asterisk (*) wildcard characters, or a mix of both. Each entry in the list is separated by commas. The following values are all valid:

- `New-Mailbox`
- `*TransportRule`
- `*Management*`
- `Set-Transport*`

This example audits the cmdlets specified in the preceding list.

```
Set-AdminAuditLogConfig -AdminAuditLogCmdlets New-Mailbox, *TransportRule, *Manag
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Specify the parameters to be audited

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to specify the parameters to be audited.

By default, audit logging creates a log entry for every cmdlet that's run, regardless of the parameters specified. If you're enabling audit logging for the first time and want this behavior, you don't have to change the parameter audit list. If you've previously specified parameters to audit and now want to audit all parameters, you can do so by specifying the asterisk (*) wildcard character with the *AdminAuditLogParameters* parameter on the **Set-AdminAuditLogConfig** cmdlet, as shown in the following command.

```
Set-AdminAuditLogConfig -AdminAuditLogParameters *
```

You can specify which parameters you want to audit by using the *AdminAuditLogParameters* parameter. When you provide the list of parameters to audit, you can provide single parameters, parameters with the asterisk (*) wildcard characters, or a mix of both. Each entry in the list is separated by commas. The following values are all valid:

- `Database`
- `*Address*`
- `Custom*`
- `*Region`

Note:
For an audit log entry to be created when a command is run, the command must include at least one or more parameters that exist on at least one or more cmdlets specified with the *AdminAuditLogCmdlets* parameter.

This example audits the parameters specified in the preceding list.

```
Set-AdminAuditLogConfig -AdminAuditLogParameters Database, *Address*, Custom*, *R
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Specify the audit log age limit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to specify the audit log age limit.

The audit log age limit determines how long audit log entries will be retained. When a log entry exceeds the age limit, it's deleted. The default is one year.

You can specify the number of days, hours, minutes, and seconds that audit log entries should be kept. To specify a value, use the format dd.hh.mm:ss where the following applies:

- **dd** Number of days to keep the audit log entry
- **hh** Number of hours to keep the audit log entry
- **mm** Number of minutes to keep the audit log entry
- **ss** Number of seconds to keep the audit log entry

Caution:
You can set the audit log age limit to a value that's less than the current age limit. If you do this, any audit log entry whose age exceeds the new age limit will be deleted.
If you set the age limit to 0, Exchange deletes all the entries in the audit log.
We recommend that you grant permissions to configure the audit log age limit only to

highly trusted users.

This example specifies an age limit of two years and six months.

```
Set-AdminAuditLogConfig -AdminAuditLogAgeLimit 913.00:00:00
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Enable or disable logging of Test cmdlets

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to enable or disable logging of **Test** cmdlets.

Cmdlets that start with the verb **Test** aren't logged by default. This is because **Test** cmdlets can generate a significant amount of data in a short time. Only enable the logging of **Test** cmdlets for short periods of time.

This command enables the logging of **Test** cmdlets.

```
Set-AdminAuditLogConfig -TestCmdletLoggingEnabled $True
```

This command disables the logging of **Test** cmdlets.

```
Set-AdminAuditLogConfig -TestCmdletLoggingEnabled $False
```

For detailed syntax and parameter information, see Set-AdminAuditLogConfig.

Other Tasks

After you configure administrator audit logging, you may also want to:

- Search the Administrator Audit Log
- View Administrator Audit Logging Settings
- Disable Administrator Audit Logging
- Configure Administrator Audit Logging

1.5.5.3 Search the Administrator Audit Log

Search the Administrator Audit Log

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can search the administrator audit logs to discover who made changes to organization, server, and recipient configuration. This can be helpful when trying to track the cause of unexpected behavior, to identify a malicious administrator, or to verify that compliance requirements are being met. For more information about administrator audit logging, see Overview of Administrator Audit Logging.

Note:
The Exchange Control Panel (ECP) Auditing Reports page, the **Search-AdminAuditLog** cmdlet, and the **New-AdminAuditLogSearch** cmdlet work only with Microsoft Exchange Server 2010 Service Pack 1 (SP1) administrator audit logs. To view the contents of an Exchange 2010 release to manufacturing (RTM) audit log mailbox, you must open that mailbox using Microsoft Office Outlook Web App or an e-mail client such as Microsoft Outlook.

If you want to search for changes to litigation hold changes, see Managing Discovery.

If you want to search the mailbox audit log, see Managing Mailbox Audit Logging.

Prerequisites

Administrator audit logging must be enabled for audit log entries to be stored in the audit log. For information about how to enable audit logging, see Configure Administrator Audit Logging.

Use the ECP to view management role group changes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

If you want to know what changes to management role group membership have been made to role groups in your organization, you can use the Administrator Role Changes report on the Auditing Reports page in the ECP. Using the Administrator Role Changes report, you can view a list of role groups that have changed during a specified date range. You can also select the specific role groups you want to view changes for.

1. Log on to Outlook Web App.
2. Click **Options**, and then click **See All Options**.
3. In the drop-down list box next to **Mail > Options**, click **My Organization** from the **Select what to manage** list.
4. Click **Reporting**, click **Auditing**, and then click **Administrator Role Changes**.
5. Select a date range using the **Start Date** and **End Date** fields.
6. Select the role groups you want to show changes for from the **Select Role Groups** field, or leave this field blank to search for changes in all role groups.
7. Click **Search**.

If any changes are found using the criteria you specified, a list of changes will be displayed in the **Search Results** pane. Clicking a role group displays the changes to the role group in the details pane.

Use the ECP to export the administrator audit log

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

If you want to create an XML file that contains changes made to your organization, you can use the Export Configuration Changes report on the Auditing Reports page in the ECP. Using the Export Configuration Changes report, you can specify a date range to search for audit log entries that contain changes made by users you specify. The XML file

is then sent to a recipient as an e-mail attachment. The maximum size of the XML file is 10 megabytes (MB).

Note:
Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another e-mail client, such as Microsoft Office Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or Configure Outlook Web App Virtual Directories.

1. Log on to Outlook Web App.
2. Click **Options**, and then click **See All Options**.
3. In the drop-down list box next to **Mail > Options**, click **My Organization** from the **Select what to manage** list.
4. Click **Reporting**, click **Auditing**, and then click **Export Configuration Changes**.
5. Select a date range using the **Start Date** and **End Date** fields.
6. Select the recipient who should receive the XML file using the **Select users to email the audit log to** field.
7. Click **Export**.

If any log entries are found using the criteria you specified, an XML file will be created and sent as an e-mail attachment to the recipient you specified.

Use the Shell to search for audit log entries

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to search for audit log entries.

You can use the Shell to search for audit log entries that meet the criteria you specify. For a list of search criteria, see Overview of Administrator Audit Logging. This procedure uses the **Search-AdminAuditLog** cmdlet and displays search results in the Shell. It can be used when you need to return a set of results that exceeds the limits defined on the **New-AdminAuditLogSearch** cmdlet or in the ECP Audit Reporting reports.

If you want to send audit log search results in an e-mail attachment to a recipient, see Use the Shell to search for audit log entries and send results to a recipient later in this topic.

To search the audit log for criteria you specify, use the following syntax.

```
Search-AdminAuditLog - Cmdlets <cmdlet 1, cmdlet 2, ...> -Parameters <parameter 1
```

Note:
The **Search-AdminAuditLog** cmdlet returns a maximum of 1,000 log entries by default. Use the *ResultSize* parameter to specify up to 250,000 log entries.

This example performs a search for all audit log entries with the following criteria:

- **Start date** 02/04/2010
- **End date** 04/03/2010
- **User IDs** davids, chrisd, kima
- **Cmdlets** **Set-Mailbox**
- **Parameters** *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, *IssueWarningQuota*, *MaxSendsize*, *MaxReceiveSize*

```
Search-AdminAuditLog -Cmdlets Set-Mailbox -Parameters ProhibitSendQuota, Prohibit
```

This example searches for changes made to a specific mailbox. This is useful if you're troubleshooting or you need to provide information for an investigation. The following criteria are used:

- **Start date** 01/01/2010
- **End date** 08/03/2010
- **Object ID** contoso.com/Users/DavidS

```
Search-AdminAuditLog -StartDate 01/01/2010 -EndDate 08/03/2010 -ObjectID contoso.
```

If your searches return many log entries, we recommend that you use the procedure provided in Use the Shell to search for audit log entries and send results to a recipient later in this topic. The procedure in that section sends an XML file as an e-mail attachment to the recipients you specify, enabling you to more easily extract the data you're interested in.

For detailed syntax and parameter information, see Search-AdminAuditLog.

View details of audit log entries

The **Search-AdminAuditLog** cmdlet returns the fields described in the "Audit log contents" section of Overview of Administrator Audit Logging. Of the fields returned by the cmdlet, two fields, **CmdletParameters** and **ModifiedProperties**, contain additional information that isn't viewable by default.

To view the contents of the **CmdletParameters** and **ModifiedProperties** fields, use the following steps. Or, you can use the procedure in Use the Shell to search for audit log entries and send results to a recipient later in this topic to create an XML file.

This procedure uses the following concepts:

- Arrays
- User-Defined Variables

1. Decide the criteria you want to search for, run the **Search-AdminAuditLog** cmdlet, and store the results in a variable using the following command.

   ```
   $Results = Search-AdminAuditLog <search criteria>
   ```

2. Each audit log entry is stored as an array element in the variable `$Results`. You can select an array element by specifying its array element index. Array element indexes start at 0 for the first array element. For example, to retrieve the 5th array element, which has an index of 4, use the following command.

   ```
   $Results[4]
   ```

3. The previous command returns the log entry stored in array element 4. To see the contents of the **CmdletParameters** and **ModifiedProperties** fields for this log entry, use the following commands.

   ```
   $Results[4].CmdletParameters
   $Results[4].ModifiedProperties
   ```

4. To view the contents of the **CmdletParameters** or **ModifiedParameters** fields in another log entry, change the array element index.

Use the Shell to search for audit log entries and send results to a recipient

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View-only administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
You can't use the EMC to search for audit log entries and send results to a recipient.

You can use the Shell to search for audit log entries that meet the criteria you specify, and then send those results to a recipient you specify as an XML file attachment. The results are sent to the recipient within 15 minutes. For a list of search criteria, see Overview of Administrator Audit Logging.

Note:
Outlook Web App doesn't allow you to open XML attachments by default. You can either configure Exchange to allow XML attachments to be viewed using Outlook Web App, or you can use another e-mail client, such as Microsoft Office Outlook, to view the attachment. For information about how to configure Outlook Web App to allow you to view an XML attachment, see View or Configure Outlook Web App Virtual Directories.

To search the audit log for criteria you specify, use the following syntax.

```
New-AdminAuditLogSearch -Cmdlets <cmdlet 1, cmdlet 2, ...> -Parameters <parameter
```

This example performs a search for all audit log entries with the following criteria:

- **Start date** 02/04/2010
- **End date** 04/03/2010
- **User IDs** davids, chrisd, kima
- **Cmdlets** **Set-Mailbox**
- **Parameters** *ProhibitSendQuota*, *ProhibitSendReceiveQuota*, *IssueWarningQuota*, *MaxSendsize*, *MaxReceiveSize*

The command sends the results to the davids mailbox with "Mailbox limit changes" included in the subject line of the message.

```
New-AdminAuditLogSearch -Cmdlets Set-Mailbox -Parameters ProhibitSendQuota, Prohi
```

Note:
The report that the **New-AdminAuditLogSearch** cmdlet generates can be a maximum of 10 MB in size. If the search you perform returns a report larger than 10 MB, change the search criteria you specified. For example, reduce the size of the date range and run multiple reports, each with a portion of the original date range.

For more information about the format of the XML file, see Administrator Audit Log Structure.

For detailed syntax and parameter information, see New-AdminAuditLogSearch.

1.5.5.4 Disable Administrator Audit Logging

Disable Administrator Audit Logging

Exchange Server 2010 > Exchange Management Shell > Administrator Audit Logging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use this topic to disable administrator audit logging if it's enabled. Administrator audit logging in Microsoft Exchange Server 2010 enables you to create a log entry each time a specified cmdlet is run. For more information about administrator audit logging, see Overview of Administrator Audit Logging.

Important:
Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all Exchange 2010 servers in your organization.
Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer.

Use the Shell to disable administrator audit logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

To disable administrator audit logging, use the following command:

```
Set-AdminAuditLogConfig -AdminAuditLogEnabled $False
```

Other Tasks

After you disable administrator audit logging, you may also want to:

- View Administrator Audit Logging Settings
- Configure Administrator Audit Logging

1.5.5.5 Enable Administrator Audit Logging

Enable Administrator Audit Logging

Exchange Server 2010 > Exchange Management Shell > Administrator Audit Logging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use this topic to enable administrator audit logging if it's disabled. Administrator audit logging in Microsoft Exchange Server 2010 enables you to create a log entry each time a specified cmdlet is run. For more information about administrator audit logging, see Overview of Administrator Audit Logging.

Important:
Administrator audit logging relies on Active Directory replication to replicate the configuration settings you specify to the domain controllers in your organization. Depending on your replication settings, the changes you make may not be immediately applied to all Exchange 2010 servers in your organization.
Changes to the audit log configuration are refreshed every 60 minutes on computers that have the Shell open at the time a configuration change is made. If you want to apply the changes immediately, close and then open the Shell again on each computer.

Prerequisites

You must specify the cmdlets and parameters you want to audit, and you must also specify the destination audit logging mailbox before you enable administrator audit logging. For more information about how to configure administrator audit logging, see Configure Administrator Audit Logging.

Use the Shell to enable administrator audit logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

To enable administrator audit logging, use the following command:

```
Set-AdminAuditLogConfig -AdminAuditLogEnabled $True
```

Other Tasks

After you enable administrator audit logging, you may also want to:

- View Administrator Audit Logging Settings
- Configure Administrator Audit Logging

1.5.5.6 View Administrator Audit Logging Settings

View Administrator Audit Logging Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use this topic to view the administrator audit logging settings that you've configured for your organization. Administrator audit logging in Microsoft Exchange Server 2010 enables you to create a log entry each time a specified cmdlet is run. For more information about administrator audit logging, see Overview of Administrator Audit Logging.

Use the Shell to view administrator audit logging settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Administrator audit logging" entry in the Exchange and Shell Infrastructure Permissions topic.

To view the administrator audit logging settings that you've configured for your organization, use the following command:

```
Get-AdminAuditLogConfig
```

1.5.6 Troubleshooting the Exchange Management Shell

Troubleshooting the Exchange Management Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

While using the remote Exchange Management Shell with Microsoft Exchange Server 2010, you may encounter problems. You can use the information in this topic to diagnose and resolve client and connection issues.

This topic addresses problems with the Shell that administrators of on-premises installations of Exchange 2010 might encounter. If you're troubleshooting problems with the remote Shell for your Microsoft Office Outlook Web App organization, see Windows PowerShell: FAQ for Administrators.

Client Issues

The following sections describe techniques for resolving client issues that you may encounter.

Script Execution Error Caused by Windows PowerShell Execution Policy

You might get the following error message when you attempt to open the Shell using the instructions in the topic Open the Shell. The error is caused by setting the script execution policy in Windows PowerShell to `Restricted` or `AllSigned`. To resolve this issue, you need to set the script execution policy to `RemoteSigned`. For more information, see Install Windows Management Framework.

```
File D:\Program Files\Microsoft\Exchange Server\V14\bin\RemoteExchange.ps1 cann
ot be loaded because the execution of scripts is disabled on this system. Pleas
e see "get-help about_signing" for more details.
At line:1 char:2
+ . <<<<  'D:\Program Files\Microsoft\Exchange Server\V14\bin\RemoteExchange.ps
1'; Connect-ExchangeServer -auto
    + CategoryInfo          : NotSpecified: (:) [], PSSecurityException
    + FullyQualifiedErrorId : RuntimeException
The term 'Connect-ExchangeServer' is not recognized as the name of a cmdlet, fu
nction, script file, or operable program. Check the spelling of the name, or if
 a path was included, verify that the path is correct and try again.
At line:1 char:98

nnect-ExchangeServer <<<<  -auto
    + CategoryInfo          : ObjectNotFound: (Connect-ExchangeServer:String)
   [], CommandNotFoundException
    + FullyQualifiedErrorId : CommandNotFoundException
```

Import-PSSession Error Caused by Windows PowerShell Execution Policy

You might get the following error message when you attempt to use the remote Shell to connect to a remote Exchange 2010 server using the instructions in the topic Connect Remote Exchange Management Shell to an Exchange Server. The error is caused by setting the script execution policy in Windows PowerShell to `Restricted` or `AllSigned`. To resolve this issue, you need to set the script execution policy to `RemoteSigned`. For more information, see Install Windows Management Framework.

```
Import-Module : There were errors in loading the format data file:

Error When the ForEach Cmdlet Is Used in a Pipeline and Cmdlets Are Used in its Script Block

You might get the following error message when you use the **ForEach** cmdlet in a pipeline and the following circumstances are true:

- The **ForEach** cmdlet accepts data from a cmdlet earlier in the pipeline.
- The script block on the **ForEach** cmdlet contains a cmdlet.

This error is caused because the Windows PowerShell remoting feature doesn't support more than one pipeline running at the same time. To resolve this issue, store the output of the cmdlet earlier in the pipeline in a variable, and then pipe the data stored in the variable to the **ForEach** cmdlet. This example results in a concurrent pipeline error.

```
Get-Mailbox | ForEach { Set-Mailbox -ProhibitSendReceiveQuota 3GB }
```

The following error message is generated.

```
Pipeline not executed because a pipeline is already executing. Pipelines cannot b
    + CategoryInfo          : OperationStopped: (Microsoft.Power...tHelperRunspac
   PSInvalidOperationException
    + FullyQualifiedErrorId : RemotePipelineExecutionFailed
```

To resolve the error, store the output of the **Get-Mailbox** cmdlet in a variable, and then pipe the variable to the **ForEach** cmdlet, as shown in this example.

```
$Mailboxes = Get-Mailbox
$Mailboxes | ForEach { Set-Mailbox -ProhibitSendReceiveQuota 3GB }
```

Incorrect Version of Windows PowerShell Installed

You might get the following error messages if you don't have the correct version of Windows PowerShell installed. You must have Windows PowerShell 2.0, available in Windows Management Framework, to connect to a remote Exchange 2010 server. For more information, see Install Windows Management Framework.

You might receive the following error message if you have Windows PowerShell 1.0 installed.

```
The term 'New-PSSession' is not recognized as a cmdlet, function, operable progra
 try again.
At line:1 char:25
+ $Session = New-PSSession  <<<< -ConfigurationName Microsoft.Exchange -Connectio
/PowerShell/ -Authentication Kerberos
```

You might receive the following error messages if you have a pre-release version of Windows PowerShell 2.0 installed.

```
New-PSSession : Cannot bind parameter 'Authentication'. Cannot convert value "Ker
mation.Runspaces.AuthenticationMechanism" due to invalid enumeration values. Spec
alues and try again. The possible enumeration values are "Default, Basic, Negotia
redssp".

    + CategoryInfo          : OpenError: (System.Manageme....RemoteRunspace:Remot
   gTransportException
    + FullyQualifiedErrorId : RemoteRunspaceOpenFailed
```

User Isn't Enabled for Remote Shell

You can receive the following error message if a user tries to connect to a remote Exchange 2010 server and the remote Shell isn't enabled. For more information about how to enable users for the remote Shell, see Enable Remote Exchange Management Shell for a User.

```
[ExchServer] Connecting to remote server failed with the following error message
request. It cannot determine the content type of the HTTP response from the desti
bsent or invalid. For more information, see the about_Remote_Troubleshooting Help
    + CategoryInfo          : OpenError: (System.Manageme....RemoteRunspace:Remot
   eption
    + FullyQualifiedErrorId : PSSessionOpenFailed
```

Server Name Provided Doesn't Exist

You can receive the following error message if the server name you specified in the remote Shell URL doesn't exist. To resolve this issue, verify the server name. For more information, see Connect Remote Exchange Management Shell to an Exchange Server.

```
[exchserver01] Connecting to remote server failed with the following error messag
The following error occured while using Kerberos authentication: The network path
 Possible causes are:
  -The user name or password specified are invalid.
  -Kerberos is used when no authentication method and no user name are specified.
  -Kerberos accepts domain user names, but not local user names.
  -The Service Principal Name (SPN) for the remote computer name and port does no
  -The client and remote computers are in different domains and there is no trust
 After checking for the above issues, try the following:
  -Check the Event Viewer for events related to authentication.
  -Change the authentication method; add the destination computer to the WinRM Tr
e HTTPS transport.
 Note that computers in the TrustedHosts list might not be authenticated.
   -For more information about WinRM configuration, run the following command: wi
 see the about_Remote_Troubleshooting Help topic.
```

```
    + CategoryInfo          : OpenError: (System.Manageme....RemoteRunspace:Remot
   eption
    + FullyQualifiedErrorId : PSSessionOpenFailed
```

Incorrect Virtual Directory Name

You can receive the following error message if you specify the wrong virtual directory when connecting to a remote Exchange 2010 server. To resolve this issue, verify the virtual directory name. For more information, see Connect Remote Exchange Management Shell to an Exchange Server.

```
[ExchServer] Connecting to remote server failed with the following error message
atus code of 403 from the remote WS-Management service. For more information, see
 topic.
    + CategoryInfo          : OpenError: (System.Manageme....RemoteRunspace:Remot
   eption
    + FullyQualifiedErrorId : PSSessionOpenFailed
```

Warning When the Import-PSSession Cmdlet Is Run

When you connect to a remote Exchange 2010 server using the procedure provided in the Connect Remote Exchange Management Shell to an Exchange Server topic, it's normal to see the following warning after you import the Exchange 2010 cmdlets into your local client.

```
WARNING: Some imported command names include unapproved verbs which might make th
 parameter for more detail or type Get-Verb to see the list of approved verbs.
```

HTTPS Used When Connecting to a Remote Server

You might receive an error message when connecting to a remote Exchange 2010 server if you use the HTTPS protocol. This error occurs because your computer doesn't trust the certification authority (CA) used to sign the Secure Sockets Layer (SSL) certificate used by the remote server. To connect to a remote Exchange 2010 server, you must use the HTTP protocol and the Kerberos authentication method. For more information, see Connect Remote Exchange Management Shell to an Exchange Server.

```
[ExchServer] Connecting to remote server failed with the following error message
ation computer (ExchServer:443) has the following errors:
The SSL certificate is signed by an unknown certificate authority. For more infor
ooting Help topic.

    + FullyQualifiedErrorId : PSSessionOpenFailed
```

1.6 Client Access

Client Access

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-03*

In Microsoft Exchange Server 2010, the Client Access server role supports the Outlook Web App and Microsoft Exchange ActiveSync client applications, and the Post Office Protocol version 3 (POP3) and Internet Message Access Protocol version 4rev1 (IMAP4)

protocols. The Client Access server role also provides access to free/busy data by using the Availability service and enables certain clients to download automatic configuration settings from the Autodiscover service. You must install the Client Access server role in every Exchange organization and every Active Directory site that has the Mailbox server role installed.

The following topics are gateways to information about the Client Access servers in Exchange 2010.

Understanding Client Access

This topic provides feature information about the Client Access server role.

Managing Client Access Servers

This topic is a collection of links that provide information about managing Client Access features in your organization.

Securing Client Access Servers

This topic provides information about the security features of your Client Access server.

Upgrade from Exchange 2003 Client Access

This topic provides overview information about upgrading your organization's Client Access infrastructure from Exchange 2003 to Exchange 2010.

Upgrade from Exchange 2007 Client Access

This topic provides overview information about upgrading your organization's Client Access infrastructure from Exchange 2007 to Exchange 2010.

1.6.1 Understanding Client Access

Understanding Client Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

The Client Access server role is one of five distinct server roles for Microsoft Exchange Server 2010. It supports the Outlook Web App and Microsoft Exchange ActiveSync client applications, and the Post Office Protocol version 3 (POP3) and Internet Message Access Protocol version 4rev1 (IMAP4) protocols. The Client Access server role also provides access to free/busy data by using the Availability service and enables certain clients to download automatic configuration settings from the Autodiscover service.

The Client Access server role accepts connections to your Exchange 2010 server from different clients. Software clients such as Microsoft Outlook Express and Eudora use POP3 or IMAP4 connections to communicate with the Exchange server. Hardware clients, such as mobile phones, use ActiveSync, POP3, or IMAP4 to communicate with the Exchange server. You must install the Client Access server role in every Exchange organization and every Active Directory site that has the Mailbox server role installed.

Looking for management tasks related to Client Access? See Managing Client Access Servers.

Contents

Client Access Server Network Architecture

In addition to needing a Client Access server in every Active Directory site that contains a Mailbox server, it's important to avoid restrict traffic among Exchange servers. Otherwise, Exchange functionality can be negatively affected. Make sure that all defined ports used by Exchange are open in both directions between all source and destination servers. Installing a firewall between Exchange servers or between an Exchange Server 2010 Mailbox server or Exchange Server 2010 Client Access server and Active Directory isn't supported. However, you can install a network device as long as traffic isn't restricted and all available ports are open between the various Exchange servers and Active Directory. For a complete list of Exchange Server 2010 ports, see Exchange Network Port Reference.

Outlook Web App

Outlook Web App lets you access your e-mail from any Web browser. Outlook Web App (known as Outlook Web Access in earlier versions of Microsoft Exchange) has been redesigned in Exchange 2010. Features such as Chat, Text Messaging, mobile phone integration, and Conversation View provide an enhanced user experience from any computer that has a Web browser. In Exchange Server 2010, these features can be accessed from an expanded set of Web browsers including versions of Internet Explorer later than 6.0, Firefox, Safari, and Google's Chrome.

For more information about Outlook Web App, see the following topics:

- Managing Outlook Web App
- Understanding Outlook Web App

Exchange ActiveSync

Exchange ActiveSync lets you synchronize data between your mobile phone and Exchange 2010. You can synchronize e-mail, contacts, calendar information, and tasks.

If you use a phone that has Windows Mobile 5.0 with the Messaging Security and Feature Pack (MSFP) installed or a later version, your mobile phone will support Direct Push. Direct Push technology is built into Exchange ActiveSync and keeps a mobile phone continuously synchronized with an Exchange mailbox.

Note:

Mobile phones and devices that are running versions of Windows Mobile earlier than Windows Mobile 5.0 with MSFP can still send and receive messages on a set schedule, but can't use Direct Push to synchronize items as they arrive. All versions of Windows Mobile and Pocket PC operating systems can synchronize items with Exchange 2010 by using a cable connection to a desktop or portable computer.

For more information about Exchange ActiveSync, see the following topics:

- Understanding Exchange ActiveSync

- Managing Exchange ActiveSync

POP3 and IMAP

In addition to supporting MAPI and HTTP clients, Exchange 2010 also supports POP3 and IMAP4 clients. By default, POP3 and IMAP4 are installed, but the services are disabled when you install the Client Access server role.

For more information about POP3 and IMAP4, see the following topics:

- Understanding POP3 and IMAP4
- Managing POP3 and IMAP4

The Availability Service

The Exchange 2010 Availability service provides secure, consistent, and up-to-date free/busy data to computers that are running Microsoft Office Outlook 2007 and later versions of Outlook. These versions of Outlook use the Autodiscover service to obtain the URL of the Availability service. Essentially, the Autodiscover service helps capable Outlook clients locate different Web services, such as the Microsoft Exchange Unified Messaging service, the Offline Address Book, and Availability services.

For more information about the Availability service, see the following topics:

- Understanding the Availability Service
- Managing the Availability Service

The Autodiscover Service

The Autodiscover service enables Outlook clients and some mobile phones to receive their necessary profile settings directly from the Exchange server by using the client's domain credentials. These settings automatically update the client with the information that's needed to create the user's profile.

For more information about the Autodiscover service, see the following topics:

- Understanding the Autodiscover Service
- Understanding Exchange ActiveSync Autodiscover

1.6.1.1 Understanding Client Access Server Namespaces

Understanding Client Access Server Namespaces

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-08*

When you plan your Microsoft Exchange Server 2010 organization, one of the most important decisions that you must make is how to arrange your organization's external namespace. A namespace is a logical structure that's usually represented by a domain

name in DNS. When you define your namespace, you must consider the different locations of your clients and the servers that house their mailboxes. In addition to the physical locations of clients, you must evaluate how they connect to Exchange 2010. The answers to these questions will determine how many namespaces you must have. Your namespaces will typically align with your DNS configuration. We recommend that each Active Directory site in a region that has one or more Internet-facing Client Access servers have a unique namespace. This is usually represented in DNS by an A record, for example, mail.contoso.com or mail.europe.contoso.com.

Before you create an Exchange 2010 organization, you must decide how your organization will be configured and how your external namespaces will be defined. The decisions that you make about your namespaces will affect the following:

- How you configure DNS.
- The certificates you must have to encrypt communications between your computers running Exchange 2010 and your client computers and devices.
- How your clients access their mailboxes when they use Outlook Anywhere, Outlook Web App, and POP3 and IMAP4 clients.

Making these decisions involves examining your physical and logical network structure and choosing an organizational topology. This topic discusses the different topologies and provides information about how each topology affects your Exchange organization.

Note:

This topic doesn't discuss internal namespace planning, which may be required if you deploy load balancing within an Active Directory site. For details about the impact of deploying load balancing internally, see Understanding Proxying and Redirection.

Exchange 2010 Organizational Models

This topic examines the following types of topology:

- **Consolidated Datacenter Model** This model consists of a single physical site. All servers are located within the site, and there's a single namespace, for example, mail.contoso.com.
- **Single Namespace with Proxy Sites** This model consists of multiple physical sites. Only one site contains an Internet-facing Client Access server. The other sites aren't exposed to the Internet. There's only one namespace for the sites in this model, for example, mail.contoso.com.
- **Single Namespace and Multiple Sites** This model consists of multiple physical sites. Each site can have an Internet-facing Client Access server. Or, there may be only a single site that contains Internet-facing Client Access servers. There's only one namespace for the sites in this model, for example, mail.contoso.com.
- **Regional Namespaces** This model consists of multiple physical sites and multiple namespaces. For example, a site that's located in New York City would have the namespace mail.usa.contoso.com, a site that's located in Toronto would have the namespace mail.canada.contoso.com, and a site that's located in London would have the namespace mail.europe.contoso.com.
- **Multiple Forests** This model consists of multiple forests that have multiple namespaces. An organization that uses this model could be made up of two partner companies, for example, Contoso and ContosoOnline. Namespaces might include mail.usa.contoso.com, mail.europe.contoso.com, mail.asia.contosoonline.com, and mail.europe.contosoonline.com.

Consolidated Datacenter Model

The consolidated datacenter model is the simplest model considered in this topic. It consists of a single physical site.

The advantages of the consolidated datacenter model are as follows:

- There are fewer DNS records to manage than with multiple namespace models.
- There are fewer certificates to manage. Communications between the Exchange Client Access server and clients can be encrypted in several ways. The recommended method for encryption is to use a single certificate that supports Subject Alternative Names.

Note:
A Subject Alternative Name is an attribute of a digital certificate that allows the site administrator to configure a single certificate that lists all the namespaces that require a server certificate.

Note:
Alternative methods for managing certificates for a consolidated datacenter model include a wildcard certificate, multiple certificates, and configuring SRV records appropriately.

- End users don't have to determine which namespace to use. All end users use the same namespace and URL to access Microsoft Exchange.

Disadvantages to the consolidated datacenter model include:

- This model doesn't support multiple datacenters.
- If regional Internet links are slow because of low bandwidth, high latency, or high use, end users in those regions will experience poor performance.

Single Namespace with Proxy Sites

This model consists of multiple physical sites that use a single namespace. Behind an ISA Server computer or another firewall, one of the sites has one or more Internet-facing Client Access servers. The other sites don't contain Internet-facing Client Access servers.

Important:
Installing a Client Access server in a perimeter network isn't supported.

Caution:
This model isn't recommended if all sites have Internet connectivity. If your topology uses multiple Active Directory sites that have Internet connectivity and aren't near to each other, consider a regional namespace model.

This model offers the following advantages:

- There are fewer DNS records to manage than with multiple namespace topologies. This reduces operational complexity.
- There are fewer certificates to manage. Communications between the Client Access server and clients can be encrypted by using a single certificate that supports Subject Alternative Names.
- End users don't have to determine which namespace to use. All end users use the same namespace and URL to access Microsoft Exchange.

Disadvantages to deploying a single namespace with proxy sites include:

- Some users will access their Mailbox server through proxying. If a user connects to a Client Access server that isn't in the same physical site as their Mailbox server, they will be proxied to a Client Access server that's in the same physical site as their Mailbox server. Because of the added proxying, WAN link costs will increase and performance won't be optimal. The effect on performance depends on the distance between the two physical datacenters and the numbers of proxied connections.

Important:
It may be necessary to configure the target virtual directories on each Client Access server in the site being proxied to for Integrated Windows authentication. For more information, see Understanding Proxying and

Redirection.

Single Namespace with Multiple Sites

This model consists of multiple physical sites that use a single namespace. There are two deployment options for this model. You can use an ISA Server computer in front of one or more sites or use a Client Access server proxy site. There can be one or more Internet-accessible servers behind each site. This model also requires a load balancing solution that splits the incoming traffic equally between the Internet-facing sites.

Important:

Installing a Client Access server in a perimeter network isn't supported.

Deployment with an ISA Server computer

In this configuration, ISA Server performs pre-authentication of the connection to determine the client's group membership. Traffic is then forwarded to the correct site based on the configured publishing rules.

The advantages of this model are as follows:

- There are fewer DNS records to manage than with multiple namespace models. This reduces operational complexity.
- There are fewer certificates to manage. Communications between the Client Access server and clients can be encrypted by using a single certificate that supports Subject Alternative Names. The ISA Server computer could be configured to use an external, trusted certificate from a recognized provider. The traffic between the ISA Server computer and the Client Access servers could be secured using an internally generated certificate.
- End users don't have to determine which namespace to use. All users use the same namespace and URL to access Microsoft Exchange.
- Mailboxes can be moved between sites without external namespace changes. This provides flexibility for administrators who want to load balance traffic between sites without changing client configuration.
- If required, a regional namespace can be added at a later stage. This same model can be repeated in another location using a different external URL.
- ISA Server 2006 forms-based authentication can be customized to suit an organization's specific requirements.

The disadvantages to deploying this model include the following:

- Wide Area Network (WAN) use will likely increase. The increased use depends on the physical location of the ISA Server computer.
- ISA Server must be deployed and configured correctly.
- Group memberships must be managed to ensure traffic is forwarded to the correct site. By default, Recipient Administrators can't create security groups, so Active Directory delegation must be configured so that dedicated Exchange Administrators can create and update group membership. Using groups creates an additional operational overhead that must be considered when new mailboxes are created or moved. Placing a global catalog server close to the ISA Server computer is the recommended way to avoid unnecessary authentication request travel on the WAN.

Deployment with a Client Access Server Proxy Site

In this model, all client connections that originate externally go to an Active Directory site that contains no user mailboxes. The connections are then proxied by a Client Access server in that site to the site that contains the user's mailbox.

The advantages of this model are as follows:

- There are fewer DNS records to manage than with multiple namespace models. This reduces operational complexity.

- There are fewer certificates to manage. Communications between the Client Access server and clients can be encrypted by using a single certificate that supports Subject Alternative Names. ISA Server can be configured to use an external, trusted certificate from a recognized provider. And traffic between the ISA Server and Client Access servers can be secured using a certificate that's internally generated.
- End users don't have to determine which namespace to use. All end users use the same namespace and URLs to access Microsoft Exchange. If split DNS is configured, this model could also be used to unify an internal namespace. If split DNS isn't configured, all internal client requests will reach the firewall and be forwarded appropriately.
- Mailboxes can be moved between sites without the namespace being changed from an external user's perspective. This provides flexibility for administrators who want to load balance between sites. It is also useful when a disaster occurs and the entire service must be moved between sites, because the client configuration doesn't have to be changed.
- A regional namespace can be added at a later stage, if required. This same model can be repeated in another location, using a different external URL.

The disadvantages of this model are as follows:

- WAN use will likely increase and depends on the physical location of the Client Access servers in the Internet-facing site.
- Additional Client Access servers must be deployed and configured correctly.
- All users will access their mailbox through proxying. When a user connects to a Client Access server in the proxy site, it isn't in the same Active Directory site as their Mailbox server. They will be proxied to a Client Access server that's in the same Active Directory site as their Mailbox server. Performance won't be optimal because of the additional proxying. The effect on performance depends on the distance between the two physical sites.
- Access to Windows SharePoint Services libraries and Windows file shares isn't possible when users connect to a Client Access server that isn't within the same site as their Mailbox server. This is because access to Windows SharePoint Services libraries and Windows file shares requires the user's user name and password. In a proxying scenario, communication to Windows SharePoint Services libraries and Windows file shares is performed through the Exchange system account. This account isn't aware of the user's user name and password.

Important:

The **ExternalURL** property on each virtual directory in a site that contains user mailboxes must be set to $null.

Important:

Client Access servers don't support multiple levels of proxying. Each site that contains user mailboxes must be accessed by the Client Access servers in the dedicated proxy site.

Note:

Additional network configuration might be required if multiple locations are used. This can include configuring hardware load balancers, multiple DNS records, and route redundancy. The physical deployment will vary based on your organization's network topology.

Regional Namespaces

The multiple site model that uses a different namespace for each site is known as a regional namespace model. The advantages of this model are as follows:

- Proxying is reduced because a larger percentage of users will be able to connect to a Client Access server in the same Active Directory site as their Mailbox server. This will improve the end-user experience and performance. Users who have mailboxes in a site that doesn't have an Internet-facing Client

Access server will still be proxied.

The disadvantages to this model are as follows:

- Multiple DNS records must be managed.
- Multiple certificates must be obtained, configured, and managed.
- Managing security is more complex because each Internet-facing site requires an ISA Server computer or other firewall.
- Each user must connect to their own regional namespace. This may result in additional helpdesk calls and training.

Important:

The regional namespace model is generally recommended for any topology that involves multiple Active Directory sites that have their own Internet connectivity.

Multiple Forests

This model consists of multiple forests with multiple namespaces. An organization that uses this model could be made up of two partner companies, Contoso and ContosoOnline. Namespaces might include mail.usa.contoso.com, mail.europe.contoso.com, mail.asia.contosoonline.com, and mail.europe.contosoonline.com.

Consider implementing a regional namespace model for each forest to provide the highest level of performance for end users. Multiple certificates must be managed for each forest.

1.6.1.2 Understanding Proxying and Redirection

Understanding Proxying and Redirection

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-12-26*

In a Microsoft Exchange Server 2010 organization, a Client Access server can act as a proxy for other Client Access servers within the organization. This is useful when multiple Client Access servers exist in different Active Directory sites in an organization, and at least one of those sites isn't exposed to the Internet.

A Client Access server can also perform redirection for Microsoft Office Outlook Web App URLs and for Exchange ActiveSync devices. Redirection is useful when users connect to a Client Access server that isn't in their local Active Directory site, or if a mailbox has moved between Active Directory sites. It's also useful if users should actually be using a more effective URL. For example, users should be using a URL that's closer to the Active Directory site in which their mailbox resides.

The Client Access server's response can vary by protocol. Typically, however, a Client Access server takes the following action if it receives a request for a user whose mailbox is in an Active Directory site other than the one to which the Client Access server belongs: In this case, the server looks for the presence of an **ExternalURL** property on the relevant virtual directory on a Client Access server that's in the same Active Directory site as the user's mailbox. If the **ExternalURL** property exists, and the client type supports redirection (for example, Outlook Web App or Exchange ActiveSync), the Client Access server issues a redirect to that client. If no **ExternalURL** property exists, or if the client type doesn't support redirection (for example, POP3 or IMAP4), the Client Access server

will try to proxy the connection to the target Active Directory site.

This topic explains proxying and redirection, the circumstances under which each is used, and how to configure your Client Access servers for each scenario.

Note:
If you don't have multiple Active Directory sites in your organization, you don't have to configure Exchange 2010 for proxying or redirection. However, you might want to configure load balancing of URLs as described later in this topic.

Note:
Client Access servers that aren't exposed to the Internet don't have to have separate Secure Sockets Layer (SSL) certificates to allow proxied traffic from another Client Access server. By default, they can use the self-signed certificate installed with Exchange 2010. However, these certificates aren't usually trusted by internal clients such as Outlook Web App or Outlook, and their use will usually result in certificate warnings. If there are internal clients in the same Active Directory sites as Client Access servers with self-signed certificates, you should replace the self-signed certificates with certificates issued by a certification authority that's trusted by the clients.

Contents

Overview of Proxying

In Microsoft Exchange Server 2003, the front-end server communicates with the back-end server over HTTP. In Exchange Server 2007 and Exchange 2010, the Client Access server communicates with an Exchange Mailbox server over RPC. You must have an Exchange 2010 Client Access server in every Active Directory site that contains an Exchange 2010 Mailbox server. Proxying occurs when one Client Access server sends traffic to another Client Access server. An Exchange 2010 Client Access server can proxy requests in the following situations:

- **Between Exchange 2010 Client Access servers** Proxying requests between two Exchange 2010 Client Access servers enables organizations that have multiple Active Directory sites to designate one Client Access server as an Internet-facing server and have that server proxy requests to Client Access servers in sites that have no Internet presence. The Internet-facing Client Access server then proxies the request to the Client Access server closest to the user's mailbox.
- **Between an Exchange 2010 Client Access server and Exchange 2007 Client Access servers** Proxying requests between an Exchange 2010 Client Access server and an Exchange 2007 Client Access server within one Active Directory site or between Active Directory sites enables Exchange 2010 and Exchange 2007 to coexist in the same organization. For more information about how to upgrade and coexistence, see Upgrade from Exchange 2003 Client Access and Upgrade from Exchange 2007 Client Access.

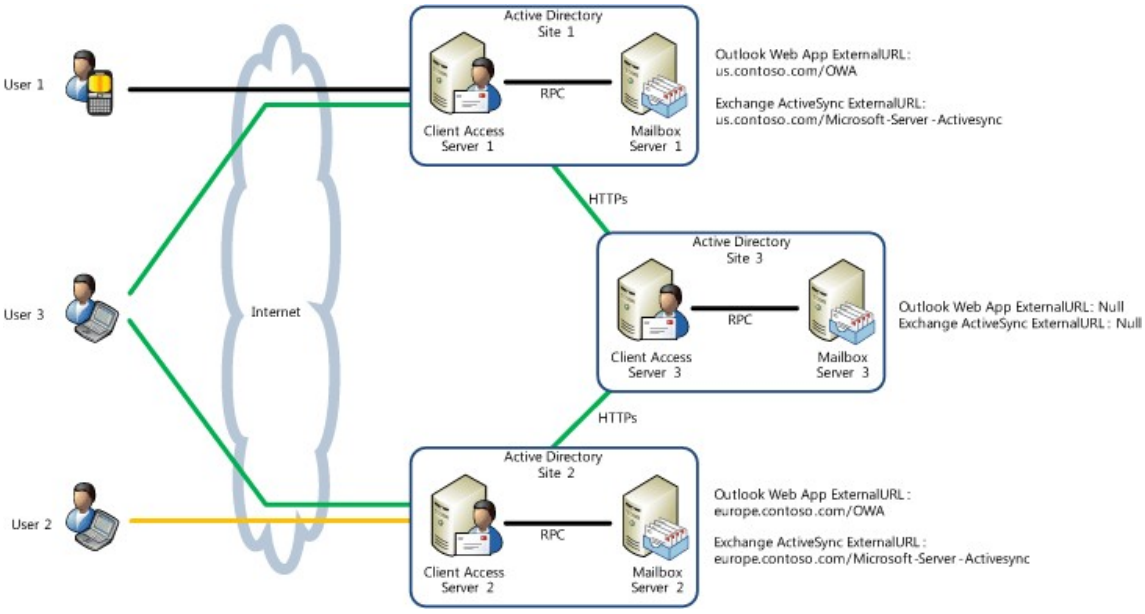
Proxying is supported for clients that use Outlook Web App, Exchange ActiveSync, the Exchange Control Panel (ECP), POP3, IMAP4, and Exchange Web Services. Proxying is supported from one Client Access server to another Client Access server when the destination Client Access server is running the same version of Microsoft Exchange as, or an earlier version of Microsoft Exchange than, the source Client Access server.

Warning:

When an IMAP4 client using NTLM authentication tries to connect to a Client Access server in an Active Directory site that doesn't contain the target mailbox, the connection will fail. If you want an IMAP4 client to be proxied from one Active Directory site to another, you have to choose an alternate authentication method.

Note:

In each Exchange organization that wants to allow access from Internet-based clients, at least one Active Directory site must be Internet facing. All non-Internet-facing Active Directory sites rely on the Internet-facing Client Access server or servers to proxy all pertinent requests from external clients.



In the previous figure, the mailbox of User 1 is located on Mailbox server 1. The mailbox of User 2 is located on Mailbox server 2, and the mailbox of User 3 is located on Mailbox server 3. Each Mailbox server is in a different Active Directory site. User 1 can access their mailbox through Client Access server 1 without using proxying, and User 2 can access their mailbox through Client Access server 2. If User 3 tries to access their mailbox through Client Access server 1 or 2, either server will proxy their request to Client Access server 3. Client Access server 3 isn't Internet facing but can receive requests from other servers inside the firewall. Proxying isn't visible to the user.

Note:

Communications between Client Access servers in different sites occur over Secure HTTP (HTTPS), but Client Access servers don't check the status of the certificate that's used by default. The certificate is used only for encryption, not authentication, and so name mismatches, expiration dates, and trust status are ignored.

Return to top

Overview of Redirection

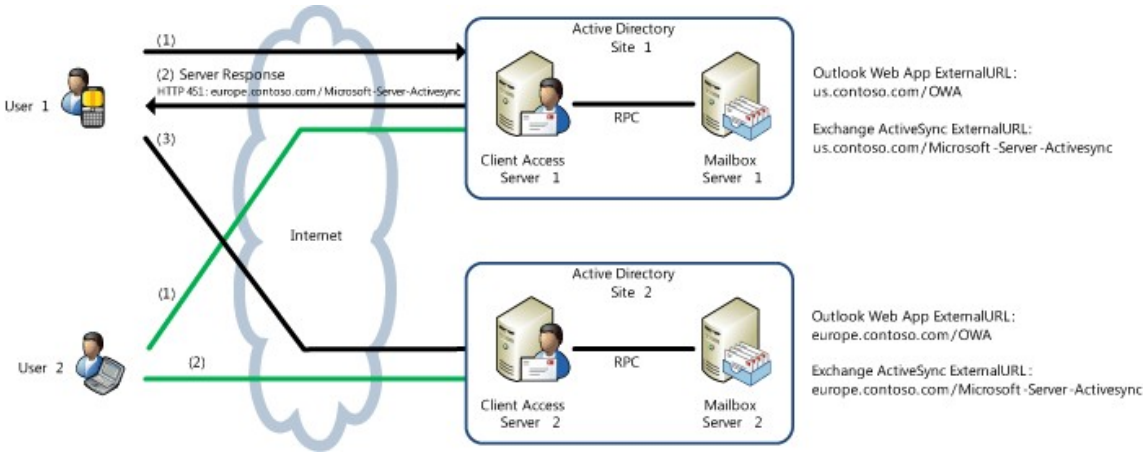
Outlook Web App users who access an Internet-facing Client Access server in a different Active Directory site than the site that contains their mailbox can be redirected to the Client Access server in the same site as their Mailbox server if that Client Access server is Internet facing. When an Outlook Web App user tries to connect to a Client Access server outside the Active Directory site that contains their Mailbox server, they'll see a Web page that contains a link to the correct Client Access server for their mailbox. This is known as manual redirection. In Exchange 2010 SP2, administrators can configure cross-site silent redirection to enable this redirection process to happen without the user's knowledge. For more information, see Cross-Site Silent Redirection later in this topic.

Note:

You cannot use cross-site silent redirection in a hybrid environment that uses an on-premises Exchange Server together with Office 365.

Exchange ActiveSync users who access an Internet-facing Client Access server in a different Active Directory site than the site that contains their mailbox can be redirected to the Client Access server in the same site as their Mailbox server if that Client Access server is Internet facing and if the client mobile phone or device has correctly implemented the redirection logic built in to the protocol that's used when communicating with Exchange 2007 and Exchange 2010. The redirection for Exchange ActiveSync users is achieved by sending the device an HTTP 451 error code that contains the URL the device should be using. The device then reconfigures itself to use the new URL.

The following figure shows how redirection works in an organization that has multiple Client Access servers in multiple Active Directory sites.



In the previous figure, User 1 usually accesses their mailbox in Active Directory site 1 using their mobile phone. The administrator then moves their mailbox to Mailbox server 2 in Active Directory site 2. The next time the device tries to synchronize, the server responds with an HTTP 451 status error. This contains the URL the device should now use for that user. In step 3 of the sequence, the device reconfigures itself and connects to the specified URL. User 2, whose mailbox is in Active Directory site 2, tries to open their mailbox using Outlook Web App by connecting to Client Access server 1 over the Internet. With manual redirection, as soon as the user authenticates, Client Access server 1 presents a page to the user, with a link to the Outlook Web App URL for the Client Access server in Active Directory site 2. The user clicks the link, is taken to Active Directory site 2, and signs in again to access their mailbox.With silent redirection, when the user authenticates, they're silently redirected to the Outlook Web App URL for the Client Access server in Active Directory site 2.

Cross-Site Silent Redirection

Note:
You cannot use cross-site silent redirection in a hybrid environment that uses an on-premises Exchange Server together with Office 365.

Exchange 2010 SP2 lets administrators configure cross-site silent redirection. Cross-site silent redirection performs silent redirection for client requests that are destined for a CAS that is located in a different Active Directory site in the same Exchange organization. For example, a user with a mailbox in Active Directory SiteA who accesses the Outlook Web App URL in Active Directory SiteB will be silently redirected to the Outlook Web App URL for Active Directory in SiteA.

To configure cross-site silent redirection, the administrator must use the new ***CrossSiteRedirectType*** parameter that's been added to the **Set-OWAVirtualDirectory** cmdlet. The parameter has two possible settings. The default setting is `Manual`.

- **Silent** When this setting is configured, a user's web browser is automatically redirected whenever a Client Access server must redirect an Outlook Web App request to Client Access server or server array located in another Active Directory site. When forms-based authentication is configured on the source and target CAS OWA virtual directories (SSL is required), then the silent redirection is also a single sign-on event. For redirection to occur, the target Client Access server Outlook Web App virtual directory must have an `ExternalURL` value configured.
- **Manual** When this setting is configured, users will receive a notification that they're accessing the wrong URL and that they must click a link to access the correct Outlook Web App URL for their mailbox. This notification only occurs when a Client Access server determines that it must redirect an Outlook Web App request to Client Access server or server array located in another Active Directory site. For redirection to occur, the target Client Access server Outlook Web App virtual directory must have an `ExternalURL` value configured.

For example:

```
Set-OWAVirtualDirectory -Identity "Contoso\owa (Default Web site)" -
CrossSiteRedirectType Silent
```

For more information about the **Set-OwaVirtualDirectory** cmdlet, see: Set-OwaVirtualDirectory

Proxying and Redirection for Exchange ActiveSync

The following series of steps shows how incoming requests are handled for a user who connects to an Exchange 2010 Client Access server named CAS-01 using a mobile phone.

1. The Client Access server queries Active Directory to determine the location of the user's mailbox and the version of Microsoft Exchange installed on the Mailbox server.
2. If the user's mailbox is on an Exchange 2003 server, the incoming request is proxied directly to the Exchange 2003 server that hosts the user's mailbox and the Exchange ActiveSync virtual directory. By default, in Exchange 2003, the Exchange ActiveSync virtual directory was installed on all mailbox servers. The Active Directory site of the user's mailbox isn't applicable in this case because Exchange 2003 doesn't use Active Directory sites to determine location. The connection is always made directly from the Exchange 2010 Client Access server to the Exchange 2003 mailbox server.

   Note:
   Users who have mailboxes on an Exchange 2003 server who try to use Exchange ActiveSync through an Exchange 2010 Client Access server will receive an error and be unable to synchronize unless Integrated Windows

authentication is enabled on the Microsoft-Server-ActiveSync virtual directory on the Exchange 2003 server. Integrated Windows authentication enables the Exchange 2010 Client Access server and the Exchange 2003 back-end server to communicate.

3. If the user's mailbox is on an Exchange 2007 Mailbox server, CAS-01 locates an Exchange 2007 Client Access server in the same Active Directory site as the user's Mailbox server. This may be the same Active Directory site as CAS-01. CAS-01 determines whether the Exchange 2007 Client Access server has the **ExternalURL** property configured on the Exchange ActiveSync virtual directory. If so, CAS-01 issues the client an HTTP error code 451 that contains the ExternalURL value and instructs the client to redirect to the location specified in the **ExternalURL** property. If no ExternalURL value is set, the connection will be proxied to the Client Access server using the FQDN specified by the **InternalURL** property, specifically to the /Proxy virtual directory, This virtual directory is located beneath the Exchange ActiveSync virtual directory in IIS and, by default, has Integrated Windows authentication enabled on it.
4. If the user's mailbox is on an Exchange 2010 Mailbox server in the same Active Directory site as CAS-01, CAS-01 provides access to the mailbox. If the user's mailbox is on an Exchange 2010 Mailbox server in a different Active Directory site, CAS-01 locates a Client Access server in the same Active Directory site as the user's Mailbox server. CAS-01 determines whether any Exchange 2010 Client Access server in that Active Directory site has the **ExternalURL** property configured on the Exchange ActiveSync virtual directory. If so, CAS-01 issues the client an HTTP error code 451 that contains the ExternalURL value and instructs the client to redirect to that location. If no ExternalURL value is set, the connection will be proxied to the Client Access server using the FQDN specified by the **InternalURL** property, specifically to the /Proxy virtual directory. This virtual directory is located beneath the Exchange ActiveSync virtual directory in IIS and, by default, has Integrated Windows authentication enabled on it.

Important:

Proxying isn't possible between virtual directories that use Basic authentication. For client communications to be proxied between Exchange ActiveSync virtual directories on different servers, the /Proxy virtual directory must use Integrated Windows authentication.

Return to top

Proxying and Redirection for Outlook Web App

The following series of steps shows how incoming requests are handled for a user who connects to an Exchange 2010 Client Access server named CAS-01 using Outlook Web App.

1. The Client Access server queries Active Directory to determine the location of the user's mailbox and the version of Microsoft Exchange installed on the Mailbox server.
2. If the user's mailbox is on an Exchange 2003 server and the user tries to access Outlook Web App using https://domain name/owa, they'll receive an error because an Exchange 2010 Client Access server can't directly provide Outlook Web App access to an Exchange 2003 mailbox. However, if the administrator configured redirection from Exchange 2010 to Exchange 2003, which would be usual during a migration from Exchange 2003 to Exchange 2010, the **Exchange2003URL** property of the Outlook Web App virtual directory was set to the value of an Exchange 2003 server facing the Internet.
3. If the user's mailbox is on an Exchange 2007 mailbox server, CAS-01 locates a Client Access server in the same Active Directory site as the user's mailbox server. If the Exchange 2007 Mailbox server is in the same Active Directory site as CAS-01, one of four possible actions will result.

- CAS-01 will look for an Exchange 2007 **ExternalURL** property that has an *ExternalAuthenticationMethods* setting that's identical to the *InternalAuthenticationMethods* setting on the Exchange 2010 Client Access server. If the settings match, CAS-01 will redirect to this external URL. If source and target CAS have Forms Based Authentication (FBA) enabled, the source CAS issues a hidden form back to the browser that contains the user's credentials and FBA settings, along with the redirect URL. This is transparent to the user.
- If a matching *ExternalURL* setting isn't found, CAS-01 will look for an Exchange 2007 Client Access server that has the **ExternalURL** property configured, regardless of matching. If one is found, CAS-01 will redirect to this external URL. This will result in the user being prompted for authentication.
- If no matching *ExternalURL* setting is found, CAS-01 will look for an Exchange 2007 Client Access server with an **InternalURL** property that has an *InternalAuthenticationMethods* setting identical to the InternalAuthenticationMethods setting on the Exchange 2010 Client Access server. If one is found, CAS-01 will redirect to this InternalURL. If forms-based authentication is enabled, this will result in a single sign-on redirection.
- If no matching InternalURL is found, CAS-01 will look for an Exchange 2007 Client Access server with an InternalURL configured, regardless of matching. If one is found, CAS-01 will redirect to this InternalURL. This will result in the user being prompted for authentication.

If the Exchange 2007 Mailbox server is in a different Active Directory site, CAS-01 determines whether the ExternalURL property is set in that Active Directory site. If it is, and cross-site silent redirection is not enabled, the CrossSiteRedirectType value is set to Manual, and a manual redirect is issued. In this scenario, the user is provided with a clickable link that redirects them to the specified URL.
If cross-site silent redirection has been enabled, the CrossSiteRedirectType value is set to Silent and the user is automatically redirected to the specified URL. If the ExternalURL property is not present, and the authentication method on the /OWA virtual directory is set to Integrated Windows authentication, CAS-01 will proxy the user's request to the Client Access server that's specified by the InternalURL property.

Important:
To allow an Exchange 2010 Client Access server to proxy Outlook Web App requests to an Exchange 2007 Client Access server in another Active Directory site, you must copy the highest-versioned folder from an Exchange 2007 Client Access server in the destination Active Directory site from the %installpath%\ClientAccess\OWA\ folder to the same path on the Exchange 2010 Client Access server that's making the proxy request.

Important:
An Exchange 2010 Client Access server will never proxy Outlook Web App requests to an Exchange 2007 Client Access server in the same Active Directory site. All requests within the same Active Directory site are redirected to an Exchange 2007 Client Access server, using either the **InternalURL** or **ExternalURL** properties for Client Access server, depending on which properties are configured.

4. If the user's mailbox is on an Exchange 2010 Mailbox server in the same Active Directory site as CAS-01, CAS-01 provides access to the mailbox. If the user's mailbox is on an Exchange 2010 Mailbox server in a different Active Directory site, CAS-01 locates a Client Access server in the same Active Directory site as the user's Mailbox server. When one is found, Exchange 2010 determines whether the Client Access server has the **ExternalURL** property set in that Active Directory site. If it is, and cross-site silent redirection hasn't been enabled, the user is provided with a clickable link that

redirects them to the specified URL. If cross-site silent redirection has been enabled, the user will be automatically redirected to the specified URL. If the **ExternalURL** isn't set and the authentication method on the virtual directory is set to Integrated Windows authentication, CAS-01 will proxy the user's request to the Client Access server that's specified by the **InternalURL** property.

Proxying for the Exchange Control Panel

Exchange 2010 provides a Web-based interface for both users and organization administrators to configure settings for their mailbox or for the organization. The Exchange Control Panel (ECP) is accessed either through the Options menu in Outlook Web App or, in Outlook 2010, by choosing the Voice Mail options, requesting message tracking information, or configuring mobile notifications. Selecting any of these options within Outlook launches a Web browser session.

The destination of the session depends on the current connection state of the Outlook client. If the Outlook client is connected using RPC over TCP, the client connects to the InternalURL value of the ECP virtual directory. If the client is connected using Outlook Anywhere, the Outlook client will launch a browser session. The browser session will try to connect to the ExternalURL value of the ECP virtual directory. The URLs are provided to the Outlook client via the Autodiscover service.

When an internal client is connected through TCP, the ECP session will always connect to a Client Access server in the same Active Directory site as the user's mailbox. Proxying isn't used in this scenario. When a client outside the corporate network uses Outlook Anywhere to connect, the client opens a browser session to the external URL of the ECP virtual directory or to the external URL of an Internet-facing Active Directory site if the user's mailbox is located in a non-Internet-facing site.

The proxying logic for the ECP is the same as for Outlook Web App. If the user's mailbox is on an Exchange 2010 Mailbox server in the same Active Directory site as the Client Access server receiving the request, that Client Access server provides access to the mailbox. If the user's mailbox is on an Exchange 2010 Mailbox server in a different Active Directory site, the Client Access server locates a Client Access server in the same Active Directory site as the user's Mailbox server. The original Client Access server will proxy the user's request to that Client Access server.

The ECP does perform redirection, but unless the user explicitly enters the URL to access the ECP, it's rarely performed. If a user accesses the ECP from Outlook Web App, Outlook Web App is responsible for making sure the user is using the correct URL. If the user is using Outlook 2010, Outlook and the Autodiscover service are responsible for making sure the user uses the correct URL for the ECP.

Return to top

Proxying for Exchange Web Services

Exchange Web Services provides an XML messaging interface that enables you to manage Exchange store items and access Exchange server functionality from client applications. From a proxy, redirection, and client perspective this functionality is usually used in the context of one of the following:

- Availability service requests
- Autodiscover requests
- Setting and checking Automatic Replies (OOF) status

An application written using Exchange Web Services can use proxying behavior for such tasks as setting an automatic-reply (Out of Office) message, which will be proxied between Active Directory sites, if required.

The following steps show how incoming requests are handled for a user who makes an Availability service request to an Exchange 2010 Client Access server named CAS-01. The

user is using Outlook Web App to check the availability of another user in the same Exchange organization.

1. CAS-01 queries Active Directory to determine the location of the user's mailbox and the version of Microsoft Exchange installed on the Mailbox server.
2. If the user's mailbox is on an Exchange 2003 server, Outlook Web App makes an HTTP connection to the /Public virtual directory of the Exchange 2003 server and retrieves the requested information from the Free/Busy system folder.
3. If the user's mailbox is on an Exchange 2007 Mailbox server, an error is returned to the user. In any Exchange organization that contains mailboxes on an Exchange 2007 Mailbox server, there must be an externally accessible Exchange 2007 Client Access server. The Autodiscover service is responsible for returning the correct Exchange Web Services URL to the client. This URL must match the version of the Mailbox server that the user's mailbox is on.
4. If the user's mailbox is on an Exchange 2010 Mailbox server in the same Active Directory site as CAS-01, CAS-01 accesses the mailbox itself to retrieve the requested information. If the user's mailbox is on an Exchange 2010 Mailbox server in a different Active Directory site, CAS-01 proxies to a Client Access server in that Active Directory site by using the FQDN specified by the **InternalURL** property of the /EWS virtual directory.

Important:

An Exchange Client Access server will proxy Availability service requests from one server to another whether the **ExternalURL** property is set or not.

Important:

Some Exchange Web Services applications use Web methods such as **GetEvents** and **Unsubscribe**, which have very strong Client Access server affinity. When one Client Access server must proxy one of these requests to another Active Directory site, it can use the **InternalNLBBypassURL** property of the Client Access server, which should always be set to the FQDN of the host server itself. This ensures the Client Access server making the request can maintain affinity with a specific Client Access server in the target Active Directory site.

Exchange Web Services itself doesn't provide redirection functionality, because the Autodiscover service, which is used to provide URLs to an application, provides the URLs required to access a specific mailbox. For example, when a mailbox is moved between Active Directory sites, Outlook receives the updated Active Directory site-specific URLs from the Autodiscover service when it next issues a query. This can sometimes result in a client making Availability service requests to a Client Access server in an Active Directory site other than the one that their mailbox is in. But, because the Availability service will still process the requests and proxy them as necessary, there's no impact on the user.

Important:

In any Exchange organization that contains mailboxes on an Exchange 2007 Mailbox server, there must be an externally accessible Exchange 2007 Client Access server. When the Autodiscover service returns the correct Exchange Web Services URL to a requesting client, this URL matches the version of server that the user's mailbox is on. For any Exchange organization that contains mailboxes on both Exchange 2007 Mailbox servers and Exchange 2010 Mailbox servers, two external URL's must be configured for Exchange Web Services, one for each installed version of Exchange.

Proxying for POP3 and IMAP4

Exchange 2010 can proxy POP3 and IMAP4 sessions between Client Access servers and Active Directory sites.

The following steps show how incoming requests are handled for a user who makes a request to an Exchange 2010 Client Access server named CAS-01 using a POP3 client.

1. CAS-01 queries Active Directory to determine the location of the user's mailbox and the version of Microsoft Exchange installed on the Mailbox server.
2. If the user's mailbox is on an Exchange 2003 server, CAS-01 proxies the connection to the POP3 service running on the Exchange 2003 server that's hosting the user's mailbox.
3. If the user's mailbox is on an Exchange 2007 Mailbox server, CAS-01 locates an Exchange 2007 Client Access server in the same Active Directory site as the user's Mailbox server, which may be in the same Active Directory site as CAS-01. CAS-01 proxies the request to the Client Access server.
4. If the user's mailbox is on an Exchange 2010 Mailbox server in the same Active Directory site as CAS-01, CAS-01 accesses the mailbox itself. If the user's mailbox is on an Exchange 2010 Mailbox server in a different Active Directory site, CAS-01 proxies to a Client Access server using the FQDN specified by the **InternalConnectionSettings** property of the POP configuration for that server.

Important:

There are no InternalURL or ExternalURL settings for the POP3 or IMAP4 services and an Exchange 2010 Client Access server will proxy POP3 and IMAP4 service requests from one server to another when it's needed.

Important:

Client Access servers trying to proxy to another Active Directory site don't check whether the POP3 or IMAP4 service is actually running on the remote Client Access server. It's important, therefore, to not only ensure that the services are running on every Client Access server in the remote Active Directory site, but to consider using a load balancer for the service. Load balances will be discussed later in this topic.

Return to top

Proxying Configuration

If your Client Access server is Internet facing, set the **ExternalURL** property on the /Microsoft-Server-ActiveSync, /OWA, /ECP, and /EWS virtual directories using the Exchange Management Console (EMC) or the Exchange Management Shell (Shell). The EWS virtual directory can only be configured using the Shell. The **InternalURL** property is configured automatically during the initial setup of Exchange 2010 and should only be changed if you want to use a load balancing solution. The **ExternalURL** property should contain the FQDN that's registered for your Exchange organization in DNS.

The following table contains the appropriate values for the **ExternalURL** and **InternalURL** properties for an Internet-facing Client Access server for an Exchange organization that accesses Outlook Web App by using the URL https://mail.contoso.com. The second table contains the appropriate **ExternalURL** and **InternalURL** property values for a non-Internet-facing Client Access server in a second Active Directory site for the same organization. You must ensure that the authentication method for all these virtual directories is set to Integrated Windows authentication. Proxying isn't supported for virtual directories that use other authentication methods except for POP3 and IMAP4, which use SSL/TLS and proxy the user's Basic authentication credentials.

Note:

If new Outlook Web App virtual directories are created using the Shell, you must manually configure the **InternalURL** property on those virtual directories.

InternalURL and ExternalURL settings for an Internet-facing Client Access server

Exchange 2010 service	InternalURL setting	ExternalURL setting
Outlook Web App	https://	https://mail.contoso.com/

	fullyqualifiedcomputername/OWA	OWA
Exchange ActiveSync	https://fullyqualifiedcomputername/Microsoft-Server-ActiveSync	https://mail.contoso.com/Microsoft-Server-ActiveSync
Exchange Web Services	https://*fullyqualifiedcomputername*/EWS/Exchange.asmx	https://mail.contoso.com/EWS/Exchange.asmx
Exchange Control Panel	https://*fullyqualifiedcomputername*/ECP	https://mail.contoso.com/ECP

InternalURL and ExternalURL settings for a non-Internet-facing Client Access server

Exchange 2010 service	InternalURL setting	ExternalURL setting
Outlook Web App	https://*fullyqualifiedcomputername*/OWA	$Null
Exchange ActiveSync	https://*fullyqualifiedcomputername*/Microsoft-Server-ActiveSync	$Null
Exchange Web Services	https://*fullyqualifiedcomputername*/EWS/Exchange.asmx	$Null
Exchange Control Panel	https://*fullyqualifiedcomputername*/ECP	$Null

Configuring Redirection

If more than one of your Active Directory sites are Internet facing, set the **ExternalURL** property on the /OWA and /Microsoft-Server-ActiveSync virtual directories using the EMC or the Shell to allow redirection between them. The **InternalURL** property is configured automatically during the initial setup of Exchange 2010 and should only be changed if you want to use a load balancing solution. The following two tables list the ExternalURL and InternalURL settings for Client Access servers in two Active Directory sites for a company named Contoso. The two sites are usa.contoso.com and europe.contoso.com.

Note:

If new Outlook Web App virtual directories are created using the Shell, you must manually configure the **InternalURL** property on those virtual directories.

InternalURL and ExternalURL property settings for an Internet-facing Client Access server in the usa.contoso.com site

Exchange 2010 service	InternalURL setting	ExternalURL setting
Outlook Web App	https://fullyqualified*computername*/OWA	https://usa.contoso.com/OWA
Exchange Control Panel	https://fullyqualified*computername*/ECP	https://usa.contoso.com/ECP

Exchange ActiveSync	https://fullyqualified*computername* / Microsoft-Server-ActiveSync	https://usa.contoso.com/Microsoft-Server-ActiveSync
Exchange Web Services	https://fullyqualified*computername* / EWS/Exchange.asmx	https://usa.contoso.com/EWS/Exchange.asmx

InternalURL and ExternalURL property settings for an Internet-facing Client Access server in the europe.contoso.com site

Exchange 2010 service	InternalURL setting	ExternalURL setting
Outlook Web App	https://fullyqualified*computername*/OWA	https://europe.contoso.com/OWA
Exchange Control Panel	https://fullyqualified*computername*/ECP	https://europe.contoso.com/ECP
Exchange ActiveSync	https://fullyqualified*computername* / Microsoft-Server-ActiveSync	https://europe.contoso.com/Microsoft-Server-ActiveSync
Exchange Web Services	https://fullyqualified*computername* / EWS/Exchange.asmx	https://europe.contoso.com/EWS/Exchange.asmx

Note:

If the **ExternalURL** property isn't set on the Exchange ActiveSync virtual directory in at least one Active Directory site, the Autodiscover service will fail when it configures mobile phones because the value set on the **ExternalURL** property is passed to the mobile phones during the Autodiscover process.

Return to top

Proxying with Network Load Balancing

In an organization that has multiple Active Directory sites and multiple Client Access servers in each site, you can use Network Load Balancing (NLB) to load balance traffic proxied between the Client Access servers in each site and for users directly accessing those servers. Just deploying a load balancer isn't enough to ensure traffic is balanced effectively. You must also perform some additional configuration of the **InternalURL** and **ExternalURL** properties. We recommend that you include only Client Access servers within the same Active Directory site in a load-balancing array. You can deploy NLB in an Internet-facing Active Directory site and in a non-Internet-facing Active Directory site.

The following table lists the settings you should configure for the virtual directories on the Client Access servers in both Internet-facing and non-Internet-facing sites. The FQDN of the NLB should be configured in DNS to resolve to the load balancing device or service. The load balancing solution will then be responsible for forwarding the traffic to the appropriate Client Access servers.

Virtual directory settings for Client Access servers in an organization that uses NLB

Virtual directory / service	InternalURL	ExternalURL (Internet-facing	ExternalURL (non-Internet-facing

		Active Directory site)	Active Directory site)
/OWA	NLB FQDN (see the following guidelines)	NLB FQDN	$null
/ECP	NLB FQDN (see the following guidelines)	NLB FQDN	$null
/Microsoft-Server-ActiveSync	NLB FQDN	NLB FQDN	$null
/OAB	NLB FQDN	NLB FQDN	$null
/EWS	NLB FQDN	NLB FQDN	$null
POP/IMAP	(InternalConnections Settings) NLB FQDN	Not applicable	Not applicable

We recommend that you use the following guidelines to set the InternalURL property:

- The InternalURL property for the /OWA and /ECP virtual directories on all Client Access servers in an Active Directory site can be set to the NLB FQDN of the servers in that site if there are internal Outlook 2010 users.
- If a Client Access server in an Active Directory site is the target of an Outlook Web App or ECP proxy request from a Client Access server in any other Active Directory site, make sure that you configure your load balancer to ensure affinity is maintained. This is because the Client Access server in the Internet-facing site cannot select a server for each individual request and maintain its own affinity

The following table lists the various authentication settings that are needed on virtual directories in an organization that uses network load balancing (NLB). In an organization that uses NLB, the NLB URL is used in place of a specific Client Access server URL for client connectivity.

Virtual directory authentication settings for Client Access servers in an organization that uses NLB URLs for fault tolerance and load balancing

Virtual directory /service	Internet-facing Active Directory site	Non-Internet-facing Active Directory site
/OWA	If Microsoft Forefront Threat Management Gateway 2010 (Forefront TMG) or Microsoft Forefront Unified Access Gateway 2010 (Forefront UAG) are being used, and forms-based authentication is enabled, use Basic or Integrated Windows authentication, depending on firewall rule delegation settings. If traffic from the Internet passes to the Client Access server with no pre-authentication, then use forms-based authentication.	Integrated Windows authentication

	The same authentication method should be enabled on the /OWA and /ECP virtual directories.	
/ECP	If Forefront TMG or Forefront UAFG are being used, and forms-based authentication is enabled, use Basic or Integrated Windows authentication, depending on firewall rule delegation settings. If traffic from the Internet passes to the Client Access server with no pre-authentication, then use forms-based authentication. The same authentication method should be enabled on the /OWA and /ECP virtual directories.	Integrated Windows authentication
/Microsoft-Server-ActiveSync	Basic authentication.	Basic authentication (Proxying is performed using the /Proxy sub virtual directory.)
/OAB	Basic or Integrated Windows authentication, depending on firewall rule delegation settings.	Basic or Integrated Windows authentication, depending on firewall rule delegation settings (OAB requests are never proxied between Active Directory sites. This virtual directory is only used by Outlook clients.)
/EWS	Basic (optional - depending on firewall rule delegation settings). Integrated Windows authentication required.	Integrated Windows authentication
POP/IMAP	As required by client connection method.	As required by client connection method

Return to top

Load Balancing Logic Used by Client Access Servers When Proxying Between Active Directory Sites

When multiple Client Access servers exist in the site that will be the target of a proxy attempt, and the server on which the user's mailbox is located is a combined Client Access server and Mailbox server, the Client Access server in the source Active Directory site will always choose that combined Client Access server and Mailbox server as the target of the proxy attempt.

Outlook Web App, the ECP, and Exchange Web Services handle load balancing differently than the Availability service and Exchange ActiveSync do. Outlook Web App, the ECP, and Exchange Web Services implement their own load balancing when they're deployed on multiple Client Access servers within the same Active Directory site. If a user tries to access Outlook Web App through https://mail.contoso.com/owa and is proxied to CAS-01, the next time that user tries to access Outlook Web App, they'll again be proxied to CAS-01, This will happen even if CAS-02 has fewer concurrent connections. This is done to ensure long-running transactions can be completed without reauthentication or requesting data again. This is known as Affinity. If CAS-01 is unavailable, the user will be proxied to CAS-02 and the user may be required to reauthenticate.

Exchange Web Services can maintain affinity when proxied between Active Directory sites despite the **InternalURL** property of the target server being configured with an NLB URL. This is because the Client Access server making the proxy request for an application that requires affinity uses the **InternalNLBBypassURL** property on the target server. The **InternalNLBBypassURL** property is configured with the FQDN of the target server and uses Windows authentication by default.

Note:

For Outlook Web App, the ECP, and Exchange Web Services, your firewall should be configured for cookie-based or IP-based affinity. This ensures that a particular client application connects to the same server every time. This is required so that the SSL negotiation isn't performed repeatedly for each request. It's important to maintain affinity from the client application through to the final Client Access server involved in the transaction.

Note:

You shouldn't change the value of the**InternalNLBBypassURL** property on a Client Access server. If you change it, you'll break proxied Exchange Web Services requests.

The process is different for Exchange ActiveSync. When an Internet-facing Client Access server proxies a request to a non-Internet-facing Client Access server, the requesting Client Access server looks for a Client Access server in the target site and tries to connect to it using the value configured in the **InternalURL** property. If the server doesn't respond, the request will fail and an error will be returned to the client. We recommend implementing round-robin load balancing within an NLB array and setting the **InternalURL** property to a load-balanced value.

We also recommend load balancing for the Availability service. Availability service requests don't have to maintain their connection state. In other words, two consecutive Availability service requests from the same client can be proxied to different Client Access servers in the destination Active Directory site without performance being affected, and there are no authentication issues if the **InternalURL** property is set to be a load balanced value. In addition, setting the **InternalURL** property to a load-balanced value benefits any Outlook 2007 and Outlook 2010 clients internally, because the Autodiscover service provides those clients with the load-balanced value set in the **InternalURL** property to allow them to complete their Availability service requests.

For more information about network load balancing, see Understanding Load Balancing in Exchange 2010.

Note:

In many deployments, the Client Access server role and the Hub Transport server role are installed on the same computer. In this topology, you can configure NLB for the Client Access server role separately from the Hub Transport server role. Currently NLB isn't supported on the Hub Transport server role. However, it's supported for the Client Access server role. To configure NLB for the Client Access server role and not the Hub Transport server role, configure ports 80 and 443 for client access. The Hub Transport server role implements its own high availability within the software.

Return to top

Summary of Client Access Methods

The following table summarizes the protocols used to access Exchange 2010 and how they're used for proxying and redirection.

Client Access protocols for redirection and proxying

Protocol/Application	Redirection supported between Client Access servers	Proxying supported between Client Access servers	Comments
Outlook Web App	Yes	Yes	Must have a Client Access server in each Active Directory site to use Outlook Web App.
Exchange Control Panel	Yes	Yes	Must have a Client Access server in each Active Directory site to use the ECP.
Exchange ActiveSync	Yes	Yes	Must have a Client Access server in each Active Directory site to use Exchange ActiveSync.
Exchange Web Services	No (The Autodiscover service provides the application with the correct ExternalURL value)	Yes	Must have a Client Access server in each Active Directory site to use Exchange Web Services.
Availability service	No (The Autodiscover service provides the application with the correct ExternalURL value)	Yes	Must have a Client Access server in each Active Directory site to use the Availability service.
POP3 and IMAP4	No	Yes	Must have a Client Access server in each Active Directory site to use POP3 and IMAP4.

Proxying Performance and Scalability

In an Exchange 2010 proxying environment, poor performance often results when the Client Access servers receive lots of concurrent requests. This problem is frequently caused by the exhaustion of threads and available connections because of Web service requests from ASP.NET. This can cause the Client Access servers to deny requests or exhibit high latency when the requests are being processed.

To resolve these issues, you can configure several ASP.NET parameters by editing the Machine.config file on the Client Access servers. For more information about how to

configure these parameters, see Microsoft Knowledge Base article 821268, Contention, poor performance, and deadlocks when you make Web service requests from ASP.NET applications.

Two of the parameters explained in Knowledge Base article 821268 must be set differently in an Exchange 2010 proxying environment. We recommend that you allow for 36 threads per processor, and that you set the *maxconnections* value to 2,000.

For more information about server performance, see Managing the .NET Framework on Windows Server 2003.

1.6.1.3 Understanding Client Throttling Policies

Understanding Client Throttling Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-30*

Microsoft Exchange Server 2010 uses client throttling policies to manage the performance of your Exchange organization. To do this, Exchange tracks the resources that each user consumes, and enforces connection bandwidth limits, as necessary.

Among other things, client throttling helps you make sure that:

- Users aren't intentionally taxing the system.
- Users aren't unintentionally taxing the system.
- Users of various connectivity methods are sharing resources proportionally.

In Exchange Server 2010 SP1, all client throttling policies are turned on by default. If you are experiencing problems that may be caused by these policies, you can turn off client throttling. To turn off client throttling, you can set all policy parameters to `$Null`.

Contents

Default and Non-Default Policies

When an Exchange organization is created, a default throttling policy is automatically created that implicitly governs all users within that organization. Although the default client throttling policy is generally sufficient to manage the load placed on your Exchange system, you can customize the default policy or add additional policies based on the needs of your organization.

If you're hosting multiple tenants in your Exchange organization, you can define an acceptable load for each user of a tenant. Similarly, if you're an on-premise organization, you can define an acceptable load on a user-by-user basis. Through policies, Exchange evaluates how each user uses the system and ensures that the resulting per-user load falls within acceptable boundaries as defined by the user's policy. The client throttling system tracks system usage on a per-user basis and uses the throttling policy associated with that user to determine if throttling should occur.

In Exchange 2010 Enterprise installations, there's a single default throttling policy called First Organization. In multi-tenant deployments, each tenant has its own default throttling policy.

Fallback Policy

The throttling framework is designed to protect Exchange resources. Therefore, if the non-default policy is corrupted or missing, the throttling policy will first fall back to the default throttling policy for the organization. However, if the default policy is corrupted or missing, the throttling policy falls back to the *fallback policy*. Because the fallback policy is embedded in Exchange, it's less likely to fail.

The fallback policy is also applied to authenticated accounts, such as computer accounts, cross-forest contacts, and Active Directory accounts that do not have mailboxes. These accounts will have the fallback policy values assigned. Because these accounts use the fallback policy, the policy values cannot be modified.

The fallback policy uses the following values:

Access Type	MaxConcurrency	PercentTimeInAD	PercentTimeInCAS	PercentTimeInRPC	Other
Anonymous	1	$null	$null	$null	
EAS	10	$null	$null	$null	10 (maxDevices) $null ($MaxDeviceDeletesPerMonth
EWS	10	50	90	60	5000 (maxSubscription) 60 (fastSearchTimeout)1000 (findCountLimit)
IMAP	$null	$null	$null	$null	
OWA	5	30	150	150	
POP	20	$null	$null	$null	
PowerShell	18				$null (maxTenantConcurrency) $null (maxCmdletsTime$null

					(MaxCmdlets) Period) $null (ExchangeMax Cmdlets) $null (maxCmdletQu eueDepth) $null (maxDestructi veCmdlets) $null (maxDestructi veCMdletsTim ePeriod)
RCA	2000	5	205	200	
CPA	20		205	200	
General					$null (MessageRate Limit) $null (RecipientRate Limit) $null (ForwardeeLi mit) $null (cpuStartPerce nt)

Return to top

Understanding Policy Parameters

You manage throttling policy settings through the Exchange Management Shell using the **Get-ThrottlingPolicy**, **Set-ThrottlingPolicy**, **New-ThrottlingPolicy**, and **Remove-ThrottlingPolicy** cmdlets.

The acceptable load of a throttling policy is defined by the cmdlet parameter values on that throttling policy. The component types covered by throttling policies are as follows:

- Microsoft Exchange ActiveSync
- Exchange Web Services
- IMAP
- Outlook Web App
- POP
- Windows PowerShell

All these component types have policy parameters that work similarly, except for the Windows PowerShell component type.

The common component types are governed by four policy parameters: *<Component Acronym>MaxConcurrency*, *<Component Acronym>PercentTimeInAD*, *<Component Acronym>PercentTimeInCAS*, and -*<Component Acronym>PercentTimeInMailboxRPC*. The parameter names are prefixed by the component type acronym. The following table lists the component type acronyms that are used for the parameters in the throttling policy

cmdlets.

Component type acronyms that are used in throttling policy cmdlets

Component Acronym	Description	Example
EAS	Exchange ActiveSync	In the parameter *EASPercentTimeInCAS*, the component acronym EAS represents the Exchange ActiveSync component.
EWS	Exchange Web Services	In the parameter *EWSPercentTimeInCAS*, the component acronym EWS represents the Exchange Web Services component.
OWA	Outlook Web App	In the parameter *OWAPercentTimeInCAS*, the component acronym OWA represents the Outlook Web App component.
IMAP	IMAP4	In the parameter *IMAPPercentTimeInCAS*, the component acronym IMAP represents the IMAP4 component.
POP	POP3	In the parameter *POPPercentTimeInCAS*, the component acronym POP represents the POP3 component.

Note:

Unified Messaging users are considered Exchange Web Services users and their connections to the Exchange server are throttled by Exchange Web Services parameters such as *EWSMaxConcurrency*, *EWSPercentTimeInAD*, *EWSPercentTimeInCAS*, and *EWSPercentTimeInMailboxRPC*.

Return to top

MaxConcurrency

The value for a *MaxConcurrency* policy parameter indicates how many concurrent connections a specified user can have against an Exchange server at one time. A connection is held from the moment a request is received until a response is sent in its entirety to the requestor. If users try to make more concurrent requests than their policy allows, the new connection attempt fails. However, the existing connections remain valid. *<Component Acronym>MaxConcurrency* has a valid range from 0 through 2147483647 inclusive. To indicate that *<Component Acronym>MaxConcurrency* should be unthrottled (no limit), this value should be set to `$null`.

Important:

Don't set throttling policy parameters to `$null` unless you have a business need to do so. Unthrottled users aren't limited in their ability to intentionally or inadvertently place a high load on the server.

PercentTimeInCAS, PercentTimeInAD, and PercentTimeInMailboxRPC

The value for a *PercentTimeInCAS*, *PercentTimeInAD*, or *PercentTimeInMailboxRPC* policy parameter indicates what percentage of a minute can be spent:

- Running Client Access server code (*<Component Acronym>PercentTimeInCAS*)
- Running LDAP requests (*<Component Acronym>PercentTimeInAD*)
- Running mailbox RPC requests (*<Component Acronym>PercentTimeInMailboxRPC*)

A value of 100 indicates that for every one-minute window, the process can spend 60 seconds of that time consuming the resource in question. Although, it appears that a process would never encounter throttling with a value set to 100, you have to consider the effect of concurrent requests. If a process makes two concurrent requests that spend 60 seconds each running code on the Client Access server, the process has effectively used 120 seconds in a 60 second window, thus representing a *<Component Acronym>PercentTimeInCAS* value of 200 percent.

To indicate that *PercentTimeInCAS*, *PercentTimeInAD*, and *PercentTimeInMailboxRPC* should be unthrottled (no limit), this value should be set to `$null`.

Important:
Don't set throttling policy parameters to `$null` unless you have a business need to do so. Users aren't limited in their ability to intentionally or inadvertently place a high load on the server.

It's important to note that *<Component Acronym>PercentTimeInCAS* is an overlapping superset of *<Component Acronym>PercentTimeInAD* and *<Component Acronym>PercentTimeInMailboxRPC*. This means that the expenditure in Client Access server processing time will always be larger than the expenditures in *<Component Acronym>PercentTimeInAD* and *<Component Acronym>PercentTimeInMailboxRPC*. This is because for the Exchange component to make an Active Directory or RPC call, it must already be running Client Access server code. In addition, the expenditure in processing time for *<Component Acronym>PercentTimeInCAS* doesn't stop while LDAP or RPC calls are being made. Even though the request might be synchronously waiting for a response from Active Directory or the Exchange store, the process is still consuming a thread on the server and therefore should continue being charged for that usage. As a result, the *<Component Acronym>PercentTimeInCAS* value must be set to a value larger than the *<Component Acronym>PercentTimeInAD* value and the *<Component Acronym>PercentTimeInMailboxRPC* value.

Return to top

Exchange Management Shell Commands and Parameters

This section discusses the following Windows PowerShell parameters:

- *PowerShellMaxConcurrency*
- *PowerShellMaxCmdlets*
- *PowerShellMaxCmdletsTimePeriod*
- *PowerShellMaxCmdletQueueDepth*

PowerShellMaxConcurrency

In the context of remote Shell, the *PowerShellMaxConcurrency* parameter defines the maximum number of remote Shell sessions that a remote Shell user can have open at the same time. In the context of Web services, the *PowerShellMaxConcurrency* parameter defines the number of concurrent cmdlets that a user can have running at the same time. This value doesn't necessarily match the number of browsers opened by the user.

PowerShellMaxCmdlets

The *PowerShellMaxCmdlets* parameter defines the number of cmdlets that can be run per time period without being throttled. This parameter directly depends on the value defined by the *PowerShellMaxCmdletsTimePeriod* parameter. Both values should be set at the same time.

PowerShellMaxCmdletsTimePeriod

The *PowerShellMaxCmdletsTimePeriod* parameter defines the time period, in seconds, that a user can run the number of cmdlets defined by the *PowerShellMaxCmdlets* parameter.

PowerShellMaxCmdletQueueDepth

The *PowerShellMaxCmdletQueueDepth* parameter defines the number of operations that a user can run at the same time. This value directly affects the behavior of the *PowerShellMaxCmdlets* and *PowerShellMaxConcurrency* parameters. For example, the *PowerShellMaxConcurrency* parameter will use up at least two of the operations defined by the *PowerShellMaxCmdletQueueDepth* parameter, but additional operations will also be counted against the throttling limit each time the cmdlet is run. The number of operations that count toward the throttling limit depends on the cmdlets that are run. We recommend that the value for the *PowerShellMaxCmdletQueueDepth* parameter be at least three times larger than the value of the *PowerShellMaxConcurrency* parameter. This parameter won't affect operations that are run using the Exchange Control Panel or operations that are run through Exchange Web Services.

Return to top

Managing Client Throttling Policies

The Exchange Management Shell enables you to modify and view the client throttling policy settings using the cmdlets described in the following table.

Cmdlets for managing client throttling policies on a Client Access server

Cmdlet name	Description
New-ThrottlingPolicy	This cmdlet creates a new throttling policy.
Remove-ThrottlingPolicy	This cmdlet removes a throttling policy.
Get-ThrottlingPolicy	This cmdlet lets you view the settings of a throttling policy.
Set-ThrottlingPolicy	This cmdlet modifies all available settings for a throttling policy.

To view the syntax and parameters for these cmdlets, see New-ThrottlingPolicy, Remove-ThrottlingPolicy, Get-ThrottlingPolicy, and Set-ThrottlingPolicy.

You can associate a throttling policy with a specific object. The object can be a user with a mailbox, a user without a mailbox, a contact, or a computer account. For the syntax and parameters for these cmdlets, see Get-ThrottlingPolicyAssociation and Set-ThrottlingPolicyAssociation.

Note:
To associate a throttling policy with a single user or a group of users, use the *ThrottlingPolicy* parameter with the New-Mailbox and Set-Mailbox cmdlets.

Managing Client Throttling Policy Settings on a Per-User Basis

You can use the *ThrottlingPolicy* parameter of the **Set-Mailbox** and **New-Mailbox** cmdlets in the Exchange Management Shell to associate client throttling policies with a user or a group of users by modifying properties on their mailbox. For more information, see Set-Mailbox and New-Mailbox.

Return to top

Common Throttling Policy Management Tasks

The following are some ways you can manage client throttling policies.

Retrieving the Default Throttling Policy

By default, client throttling policies have the *IsDefault* parameter set to true. You can retrieve the default throttling policy using the `where-object` filter. The following example shows how to retrieve the default throttling policy.

```
Get-ThrottlingPolicy | where-object {$_.IsDefault -eq $true}
```

Retrieving the Throttling Policy That Governs a User

You can set throttling policies on a per-user basis. Therefore, you may want to retrieve the policy governing a specific user. You can obtain the `ThrottlingPolicy` parameter from the mailbox of the user you're interested in and pass it to the **Get-ThrottlingPolicy** cmdlet. In the following example, the mailbox of a user named Tony Smith is used.

```
$policy = $null;
$policyLink = (Get-Mailbox tonysmith).ThrottlingPolicy;
if ($policyLink -eq $null)
{
    $policy = Get-ThrottlingPolicy | ? {$_.IsDefault};
}
else
{
    $policy = $policyLink | Get-ThrottlingPolicy;
}
```

Return to top

Creating a New, Non-Default Throttling Policy

To create a new, non-default throttling policy, run the **New-ThrottlingPolicy** cmdlet and set the parameters you want. Any parameters that you omit will inherit the values from the default throttling policy. The following example creates a new throttling policy, `ClientThrottlingPolicy2`. The new policy has nearly the same settings as the default throttling policy. The difference is that the new non-default throttling policy, `ClientThrottlingPolicy2`, sets `EWSPercentTimeInCAS` to 80 and turns off `EWSPercentTimeInAD` throttling.

```
New-ThrottlingPolicy -Name ClientThrottlingPolicy2 -EWSPercentTimeInCAS 80 -EWSPe
```

Assigning a Non-Default Throttling Policy to a User

To assign a non-default throttling policy to a user, use the **Set-Mailbox** cmdlet, as follows.

```
$b = Get-ThrottlingPolicy ClientThrottlingPolicy2;
Set-Mailbox -Identity tonysmith -ThrottlingPolicy $b;
```

If a user is governed by a non-default throttling policy and you want the user to use the default policy, you might think you can make this change by setting the *ThrottlingPolicy* parameter to `$null`. Unfortunately, setting the *ThrottlingPolicy* parameter to `$null` doesn't modify the Mailbox object. To make the default throttling policy apply to the user, you must explicitly set the default throttling policy for that user by using the following command.

```
$policy = Get-ThrottlingPolicy | where-object {$_.IsDefault -eq $true};
Set-Mailbox -Identity tonysmith -ThrottlingPolicy $policy;
```

Return to top

Finding All Users Governed by a Specific Throttling Policy

If you want to learn which users are governed by a specific throttling policy, run the **Get-Mailbox** cmdlet and filter the throttling policy identity as shown in the following example. In this example, `$policy` is the policy for which you are filtering.

```
Get-Mailbox | where-object {$_.ThrottlingPolicy -eq $policy.Identity}
```

Removing Throttling Policies

You can only remove throttling policies that are non-default policies and aren't associated with any mailboxes. To do this, run the **Remove-ThrottlingPolicy** cmdlet and pass the identity of the throttling policy, using the following command.

```
Remove-ThrottlingPolicy ClientThrottlingPolicy2
```

If you have a throttling policy associated with users, you must first reassign those users to another policy, and then you can remove the policy you want to remove. The following example shows how to do this.

```
$policy = Get-ThrottlingPolicy ClientThrottlingPolicy2;
$mailboxes = Get-Mailbox | where-object {$_.ThrottlingPolicy -eq $policy.Identity
$defaultPolicy = Get-ThrottlingPolicy | where-object {$_.IsDefault -eq $true};
foreach ($mailbox in $mailboxes)
{
Set-Mailbox -Identity $mailbox.Identity -ThrottlingPolicy $defaultPolicy;
}
Remove-ThrottlingPolicy ClientThrottlingPolicy2;
```

Return to top

Modifying Throttling Policies

You modify an existing throttling policy (including the default) by running the **Set-ThrottlingPolicy** cmdlet and specifying which parameters to change. For example, to change the *EWSMaxConcurrency* parameter value for the default throttling policy to 4, you could use the following command.

```
$a = Get-ThrottlingPolicy | where-object {$_.IsDefault -eq $true}
$a | Set-ThrottlingPolicy -EWSMaxConcurrency 4
```

Throttling Performance Counters

Because throttling helps govern the overall usage of Exchange components on an Exchange server, it's often useful to examine how throttling is affecting the system. Exchange offers a set of throttling performance counters per process. An Exchange process such as Outlook Web App will have its own set of counters, for example, and Exchange Web Services will have its own set. In the Windows Performance tool, these counters are called instances.

Enable throttling logging in the RPC Client Access log

By default, throttling logging is disabled for the RPC client access service. Therefore, you will not see throttling information in the RPC Client Access logs. To enable throttling logging, follow these steps:

1. Open the following file in a text editor, such as Notepad: **C:\Program Files\Microsoft\Exchange Server\V14\Bin\Microsoft.Exchange.RpcClientAccess.Service.exe.config**
2. In the file, locate the **<add key="LoggingTag" value="ConnectDisconnect, Logon, Failures, ApplicationData, Warnings" />** section.

3. Type **Throttling** in the comma-separated string. For example, type **Throttling** in the string that resembles the following: **<add key="LoggingTag" value="ConnectDisconnect, Logon, Failures, ApplicationData, Warnings, Throttling" />**.
   Save and then close the file.
4. Restart the RPC Client Access service.

Return to top

1.6.1.4 Understanding Exchange ActiveSync

Understanding Exchange ActiveSync

Exchange Server 2010 > Client Access > Understanding Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-09*

By default, when you install the Client Access server role on a computer that's running Microsoft Exchange Server 2010, you enable Microsoft Exchange ActiveSync. Exchange ActiveSync lets you synchronize a mobile phone with your Exchange 2010 mailbox.

Overview of Exchange ActiveSync

Exchange ActiveSync is a Microsoft Exchange synchronization protocol that's optimized to work together with high-latency and low-bandwidth networks. The protocol, based on HTTP and XML, lets mobile phones access an organization's information on a server that's running Microsoft Exchange. Exchange ActiveSync enables mobile phone users to access their e-mail, calendar, contacts, and tasks and to continue to be able to access this information while they're working offline.

Note:
Exchange ActiveSync can synchronize e-mail messages, calendar items, contacts, tasks, and notes.

Important:
Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Windows Phone 7 Synchronization.

Features in Exchange ActiveSync

Exchange ActiveSync provides the following:

- Support for HTML messages
- Support for follow-up flags
- Conversation grouping of e-mail messages
- Ability to synchronize or not synchronize an entire conversation
- Synchronization of SMS messages with a user's Exchange mailbox
- Support for viewing of message reply status
- Support for fast message retrieval
- Meeting attendee information
- Enhanced Exchange Search
- PIN reset
- Enhanced device security through password policies
- Autodiscover for over-the-air provisioning
- Support for setting auto-replies when users are away, on vacation, or out of the office

- Support for tasks synchronization
- Direct Push
- Support for availability information for contacts

Managing Exchange ActiveSync

By default, Exchange ActiveSync is enabled. All users who have an Exchange mailbox can synchronize their mobile phone with the Microsoft Exchange server.

You can perform the following Exchange ActiveSync tasks:

- Enable and disable Exchange ActiveSync for users
- Set policies such as minimum password length, device locking, and maximum failed password attempts
- Initiate a remote wipe to clear all data from a lost or stolen mobile phone
- Run a variety of reports for viewing or exporting into a reporting solution

Security in Exchange ActiveSync

You can configure Exchange ActiveSync to use Secure Sockets Layer (SSL) encryption for communications between the Exchange server and the mobile phone client. Certificate-based authentication works with a self-signed certificate, a certificate from an existing public key infrastructure, or a third-party commercial certificate. You can use certificate-based authentication together with other security features, such as local device wipe and a device password, to turn the mobile phone into a smartcard. The private key and certificate for client authentication are stored in memory on the mobile phone. If an unauthorized user tries to bypass the mobile phone password, all user data is purged. This includes the certificate and private key. For more security, you can deploy RSA SecurID two-factor authentication on the Exchange server.

Device Security Features in Exchange ActiveSync

In addition to the ability to configure security options for communications between the Exchange server and your mobile phones, Exchange ActiveSync offers the following features to enhance the security of mobile phones:

- **Remote wipe** If a mobile phone is lost, stolen, or otherwise compromised, you can issue a remote wipe command from the Exchange Server computer or from any Web browser by using Outlook Web App. This command erases all data from the mobile phone.
- **Device password policies** Exchange ActiveSync lets you configure several options for device passwords. These options include the following:
  - **Minimum password length (characters)** This option specifies the length of the password for the mobile phone. The default length is 4 characters, but as many as 18 can be included.
  - **Minimum number of character sets** Use this text box to specify the complexity of the alphanumeric password and force users to use a number of different sets of characters from among the following: lowercase letters, uppercase letters, symbols and numbers.
  - **Require alphanumeric password** This option determines password strength. You can enforce the usage of a character or symbol in the password in addition to numbers.
  - **Inactivity time (seconds)** This option determines how long the mobile phone must be inactive before the user is prompted for a password to unlock the mobile phone.
  - **Enforce password history** Select this check box to force the mobile phone to prevent the user from reusing their previous passwords. The number that you set determines the number of past passwords that the user won't be allowed to reuse.
  - **Enable password recovery** Select this check box to enable password recovery for the mobile phone. Users can use Outlook Web App to look up their recovery password and unlock their mobile phone. Administrators can use the EMC to look up a user's recovery password.

- **Wipe device after failed (attempts)** This option lets you specify whether you want the phone's memory to be wiped after multiple failed password attempts.

- **Device Encryption Policies** There are a number of mobile phone or device encryption policies that you can enforce for a group of users. These policies include the following:
  - **Require encryption on device** Select this check box to require encryption on the mobile phone. This increases security by encrypting all information on the mobile phone.
  - **Require encryption on storage cards** Select this check box to require encryption on the mobile phone's removable storage card. This increases security by encrypting all information on the storage cards for the mobile phone.

Windows Phone 7 Synchronization

If you have Windows Phone 7 mobile phones in your organization, these phones will experience synchronization problems if certain Exchange ActiveSync mailbox policy properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to true or only configure the following Exchange ActiveSync mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration
- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

1.6.1.4.1 Understanding Direct Push

Understanding Direct Push

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-03-18*

Direct Push is a feature that's built into Microsoft Exchange Server 2010. Direct Push keeps a mobile phone current over a cellular network connection. It provides notification to the mobile phone when new content is ready to be synchronized to the mobile phone.

Overview

For Direct Push to work, the mobile phone or other mobile device must be Direct Push capable. These devices include the following:

- Mobile phones that have Windows Mobile 5.0 with the Messaging and Security Feature Pack (MSFP) or a later version of Windows Mobile.

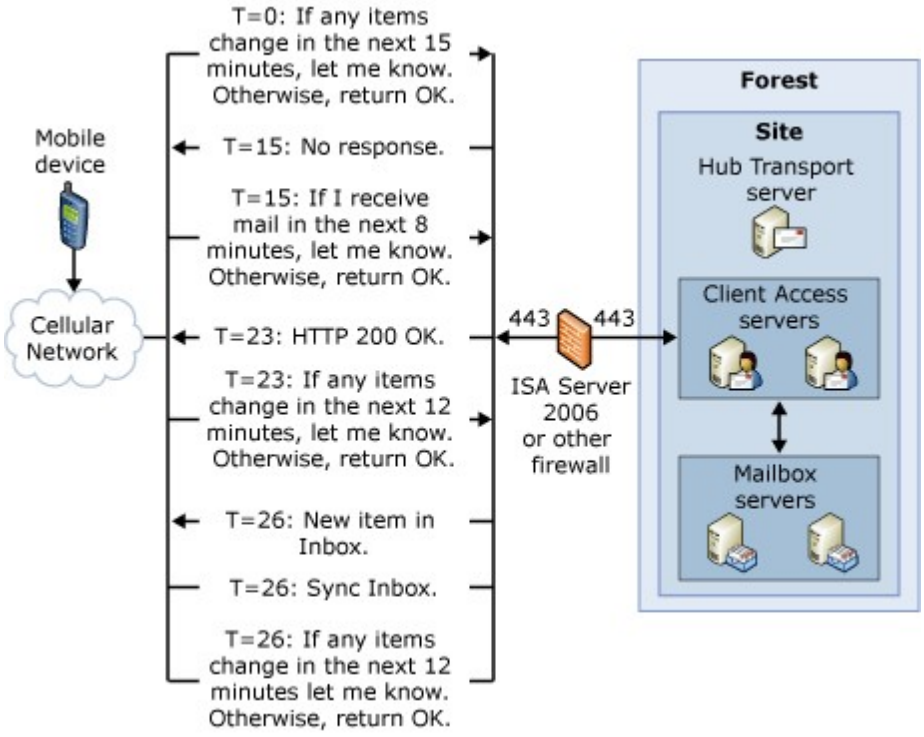
- Mobile phones that are produced by Microsoft Exchange ActiveSync licensees and are designed specifically to be Direct Push compatible.

By default, Direct Push is enabled in Exchange 2010. Mobile phones that support Direct Push issue a long-lived HTTPS request to the server running Microsoft Exchange. The Exchange server monitors activity on the user's mailbox and sends a response to the device if there are any changes, such as new or changed e-mail messages or calendar or contact items. If changes occur within the lifespan of the HTTPS request, the Exchange server issues a response to the device that states that changes have occurred and the device should initiate synchronization with the Exchange server. The device then issues this request to the server. When synchronization is complete, a new long-lived HTTPS request is generated to start the process again. This guarantees that e-mail, calendar, contact, and task items are delivered quickly to the mobile phone, and the device is always synchronized with the Exchange server.

Direct Push Topology

The following figure shows a typical Exchange 2010 topology that's configured for Direct Push. This figure assumes you have the Client Access and Mailbox server roles installed on two separate Exchange computers. You can also install both server roles on the same physical Exchange 2010 computer.

Direct Push network design



Direct Push operates in the following way:

1. A mobile phone that's configured to synchronize with an Exchange 2010 server issues an HTTPS request to the server. This request is known as a PING. The request tells the server to notify the device if any items change in any folder that's configured to synchronize in the next 15 minutes. Otherwise, the server should return an HTTP 200 OK message. The mobile phone then stands by. The 15-minute time span is known as a heartbeat interval.
2. If no items change in 15 minutes, the server returns a response of HTTP 200 OK. The mobile phone receives this response, resumes activity (known as

waking up), and issues its request again. This restarts the process.

3. If any items change or new items are received within the 15-minute heartbeat interval, the server sends a response that informs the mobile phone that there's a new or changed item and provides the name of the folder in which the new or changed item resides. After the mobile phone receives this response, it issues a synchronization request for the folder that has the new or changed items. When synchronization is complete, the mobile phone issues a new PING request and the whole process starts over.

Direct Push depends on network conditions that support a long-standing HTTPS request. If the carrier network for the mobile phone or the firewall doesn't support long-standing HTTPS requests, the HTTPS request is stopped. The following steps describe how Direct Push operates when a mobile phone's carrier network has a time-out value of 13 minutes:

1. A mobile phone issues an HTTPS request to the server. The request tells the server to notify the device if any items change in any folder that is configured to synchronize in the next 15 minutes. Otherwise, the server should return an HTTP 200 OK message. The mobile phone then stands by.
2. If the server does not respond after 15 minutes, the mobile phone wakes up and concludes that the connection to the server was timed out by the network. The device reissues the HTTPS request, but this time it uses a heartbeat interval of 8 minutes.
3. After 8 minutes, the server sends an HTTP 200 OK message. The device then tries to gain a longer connection by issuing a new HTTPS request to the server that has a heartbeat interval of 12 minutes.
4. After 4 minutes, a new e-mail message is received and the server responds by sending an HTTPS request that tells the device to synchronize. The device synchronizes and reissues the HTTPS request that has a heartbeat of 12 minutes.
5. After 12 minutes, if there are no new or changed items, the server responds by sending an HTTP 200 OK message. The device wakes up and concludes that network conditions support a heartbeat interval of 12 minutes. The device then tries to gain a longer connection by reissuing an HTTPS request that has a heartbeat interval of 16 minutes.
6. After 16 minutes, no response is received from the server. The device wakes up and concludes that network conditions cannot support a heartbeat interval of 16 minutes. Because this failure occurred directly after the device tried to increase the heartbeat interval, it concludes that the heartbeat interval has reached its maximum limit. The device then issues an HTTPS request that has a heartbeat interval of 12 minutes because this was the last successful heartbeat interval.

The mobile phone tries to use the longest heartbeat interval the network supports. This extends battery life on the device and reduces how much data is transferred over the network. Mobile carriers can specify a maximum, minimum, and initial heartbeat value in the registry settings for the mobile phone.

Configuring Direct Push to Work Through Your Firewall

For Direct Push to work through your firewall, you must open TCP port 443. This port is required for Secure Sockets Layer (SSL) and must be opened between the Internet and the Client Access server.

In addition to opening ports on your firewall, for optimal Direct Push performance, you should increase the time-out value on your firewall from the default of 15 minutes to 30 minutes. The maximum length of the HTTPS request is determined by the following settings:

- The maximum time-out value that's set on the firewalls that control the traffic from the Internet to the Client Access server
- The Firewall time-out values that are set by the mobile service provider

A short time-out value causes the device to initiate a new HTTPS request more frequently. This can shorten battery life on the device. For more information about how to configure your firewall, see the ISA Server Product Documentation.

1.6.1.4.2 Understanding Exchange ActiveSync Mailbox Policies

Understanding Exchange ActiveSync Mailbox Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-02*

This topic discusses Microsoft Exchange ActiveSync mailbox policies and how they can be used in your Microsoft Exchange Server 2010 environment.

Overview

Exchange ActiveSync mailbox policies let you apply a common set of policy or security settings to a user or group of users. The following table summarizes the settings you can specify by using Exchange ActiveSync mailbox policies.

Important:
Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Windows Phone 7 Synchronization later in this topic.

Exchange ActiveSync mailbox policy settings

Setting	Description
Allow Bluetooth	This setting specifies whether a mobile phone allows Bluetooth connections. The available options are Disable, HandsFree Only, and Allow. This policy setting requires an Enterprise Client Access License.
Allow Browser	This setting specifies whether Pocket Internet Explorer is allowed on the mobile phone. This setting doesn't affect third-party browsers installed on the phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow Camera	This setting specifies whether the mobile phone camera can be used. This policy setting requires an Exchange Enterprise Client Access License.
Allow Consumer Mail	This setting specifies whether the mobile phone user can configure a personal e-mail account (either POP3 or IMAP4) on the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow Desktop Sync	This setting specifies whether the mobile phone can synchronize with a computer

	through a cable, Bluetooth, or IrDA connection. This policy setting requires an Exchange Enterprise Client Access License.
Allow HTML E-mail	This setting specifies whether e-mail synchronized to the mobile phone can be in HTML format. If this setting is set to `$false`, all e-mail is converted to plain text.
Allow Internet Sharing	This setting specifies whether the mobile phone can be used as a modem for a desktop or a portable computer. This policy setting requires an Exchange Enterprise Client Access License.
AllowIrDA	This setting specifies whether infrared connections are allowed to and from the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow non-provisionable devices	This setting specifies whether older phones that may not support application of all policy settings are allowed to connect to Exchange 2010 by using Exchange ActiveSync.
Allow POPIMAPEmail	This setting specifies whether the user can configure a POP3 or an IMAP4 e-mail account on the mobile phone.
Allow Remote Desktop	This setting specifies whether the mobile phone can initiate a remote desktop connection. This policy setting requires an Exchange Enterprise Client Access License.
Allow simple password	This setting enables or disables the ability to use a simple password such as 1234. The default value is `$true`.
Allow S/MIME software certificates	This setting specifies whether S/MIME software certificates are allowed on the mobile phone.
Allow storage card	This setting specifies whether the mobile phone can access information that's stored on a storage card.
Allow text messaging	This setting specifies whether text messaging is allowed from the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow unsigned applications	This setting specifies whether unsigned applications can be installed on the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow unsigned installation packages	This setting specifies whether an unsigned installation package can be run on the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Allow Wi-Fi	This setting specifies whether wireless

	Internet access is allowed on the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Alphanumeric password required	This setting requires that a password contains numeric and non-numeric characters.
Approved Application List	This setting stores a list of approved applications that can be run on the mobile phone. This policy setting requires an Exchange Enterprise Client Access License.
Attachments enabled	This setting enables attachments to be downloaded to the mobile phone.
Device encryption enabled	This setting enables encryption on the mobile phone. Not all mobile phones can enforce encryption. For more information, see the phone and mobile operating system documentation.
Password enabled	This setting enables the mobile phone password.
Password expiration	This setting enables the administrator to configure a length of time after which a mobile phone password must be changed.
Password history	This setting specifies the number of past passwords that can be stored in a user's mailbox. A user can't reuse a stored password.
Policy refresh interval	This setting defines how frequently the mobile phone updates the Exchange ActiveSync policy from the server.
Maximum attachment size	This setting specifies the maximum size of attachments that are automatically downloaded to the mobile phone.
Maximum calendar age filter	This setting specifies the maximum range of calendar days that can be synchronized to the mobile phone. The value is specified in days.
Maximum failed password attempts	This setting specifies how many times an incorrect password can be entered before the mobile phone performs a wipe of all data.
Maximum inactivity time lock	This setting specifies the length of time that a mobile phone can go without user input before it locks.
Minimum password length	This setting specifies the minimum password length.
Maximum e-mail age filter	This setting specifies the maximum number of days' worth of e-mail items to synchronize to the mobile phone. The value is specified

	in days.
Maximum HTML e-mail body truncation size	This setting specifies the size beyond which HTML-formatted e-mail messages are truncated when they are synchronized to the mobile phone. The value is specified in kilobytes (KB).
Minimum device password complex characters	This setting specifies the minimum number of complex characters required in a mobile phone password. A complex character is any character that is not a letter.
Maximum e-mail body truncation size	This setting specifies the size beyond which e-mail messages are truncated when they are synchronized to the mobile phone. The value is specified in kilobytes (KB).
Password recovery	When this setting is enabled, the mobile phone generates a recovery password that's sent to the server. If the user forgets their mobile phone password, the recovery password can be used to unlock the mobile phone and enable the user to create a new mobile phone password.
Require Device Encryption	This setting specifies whether device encryption is required. If set to `$true`, the mobile phone must be able to support and implement encryption to synchronize with the server.
Require encrypted S/MIME messages	This setting specifies whether S/MIME messages must be encrypted.
Require manual synchronization while roaming	This setting specifies whether the mobile phone must synchronize manually while roaming. Allowing automatic synchronization while roaming will frequently lead to larger-than-expected data costs for the mobile phone plan.
Require storage card encryption	This setting specifies whether the storage card must be encrypted. Not all mobile phone operating systems support storage card encryption. For more information, see your mobile phone and mobile operating system for more information.
Unapproved InROM application list	This setting specifies a list of applications that cannot be run in ROM. This policy setting requires an Exchange Enterprise Client Access License.

Return to top

The following mailbox policies require an Exchange Enterprise Client Access License:

- Disable desktop ActiveSync
- Disable removable storage
- Disable camera
- Disable SMS text messaging

- Disable Wi-Fi
- Disable Bluetooth
- Disable IrDA
- Allow Internet sharing from device
- Allow desktop sharing from device
- Disable POP3/IMAP4 email
- Allow consumer email
- Allow web browser
- Allow unsigned applications
- Allow unsigned CABs
- Application allow list
- Application block list
- Unapproved InROM application list

For example, you can create a policy that you apply to all users in your Exchange organization. The following table lists possible settings for this policy.

Sample Exchange ActiveSync mailbox policy settings for all users

Setting	Value
Allow non-provisionable devices	False
Allow POPIMAPEmail	True
Allow Remote Desktop	True
Allow simple password	True
Allow S/MIME software certificates	True
Allow storage card	False
Allow text messaging	True
Allow unsigned applications	False
Allow unsigned installation packages	True
Allow Wi-Fi	False
Alphanumeric password required	True
Approved Application List	Null
Attachments enabled	True
Device encryption enabled	True
Maximum calendar age filter	15
Maximum attachment size	500 kilobytes (KB)
Maximum failed password attempts	4
Minimum password length	4
Maximum e-mail age filter	10
Maximum e-mail body truncation size	3 KB
Minimum device password complex characters	2
Maximum HTML e-mail body truncation size	7 KB

Password enabled	True
Password expiration	10 days
Password history	8 passwords stored
Require manual synchronization while roaming	True
UNC file access	Disabled
WSS file access	Disabled

Note:
You don't have to specify all policy settings when you create a new Exchange ActiveSync mailbox policy. Any policy setting you don't explicitly set will keep its default value.

Exchange ActiveSync mailbox policies can be created in the Exchange Management Console or the Exchange Management Shell. If you create a policy in the EMC, you can configure only a subset of the available settings. You can configure the rest of the settings using the Shell.

When you install Exchange 2010, a default Exchange ActiveSync mailbox policy is created. The default policy is automatically applied when a new user is created through the EMC or the Shell.

Return to top

You don't have to assign a user to an Exchange ActiveSync mailbox policy. The following table summarizes the policy settings used if you don't assign a user to a policy.

Default Exchange ActiveSync settings

Setting	Value
Allow Bluetooth	Allow
Allow Browser	True
Allow Camera	True
Allow Consumer Email	True
Allow Desktop Sync	True
Allow HTML E-mail	True
Allow Internet Sharing	True
AllowIrDA	True
Allow non-provisionable devices	True
Allow simple password	False
Allow POPIMAPEmail	True
Allow Remote Desktop	True
Alphanumeric password required	False
Allow S/MIME software certificates	True

Allow storage card	True
Allow text messaging	True
Allow unsigned applications	True
Allow unsigned installation packages	True
Allow Wi-Fi	True
Attachments enabled	True
Device encryption enabled	False
Maximum calendar age filter	7
Password enabled	False
Password expiration	Unlimited
Password history	0
Policy refresh interval	Unlimited
Document browsing enabled	True
Maximum attachment size	Unlimited
Maximum failed password attempts	4
Maximum inactivity time lock	15 minutes
Minimum password length	4
Maximum e-mail age filter	3
Maximum e-mail body truncation size	3 KB
Minimum device password complex characters	0
Maximum HTML e-mail body truncation size	3 KB
Require Device Encryption	False
Require encrypted S/MIME messages	False
Require manual synchronization while roaming	False
Require storage card encryption	False
Unapproved InROM application list	Null
Password recovery	Disabled
UNC file access	Enabled
WSS file access	Enabled

Windows Phone 7 Synchronization

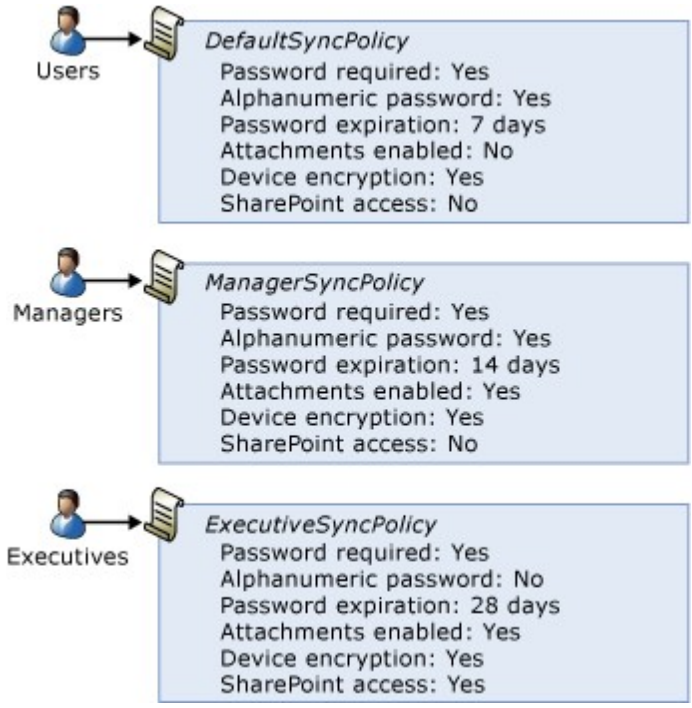
If you have Windows Phone 7 mobile phones in your organization, these phones will experience synchronization problems if certain Exchange ActiveSync mailbox policy

properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to true or only configure the following Exchange ActiveSync mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration
- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

Exchange ActiveSync Mailbox Policy Examples

The following figure shows how Exchange ActiveSync mailbox policies can be created to control different settings for three groups of users.



Return to top

Understanding Remote Device Wipe

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-24*

Mobile phones can store sensitive corporate data and provide access to many corporate resources. If a device is lost or stolen, that data can be compromised. Through Microsoft Exchange ActiveSync policies, you can add a password requirement to your mobile phones. This requires users to enter a password to access their mobile phones. We recommend that, in addition to requiring a device password, you configure your mobile phones to automatically prompt for a password after a period of inactivity. The combination of a device password and inactivity locking provides more security for your corporate data.

In addition to these features, Microsoft Exchange Server 2010 provides a remote device wipe feature. You can issue a remote device wipe command from the Exchange Management Shell. Users can issue their own remote device wipe commands from the Microsoft Office Outlook Web App user interface.

The remote device wipe feature also includes a confirmation function that writes a time stamp in the sync state data of the user's mailbox. This time stamp is displayed in Outlook Web App and in the user's mobile phone properties dialog box in the Exchange Management Console.

Important:

In addition to resetting the mobile phone to factory default condition, a remote device wipe also deletes any data on any storage card that's inserted in the mobile phone. If you're performing a remote device wipe on a mobile phone in your possession and want to keep the data on the storage card, remove the storage card before you initiate the remote device wipe.

Caution:

After a remote device wipe has occurred, data recovery is very difficult. However, no data removal process leaves a device as free from residual data as when it's new. Recovery of data from a device may still be possible using sophisticated tools.

Remote Device Wipe vs. Local Device Wipe

Local device wipe is the mechanism by which a mobile phone wipes itself without the request coming from the server. If your organization has implemented Exchange ActiveSync policies that specify a maximum number of password attempts and that maximum is exceeded, the mobile phone performs a local device wipe. The result of a local device wipe is the same as that of a remote device wipe. The device is returned to its factory default condition. When a mobile phone performs a local device wipe, no confirmation is sent to the Exchange server.

Understanding Exchange ActiveSync Autodiscover

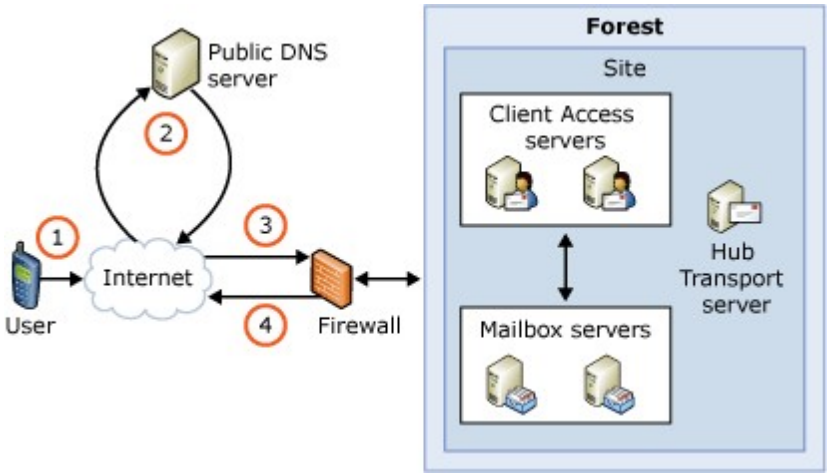
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-09*

Microsoft Exchange Server 2010 includes the Autodiscover service, which simplifies the provisioning of your mobile phone by returning the required system settings after a user enters their e-mail address and password. The Autodiscover service is enabled by default in Exchange 2010. Looking for more information about managing the Autodiscover service? See Managing the Autodiscover Service.

Overview of Autodiscover with Exchange ActiveSync

If your mobile phone supports Autodiscover, you can configure your mobile phone to synchronize with Exchange 2010. The following figure shows this synchronization process.



1. The user enters their e-mail address and password on the mobile phone.
2. The mobile phone connects to a root DNS server to retrieve the URL for the Autodiscover service and the IP address for the user's domain.
3. The mobile phone uses a Secure Sockets Layer (SSL) connection to connect through the firewall to the Autodiscover service virtual directory. The Autodiscover service assembles the XML response based on the server synchronization settings.
4. The Autodiscover service sends the XML response through the firewall over SSL. This XML response is interpreted by the mobile phone, and synchronization settings are configured automatically on the mobile phone.

Note:

The ability to use Autodiscover depends on the operating system of the mobile phone you're using. Not all mobile phone operating systems that support synchronization with Exchange 2010 support Autodiscover. For more information about operating systems that support Autodiscover, contact the manufacturer of your mobile phone.

Note:

Windows Mobile 5.0 doesn't support Autodiscover.

1.6.1.4.5 Understanding Mobile Phone Connectivity

Understanding Mobile Phone Connectivity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-03*

Many different mobile phones can synchronize with Microsoft Exchange Server 2010. These mobile phones can run operating systems such as Windows Mobile, Symbian, Palm, and Nokia. For an overview of the different mobile phones that are enabled for Microsoft Exchange ActiveSync, see Understanding Mobile Phones.

Regardless of the type of mobile phone you choose, you have two primary options to connect to Exchange 2010: by using cellular connectivity, and by using wireless connectivity. This topic provides an overview of these connectivity options.

Cellular Connectivity

All mobile phones that are enabled for Exchange ActiveSync can use cellular connectivity to synchronize with Exchange 2010. There are several types of cellular data networks. Regardless of the type of cellular data network that your mobile phone uses, the method of synchronization is the same. If you have a Windows Mobile phone, or another phone that supports Direct Push, synchronization is done through Direct Push. If your mobile phone has another operating system, manual synchronization is used. When a mobile phone uses Direct Push to synchronize with Exchange 2010, it establishes a long-standing HTTPS connection with the server running Exchange. When the connection is first established, the mobile phone sets what is called a heartbeat interval. The default heartbeat interval is 15 minutes. If any new messages are added to monitored folders on the Exchange server within this heartbeat interval, the server informs the mobile phone and the mobile phone initiates synchronization. When synchronization is complete, a new HTTPS request is initiated and the process is repeated. For more information about Direct Push, see Understanding Direct Push.

Cellular data plans can charge by the minute, by the megabyte, or offer unlimited data transfer. When you use a cellular data connection with Exchange 2010 Direct Push, we recommend purchasing an unlimited data plan.

Wireless Connectivity

Many mobile phones and other mobile devices that are enabled for Exchange ActiveSync can connect to a wireless LAN. A wireless LAN connection can provide faster network speeds and better coverage in areas where cellular coverage is unreliable. In addition, wireless access is sometimes offered at commercial locations such as coffee shops and book stores.

Understanding Mobile Phones

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-17*

Mobile phones that are enabled for Microsoft Exchange ActiveSync let users access most of their Microsoft Exchange mailbox data any time, anywhere. There are many different devices enabled for Exchange ActiveSync. These include Windows Mobile phones, Nokia mobile phones, and Palm mobile phones. This topic provides an overview of these mobile phones.

Although there are several non-phone devices that support Exchange ActiveSync, in most Exchange ActiveSync documentation, these devices are referred to as *mobile phones*. Unless the feature or features we're discussing require a cellular telephone signal, such as SMS message notification, the term mobile phone means both mobile phone and mobile device.

Exchange ActiveSync

Exchange ActiveSync is a communications protocol that enables mobile access, over the air, to e-mail messages, scheduling data, contacts, and tasks. Exchange ActiveSync is available on Windows Mobile phones and third-party phones that are enabled for Exchange ActiveSync.

Exchange ActiveSync offers Direct Push technology. Direct Push uses an encrypted HTTPS connection that's established and maintained between the phone and the server to push new e-mail messages and other Exchange data to the phone.

To use Direct Push with Microsoft Exchange Server 2010, your users must have a Windows Mobile phone or a phone with another mobile operating system that's designed to support Direct Push.

Exchange ActiveSync Features

Exchange ActiveSync provides access to many different features. These features enable you to enforce security policies on mobile phones. By using Exchange 2010, you can configure multiple Exchange ActiveSync policies and control which phones can synchronize with your Exchange server. Exchange ActiveSync enables you to send a remote device wipe command that wipes all data from a mobile phone in case that phone is lost or stolen. Users can also initiate a remote device wipe from Outlook Web App.

Exchange ActiveSync allows users to generate a recovery password. This recovery password is saved on the mobile phone and is used when a user forgets their password. The user generates the recovery password at the same time that they generate the device password or PIN. This recovery password can be used to unlock the phone. Immediately after this recovery password is used, the user will be required to create a new PIN.

Mobile Phones Enabled for Exchange ActiveSync

Users can take advantage of the features offered by Exchange ActiveSync by selecting mobile phones that are compatible with Exchange ActiveSync. These phones are available from many manufacturers. For more information, see the documentation for the phone

you're considering.

Mobile phones that are compatible with Microsoft Exchange include the following:

- **Apple** The Apple iPhone offers Exchange ActiveSync functionality. Users can configure an Exchange ActiveSync account on their Apple iPhone and synchronize e-mail, calendar, and contact data. When a user uses the Apple iPhone to synchronize e-mail messages, all e-mail messages in their inbox are synchronized to the iPhone. Users can't limit the synchronization to only 3 days of e-mail messages as they can with other phones. The iPhone is compatible with Exchange ActiveSync version 2.5 and doesn't support all the features included with Exchange ActiveSync for Exchange 2010. Specifically, the Apple iPhone supports only the following policies:
  - Remote wipe
  - Enforce password on device
  - Minimum password length
  - Require alphanumeric password
  - Require complex password
  - Inactivity time lockout
- **Nokia** Nokia offers Mail for Exchange on their Eseries mobile phones. E-mail, calendar, and contact data can be synchronized over a cellular network or a wireless LAN.
- **Sony Ericsson** Sony Ericsson offers Exchange ActiveSync support on several of their newer smartphones. They also support Direct Push through a third-party program.
- **Palm** Palm offers several Windows Mobile phones.
- **Motorola** Motorola has its own synchronization framework that enables over-the-air synchronization through Exchange ActiveSync on many its devices.
- **Symbian** Symbian Limited licenses Exchange ActiveSync for use in the Symbian operating system. This operating system is an open standard operating system for mobile telephones.

Windows Mobile Software Feature Matrix

Mobile phones that have a version of Windows Mobile software as their operating system offer the greatest functionality when synchronizing with Exchange 2010. The following table shows some features that are available with the different versions of Windows Mobile software.

Windows Mobile software feature matrix

Operating system	Productivity enhancements	Security enhancements	Administration enhancements
Windows Mobile 6 and later versions	• Direct Push • HTML e-mail support • Message flags • Quick message retrieval • Enhanced calendar views • Meeting attendee information • Ability to send auto-replies when you're away, on	• Enforcement of Exchange ActiveSync mailbox policies • Remote device wipe • Certificate-based authentication • S/MIME support • Device storage card encryption • Rights management	• Detailed device monitoring • Error reporting

	vacation, or out of the office • Exchange search • Windows SharePoint Services and Windows file share (UNC) document access	support	

For more information about how to manage Windows Mobile phones, visit the Windows Mobile Center Web site..

Windows Phone 7 synchronization

If you're configuring a Windows Phone 7 mobile phone to synchronize with an Exchange mailbox using Exchange ActiveSync, synchronization will fail under the following two simultaneous conditions:

- If the **AllowNonProvisionableDevices** property of the Exchange ActiveSync mailbox policy is set to False.
- If any policy properties that aren't included in the following list are configured for the Exchange ActiveSync mailbox policy:
  - PasswordRequired
  - MinPasswordLength
  - IdleTimeoutFrequencyValue
  - DeviceWipeThreshold
  - AllowSimplePassword
  - PasswordExpiration
  - PasswordHistory
  - DisableRemovableStorage
  - DisableIrDA
  - DisableDesktopSync
  - BlockRemoteDesktop
  - BlockInternetSharing

If you have Windows Phone 7 mobile phones in your organization, you can set **AllowNonProvisionalDevices** property to true or you can create a separate Exchange ActiveSync mailbox policy for users with Windows Phone 7 mobile phones. This new Exchange ActiveSync mailbox policy should either have the **AllowNonProvisionalDevices** property set to true or only have the preceding list of policy properties configured. For more information about Exchange ActiveSync Mailbox Policy properties and Windows Phone 7, see Understanding Exchange ActiveSync Mailbox Policies.

1.6.1.4.7 Understanding Exchange ActiveSync Reporting Services

Understanding Exchange ActiveSync Reporting Services

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-30*

Microsoft Exchange Server 2010 and Exchange ActiveSync offer many different features for both users and administrators. As an administrator, it's important that you know the

volume and usage patterns of your deployment. This information can help you effectively manage your Exchange ActiveSync deployment, better understand user productivity, and plan for future needs. Reporting in Exchange ActiveSync for Exchange 2010 is a Windows PowerShell task that compiles a set of Internet Information Services (IIS) logs and processes to create a series of output files. Each file is a separate report that can help you understand your Exchange ActiveSync deployment. This topic provides an overview of the cmdlet you can use to generate these reports, and information about the content of these reports.

Contents

Generating Exchange ActiveSync Reports

You can generate Exchange ActiveSync reports using the **Export-ActiveSyncLog** cmdlet. This cmdlet lets you specify many input parameters. These parameters include the location of the IIS log files, the start dates and the end dates for the reports, and the output path for the reports. To run this cmdlet, you must be delegated the permissions associated with the Exchange Server Administrator or Exchange Organization Administrator role. You must also have read access to the directory where the IIS logs are located. For more information about the syntax of the **Export-ActiveSyncLog** cmdlet, see Export-ActiveSyncLog.

Available Exchange ActiveSync Reports

The different Exchange ActiveSync reports available include the following:

- **Exchange ActiveSync Usage Report** This report includes several monitored parameters. These include the total bytes that were sent and received in addition to a count of each type of item sent and received. Item types are e-mail messages, calendar items, contact items, and task items.
- **Hits Report** This report lets you see the total number of synchronization requests processed per hour, in addition to the total number of unique devices that are initiating synchronization requests.
- **HTTP Status Report** This report provides a general overview of the performance of the Client Access server. It includes a summary of the different error response codes and the percentage of the time each code was encountered.
- **Policy Compliance Report** This report provides information about the number of fully compliant, partially compliant, and noncompliant devices. A fully compliant device is one that has accepted the Exchange ActiveSync policy and can implement all aspects of the policy. A partially compliant device is one that has accepted the policy, but has a mobile device operating system that's unable to enforce all aspects of the policy. A noncompliant device is either unable to accept the policy or has rejected the policy.
- **User Agent List** This report returns the total number of unique users, organized by mobile phone operating system.

Interpreting the Internet Information Services Log Files

The following table lists the different elements of the Exchange ActiveSync IIS logs. In the log file, each element is separated by an underscore character.

Elements of the Exchange ActiveSync protocol logs

<table>
<tr><th>Letter identifier</th><th>Element name</th><th>Definition</th><th>Possible values</th></tr>
<tr><td>V</td><td>Protocol version</td><td>The protocol version the device is using to synchronize with the Exchange server.</td><td><table><tr><th>Value</th><th>Meaning</th></tr><tr><td>120</td><td>Version 12</td></tr><tr><td>25</td><td>Version 2.5</td></tr><tr><td>21</td><td>Version 2.1</td></tr><tr><td>20</td><td>Version 2.0</td></tr><tr><td>10</td><td>Version 1.0</td></tr></table></td></tr>
<tr><td>Ty</td><td>Type</td><td>The type of folder that's being synchronized.</td><td><table><tr><th>Value</th><th>Meaning</th></tr><tr><td>Em</td><td>E-mail</td></tr><tr><td>Co</td><td>Contacts</td></tr><tr><td>Ca</td><td>Calendar</td></tr><tr><td>Ta</td><td>Tasks</td></tr></table></td></tr>
<tr><td>Fid</td><td>Folder ID</td><td>The ID of the folder that's being synchronized.</td><td>Positive Integer</td></tr>
<tr><td>Fc</td><td>Folder count</td><td>The number of folders that are being synchronized.</td><td>Positive Integer</td></tr>
<tr><td>Filt</td><td>Filter type</td><td>The data that the user requested.</td><td><table><tr><th>Value</th><th>Meaning</th><th>E-mail?</th><th>Calendar?</th><th>Tasks?</th></tr><tr><td>0</td><td>No filter</td><td>Yes</td><td>Yes</td><td>Yes</td></tr><tr><td>1</td><td>1 day back</td><td>Yes</td><td>No</td><td>No</td></tr><tr><td>2</td><td>3 days back</td><td>Yes</td><td>No</td><td>No</td></tr><tr><td>3</td><td>1 week back</td><td>Yes</td><td>No</td><td>No</td></tr><tr><td>4</td><td>2 weeks back</td><td>Yes</td><td>Yes</td><td>No</td></tr><tr><td>5</td><td>1 month</td><td>Yes</td><td>Yes</td><td>No</td></tr></table></td></tr>
</table>

			<table><tr><td></td><td>back</td><td></td><td></td><td></td></tr><tr><td>6</td><td>3 months back</td><td>No</td><td>Yes</td><td>No</td></tr><tr><td>7</td><td>6 months back</td><td>No</td><td>Yes</td><td>No</td></tr><tr><td>8</td><td>Incomplete</td><td>No</td><td>No</td><td>Yes</td></tr></table>
St	Sync type	The type of synchronization that's being performed.	<table><tr><th>Value</th><th>Meaning</th></tr><tr><td>F</td><td>First sync</td></tr><tr><td>S</td><td>Subsequent sync</td></tr><tr><td>R</td><td>Recovery sync</td></tr><tr><td>I</td><td>Invalid sync</td></tr></table>
Sk	Sync key	The actual sync key that's used between the mobile phone and the Exchange server.	Positive integer
Cli:	Client statistics	Stores the count of each type of activity from the Client. Output is in the form `Cli:0A0C3D1F0E`.	<table><tr><th>Identifier value</th><th>Meaning</th></tr><tr><td>A</td><td>Adds</td></tr><tr><td>C</td><td>Changes</td></tr><tr><td>D</td><td>Deletes</td></tr><tr><td>F</td><td>Fetches</td></tr><tr><td>E</td><td>Errors</td></tr></table>
Srv:	Server statistics	Stores the count of each type of activity from the server. Output is in the form `Srv:2A0C2D1F1E`.	<table><tr><th>Identifier value</th><th>Meaning</th></tr><tr><td>A</td><td>Adds</td></tr><tr><td>C</td><td>Changes</td></tr><tr><td>D</td><td>Deletes</td></tr><tr><td>F</td><td>Fetches</td></tr><tr><td>E</td><td>Errors</td></tr></table>
E	Number of errors	The number of errors encountered	Positive integer

		in a request.	
Io	Items opened	The number of items that were opened. This feature hasn't yet been implemented.	Positive integer
Hb	Heartbeat interval	The Heartbeat interval that's used for the PING command.	Positive integer
Ssp	SharePoint documents	The number of files that were accessed from Windows SharePoint Services.	Positive integer
Sspb	SharePoint bytes	The number of bytes that were accessed from Windows SharePoint Services.	Positive integer
Unc	UNC files	The number of files that were accessed through Windows file shares.	Positive integer
Uncb	UNC bytes	The number of bytes that were accessed through Windows file shares.	Positive integer
Att	Attachments	The number of attachments that were retrieved.	Positive integer
Attb	Attachment bytes	The number of bytes that were retrieved for attachments.	Positive integer
Pk	Policy key received	The element that's used by the client and server to correlate acknowledgements to a particular policy setting.	Not applicable
Pa	Policy acknowledge status	The element that indicates success if all the policy settings were applied correctly.	**Value** / **Meaning** 1 / Policy was successfully applied 2 / Policy was partially applied 3 / Policy was not applied

Oof	OOf action	The action that is performed on the Out of Office status stored on the Exchange server.	**Value** / **Meaning** Get / Retrieves the OOF status and message Set / Sets the OOF status and message
UserInfo	User information action	The parameter that specifies retrieval of the user information data.	Get
DevModel	Device model	The device information that is supplied by the device manufacturer.	Possible values include manufacturer name, model name, and model number.
DevIMEI	IMEI	The International Mobile Equipment Identity (IMEI). It is a 15-digit code that's assigned to each device.	String
DevName	Device friendly name	This element stores the user's description of their device.	String
DevOS	Device OS	The operating system that is running on the device.	String
DevLang	Device OS language	The localized language of the device operating system.	String
Error	Error	The error section of the request.	String
S	Status	This element returns the status of the device.	String
R	Not Relevant	This element returns a count of items that have changed but aren't relevant to the mobile phone or device.	Positive integer

The following is a sample log for mobile device synchronization:

&Log=V123_Ty:Em_Fid:37_Fc1_Filt2_St:S_SK:1805_Srv:1a0c0d0s0e0r_Pk2260121383_S1

1.6.1.4.8 Understanding Mobile Device Management

Understanding Mobile Device Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-03*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) and Microsoft Exchange ActiveSync offer many different features for both users and administrators. As an administrator, you can create allow lists, block lists, and quarantine lists specifying which mobile devices are allowed to access your Exchange mailboxes. A quarantine list lets you allow only a user's assigned device to connect to the Exchange server.

Note:

Throughout this topic, the term mobile device refers to mobile devices with and without cellular telephone service. All mobile phones and devices are assumed to have some form of Internet connectivity, either with a cellular data plan or with wireless Internet access.

Contents

Determining a Mobile Device's Access State

Exchange 2010 SP1 servers follow a simple, logical sequence to determine the access state of each mobile device. Every device can be either allowed, blocked, or quarantined. You can define the access state of each device through an organizational rule or through an *exemption*. An exemption is a rule that's applied to a single user or single device. This occurs each time an Exchange ActiveSync request is received from a mobile device that's trying to synchronize data from a mailbox stored on an Exchange 2010 server. The sequence of challenges includes the following steps:

1. **Is the mobile device authenticated?** If not, challenge the mobile device for the correct credentials. Otherwise, go on to the next step.
2. **Is Exchange ActiveSync enabled for the current user?** If not, return an "access restricted" error to the device. Otherwise, go on to the next step.
3. **Are the mobile policy enforcement criteria met by the current mobile device?** If not, block access. Otherwise, go on to the next step.
4. **Is this mobile device blocked by a personal exemption for the user?** If so, block access. Otherwise, go on to the next step.
5. **Is this mobile device allowed by a personal exemption for the user?** If so, grant full access. Otherwise, go on to the next step.
6. **Is this mobile device blocked by a device access rule?** If so, block access. Otherwise, go on to the next step.

7. **Is this mobile device quarantined by a device access rule?** If so, quarantine the device. Otherwise, go on to the next step.
8. **Is this mobile device allowed by a device access rule?** If so, grant full access. Otherwise, go on to the next step.
9. **Apply the default access state per the Exchange ActiveSync organizational settings.** This grants access, blocks access, or quarantines the current device, depending on the organizational settings.

Return to top

Understanding Device Access States

A *device access state* is the status of a particular device. The access state of a device can be one of the following: allowed, blocked, or quarantined. You can control device access states in several ways. A mobile device will behave differently in each access state.

The Allow Access State

In the allow access state, a mobile device can synchronize through Exchange ActiveSync and connect to the Exchange server to retrieve e-mail and manipulate calendar information, contacts, tasks, and notes. This will continue as long as the device complies with the Exchange ActiveSync mailbox policies that you've configured.

For more information, see View or Configure Exchange ActiveSync Mailbox Policy Properties.

The Block Access State

A mobile device that's blocked because of a device access setting you configured won't be allowed to connect to the Exchange server and will receive HTTP 403 Forbidden errors. The user will receive an e-mail message from the Exchange server telling them that the mobile device was blocked from accessing their mailbox. You can add customized text to this message to provide instructions for users whose devices are blocked.

A mobile device may also be blocked because it fails to apply the Exchange ActiveSync mailbox policies. If this is the case, the user won't receive an e-mail message that tells them that the mobile device was blocked from accessing their mailbox. However, the mobile device information displayed in Outlook Web App will show that it's blocked due to the failure by the device to apply the Exchange ActiveSync mailbox policies.

The Quarantine Access State

When a mobile device is quarantined, the mobile device is allowed to connect to the Exchange server. However, it is given only limited access to data. The user can add content to their own Calendar, Contacts, Tasks, and Notes folders but the server won't allow the device to retrieve any content from the user's mailbox. The user will receive a single e-mail message that tells them that the mobile device is quarantined. This message will be received by the device and will also be available in the user's mailbox. You can add customized text to this message to provide instructions for users whose devices are quarantined.

When you configure the Exchange ActiveSync organizational settings, you can specify one or more administrators who will receive an e-mail message the first time a quarantined device tries to connect to the Exchange server. The administrators can then decide whether to release the mobile device from quarantine by creating a personal exemption, block the device completely, or create a rule that will take action on the mobile device and other similar mobile devices.

Note A default *Upgrade Grace Period* allows quarantined devices to continue to sync with mailboxes that have been moved from previous versions of Exchange to Exchange Server 2010. The default Upgrade Grace Period is seven (7) days, beginning when the device synchronization state is upgraded. The device access state is upgraded only when a

device contacts the Exchange server. Therefore, if the device does not contact a server, its access state is not upgraded.

Also, if a synchronization state is not detected for the device before the upgrade when it is running on the previous version of Exchange, the device does not receive an Upgrade Grace Period.

The Device Discovery Access State

When a mobile device first connects to Exchange ActiveSync, the device is momentarily in the device-discovery access state. In this state, the device is quarantined until it's recognized by the server. This state can last from 1 to 14 minutes. No email message is sent to administrators or to the user when a mobile device is in this state.

The Mailbox Upgrade Access State

When a mobile device is in the mailbox upgrade access state, it's granted full access to the user's mailbox. The mailbox upgrade access state is the same as the allowed state, except that it lasts no more than seven days from the first time the device connects to an Exchange 2010 server after a mailbox move from an earlier version of Microsoft Exchange. This state is necessary to give mobile devices time to correctly upgrade their information and communication protocols to the latest Exchange ActiveSync version and be recognized by the device access management system. As soon as a mobile device is recognized, Exchange applies the appropriate access based on the Exchange 2010 configuration.

Return to top

Controlling Device Access

You can control device access by configuring the following:

- Personal exemptions for users.
- Organization-wide rules for mobile device families or specific models.
- A default access state for all devices that don't belong in another category.

Creating Personal Exemptions

You can assign a particular mobile device to a particular user. This assignment allows you to explicitly grant access for a particular device or explicitly block a particular device regardless of the rules and other device access settings. If a mobile device is not explicitly granted or blocked for the particular user, then the device's access will be determined according to the numbered steps discussed previously.

Note:

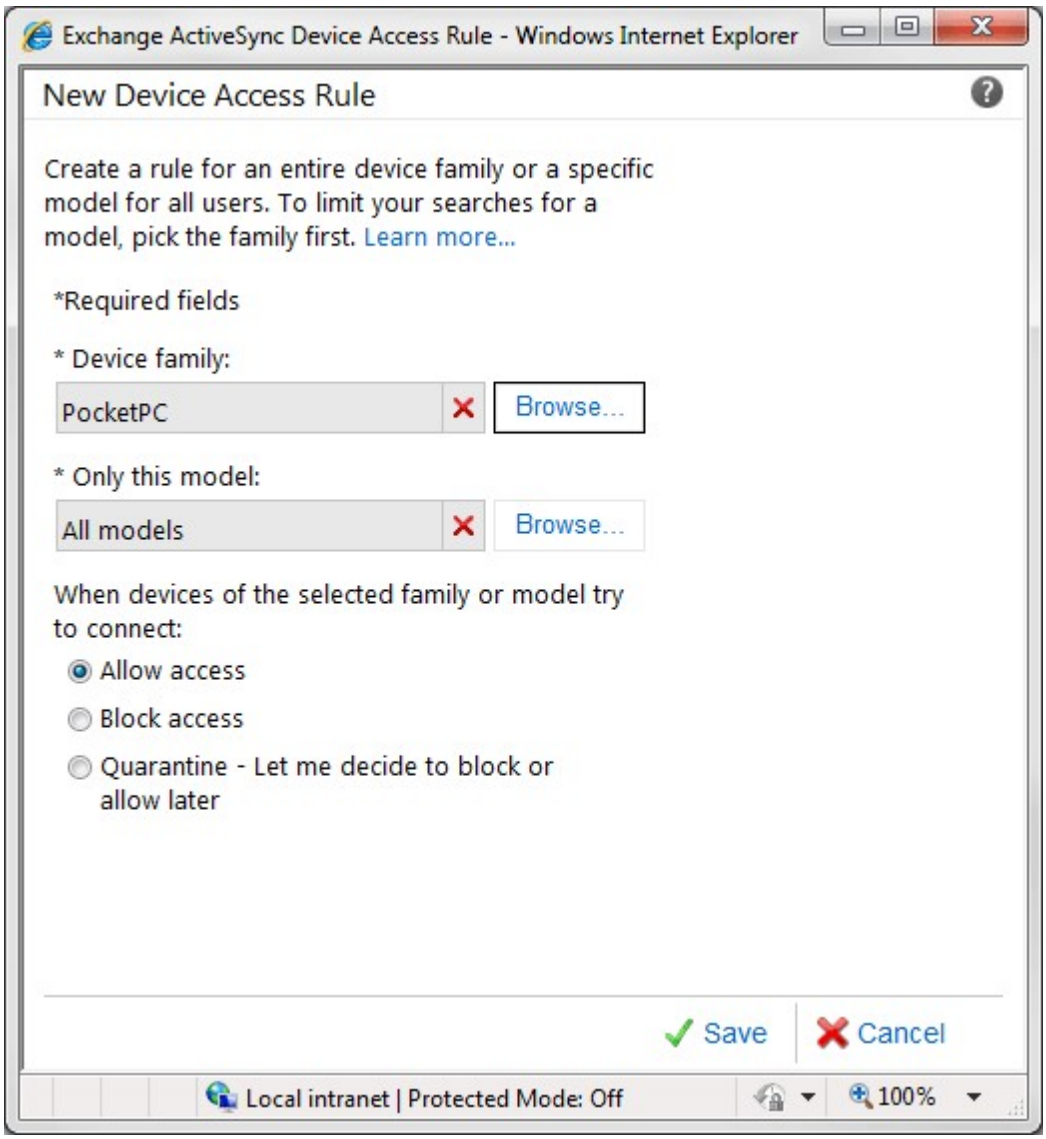
Unlike Microsoft Exchange Server 2007, explicitly granting access for a specific device for a user doesn't implicitly deny access for other devices. If a user tries to connect a different device, that device's access state will be determined by the organization's device access settings.

Personal exemptions can be created by using the **Set-CASMailbox** cmdlet or the Exchange Control Panel (ECP).

Creating Organization Access Rules

Organizational access rules let you set the type of access available to a particular group of devices based on some properties of the device, such as model. To create these rules, you need to know the device model and family information. This information can be obtained after a mobile device has successfully synchronized with the Exchange server.

Organizational access rules can be created by using the **Set-CASMailbox** cmdlet or through the ECP, as shown in the following figure.



When you set up a rule for a device, it's important to understand the difference between the device "family" and the specific device. This information is communicated as part of the EAS protocol, and it's reported by the device itself. For example, a device rule applies only to a specific device type. A device family represents a range of similar devices, such as a Pocket PC. This distinction is important because many device manufacturers release the same device by using different names on different carriers. When you create a rule, you select the device family or the specific model, but not both.

On the **New Device Access Rule** page, click **Browse**, to display a list of all the devices or device families that have recently connected to your Exchange server. Then, select the action to take. You can select any of the following actions:

Allow access

Block access

Quarantine

Quarantine notifications

Quarantine notifications let you specify who receives an email alert when a device is placed in quarantine. You can add one or more administrators, users, or distribution groups to the list. Anyone who is on this list receives an email notification that provides information about the device, the person who tried to connect the device, and the time that the attempt was made.

Setting the Default Organizational Access State

The default organizational access state for Exchange ActiveSync determines the access level that's granted to mobile devices that aren't managed by organizational rules or personal exemptions. The default organizational access state can be set by using the **Set-CASMailbox** cmdlet or the ECP.

Return to top

Configuring Common Access Management Strategies

Before you specify the level of access for mobile devices, you might want to get a list of all mobile phones and devices within your organization. You can get this list by using the **Get-CASMailbox** cmdlet with the **Get-ActiveSyncDeviceStatistics** cmdlet. For more information, see Get-ActiveSyncDeviceStatistics.

Creating an Allow List

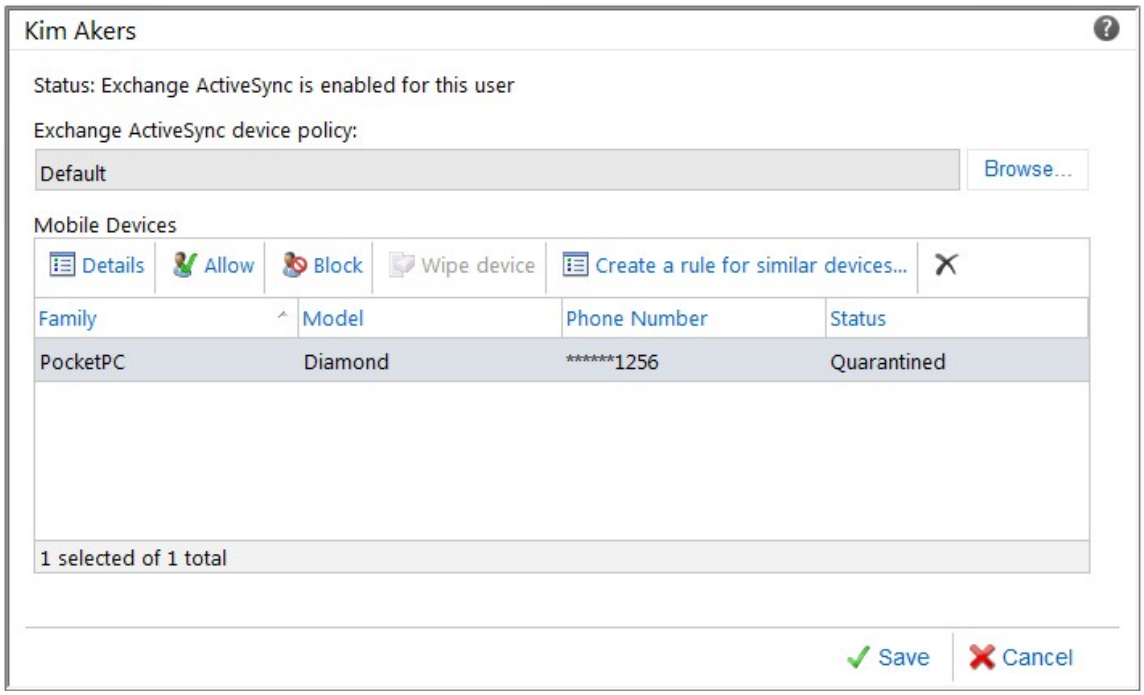
You can use an allow list to grant access to a list of known devices and restrict access for everything else. To do this, you must create rules so that the specific devices you want are allowed to access users' mailboxes. As soon as you create such a rule, you must set the organization’s default access state to block all other devices. To add a new device to the allow list, create a new rule.

Creating a Block List

You can use a block list to grant access to all devices by default, but to block access for a set of devices that you don't want to access your organization. You create a block list by creating block rules for the devices that you don't want to synchronize with the organization’s mailboxes. The organizational settings should be set to allow everything by granting access to all devices that aren't explicitly blocked by the existing rules. To add a new device or set of devices to the block list, create a new rule.

Mixed Allow and Block List Environments

In addition to creating allow and block lists, you can quarantine new mobile devices as they're introduced into the organization while you evaluate them. For example, if you have a block list for mobile devices that aren't allowed within your organization, and an allow list for mobile devices that are allowed within the organization, you can set the default organizational access setting to quarantine. All other devices will automatically be quarantined, which lets you discover new devices as they're introduced to the organization and decide whether to add them to the allow list or the block list. The following figure shows a mobile device that's been quarantined for a specific user.



Live Auditing

You can use live auditing to discover all the devices that are currently synchronizing with the Exchange server in your organization. You set up live auditing by setting the default organizational access setting to quarantine.

A list of quarantined devices will be generated within a few minutes of time the default organizational access setting is switched to quarantine. You can use that list to create your allow and block lists. All users will be prevented from synchronizing with the Exchange server until the allow and block lists have been created.

1.6.1.5 Understanding POP3 and IMAP4

Understanding POP3 and IMAP4

Exchange Server 2010 > Client Access > Understanding Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-06*

By default, POP3 and IMAP4 are disabled in Microsoft Exchange Server 2010. To support clients that still rely on these protocols, you must first start the POP3 and IMAP4 services on the Exchange 2010 Client Access server. You must also configure SMTP for your POP3 and IMAP4 clients to send e-mail.

For detailed steps for enabling the POP3 and IMAP4 services, see Enable POP3 in Exchange 2010 and Enable IMAP4 in Exchange 2010.

By default, users who have mailboxes on computers that are running Exchange 2010 can access their mailboxes by using Microsoft Outlook or Outlook Web App, Microsoft Exchange ActiveSync, or Outlook Voice Access. Outlook, Outlook Web App, and Outlook

Voice Access enable your e-mail users to use the comprehensive set of features that are available to clients that have mailboxes on Exchange 2010 servers.

Contents

Overview of POP3 and IMAP4 Functionality

This section describes the POP3 and IMAP4 functionality for Exchange 2010.

These two protocols have the following benefits and limitations:

- **POP3** POP3 was designed to support offline mail processing. With POP3, e-mail messages are removed from the server and stored on the local POP3 client, unless the client has been set to leave mail on the server. This puts the data management and security responsibility in the hands of the user. POP3 doesn't offer advanced collaboration features such as calendaring, contacts, and tasks.
- **IMAP4** IMAP4 offers offline and online access, but like POP3, IMAP4 doesn't offer advanced collaboration features such as calendaring, contacts, and tasks.

POP3 and IMAP4 can't be used to send messages from a client application to the e-mail server. E-mail applications that use POP3 and IMAP4 to send messages rely on the SMTP protocol to send messages. The connector for receiving e-mail submissions from client applications that use POP3 or IMAP4 is created automatically on every Hub Transport server. For more information about connectors, see Understanding Receive Connectors.

POP3 and IMAP4 Cross-Site Connectivity

In earlier versions of Exchange, you had to perform a manual configuration step to allow your POP3 and IMAP4 clients to connect to their mail from one site in your organization when their mailbox was located in a different site in your organization. By default, Exchange 2010 automatically proxies from a Client Access server in one site to the correct server.

Managing POP3 and IMAP4 with Exchange 2003

When you deploy Client Access servers to support clients that use POP3 and IMAP4, and their mailboxes are located on Exchange Server 2003 back-end servers, you must use Basic authentication. Also, you won't be able to use Secure Sockets Layer (SSL) encryption. Instead, you must use Internet Protocol security (IPsec) to help secure the communication between these servers.

Using Non-Standard Accounts with POP3 and IMAP4

You can't use an Anonymous account or Guest account to sign in to an Exchange 2010 mailbox through POP3 or IMAP4. This kind of access is blocked because of security vulnerabilities when you use non-standard accounts for POP3 and IMAP4 access. Additionally, you can't connect to the Administrator mailbox through POP3 or IMAP4. This limitation was included intentionally in Exchange 2010 to enhance security for the Administrator mailbox. To access the Administrator mailbox, you must use Microsoft Office Outlook or Outlook Web App.

Understanding Differences Between POP3 and IMAP4

POP3 is a frequently used e-mail Internet protocol. By default, when POP3 e-mail applications download e-mail messages to a client computer, the downloaded messages are removed from the server. When a copy of your user's e-mail isn't kept on the e-mail server, the user can't access the same e-mail messages from multiple computers. However, some POP3 e-mail applications can be configured to keep copies of the messages on the server so that the same e-mail messages can be accessed from another computer. POP3 client applications can only be used to download messages from the e-mail server to a single folder (usually the Inbox) on the client computer. The POP3 protocol can't synchronize multiple folders on the e-mail server with multiple folders on the client computer. POP3 also doesn't support public folder access.

E-mail client applications that use IMAP4 are more flexible and generally offer more features than e-mail client applications that use POP3. By default, when IMAP4 e-mail applications download e-mail messages to a client computer, a copy of downloaded messages remains on the e-mail server. Because a copy of the user’s e-mail message is kept on the e-mail server, the user can access the same e-mail message from multiple computers. With IMAP4 e-mail, the user can access and create multiple e-mail folders on the e-mail server. Users can then access any of their messages on the server from computers in multiple locations. For example, most IMAP4 applications can be configured to keep a copy of a user's sent items on the server so that they can view their sent items from any other computer. IMAP4 supports additional features that are supported by most IMAP4 applications. For example, some IMAP4 applications include a feature that lets the user view only the headers of their e-mail messages on the server—who the message is from and the subject—and then download only the messages that they want to read. IMAP4 doesn’t support public folder access.

Note:

IMAP4 and POP3 clients have limited access to calendar information for Exchange. For more information, see Configure Calendar Options for IMAP4 and Configure Calendar Options for POP3.

Send Receive Options for POP3 and IMAP4 E-Mail Applications

POP3 and IMAP4 e-mail applications let users choose when they want to connect to the

server to send and receive e-mail. This section discusses some of the most common connectivity options and also provides some factors your users should consider when they select connection options available in their POP3 and IMAP4 e-mail applications.

Common Configuration Settings

Three of the most common connection settings that can be set on the POP3 or IMAP4 client application are:

- To send and receive messages every time the e-mail application is started. When this option is used, mail is only sent and received upon starting the e-mail application.
- To send and receive messages manually. When this option is used, messages are only sent and received when the user clicks a "send and receive" option in the client user interface.
- To send and receive messages every set number of minutes. When this option is used, the client application connects to the server every set number of minutes to send messages and download any new messages.

For information about how to configure these settings for the e-mail application that you use, see the Help documentation that's provided with the respective e-mail application.

Considerations When Selecting Send Receive Options

If the device or computer that's running the POP3 or IMAP4 e-mail application is always connected to the Internet, users may want to configure their e-mail application to send and receive messages every set number of minutes. Connecting to the server at frequent intervals lets the user keep their e-mail application up-to-date with the most current information on the server. However, if the device or computer that's running the POP3 or IMAP4 e-mail application isn't always connected to the Internet (for example, if the user connects to the Internet by using a dial-up connection), the user may want to configure the e-mail application to send and receive messages manually. In a dial-up connectivity scenario, sending and receiving messages manually can potentially reduce the time that a user is connected to the Internet.

Note:

If the user is using an IMAP4-compliant e-mail application that supports the IMAP4 IDLE command, the user may be able to send e-mail to and receive e-mail from their Exchange mailbox in near real time. For this connection method to work, both the e-mail server application and the client application must support the IMAP4 IDLE command. In most cases, users don't have to configure any settings in their IMAP4 application to use this connection method.

POP3 and IMAP4 Applications

Because Exchange 2010 supports POP3 and IMAP4, users can use any applications that support POP3 and IMAP4 client applications to connect to Exchange 2010. These applications include Outlook, Windows Mail, Microsoft Outlook Express, Entourage, and many third-party applications such as Mozilla Thunderbird and Eudora. The features supported by each e-mail client applications vary. For information about the specific features offered by specific POP3 and IMAP4 client applications, see the documentation that's included with each application.

User Settings to Configure POP3 or IMAP4 Access to Their Exchange 2010 Mailboxes

After you enable POP3 and IMAP4 client access on your Client Access servers, you have to give users the information they need to connect their e-mail programs to their Exchange 2010 mailbox. They'll need the following information:

To connect from inside the corporate network, users will need the following information:

- Internal POP3 or IMAP4 server name
- Internal POP3 or IMAP4 port number
- Internal POP3 or IMAP4 encryption method
- Internal SMTP (outgoing server) name
- Internal SMTP (outgoing server) port number
- Internal SMTP (outgoing server) encryption method

To connect from the Internet, they'll need the following information:

- External POP3 or IMAP4 server name
- External POP3 or IMAP4 port number
- External POP3 or IMAP4 encryption method
- External SMTP (outgoing server) name
- External SMTP (outgoing server) port number
- External SMTP (outgoing server) encryption method

You can make these settings available to your users through e-mail or other manual communication methods. You can also configure Exchange so that your users can use Outlook Web App to look up their own settings.

Configuring Exchange So Users Can Look Up Their Internal POP3, IMAP4, and SMTP Server Settings

By default, your users can look up their internal POP3 and IMAP4 server settings through Outlook Web App. However, to allow your users to access internal SMTP (outgoing) server settings, you must run the **Set-ReceiveConnector** cmdlet with the *AdvertiseClientSettings* parameter. After you run this command, your users can access their internal POP, IMAP, and SMTP server settings through Outlook Web App by clicking the drop-down arrow next to the Help question mark, and then clicking **About**.

For detailed information about how to configure this setting, see Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App.

Configuring Exchange So Users Can Look Up Their External POP3, IMAP4, and SMTP Server Settings

By default, external POP3, IMAP4, and SMTP server settings aren't available to your users through Outlook Web App. You can change the default setting as follows:

- To allow your users to look up their own external POP3 settings, you must run the **Set-POPSettings** cmdlet with the *ExternalConnectionSettings* parameter.
- To allow your users to look up their own external IMAP4 settings, you must run the **Set-IMAPSettings** cmdlet with the *ExternalConnectionSettings* parameter.
- To allow your users to access external SMTP server settings, you must run the **Set-ReceiveConnector** cmdlet with the *AdvertiseClientSettings* parameter.

After you change your default settings by running the **Set-POPSettings**, **Set-IMAPSettings**, and **Set-ReceiveConnector** cmdlets, your users can look up their external POP, IMAP, and SMTP server settings in Outlook Web App as follows:

- If you're running Exchange Server 2010 SP1, your users can look up their settings in Outlook Web App by clicking **Options** > **All Options** > **Account** > **My Account** > **Settings for POP, IMAP, and SMTP access**.
- If you're running the RTM version of Exchange 2010, your users can look up their settings in Outlook Web App by clicking the drop-down arrow next to the Help question mark, and then clicking **About**.

For detailed information about how to configure this setting, see Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App.

Leaving a Copy of Messages on the Server

The default setting on some e-mail programs isn't to keep a copy of messages on the server after they're retrieved. Be sure to recommend that your users set up their e-mail program to keep a copy of all messages the client retrieves on the server. By keeping a copy of messages on the server, your users can access their messages from a different e-mail program.

1.6.1.5.1 Understanding POP3 and IMAP4 Settings

Understanding POP3 and IMAP4 Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

If you administer POP3 and IMAP4, you'll perform all your administrative tasks in the Exchange Management Shell or the Exchange Management Console.

Managing POP3 and IMAP4 Using the Shell

You can use the Shell to manage the POP3 and IMAP4 services on a per-server basis or on a per-user basis in Microsoft Exchange Server 2010.

Managing POP3 and IMAP4 on Per-Server Basis

You can view and configure POP3 and IMAP4 settings on the Exchange 2010 Client Access server by using the cmdlets included in the following table.

Cmdlets for managing POP3 and IMAP4

Cmdlet name	Description
Set-PopSettings	This cmdlet can be used to configure all available settings for POP3 on a Client Access server.
Set-ImapSettings	This cmdlet can be used to configure all available settings for IMAP4 on a Client Access server.

For more information about how to use the **Set-PopSettings** and **Set-ImapSettings** cmdlets to manage POP3 and IMAP4 settings for a user, see Set-PopSettings and Set-ImapSettings.

Managing POP3 and IMAP4 Settings on a Per-User Basis

You can use the **Set-CASMailbox** cmdlet in the Shell to manage POP3 and IMAP4 settings for individual users by modifying properties on their mailboxes. The following table describes the parameters that you can use with the **Set-CASMailbox** cmdlet.

Parameters to use with the Set-CASMailbox cmdlet to manage POP3 and IMAP4

Parameter name	Description
`ImapEnabled`	This parameter specifies whether the IMAP4 protocol is enabled for this mailbox.

ImapMessagesRetrievalMimeFormat	This parameter specifies the format of messages retrieved from the server.
ImapUseProtocolDefaults	This parameter specifies whether to use the default protocol settings specified on the Client Access server for the IMAP4 protocol.
PopEnabled	This parameter specifies whether the POP3 protocol is enabled for a mailbox.
PopMessagesRetrievalMimeFormat	This parameter specifies the format of messages retrieved from the server.
PopUseProtocolDefaults	This parameter specifies whether to use the default protocol settings specified on the Client Access server for the POP3 protocol.

For more information about how to use the **Set-CASMailbox** cmdlet to manage POP3 and IMAP4 settings for a user, see Set-CASMailbox.

Managing POP3 and IMAP4 Using the EMC

1. In the console tree, navigate to **Server Configuration**> **Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab
3. Select either POP3 or IMAP4 and then, in the action pane, under **IMAP4** or **POP**, click **Properties**.
4. Click any of the available tabs to view and configure POP3 or IMAP4 settings.

1.6.1.5.2 Understanding Protocol Logging for POP3 and IMAP4

Understanding Protocol Logging for POP3 and IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use protocol logging to review the POP3 and IMAP4 connections in your Exchange environment. This can be useful if you're troubleshooting issues related to POP3 or IMAP4 performance.

Enabling POP3 and IMAP4 Protocol Logging

You can enable or disable protocol logging using the Exchange Management Shell. If you enable protocol logging using the Shell, the default protocol logging settings will be used. These default settings are generally recommended.

Alternatively, you can enable, disable, and modify protocol logging options by editing the Microsoft.Exchange.Pop3.exe.config and Microsoft.Exchange.Imap4.exe.config configuration files located on your Microsoft Exchange Server 2010 Client Access server.

For more information about how to manage POP3 and IMAP4 protocol settings, see Configure Protocol Logging for POP3 and IMAP4.

Reviewing the Protocol Log

The information included on each line of the POP3 and IMAP4 protocol logs is organized by fields that are separated by commas. The following table explains the fields that are used to classify each protocol event.

Fields used to classify each protocol event

Field name	Description
date-time	The date and time of the protocol event. The value is formatted as *yyyy-mm-ddhh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu. Zulu is another way to indicate Coordinated Universal Time (UTC).
connector-id	This field is not used for POP3 and IMAP4 protocol logging.
session-id	A GUID that is unique for each SMTP session but is the same for each event that is associated with that SMTP session.
sequence-number	A counter that starts at 0 and is incremented for each event in the same session.
local-endpoint	The local endpoint of a POP3 or IMAP4 session. This consists of an IP address and TCP port number that is formatted as *<IP address>:<port>*.
remote-endpoint	The remote endpoint of a POP3 or IMAP4 session. This consists of an IP address and TCP port number that is formatted as *<IP address>:<port>*.
event	A single character that represents the protocol event. The possible values for the event are as follows: • + Connect • - Disconnect • > Send • < Receive • * Information
data	Text information that is associated with the POP3 or IMAP4 event.
context	This field is not used for POP3 and IMAP4 protocol logging.

1.6.1.6 Understanding Outlook Web App

Understanding Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-06-13*

By default, when you install the Client Access server role on a computer that's running Microsoft Exchange Server 2010, you enable Outlook Web App. Microsoft Office Outlook Web App lets you access your Exchange mailbox from almost any Web browser.

Note:
Outlook Web App was called Outlook Web Access in previous versions of Microsoft Exchange.

Looking for management tasks related to Outlook Web App? See Managing Outlook Web App.

Contents

New Features in Outlook Web App

Outlook Web App has been redesigned for Exchange 2010 to create a new look, add new features, and improve usability.

New features in Outlook Web App include:

- **Outlook Web App mailbox policies** In previous versions of Outlook Web App, you controlled users' access to features by configuring the Outlook Web App virtual directories or by configuring individual mailboxes. In Exchange 2010, you can use Outlook Web App mailbox policies to control users' access to features in Outlook Web App. For more information, see Understanding Outlook Web App Mailbox Policies.
- **More Web browsers supported** In Exchange 2010, users have access to the standard version of Outlook Web App through Safari and Firefox, in addition to Internet Explorer. For more information, see Outlook Web App Supported Browsers.
- **Conversation view** Conversation view lets users see all messages in a thread, including messages not in the current folder.
- **Chat** Outlook Web App can be configured to work with Microsoft Office Communications Server 2007 or with Microsoft Lync Server 2010 to allow users to chat without having to install Office Communicator 2007 or Lync 2010. For more information, see Understanding Outlook Web App and Instant Messaging Integration.
- **Filters** Users have access to a set of predefined filters to quickly search the contents of folders.
- **Right-click** More actions have been added to the right-click menus in Outlook Web App.
- **Attach messages to messages** Users can attach a message from their

mailbox to a new message. In previous versions of Outlook Web App, users could attach files to messages, but couldn't attach a message to a message.

For more information about new features for users in Outlook Web App, see What's New in Outlook Web App.

Managing Outlook Web App

When you install the Client Access server role, a default virtual directory named owa is created. For more information about Outlook Web App virtual directories, see Managing Outlook Web App Virtual Directories.

In Exchange 2010, the most common Outlook Web App management tasks can be accomplished in the Exchange Management Console. All these tasks, and many other tasks, can be accomplished by using the Exchange Management Shell. You'll still use tools such as Internet Information Services (IIS) Manager for some tasks, for example, configuring Secure Sockets Layer (SSL) or setting up simple URLs for users.

For more information about how to manage Outlook Web App, see the following topics:

- Managing Outlook Web App
- Managing Outlook Web App Security

Tools for Managing Outlook Web App

The following table lists the tools that you can use to configure and manage Outlook Web App in Exchange 2010.

Tools for managing Outlook Web App

Tool	Description
Exchange Management Console	This graphical user interface is used to manage an Exchange 2010 organization. The EMC can be used to manage the most common settings for Outlook Web App.
Exchange Management Shell	This command-line interface for Exchange Server and the associated command-line plug-ins automate administrative tasks and management for many features that aren't included in the EMC.
Internet Information Services (IIS) Manager	IIS Manager is used to manage user access to the Outlook Web App virtual directories, for example, for simplifying the URL and forcing users to use an HTTPS address.
Web.config	Some Outlook Web App settings, such as the `ConnectionCacheSize` and `MaxRequestLength` values, must be configured by modifying Web.config because these settings are specific to ASP .NET. Web.config should be modified only by using tools such as Notepad. If you modify Web.config by using IIS, the file will become corrupted.
Registry Editor	Some Outlook Web App configuration settings, such as the `PublicClientTimeout`, `TrustedClientTimeout`, and `SSLOffloaded` values, must be configured by using Registry

	Editor. **Caution:** Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Return to top

Administrative Tasks for Managing Outlook Web App

The following table lists the configuration and management tasks that you can perform for Outlook Web App.

Configuration and management tasks for Outlook Web App

Task	Description	Link
Configure the virtual directories that are created for Web access to Exchange content	When you install the Client Access server role on your Exchange server, four virtual directories are created in the default IIS Web site on the Exchange 2010 server.	Managing Outlook Web App Virtual Directories
Simplify the Outlook Web App URL	By using IIS Manager, you can simplify the Outlook Web App URL that users use to access Outlook Web App.	Simplify the Outlook Web App URL
Modify attachment handling settings	You can configure the types of attachments that can be accessed in Outlook Web App and how those attachments are displayed.	Managing File and Data Access for Outlook Web App
Configure authentication methods	You can configure authentication methods, such as standard and forms-based authentication, for Outlook Web App.	Managing Outlook Web App Security
Modify language and character handling settings	You can configure the default language and character settings for an Outlook Web App virtual directory.	Configure Language Settings for Outlook Web App
Configure Gzip compression settings	Gzip enables data compression. By using Gzip, you can improve performance for users who are using Outlook Web App over slow network connections.	Configure Gzip Compression Settings

Disable Web beacons	Outlook Web App prevents senders from using Web beacons in junk e-mail messages to retrieve e-mail addresses.	Configure Web Beacon and HTML Form Filtering for Outlook Web App
Configure segmentation settings	You can enable or disable specific Outlook Web App features according to the needs of your organization.	Configure Segmentation in Outlook Web App
Configure Outlook Web App mailbox policies	Outlook Web App mailbox policies can be used to manage users' access to features through Outlook Web App at the organization level.	Understanding Outlook Web App Mailbox Policies

Return to top

1.6.1.6.1 Understanding Outlook Web App Virtual Directories

Understanding Outlook Web App Virtual Directories

Client Access > Understanding Client Access > Understanding Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-01*

When you install the Client Access server role on your Exchange server, one Microsoft Office Outlook Web App virtual directory is created in the default Internet Information Services (IIS) Web site on the Exchange server. You can manage the virtual directory by using the Exchange Management Shell, the Exchange Management Console, and IIS Manager.

Looking for management tasks related to Outlook Web App virtual directories? See Managing Outlook Web App Virtual Directories.

Configuring Outlook Web App Virtual Directories

Exchange 2010 supports access to mailboxes on Exchange 2010 servers through Exchange 2010 Client Access servers.

Most organizations find that the default Outlook Web App virtual directory that's created during installation of the Exchange 2010 Client Access server role is sufficient. You may not need to create new Outlook Web App virtual directories. Generally, new Outlook Web App virtual directories are created by businesses that provide hosting or for troubleshooting issues, such as the deletion and re-creation of Outlook Web App virtual directories.

Note:

You can’t create more than one Outlook Web App virtual directory in a site. To create multiple Outlook Web App virtual directories, you must create additional sites in IIS Manager.

Perform the following tasks on Outlook Web App virtual directories, depending on the needs of your organization.

- **Create a new Outlook Web App virtual directory** You can use the Exchange Management Shell to create a new Outlook Web App virtual directory. For more information, see Create an Outlook Web App Virtual Directory.

  Note:
  When the Client Access server role is installed, the Outlook Web App virtual directory is installed under the default Web site. All new virtual directories are installed under the default Web site unless a different Web site is specified when the virtual directory is created.

- **View or configure properties of an Outlook Web App virtual directory** You can use the Shell and the EMC to view or configure the properties of an Outlook Web App virtual directory. For more information, see View or Configure Outlook Web App Virtual Directories.
- **Manage properties on an Outlook Web App virtual directory** If you're running only the Client Access server role on a computer, you manage the properties of the virtual directories from the **Outlook Web App** tab in the EMC. You can access the **Outlook Web App** tab by clicking **Server Configuration** and then clicking **Client Access**.

1.6.1.6.2 Understanding Outlook Web App URLs

Understanding Outlook Web App URLs

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

Microsoft Office Outlook Web App in Microsoft Exchange Server 2010 enables users to read and manage the contents of Exchange 2010 mailboxes from most Internet browsers. You can use Internet Information Services (IIS) Manager to manage the default URLs to make connecting to Outlook Web App more secure and easier for users.

Looking for management tasks related to Outlook Web App URLs? See Managing Outlook Web App URLs.

Default Outlook Web App URL

When you install the Client Access server role on an Exchange 2010 server, one virtual directory is created for Outlook Web App. This virtual directory is named owa. For more information about virtual directories, see Managing Outlook Web App Virtual Directories.

The default URL for Outlook Web App for mailboxes on an Exchange 2010 server is http://*<server name>*/owa.

Understanding File and Data Access for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-07*

You can manage the different ways users access information in Microsoft Office Outlook Web App by using the Exchange Management Console.

Looking for management tasks related to file and data access for Outlook Web App? See Managing File and Data Access for Outlook Web App.

Contents

WebReady Document Viewing

Microsoft Exchange Server 2010 includes a feature named WebReady Document Viewing. WebReady Document Viewing lets users view common file types in the Outlook Web App Web browser without having the applications associated with those file types installed on the computer they're using. Users can view the following kinds of files using WebReady Document Viewing:

- .doc
- .docx
- .pdf
- .ppt
- .pptx
- .xls
- .xlsx

Additionally, the following MIME types are supported:

- application/pdf
- application/vnd.ms-excel
- application/vnd.ms-powerpoint
- application/word
- application/x-mspowerpoint
- application/x-msexcel

For more information about how to manage WebReady Document Viewing for users, see Configure WebReady Document Viewing.

Public and Private Computer File Access

You can configure how users interact with files by using the Allow, Block, or Force Save options for direct file access in the Exchange Management Console. This means that you can specify the types of files that users can access. More important, you can directly specify which types of files are prohibited. For more information about how to manage public and private computer file access, see Configure Public and Private Computer File Access.

Understanding Outlook Web App Advanced Features

Client Access > Understanding Client Access > Understanding Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-06*

You can manage advanced features in Outlook Web App in Microsoft Exchange Server 2010 by using the Exchange Management Console and the Exchange Management Shell. In Exchange 2010, you can enable and disable Outlook Web App features for your whole organization or for individual users by using segmentation. To increase protection against spammers, you can disable Web beacons in Outlook Web App. If the default language and character settings for Outlook Web App at initial sign-in aren't appropriate for your users, you can change them using the language and character settings. If users will be using Outlook Web App over a slow network connection, you can enable Gzip compression to improve the performance of Outlook Web App on the client computer.

Looking for management tasks related to Outlook Web App advanced features? Check out Managing Outlook Web App Advanced Features.

Contents

Segmentation of Features in Outlook Web App

Segmentation lets you enable and disable features that are available to users in Outlook Web App. By default, any mail-enabled user in your Exchange 2010 organization can access their mailbox by using Outlook Web App. Depending on the needs of your organization, you can use segmentation to configure the following restrictions for user access:

- Restrict access to Outlook Web App for specific users.
- Control access to certain Outlook Web App features for specific users.
- Disable an Outlook Web App feature completely.

Many features can be set for an Outlook Web App virtual directory by using the EMC. You can use the Set-OwaVirtualDirectory cmdlet in the Shell to enable or disable the same features that you can enable and disable by using the EMC, in addition to many other Outlook Web App features for an Outlook Web App virtual directory. For example, you can use the `RemindersandNotificationsEnabled` parameter to disable the **Reminders** feature in Outlook Web App. The **Reminders** feature enables users to receive new mail notifications. You can also modify other Outlook Web App features, such as Tasks and

Contacts.

For more information about the parameters that you can use to configure segmentation for all users, see Set-OwaVirtualDirectory.

For more information about the features that can be configured using the EMC, see Configure Segmentation in Outlook Web App.

For more information about how to enable and disable features for specific users, see Set-CASMailbox.

Return to top

Segmentation Features in Exchange 2003 vs. Exchange 2010 and Exchange 2007

The following table lists the differences between Outlook Web App segmentation in Exchange Server 2003 vs. Exchange 2010 and Exchange Server 2007.

Outlook Web App segmentation in Exchange 2003 vs. Exchange 2010 and Exchange 2007

Type	Exchange 2003	Exchange 2010 and Exchange 2007
Segmentation basis	Segmentation can be performed for individual users and for individual servers. The segmentation setting for each Outlook Web App feature is stored as a DWORD value in the registry. If the DWORD value is 1, the Outlook Web App feature is enabled. If the DWORD value is 0, the Outlook Web App feature is disabled. By default, all features are enabled.	Segmentation can be performed for individual users and for individual virtual directories. You can administer the user and virtual directory segmentation settings for each Outlook Web App feature by using the Shell. Unlike Exchange 2003, segmentation settings in Exchange 2010 and Exchange 2007 aren't configured by editing the registry.
Storing segmentation values	The DWORD values that are set for users and for servers are the same. However, they're stored in different locations. • The server DWORD value is stored in a registry key. • The user DWORD value is stored in the **msExchMailboxFolderSet** Active Directory attribute on the user object. By default, the **msExchMailboxFolderSet** attribute exists, but the value isn't configured.	• The segmentation value that's set for an Outlook Web App virtual directory is stored on the virtual directory object. • The segmentation value that's set for a user is stored in the **msExchMailboxFolderSet** Active Directory attribute on the user object. By default, the **msExchMailboxFolderSet** attribute exists for each user, but the value isn't configured. Use the Set-

		CASMailbox cmdlet to configure values for individual users.
Features in Outlook Web App in Exchange 2010 or Exchange 2007 that can be segmented	• Not applicable	• You can segment the following Outlook Web App features: • Unified Messaging integration • Windows SharePoint Services and Windows file shares integration • Exchange ActiveSync integration from **Mobile Settings** on the **Options** page

Return to top

Understanding Web Beacons

A Web beacon is a file object, such as a transparent graphic or an image, which is put on a Web site or in an e-mail message. Web beacons are typically used together with HTML cookies to monitor user behavior on a Web site or to validate a recipient's e-mail address when an e-mail that contains a Web beacon is opened. Web beacon configuration is set on a per virtual directory basis for each Outlook Web App virtual directory in your organization.

Web beacons frequently come in the form of images that are downloaded onto a user's computer when the user opens a junk e-mail message. After the images are downloaded, a Web beacon notification is sent to the sender of the junk e-mail that informs the sender that the recipient e-mail address is valid. After a user opens a message that sends a Web beacon notification back to the junk e-mail sender, the user may receive junk e-mail more frequently because the junk e-mail sender has verified that the user's e-mail address is valid. Web beacons can also contain harmful code and be used to circumvent e-mail filters to deliver a spammer's message.

Note:

By default, Outlook Web App disables all potential Web beacon content in e-mail messages.

In Outlook Web App, an incoming e-mail message that has any content that can be used as a Web beacon, regardless of whether the message actually contains a Web beacon, prompts Outlook Web App to display a warning message to the user to inform the user that the content has been blocked. If a user knows that a message is legitimate, they can enable the blocked content. If a user doesn't recognize the sender or the message, they can open the message without unblocking the content and then delete the message without triggering beacons. If your organization doesn't want to use this feature, you can disable the blocking option for Outlook Web App.

Return to top

Configuring Web Beacons

The configuration settings for filtering Web beacons are stored in Active Directory. You can configure how Web beacons are filtered by using the Set-OwaVirtualDirectory cmdlet in the Shell. For more information about syntax and parameters, see Set-OwaVirtualDirectory.

The following list describes the parameters in the **FilterWebBeacons** property for Web beacon filtering in Outlook Web App:

- `UserFilterChoice` You can let users decide whether they want to enable or continue to disable blocked Web beacon content by using the `UserFilterChoice` parameter. Outlook Web App blocks all potential Web beacon content in an e-mail message and displays a message in the information bar when a user receives an e-mail message that contains potential Web beacon content warning them that content is blocked. To view the blocked Web beacon content, the user can click **Click Here** in the infobar message.

  Note:
  By default, the `UserFilterChoice` parameter is enabled on Outlook Web App.

- `ForceFilter` You can block all potential Web beacon content by using the `ForceFilter` parameter. Users can't override the `ForceFilter` parameter to view the blocked Web beacon content.
- `DisableFilter` You can enable all Web beacon content on Outlook Web App by using the `DisableFilter` parameter setting.

For more information about how to disable Web beacons, see Configure Web Beacon and HTML Form Filtering for Outlook Web App.

Return to top

Language Settings

You can configure the following language parameter settings on an Outlook Web App virtual directory by using the Set-OwaVirtualDirectory cmdlet in the Shell:

- `DefaultClientLanguage` The `DefaultClientLanguage` parameter, a Regional property setting, specifies the Outlook Web App language that's used when a user who hasn't selected a specific language on the **Options** page signs in to Outlook Web App. This prevents the user from being able to view the initial page to set the time zone and language, but doesn't prevent the user from changing these settings using **Options** in Outlook Web App after they've signed in. This parameter doesn't apply to Microsoft Exchange 2000 Server or Exchange 2003 virtual directories.
- `LogonAndErrorLanguage` The `LogonAndErrorLanguage` parameter specifies which language Outlook Web App uses for forms-based authentication and for error messages that occur when a user's current language setting can't be read. This parameter applies to Exchange 2003 virtual directories.

The user can configure the language that's used by Outlook Web App by using the **Regional Settings** option in the **Options** menu after he or she is successfully authenticated for an Outlook Web App session. The `LogonAndErrorLanguage` parameter can be configured only by an administrator. The administrator must configure the `LogonAndErrorLanguage` parameter before the user authenticates into Outlook Web App.

Note:
To make all Arabic, Asian, Hebrew, and Urdu text display correctly in Outlook Web App, support for languages that are read from right-to-left and script languages must be installed on the client computer. Other languages may also require that the appropriate language pack be installed on the client computer.

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

For more information about how to configure the language settings for an Outlook Web App virtual directory, see Configure Language Settings for Outlook Web App.

Return to top

Character Settings

The Charset parameter specifies how the Web browser decodes data and appends the character set, for example, ISO-8859-15, of the content-type header in the Response object of the Web page. You can use the Response object to send output to the client.

You can configure the character settings on an Outlook Web App virtual directory by using the **Set-OwaVirtualDirectory** cmdlet in the Shell. You can configure the following character settings on an Outlook Web App virtual directory:

- OutboundCharset The OutboundCharset parameter specifies the character set that's used on messages that are sent by users on a specific Outlook Web App virtual directory. It accepts three settings: autodetect, alwaysUTF8, and UserLanguageChoice. Autodetect causes Exchange to examine the first 2 kilobytes (KB) of text and deduce the character set to use. This is the preferred method. AlwaysUTF8 causes Exchange to always use UTF-8 encoded UNICODE characters on outgoing messages. UserLanguageChoice causes Exchange to use the language that's used in the Outlook Web App user interface to encode messages. This can be a problem if the preferred language and the language that's used on an individual message aren't the same.
- UseGB18030 The UseGB18030 parameter, a Regional property setting, specifies when the character set GB18030 is used. This parameter is a character-handling key in Active Directory that works in coordination with the OutboundCharset registry key. If USEGB18030 is on and OutboundCharset is set to Autodetect, Outlook Web App will use GB18030 whenever GB18032 is detected.
- UseISO8859-15 The UseISO8859-15 parameter, a Regional property setting, specifies when the character set ISO8859-15 is used. This parameter is a character-handling key in Active Directory that works in coordination with the OutboundCharset registry key. If USEISO8859-15 is on and OutboundCharset is set to Autodetect, Outlook Web App will use ISO8859-15 whenever ISO8859-1 is detected

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

For more information about how to configure the character settings for Outlook Web App, see Configure Character Settings for Outlook Web App.

Return to top

Gzip Compression Settings

Gzip compression enables data compression. Data compression helps optimize response time over slow network connections. Depending on the type of compression setting that you select, Outlook Web App compresses static Web pages, dynamic Web pages, or both static Web pages and dynamic Web pages. Gzip compression is performed by the Client Access server.

You can configure Gzip compression settings on an Outlook Web App virtual directory by using the Set-OwaVirtualDirectory cmdlet in the Shell. You can use the Get-OwaVirtualDirectory cmdlet to retrieve information about the current settings on an

Outlook Web App virtual directory. For more information about syntax and parameters, see Set-OwaVirtualDirectory.

The following table describes the three levels of data compression settings for Outlook Web App.

Data compression settings for Outlook Web App

Data compression setting	Description
High	This setting compresses static and dynamic pages.
Low	This setting compresses only static pages. By default, Gzip compression is set to *low*.
Off	No compression is used.

For more information about how to configure Gzip settings, see Configure Gzip Compression Settings.

Return to top

Customizing the Forms-Based Authentication Sign-In Page

You can customize the appearance of the forms-based authentication page by writing a new version of the sign-in page that sends the same HTML form to Outlook Web App as the original forms-based authentication sign-in page.

The forms-based authentication page is enabled for anonymous access. Therefore, you must use caution when you decide what content to display on the Outlook Web App sign-in page. Don't reveal any sensitive data that may pose a security risk for your organization on the Outlook Web App sign-in page.

If you customize the sign-in page, your changes may be overwritten when you install hot fixes and service packs on the Client Access server that provides the sign-in page. For more information about how to customize the forms-based authentication sign-in page, see Customize the Outlook Web App Sign-In and Sign-Out Pages.

Return to top

Creating a Custom Theme for Outlook Web App

You can create a custom theme for Outlook Web App by copying an existing theme and modifying the files that define the icons, logos, and colors. For more information, see Create a Theme for Outlook Web App.

Understanding Outlook Web App Mailbox Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-16*

Use Microsoft Office Outlook Web App mailbox policies to create organization-level policies to manage access to features in Outlook Web App. Outlook Web App mailbox policies allow you to create multiple policies at the organization level and apply them to individual mailboxes.

Looking for management tasks related to Outlook Web App mailbox policies? See Managing Outlook Web App Mailbox Policies.

Contents

Outlook Web App Mailbox Policies

In Exchange 2010, you can create multiple Outlook Web App mailbox policies and apply them to individual mailboxes. When an Outlook Web App mailbox policy is applied to a mailbox, it will override the settings of the virtual directory.

In previous versions of Exchange, Outlook Web App features were managed by configuring the Outlook Web App virtual directories. Exceptions for individual mailboxes were accommodated by enabling or disabling features on individual mailboxes.

Configuring Outlook Web App Mailbox Policies

A default Outlook Web App mailbox policy is created automatically when the Client Access server role is installed. By default, all options are enabled on the default Outlook Web App mailbox policy. You can create as many Outlook Web App mailbox policies as necessary to meet the needs of your organization.

Note:
The default Outlook Web App mailbox policy is not automatically applied to any mailboxes.

For example, you may want to create a policy that forces users to use WebReady Document Viewing to view attachments or a policy that limits users to the Light version of Outlook Web App.

You can use the Exchange Management Console or the Exchange Management Shell to create and configure Outlook Web App mailbox policies.

Applying Outlook Web App Mailbox

Policies

Only one Outlook Web App mailbox policy can be applied to a mailbox.

If there's no Outlook Web App mailbox policy applied to a mailbox, the settings defined on the virtual directory will be applied.

An Outlook Web App mailbox policy can be applied to a mailbox as part of the new mailbox wizard, by using the EMC to modify an existing mailbox, or by using the Shell and the Set-CASMailbox cmdlet to apply a mailbox policy.

1.6.1.6.6 Understanding Outlook Web App and Instant Messaging Integration

Understanding Outlook Web App and Instant Messaging Integration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-01*

Microsoft Office Outlook Web App in Microsoft Exchange Server 2010 supports the integration of Outlook Web App and Microsoft Office Communications Server 2007 or Microsoft Lync Server 2010. When integration with either instant messaging server is configured and instant messaging is enabled in Outlook Web App, users will see their instant messaging contacts and groups in the Navigation Pane of Outlook Web App.

Users can respond to or initiate IM sessions in Outlook Web App and can manage their instant messaging contacts and groups from Outlook Web App.

Looking for management tasks related to Outlook Web App and Communications Server 2007 or Lync Server 2010 integration? See Managing Outlook Web App and Instant Messaging Integration.

1.6.1.6.7 Understanding the Mini Version of Outlook Web App

Understanding the Mini Version of Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-08*

The mini version of Outlook Web App is a lightweight browser-based client, similar to the Outlook Mobile Access client in Exchange 2003. It provides access from simple HTML-compatible browsers that support cookies and it’s designed to be used on a mobile operating system.

Functionality in the mini version of Outlook Web App

The mini version of Outlook Web App provides functionality that lets users:

- Access e-mail, calendar, contacts, tasks, and the global address list.
- Access e-mail subfolders.
- Compose, reply, and forward e-mail messages.
- Create calendar, contact, and task items.
- Handle meeting requests.
- Set the time zone and automatic-reply messages for when they're out of the office, away, or not available to respond to e-mail.

The mini version of Outlook Web App is based on Outlook Web App architecture. Because it's an application within Outlook Web App, it uses all the segmentation flags that exist in Outlook Web App.

Authentication and Security Concerns

In order to be compatible with the widest array of mobile phone browsers, the mini version of Outlook Web App is designed to use Basic authentication. Basic authentication allows the credentials to be exchanged within the header of the HTTP request. The request should always be sent using a secure socket layer (SSL) encrypted channel.

Different browsers handle passing credential information differently. Some request that the user type the information for each new session. Others only request the information if it has changed.

Warning:
If a user's mobile phone is lost or stolen, the user's password should be changed immediately.

The mini version of Outlook Web App uses the same public session time-out value used by Outlook Web App. Users who don't complete operations such as the creation of a new e-mail or calendar item might see blank items created in their drafts folder, Calendar folder, or Contacts folder.

There is no logoff functionality in the mini version of Outlook Web App because there is no guarantee that the mobile device browser will forget the stored password after the default time-out value.

Accessing the mini version of Outlook Web App

The mini version of Outlook Web App is implemented as a virtual directory named OMA, which is created below the Outlook Web App virtual directory. You can access the mini version of Outlook Web App by appending /oma to your Outlook Web App URL. For example, if your Outlook Web App URL is https://mail.contoso.com, the URL for the mini version of Outlook Web App would be something like https://mail.contoso.com/owa/oma. There is no client detection logic or configurable redirection on the virtual directory for the mini version of Outlook Web App. The user must specify the full URL to access it.

When you use the mini version of Outlook Web App, the same segmentation flags that are used for Outlook Web App are leveraged. For example, if access to the user's calendars is disabled, the mini version of Outlook Web App won't provide access to the user's calendars. For more information about segmentation flags, see Understanding Segmentation for Outlook Web App.

1.6.1.7 Understanding Outlook Anywhere

Understanding Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-03*

In Microsoft Exchange Server 2010, the Outlook Anywhere feature, formerly known as RPC over HTTP, lets clients that use Microsoft Office Outlook 2010, Outlook 2007, or Outlook 2003 connect to their Exchange servers from outside the corporate network or over the Internet using the RPC over HTTP Windows networking component. This topic describes the Outlook Anywhere feature, provides information about deploying Outlook Anywhere, discusses coexistence with older versions of Exchange, and lists the benefits of using Outlook Anywhere.

Looking for management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Contents

Outlook Anywhere and Exchange 2010

The Windows RPC over HTTP Proxy component, which Outlook Anywhere clients use to connect, wraps remote procedure calls (RPCs) with an HTTP layer. This allows traffic to traverse network firewalls without requiring RPC ports to be opened. In Exchange 2010, as in Exchange 2007, it's easy to deploy and manage this feature. To deploy Outlook Anywhere in your Exchange 2010 messaging environment, you need to enable Outlook Anywhere on at least one Client Access server using the Enable Outlook Anywhere wizard in the Exchange Management Console.

Note:

Outlook Anywhere should be enabled only on Client Access servers that are exposed to the Internet. Do not enable Outlook Anywhere on internal Client Access servers.

Benefits of Using Outlook Anywhere

Outlook Anywhere offers the following benefits to clients that use Outlook 2010, Outlook 2007, or Outlook 2003 to access your Exchange messaging infrastructure:

- Users have remote access to Exchange servers from the Internet.
- You can use the same URL and namespace that you use for Outlook Web App and Microsoft Exchange ActiveSync.
- You can use the same Secure Sockets Layer (SSL) server certificate that you use for both Outlook Web App and Exchange ActiveSync.
- Unauthenticated requests from Outlook can't access Exchange servers.
- You don't have to use a virtual private network (VPN) to access Exchange servers across the Internet.

- You don't have to configure anything in Exchange 2010 when you're using SSL session ID load balancing on the Client Access server with Outlook Anywhere.
- If you already use Outlook Web App with SSL or Exchange ActiveSync with SSL, you don't have to open any additional ports from the Internet.
- You can test end-to-end client connectivity for Outlook Anywhere and TCP-based connections by using the **Test-OutlookConnectivity** cmdlet.

Return to top

Deploying Outlook Anywhere

Deploying Outlook Anywhere for your organization is straightforward. The following recommendations should be followed to successfully deploy Outlook Anywhere:

- **Use at least one Client Access server per site** In Exchange 2010, a site is a network location with high-bandwidth connectivity between all computers. We recommend that you install at least one Client Access server in each site to provide client access to the Mailbox server. However, you can have multiple Client Access servers in each site for increased performance and reliability.
- **Enable Outlook Anywhere on an Internet-exposed Client Access server** Outlook Anywhere should be enabled on Internet-exposed Client Access servers only. This lets clients that use Outlook 2010 or Outlook 2007 connect to a user's mailbox through the Client Access server in the site. Users will connect by using HTTPS to the Client Access server that's in the site where the user's mailbox is located.

For more information, see Enable Outlook Anywhere.

Managing Outlook Anywhere

You can manage Outlook Anywhere by using the Exchange Management Console or the Exchange Management Shell. By default, when you enable Outlook Anywhere on a Client Access server, all users who have mailboxes on Exchange 2010 Mailbox servers are enabled for Outlook Anywhere. For more information, see Managing Outlook Anywhere.

Return to top

Coexistence

For mailboxes on Exchange 2010 Mailbox servers, clients must connect through Exchange 2010 Client Access servers. Outlook Anywhere can be used in environments where Microsoft Exchange Server 2007 and Exchange Server 2003 servers are still being used. If you have users with mailboxes on Exchange 2003 servers, and these users are using Outlook 2007 or Outlook 2003 to connect, you must configure these clients manually. To configure Outlook Anywhere with Exchange 2007 or Exchange 2003, see Configure Outlook Anywhere in an Environment with Earlier Versions of Exchange.

Return to top

Outlook Anywhere in Multiple Active Directory Sites

If you have multiple Active Directory sites that are separated by low-bandwidth network connectivity, you can enable a Client Access server in each site. The Autodiscover service will then automatically detect which Client Access server is closest to the user's mailbox

that resides either on an Exchange 2003 back-end server enabled for RPC over HTTP or on a later Exchange version running the Mailbox server role. After the user has connected across the Internet using RPC over HTTP, the Client Access server will then use RPC requests. This ensures that RPC requests stay within the site's intranet. For more information about how to provide an external host name for Outlook Anywhere, see Configure an External Host Name for Outlook Anywhere.

Users

Users with mailboxes on Exchange Server 2003 servers with SP1 or a later version or Exchange 2003 servers enabled for RPC over HTTP will also be able to access their Exchange information from the Internet. For these users, you can use the Shell to manage the Outlook Anywhere feature on the Exchange 2010 Client Access server in the site.

Return to top

Testing Outlook Anywhere Connectivity

After you enable Outlook Anywhere in your Microsoft Exchange Server 2010 organization, you can test for end-to-end client Outlook connectivity. You can test end-to-end Outlook connectivity by doing either of the following:

- Running the **Test-OutlookConnectivity** cmdlet. The cmdlet tests for Outlook Anywhere (RPC over HTTP) and TCP/IP connections. If the cmdlet test fails, the output notes the step that failed.
- Running the Outlook Anywhere connectivity test using the Exchange Remote Connectivity Analyzer (ExRCA). When you run this test, you get a detailed summary showing where the test failed and what steps you can take to fix issues.

Both tests try to log on through Outlook Anywhere after obtaining server settings from the Autodiscover service. End-to-end verification includes the following:

- Testing for Autodiscover connectivity
- Validating DNS
- Validating certificates (whether the certificate name matches the Web site, whether the certificate has expired, and whether it's trusted)
- Checking that the firewall is set up correctly (ExRCA checks overall firewall setup. The cmdlet tests for Windows firewall configuration.)
- Verifying client connectivity by logging on to the user's mailbox

For more information, see Test Outlook Anywhere Connectivity.

Return to top

1.6.1.7.1 Understanding SSL for Outlook Anyw here

Understanding SSL for Outlook Anywhere

Client Access > Understanding Client Access > Understanding Outlook Anywhere >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-11*

Outlook Anywhere client connectivity is encrypted using Secure Sockets Layer (SSL) on the Microsoft Exchange Server 2010 Client Access server. This topic explains SSL

certificates, SSL offloading, and using SSL to manage security for Outlook Anywhere.

Looking for management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Contents

Valid SSL Certificate

The default self-signed certificate that's available in Exchange 2010 Setup works with Outlook Web App and Exchange ActiveSync, but it doesn't work with Outlook 2007 or Outlook 2010 and Outlook 2003 clients that are using Outlook Anywhere. Instead, you must use a valid SSL certificate that's created by a certification authority (CA) that's trusted by the client computer's operating system. For more information about how to install a valid SSL certificate from a CA that the client trusts, see Obtain a Server Certificate from a Certification Authority.

After you obtain a valid SSL certificate to use with the Client Access server on the default Web site or on the Web site where you host your /rpc virtual directory, you can configure the Web site to require SSL. You can enable SSL for all Web sites that are hosted by the Client Access server or enable SSL only for the /rpc virtual directory.

SSL Offloading

If you plan to close the SSL connection from the client computer running Outlook 2007, Outlook 2010, or Outlook 2003 to the firewall, you can use SSL offloading. With SSL offloading, the traffic from the firewall to the Client Access server won't be encrypted by using SSL. For SSL offloading to work, you must have a certificate on the firewall that the client trusts. We recommend that you encrypt all traffic from the client to the Client Access server. For more information, see Configure SSL Offloading for Outlook Anywhere.

Return to top

Managing Security for Outlook Anywhere

When you install Exchange Server 2010, a default virtual directory named /rpc is created on the default Internet Information Services (IIS) Web site on the Exchange Server 2010 Client Access server. You can configure the /rpc virtual directory to use SSL to manage security for Outlook Anywhere and external client access. For more information, see Configure SSL for Outlook Anywhere. Configuring the /rpc virtual directory to use SSL is only one step in managing security. For more information, see Securing Client Access Servers and Managing Outlook Anywhere Security.

Return to top

1.6.1.7.2 Understanding Redirection for Outlook Anywhere with a Single SSL Certificate

Understanding Redirection for Outlook Anywhere with a Single SSL Certificate

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-04*

When Microsoft Office Outlook 2007 or Outlook 2010 clients aren't joined to your domain or don't have direct access to Active Directory in your Exchange forest, you can redirect them. When the Outlook clients are redirected, they can access Exchange Web services, such as the Autodiscover service, the offline address book, and Unified Messaging, in your Exchange 2010 organization.

You can set up your Outlook Anywhere deployment to use a single Secure Sockets Layer (SSL) certificate with redirection. For information about how to do this, see Configure Outlook Anywhere to Use an SSL Certificate with Redirection.

Looking for other management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Using a Single SSL Certificate with Redirection

After you configure Exchange to use an SSL certificate with redirection, clients that aren't domain-joined and clients that don't have direct connectivity to Active Directory receive a redirect from the Autodiscover site to the site that's dedicated to handling e-mail. When this occurs, a warning message is displayed in Outlook 2007 and Outlook 2010 that says **Allow this website to configure server settings?** Both Outlook 2007 and Outlook 2010 give users the opportunity to prevent this warning message appearing in the future. We recommend that you inform your users that they can turn off the warning message on their Outlook 2010 or Outlook 2007 client.

Using a Single SSL Certificate with Redirection for Hosting Scenarios

You can use a single SSL certificate with redirection if you're hosting multiple Simple Mail Transfer Protocol (SMTP) domains and you don't want to obtain a separate SSL certificate for each domain. In this hosting scenario, after you've configured the Autodiscover redirect site, you would need to create a DNS entry in each of the domains to have the Autodiscover service point to this non-SSL redirect site. This redirect site would redirect all clients that are connecting to your SMTP domains to a single URL, such as https://mail.contoso.com/autodiscover/autodiscover.xml. For more information, see Configure Outlook Anywhere to Use an SSL Certificate with Redirection.

1.6.1.8 Understanding the Autodiscover Service

Understanding the Autodiscover Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-28*

Microsoft Exchange Server 2010 includes a service named the Autodiscover service. This topic gives an overview of the service, explains how it works, how it configures Outlook clients, and what options there are for deploying the Autodiscover service in your messaging environment.

The Autodiscover service does the following:

- Automatically configures user profile settings for clients running Microsoft Office Outlook 2007 or Outlook 2010, as well as supported mobile phones. Phones running Windows Mobile 6.1 or a later version are supported. If your phone isn't a Windows Mobile phone, check your mobile phone documentation to see if it's supported.
- Provides access to Exchange features for Outlook 2007 or Outlook 2010 clients that are connected to your Exchange messaging environment.
- Uses a user's e-mail address and password to provide profile settings to Outlook 2007 or Outlook 2010 clients and supported mobile phones. If the Outlook client is joined to a domain, the user's domain account is used.

Looking for management tasks related to the Autodiscover service? See Managing the Autodiscover Service.

Contents

Overview of the Autodiscover Service

The Autodiscover service makes it easier to configure Outlook 2007 or Outlook 2010 and some mobile phones. You can't use the Autodiscover service with earlier versions of Outlook, including Outlook 2003. In earlier versions of Microsoft Exchange (Exchange 2003 SP2 or earlier) and Outlook (Outlook 2003 or earlier), you had to configure all user profiles manually to access Exchange. Extra work was required to manage these profiles if changes occurred to the messaging environment. Otherwise, the Outlook clients would stop functioning correctly.

The Autodiscover service uses a user's e-mail address and password to automatically configure a user's profile. Using the e-mail address, the Autodiscover service provides the following information to the client:

- The user’s display name
- Separate connection settings for internal and external connectivity
- The location of the user’s Mailbox server
- The URLs for various Outlook features that govern functionality such as free/busy information, Unified Messaging, and the offline address book
- Outlook Anywhere server settings

When a user's Exchange information is changed, Outlook automatically reconfigures the user's profile using the Autodiscover service. For example, if a user's mailbox is moved or the client can't connect to the user's mailbox or to available Exchange features, Outlook will contact the Autodiscover service and automatically update the user's profile to include the information that's required to connect to the mailbox and Exchange features.

Return to top

How the Autodiscover Service Works

When you install the Client Access server role on a computer running Exchange 2010, a default virtual directory named Autodiscover is created under the default Web site in Internet Information Services (IIS). This virtual directory handles Autodiscover service requests from Outlook 2007 or Outlook 2010 clients and supported mobile phones under the following circumstances:

- When a new user account is configured or updated
- When an Outlook client periodically checks for changes to the Exchange Web Services URLs
- When underlying network connection changes occur in your Exchange messaging environment

Additionally, a new Active Directory object named the service connection point (SCP) is created on the server where you install the Client Access server role.

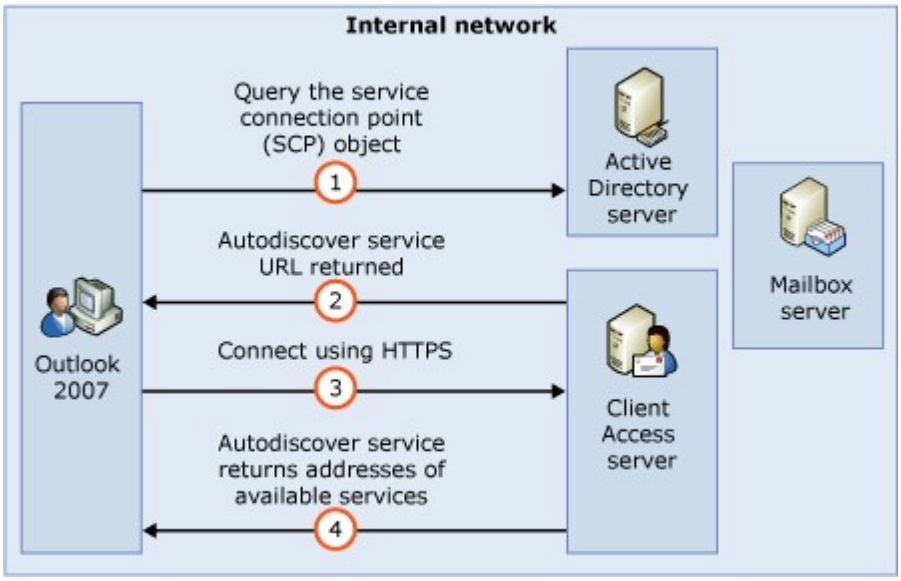
The SCP object contains the authoritative list of Autodiscover service URLs for the forest. You can use the **Set-ClientAccessServer** cmdlet to update the SCP object. For more information, see Set-ClientAccessServer.

Important:

Before you run the **Set-ClientAccessServer** cmdlet, make sure the Authenticated Users account on the Client Access server has Read permissions for the SCP object. If users don't have the correct permissions, they can't search for and read items.

For more information about SCP objects, see Publishing with Service Connection Points.

The following figure shows how a client connects to a Client Access server the first time from inside the internal network.



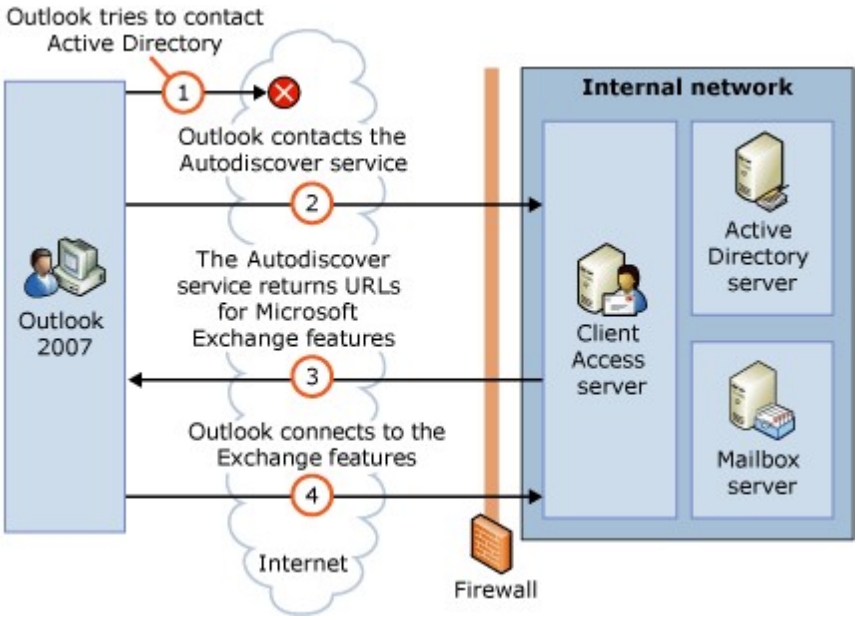
For external access, or using DNS, the client locates the Autodiscover service on the Internet by using the primary SMTP domain address from the user's e-mail address.

Note:

You must provide a host record for the Autodiscover service for external DNS. For more

information, see your Windows documentation for how to configure DNS, and also see the White Paper: Exchange 2007 Autodiscover Service.

Depending on whether you've configured the Autodiscover service on a separate site, the Autodiscover service URL will be either https://*<smtp-address-domain>*/autodiscover/autodiscover.xml or https://autodiscover.*<smtp-address-domain>*/autodiscover/autodiscover.xml, where ://*<smtp-address-domain>* is the primary SMTP domain address. For example, if the user's e-mail address is tony@contoso.com, the primary SMTP domain address is contoso.com. The following figure shows a simple topology with a client connecting from the Internet.



When the client connects to Active Directory, the client looks for the SCP object created during Setup. In deployments that include multiple Client Access servers, an Autodiscover SCP object is created for each Client Access server. The SCP object contains the *ServiceBindingInfo* attribute with the fully qualified domain name (FQDN) of the Client Access server in the form https://CAS01/autodiscover/autodiscover.xml, where CAS01 is the FQDN for the Client Access server. Using the user credentials, the Outlook 2007 or Outlook 2010 client authenticates to Active Directory and searches for the Autodiscover SCP objects. After the client obtains and enumerates the instances of the Autodiscover service, the client connects to the first Client Access server in the enumerated list and obtains the profile information in the form of XML data that's needed to connect to the user's mailbox and available Exchange features.

Return to top

Deployment Options for the Autodiscover Service

The Autodiscover service must be deployed and configured correctly for Outlook 2007 and Outlook 2010 clients to automatically connect to Exchange features such as the offline address book, the Availability service, and Unified Messaging (UM). Deploying the Autodiscover service is only one step in making sure your Microsoft Exchange services, such as the Availability service, can be accessed by Outlook 2007 or Outlook 2010 clients. For more information, see Configure Exchange Services for the Autodiscover Service.

Configuring Autodiscover for Cross-Forest Moves

The Autodiscover service can provide user profile information to connecting Outlook clients for mailboxes that have been moved from one Microsoft Exchange forest to another. For this to happen, you must configure a mail-enabled user in both the original forest where the user's mailbox resided and in the target forest using the **New-MailUser** cmdlet. In the source forest, you should use the *ExternalEmailAddress* parameter in the cmdlet to specify the new e-mail address of the mailbox in the target forest. For more information, see New-MailUser.

When you configure a mail-enabled user, the Autodiscover service in the original forest will redirect the authenticating user to the new e-mail address in the target forest. The connecting Outlook client will then be redirected to the Client Access server in the target forest where the mailbox has been moved. For more information, see Understanding Move Requests.

Return to top

1.6.1.9 Understanding the Availability Service

Understanding the Availability Service

Exchange Server 2010 > Client Access > Understanding Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-24*

The Microsoft Exchange Server 2010 Availability service makes free/busy information available to Microsoft Office Outlook 2007 and Outlook Web App clients. The Availability service improves information workers' calendaring and meeting scheduling experience by providing secure, consistent, and up-to-date free/busy information. By default, this service is installed with Exchange 2010.

Outlook 2007 and Outlook Web App use the Availability service to perform the following tasks:

- Retrieve current free/busy information for Exchange 2010 mailboxes
- Retrieve current free/busy information from other Exchange 2010 organizations
- Retrieve published free/busy information from public folders for mailboxes on servers that have versions of Exchange earlier than Exchange 2010
- View attendee working hours
- Show meeting time suggestions

Contents

Distribution Group Handling

Availability Service API

Availability Service Network Load Balancing

Methods Used to Retrieve Free/Busy Information

Overview of the Availability Service

The Availability service retrieves free/busy information directly from the target mailbox for users on Exchange 2010 and Exchange 2007 and can be configured to retrieve free/busy information for users on earlier versions of Exchange. For topologies that have Exchange 2007 or Exchange 2010 mailboxes in which all clients are running Outlook 2007, the Availability service is used to retrieve free/busy information.

Note:

If you have Outlook 2007 clients running on Exchange Server 2003 mailboxes, Outlook 2007 will use public folders to retrieve free/busy information.

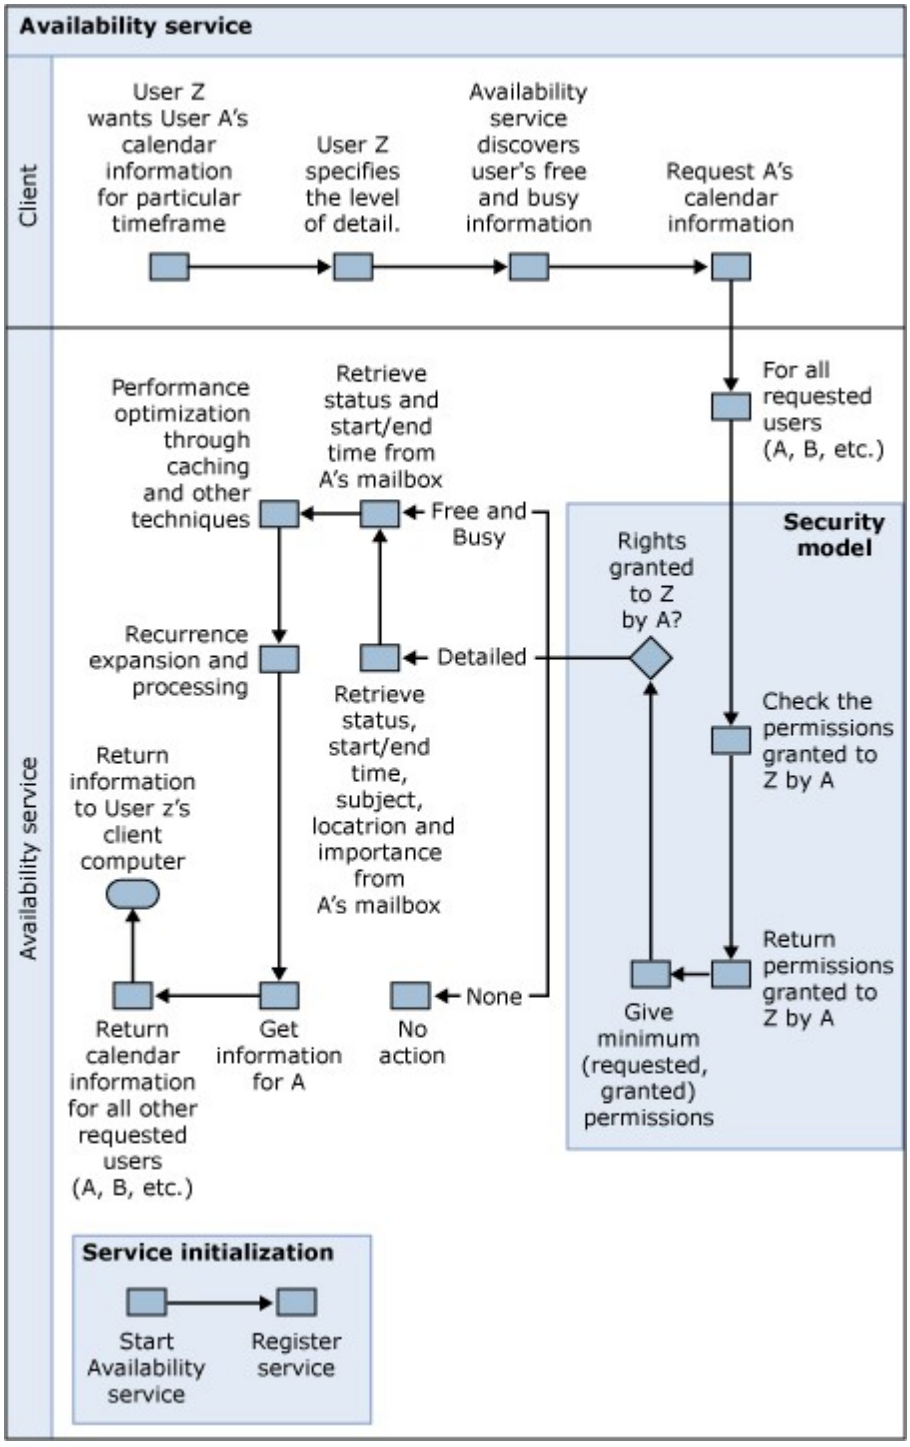
Outlook 2007 uses the Exchange Server 2010 Autodiscover service to obtain the URL of the Availability service. For more information about the Autodiscover service, see Managing the Autodiscover Service.

The Availability service is part of the Exchange 2010 programming interface. It is available as a public Web service to allow developers to write third-party tools for integration purposes.

You can use the Exchange Management Shell to configure the Availability service. You can't use the Exchange Management Console to configure the Availability service.

Availability Service Process Flow

The following figure illustrates the process flow for the Availability service.



Return to top

Improvements Over Exchange 2003 Free/Busy

The following table lists the improvements to free/busy functionality that Exchange 2010

and Exchange 2007 provide over Exchange 2003.

Free/busy improvements

Free/busy component	Outlook 2003 running on Exchange 2003	Outlook 2007 running on Exchange 2010 or Exchange 2007
Up-to-date information	There was no guarantee that free/busy information was up-to-date. There were multiple factors that caused free/busy information to be outdated: • By default, Outlook only updated free/busy information every 45 minutes. Also, because of bandwidth and scalability issues, you could not decrease this interval. • There were latencies that resulted from public folder replication. • In cross-forest scenarios, there were delays when you used the Microsoft Exchange Inter-Organization Replication tool to replicate free/busy information across forests.	Free/busy information is guaranteed to be up to date within a small time period (60 seconds) on all the data retrieved.
Granularity	The four meeting states (**Free**, **Tentative**, **Busy**, and **Out-Of-Office**) were available in one stream. To retrieve appointment details, additional MAPI calls were required.	By default, free/busy information displays the start and end times for individual appointments. Additional calendar properties (such as **Subject** and **Location**) will be available through the Availability service.
Security	For any authenticated user, all free/busy data was available in a public folder. This meant that any authenticated user could delete, modify, or publish another user's free/busy information.	Free/busy information provides increased security, similar to general calendar sharing. In compliance with your company's policy, you can specify how much free/busy information to share with a specific user. Because the Availability service reads directly from a user's mailbox, a user cannot modify or publish another user's free/busy information.
Publishing frequency	Outlook 2003 has a 45-minute default publishing interval.	No publishing is required in an Exchange 2010 and Outlook 2007 organization.

Return to top

Information About Away Status

The Availability service also provides access to automatic-reply messages that users send when they are out of the office or away for an extended period of time.

Information workers use the Automatic Replies feature (formerly known as Out of Office) in Outlook and Outlook Web App to alert others when they're unavailable to respond to e-mail messages. This functionality makes it easier to set and manage automatic-reply messages for both information workers and administrators.

For more information, see Managing Automatic Replies.

Performance

You can use the performance counters listed under **MSExchange Availability Service** in the Performance Monitor tool to automatically collect performance data about the Availability service from local or remote computers that are running Exchange 2010.

Return to top

Distribution Group Handling

In Exchange 2010, distribution group expansion is processed on the Exchange 2010 server instead of on the Outlook client. In Exchange 2007, distribution group expansion is processed on the Exchange 2007 server. The primary benefit of moving distribution group expansion to Exchange 2010 is to provide consistent behavior for any Availability service consumer. In Exchange 2003 and earlier versions of Exchange, if the number of users in a distribution group was too large, the free/busy data for the distribution group members would not display when the group was expanded.

In Exchange 2010, the following improvements have been made to the handling of distribution groups:

- The Availability service expands a distribution group up to only two-levels deep, regardless of the total number of distribution group members.
- A distribution group's free/busy data can expand up to a maximum of one hundred members.

Availability Service API

The Availability service is part of the Exchange 2010 programming interface. It's available as a Web service to let developers write third-party tools for integration purposes.

Availability Service Network Load Balancing

Using Network Load Balancing (NLB) on your Client Access servers that are running the Availability service can improve performance and reliability for your users who rely on free/busy information. Outlook 2007 discovers the Availability service URL using the Autodiscover service. To use network load balancing with the Availability service, you must make changes to your configuration.

The internal URL is used from the intranet, and the external URL is used from the Internet. If you want to use the same URL for both internal and external traffic, make sure that DNS is correctly configured to route internal traffic directly to the internal URL. Also, make sure that the URL can be accessed both internally and externally. For the Autodiscover and Availability services to work, DNS must be configured so that mail.<*domain name*>.com and autodiscover.mail.<*domain name*>.com point to the Network Load Balancing (NLB) array of Client Access servers, where <*domain name*> is the name of your domain.

Note:

For more information, see Network Load Balancing Technical Reference and Network Load Balancing Clusters. You can also search for third-party load-balancing software Web sites.

For information, see Configure the Availability Service for Network Load Balanced Computers.

Return to top

Methods Used to Retrieve Free/Busy Information

The following table lists the different methods used to retrieve free/busy information in different single-forest topologies.

Client	Mailbox retrieving free/busy information is running	Target mailbox is running	Free/busy retrieval method
Outlook 2007	Exchange 2010 or Exchange 2007	Exchange 2010 or Exchange 2007	The Availability service reads free/busy information from the target mailbox.
Outlook 2007	Exchange 2010 or Exchange 2007	Exchange 2003	The Availability service makes HTTP connections to the /public virtual directory of the Exchange 2003 mailbox.
Outlook 2003	Exchange 2010 or Exchange 2007	Exchange 2010 or Exchange 2007	Free/busy information is published in local public folders.
Outlook 2003	Exchange 2010 or Exchange 2007	Exchange 2003	Free/busy information is published in local public folders.
Outlook Web App	Exchange 2010 or Exchange 2007	Exchange 2010 or Exchange 2007	Outlook Web App in Exchange 2010 or Outlook Web Access in Exchange 2007 calls the Availability service API, which reads the free/busy information from the target mailbox.

Outlook Web App	Exchange 2010 or Exchange 2007	Exchange 2003	Outlook Web App in Exchange 2010 or Outlook Web Access in Exchange 2007 calls the Availability service API, which makes an HTTP connection to the /public virtual directory of the Exchange 2003 mailbox.
Any	Exchange 2003	Exchange 2010 or Exchange 2007	Free/busy information is published in local public folders.

1.6.1.10 Understanding Client Access Server Publishing

Understanding Client Access Server Publishing

Exchange Server 2010 > Client Access > Understanding Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-20*

When you publish Microsoft Exchange for access from the Internet, Microsoft offers two software-based options: Microsoft Forefront Threat Management Gateway 2010 and Microsoft Forefront Unified Access Gateway 2010. Both options offer publishing wizards and security features to provide secure access to Exchange when it's accessed from outside the safety of the corporate network. For more information about Forefront Unified Access Gateway 2010 and Forefront Threat Management Gateway 2010, see Publishing Exchange Server 2010 with Forefront Unified Access Gateway 2010 and Forefront Threat Management Gateway 2010.

1.6.1.11 Understanding Client Access Security

Understanding Client Access Security

Exchange Server 2010 > Client Access > Understanding Client Access >

Topic Last Modified: *2010-08-20*

Security is an important aspect of any Microsoft Exchange Server 2010 installation. By default, all Exchange 2010 protocols, including Microsoft Office Outlook Web App, Microsoft Exchange ActiveSync, and the Autodiscover service are automatically configured for Secure Sockets Layer (SSL) connectivity. For more information about Exchange Client Access and SSL see Understanding Digital Certificates and SSL.

Installing a Client Access Server in a

Perimeter Network

It is not supported to locate an Exchange 2010 Client Access server in a perimeter network. Exchange 2010 Client Access servers have direct access to Exchange 2010 Mailbox servers.

Client Access Protocols and Security

Each of the various Exchange 2010 Client Access protocols has a variety of security settings you can configure for your organization. For more information, see the following topics.

- Understanding Security for Exchange ActiveSync
- Understanding Security for Outlook Anywhere
- Understanding Security for POP3 and IMAP4
- Understanding Security for Outlook Web App

1.6.1.11.1 Understanding Digital Certificates and SSL

Understanding Digital Certificates and SSL

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-04*

Secure Sockets Layer (SSL) is a method for securing communications between a client and a server. For a Microsoft Exchange Server 2010 Client Access server, SSL is used to help secure communications between the server and clients. Clients include mobile devices, computers inside an organization's network, and computers outside an organization's network. These include clients with and without virtual private network (VPN) connections.

By default, when you install Exchange 2010, client communications are encrypted using SSL when you use Microsoft Office Outlook Web App, Exchange ActiveSync, and Outlook Anywhere. By default, Post Office Protocol version 3 (POP3) and Internet Message Access Protocol Version 4 rev1 (IMAP4) aren't configured to communicate over SSL.

SSL requires that you use digital certificates. This topic summarizes the different types of digital certificates, and information about how to configure the Client Access server to use these types of digital certificates.

Note:

Cryptography Next Generation (CNG) certificates are not supported in Microsoft Exchange Server 2010.

Contents

Client Limitations

Overview of Digital Certificates

Digital certificates are electronic files that work like an online password to verify the identity of a user or a computer. They're used to create the SSL encrypted channel that's used for client communications. A certificate is a digital statement that's issued by a certification authority (CA) that vouches for the identity of the certificate holder and enables the parties to communicate in a secure manner using encryption.

Digital certificates do the following:

- They authenticate that their holders—people, Web sites, and even network resources such as routers—are truly who or what they claim to be.
- They protect data that's exchanged online from theft or tampering.

Digital certificates can be issued by a trusted third-party CA or a Microsoft Windows public key infrastructure (PKI) using Certificate Services, or they can be self-signed. Each type of certificate has advantages and disadvantages. Each type of digital certificate is tamper-proof and can't be forged.

Certificates can be issued for several uses. These uses include Web user authentication, Web server authentication, Secure/Multipurpose Internet Mail Extensions (S/MIME), Internet Protocol security (IPsec), Transport Layer Security (TLS), and code signing.

A certificate contains a public key and attaches that public key to the identity of a person, computer, or service that holds the corresponding private key. The public and private keys are used by the client and the server to encrypt the data before it's transmitted. For Windows-based users, computers, and services, trust in a CA is established when there's a copy of the root certificate in the trusted root certificate store and the certificate contains a valid certification path. For the certificate to be valid, the certificate must not have been revoked and the validity period must not have expired.

Types of Certificates

There are three primary types of digital certificates: self-signed certificates, Windows PKI-generated certificates, and third-party certificates.

Self-Signed Certificates

When you install Exchange 2010, a self-signed certificate is automatically configured. A self-signed certificate is signed by the application that created it. The subject and the name of the certificate match. The issuer and the subject are defined on the certificate. A self-signed certificate will allow some client protocols to use SSL for their communications. Exchange ActiveSync and Outlook Web App can establish an SSL connection by using a self-signed certificate. Outlook Anywhere won't work with a self-signed certificate. Self-signed certificates must be manually copied to the trusted root certificate store on the client computer or mobile device. When a client connects to a server over SSL and the server presents a self-signed certificate, the client will be prompted to verify that the certificate was issued by a trusted authority. The client must explicitly trust the issuing authority. If the client confirms the trust, then, SSL communications can continue.

Frequently, small organizations decide not to use a third-party certificate or not to install their own PKI to issue their own certificates. They might make this decision because those solutions are too expensive, because their administrators lack the experience and knowledge to create their own certificate hierarchy, or for both reasons. The cost is minimal and the setup is simple when you use self-signed certificates. However, it's much more difficult to establish an infrastructure for certificate life-cycle management, renewal, trust management, and revocation when you use self-signed certificates.

Windows Public Key Infrastructure Certificates

The second type of certificate is a Windows PKI-generated certificate. A PKI is a system of digital certificates, certification authorities, and registration authorities (RAs) that verify and authenticate the validity of each party that's involved in an electronic transaction by using public key cryptography. When you implement a PKI in an organization that uses Active Directory, you provide an infrastructure for certificate life-cycle management, renewal, trust management, and revocation. However, there is some additional cost involved in deploying servers and infrastructure to create and manage Windows PKI-generated certificates.

Certificate Services are required to deploy a Windows PKI and can be installed through **Add Or Remove Programs** in Control Panel. You can install Certificate Services on any server in the domain.

If you obtain certificates from a domain-joined Windows CA, you can use the CA to request or sign certificates to issue to your own servers or computers on your network. This enables you to use a PKI that resembles a third-party certificate vendor, but is less expensive. These PKI certificates can't be deployed publicly, as other types of certificates can be. However, when a PKI CA signs the requestor's certificate by using the private key, the requestor is verified. The public key of this CA is part of the certificate. A server that has this certificate in the trusted root certificate store can use that public key to decrypt the requestor's certificate and authenticate the requestor.

The steps for deploying a PKI-generated certificate resemble those required for deploying a self-signed certificate. You must still install a copy of the trusted root certificate from the PKI to the trusted root certificate store of the computers or mobile devices that you want to be able to establish an SSL connection to Microsoft Exchange.

A Windows PKI enables organizations to publish their own certificates. Clients can request and receive certificates from a Windows PKI on the internal network. The Windows PKI can renew or revoke certificates.

Trusted Third-Party Certificates

Third-party or commercial certificates are certificates that are generated by a third-party or commercial CA and then purchased for you to use on your network servers. One problem with self-signed and PKI-based certificates is that, because the certificate is not automatically trusted by the client computer or mobile device, you must make sure that you import the certificate into the trusted root certificate store on client computers and devices. Third-party or commercial certificates do not have this problem. Most commercial CA certificates are already trusted because the certificate already resides in the trusted root certificate store. Because the issuer is trusted, the certificate is also trusted. Using third-party certificates greatly simplifies deployment.

For larger organizations or organizations that must publicly deploy certificates, the best solution is to use a third-party or commercial certificate, even though there is a cost associated with the certificate. Commercial certificates may not be the best solution for small and medium-size organizations, and you might decide to use one of the other certificate options that are available.

Return to top

Choosing a Certificate Type

When you choose the type of certificate to install, there are several things to consider. A certificate must be signed to be valid. It can be self-signed or signed by a CA. A self-signed certificate has limitations. For example, not all mobile devices let a user install a digital certificate in the trusted root certificate store. The ability to install certificates on a mobile device depends on the mobile device manufacturer and the mobile service provider. Some manufacturers and mobile service providers disable access to the trusted root certificate store. In this case, neither a self-signed certificate nor a certificate from a Windows PKI CA can be installed on the mobile device.

Most mobile devices have several trusted third-party commercial certificates preinstalled. For the optimal user experience, implement certificate-based authentication for Exchange ActiveSync by using devices that are running Windows Mobile 6.0 or a later version and use a digital certificate from a trusted third-party CA.

Default Exchange Certificates

By default, Exchange installs a default self-signed certificate so that all network communication is encrypted. Encrypting all network communication requires that every Exchange server have an X.509 certificate that it can use. You should replace this self-signed certificate with one that is automatically trusted by your clients.

"Self-signed" means that a certificate was created and signed only by the Exchange server itself. Because it wasn't created and signed by a generally trusted CA, the default self-signed certificate won't be trusted by any software except other Exchange servers in the same organization. The default certificate is enabled for all Exchange services. It has a Subject Alternative Name (SAN) that corresponds to the server name of the Exchange server that it's installed on. It also has a list of SANs that include both the server name and the fully qualified domain name (FQDN) of the server.

Although other Exchange servers in your Exchange organization trust this certificate automatically, clients like Web browsers, Outlook clients, mobile phones, and other e-mail clients in addition to external e-mail servers won't automatically trust it. Therefore, consider replacing this certificate with a trusted third-party certificate on your Exchange servers that have the Client Access server role installed and also on any external-facing Hub Transport servers. If you have your own internal PKI, and all your clients trust that entity, you can also use certificates that you issue yourself.

Certificate Requirements by Service

Certificates are used for several things in Exchange. Most customers also use certificates on more than one Exchange server. In general, the fewer certificates you have, the easier certificate management becomes.

IIS

All the following Exchange services use the same certificate on a given Exchange server:

- Outlook Web App
- Exchange Control Panel
- Exchange Web Services
- Exchange ActiveSync
- Outlook Anywhere
- Autodiscover
- Outlook Address Book distribution

Because only a single certificate can be associated with a Web site, and because all these services are offered under a single Web site by default, all the names that clients of these services use must be in the certificate (or fall under a wildcard name in the certificate).

POP/IMAP

Certificates that are used for POP or IMAP can be specified separately from the certificate that's used for IIS. However, to simplify administration, we recommend that you include the POP or IMAP service name in your IIS certificate and use a single certificate for all these services.

SMTP

A separate certificate can be used for each receive connector that you configure on your Hub Transport servers or Edge Transport servers. The certificate must include the name that SMTP clients (or other SMTP servers) use to reach that connector. To simplify certificate management, consider including all names for which you have to support TLS traffic in a single certificate.

Live Federation

The certificate that's used for federating with Windows Live for Exchange sharing scenarios can include any name. During the federation process, you identify the certificate that you want your Exchange server to use. This certificate must be issued by a third-party certification authority that's trusted by Windows Live. If you get your Exchange certificate for other services from a third-party certification authority that's trusted by Windows Live, you can use a single certificate for those services and also for federation with Windows Live.

Unified Messaging

When you connect Exchange Unified Messaging servers to Microsoft Office Communications Server 2007 R2 servers or to third-party SIP gateways or Private Branch eXchange (PBX) telephony equipment, you can use self-signed or trusted third-party certificates in order to establish secured sessions. You can use a single certificate on all the Unified Messaging servers as long as the certificate has the FQDNs of all the Unified Messaging servers in its SAN list. Or, you will have to generate a different certificate for each Unified Messaging server, wherein the FQDN of the Unified Messaging server is present in the subject common name (CN) or SAN lists. Exchange Unified Messaging doesn't support wildcard certificates with Communications Server 2007 and Communications Server 2007 R2.

Outlook Web App Instant Messaging with Office Communications Server 2007 R2

Outlook Web App in Exchange 2010 includes a programming interface that allows instant messaging providers to write add-ins to control presence and instant messaging functionality. An add-in exists for Communications Server 2007 R2. When you use this add-in, you must use a certificate to secure the connection between the Communications Server 2007 R2 server and the Exchange 2010 Client Access server. The certificate must be installed on the Exchange Client Access servers. You can use multiple certificates or a single certificate on all Exchange 2010 Client Access servers, as long as one of the host names in the certificate CN or SAN is present in the Host Authorization List on the Communications Server. This value can be any host name which is available in the certificate, for example mail.contoso.com. Wildcard certificates aren't supported for establishing secure connections to Communications Server 2007 or 2007 R2.

Legacy Exchange Servers

If you follow the best practices for transitioning from Microsoft Exchange Server 2003 or Exchange Server 2007 to Exchange 2010, you'll be introducing a new host name - legacy.contoso.com for use during the coexistence period when you have mailboxes both on legacy versions of Exchange and on Exchange 2010. This legacy host name should also be included in the certificate that you use. For more information about how to upgrade from Exchange Server 2003 and Exchange 2007 to Exchange 2010, see Upgrade from Exchange 2003 Client Access and Upgrade from Exchange 2007 Client Access.

Return to top

Digital Certificates and Proxying

Proxying is the method by which one Client Access server sends client connections to another Client Access server. There are two scenarios where one Client Access server will proxy traffic to another Client Access server.

1. Client Access servers in an Internet-facing Active Directory site will proxy traffic to Client Access servers in a non-Internet-facing site. This ensures that all processing of client requests is handled as close to the client's Mailbox server as possible.
2. Client Access servers for Exchange 2010 will proxy connections from clients that have mailboxes on Exchange 2003 or Exchange 2007. These client connections will be proxied to Exchange 2007 Client Access servers. This happens because, for many Exchange services, the Client Access server can't

process requests for Mailbox servers that are running an older version of Exchange.

When Client Access servers proxy requests, SSL is used for encryption but not for authentication. In most cases, a self-signed certificate can be used for Client Access server proxying. If your organization requires extraordinary security rules, there's a configuration key you can set to require trusted certificates for Client Access server proxying. You can configure the following key by setting it to false for this scenario:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchangeOWA
\AllowInternalUntrustedCerts

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

For more information about proxying, see Understanding Proxying and Redirection.

Reverse Proxies and Certificates

Most Exchange deployments use reverse proxies to publish Exchange services on the Internet. Examples of popular Reverse Proxy products are Microsoft Internet Security and Acceleration (ISA) Server and Checkpoint. These reverse proxies can be configured to terminate SSL encryption, examine the traffic in the clear on the server, and then open a new SSL encryption channel from the reverse proxy server to the Exchange servers behind them. This is known as SSL bridging. Another way to configure the reverse proxy servers is to let the SSL connections pass straight through to the Exchange servers behind the reverse proxy servers. With either deployment model, the clients on the Internet connect to the reverse proxy server using a host name for Exchange access, such as mail.contoso.com. Then the reverse proxy server connects to Exchange using a different host name, such as the machine name of the Exchange Client Access server. You don't have to include the machine name of the Exchange Client Access server on your certificate because most common reverse proxy servers are able to match the original host name that's used by the client to the internal host name of the Exchange Client Access server.

Load Balancing and Certificates

If you have more than one Client Access server, consider configuring a Client Access server array. This array will allow all clients to connect to your Exchange Client Access servers through a single host name. You can add as many Client Access server computers as you want to one Client Access server array provided that all the Client Access servers are located within the same Active Directory site. For more information about load balancing and Client Access server arrays, see Understanding Proxying and Redirection and Managing Client Access Servers.

SSL and Split DNS

Split DNS is a technology that allows you to configure different IP addresses for the same host name, depending on where the originating DNS request came from. This is also known as split-horizon DNS, split-view DNS, or split-brain DNS. Split DNS can help you reduce the number of host names that you must manage for Exchange by allowing your clients to connect to Exchange through the same host name whether they're connecting from the Internet or from the Intranet. Split DNS allows requests that originate from the Intranet to receive a different IP address than requests that originate from the Internet.

Split DNS is usually unnecessary in a small Exchange deployment because users can access the same DNS endpoint whether they're coming from the Intranet or the Internet. However, with larger deployments, this configuration will result in too high of a load on your outgoing Internet proxy server and your reverse proxy server. For larger deployments, configure split DNS so that external users access mail.contoso.com and internal users access internal.contoso.com. Using split DNS for this configuration ensures that your users won't have to remember to use different host names depending on where

they're located.

Remote PowerShell

Kerberos authentication and Kerberos encryption are used for Remote PowerShell access, both from the Exchange Management Console and the Exchange Management Shell. Therefore, you won't have to configure your SSL certificates for use with Remote PowerShell.

Return to top

Digital Certificates Best Practices

Although the configuration of your organization's digital certificates will vary based on its specific needs, information about best practices has been included to help you choose the digital certificate configuration that's right for you.

Best Practice: Use a Trusted Third-Party Certificate

To prevent clients from receiving errors regarding untrusted certificates, the certificate that's used by your Exchange server must be issued by someone that the client trusts. Although most clients can be configured to trust any certificate or certificate issuer, it's simpler to use a trusted third-party certificate on your Exchange server. This is because most clients already trust their root certificates. There are several third-party certificate issuers that offer certificates configured specifically for Exchange. You can use the Exchange Management Console to generate certificate requests that work with most certificate issuers.

How to Select a Certification Authority

A certification authority is a company that issues and ensures the validity of certificates. Client software (for example, browsers such as Microsoft Internet Explorer, or operating systems such as Windows or Mac OS) have a built-in list of CAs they trust. This list can usually be configured to add and remove CAs, but that configuration is often cumbersome. Use the following criteria when you select a CA to buy your certificates from:

- Ensure the CA is trusted by the client software (operating systems, browsers, and mobile phones) that will connect to your Exchange servers.
- Choose a CA that says it supports "Unified Communications certificates" for use with Exchange server.
- Make sure that the CA supports the kinds of certificates that you'll use. Consider using Subject Alternative Name (SAN) certificates. Not all CAs support SAN certificates, and other CAs don't support as many host names as you might need.
- Make sure that the license you buy for the certificates allows you to put the certificate on the number of servers that you intend to use. Some CAs only allow you to put a certificate on one server.
- Compare certificate prices between CAs.

Best Practice: Use SAN Certificates

Depending on how you configure the service names in your Exchange deployment, your Exchange server may require a certificate that can represent multiple domain names. Although a wildcard certificate, such as one for *.contoso.com, can resolve this problem, many customers are uncomfortable with the security implications of maintaining a certificate that can be used for any sub-domain. A more secure alternative is to list each of the required domains as SANs in the certificate. By default, this approach is used when certificate requests are generated by Exchange.

Best Practice: Use the Exchange Certificate Wizard to Request Certificates

There are many services in Exchange that use certificates. A common error when

requesting certificates is to make the request without including the correct set of service names. The certificate request wizard in the Exchange Management Console will help you include the correct list of names in the certificate request. The wizard lets you specify which services the certificate has to work with and, based on the services selected, includes the names that you must have in the certificate so that it can be used with those services. Run the certificate wizard when you've deployed your initial set of Exchange 2010 servers and determined which host names to use for the different services for your deployment. Ideally you'll only have to run the certificate wizard one time for each Active Directory site where you deploy Exchange.

Instead of worrying about forgetting a host name in the SAN list of the certificate that you purchase, you can use a certification authority that offers, at no charge, a grace period during which you can return a certificate and request the same new certificate with a few additional host names.

Best Practice: Use As Few Host Names as Possible

In addition to using as few certificates as possible, you should also use as few host names as possible. This practice can save money. Many certificate providers charge a fee based on the number of host names you add to your certificate.

The most important step you can take to reduce the number of host names that you must have and, therefore, the complexity of your certificate management, is not to include individual server host names in your certificate's subject alternative names.

The host names you must include in your Exchange certificates are the host names used by client applications to connect to Exchange. The following is a list of typical host names that would be required for a company named Contoso:

- **Mail.contoso.com** This host name covers most connections to Exchange, including Microsoft Office Outlook, Outlook Web App, Outlook Anywhere, the Offline Address Book, Exchange Web Services, POP3, IMAP4, SMTP, Exchange Control Panel, and ActiveSync.
- **Autodiscover.contoso.com** This host name is used by clients that support Autodiscover, including Microsoft Office Outlook 2007 and later versions, Exchange ActiveSync, and Exchange Web Services clients.
- **Legacy.contoso.com** This host name is required in a coexistence scenario with Exchange Server 2003 or Exchange 2007. If you'll have clients with mailboxes on both a legacy version of Exchange and Exchange 2010, configuring a legacy host name prevents your users from having to learn a second URL during the upgrade process. For more information about upgrade and coexistence, see Upgrade from Exchange 2003 Client Access and Upgrade from Exchange 2007 Client Access.

Understanding Wildcard Certificates

A wildcard certificate is designed to support a domain and multiple subdomains. For example, configuring a wildcard certificate for *.contoso.com results in a certificate that will work for mail.contoso.com, web.contoso.com, and autodiscover.contoso.com.

Return to top

Client Limitations

Several Exchange clients limit the certificates they support. These clients and their limitations are summarized as follows:

- **Outlook on Windows XP or earlier operating systems** The Windows RPC over HTTP component used for Outlook Anywhere requires that the SAN or common name of the certificate must match the Certificate Principal Name configured for Outlook Anywhere. Outlook 2007 and later versions use Autodiscover to obtain this Certificate Principal Name. To configure this value on your Exchange 2010 Client Access server, use the **Set-OutlookProvider**

command with the *-CertPrincipalName* parameter. Set this parameter to the external host name that Outlook clients use to connect to Outlook Anywhere.

- **Versions of Outlook earlier than Outlook 2010 don't support SAN certificates for POP3 and IMAP4 access** A hotfix is available for SAN support in Outlook 2007 Service Pack 2. That hotfix can be found here.
- **Mobile devices** Some mobile devices, including those running Windows Mobile 5.0 and some Palm devices, don't support wildcard certificates.

1.6.1.11.2 Understanding Security for Exchange ActiveSync

Understanding Security for Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-25*

When you allow mobile phones or other mobile devices to synchronize with your Exchange 2010 server, you allow sensitive corporate information to be stored on small, portable devices that can be easily lost or stolen. Before you deploy Exchange ActiveSync, we recommend that you familiarize yourself with the various security settings you can configure to keep your corporate information safe. You can configure an authentication method for Exchange ActiveSync, deploy Exchange ActiveSync mailbox policies, and use remote device wipe to remove personal and corporate data from a lost or stolen mobile phone.

Exchange ActiveSync Server Security

There are several security-related tasks you can perform on a server that's running Exchange ActiveSync. One of the most important tasks is to configure an authentication method. Exchange ActiveSync runs on a computer running Exchange 2010 that has the Client Access server role installed. This server role is installed with a default self-signed digital certificate. Although the self-signed certificate is supported for Exchange ActiveSync, it isn't the most secure method of authentication. For additional security, consider deploying a trusted certificate from a third-party commercial certification authority (CA) or a trusted Windows public key infrastructure (PKI) certification authority. For more information about how to configure a trusted digital certificate, see Configure SSL for Exchange ActiveSync.

Selecting an Authentication Method for Exchange ActiveSync

In addition to deploying a trusted digital certificate, you should consider the different authentication methods that are available for Exchange ActiveSync. By default, when the Client Access server role is installed, Exchange ActiveSync is configured to use Basic authentication with Secure Sockets Layer (SSL). To provide increased security, consider changing your authentication method to Digest authentication or Integrated Windows authentication.

Device Security

In addition to enhancing the security of the Exchange ActiveSync server, you should also consider enhancing the security of your users' mobile phones. There are several methods that you can use to enhance the security of mobile phones.

Exchange ActiveSync Mailbox Policies

Exchange ActiveSync for Exchange 2010 enables you to create Exchange ActiveSync mailbox policies to apply a common set of security settings to a collection of users. These settings include the following:

- Requiring a password
- Specifying the minimum password length
- Requiring numbers or special characters in the password
- Designating how long a mobile phone can be inactive before the user is required to re-enter the password
- Specifying that the mobile phone or mobile device be wiped if an incorrect password is entered more than a specific number of times

For more information about Exchange ActiveSync mailbox policies, see Managing Exchange ActiveSync with Policies.

Remote Device Wipe

Mobile phones can store sensitive data that belongs to your organization and provide access to many of your organization's resources. If a mobile phone is lost or stolen, that data can be compromised. Remote device wipe is a feature that enables the Exchange server to set a mobile phone to delete all data the next time that the mobile phone connects to the Exchange server. A remote device wipe effectively removes all synchronized information and personal settings from a mobile phone. This can be useful when a mobile phone is lost, stolen, or otherwise compromised.

Warning:

After a remote device wipe has occurred, data recovery is very difficult. However, no data removal process leaves a mobile phone or other mobile device as free from residual data as it is when it's new. Recovery of data from a mobile phone or other mobile device may still be possible using sophisticated tools.

For more information about remote device wipe, see Understanding Remote Device Wipe.

1.6.1.11.2.1 Configuring Authentication for Exchange ActiveSync

Configuring Authentication for Exchange ActiveSync

Understanding Client Access > Understanding Client Access Security > Understanding Security for Exchange ActiveSync >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-01*

Authentication is the process by which a client and a server verify their identities for transmitting data. In Microsoft Exchange Server 2010, authentication is used to determine whether a user or client that wants to communicate with the Exchange server is who or what it says it is. You can use authentication to verify that a device belongs to a particular individual or that a particular individual is trying to sign in to Microsoft Office Outlook Web App.

When you install Exchange 2010 and the Client Access server role, virtual directories are configured for several services. These include Outlook Web App, the Availability service, Unified Messaging, and Microsoft Exchange ActiveSync. By default, each virtual directory is configured to use an authentication method. For Exchange ActiveSync, the virtual directory is configured to use Basic authentication and Secure Sockets Layer (SSL). You can change the authentication method for your Exchange ActiveSync server by changing the authentication method on the Exchange ActiveSync virtual directory.

This topic summarizes the authentication methods available for your Exchange ActiveSync server. For Exchange ActiveSync, the client is the physical device used to synchronize with the Exchange 2010 server.

Looking for management tasks related to Exchange ActiveSync? See Managing Exchange ActiveSync.

Contents

Choosing an Authentication Method

There are three primary types of authentication you can choose for Exchange ActiveSync: Basic authentication, certificate-based authentication, and token-based authentication. When you install the Client Access server role on a computer that's running Exchange 2010, Exchange ActiveSync is configured to use Basic authentication with SSL. To establish the SSL connection, certificate-based authentication requires a mobile device to have a valid client certificate installed that was created for user authentication. In addition, the mobile device must have a copy of the trusted root certificate from the server. If you choose token-based authentication, you'll have to work with the token vendor for configuration.

Basic Authentication

Basic authentication is the simplest method of authentication. With Basic authentication, the server requests that the client submit a user name and a password. That user name and password are sent in clear text over the Internet to the server. The server verifies that the supplied user name and password are valid and grants access to the client. By default, this kind of authentication is enabled for Exchange ActiveSync. However, we recommend that you disable Basic authentication unless you're also deploying SSL. When you're using Basic authentication over SSL, the user name and password are still sent in plain text, but the communication channel is encrypted.

Certificate-Based Authentication

Certificate-based authentication uses a digital certificate to verify an identity. Other credentials are provided, in addition to the user name and password. These prove the identity of the user who's trying to access the mailbox resources that are stored on the Exchange 2010 server. A digital certificate consists of two components: the private key that's stored on the device and the public key that's installed on the server. If you configure Exchange 2010 to require certificate-based authentication for Exchange ActiveSync, only devices that meet the following criteria can synchronize with Exchange 2010:

- The device has a valid client certificate installed that was created for user authentication.
- The device has a trusted root certificate for the server to which the user is connecting to establish the SSL connection.

Deploying certificate-based authentication prevents users who have only a user name and password from synchronizing with Exchange 2010. As an additional level of security, the client certificate for authentication can be installed only when the device is connected to a domain-joined computer through either Desktop ActiveSync 4.5 or a later version in Windows XP or the Windows Mobile Device Center in Windows Vista or Windows 7.

Token-Based Authentication Systems

A token-based authentication system is a two-factor authentication system. Two-factor authentication is based on a piece of information the user knows, such as their password, and an external device that usually takes the form of a credit card or a key fob a user can carry with them. Each device has a unique serial number. In addition to hardware tokens, some vendors offer software-based tokens that can run on mobile devices.

Tokens work by displaying a unique number, typically six digits long, that changes every 60 seconds. When a token is issued to a user, it's synchronized with the server software. To authenticate, the user enters their user name, password, and the number that's currently displayed on the token. Some token-based authentication systems also require the user to enter a PIN.

Token-based authentication is a strong form of authentication. The disadvantage of token-based authentication is that you must install authentication server software and deploy the authentication software on every user's computer or mobile device. There's also the risk that the user can lose the external device. This can be financially costly because you'll need to replace lost external devices. However, the device is useless to a third party without the original user's authentication information.

Several companies issue token-based authentication systems. One company is RSA. Their product, SecurID, comes in many different forms, including a key fob and a credit card. A one-time authentication code is issued through the token. Each authentication code is valid for 60 seconds. Most tokens also have an expiration indicator on the device, for example, a series of dots that disappear as the length of time that the code has left decreases. This helps prevent a user from entering the correct code only to have it expire before the authentication process is complete. After authentication has finished, the user doesn't have to authenticate with a new code unless they're signed out, either by choice or because the device times out because of inactivity. For more information about how to configure a token-based authentication system, see the documentation for the particular system.

1.6.1.11.2.2 Configuring SSL and Exchange ActiveSync

Configuring SSL and Exchange ActiveSync

Understanding Client Access > Understanding Client Access Security > Understanding Security for Exchange ActiveSync >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-19*

By default, when you install the Client Access server role on a computer that's running Microsoft Exchange Server 2010, a Microsoft Exchange ActiveSync virtual directory is created on the default Internet Information Services (IIS) Web site on the Exchange server.

After you obtain a Secure Sockets Layer (SSL) certificate to use together with the Client

Access server on the default Web site or on the Web site where you host your Exchange ActiveSync virtual directory, you can configure the Web site to require SSL. You can enable SSL for all Web sites hosted by the Client Access server or enable SSL only for Exchange ActiveSync.

Configuring an Exchange ActiveSync virtual directory to use SSL is just one step in managing security for Exchange ActiveSync. For more information about how to manage security for Exchange ActiveSync, see Managing Exchange ActiveSync Security.

1.6.1.11.2.3 Configuring Exchange ActiveSync Policies

Configuring Exchange ActiveSync Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-06*

In Microsoft Exchange Server 2010, you can create Microsoft Exchange ActiveSync mailbox policies to apply a common set of policies or security settings to a collection of users. After you deploy Exchange ActiveSync in your Exchange 2010 organization, you can create new Exchange ActiveSync mailbox policies or modify existing policies. This topic discusses Exchange ActiveSync mailbox policies and how they can be managed in your Exchange 2010 organization.

Looking for management tasks related to Exchange ActiveSync policies? See Managing Exchange ActiveSync with Policies.

Important:

Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Windows Phone 7 Synchronization.

Overview of Exchange ActiveSync Mailbox Policies

You can use Exchange ActiveSync mailbox policies to manage many different settings. These include the following:

- Require a password
- Specify the minimum password length
- Require a number or special character in the password
- Designate how long a device can be inactive before requiring the user to re-enter a password
- Wipe a device after a specific number of failed password attempts

For more information about all the settings you can configure, see Set-ActiveSyncMailboxPolicy.

Managing Exchange ActiveSync Mailbox Policies

After you install the Client Access server role on an Exchange 2010 computer, you can

create, configure, and manage Exchange ActiveSync mailbox policies. After you create an Exchange ActiveSync mailbox policy, you can add users individually or add a filtered list of users to the policy using the Exchange Management Shell.

You can use the Exchange Management Console to manage some Exchange ActiveSync mailbox policy settings and the Shell to manage all the Exchange ActiveSync mailbox policy settings.

Windows Phone 7 Synchronization

If you have Windows Phone 7 mobile phones in your organization, these phones will experience synchronization problems if certain Exchange ActiveSync mailbox policy properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to True or only configure the following Exchange ActiveSync mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration
- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

1.6.1.11.3 Understanding Security for Outlook Anywhere

Understanding Security for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-13*

There are several methods available to help secure Outlook Anywhere (formerly known as RPC over HTTP). In a Microsoft Exchange Server 2010 messaging environment enabled for Outlook Anywhere, users can access Exchange from the Internet. When a user accesses their mailbox over the Internet using Outlook Anywhere, each time they create or update their Outlook profile, the Autodiscover service automatically detects their Outlook profile information and provides the user access to Exchange Web services including the Offline Address Book, the Availability service, and Unified Messaging. Because traffic on the Internet is vulnerable to interception and attack, consider a security strategy that involves as many security options as possible.

Looking for management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Contents

Using an Advanced Firewall Server for Outlook Anywhere

Using an advanced firewall server such as Microsoft Internet Security and Acceleration (ISA) Server 2006 improves security for your Outlook Anywhere deployment. ISA Server 2006 provides a setup wizard that lets you configure ISA Server 2006 for Exchange 2010 to work with Outlook Anywhere. For more information, see Using ISA Server with Outlook Anywhere.

Using SSL with Outlook Anywhere

When you use Outlook Anywhere to access Exchange information from the Internet, you must install a valid Secure Sockets Layer (SSL) certificate issued by a certification authority (CA) that's trusted by the client computer's operating system. For more information about how to use SSL certificates for client access, see Understanding Digital Certificates and SSL. For more information about how to use SSL with Outlook Anywhere, see Configure SSL for Outlook Anywhere.

For Outlook 2007 and Outlook 2010 clients that are located outside the organization, Outlook Anywhere provides connectivity to the Exchange organization. In this situation, Outlook 2007 or Outlook 2010 uses Domain Name System (DNS) to locate information about how to connect to the Autodiscover service. Because DNS is open to several kinds of malicious attacks, Outlook 2007 and Outlook 2010 request Autodiscover service information from only two URL combinations secured by SSL.

For an organization named www.contoso.com that has e-mail addresses that are derived from the main site name, for example, kwekua@contoso.com, the two URL combinations would be formed as follows:

1. Outlook will first try the URL https://contoso.com/autodiscover/autodiscover.xml.
2. If the previous URL cannot locate the Autodiscover service, Outlook will then try https://autodiscover.contoso.com/autodiscover/autodiscover.xml.

Return to top

Choosing an SSL Deployment Option for Outlook Anywhere

There are several ways to use Secure Sockets Layer (SSL) to help secure communication between Outlook 2007 and Outlook 2010 clients and the Autodiscover service. With Outlook Anywhere, Outlook clients query DNS for the Autodiscover service connection point. We recommend that you use the Subject Alternative Name field on your SSL certificate to help secure communication between clients and the Client Access server

that's hosting the Autodiscover service. For more information about how to configure the Subject Alternative Name for an SSL certificate, see Configure SSL Certificates to Use Multiple Client Access Server Host Names.

Alternatively, you can use multiple SSL certificates. For more information, see Configure Outlook Anywhere to Use Multiple SSL Certificates.

Another option is to use an SSL certificate together with redirection. For more information, see Configure Outlook Anywhere to Use an SSL Certificate with Redirection.

Using SSL Offloading for Outlook Anywhere

If you have a hardware solution for offloading the SSL encryption for traffic that's destined for your Client Access server, you must configure SSL offloading for Outlook Anywhere. For more information, see Configure SSL Offloading for Outlook Anywhere.

Return to top

Configuring Authentication for Outlook Anywhere

When you use the Enable Outlook Anywhere wizard to configure your Client Access server to provide Outlook Anywhere access, you must select an authentication method for your Outlook clients to use. After you select an authentication method, you can change this method by using the **Set-OutlookAnywhere** cmdlet in the Exchange Management Shell.

Understanding Authentication for Outlook Anywhere and the RPC Virtual Directory

The authentication method you select for Outlook Anywhere is the authentication method that will be used by the Outlook 2007 or Outlook 2010 client. This authentication method is automatically provided to the client by the Autodiscover service. You choose the authentication type for the RPC virtual directory when you enable Outlook Anywhere. You can choose to allow Basic authentication, NTLM authentication, or both Basic authentication and NTLM authentication. You may want to enable both Basic and NTLM authentication if you're using the IIS virtual directory with multiple applications that require different authentication methods.

Note:

When you configure this setting using the IIS interface, you can enable as many authentication methods as you want.

The authentication method on the RPC virtual directory can be modified by using the **Set-OutlookAnywhere** cmdlet. For more information, see Configure Authentication for Outlook Anywhere.

Return to top

Basic Authentication and Outlook Anywhere

You can use Basic authentication with Outlook Anywhere. Basic authentication requires a user name and password, and then sends the user name and password over the Internet in plain text. As long as you use Secure Sockets Layer (SSL) to help secure the

connection between the Microsoft Office Outlook Web App client and the Exchange messaging infrastructure, using Basic authentication with Outlook Anywhere is supported. For more information, see Configure Authentication for Outlook Anywhere.

Integrated Windows Authentication and Outlook Anywhere

ISA Server 2006 supports using Integrated Windows authentication for Outlook Anywhere. However, if you're using a firewall that doesn't handle Integrated Windows authentication, you must use Basic authentication with SSL. For more information, see Configure Authentication for Outlook Anywhere.

Return to top

1.6.1.11.4 Understanding Security for POP3 and IMAP4

Understanding Security for POP3 and IMAP4

Client Access > Understanding Client Access > Understanding Client Access Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic explains security settings that you can use on the Microsoft Exchange Server 2010 Client Access server that has the POP3 and IMAP4 services installed.

Looking for management tasks related to POP3 and IMAP4? See Managing POP3 and IMAP4.

Configuring SSL and TLS for POP3 and IMAP4 Clients

To help secure communications between POP3 and IMAP4 clients and the Exchange 2010 Client Access server, we strongly recommend that you use Secure Sockets Layer (SSL) or Transport Layer Security (TLS). By default, Exchange Setup provides a self-signed certificate for test environments. However, we recommend that you install a certificate from a certification authority (CA) that's trusted by the client's operating system. For more information, see Managing SSL for a Client Access Server.

You can use the Exchange Management Console or the Exchange Management Shell to configure SSL or TLS for POP3 and IMAP4 on an Exchange 2010 server.

For more information about how to use the EMC or the Shell to configure SSL or TLS for POP3 and IMAP4, see the following topics:

- Configure POP3 to Use TLS or SSL
- Configure IMAP4 to Use TLS or SSL

Configuring Authentication for POP3 and IMAP4

When you use POP3 and IMAP4 clients, you can set authentication options such as the ability to use SSL or TLS encryption and the ability to configure ports to communicate with clients. When you use SSL or TLS for POP3 and IMAP4 access, the Exchange server uses the ports listed in the following table to communicate with clients.

Ports for POP3 and IMAP4 access when using SSL

Protocol	Default port
IMAP4 with SSL	993 (TCP)
IMAP4 with or without TLS	143 (TCP)
POP3 with SSL	995 (TCP)
POP3 with or without TLS	110 (TCP)

By default, the values in the previous table are used for communicating with clients. You can specify other ports to use with POP3 and IMAP4 clients if you want to disable communication through the default ports.

For more information about how to configure authentication for POP3, see the following topics:

- Configure Authentication for POP3
- Configure Ports for POP3 Authentication

For more information about how to configure authentication for IMAP4, see the following topics:

- Configure Authentication for IMAP4
- Configure Ports for IMAP4 Authentication

1.6.1.11.5 Understanding Security for Outlook Web App

Understanding Security for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-30*

Outlook Web App for Microsoft Exchange Server 2010 offers a variety of security features that you can configure to suit your organization's security requirements. Because Outlook Web App may be used to provide users access to their mailboxes from workstations that are not secure, security is a priority. By default, when you install the Client Access server role on an Exchange 2010 server, Outlook Web App is configured to use Secure Sockets Layer (SSL) and forms-based authentication.

Looking for management tasks related to securing Outlook Web App? See Managing Outlook Web App Security.

Contents

Authentication

You can configure the following types of authentication methods on the Exchange 2010 Client Access server:

- Standard authentication methods such as the following:
  - Basic authentication
  - Integrated Windows authentication
  - Digest authentication
- Forms-based authentication

For more information about authentication methods for Outlook Web App, see Understanding Authentication for Outlook Web App.

Segmentation

Segmentation lets you enable and disable features that are available to users in Exchange 2010 Outlook Web App. By default, any mail-enabled user in your Exchange 2010 organization can access their mailbox by using Outlook Web App. Depending on the needs of your organization, you can use segmentation to configure the following for user access:

- Restrict access to Outlook Web App for specific users.
- Control access to certain Outlook Web App features for specific users.
- Disable an Outlook Web App feature completely.

For more information about segmentation in Outlook Web App, see Understanding Segmentation for Outlook Web App.

Web Beacons

A Web beacon is a file object, such as a transparent graphic or an image, which is put on a Web site or in an e-mail message. Web beacons are typically used together with HTML cookies to monitor user behavior on a Web site or to validate a recipient's e-mail address when an e-mail that contains a Web beacon is opened.

Note:

By default, Outlook Web App disables all potential Web beacon content in e-mail messages.

For more information about how to deal with Web beacons in Outlook Web App, see Understanding Web Beacon and HTML Form Filtering in Outlook Web App.

File and Data Access

There are a variety of features that enable users to access files and data in Outlook Web App. Each of these features includes options for controlling access to files and data from Outlook Web App.

WebReady Document Viewing

Exchange 2010 includes a feature named WebReady Document Viewing. WebReady Document Viewing lets users view common file types in the Outlook Web App Web browser without having the applications that are associated with those file types installed on the computer they are using. Allowing files that are accessed through Outlook Web App to be viewed only by using WebReady Document Viewing protects against the potential security risk that is caused when files that are opened from within Outlook Web

App are cached on the client computer. For more information about how to configure file and data access for Outlook Web App, see Understanding Security for File and Data Access for Outlook Web App.

Return to top

Direct File Access

Direct file access enables users to open attached files directly from inside Outlook Web App. You can also configure how users interact with files by using the Allow, Block, or Force Save options for direct file access in the Exchange Management Console. This means that you can specify the types of files that users can access. More important, you can specify which types of files are prohibited.

For more information about how to configure file and data access for Outlook Web App, see Understanding Security for File and Data Access for Outlook Web App.

Windows File Share Integration

By using Outlook Web App, users can access remote files that are stored on Microsoft Windows file share (also known as UNC) servers. You can configure how users interact with files on these servers by using the Allow and Block options in the Exchange Management Console. This means that you can specify which servers your users can access. You can also specify the behavior for Windows file share servers that have not been specifically allowed or blocked when users try to access them by using Outlook Web App.

For more information about how to configure file and data access for Outlook Web App, see Understanding Security for File and Data Access for Outlook Web App.

Secure Sockets Layer

SSL is a method for securing communications between a client and a server. For a computer that is running Exchange 2010 that has the Client Access server role installed, SSL is used to help secure communications between the server and the clients. Clients include mobile phones, computers inside an organization's network, and computers outside an organization's network. These include clients that have and do not have virtual private network (VPN) connections.

For more information about SSL, see the following topics:

- Understanding Digital Certificates and SSL
- Understanding SSL for Outlook Web App

1.6.1.11.5.1 Understanding Segmentation for Outlook Web App

Understanding Segmentation for Outlook Web App

Understanding Client Access > Understanding Client Access Security > Understanding Security for Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

Segmentation lets you enable and disable features that are available to users in the version of Microsoft Office Outlook Web App released with Microsoft Exchange Server 2010. By default, any mail-enabled user in your Exchange 2010 organization can access

their mailbox using Outlook Web App. Depending on the needs of your organization, you can use segmentation to do the following:

- Restrict access to Outlook Web App for specific users.
- Control access to certain Outlook Web App features for specific users.
- Disable an Outlook Web App feature completely.

Looking for management tasks related to Outlook Web App features? See Managing Outlook Web App.

Configuring Segmentation

Many features can be set for an Outlook Web App virtual directory using the Exchange Management Console. You can also use the **Set-OwaVirtualDirectory** cmdlet in the Exchange Management Shell to enable or disable the same features that you can enable and disable using the EMC, plus some features that you can't configure using the EMC.

For more information about the parameters you can use to configure segmentation for all users, see Set-OwaVirtualDirectory.

For more information about the features that you can configure using the EMC and how to configure them, see Configure Segmentation in Outlook Web App.

For more information about how to enable and disable features for specific users, see Set-CASMailbox and Understanding Outlook Web App Mailbox Policies.

1.6.1.11.5.2 Understanding Security for File and Data Access for Outlook Web App

Understanding Security for File and Data Access for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-30*

There are two methods for accessing files and data from inside Outlook Web App. These data access methods include WebReady Document Viewing and direct file access. You can allow or block these features as needed to meet the requirements of your organization.

Looking for management tasks related to file and data access for Outlook Web App? See Configure WebReady Document Viewing, Configure Public and Private Computer File Access, and Set-OwaVirtualDirectory.

WebReady Document Viewing

Microsoft Exchange Server 2010 includes a feature named WebReady Document Viewing. WebReady Document Viewing lets users view common file types in the Outlook Web App Web browser without having the applications associated with those file types installed on the computer they're using. Users can view the following kinds of files using WebReady Document Viewing:

- .doc
- .pdf
- .ppt
- .xls

- .docx
- .xslx
- .pptx

Additionally, the supported MIME types are as follows:

- application/pdf
- application/vnd.ms-excel
- application/vnd.ms-powerpoint
- application/word
- application/x-mspowerpoint
- application/x-msexcel

Direct File Access

You can control direct file access through Outlook Web App by specifying the types of files that users can access and how the files can be accessed. You do this using the Allow, Block, and Force Save options for direct file access in the Exchange Management Console, or by using the file access parameters available in the **Set-OWAVirtualDirectory** cmdlet in the Exchange Management Shell. In addition to being able to specify Allow, Block, or Force Save for different file types, you can configure the file access options depending on whether the user clicks **This is a public computer** or **This is a private computer** when they sign in to Outlook Web App. For more information about how to manage file access, see Configure Public and Private Computer File Access and Set-OwaVirtualDirectory.

1.6.1.11.5.3 Understanding Web Beacon and HTML Form Filtering in Outlook Web App

Understanding Web Beacon and HTML Form Filtering in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Web beacons frequently come in the form of images that are downloaded onto a user's computer when the user opens a junk e-mail message. After the images are downloaded, a Web beacon notification is sent to the sender of the junk e-mail message that informs the sender that the recipient e-mail address is valid. After a user opens a message that sends a Web beacon notification back to the junk e-mail sender, the user may receive junk e-mail more frequently because the junk e-mail sender has verified that the user's e-mail address is valid. Web beacons can also contain harmful code and can be used to circumvent e-mail filters to deliver an e-mail message from someone who is sending unsolicited commercial e-mail.

Note:

By default, Outlook Web App enables users to choose to allow or disable potential Web beacon content in individual e-mail messages.

Controlling Web Beacon and HTML Form Filtering

In Outlook Web App, an incoming e-mail message that contains content that can be used as a Web beacon prompts Outlook Web App to display a warning message to the user to inform the user that the content has been blocked. This occurs regardless of whether the

message actually contains a Web beacon. If a user knows that a message is legitimate, they can enable the blocked content. If a user does not recognize the sender of the message, they can open the message without unblocking the content, and then delete the message without triggering beacons. If your organization does not want to use this feature, you can disable the blocking option for Outlook Web App.

The settings for filtering Web beacons are stored in Active Directory. You can configure how potential Web beacon content is filtered by using the **Set-OwaVirtualDirectory** cmdlet in the Exchange Management Shell. For more information about syntax and parameters, see Set-OwaVirtualDirectory.

The following list describes the parameters in the *FilterWebBeacons* property for Web beacon filtering in Outlook Web App:

- **UserFilterChoice** By using the *UserFilterChoice* parameter, you can let users decide whether they want to enable or continue to disable the blocked Web beacon content. Outlook Web App blocks all potential Web beacon content in an e-mail message and displays the following message in the information bar when a user receives an e-mail message that contains potential Web beacon content: "To help protect your privacy, Outlook Web App has blocked some images, sounds, or forms that can communicate your information to other Web sites. If you are sure that this message is from a trusted sender and you want to re-enable the blocked features, Click Here." To view the blocked content, the user can click the **Click Here** option.

  Note:
  By default, the *UserFilterChoice* parameter is enabled in Outlook Web App.

- **ForceFilter** By using the *ForceFilter* parameter, you can block all potential Web beacon content. Outlook Web App blocks all potential Web beacon content in an e-mail message and displays the following message in the information bar when a user receives an e-mail message that contains potential Web beacon content: "To help protect your privacy, Outlook Web App has blocked some images, sounds, or forms that can communicate your information to other Web sites." Users cannot override the *ForceFilter* parameter to view the blocked Web beacon content.
- **DisableFilter** By using the *DisableFilter* parameter setting, you can enable all potential Web beacon content in Outlook Web App.

1.6.1.11.5.4 Understanding Authentication for Outlook Web App

Understanding Authentication for Outlook Web App

Understanding Client Access > Understanding Client Access Security > Understanding Security for Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-19*

This topic explains the types of authentication that are available for Outlook Web App in Microsoft Exchange Server 2010. The authentication method that's best for your organization depends on your organization's security needs. By default, Outlook Web App uses forms-based authentication and is configured to use Secure Sockets Layer (SSL) encryption.

Forms-Based Authentication

Forms-based authentication enables a sign-in page for Outlook Web App that uses a cookie to store a user's encrypted sign-in credentials in the Internet browser. Tracking the use of this cookie enables the Exchange server to monitor the activity of Outlook Web App sessions on public and private computers. If a session is inactive for too long, the server blocks access until the user re-authenticates.

The first time that the user name and password are sent to the Client Access server to authenticate an Outlook Web App session, an encrypted cookie is created that's used to track user activity. When the user closes the Internet browser or clicks **Sign Out** to sign out from their Outlook Web App session, the cookie is cleared. The user name and password are sent to the Client Access server only for the initial user sign-in. After the initial sign-in is complete, only the cookie is used for authentication between the client computer and the Client Access server.

For more information about forms-based authentication and how to configure it, see:

- Setting Up Forms-Based Authentication for Outlook Web App
- Configure Forms-Based Authentication for Outlook Web App

Single Sign On for Outlook Web App and Exchange Control Panel

To support single sign on between Outlook Web App and Exchange Control Panel, a new service, the Exchange FBA Authentication service, is available in Exchange 2010. To use this new feature, ensure that the authentication mode for both Outlook Web App and Exchange Control Panel virtual directories is set to forms-based authentication.

Setting the Value for Cookie Time-Out

The cookie time-out is set based on the user's choice of either the **This is a public or shared computer** option or the **This is a private computer** option on the Outlook Web App sign-in page. By default, the cookie on the computer expires automatically and the user is signed out after they haven't used Outlook Web App for between 15 and 22.5 minutes if they've selected the public computer option, and after they haven't used Outlook Web App for between eight and twelve hours if they've selected the private computer option.

Automatic time-out is valuable because it helps protect users' accounts from unauthorized access. To match the security requirements of your organization, you can configure the inactivity time-out values on the Exchange Client Access server.

Although automatic time-out greatly reduces the risk of unauthorized access, it doesn't completely eliminate the possibility that an unauthorized user might access an Exchange mailbox if a session is left running on a public computer. Therefore, make sure that you warn users to take precautions to avoid risks, such as by telling them to sign out from Outlook Web App and close the Web browser after they've finished using Outlook Web App.

For more information about how to configure the cookie time-out values for public and private computers, see:

- Set the Forms-Based Authentication Public Computer Cookie Time-Out Value
- Set the Forms-Based Authentication Private Computer Cookie Time-Out Value

Return to top

Standard Authentication Methods

In Exchange 2010, Client Access servers support Integrated Windows authentication and HTTP 1.1 Digest authentication for Exchange 2010 virtual directories.

For more information about standard authentication methods, see Setting Up Standard Authentication Methods for Outlook Web App.

Basic Authentication

Basic authentication is a simple authentication mechanism that's defined by the HTTP specification that encodes a user's sign-in name and password before the user's credentials are sent to the server.

Basic authentication doesn't support single sign-on. Windows Server 2008 and Windows Server 2003 authentication enable single sign-on to all network resources. With single sign-on, a user can sign in to the domain one time by using a single password or smart card and authenticate to any computer in the domain.

Basic authentication is supported by all Web browsers, but is not secure unless you require SSL encryption.

For more information about how to configure Basic authentication on an Outlook Web App virtual directory, see Configure Basic Authentication.

Digest Authentication

Digest authentication transmits passwords over the network as a hash value for additional security. Digest authentication can be used only in Windows Server 2008, Windows Server 2003, and Microsoft Windows 2000 Server domains for users who have an account that's stored in Active Directory. For more information about Digest authentication, see the Windows Server 2003 and Internet Information Services (IIS) Manager documentation.

Digest authentication is available only on Exchange 2010 virtual directories.

Important:

If you're using Digest or Basic authentication, when a user uses a kiosk, caching credentials can pose a security risk if the user doesn't close the browser and end the browser process between sessions. This risk occurs because a user's credentials remain in the cache when the next user accesses the kiosk. To enable Outlook Web App on a kiosk, make sure that the user can close the browser between sessions and end the browser processes. Otherwise, consider using a third-party product that incorporates two-factor authentication, in which the user must present a physical token together with a password to use Outlook Web App on a kiosk.

For more information about how to configure Digest authentication on an Outlook Web App virtual directory, see Configure Digest Authentication.

Return to top

Integrated Windows Authentication

Integrated Windows authentication requires that users have a valid Windows Server 2008, Windows Server 2003, or Windows 2000 Server user account name and password to access information. Users signed in to the local network aren't prompted for their user names and passwords. Instead, the server negotiates with the Windows security packages that are installed on the client computer. This method enables the server to authenticate users without prompting them for sign-in information. The authentication credentials are protected, but all other communication will be sent in clear text unless SSL is used.

Microsoft Internet Explorer allows single sign-on for Web applications that include Outlook Web App Web Parts if the server that's being accessed has Integrated Windows authentication enabled. Users must enter credentials only one time for each browser session. However, their credentials are cached in the browser process.

On an Exchange 2010 server on which only the Client Access server role is installed, Integrated Windows authentication can be used only with Exchange 2010 virtual directories. On a server that has both the Client Access and Mailbox roles installed, Integrated Windows authentication can be used with any virtual directory. For more information about Integrated Windows authentication, see the Windows Server 2003 documentation.

Note:

Integrated Windows authentication is supported only on computers that are running a Windows operating system and Internet Explorer. Integrated Windows authentication may work with other Web browsers if they've been configured to pass the user's sign-in credentials to the server that's requesting authentication.

For more information about how to configure Integrated Windows authentication on an Outlook Web App virtual directory, see Configure Integrated Windows Authentication.

1.6.1.11.5.5 Understanding SSL for Outlook Web App

Understanding SSL for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

Secure Sockets Layer (SSL) encryption is used in Outlook Web App to help secure the connection between the Exchange Server 2010 Client Access server and the client. By default, Outlook Web App uses forms-based authentication and requires SSL encryption.

Looking for management tasks related to using SSL in Outlook Web App? See Managing Outlook Web App Security.

SSL Encryption and Outlook Web App

When you install the Client Access server role, four Outlook Web App virtual directories are created in the default Internet Information Services (IIS) Web site on the Exchange server. The four virtual directories are named \owa, \exchange, \public, and \exchweb. By default, these virtual directories and the default Web site are configured to require SSL.

If you want to use SSL to help secure additional Outlook Web App virtual directories or Web sites that you have created, you must do so manually. To configure a site to use SSL, you must obtain a certificate and configure the Web site or virtual directory to require SSL by using that certificate.

1.6.1.12 Understanding RPC Client Access

Understanding RPC Client Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-09-21*

In Microsoft Exchange Server 2007, the Client Access server role was introduced to handle incoming client connections to Exchange mailboxes. Although the majority of types of client connections were made to the Client Access server, Microsoft Office Outlook still connected directly to the Mailbox server when it was running internally with the MAPI protocol.

A new service was introduced with Exchange Server 2010 to allow these MAPI connections to be handled by the Client Access server. The RPC Client Access service provides data access through a single, common path of the Client Access server, with the exception of public folder requests, which are still made directly to the Mailbox server. This change applies business logic to clients more consistently, and provides a better client experience when failover occurs.

Contents

RPC Client Access Service and the Address Book Service

In addition to moving processing of incoming Outlook Mailbox connections to the Client Access server, in Exchange 2010, directory access is also handled by the Client Access server. For more information about directory access, see Understanding the Address Book Service.

Microsoft Outlook still connects directly to the Mailbox server to access Public Folder databases. If a client tries to connect to a Mailbox server for public folder access, the RPC Client Access service (MsExchangeRpc) answers the RPC endpoint. If the endpoint is on a server that has the Mailbox server role installed, the RPC Client Access service will only allow public folder logons and will provide a referral to a Client Access server or a Client Access server array. If the endpoint is on a Client Access server or Client Access server array, it will allow only Private folder logons and will provide a referral to a Mailbox server for public folder access.

Advantages of the RPC Client Access Service

There are a number of advantages to the RPC Client Access service. Clients encounter less downtime during a mailbox failover, because all connections are made through the Client Access servers. When failover occurred in Exchange 2007, Outlook clients would be disconnected from the Mailbox server for a period of time that depended on their network configuration. In Exchange 2010, if a single Client Access server in a Client Access server array fails, the client will immediately be redirected to another Client Access server in the array. If a Mailbox server that is part of a Database Availability Group (DAG) fails, the client is disconnected for only the amount of time it takes for a failover database to be mounted.

A load-balanced array of Client Access servers lets you spread the traffic load over all Client Access servers in the array equally.

Other problems resolved by this new architecture include the following:

- Some issues with messages displaying differently on different clients.
- Problems uploading certificates to the global address list.
- The inability to create profiles for hidden users.
- Inconsistent application of business logic to clients.
- Public folders connecting to the RPC Client Access service on the Mailbox server, rather than the Client Access server.

Additionally, the DSProxy service has been removed and the new Address Book service is responsible for updating certificates and distribution list membership and maintaining delegate information for Outlook clients.

MAPI Client Connections

In Exchange 2007, Outlook and other MAPI clients communicated with the Client Access server for HTTPS connections such as Exchange Web Services (including the Availability service and Out of Office settings), and Offline Address Book downloads, but communicated directly with the MAPI RPC component on the Mailbox server and the NSPI endpoint on Global Catalog servers for Directory Service inquiries.

In Exchange 2010, these connections are made to the MAPI RPC connection point on the Client Access server or the Client Access server array.

The Address Book Service

In previous versions of Exchange, DSProxy, a referral service that told Outlook clients where to find the Name Service Provider Interface (NSPI) endpoint, was responsible for directing Outlook to a global catalog server. DSProxy was located on the Mailbox server. DSProxy has been eliminated in Exchange 2010 and replaced with the Address Book service.

Currently, when an Outlook client makes a request of the Client Access server, it results in one of two possible actions.

- If the user's mailbox is on an Exchange 2010 Mailbox server, then either the request is handled by a Client Access server in the current Active Directory site, or if the user’s mailbox is in a different Active Directory site, the request is proxied to the destination Active Directory site.
- If the user's mailbox is on a legacy Exchange Mailbox server, the directory request is referred to the user's Mailbox server. Legacy Mailbox servers can't communicate directly with Exchange 2010 Client Access servers for directory information.

The Address Book service also provides information about writable domain controllers as well as global address list access. For more information about the Address Book service, see Understanding the Address Book Service.

The Client Access Server Array

In addition to the RPC Client Access service, Exchange 2010 introduced a new logical structure to the Exchange organization: the Client Access server array. When a Client Access server array is defined in an Active Directory site, it serves as a single contact point for all client connections within that Active Directory site. A Client Access server array can include one or many Client Access servers.

Each Active Directory site can have a single Client Access server array. A Client Access server array doesn’t provide load balancing. A separate load balancing solution is still needed. For more information about load balancing, see Understanding Load Balancing in Exchange 2010.

We recommend that you create a Client Access server array even if you only have a single

Client Access server within your organization. When a Client Access server array is created, clients connect through the virtual name of the Client Access server array rather than directly to the fully-qualified domain name (FQDN) of your single Client Access server. If a single Client Access server needs to be replaced within an Active Directory site or a second Client Access server is added, no profile updates are necessary on the clients.

After a Client Access server array is defined within an Active Directory site, all Client Access servers within that Active Directory site are automatically part of the Client Access server array.

Configuring the RPC Client Access Service and the Address Book Service

To configure the RPC Client Access service and the Address Book service, you must perform the following steps.

1. Create a Client Access array
2. Configure load balancing
3. Configure IP ports
4. Configure RPC encryption settings
5. Configure your Mailbox databases
6. Ensure low latency and sufficient network speed

Create a Client Access Array

You can create a Client Access array within your Active Directory site by using the following command.

```
New-ClientAccessArray -Name name -Site site_name -FQDN internal_only_CAS_Array_FQ
```

Note:

After the Client Access array has been created, you'll also need to create the address in DNS and associate it with the virtual IP address used for the Client Access array.

It's important that the (FQDN) specified in the command be only resolvable internally. If the name is also resolvable externally, these external clients will attempt to connect to the array via a TCP connection instead of HTTPS.

Configure Load Balancing

Load balancing is recommended for high availability, failover, and for spreading the traffic load over multiple servers to help performance. When you choose a load balancing solution, consider the following:

- Windows Network Load Balancing isn't supported on Windows failover cluster servers.
- You can't use a Client Access array across multiple Active Directory sites. Instead, create two Client Access arrays and load balance separately within the sites.
- Hardware load balancers typically monitor return traffic, port availability, or service availability to ensure that servers that can't answer client requests aren't given network connections.
- Some load balancing solutions, such as ISA 2006 or TMG 2010, can't do RPC load balancing or monitor RPC services. These solutions aren't recommended unless all clients are connecting via Outlook Anywhere and all traffic is encapsulated inside HTTP.

For more information about load balancing, see Understanding Load Balancing in Exchange 2010.

Configure IP Ports

An IP port is an opening through which information can pass from the originating computer to the destination computer. By default, the dynamic port range for outgoing connections on Windows Server 2008 R2 is 49152 to 65535. Exchange 2010 Client Access changes this range to 6005 through 65535. The range was expanded to provide sufficient scaling for large deployments. This is a large range of ports to balance through your firewall between the client and the Client Access servers or Client Access array.

By fixing the MAPI and directory endpoints, you can greatly reduce the number of ports that need to be load balanced. The MAPI endpoint can be statically configured in the registry and the directory endpoint can be fixed in a configuration file.

To fix the MAPI endpoint, use the following setting in the registry.

HKLM\SYSTEM\CurrentControlSet\ Services\MSExchangeRPC\ParametersSystem \TCP/IP Port [DWORD] is the value for the IP port to use.

To fix the directory services endpoint, edit the RpcTcpPort value in the configuration file Microsoft.Exchange.AddressBook.Service.Exe.config.

Note:

We don't recommend that you change the default value of the Outlook Anywhere ports.

Configure RPC Encryption Settings

In the RTM version of Exchange 2010, the RPC endpoint is encrypted by default. However, Outlook 2003 doesn't enforce encrypted MAPI connections. When you upgrade your organization to the RTM version of Exchange 2010, your clients running Outlook 2007 or later versions will automatically be compatible with the change to RPC Client Access, since they support RPC encryption by default. Outlook 2003 doesn't use RPC encryption, however, and RPC Client Access requires it by default. If you haven't turned off RPC encryption, which we don't recommend, your users will need to configure Outlook 2003 for RPC encryption or you'll need to use a Group Policy to force Outlook 2003 to use RPC encryption.

Symptoms of this problem include the following error messages:

- Cannot start Microsoft Office Outlook. Unable to open the Office window. The set of folders could not be opened.
- Unable to open your default e-mail folders. The information store could not be opened.

If your users are using Cached Exchange Mode, Office won't display an error, but will start in disconnected mode.

By default, Exchange 2010 Service Pack 1 (SP1) doesn't encrypt the RPC endpoint. If you've completed the installation of Exchange 2010 SP1 in your organization, Outlook 2003 clients will be able to connect to the Exchange server without further configuration.

For more information about this issue, including workarounds, see Outlook Connection Issues with Exchange 2010 Mailboxes.

Configure Outlook 2003 to Use RPC Encryption

To configure Outlook 2003 to use RPC encryption, use the following steps.

1. Click **Tools** > **E-Mail Accounts** > **View or Change an Existing Account**.
2. Select the account and click **More Settings**.
3. Select the **Security** tab.
4. Select **Encrypt data between Microsoft Office Outlook and Microsoft Exchange Server**.
5. Click **OK**.

Configure Your Mailbox Database

Each Mailbox database contains an **RPCClientAccessServer** value. This value is established when the database is created and it determines the Client Access server or

Client Access array that the clients with mailboxes on that Mailbox server will use. This value also determines the location of the RPC end point. For Outlook 2007 and Outlook 2010 clients, this value is obtained from the Autodiscover service.

The default value of the **RPCClientAccessServer** is determined by the following rules:

- If you have configured a Client Access Server array within your Active Directory site, the address of that array will be used.
- If an array does not exist within the Active Directory site and if you have both the Client Access server role and the Mailbox server role on the same physical server, the value of **RPCClientAccessServer** property for a particular Mailbox server will be the same as the Mailbox server.
- Otherwise, the value of the **RPCClientAccessServer** property for a particular Mailbox server will be set to a random Client Access server within the Active Directory site.

Note:
We don't recommend that you install all the server roles on a single computer that's also a domain controller. Although this configuration is supported, it's not recommended.

- If you created a Mailbox database before the creation of a Client Access array or the installed a Client Access server within the Active Directory site, you'll need to reconfigure the value of the **RPCClientAccessServer** property. If no Client Access server exists in the Active Directory site when the Mailbox database is created, the value of the **RPCClientAccessServer** property will be set to the FQDN of the Mailbox server. To configure the value of the **RPCClientAccessServer** property, use the following command.

```
Set-MailboxDatabase <name> -RPCClientAccessServer <internal_only_CAS_Ar
```

Latency and Bandwidth Requirements

For users running Outlook without Cached Exchange Mode, high latency times between the client and the server directly affect how frequently Outlook is unresponsive. In general, a latency of greater than 200 milliseconds (ms) to the home Mailbox server will result in poor client performance.

Because latency between the Client Access server and the mailbox should be less than 10 ms, we recommend that the value of the **RPCClientAccessServer** property always be configured to a Client Access array in the active Mailbox database site.

Note:
Changing the value of the **RPCClientAccessServer** property will force all clients to reconnect.

Configuring the Address Book Service

The Address Book service is configured through the Microsoft.Exchange.AddressBook.Service.config file. This file allows you to configure the following:

- The number of concurrent connections per user (the default limit is 50).
- Disable or enable logging.
- The location, size, and retention period for the log files.

To enable logging, use the following value:

```
< add key="ProtocolLoggingEnabled" value="true" />
```

1.6.1.13 Understanding the Address Book Service

Understanding the Address Book Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-12*

In versions of Microsoft Exchange earlier than Exchange Server 2010, Exchange provided a referral service that told clients such as Outlook where they could find a server running the NSPI service. This referral usually pointed Outlook to a global catalog server. But some Outlook Anywhere connections would point Outlook back to the local server, and the NSPI calls would be proxied to a global catalog server.

Outlook expects to find this referral service on the same server that's used for mailbox access. In Exchange 2010, both mailbox access and directory access are handled by the Client Access server.

Directory Access on a Client Access Server

When Outlook contacts the Client Access server, two possible actions occur. If the user's mailbox is on an Exchange Server 2007 Mailbox server or an Exchange Server 2003 server, the directory request is referred to the user's mailbox server. If the user's mailbox is on an Exchange 2010 Mailbox server, then one of two actions happens.

If the user's mailbox is in the same site as the Client Access server, the request is referred to the Client Access server. If the user's mailbox is in a different site, the request is referred to a Client Access server in the remote site.

For Exchange 2010, the Client Access server hosts both the referral service and the NSPI endpoint. These two components are necessary for directory access to flow through the Client Access server.

Note:

If your Client Access server is installed on a domain controller, Outlook will communicate directly with the domain controller and will bypass the Client Access server.

Exchange 2007 Users

If a user who has a mailbox on a Microsoft Exchange Server 2007 Mailbox server queries the referral service, the Exchange 2010 Client Access server will refer the user to the Exchange 2007 Mailbox server. This is the same behavior that was experienced in a pure Exchange 2007 environment.

1.6.1.14 Client Access Availability and Scalability

Client Access Availability and Scalability

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-03*

When you plan the deployment of your Exchange Server 2010 organization, performance and scalability are two important considerations. It's very important to estimate your Exchange 2010 Client Access server capacity needs. The Client Access server is the entry

point for all users. In addition, the Client Access server hosts important services that are used by the other Exchange server roles. For information about the relative CPU weights of different protocols on the Client Access server, see White Paper: Understanding Granular and Relative Costs of Client Access Server Workloads In Exchange Server.

1.6.1.15 Sizing Client Access Servers

Sizing Client Access Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-18*

It's very important that you estimate your Microsoft Exchange Server 2010 Client Access server capacity needs when you plan the deployment of your Exchange 2010 organization. The Client Access server is the entry point for all users. In addition, the Client Access server hosts important services that are used by the other Exchange server roles.

For information about the relative CPU weights of different protocols on the Client Access server, see White Paper: Understanding the Relative Costs of Client Access Server Workloads In Exchange Server 2010.

1.6.1.16 Understanding Exchange Web Services Virtual Directories

Understanding Exchange Web Services Virtual Directories

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-03-18*

When you install the Client Access server role on your Exchange server, one Exchange Web Services virtual directory is created in the default Internet Information Services (IIS) Web site on the Exchange server. You can manage the virtual directory by using the Exchange Management Shell, IIS Manager, and through a configuration file located in the directory to which you installed Microsoft Exchange Server 2010.

Exchange Web Services virtual directories support the calendar sharing and other functionality offered by Exchange Web Services. The Exchange Web services included in Exchange 2010 provide an XML messaging interface that enables you to manage Exchange store items and access Exchange server functionality from client applications. For an overview of Exchange Web Services, see Introduction to Web Services.

Looking for management tasks related to Exchange Web Services virtual directories? Check out the Exchange Web Services virtual directory cmdlets referenced in the Client Access Cmdlets topic.

Contents

Configuring Exchange Web Services Virtual Directories

Most organizations find that the default Exchange Web Services virtual directory that's created during installation of the Exchange 2010 Client Access server role is sufficient. However, you can remove, create, and modify the settings of an Exchange Web Services virtual directory.

Managing Exchange Web Services Information in Your Infrastructure

For the functionality provided by Exchange Web Services to work, you must keep the information in the following locations in sync:

- Internet Information Services (IIS)
- Active Directory
- The Exchange Web Services web.config file

If there's a discrepancy between what you've configured in IIS for the Exchange Web Services virtual directory, what's configured in the web.config file, and what's is stored in Active Directory, Exchange Web Services won't initialize and calendaring sharing and other functionality won't work.

When Exchange Web Services doesn't initialize, an event is logged with the following error code: `ServiceActivationException`. If you get this error, it's a best practice to remove and then re-create the Exchange Web Services virtual directory. For more information about the cmdlets and parameters you need to use to perform these actions, see Remove-WebServicesVirtualDirectory and New-WebServicesVirtualDirectory.

Configuring Exchange Web Services to Manage SSL Offloading

SSL is enabled by default on Exchange Web Services virtual directories. If you want to enable SSL offloading, you must disable SSL on each Client Access server in your organization.

If you don't have an SSL offloading device and you want to maintain secure communication between client and server, SSL must be enabled on each Client Access server in your organization.

Important:

You can't disable or enable SSL using the Shell. If you disable or enable SSL on an Exchange Web Services virtual directory, you must make the configuration change in both IIS Manager and the Exchange Web Services web.config file.

For more information about how to manage SSL on Exchange Web Services virtual directories, see Enable or Disable SSL on Exchange Web Services Virtual Directories.

1.6.1.17 Understanding External Access to Exchange 2010

Understanding External Access to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-20*

This topic describes how to configure firewalls for use with a Microsoft Exchange Server 2010 Client Access server. You can use software and hardware solutions as a firewall to help secure your messaging environment. We recommend that you use an advanced firewall server such as Microsoft Internet Acceleration and Security (ISA) Server 2006 with Exchange 2010 because these two products are designed to work together to help secure and enhance the client access experience.

Forefront Unified Access Gateway 2010 and Forefront Threat Management Gateway 2010

When you publish Exchange for access from the Internet, Microsoft offers two software-based options: Microsoft Forefront Threat Management Gateway 2010 and Microsoft Forefront Unified Access Gateway 2010. Both options offer publishing wizards and security features to provide secure access to Exchange when it's accessed from outside the safety of the corporate network. For more information about Forefront Unified Access Gateway 2010 and Forefront Threat Management Gateway 2010, see Publishing Exchange Server 2010 with Forefront Unified Access Gateway 2010 and Forefront Threat Management Gateway 2010.

ISA Server 2006 and Exchange 2010

ISA Server 2006 and Exchange 2010 coexist and provide an increased level of security for your messaging environment. When you use the New Exchange Publishing Rule Wizard to configure your ISA Server computer to allow client access, you automatically configure ISA Server settings that are required for the features in both Exchange 2010 and ISA Server 2006 to work correctly.

Earlier Versions of ISA Server and Exchange 2010

When you deploy Exchange 2010, we recommend that you upgrade any earlier versions of ISA Server that you're using. Deploying Exchange 2010 in an environment that was configured to use an earlier version of ISA Server, such as ISA Server 2004, requires changes to any ISA Server rules you configured for client access.

When you configure ISA Server 2004 or ISA Server 2000, you'll have to create new server or Web publishing rules for the Client Access servers you want your users to access. The following table describes the virtual directories to use as paths for the Web and server publishing rules you must create for client access to Exchange when you use an earlier version of ISA Server than ISA Server 2006. Make sure that you use only the paths for the client applications you plan to use. For example, if you don't plan to use Microsoft Exchange ActiveSync, you don't have to publish the Microsoft-Server-ActiveSync virtual directory.

Exchange 2010 virtual directories used as paths in ISA Server publishing rules

Path Name	Description
/owa	This virtual directory is used by Outlook Web App to access mailboxes on Exchange 2007 or Exchange 2010 Mailbox servers.
/public	This virtual directory is used by Outlook Web App to access public folders for mailboxes that are located on computers running Exchange 2010, Microsoft Exchange Server 2007, Exchange Server 2003, or Exchange 2000 Server.
/exchweb	This virtual directory is used by Outlook Web App for mailboxes on computers running Exchange 2003 or Exchange 2000.
/ecp	This virtual directory is used by the Exchange Control Panel.
/exchange	This virtual directory is used by Outlook Web App to access mailboxes on computers running Exchange 2003 or Exchange 2000.
/UnifiedMessaging	This virtual directory is used for access to Unified Messaging.
/Microsoft-Server-ActiveSync	This virtual directory is used by ActiveSync in Exchange 2007 or Exchange 2010.
/EWS	This virtual directory is used for Exchange Web Services.
/Autodiscover	This virtual directory is used by the Autodiscover service for the Exchange ActiveSync and Outlook clients.
/rpc	This virtual directory is used by the Outlook Anywhere feature in Outlook 2007 or Exchange 2010.

1.6.1.18 Understanding Load Balancing in Exchange 2010

Understanding Load Balancing in Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-29*

Load balancing is a way to manage which of your servers receive traffic. Load balancing provides failover redundancy to ensure your users continue to receive Exchange service in case of computer failure. It also enables your deployment to handle more traffic than one server can process while offering a single host name for your clients.

In addition to load balancing, Microsoft Exchange Server 2010 provides several solutions for switchover and failover redundancy. These solutions include the following:

- **High availability and site resilience** You can deploy two Active Directory sites in separate geographic locations, keep the mailbox data synchronized between the two, and have one of the sites take on the entire load if the other fails. Exchange 2010 uses database availability groups (DAGs) to keep multiple copies of your mailboxes on different servers synchronized.
- **Online mailbox moves** In an online mailbox move, end users can access their e-mail accounts during the move. Users are only locked out of their accounts for a brief time at the end of the process, when the final synchronization occurs. Online mailbox moves are supported between Exchange 2010 databases and between Exchange Server 2007 Service Pack 3 (SP3) or a later version of Exchange 2007 and Exchange 2010 databases. You can perform online mailbox moves across forests or in the same forest.
- **Shadow redundancy** Shadow redundancy protects the availability and recoverability of messages while they're in transit. With shadow redundancy, the deletion of a message from the transport databases is delayed until the transport server verifies that all the next hops for that message have completed. If any of the next hops fail before reporting successful delivery, the message is resubmitted for delivery to the hop that didn't complete.

Contents

Overview of Load Balancing

Load balancing serves two primary purposes. It reduces the impact of a single Client Access server failure within one of your Active Directory sites. In addition, load balancing ensures that the load on your Client Access server and Hub Transport computers is evenly distributed.

Architectural Changes in Exchange 2010 Load Balancing

Several changes in Exchange 2010 make load balancing important for your organization. The Exchange RPC Client Access service and the Exchange Address Book service on the Client Access server role improve the user's experience during Mailbox failovers by moving the connection endpoints for mailbox access from Outlook and other MAPI clients to the Client Access server role instead of to the Mailbox server role. In earlier versions of Exchange, Outlook connected directly to the Mailbox server hosting the user's mailbox, and directory connections were either proxied through the Mailbox server role or referred directly to a particular Active Directory global catalog server. Now that these connections are handled by the Client Access server role, both external and internal Outlook connections must be load balanced across the array of Client Access servers in a deployment to achieve fault tolerance.

A load-balanced array of Client Access servers is recommended for each Active Directory site and for each version of Exchange. It isn't possible to share one load-balanced array of Client Access servers for multiple Active Directory sites or to mix different versions of Exchange or service pack versions of Exchange within the same array.

When you install Exchange 2010 within your existing organization and configure a legacy namespace for coexistence with previous versions of Exchange, your clients will

automatically connect to the Exchange 2010 Client Access server or server array. The Exchange 2010 Client Access server or Client Access server array will then proxy or redirect client requests for mailboxes on older Exchange versions to either Exchange 2003 front-end servers or Exchange 2007 Client Access servers that match the mailbox version. For more information, see Understanding Upgrade to Exchange 2010.

Note:
You can mix Quick Fix Engineering (QFEs) and update rollups when you apply them to all or parts of an array. We recommend that you apply QFEs and update rollups to all computers within an array.

Your load balancing configuration will have a direct effect on the host names that your clients use to connect and the Secure Sockets Layer (SSL) certificates that you use. For more information about Exchange 2010 certificates, see Understanding Digital Certificates and SSL.

Configuring the Client Access Server Array

You can configure one Client Access server array per Active Directory site. As soon as the Client Access server array has been configured, you can configure the Mailbox database to use the Client Access server array as the MAPI endpoint instead of a specific Client Access server.

For more information about the Client Access server array and how to configure the Mailbox database to use the Client Access server array for the specific Active Directory site, see Understanding RPC Client Access.

Understanding Exchange 2010 Traffic Loads

Before you configure load balancing, you should understand the loads that are placed on an Exchange 2010 Client Access server. An Exchange 2010 Client Access server receives the following three types of traffic:

- Traffic from external clients
- Traffic from internal clients
- Proxy traffic from other Client Access servers

Proxy traffic from other Client Access servers is traffic that is originally sent by an external or internal client to one Client Access server but is then proxied to another Client Access server. This can happen for several reasons, but generally it happens because the originating client can't connect directly to the destination Client Access server. This can occur when a user is trying to access a mailbox from the Internet, but the mailbox is located in a non-Internet facing Active Directory site. For more information about proxying, see Understanding Proxying and Redirection.

Each of the types of traffic received by Client Access servers includes requests from a list of protocols and comes from client devices and computers with different characteristics. These differences affect which load balancing strategies can be used.

Return to top

Understanding Load Balancing Options

There are several key technology differences between the different load balancing solutions.

- **Performance** How many requests per second can the solution handle?
- **Manageability** How simple is it to configure and deploy the load balancing

solution?

- **Failover automation and detection** How smart is the load balancer about detecting when a Client Access server or service has failed?
- **Affinity** Which types of client to Client Access server affinity does the load balancing solution support?

Understanding Affinity

When a load balancing solution provides client-to-Client Access server affinity, it means that there is a long-standing association between a particular client and a particular Client Access server. The client can be Outlook running on a laptop, Microsoft Exchange ActiveSync running on a mobile device, Microsoft Office Outlook Web App, Exchange Web Services, or another client application.

This long-standing association, or affinity, ensures that all requests sent from the client go to the same Client Access server. Some Exchange 2010 protocols require affinity and other Exchange protocols do not.

Windows Network Load Balancing

Windows Network Load Balancing (WNLB) is the most common software load balancer used for Exchange servers. There are several limitations associated with deploying WNLB with Microsoft Exchange.

- WNLB can't be used on Exchange servers where mailbox DAGs are also being used because WNLB is incompatible with Windows failover clustering. If you're using an Exchange 2010 DAG and you want to use WNLB, you need to have the Client Access server role and the Mailbox server role running on separate servers.
- Due to performance issues, we don't recommend putting more than eight Client Access servers in an array that's load balanced by WNLB.
- WNLB doesn't detect service outages. WNLB only detects server outages by IP address. This means if a particular Web service, such as Outlook Web App, fails, but the server is still functioning, WNLB won’t detect the failure and will still route requests to that Client Access server. Manual intervention is required to remove the Client Access server experiencing the outage from the load balancing pool.
- WNLB configuration can result in port flooding, which can overwhelm networks.
- Because WNLB only performs client affinity using the source IP address, it's not an effective solution when the source IP pool is small. This can occur when the source IP pool is from a remote network subnet or when your organization is using network address translation.

Load Balancing Recommendations

There are several load balancing options available. The option you use depends on the size and configuration of your network.

Windows Network Load Balancing with Source IP Affinity

The first load balancing option is WNLB with source IP affinity. This solution is suitable if you have more than one Client Access server per Active Directory site but fewer than eight. This solution is built into Windows and doesn't require additional computers.

There are two scenarios in which you will not want to use WNLB.

- Your organization has a reverse proxy server that communicates directly with the Client Access server and not through the WNLB virtual IP address. The reverse proxy server hides the client IP addresses from the Client Access server array. Therefore, source IP affinity won't work as expected. However you may still want to use WNLB to load balance internal traffic.
- Your organization has many clients accessing your Client Access servers through a very small set of IP addresses. WNLB tends to affinitize an entire class C subnet to one Client Access server.

Hardware Load Balancing

If you have more than eight Client Access servers in a single Active Directory site, your organization will need a more robust load balancing solution. Although there are robust software load balancing solutions available, a hardware load balancing solution provides the most capacity. For more information about Exchange 2010 server load balancing solutions, see Microsoft Unified Communications Hardware Load Balancer Deployment.

Hardware load balancers support very high traffic throughput and can be configured to load balance in many ways. Most hardware load balancer vendors have detailed documentation about how their product works with Exchange 2010. The simplest way to configure hardware load balancers is to create a fallback list of the affinity methods that will be applied by the load balancer. For example, the load balancer will try cookie-based affinity first, then SSL session ID, and then source IP affinity.

Reverse Proxy Solutions

If you have a reverse proxy solution that can perform load balancing for the servers it publishes to the Internet, such as Microsoft Forefront Threat Management Gateway (TMG) or Forefront Unified Access Gateway (UAG), we recommend that you use it.

As traffic passes through the reverse proxy server to reach your Client Access servers, the client's original IP address is replaced by the IP address of the reverse proxy server. This breaks source IP affinity. There are ways to resolve this problem, including configuring the reverse proxy server to be the default gateway for the subnet it is proxying to.

However, most current reverse proxy servers can do load balancing for the services they publish to the Internet. These reverse proxy servers support load balancer-created cookie load balancing for the Exchange services that support this. This solution is more reliable than source IP load balancing. For this to work, the reverse proxy server must be able to read and modify the HTTP data stream. If you're using SSL, this means that the reverse proxy server must decrypt the traffic to read the contents and create the cookie within the stream. This decryption isn't possible in some circumstances, such as when you're using client certificate authentication, where the client connects to the Client Access server.

Return to top

Affinity Options

Different load balancing solutions offer different methods for associating clients with a specific Client Access server. There are several common types of affinity available in different load balancing products, both hardware and software. Not all types of affinity will be available in every load balancing option, as described in the following examples:

- WNLB only supports source IP affinity or no affinity.
- A software load balancer in a separate server array can use load balancer-created cookies for the protocols that support those cookies and source IP affinity for the remaining protocols.
- Hardware load balancers with SSL offloading let you configure more complex behavior. For example, you can configure a set of existing cookies that will take effect for protocols that support those cookies, as well as a load balancer-created cookie, SSL session ID, and source IP.

In addition to the options that are supported by the different load balancing solutions, you can also configure some of these steps to be applied only for certain Exchange protocols and services. Because each protocol behaves differently, this can help optimize performance.

Existing Cookies or HTTP Headers

Using existing cookies or HTTP headers is the most reliable way to identify a client and associate it with a specific Client Access server. These cookies and headers are created by the client or server as part of the communications protocol. This option also doesn't require the load balancer to modify the traffic, which helps performance.

When you use this affinity option, be aware of the following:

- Your load balancer must support this type of affinity. Currently only hardware load balancers support this affinity.
- This affinity only works for protocols that pass traffic on HTTP.
- There must be an existing cookie or header that remains constant during the client session and is unique to each specific client, or small set of clients, in the protocol.
- The load balancer solution must be able to read and interpret the HTTP data stream. If you're using SSL, this means that the load balancer must decrypt the traffic to read the contents. Sometimes this results in an increased load on the load balancer. Also, this decryption isn't possible in some circumstances, such as when you use client certificate authentication with the SSL session where the client connects to the Client Access server.

The existing cookies and HTTP headers suitable for load balancing that are available in Exchange 2010 protocols are the following:

- **HTTP Basic authentication authorization header** This header works when HTTP Basic authentication is used. Basic authentication is the default and most commonly used type of authentication for Exchange ActiveSync. This header is uncommon for other protocols and authentication methods. The Basic authentication authorization header sends all traffic that uses Basic authentication and that is from a specific user to the same Client Access server. This header is also used when Outlook traffic is transmitted completely via HTTP and clients are behind a reverse proxy server.
- **HTTP OWA UserContext cookie** This cookie works for Outlook Web App, which is the only client that uses it. When you use forms-based authentication (FBA) with Outlook Web App, which is the default configuration, a small set of requests are made at the start of an Outlook Web App session before the *UserContext* cookie is created. To ensure that those requests use affinity to connect the client to the same Client Access server, which is required for forms-based authentication to work, there has to be a fallback affinity option when you use the *UserContext* cookie. We recommend that you use the SSL session ID or source IP affinity as a fallback to provide affinity for those initial requests, before the load balancer gets the *UserContext* cookie to use.

  Note:

  Outlook Web App requests that use explicit logon to access a specific mailbox result in the use of a *UserContext* cookie with a different name and ID. The cookie starts with *UserContext*, but a string that identifies the individual mailbox is appended. This complicates load balancing with the *UserContext* cookie because the load balancer must first find a cookie starting with *UserContext*. This can result in decreased performance.

- **HTTP Exchange Control Panel msExchEcpCanary cookie** This cookie only works for the Exchange Control Panel.
- **HTTP Outlook 2010 OutlookSession cookie** Hardware load balancers support the OutlookSession cookie and other generic cookies. The following table describes the OutlookSession client cookie support requirements for Outlook RPC/HTTP:

	Windows XP	**Windows Vista**	**Windows 7**
Outlook 2003	Not supported	Not supported	Not supported
Outlook 2007	Not supported	Not supported	Not supported
Outlook 2007 Hosting Pack	Not supported	Supported	Supported

(KB2544404)			
Outlook 2010	Not supported	Supported	Supported

Note:
Microsoft Outlook running on Windows XP does not support the OutlookSession cookie for load balancing. In this scenario, we recommend that you use IP load balancing.

- **HTTP Remote PowerShell MS-WSMAN cookie** This method works only for Remote PowerShell.

Return to top

Load Balancer Created Cookie

The second most reliable way to associate a client session with a Client Access server is by using a load balancer-created cookie. The load balancer adds an HTTP cookie to the client/server protocol conversation and then uses that cookie to determine which Client Access server should handle an incoming request. The Exchange 2010 applications that support this method are Outlook Web App, Exchange Control Panel, and Remote PowerShell. This type of cookie has several limitations.

- The load balancer must support this type of affinity. Currently only hardware load balancers and software load balancers that run on a separate server tier support this affinity.
- This method only works for protocols that pass traffic on HTTP. You can't use this method for the RPC Client Access service, Exchange Address Book service, POP3, or IMAP4.
- The load balancer solution must be able to read and interpret the HTTP data stream. If you're using SSL, this means that the load balancer must decrypt the traffic to read the contents. Sometimes this results in a bigger load on the load balancer. In other cases, it isn't possible for the load balancer to interpret the HTTP data stream, such as when you use client certificate authentication on the Client Access server.
- The client must be able to receive arbitrary cookies from the server and must then include those cookies in all future requests sent from the client to the server. Exchange ActiveSync clients, Outlook Anywhere clients, and some Exchange Web Service clients such as Microsoft Office Communications Server 2007 devices don't support this.

SSL Session ID

Load balancing based on the SSL session ID provides more detail than source IP affinity and lets you split up traffic from different clients even if those clients are coming in from the same IP address. SSL session ID load balancing also has the advantage of letting you load balance without decrypting the SSL traffic. This is required when you use client certificate authentication and when you end the SSL connection at the Client Access server.

SSL session ID affinity isn't recommended in the following two situations:

- Some clients, such as Internet Explorer 8, re-create their SSL session for each browser process that runs on the client computer. This results in a new SSL session for each Outlook Web App window. Because this breaks client affinity for Outlook Web App, deploying load balancing in this manner is not supported for Exchange 2010. Some mobile devices, such as the Apple iPhone, also create new SSL sessions for some parts of their Exchange ActiveSync communication with Exchange.

Note:
When you use client certificate authentication, browsers will use the same SSL session for all traffic to a given host name. As long as client certificate authentication is enabled, SSL session ID is a valid affinity option for Outlook Web App and Exchange Control Panel.

- In the case of Outlook Anywhere, the Client Access servers will use the Windows RPC Proxy component to pair up the RPC_DATA_IN and the RPC_DATA_OUT connections. This can adversely affect performance.

Source IP

The most common way to provide affinity between clients and Client Access servers is by using source IP affinity. The load balancer examines a client's IP address and sends all traffic from a specific source IP to a specific Client Access server. This is the only type of affinity supported by WNLB. There are two important aspects to consider when you use source IP affinity.

- Affinity breaks when the client changes IP address. This can occur when a laptop is moved from a wired LAN to Wi-Fi or roams between different Wi-Fi networks. There is a user impact when the client changes IP address. For example, when they're using Outlook Web App, users will have to authenticate every time their computer obtains a new IP address.
- If many of your clients access your load balancing solution from the same IP address, the load distribution will become uneven. The impact of this depends on how many clients are masked behind a given IP address. For example, if you have four Client Access servers and 50 percent of your clients access your load balancer from the same IP address, at least 50 percent of your traffic will go to one Client Access server and the other three Client Access servers will handle the rest of the traffic. There are two main reasons why most clients will access your Exchange organization through a single IP address.
  - Network address translators (NATs) or outgoing proxy servers, such as Microsoft Forefront Threat Management Gateway (TMG). When there is a NAT or outgoing proxy server between your clients and your Client Access servers, the original client IP addresses are masked by the NAT or outgoing proxy server IP address.
  - Client Access server to Client Access server proxy traffic. In some scenarios, one Client Access server proxies traffic to another Client Access server. Typically, this happens between Active Directory sites because a client must access the Client Access server within the same Active Directory site as their mailbox. For more information about proxying, see Understanding Proxying and Redirection.

No Affinity

The last type of affinity is no affinity. When you don't use affinity, each request from a client is assigned to a random Client Access server. We don't recommend this option for protocols that require affinity or those that experience performance benefits from affinity.

It's recommended that you not use affinity for protocols that don't need affinity when SSL offloading is configured.

Return to top

Summary of Load Balancing Options

The following table provides a summary of the load balancing options that are available.

Solution	Client to Client Access server affinity	Failover method	Capacity	Cost
Hardware load balancer	Depending on the protocol and the client, fall back between the following: • Existing cookie • Load balancer-created cookie • SSL ID • Source IP	Automatic failover with minimal client downtime. Hardware load balancers also are able to provide failover for a	++++	$$$

		specific protocol.		
Software load balancer in a separate server layer Note: TMG and UAG are the only workable solutions for external traffic.	Either load balancer-created cookie or source IP, depending on the protocol and client.	Automatic failover with minimal client downtime.	++	$$
Software load balancer in the same server layer as the Client Access server (WNLB)	Source IP.	Automatic failover with minimal client downtime.	+	$
DNS round robin	Each client gets a random Client Access server IP address.	Manual steps to detect issues and recover. Browser and operating system DNS caching behavior may inhibit client connections even after recovery has been performed by an administrator. This solution breaks affinity for many protocols, including RPC Client Access, Outlook Web App, Exchange Web Services, and Exchange Control Panel.	+++	$
No load balancer	Separate host names are manually assigned for each Client Access server.	Manual steps to detect issues and failover. Client DNS caches cause slow failover.	+	N/A

There are several advantages and disadvantages to each of these options.

- Hardware load balancers usually include performance and security functionality such as SSL offloading and traffic inspection.
- Software load balancers in a separate server layer are usually included as parts of larger software packages, with reverse proxy capabilities like pre-authentication, SSL offloading, and extensive traffic inspection. When software load balancers pre-authenticate users, those users don't need to re-authenticate if the Client Access server they are affinitized to fails. However, some software load balancers require an affinity between the client and the reverse proxy server. In this case, you need an additional load balancing layer in front of the reverse proxy servers before those reverse proxy servers can perform load balancing duties for your Client Access servers.

1.6.1.18.1 Load Balancing Requirements of Exchange Protocols

Load Balancing Requirements of Exchange Protocols

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-02*

Microsoft Exchange protocols and client access services have different load balancing requirements. Some Microsoft Exchange protocols and client access services require client to Client Access server affinity. Others will work without it but will display performance improvements from such affinity. Other Exchange protocols don't require client to Client Access server affinity and performance doesn't decrease without affinity.

Contents

Exchange Protocols That Require Client to Client Access Server Affinity

The following Exchange protocols require client to Client Access server affinity. Affinity must last during a client session.

- **Outlook Web App and the Exchange Control Panel** Microsoft Office Outlook Web App and the Exchange Control Panel both require client to Client Access server affinity. When you use forms-based authentication, which is the default in Microsoft Exchange Server 2010, both Outlook Web App and the Exchange Control Panel must be affinitized to the same Client Access server. This is because they share the same authentication cookie and this cookie can only be decrypted by one specific Client Access server.
- **Exchange Web Services** Only a subset of Exchange Web Services requires affinity. Availability Service requests don't require affinity, but subscriptions do. All aspects of Exchange Web Services experience performance enhancements from affinity. An affinity timeout value of 45 minutes is recommended for

Exchange Web Services clients to ensure that periodic polling for events associated with a subscription are not directed to a new Client Access server resulting in inefficient new subscriptions for each request. We don't support the use of Exchange Web Services without affinity.

- **Outlook RPC over TCP on the Intranet** Outlook clients on the Intranet assume that all RPC connections are made to the same server. Outlook uses multiple sessions per user and assumes that all sessions connect to the same server.

Exchange Protocols That Benefit From Client to Client Access Server Affinity

The following Exchange protocols and services will work without affinity. However, performance is significantly reduced when they're deployed without affinity.

- **Outlook Anywhere** Outlook Anywhere connections are unidirectional and split a single RPC data connection into two HTTP connections. One connection is for incoming data and one is for outgoing data. When there's no affinity between these two types of connections, Outlook Anywhere tries to correlate the connections by coordinating with other members of the Client Access server array. This increases traffic between Client Access servers by about 50% for a two-server array and up to 100% for an array with a large number of servers.
- **Exchange ActiveSync** Microsoft Exchange ActiveSync transmits new mail notifications to clients through a long-standing HTTPS request from the client to the server. When an Exchange ActiveSync client is assigned to a new Client Access server, that server must re-create the notification subscription against the user's mailbox. This results in a significant performance penalty.
- **Exchange Address Book service** This is a new service in Exchange 2010 that provides directory access for clients. Not using affinity results in a significantly higher level of communication between the client and the Client Access servers.
- **Remote PowerShell** Without affinity, users will need to reauthenticate if a connection is interrupted.

Exchange Protocols That Don't Require Affinity

There are several Exchange protocols and services that don't require affinity because they're transactional. This means that the connection is established, the transaction is completed, and the connection is closed. These protocols don't experience performance benefits from affinity.

- Offline address book
- Autodiscover service
- POP3
- IMAP4

Understanding IP Ports

Most Exchange 2010 services are built on top of HTTP and use port 443 for Secure Sockets Layer (SSL) access and port 80 for non-SSL access. Outlook Web App, Exchange ActiveSync, Outlook Anywhere, and Exchange Web Services are such services. POP3 and IMAP4 use ports 110 and 143 respectively when not encrypted with SSL and ports 995 and 993 respectively when encrypted with SSL.

Other Exchange services, such as the RPC Client Access service and the Exchange Address Book service, are RPC services. When an Outlook client connects directly to the

Client Access server using these protocols, instead of using Outlook Anywhere, the endpoint TCP ports for these services are allocated by the RPC endpoint manager. Allocation occurs when the services are started. This requires a large range of destination ports to be configured for load balancing without the ability to specifically target traffic for these services based on port number. You can statically map these services to specific port numbers to simplify load balancing. If the ports for these services are statically mapped, the traffic will be restricted to port 135 and the two specific ports that were selected for these services.

Configuring Static Port Mapping for RPC-Based Services

The static port for the RPC Client Access service is configured in the registry. The following registry key should be configured on each Client Access server. Set the key to the value of the port that you want to use for TCP connections to the RPC Client Access service.

```
Key: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchangeRPC\Parameter
Value: TCP/IP Port
Type: DWORD
```

Note:

This change will only affect internal connections via TCP and won't affect Outlook Anywhere connections that use RPC/HTTP tunneling. Outlook Anywhere connections to the RPC Client Access service occur on port 6001. This isn't configurable.

This process should also be performed on any public folder servers in your organization.

In Exchange 2010 SP1, the static ports for the two RPC endpoints maintained by the Exchange Address Book service are configured in the registry. Use the following registry key to configure these endpoints.

```
Key: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchangeAB\Parameters
Value: RpcTcpPort
Type: REG_SZ (String)
```

Warning:

When you apply Exchange 2010 SP1 to a machine that previously had the static ports configured by editing the Microsoft.Exchange.AddressBook.Service.Exe.config file, the upgrade process will not recognize the static ports configured in the file. If you are planning to deploy Exchange 2010 SP1, we recommend you create the registry key before you install Exchange 2010 SP1. The registry key has no impact prior to SP1, so configuring it before installation can prevent service interruptions.

1.6.1.19 Understanding the Remote Connectivity Analyzer

Understanding the Remote Connectivity Analyzer

Exchange Server 2010 > Client Access > Understanding Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-22*

The Microsoft Exchange Remote Connectivity Analyzer (ExRCA) can help you confirm that connectivity for your Exchange servers is configured correctly and diagnose any connectivity issues. The Remote Connectivity Analyzer Web site offers tests for Microsoft Exchange ActiveSync, Exchange Web Services, Microsoft Office Outlook, and Internet e-mail.

Remote Connectivity Analyzer Tests

There are several tests that you can perform with the ExRCA. These tests work on Exchange Server 2003 Service Pack 2 and later versions.

The Remote Connectivity Analyzer performs tests for the following:

- Exchange ActiveSync
- Exchange Web Services
- Outlook
- Internet e-mail

Exchange ActiveSync Tests

There are two tests that you can run for Exchange ActiveSync, as follows:

- **Exchange ActiveSync** This test simulates the steps that a mobile device uses to connect to the Exchange server. It performs a full synchronization against a mailbox when you enter an e-mail address, user name, and password.
- **Exchange ActiveSync Autodiscover** This test doesn't perform a full synchronization. It validates the Autodiscover service settings for Exchange ActiveSync.

Exchange Web Services Tests

The Exchange Web Services tests validate settings for many of the Exchange Web Services. To troubleshoot external access to Exchange from Entourage, Web Services Edition, use the following tests:

- **Synchronization, Notification, Availability, and Automatic Replies (OOF**) This test determines whether programs that have to access this information can connect correctly. The test runs against a specific mailbox. To perform this test, the Inbox of the account that's used must be empty.
- **Service Account Access** This test determines whether developer connections to Exchange Web Services are configured correctly. The test verifies that a service account can access a mailbox, create and delete items in that mailbox, and access it through Exchange Impersonation.

Outlook Tests

To validate settings for connectivity to Outlook, use the following tests:

- **Outlook Anywhere (RPC over HTTP)** This test validates the connectivity for Outlook Anywhere for a specific mailbox. You can use the Autodiscover service to validate these settings or manually specify the server settings.
- **Outlook Autodiscover** This test verifies that the Autodiscover service is configured correctly for Outlook Anywhere. This test doesn't actually connect to a mailbox.

Internet E-Mail Tests

There are two Internet e-mail tests that you can run using the ExRCA, as follows:

- **Inbound SMTP E-Mail** This test confirms that you can receive an inbound SMTP message at a specified e-mail address.
- **Outbound SMTP E-Mail** This test checks your outbound IP address settings for Reverse DNS, Sender ID, and RBL checks.

1.6.1.20 Exchange 2010 and BlackBerry Enterprise Server Coexistence

Exchange 2010 and BlackBerry Enterprise Server Coexistence

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-08*

If you have BlackBerry devices in your organization and use a server running BlackBerry Enterprise Server to handle the communication between those devices and Microsoft Exchange Server 2010, there are specific updates that must be made to address known compatibility and performance issues.

Updates required for BlackBerry Enterprise Server and Exchange 2010

For Exchange 2010 and BlackBerry Enterprise Server to function together successfully, we recommend the following:

- Install the Microsoft Exchange Server MAPI Client and Collaboration Data Objects 1.2.1 update on the machines running BlackBerry Enterprise Server.
- Install the 5.0.2 Maintenance Release 4 of Blackberry Enterprise Server.
  - Download service packs and maintenance releases for BlackBerry Enterprise Server v5.0.
- Install the latest rollup for Exchange Server 2010 Service Pack 1 (SP1) on all of your Exchange 2010 Client Access servers and Mailbox servers or ensure that your Exchange 2010 Client Access servers and Mailbox servers have been upgraded to Exchange 2010 Service Pack 2 (SP2). Refer to Install the Latest Update Rollup for Exchange 2010 for more information about how to deploy the update rollup successfully.
- Install the following Windows Kernel Memory Manager hotfixes:
  - A computer that is running Windows 7 or Windows Server 2008 R2 becomes unresponsive when you run a large application
  - Poor performance occurs on a computer that has NUMA-based processors and that is running Windows Server 2008 R2 or Windows 7 if a thread requests lots of memory that is within the first 4 GB of memory

1.6.2 Managing Client Access Servers

1.6.2.1 Services Used by a Client Access Server

Services Used by a Client Access Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-20*

This topic describes the services used by a computer running Microsoft Exchange Server 2010 that has the Client Access server role installed. Depending on the protocols that are made available on the Client Access server and the Client Access method or methods used to access the Client Access server, some or all the following Exchange services may be required.

Enabling Services

To enable services used by a Client Access server, use the Services snap-in in the Microsoft Management Console (MMC). The following table shows the Exchange services that may be required.

Services that may be required by a Client Access server

Service name	Display name	Comments
W3SVC	World Wide Web Publishing Service	This service is required and must be started.
MSExchangeADTopology	Microsoft Exchange Active Directory Topology Service	This service provides Active Directory topology information to several Exchange Server components. This service doesn't have any dependencies.
POP3Svc	Microsoft Exchange POP3	By default, this service is stopped. For clients to use POP3 to connect to Microsoft Exchange, this service must be started. This service

		depends on the Microsoft Exchange Active Directory Topology service.
IMAP4Svc	Microsoft Exchange IMAP4	By default, this service is stopped. For clients to use IMAP4 to connect to Microsoft Exchange, this service must be started. This service depends on the Microsoft Exchange Active Directory Topology service.
IISAdmin	Internet Information Services Admin Service	This service manages the Internet Information Services (IIS) metabase and provides support for the World Wide Web Publishing Service (W3SVC) service, the POP3 service, and the IMAP4 service. These services are required by the Client Access server. IIS Admin also supports other applications, such as the metabase update service, which is an internal component of the system attendant.
MSExchangeServiceHost	Microsoft Exchange Service Host	This service configures the /rpc virtual directory in IIS and registry data for Outlook Anywhere. This service depends on the Microsoft Exchange Active Directory Topology service.
MSExchangeFDS	Microsoft Exchange File Distribution Service	This service is used to distribute offline address book and custom Unified Messaging prompts. This service depends on the Microsoft Exchange Active Directory Topology service.

Topic Last Modified: *2012-07-23*

You can use the Shell to create a Microsoft Office Outlook Web App virtual directory in Microsoft Exchange Server 2010.

By default, when Exchange 2010 is installed, a new virtual directory named "owa" is created in the default Web site in Internet Information Services (IIS). Alternatively, when you run the **New-OWAVirtualDirectory** cmdlet in the Shell, a new virtual directory named "owa" is created in the default IIS Web site on the local Exchange 2010 server.

To create a new Outlook Web App virtual directory, the following conditions must be true:

- The local Exchange 2010 server has the Client Access server role installed.
- There is a default IIS Web site, for example, */w3svc/1/root*.
- An Outlook Web App virtual directory named "owa" doesn't already exist.

If you have to create a new virtual directory for Outlook Web App, make sure that users are aware of the changes you're making. You'll be interrupting mail flow for your users.

Important:

When the default owa virtual directory is created, both forms-based authentication and

Secure Sockets Layer (SSL) encryption are enabled. However, when you create a new virtual directory by using the **New-OWAVirtualDirectory** cmdlet, neither forms-based authentication or SSL encryption is enabled.

Looking for other management tasks related to Outlook Web App virtual directories? Check out Managing Outlook Web App Virtual Directories.

Use the Shell to create an Outlook Web App virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example creates a new Outlook Web App virtual directory under the contoso.com Web site.

```
New-OwaVirtualDirectory -Name "Contoso" -WebSite "Contoso.com"
```

For more information about syntax and parameters, see New-OwaVirtualDirectory.

Other Tasks

After you create an Outlook Web App virtual directory, you may also want to:

- View or Configure Outlook Web App Virtual Directories
- Remove an Outlook Web App Virtual Directory

1.6.2.2.1.2 View or Configure Outlook Web App Virtual Directories

View or Configure Outlook Web App Virtual Directories

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Virtual Directories >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the EMC or the Shell to view or configure the properties of an Outlook Web App virtual directory.

If you use the Shell to view the properties of an Outlook Web App virtual directory, the information returned is a subset of the information that's available. For example, if you use the **Get-OWAVirtualDirectory** cmdlet to view properties, Exchange returns the following information:

- Virtual directory name
- Server name
- Exchange server version

You can also retrieve information for a specific virtual directory on a specific server by using the available parameters. For more information about the **Get-OWAVirtualDirectory** cmdlet parameters, see Get-OwaVirtualDirectory.

If you use the EMC to view the properties of an Outlook Web App virtual directory, you'll be able to view a complete set of properties for the Exchange server that you're on.

Looking for other management tasks related to Outlook Web App? Check out Managing Outlook Web App.

What Do You Want to Do?

- Use the EMC to view or configure Outlook Web App virtual directory properties
- Use the Shell to configure Outlook Web App virtual directory properties
- Use the Shell to view Outlook Web App virtual directory properties

Use the EMC to view or configure Outlook Web App virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the result pane, click the server you want.
3. In the work pane, click the **Outlook Web App** tab, right-click the virtual directory that you want to view or modify, and then click **Properties**.

4. On the **General** tab, you can view the properties of the Outlook Web App default Web site and specify an external URL and an internal URL. View or select the following options:
   - **Server** (Read-only.) **Server** displays the name of the server that hosts the Outlook Web App virtual directory.
   - **Web site** (Read-only.) **Web site** displays the name of the Web site.
   - **Version** (Read-only.) **Version** displays the version of Exchange that the virtual directory supports.
   - **Modified** (Read-only.) **Modified** displays the last date and time that the virtual directory was modified.
   - **Internal URL** In this text box, specify the URL used to access this Web site from an internal network. An internal URL is configured automatically during Exchange 2010 Setup. The default internal URL setting for an Internet-facing or non-Internet-facing Client Access server is https://<Computer Name>/owa.
   - **External URL** In this text box, specify the URL used to access the Web site from the Internet. By default, **External URL** is blank. For Internet-facing Client Access servers, **External URL** should be set to the value published in DNS for that Active Directory site. For Client Access servers that don't have an Internet presence, the **External URL** setting should remain blank.

5. On the **Authentication** tab, specify authentication methods, sign-in format, and sign-in domain:
   - **Use one or more standard authentication methods** Select this option to use one or more of the following standard authentication methods:
     Integrated Windows authentication This method requires that users have a valid Windows Server 2008, Windows Server 2003, or Microsoft Windows 2000 Server user account name and password to access information. Users aren't prompted for their account names and passwords. Instead, the server negotiates with the Windows security packages installed on the client computer. Integrated Windows authentication enables the server to authenticate users without prompting them for

information and without transmitting information that isn't encrypted over the network. For this method to work, the client computer must be a member of the same domain as the servers running Exchange, or of a domain that's trusted by the domain that the Exchange server is in.

Digest authentication for Windows domain servers This method transmits passwords over the network as a hash value for additional security. Digest authentication can be used only in Windows Server 2008, Windows Server 2003, and Windows 2000 Server domains for users who have an account that's stored in Active Directory. For more information about Digest authentication, see the Windows Server documentation.

Basic authentication (password is sent in clear text) This method is a simple authentication mechanism defined by the HTTP specification that encodes a user's sign-in name and password before the user's credentials are sent to the server. To make sure that the password is as secure as possible, you should use Secure Sockets Layer (SSL) encryption between client computers and the server that has the Client Access server role installed.

- **Use forms-based authentication** Forms-based authentication provides enhanced security for Outlook Web App virtual directories located on Client Access servers.

  Forms-based authentication creates a sign-in page for Outlook Web App. You can configure the type of sign-in prompt used by forms-based authentication. For example, you can configure forms-based authentication to require users to provide their domain and user name information, in the domain\user name format on the Outlook Web App sign-in page.

  Important:

  Forms-based authentication won't provide a secure channel unless SSL is enabled.

  Complete the following:

  Domain\user name Requires the user to enter their domain and user name in the format domain\user name. For example, for a user named Kweku in the domain Contoso, the sign-in would be contoso\kweku.

  User principal name (UPN) If the user principal name (UPN) sign-in format is specified, the **User Name** field on the Outlook Web App sign-in page guides users to enter their e-mail address, for example, kweku@contoso.com. If a user's UPN isn't identical to the e-mail address, the user can't access Outlook Web App by using the **PrincipalName** sign-in prompt. It's a best practice to use the **PrincipalName** sign-in prompt only if users' UPNs match their e-mail addresses.

  User name only The user enters their user name only, without the domain name, for example, Kweku. If you use the **UserName** sign-in prompt for forms-based authentication, you must also specify the **DefaultDomain** property. The **DefaultDomain** property determines the default domain to use when a user tries to access Outlook Web App. For example, if the default domain is Contoso, and a domain user named Kweku signs in to Outlook Web App, only Kweku must be entered as the user name. The server will use the default domain Contoso. If the user isn't a member of the Contoso domain, the domain and user name must be entered.

6. On the **Segmentation** tab, specify the features that you want to enable or disable for Outlook Web App users on a virtual directory.

Note:
Segmentation settings for individual users override virtual directory settings. You can change segmentation settings for individual users by using the **Set-CASMailbox** cmdlet or by using Outlook Web App mailbox policies. For more information, see Managing Outlook Web App Mailbox Policies.

View or specify the following:

- **Enable** Select a disabled feature in the list, and then click **Enable** to enable that feature.
- **Disable** Select an enabled feature in the list, and then click **Disable** to disable that feature.
- **Feature** The **Feature** column shows the list of features that are potentially available to Outlook Web App users on a virtual directory.
- **Status** The **Status** column shows whether each feature is enabled or disabled.
- **Description** This section displays a description for the selected feature in the list.

7. On the **Public Computer File Access** tab, configure the file access and viewing options available if users select **This is a public computer** while they're signing in to Outlook Web App. File access lets a user open or view the contents of files attached to an e-mail message.
   Direct file access
   - **Enable direct file access** Select this check box if you want to enable direct file access. Direct file access lets users open files attached to e-mail messages.
   - **Customize** After you select **Enable direct file access**, click **Customize** to customize the direct file access settings.

     Note:
     The direct file access settings are applied to private and public computer file access. Even though the settings can be set from either the **Private Computer File Access** tab or the **Public Computer File Access** tab, you can't have different settings on the two tabs.

     In the **Direct File Access Settings** dialog box, specify how files will be allowed, blocked, or handled in Outlook Web App. The Allow list overrides the Block list and the Force Save list. The Block list overrides the Force Save list. Select the following:
     Allow Click the **Allow** button to specify which types of files should always be allowed. The Allow list overrides the Block list and Force Save list.
     Block Click the **Block** button to specify which types of files should be blocked. The Block list overrides the Force Save list and is overridden by the Allow list.
     Force Save Click the **Force Save** button to specify which types of files the user must save to disk before opening. The Force Save list is overridden by the Allow and Block lists.
     Unknown Files Using the **Unknown Files** list, specify how Outlook Web App handles unknown files that aren't in the Allow list, Block list, or Force Save list.
     When you click **Allow**, **Block**, or **Force Save**, a new window opens in which you can add file name extensions and MIME types to the list you have selected, edit them, or remove them.
     After you have selected **Allow**, **Block**, or **Force Save**:
     To add a file name extension or MIME type, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (**.**), for example, .exe.
     To edit a file name extension or MIME type, select it, and then click **Edit**.

To remove a file name extension or MIME type, select it, and then click **Remove**.
After you finish modifying the lists of file name extensions and MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.

WebReady Document Viewing

- **Enable WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a Web browser.

> **Note:**
> WebReady Document Viewing settings are available for public and private computer file access, and can be different for each.

- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a Web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if direct file access has been enabled.
- **Supported** After you select **Enable WebReady Document Viewing**, click **Supported** to select supported document types for **WebReady Document Viewing**.

Select document types to view from an Internet browser
To allow all supported document types to be viewed from an Internet browser, select **All supported document types**.
To allow only specific document types to be viewed, select **Specific document types**.
Add After you select **Specific document types**, click **Add** to add a document type to the list.
Remove After you select **Specific document types**, click the document type that you want to remove, and then click the remove icon.
Select the MIME types of documents Using this list, add the MIME types of documents to the list of types that can be viewed from an Internet browser or remove them from the list.
Add After you select **Specific document types**, click **Add** to add a MIME type to the list.
Remove After you select **Specific document types**, click the MIME type that you want to remove, and then click the remove icon.

8. On the **Private Computer File Access** tab, configure the file access and viewing options available if users select **This is a private computer** while they're signing in to Outlook Web App, or if users sign-in using an authentication method other than forms-based authentication. File access lets users open or view the contents of files attached to an e-mail message.

Direct file access

- **Enable direct file access** Select this check box if you want to enable direct file access. Direct file access lets users open files attached to e-mail messages.
- **Customize** After you select **Enable direct file access**, click **Customize** to customize the direct file access settings.

> **Note:**
> The settings for direct file access are divided into public computer file access settings and private computer file access settings. You can configure these settings on either the **Private Computer File Access** tab or the **Public Computer File Access** tab. However, you can't have different settings on the two tabs.

In the **Direct File Access Settings** dialog box, specify how files will be allowed, blocked, or handled in Outlook Web App. The

Allow list overrides the Block list and the Force Save list. The Block list overrides the Force Save list. Select the following:
Allow Click the **Allow** button to specify which types of files should always be allowed. The Allow list overrides the Block list and the Force Save list.
Block Click the **Block** button to specify which types of files should be blocked. The Block list overrides the Force Save list and is overridden by the Allow list.
Force Save Click the **Force Save** button to specify which types of files the user must save to disk before opening. The Force Save list is overridden by the Allow and Block lists.
Unknown Files Using the **Unknown Files** list, specify how Outlook Web App handles unknown files that aren't in the Allow list, Block list, or Force Save list.
When you click **Allow**, **Block**, or **Force Save**, a new window opens in which you can add file name extensions and MIME types to the list you have selected, edit them, or remove them.
After you have selected **Allow**, **Block**, or **Force Save**:
To add a file name extension or MIME type, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (**.**), for example, .exe.
To edit a file name extension or MIME type, select it, and then click **Edit**.
To remove a file name extension or MIME type, select it, and then click **Remove**.
After you finish modifying the lists of file name extensions and MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.

WebReady Document Viewing

- **Enable WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a Web browser.

  Note:
  WebReady Document Viewing settings are available for public and private computer file access, and can be different for each.

- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a Web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if direct file access has been enabled.
- **Supported** After you select **Enable WebReady Document Viewing**, click **Supported** to select supported document types for **WebReady Document Viewing**.

  Select document types to view from an Internet browser
  To allow all supported document types to be viewed from an Internet browser, select **All supported document types**.
  To allow only specific document types to be viewed, select **Specific document types**.
  Add After you select **Specific document types**, click **Add** to add a document type to the list.
  Remove After you select **Specific document types**, click the document type that you want to remove, and then click the remove icon.
  Select the MIME types of documents Using this list, add the MIME types of documents to the list of types that can be viewed from an Internet browser or remove them from the list.
  Add After you select **Specific document types**, click **Add** to add a MIME type to the list.
  Remove After you select **Specific document types**, click the

MIME type that you want to remove, and then click the remove icon.

9. On the **Remote File Servers** tab, specify remote file server access. Outlook Web App accesses only internal Windows file shares. A file name can also be specified by using a fully qualified domain name (FQDN) that's internal or that's included in the list of sites that are to be treated as internal. Outlook Web App uses a simple set of criteria to determine whether an address is internal or external. If there are no dots in a URL that a user clicks, it's treated as internal. If there are one or more dots in the URL, it's treated as internal only if the domain suffix has been added to the list of sites to be treated as internal. Specify the following:
   - **Block** Click this button to specify the host names of servers that aren't allowed to be accessed through Outlook Web App.

     In the **Block List** dialog box, specify the types of files and the MIME types that you want to block from Outlook Web App. The options that you specify in the Block list override the settings that you specify in the Force Save list but are overridden by the settings in the Allow list.

     Note:
     The settings for direct file access are divided into public computer file access settings and private computer file access settings. You can configure these settings on either the **Private Computer File Access** tab or the **Public Computer File Access** tab. However, you can't have different settings for each tab.

     Enter the file extensions you want to block, one at a time In this section, do the following:
     To add a file name extension, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (.), for example, .exe.
     To edit a file name extension, select it, and then click **Edit**.
     To remove a file name extension, select it, and then click **Remove**.
     After you finish modifying the lists of file name extensions, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.
     Enter the MIME types of files that are blocked In this section, do the following:
     To add a MIME type, enter it in the appropriate box, and then click **Add**.
     To edit a MIME type, select it, and then click **Edit**.
     To remove a MIME type, select it, and then click **Remove**.
     After you finish modifying the MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.
   - **Allow** Click this button to specify the host names of servers allowed to be accessed through Outlook Web App.

     In the **Allow List** dialog box, specify the types of files and the MIME types that you want to allow in Outlook Web App. The options that you specify in the Allow list override the settings that you specify in the Block list and Force Save list.

     Note:
     The settings for direct file access are divided into public computer file access settings and private computer file access settings. You can configure these settings on either the **Private Computer File Access** tab or the **Public Computer File Access** tab. However, you can't have different settings for each tab.

     Enter the file extensions you want to allow, one at a time In

this section, do the following:
To add a file name extension, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (.), for example, .exe.
To edit a file name extension, select it, and then click **Edit**.
To remove a file name extension, select it, and then click **Remove**.
After you finish modifying the lists of file name extensions, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.
Enter the MIME types of files that are allowed In this section, do the following:
To add a MIME type, enter it in the appropriate box, and then click **Add**.
To edit a MIME type, select it, and then click **Edit**.
To remove a MIME type, select it, and then click **Remove**.
After you finish modifying the MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.

- **Unknown Servers** Select **Allow** or **Block** in the **Unknown Servers** list to specify how to handle accessing files from servers that aren't in the Block and Allow lists.
- **Configure** Click this button to specify the domain suffixes of sites that are to be treated as internal. You can also add FQDNs to this list of addresses that are to be treated as internal.

Note:
When you add host names to the Block and Allow lists, you must enter a server name. Entering a Windows file share name won't work.

Use the Shell to configure Outlook Web App virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example enables forms-based authentication on the default Outlook Web App virtual directory on the server Contoso.

```
set-OwaVirtualDirectory -Identity "Contoso\owa (default web site)" -FormsAuthenti
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Use the Shell to view Outlook Web App virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example lets you view the properties for all Outlook Web App virtual directories in all Internet Information Services (IIS) Web sites on all computers that have the Client Access server role installed in an Exchange.

```
Get-OWAVirtualDirectory
```

This example lets you view the properties for an Outlook Web App virtual directory on the default IIS Web site on the local Exchange server.

```
Get-OWAVirtualDirectory -identity "<Exchange Server Name>\owa (default web site)"
```

This example lets you view the properties for all Outlook Web App virtual directories on an IIS Web site on a specific Exchange server.

```
Get-OWAVirtualDirectory -server <Exchange Server Name>
```

This example lets you view the values of the properties for every Outlook Web App virtual directory in all IIS Web sites on all Client Access servers in an Exchange organization.

```
Get-OWAVirtualDirectory | format-list
```

For more information about syntax and parameters, see Get-OwaVirtualDirectory.

1.6.2.2.1.3 Remove an Outlook Web App Virtual Directory

Remove an Outlook Web App Virtual Directory

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Virtual Directories >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to remove a Microsoft Office Outlook Web App virtual directory.

Don't use Internet Information Services (IIS) Manager to remove an Outlook Web App virtual directory. Using IIS Manager to do this may result in what's known as an "orphan" virtual directory. Instead, use the procedure in this topic. You can use the same procedure to remove orphan virtual directories.

If the last Outlook Web App virtual directory to be removed was an orphan virtual directory, you must manually remove the Outlook Web App ISAPI filter from the associated Web site. See the procedures in this topic for how to find orphan virtual directories, and manually remove them.

Looking for other management tasks related to Outlook Web App virtual directories? Check out Managing Outlook Web App Virtual Directories.

Use the Shell to remove an Outlook Web App virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example deletes a virtual directory named `Legacy` from a site named "`second Web site`" on the server named `Contoso`.

```
Remove-OwaVirtualDirectory -identity "Contoso\Legacy (second Web site)"
```

Use the Shell to find orphan virtual directories

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example finds any orphan virtual directories.

```
Get-OwaVirtualDirectory | ? { ![DirectoryServices.DirectoryEntry]::Exists($_.Meta
```

Use IIS Manager to remove the ISAPI filter when the last Outlook Web App virtual directory to be removed was an orphan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IIS Manager" entry in the Client Access Permissions topic.

1. Open IIS Manager.
2. Navigate to the Web site that hosted the Outlook Web App virtual directory, right-click the Web site name, and then click **Properties**.
3. Click the **ISAPI filters** tab.
4. Remove the *Exchange OWA Cookie Authentication ISAPI filter* entry.

For more information about syntax and parameters, see Remove-OwaVirtualDirectory.

Other Tasks

After you remove an Outlook Web App virtual directory, you may also want to:

- Create an Outlook Web App Virtual Directory
- View or Configure Outlook Web App Virtual Directories

1.6.2.2.1.4 Rename an Outlook Web App Web Site

Rename an Outlook Web App Web Site

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Virtual Directories >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Internet Information Services (IIS) and the Shell to rename a Microsoft Office Outlook Web App Web site.

Looking for other management tasks related to Outlook Web App virtual directories? Check out Managing Outlook Web App Virtual Directories.

Use the Shell and IIS to rename an Outlook Web App Web site

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" and "IIS Manager" entries in the Client Access Permissions topic.

Important:

Don't rename the Web site that's used by Microsoft Exchange ActiveSync.

1. Remove the Outlook Web App virtual directories that are associated with the Web site that you want to rename. For more information, see Remove an Outlook Web App Virtual Directory.
2. Open IIS Manager, locate the Web Sites/*<Web site to be renamed>* directory. Right-click *<Web site to be renamed>*, and then click **Rename**.
3. Enter the new name and press ENTER.
4. Create new Outlook Web App virtual directories to replace the virtual directories that were deleted in step 1. For more information, see Create an Outlook Web App Virtual Directory.
5. Open a command prompt, and then type `iisreset /noforce` to stop and start IIS.

For more information about syntax and parameters, see Remove-OwaVirtualDirectory and New-OwaVirtualDirectory.

1.6.2.2.2 Managing Outlook Web App URLs

Managing Outlook Web App URLs

Client Access > Managing Client Access Servers > Managing Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-22*

Enable Explicit Sign-in in Outlook Web App

Simplify the Outlook Web App URL

Configure Redirection for Outlook Web App

1.6.2.2.2.1 Enable Explicit Sign-in in Outlook Web App

Enable Explicit Sign-in in Outlook Web App

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App URLs >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use either the EMC or the Shell to grant access to a user to open another user's mailbox or a resource mailbox.

Explicit sign-in enables a user to open another user's mailbox or a resource mailbox by using Outlook Web App. To use this feature, the user must have Full Access permission to the mailbox to be opened. Full Access permission doesn't give the user Send As permission or Delegate access to the mailbox.

When explicit sign-in is used to open a resource mailbox in Outlook Web App, there will be a set of options available to manage that resource.

Looking for other management tasks related to Outlook Web App URLs? Check out Managing Outlook Web App URLs.

Use the EMC to grant Full Access permission to a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Right-click on the mailbox you want to grant access to, and then select **Manage Full Access Permission**.
3. Click **Add**, and then select the user or group you want to have Full Access permission to the mailbox. You can select multiple users or groups. Click **OK** after you've made your selection.
4. Click **Manage** to run the wizard.
5. Click **Finish** to close the wizard and return to the EMC.

Use the Shell to grant full access to a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

This example grants Full Access permission to the mailbox named `TestA` to the user named `TestB`.

```
Add-MailboxPermission -identity TestA -User TestB -AccessRights FullAccess
```

Open any mailbox from a URL

You must have Full Access permission for the mailbox that you want to open to perform this procedure.

1. Open a Web browser.
2. Enter the URL for your organization's Outlook Web App, and then add the SMTP address of the mailbox that you want to open to the end of the URL. For example, to open the mailbox `conferenceroom@contoso.com`, you would enter *<Outlook Web App URL>*`/conferenceroom@contoso.com`. A mailbox can have more than one SMTP address. You can use any of them to open the mailbox.
3. Sign in by using your user name and password.

Open another user's mailbox or a resource mailbox from Outlook Web App

You must have Full Access permission for the mailbox that you want to open to perform

this procedure.

1. Sign in to Outlook Web App.
2. At the top of the Outlook Web App window, click the drop-down arrow next to your mailbox name, and then click the **Open Other Mailbox** window.
3. Enter the name of the mailbox that you want to open, and then click **Open**.

Note:
To open another user's mailbox or a resource mailbox, your mailbox and the mailbox that you're opening must be Exchange 2010 mailboxes.

For more information about syntax and parameters, see Add-MailboxPermission.

1.6.2.2.2.2 Simplify the Outlook Web App URL

Simplify the Outlook Web App URL

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Internet Information Services (IIS) Manager to simplify the Microsoft Office Outlook Web App URL that users use to access their Microsoft Exchange Server 2010 mailbox.

The first procedure below configures a request that's sent to the root of the Web server (https://*server name*) to redirect to the Exchange virtual directory. For example, a request to https://*server*/ is directed to https://*server*/owa.

The second procedure redirects a request to http://*server* to https://*server*/owa. To help secure the information that's sent between the client and the server, the default Web site is set to require Secure Sockets Layer (SSL) at installation. To simplify access to Outlook Web App for your users, you may want to configure the Outlook Web App Web page, which is usually the default Web site in IIS, to automatically redirect users to https.

When you configure redirection from a top-level directory in Windows Server 2008, the settings are propagated to lower-level directories. For example, when you configure redirection on the Default Web Site to the /owa virtual directory, the settings that you configure also appear on the HTTP Redirect page of all the virtual directories, such as /Autodiscover, /Exchange, and /Public. Therefore, you must remove redirection from all the virtual directories except the one that you want redirected.

Looking for other management tasks related to Outlook Web App URLs? Check out Managing Outlook Web App URLs.

Use IIS Manager and Notepad to simplify the Outlook Web App URL when SSL isn't required

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IIS Manager" entry in the Client Access Permissions topic.

1. Start IIS Manager.
2. Expand the local computer, expand Sites, and then click **Default Web Site**.
3. At the bottom of the Default Web Site Home pane, click **Features View** if this

option isn't already selected.
4. In the IIS section, double-click **HTTP Redirect**.
5. Select the **Redirect requests to this destination** check box, and then type /owa.
6. Under **Redirect Behavior**, select the **Only redirect requests to content in this directory (not subdirectories)** check box.
7. In the Status code list, click **Found (302)**.
8. In the Actions pane, click **Apply**.
9. Close IIS Manager
10. Find the Outlook Web App Web.config file on the Client Access server. The default location is *<drive>*\Program Files\Microsoft\Exchange Server*<version>*\ClientAccess\Owa.
11. Make a backup copy of the file.
12. Open the original file using an editor such as Notepad. Don't use IIS Manager to edit the Web.config file.
13. Find *httpCookies httpOnlyCookies="false" requireSSL="true" domain=""* and change the requireSSL flag to false.
14. Save and close the file.

Note:
If Outlook Web App is configured for plain-text HTTP only for the purpose of SSL offloading, then this additional step of modifying the web.config file is not required.

15. For the new settings to take effect, open a Command Prompt window, and then type *iisreset /noforce* to restart IIS.

Note:
If SSL is required, you must redirect HTTP to HTTPS and then also redirect to the /owa virtual directory. If you don't do this, users will receive an error message when they try to access Outlook Web App without specifying the virtual directory. To do this, use the following procedure.

Use IIS Manager to simplify the Outlook Web App URL when SSL is required

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IIS Manager" entry in the Client Access Permissions topic.

1. Start IIS Manager.
2. Expand the local computer, expand Sites, and then click **Default Web Site**.
3. At the bottom of the Default Web Site Home pane, click **Features View** if this option isn't already selected.
4. In the **IIS** section, double-click **HTTP Redirect**.
5. Select the **Redirect requests to this destination** check box.
6. Type the absolute path of the /owa virtual directory. For example, type https://mail.contoso.com/owa.
7. Under **Redirect Behavior**, select the **Only redirect requests to content in this directory (not subdirectories)** check box.
8. In the **Status code** list, click **Found (302)**.
9. In the Actions pane, click **Apply**.
10. Click **Default Web Site**.
11. In the Default Web Site Home pane, click **SSL Settings**.
12. In SSL Settings, clear **Require SSL**.

Note:
If you don’t clear Require SSL, users won’t be redirected when they enter an unsecured URL. Instead, they’ll get an access denied error.

13. For the new settings to take effect, open a Command Prompt window, and then type *iisreset /noforce* to restart IIS.

Modify permissions on the Offline Address Book web.config file

After you've configured redirection for the Default Web Site, you have to edit the permissions on the Offline Address Book web.config file. If you don't complete this step, users won't be able to download the Offline Address Book when using Outlook.

1. Find the Offline Address Book Web.config file on the Client Access server. The default location is <*drive*>\Program Files\Microsoft\Exchange Server\<*version*>\ClientAccess\oab.
2. Right-click the file and click **Properties**.
3. Click the **Security** tab.
4. Click **Edit**.
5. Under **Group or user names**, select **Authenticated Users**. Under **Permissions for Authenticated Users**, click **Read & execute**.
6. Click **OK** twice to save your changes and close the properties window.

Use IIS Manager to remove redirection from a virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IIS Manager" entry in the Client Access Permissions topic.

To remove redirection from a virtual directory, perform the following steps:

1. Start IIS Manager.
2. Navigate to the virtual directory.
3. Double-click the **HTTP Redirect** icon in the **Features** view of the virtual directory.
4. Clear the **Redirect requests to this destination** check box.
5. In the Actions pane, click **Apply**.
6. For the new settings to take effect, open a Command Prompt window, and then type *iisreset /noforce* to restart IIS.

You may not be able to use the procedure above to remove redirection from a virtual directory that doesn't have a physical path, such as /Exchange, /Exchweb, or /Public. Use the following procedure to remove redirection from a virtual directory that doesn't appear in IIS Manager.

1. Open a command window
2. Navigate to <Window directory>\System32\Inetsrv
3. Run the following commands:

```
3.a.appcmd set config "Default Web Site/autodiscover" /
  section:httpredirect /enabled:false -commit:apphost
3.b.appcmd set config "Default Web Site/ecp" /
  section:httpredirect /enabled:false -commit:apphost
3.c.appcmd set config "Default Web Site/ews" /
  section:httpredirect /enabled:false -commit:apphost
3.d.appcmd set config "Default Web Site/owa" /
  section:httpredirect /enabled:false -commit:apphost
3.e.appcmd set config "Default Web Site/oab" /
  section:httpredirect /enabled:false -commit:apphost
3.f.appcmd set config "Default Web Site/powershell" /
  section:httpredirect /enabled:false -commit:apphost
3.g.appcmd set config "Default Web Site/rpc" /
  section:httpredirect /enabled:false -commit:apphost
3.h.appcmd set config "Default Web Site/rpcwithcert" /
  section:httpredirect /enabled:false -commit:apphost
3.i.appcmd set config "Default Web Site/Microsoft-Server-
```

```
ActiveSync" /section:httpredirect /enabled:false -
commit:apphost
```

4. Finish by running the command `iisreset/noforce`.

When you configure redirection from a top-level directory, a web.config file may be created under <*drive*>\Program Files\Microsoft\Exchange Server\<*version*>\ClientAccess\oab. If this has happened and you later remove redirection, Outlook 2007 and Outlook 2010 may freeze when users click **Send and Receive**. To avoid this happening after you remove redirection, delete the web.config file from <*drive*>\Program Files\Microsoft\Exchange Server\<*version*>\ClientAccess\oab.

Other Tasks

After you simplify the Outlook Web App URL, you may also want to Enable Explicit Sign-in in Outlook Web App.

1.6.2.2.2.3 Configure Redirection for Outlook Web App

Configure Redirection for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

In a Microsoft Exchange Server 2010 organization, Microsoft Office Outlook Web App is provided by a Client Access server. If you have multiple Active Directory sites that have Client Access servers that can be reached from the Internet, you can use redirection to route users to the Client Access server that will give them the best Outlook Web App experience. If you have multiple Client Access servers in different Active Directory sites in an organization, and only one is exposed to the Internet, you can use Client Access server-to-Client Access server proxying to direct users to the Client Access server that will give them the best Outlook Web App experience.

1.6.2.2.3 Managing File and Data Access for Outlook Web App

Managing File and Data Access for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-21*

Configure Public and Private Computer File Access

Configure WebReady Document Viewing

Configure Maximum Message Size in Outlook Web App

Configure Public and Private Computer File Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Direct file access lets users open files that are attached to e-mail messages and files that are stored in Windows file shares. You can manage direct file access for Microsoft Office Outlook Web App in Microsoft Exchange Server 2010 for both public and private computers.

By default, public computer direct file access is enabled for new installations and upgrades of Outlook Web App. Therefore, when users in your organization select **This is a public or shared computer** or **This is a private computer** on the Outlook Web App sign-in page, they will be able to access files that are attached to e-mail messages.

When you enable private or public computer file access for users, you can use the EMC to specify individual file types and MIME types. The following table lists the file name extensions and MIME types that, by default, are set to Allow, Block, or Force Save for the \owa virtual directory.

- **Allow** File and MIME types in the Allow list can be opened from Outlook Web App if the application that's needed to open the files is installed on the client computer. Allow overrides Block and Force Save.
- **Block** File and MIME types in the Block list can't be opened. Block overrides Force Save and is overridden by Allow.
- **Force Save** File and MIME types in the Force Save list must be saved to the client computer before they can be opened. Force Save is overridden by Allow and Block.

Note:

Although it appears that you can set the values for private and public computer access individually, you can't. When you specify behavior for private access, you also set it for public access.

Default file name extensions and MIME values for the Allow, Block, and Force Save settings for the \owa virtual directory

Option	Description	Default file name extensions	Default MIME types
Allow	This option specifies the file types that are always enabled for direct file access.	.rpmsg, .xlsx, .xlsm, .xlsb, .pptx, .pptm, .ppsx, .ppsm, .docx, .docm, .xls, .wmv, .wma, .wav, vsd, .txt, .tif, .rtf, .pub, .ppt, .png, .pdf, .one, .mp3, .jpeg, .gif, .doc, .bmp, .avi	image/jpeg, image/png, image/gif, image/bmp
Block	This option specifies the file types that are always blocked from direct file access.	.ade, .adp, .asx, .app, .asp, .aspx, .bas, .bat, .cer, .chm, .cmd, .com, .cpl, .crt, .csh, .dir, .dcr, .der, .exe, .fxp, .hlp, .hta, .inf, .ins, .isp	application/x-javascript, application/javascript, application/msaccess, x-internet-signup, text/javascript,

		, .its, .js, .jse, .ksh, .lnk, .mad, .maf, .mag, .mam, .maq, .mar, .mas, .mat, .mau, .mav, .maw, .mda, .mdb, .mde, .mdt, .mdw, .mdz, .msc,.msh, .msh1, .mshxml, .msh1xml, .msi, .msp,.mst, .ops, .pcd, .pif, .plg, .prf,.prg, .ps1, .ps2, .psc1, .psc2, .ps1xml, .ps2xml, .pst, .reg, .scf, .scr, .sct, .shb, .shs, .spl, .swf, .tmp, .url, .vb, .vbe, .vbs, .vsmacros, .vss, .vst, .vsw, .ws, .wsc, .wsf, .wsh, .xml	application/prg, application/hta, text/scriptlet
Force Save	This option specifies the files that users can access only after they've saved them to the local computer.	.vsmacros, .mshxml, .aspx, .xml, .wsh, .wsf, .wsc, .vsw, .vst, .vss, .vbs, .vbe, .url, .tmp, .swf, .spl, .shs, .shb, .sct, .scr, .scf, .reg, .pst, .prg, .prf, .plg, .pif, .pcd, .ops, .mst, .msp, .msi, .msh, .msc, .mdz, .mdw, .mdt, .mde, .mdb, .mda, .maw, .mav, .mau, .mat, .mas, .mar, .maq, .mam, .mag, .maf, .mad, .lnk, .ksh, .jse, .its, .isp, .ins, .inf, .hta, .hlp, .fxp, .exe, .dir, .dcr, .csh, .crt, .cpl, .com, .cmd, .chm, .cer, .bat, .bas, .asx, .asp, .app, .adp, .ade, .ws, .vb, .js	Application/x-shockwave-flash, Application/octet-stream, Application/futuresplash, Application/x-director, Application/xml, text/xml

There is also a default setting for unknown file types. You can set the setting for unknown file types to one of the following values:

- Allow
- Block
- Force Save

Note:

By default, attachment types that are marked as **Force Save** will be excluded from security checks for XML or HTML. You can change this behavior by setting the *ForceSaveAttachmentFilteringEnabled* parameter to `$true` by using either the Set-OwaMailboxPolicy or the Set-OwaVirtualDirectory cmdlet.

Looking for other management tasks related to accessing files from Outlook Web App? Check out Managing File and Data Access for Outlook Web App.

Use the EMC to configure direct file access

policy settings for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, in **Outlook Web App**, click **Properties**.
3. On the **Outlook Web App Properties** page, click either the **Public Computer File Access** tab or the **Private Computer File Access** tab.
4. Under **Direct file access**, select the check box next to **Enable direct file access** to let users download attachments.
5. To modify the types of attachments that you want users to be able to access, click **Customize** next to **Customize direct file access**.
6. On the **Direct File Access Settings** page, do one of the following:
   - To set the file types and MIME types that you want users to access, click **Allow**, and then set the file name extensions and MIME values on the **Allow List** page.
   - To set the file types and MIME types that you want to block users from accessing, click **Block**, and then and set the file name extensions and MIME values on the **Block List** page.
   - To set the file types and MIME types that you want to force users to save before they access them, click **Force Save**, and then set the file name extensions and MIME values on the **Force Save List** page.
   - For unknown file types, select an option from the list in the **Unknown Files** box. Select **Allow**, **Block**, or **Force Save**.
7. Click **OK** to save your settings.

Use the Shell to configure attachments policy settings for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example prevents users on public computers from downloading files.

```
Set-OwaVirtualDirectory -identity "owa (Default Web Site)" -DirectFileAccessOnPub
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure direct file access, you may also want to:

- Configure WebReady Document Viewing
- Configure Maximum Message Size in Outlook Web App

1.6.2.2.3.2 Configure WebReady Document Viewing

Configure WebReady Document Viewing

Managing Client Access Servers > Managing Outlook Web App > Managing File and Data Access for Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

WebReady Document Viewing lets users access file attachments in Microsoft Office Outlook Web App. Users can access common file types such as Microsoft Word documents without having the application installed.

You can manage WebReady Document Viewing for Outlook Web App in Microsoft Exchange Server 2010.

When you manage WebReady Document Viewing, you can specify files that you want users to be able to access within Outlook Web App for private and public computers. However, you can't specify individual settings for only private or public computers.

By default, public computer file access isn't enabled for Outlook Web App. Therefore, when users select the **This is a public or shared computer** option or the **This is a private computer** option on the Outlook Web App sign-in page, they won't be able to access files attached to e-mail messages.

Looking for other management tasks related to accessing files from Outlook Web App? Check out Managing File and Data Access for Outlook Web App.

Use the EMC to manage WebReady Document Viewing settings for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the work pane, select **owa (Default Web Site)**, and then, in the action pane, click **Properties**.
3. On the **Outlook Web App Properties** page, click the **Private Computer File Access** or **Public Computer File Access** tab.
4. Under **WebReady Document Viewing**, select the check box next to **Enable WebReady Document Viewing** to let users view common file types in Outlook Web App.
5. To modify the types of files that you want users to be able to view in Outlook Web App, click **Supported** under **WebReady Document Viewing**.
6. On the **WebReady Document Viewing Settings** page, select the default values or delete one or more of the file types.
7. Click **OK** to save your changes.

Use the Shell to configure attachment policy settings for Outlook Web App

You need to be assigned permissions before you can run this cmdlet. Although all parameters for this cmdlet are listed in this topic, you may not have access to some parameters if they're not included in the permissions assigned to you. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example uses the **Set-OwaVirtualDirectory** cmdlet to prevent users on public computers from downloading files.

```
Set-OwaVirtualDirectory -identity "owa (Default Web Site)" -WebReadyDocumentViewi
```

For information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure WebReady Document Viewing settings, you may also want to:

- Configure Public and Private Computer File Access
- Configure Maximum Message Size in Outlook Web App

1.6.2.2.3.3 Configure Maximum Message Size in Outlook Web App

Configure Maximum Message Size in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can edit the Web.config file on a Client Access server to enable large messages to be sent by using Outlook Web App. Outlook Web App is an application that uses ASP.NET and is affected by the configuration of ASP.NET settings.

The ASP.NET setting that determines the maximum amount of data that the Web browser can submit to the Client Access server is *maxRequestLength*. The *maxRequestLength* setting is found in the Web.config file. If the setting for the maximum message size for sending on a mailbox is more than the *maxRequestLength* setting, messages that are sent from Outlook Web App that exceed the *maxRequestLength* value will generate an error that might be confusing to users. To avoid this, you must configure the *maxRequestLength* to be at least as large as the largest maximum send size on the mailboxes in your organization.

Conditions and Associated Warnings

If a user tries to create or send a message that exceeds the maximum message size or *maxRequestLength*, a warning will appear in Outlook Web App. The text of the warning will vary, depending on the conditions that generated it.

- If a user tries to upload an attachment that's larger than the maximum message size, they receive the following error message in the upload dialog box: "Your attachment is larger than the maximum limit for attachments."
- If a user tries to upload one or more attachments that are larger than the ASP.NET *MaxRequestLength*, they receive the following error message in the Information Bar within the message: "The files *<file names>* weren't attached because they exceed the maximum size limit of *<size limit>* MB for attachments."
- If a user attaches several files, each of which is smaller than either the maximum message size or *maxRequestLength* but which, together, amount to more than the maximum message size, Outlook Web App displays the following message as a banner on the message form when the user clicks **Send**: "This message couldn't be sent because it exceeds the maximum size allowed."

- The default attachment size limit for a single attachment is 10 MB. To change this value for the organization, you can change the **Maximum receive size (KB)** and **Maximum send size (KB)** settings. After you change one or more these settings, you must restart the Exchange Information Store service for the changes to take effect.
  For more information about how to change the Exchange 2010 Transport Settings, see: Configure Transport Settings Properties.

Looking for other management tasks related to accessing files from Outlook Web App? Check out Managing File and Data Access for Outlook Web App.

Use Notepad to change the maxRequestLength value

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Text editor" entry in the Client Access Permissions topic.

1. Find the Outlook Web App Web.config file on the Client Access server. The default location is *<drive>*\Program Files\Microsoft\Exchange Server\V14 \ClientAccess\Owa.
2. Make a backup of the file.
3. Open the original file in a text editor, such as Notepad. Don't use Internet Information Services (IIS) Manager to edit the Web.config file.
   Change the requestLimits maxAllowedContentLength and httpRuntime maxRequestLength values to increase or decrease the message size
4. Find *maxRequestLength*, and change it to the value that you want. The value is stored in kilobytes (KB). The default value is 35000. The following example shows the *maxRequestLength* value in the Web.config file.
   `<httpRuntime maxRequestLength="35000" />`
5. Find *maxAllowedContentLength* and change it to the value that you want. The value is stored in bytes. The default value is 35000000, for example:
   `<requestLimits maxAllowedContentLength="35000000" />`
6. Save and close the file.

Caution:

Before you make changes to the Web.config file, make a copy of the file, and store it in a safe location.

Other Tasks

After you set the maximum message size, you may also want to do the following:

- Configure Public and Private Computer File Access
- Configure WebReady Document Viewing

1.6.2.2.4 Managing Outlook Web App Advanced Features

Managing Outlook Web App Advanced Features

Client Access > Managing Client Access Servers > Managing Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-12*

1.6.2.2.4.1 Configure Segmentation in Outlook Web App

Configure Segmentation in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Segmentation lets you enable and disable many features in Outlook Web App. You can manage segmentation using the EMC or the Shell.

By default, segmentation changes take effect after 60 minutes of inactivity for users who are signed in to Outlook Web App, or when a user signs in to Outlook Web App. To force the changes to take effect immediately, restart Internet Information Services (IIS) by running the command `iisreset/noforce` on the Client Access server.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Segmentation in the EMC and the Shell

The following table lists the segmentation options that are available in the EMC and by using the Shell.

Segmentation options that can be set in the EMC and by using the Shell

EMC	Shell parameter	Description
All Address Lists	*AllAddressListsEnabled*	If it's enabled, this option lets users see all address lists in the Exchange organization. If it's disabled, the user will see only the

		default global address list.
Calendar	*CalendarEnabled*	If it's enabled, this option lets users see Calendar folders using Outlook Web App. If it's disabled, the Calendar is still available using Outlook but won't be visible from Outlook Web App.
Change Password	*ChangePasswordEnabled*	If it's enabled, this option lets users change their Active Directory account password using Outlook Web App.
Contacts	*ContactsEnabled*	If it's enabled, this option lets users see Contacts folders using Outlook Web App. If it's disabled, Contacts folders are still available using Outlook but won't be visible from Outlook Web App.
E-mail Signature	*SignaturesEnabled*	If it's enabled, this option lets users use the Outlook Web App **Options** to manage signatures for outgoing e-mail messages.
Exchange ActiveSync Integration	*ActiveSyncIntegrationEnabled*	If it's enabled, this option lets users manage a mobile phone by using the **Options** feature in Outlook Web App. If it's disabled, the option isn't visible.
Instant Messaging	*InstantMessagingEnabled*	If it's enabled, this option makes instant messaging in Outlook Web App available to users. This feature isn't available in the light version of Outlook Web App.
Journal	*JournalEnabled*	If it's enabled, this option lets users see the Journal folder using Outlook Web App. If it's disabled, the Journal is still available using Outlook but won't be visible from Outlook Web App.
Junk E-mail Filtering	*JunkEmailEnabled*	If it's enabled, this option enables users to control the junk e-mail settings for their mailbox from Outlook Web App. If it's disabled, the user

		won't be able to control the junk-email settings from Outlook Web App. But any settings that are set by an administrator or by using Outlook will still be applied.
Notes	*NotesEnabled*	If it's enabled, this option makes the Notes folder visible in Outlook Web App. Outlook Web App provides view-only access to Notes.
Premium Client	*PremiumClientEnabled*	If it's enabled, this option lets users access the standard Outlook Web App client. If it's disabled, only the light version of Outlook Web App will be available.
Public Folders	*PublicFoldersEnabled*	If it's enabled, this option lets users browse or read items in public folders using Outlook Web App.
Recover Deleted Items	*RecoverDeletedItemsEnabled*	If it's enabled, this option lets users view, recover, or permanently delete items that were deleted from the Deleted Items folder by using Outlook Web App.
Reminders and Notifications	*RemindersAndNotificationsEnabled*	If it's enabled, this option lets users receive reminders for calendar items and tasks and notifications for new messages. If it's disabled, users won't receive reminders and notifications. Reminders and notifications are not available in the light version of Outlook Web App.
Rules	*RulesEnabled*	If it's enabled, this option lets users view, create, or modify server-side rules using Outlook Web App.
S/MIME	*SMimeEnabled*	If it's enabled, this option lets users download the S/MIME control for Outlook Web App and use it to read and compose signed and encrypted messages.
Search Folders	*SearchFoldersEnabled*	If it's enabled, this option lets users see the **Search Folders** icon in the Outlook Web App navigation pane

		and lets them access any search folders that exist on the server. If it's disabled, the **Search Folders** icon remains visible in Outlook Web App. But the folders won't be available. For more information about how to create search folders, see the Outlook Help.
Spelling Checker	*SpellCheckerEnabled*	If it's enabled, this option lets users check spelling in Outlook Web App. This feature isn't available in the light version of Outlook Web App.
Tasks	*TasksEnabled*	If it's enabled, this option makes the **Tasks** features in Outlook Web App available to users. This feature isn't available in the light version of Outlook Web App.
Text Messaging	*TextMessagingEnabled*	If it's enabled, this option lets user send and receive text messages in Outlook Web App. This feature isn't available in the light version of Outlook Web App.
Theme Selection	*ThemeSelectionEnabled*	If it’s enabled, this parameter allows users to select a theme in Outlook Web App.
Unified Messaging Integration	*UMIntegrationEnabled*	If it's enabled, this option lets users manage their Unified Messaging settings by using Outlook Web App.

Use the EMC to configure Outlook Web App segmentation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the work pane, select the server that hosts the Outlook Web App virtual directory you want to modify.
3. From the work pane, on the **Outlook Web App** tab, select **owa (Default Web Site)**, and then, in the action pane, click **Properties**.
4. On the **owa (Default Web Site) Properties** page, click the **Segmentation** tab.
5. The **Segmentation** window provides a list of features for Outlook Web App that you can enable or disable for all users.
6. To enable or disable a feature for Outlook Web App for all users, select a

feature, and then click **Enable** or **Disable**.
7. The status for all features is displayed in the center section in the **Segmentation** window.

Use the Shell to configure Outlook Web App segmentation

For a detailed description and examples of how to use the Shell to configure Outlook Web App segmentation, see Set-OwaVirtualDirectory.

1.6.2.2.4.2 Configure Gzip Compression Settings

Configure Gzip Compression Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure Gzip compression for Microsoft Office Outlook Web App in Microsoft Exchange Server 2010. Gzip compression improves performance over slow network connections by compressing content on the server. Gzip compression might slow performance on the server.

Note:
By default, Gzip compression is set to low.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Use the Shell to configure Gzip compression

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures Gzip compression to `High` on an Outlook Web App virtual directory that's named `owa` in the default Internet Information Services (IIS) Web site on the local server.

```
Set-OwaVirtualDirectory -identity "owa (Default Web Site)" -GzipLevel High
```

This example sets Gzip compression to `Off` on an Outlook Web App virtual directory that's named `owa` in the default IIS Web site on the local server.

```
Set-OwaVirtualDirectory -identity "owa (Default Web Site)" -GzipLevel Off
```

Note:
You must restart IIS by using the command `iisreset/noforce` for these changes to take effect.

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

1.6.2.2.4.3 Configure Character Settings for Outlook Web App

Configure Character Settings for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure the character settings on Microsoft Office Outlook Web App virtual directories in Microsoft Exchange Server 2010. For more information about character settings in Outlook Web App, see Managing Outlook Web App Advanced Features.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Use the Shell to configure character settings for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures Outlook Web App to always use UTF-8 encoded UNICODE characters on all outgoing e-mail messages.

```
Set-OwaVirtualDirectory -identity "Owa (Default Web Site)" -OutboundCharset Alway
```

Note:
The *AlwaysUTF8* character setting on the Outlook Web App virtual directory takes precedence over user-defined settings. Outlook Web App sets the UTF-8 character on all outgoing e-mail messages, regardless of the user's language choice in Outlook Web App.

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure character settings for Outlook Web App, you may also want to Configure Language Settings for Outlook Web App.

1.6.2.2.4.4 Configure Language Settings for Outlook Web App

Configure Language Settings for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The language setting determines the language of the Microsoft Office Outlook Web App sign-in page and error messages. It can be changed by the user at any time. You can use Outlook Web App or the Microsoft to configure language settings for Outlook Web App.

About Language Settings

You can configure three language settings for Outlook Web App.

- The sign-in and error language setting applies to individual Outlook Web App virtual directories. The sign-in and error language is the language that will be used for errors and the forms-based authentication sign-in page. If a value isn't set for this language, the default value is *0*. This means that the default sign-in and error language isn't defined. If the sign-in and error language isn't defined, Outlook Web App will default first to the language set on the Web browser on the client computer. If the language set on the Web browser on the client computer isn't supported by Outlook Web App, Outlook Web App will use the language of the Client Access server.
- The default client language setting applies to individual Outlook Web App virtual directories. The default client language is the client language that's used by Outlook Web App unless the user uses **Regional Settings** in Outlook Web App to change the language and time zone. The default value for this setting is *0*. This means the default client language isn't defined. If the default client language isn't defined, users will be prompted to choose a language and time zone the first time that they sign in to Outlook Web App. If the default client language value is defined, users won't be prompted to choose a language and the Outlook Web App time zone will use the time zone of the Client Access server. Defining the default client language causes the default folders to be renamed based on the specified language. Users can change the client language and time zone by using **Regional Settings** in Outlook Web App and can rename the default folders after they sign in.
- The client languages are set on individual mailboxes and affect the language that's used in Outlook and Outlook Web App. If multiple languages are configured, the first language in the list that's supported by the Web browser will be used. If none of the languages in the default languages list are supported by the Web browser, the Client Access server language will be used.
- To support labels such as **To** and **From** in languages other than English, the appropriate language pack must be installed on the Client Access server and the Mailbox server.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Prerequisites

Note:
For all Arabic, Hebrew, and Urdu text to be displayed correctly in Outlook Web App, support for languages that are read from right-to-left and for script languages must be installed on the client computer. Asian languages might also require that the East Asian language support be installed on the client computer.

The following table lists the languages and locales that can be configured in the Shell, and their associated codes.

Available languages and locales and their associated codes

Language (Locale)	Code

Arabic (Algeria)	5121
Arabic (Bahrain)	15361
Arabic (Egypt)	3073
Arabic (Iraq)	2049
Arabic (Jordan)	11265
Arabic (Kuwait)	13313
Arabic (Lebanon)	12289

Use the Outlook Web App client to configure language settings

1. Use a Web browser to sign in to a mailbox that you have full access permission to via Outlook Web App.
2. Click **Options**, and then click **Regional Settings**.
3. Under **Language**, in the **Choose language** list, click the language that you want to use.

   Note:
   The language that you select will determine the date and time settings in the **Date and Time Formats** section.

4. Click **Save** to save your language settings.

Use the Shell to configure language settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

Use the Shell to configure the sign-in and error language settings for Outlook Web App

This example sets the sign-in and error language setting.

```
Set-OwaVirtualDirectory -identity "Owa (Default Web Site)" -LogonAndErrorLanguage
```

Use the Shell to configure the default client language setting for an Outlook Web App virtual directory

This example sets the default client language setting.

```
Set-MailboxRegionalConfiguration -Identity <Username> -Language <language code>
```

Use the Shell to configure the client language setting for an individual mailbox

This example sets the client languages setting for an individual mailbox.

```
Set-Mailbox -identity <mailbox identity> -languages <language code>
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory and Set-

Mailbox.

Other Tasks

After you configure language settings, you may also want to Configure Character Settings for Outlook Web App.

1.6.2.2.4.5 Configure Web Beacon and HTML Form Filtering for Outlook Web App

Configure Web Beacon and HTML Form Filtering for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to disable Web beacons and HTML forms on Outlook Web App. A Web beacon is a file object, such as a transparent graphic or an image, that's put on a Web site or in an e-mail message. Web beacons are typically used together with HTML cookies to monitor user behavior on a Web site or to validate a recipient's e-mail address when an e-mail message that contains a Web beacon is opened. Web beacons and HTML forms can also contain harmful code and can be used to circumvent e-mail filters.

By default, Web beacons and HTML forms are set to *UserFilterChoice*. This blocks all Web beacons and HTML forms but lets the user unblock them on individual messages. An administrator can use the Shell to change the type of filtering that's used for Web beacon and HTML form content in Outlook Web App.

Web beacon configuration is set on a per virtual directory basis for each Outlook Web App virtual directory in your organization.

For more information about Web beacons, see Managing Outlook Web App Advanced Features.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Use the Shell to block Web beacons and HTML forms in Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example blocks all Web beacon and HTML form content on an Outlook Web App virtual directory named `Owa` in the default Internet Information Services (IIS) Web site on the local server.

```
Set-OwaVirtualDirectory -identity "Owa (Default Web Site)" -FilterWebBeaconsAndHt
```

The possible values for `FilterWebBeaconsandHtmlforms` are as follows:

- `UserFilterChoice` By default, this value blocks Web beacons and HTML

forms, but lets the user allow Web beacons and HTML forms on individual messages.
- `ForceFilter` This value blocks all Web beacons and HTML forms.
- `DisableFilter` This value allows Web beacons and HTML forms.

Note:
Both `UserFilterChoice` and `ForceFilter` give the user an option to unblock blocked content on individual messages. If the parameter has been set to `ForceFilter`, the content will remain blocked regardless of the user's choice.

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

1.6.2.2.4.6 Specify Address Lists in Outlook Web App

Specify Address Lists in Outlook Web App

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Advanced Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use ADSI Edit to control which address lists are available to users when they use Outlook Web App for Microsoft Exchange Server 2010.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Use ADSI Edit to limit the address lists that are available to a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. Open ADSI Edit.
2. Locate the user for whom you want to set an address list value.
3. Open the properties for that user, and then add the appropriate value for the *querybaseDN* parameter.
4. Save the changes to that user's properties.

How QuerybaseDN Is Used

The *querybaseDN* parameter is found on Active Directory user objects. By setting the value of *querybaseDN*, you can control which address list a user has access to through Outlook Web App. You do this by assigning the distinguished name of an address list or organizational unit (OU) to the *querybaseDN* parameter.

The following conditions apply to the use of *querybaseDN*:

- If the *querybaseDN* parameter isn't used, the user will have access to the first global address list (GAL) that's listed in the **globalAddressList** attribute for that user.
- If the *querybaseDN* parameter is set to a specific address list, the user will have access only to that address list.
  - If the user uses **Select Rooms** in the Scheduling Assistant, they'll see only resources from the specified address list.
- If the *querybaseDN* parameter is set to a specific OU and the

displayAddressLists parameter is set to `$false`, the user won't have access to any address lists. If the *querybaseDN* parameter is set to a specific OU and the *displayAddressLists* parameter is set to `$true`, the user will have access only to users in the OU that is specified by the *querybaseDN* parameter.

- If the user uses **Select Rooms** in the Scheduling Assistant, they'll see only resources from the specified OU.

Use ADSI Edit to find the distinguished name of an address list or organizational unit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. Open ADSI Edit.
2. Find the address list or OU that you want to use, right-click it, and then click **Properties**.
3. Find the distinguished name of the address list or OU.

Use the Shell to find address lists in your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Enter **Get-AddressList** to return all the address lists under the All Address Lists container.

For more information about syntax and parameters, see Get-AddressList.

1.6.2.2.4.7 Configuring the Change Password Feature in Outlook Web App

Configuring the Change Password Feature in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Change Password feature in Microsoft Office Outlook Web App enables domain users to change their password when they're using Outlook Web App. This topic discusses the Change Password feature and how it's implemented in Microsoft Exchange Server 2010.

Password Overview

Three types of Account policies are found in Windows Server 2008 or Windows Server 2003 domains: password policies, account lockout policies, and Kerberos authentication protocol policies. A single domain will have one of each of these policies. In Active Directory domains, you can apply one password and account lockout policy. This password is specified in the Default Domain Policy for the domain. The settings that are configured will apply to all users within the domain. This includes Outlook Web App users.

Password and account lockout settings protect accounts and data in your organization by

preventing a person from guessing another user's account password. You can use the Account Lockout and Password Policy nodes of the Default Domain policy settings to configure the account lockout policies and password policy settings that will affect the Outlook Web App users in your Exchange organization and be enforced. Password policies include the following settings:

- Password Complexity
- Password History
- Minimum Password Length
- Maximum Password Age
- Minimum Password Age

When you create a user account and mailbox-enable the user, the password policies and the settings on the user's account will be applied to the user. However, there are other user password settings that may also affect Outlook Web App users, such as **User Must Change Password at First Logon** and **User Cannot Change Password**.

Change Password Feature in Outlook Web App

By default, the domain password that's used by the user to access a Windows-based network is the same as the password that's used to access Outlook Web App. A user can change their domain password using a Web browser by using the Change Password feature within Outlook Web App.

Outlook Web App provides the functionality to change passwords that haven't expired yet. However, if a password has already expired or is required to be changed at the first sign-in, the password can't be changed via Outlook Web App unless you make a configuration change on the Client Access server to enable changing expired passwords.

If you don't enable changing expired passwords, a user whose password must be changed will have to contact their administrator to have their password reset. When the password is reset, the administrator must clear the **User must change password at next logon** check box.

If you haven't enabled changing expired passwords and are using forms-based authentication, a user who must change their password will be returned to the sign-in page, and the following error message will be displayed: **The user name or password you entered isn't correct. Try entering it again**. If forms-based authentication isn't used for Outlook Web App, the user will be returned to the sign-in window but won't see any error message.

Important:

When Basic authentication or forms-based authentication is used with Outlook Web App, the Change Password feature may not work correctly when a user uses a password that includes extended ASCII or Unicode characters. This happens because passwords that use extended ASCII or Unicode characters aren't transmitted correctly between IIS and some Web browsers. We recommend that Outlook Web App users use only ASCII characters if they'll be using the Change Password feature in Outlook Web App.

You can enable or disable the Change Password feature for a single user by configuring the user's mailbox, or for multiple users by configuring the /owa virtual directory or another virtual directory that's used for Outlook Web App. You can enable or disable the Change Password feature by using segmentation. For more information, see Configure Segmentation in Outlook Web App.

Enable Users to Change Expired Passwords

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App Registry Editor" entry in the Client Access Permissions topic.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Log on to the Client Access server.
2. Start Registry Editor (regedit).
3. Locate the following registry subkey: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA**.
4. Create the following DWORD value if it doesn't already exist: **ChangeExpiredPasswordEnabled**. The value type will be **REG_DWORD**.
5. Set the value of **ChangeExpiredPasswordEnabled** to **1**.
6. Exit Registry Editor.

Note:

You must make this change on each Client Access server that supports Outlook Web App.

1.6.2.2.4.8 Using Outlook Web App Web Parts

Using Outlook Web App Web Parts

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Microsoft Office Outlook Web App Web Parts to specify the mailbox to open, the folder within that mailbox to open, and the content view to use.

Outlook Web App Web Parts let you access Outlook Web App content directly from a URL. The URL can be entered into a Web browser or embedded in an application. Generally, Web Parts aren't created manually. Instead, they're created programmatically based on selections made in a user interface (UI), or they're embedded directly in an application, such as a Microsoft Office SharePoint Server 2007 or SharePoint Server 2010 page. The code behind the UI then creates the URL. One use for Outlook Web App Web Parts is to display a user's Inbox or Calendar on a SharePoint Server 2007 or SharePoint Server 2010 page.

Note:

To use Outlook Web App Web Parts, both the user's mailbox and the mailbox being opened through a Web Part must be located in the same Active Directory forest.

Permissions for Using Outlook Web Access Web Parts

To use Outlook Web App Web Parts, you must, at a minimum, be delegated "Reviewer"

access to the content that you're opening. If you've embedded an Outlook Web App Web Part that requires authentication into an application, you must pass authentication information through together with the request for the Web Part. One way to do this is by configuring the Outlook Web App virtual directory to use Integrated Windows authentication. Integrated Windows authentication lets users who've already logged on by using their Active Directory account use Outlook Web App without having to enter their credentials again.

Outlook Web App Web Parts Syntax

Outlook Web App in Microsoft Exchange Server 2010 has a new URL format to use for requests to the /owa virtual directory. These requests can be made by typing a URL directly into a Web browser or by embedding the URL in a Web application, such as a SharePoint Server page.

Outlook Web App Web Parts can be used to create URLs of varying complexity. A simple Web Part URL can be used to open the Inbox of any mailbox. A more complex Web Part URL could be used to specify the mailbox to open, the folder within that mailbox to open, and the content view to use.

For example, the simple Web Part URL https://<*server name*>/owa/?cmd=contents will open the Inbox of the mailbox that's determined by the user's logon. The more complex Web Part URL https://<*server name*>/owa/<SMTP address>/?cmd=contents&fpath=inbox%2fProjects&view=by%20subject will open the mailbox that's specified by the SMTP address to the subfolder Projects, sorted by subject.

Depending on the security measures that have been applied to your network, you may have to configure encoding for the Web Parts URL. After you configure the encoding, the code behind the UI will create the URL by using the URL-encoded parameters. URL-encoded parameters use %20 in place of spaces and %2f in place of the path delimiter "/". All examples in this topic use encoded parameters.

The following table lists the parameters of a Web Part and examples of how they're used.

Web Part parameters and how they're used

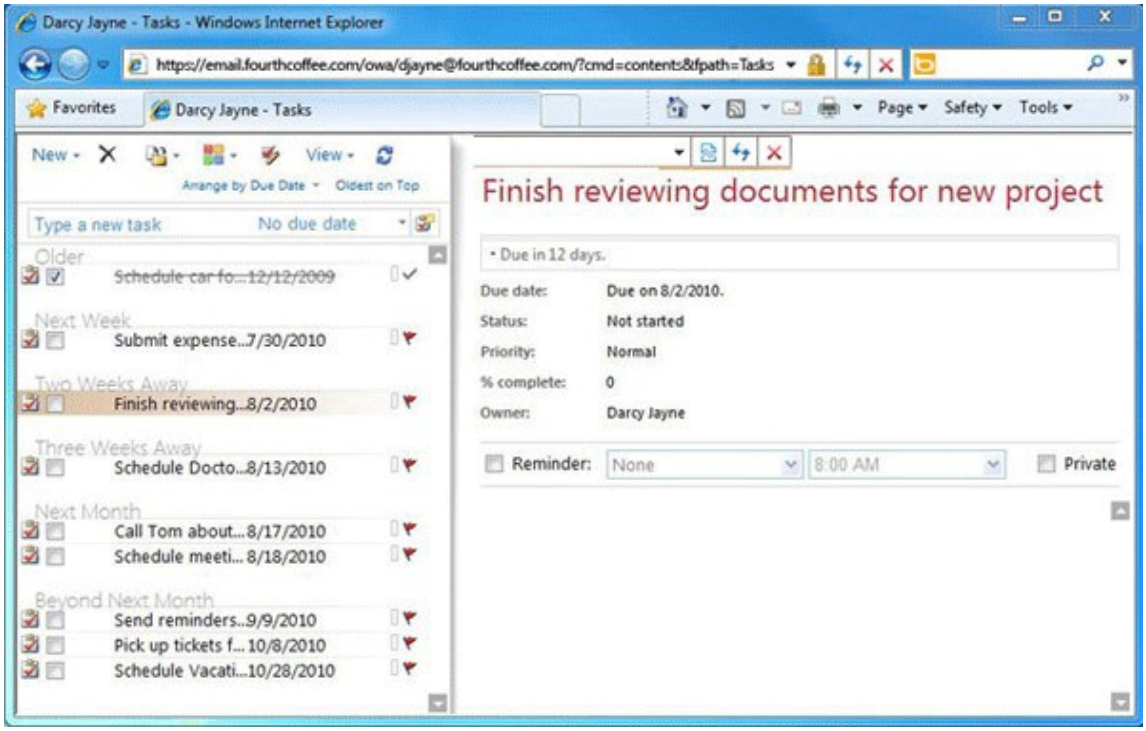
URL parameter	Description	Values and examples
Server name and directory (required)	The URL of the Outlook Web App virtual directory.	This may be the same URL that users use to sign in to Outlook Web App, for example: https://<*server name*>/owa
Exchange 2010 explicit logon mailbox identification (optional)	Any SMTP address that's associated with the mailbox to be opened. If this section of the URL is missing, the default mailbox of the authenticated user is opened. If no additional parameters are specified, the default behavior is to open the Inbox.	To open the mailbox with the SMTP address tsmith@fourthcoffee.com, use the following URL: https://<*server name*>/owa/tsmith@fourthcoffee.com
cmd (required if you're specifying any parameter other than the	?cmd=contents displays the Outlook Web App Web Part that's specified by the parameters instead of the full Outlook Web	If no mailbox is specified, the cmd parameter comes after the sign-in address, as follows: https://<*server name*>/owa/?

explicit logon mailbox identification)	App user interface.	cmd=contents If a mailbox is specified, the cmd parameter comes after the explicit mailbox identification, as follows: https://*<server name>*/owa/*<SMTP address>*/?cmd=contents If no additional parameters are specified, the default behavior is to open the Inbox.
id (optional)	The folder ID of the folder from which the Web Part should display contents. This can be obtained by using Web services and can be used in applications to dynamically select which folder to open.	The folder ID is the Base64-encoded PR_ENTRY_ID of the folder, for example: https://*<server name>*/owa/?cmd=contents&id=*<PR_ENTRY_ID>*
fpath (optional)	A string that specifies the mailbox folder to be shown in the Web Part. The Web Part URL may have to be written by using URL encoding so that it can pass through firewalls. When you use URL encoding, a space becomes %20, and a path delimiter (/) becomes %2f. The folder hierarchy should start from the mailbox root. This folder path can point to ordinary folders or search folders.	To open the subfolder Projects in the Inbox, use the following URL: https://*<server name>*/owa/?cmd=contents&fpath= inbox%2fprojects
module (optional)	This parameter can be used to specify any of the four default folders without knowing the localized name.	Values for the module parameter aren't case sensitive, and include the following: • Inbox • Calendar • Contacts • Tasks • Publicfolders To open the calendar of a mailbox regardless of localization, use the following URL: https://*<server name>*/owa/?cmd=contents&module=calendar
view (optional)	This parameter specifies the view to be displayed for the folder. The default views when this parameter is not present are as	The views available vary according to the folder type. Calendar views: • Daily The daily

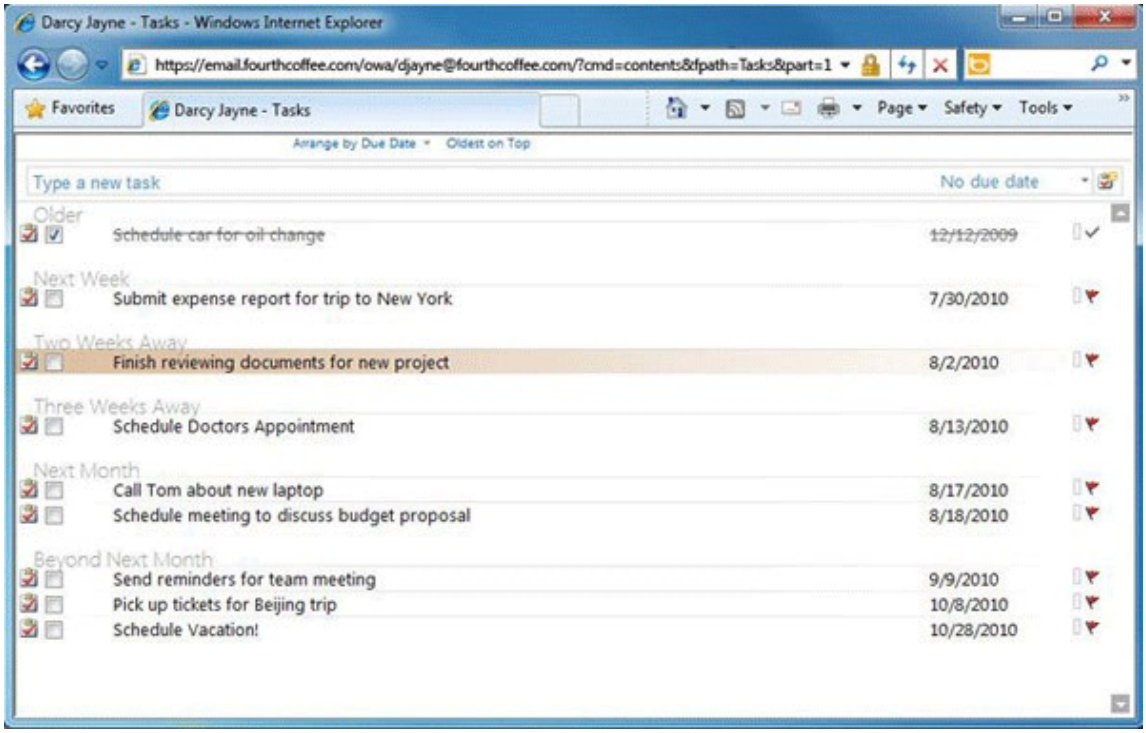
	follows: • Calendar Daily • Messages Messages • Contacts Two%20Line • Tasks By%20Due%20Date **Note:** The strings for the default views are automatically URL encoded. The default sort for a view is the way the folder would be sorted if it was opened in the Outlook Web App client. The strings identifying the views aren't localized and not case sensitive.	calendar view • Weekly The weekly calendar view • Monthly The monthly calendar view Message views: • Messages Message view, with default sort • By%20Sender Message view sorted by From with sender names that begin with "a" on top • By%20Subject Message view sorted by Subject with subjects that begin with "a" on top • By%20Conversation%20Topic Conversation View, not available in the light version of Outlook Web App Contact Views: • Phone%20List Contact view, with default sort Tasks: • By%20Due%20Date Tasks view with default sort • By%20Subject Tasks view sorted by subject, with a on top https://<*server name*>/owa/?cmd=contents&fpath=Calendar&view=Weekly will display the requested calendar in Weekly view.
d, m, y (optional)	Specifies the date for which the calendar should be displayed. These parameters can be entered in any order and can be used singly or together. If any of these parameters aren't specified, the default values are the current day, month, and year values. For example, if the current day is May 3, 2010 and you specify a month value of "9" for September, the date displayed will be September 3, 2010.	The valid values for the data parameters are as follows: d=[1-31] m=[1-12] y=[four digit year] To open a calendar to the date May 3, 2007, you would use the following URL: https://<*server name*>/owa/?cmd=content&fpath=calendar&view=daily&d=3&m=5&y=2007

part (optional)	Specifies that Outlook Web App should display a smaller Web Part.	When you use Web Parts to access Outlook Web App content, the UI that is displayed will be smaller than the full Outlook Web App UI. The part parameter reduces the UI further. The following example URL shows the Tasks list in the smallest Web Part format: https://*<server name>*/owa/?cmd=contents&fpath=tasks&part=1 The part parameter doesn't apply to the calendar module.

The following figure shows the Outlook Web App Tasks Web Part without the parameter *part=1*.



The following figure shows the Outlook Web App Tasks Web Part with the parameter *part=1*.



You can use multiple parameters to specify the folder to be displayed and the format to display it in. If more than one folder parameter is used, the precedence order is *id*, *f*, and then *module*. If none of these parameters is present, the Inbox will be shown by default.

Note:

If a feature has been turned off by using segmentation, that feature won't be available as a Web Part. For example, if the Outlook Web App calendar has been disabled, you won't be able to access calendars by using Outlook Web App Web Parts.

Enter Outlook Web App Web Parts manually

Outlook Web App Web Parts can be also be entered manually in a Web browser. For example, a user can use an Outlook Web App Web Part URL to open another user's calendar.

To open a specific calendar in Weekly view:

1. Open a Web browser window.
2. Enter the URL for Outlook Web App and add the following string to the end of the URL: *<mailbox SMTP address>*/?cmd=contents&fpath=calendar&view=weekly.
3. Enter sign-in credentials, if you're prompted to do this.

For example, if the URL of Outlook Web App is https://email.fourthcoffee.com/owa, then the following URL will open the calendar that belongs to the user tsmith in Weekly view: https://email.fourthcoffee.com/owa/tsmith@fourthcoffee.com/?cmd=contents&fpath=calendar&view=weekly

1.6.2.2.4.9 Customize the Outlook Web App Sign-In and Sign-Out Pages

Customize the Outlook Web App Sign-In and Sign-Out Pages

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Advanced Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to create custom sign-in and sign-out pages for Outlook Web App.

Looking for other advanced management tasks for Outlook Web App? Check out Managing Outlook Web App Advanced Features.

Customize the sign-in and sign-out pages

The Outlook Web App sign-in, language selection, and sign-out pages are created based on graphics and the logon.css file in the base theme folder. Therefore, to use custom sign-in and sign-out pages, you must modify the files in the base theme folder. You can find the base theme folder in the Exchange installation directory at \V14\Client Access \OWA\<version number>\themes\base.

Note:

In Exchange Server 2010 SP1, the path is \V14\Client Access\OWA\<version number> \themes\resources.

The sign-in, language selection, and sign-out pages use the logon.css file to define text styles and colors. The pages are created by combining several images for the border top, bottom, and sides and also include repeating images and corners for expansion. The following files create the sign-in page:

- logon.css
- lgnbotl.gif
- lgnbotm.gif
- lgnbotr.gif
- lgnexlogo.gif
- lgnleft.gif
- lgnright.gif
- lgntopl.gif
- lgntopm.gif
- lgntopr.gif

It is easiest to create a new look by using a solid color because the same collection of images is used for three pages: the sign-in page, the language selection page that is shown on the first sign-in per mailbox, and the sign-out page. The pages resize horizontally and vertically based on the contents of the page.

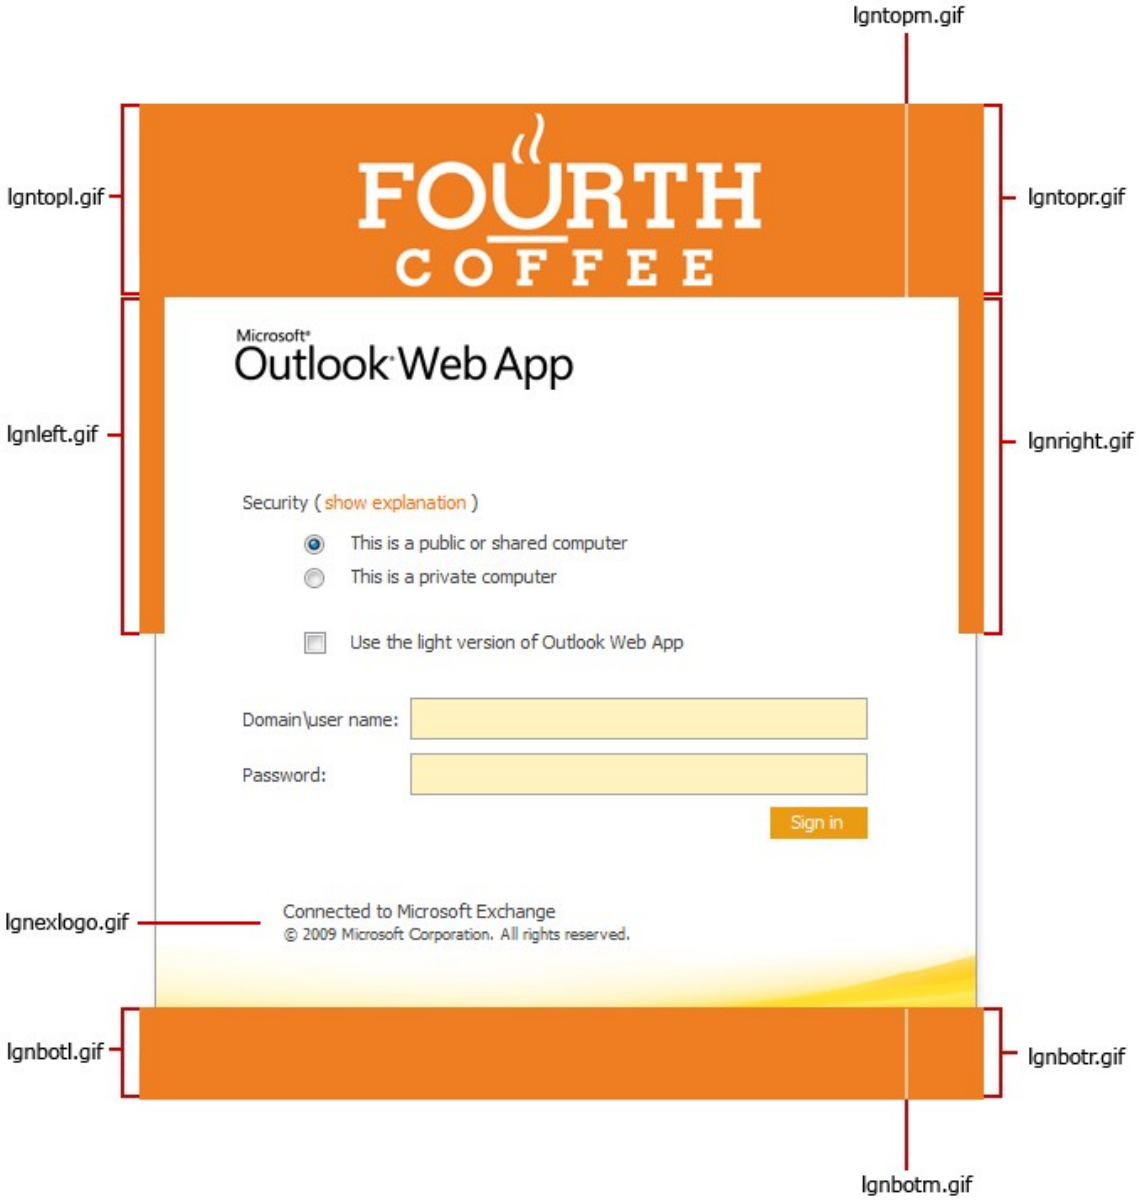
If you have multiple Client Access servers and want them all to use the same sign-in and sign-out pages, you must copy the modified sign-in and sign-out files to each Client Access server. You should also create a back-up copy of your customized files. If you reinstall or upgrade Exchange, all files in the themes folders will be overwritten. You'll have to copy your customized files back to the appropriate theme folder after the

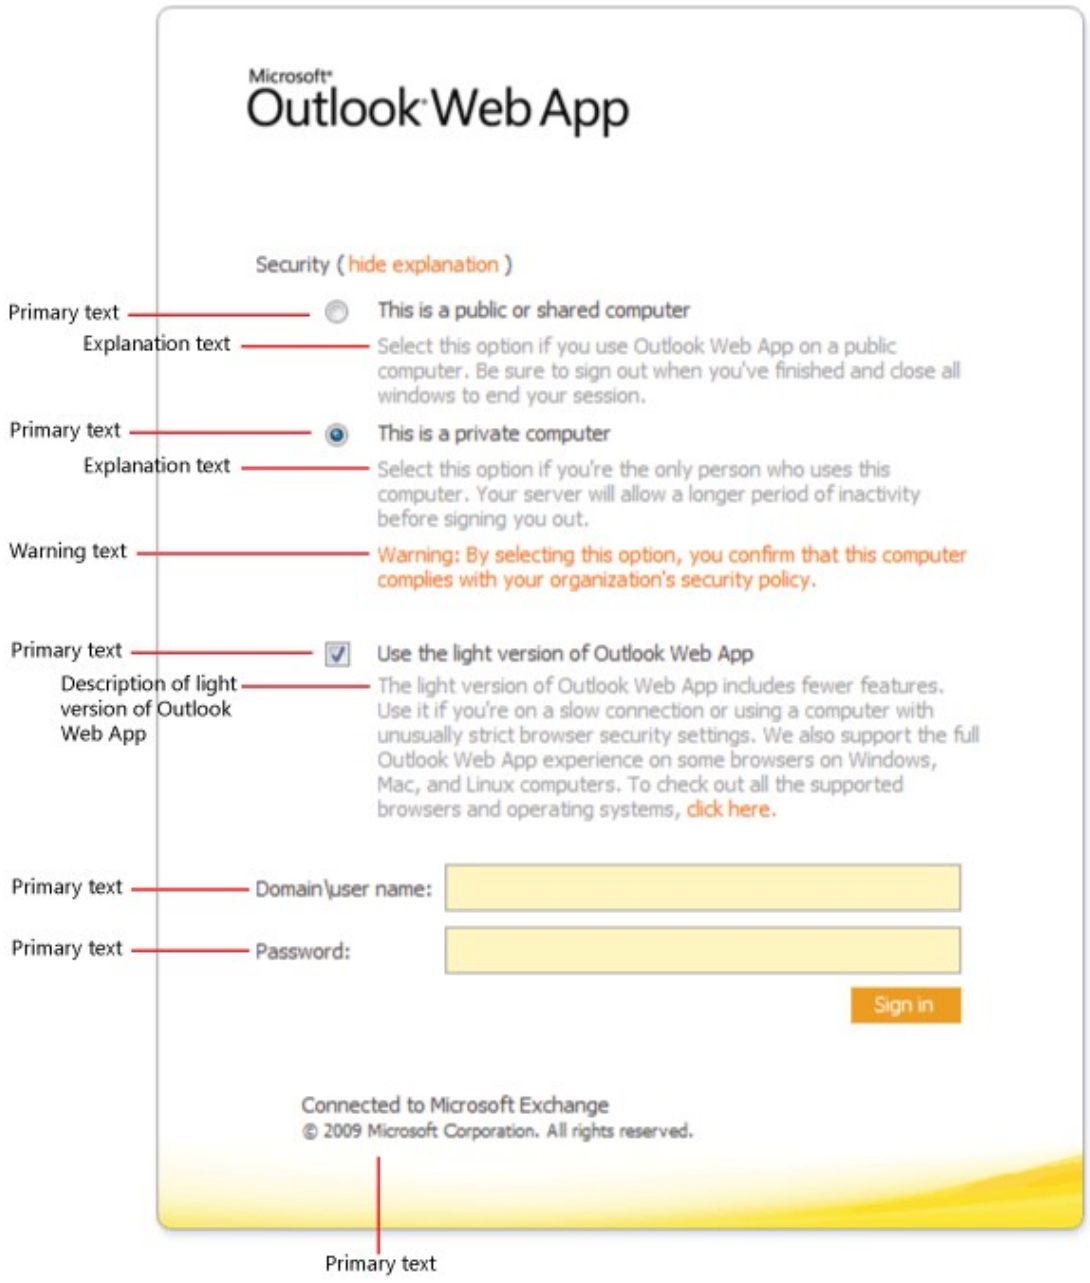
reinstallation or upgrade is complete.

Caution:

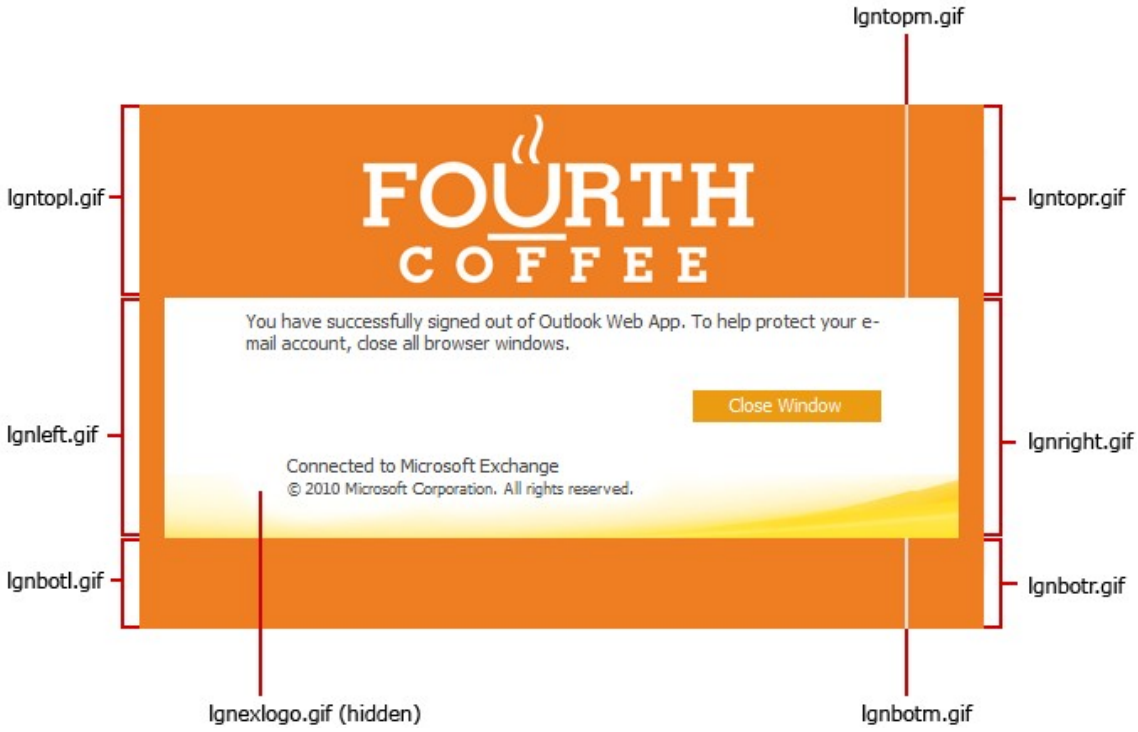
Before you change the files to create custom sign-in and sign-out pages, back up copies of all the files that you'll be changing before you start to create your custom sign-in and sign-out pages.

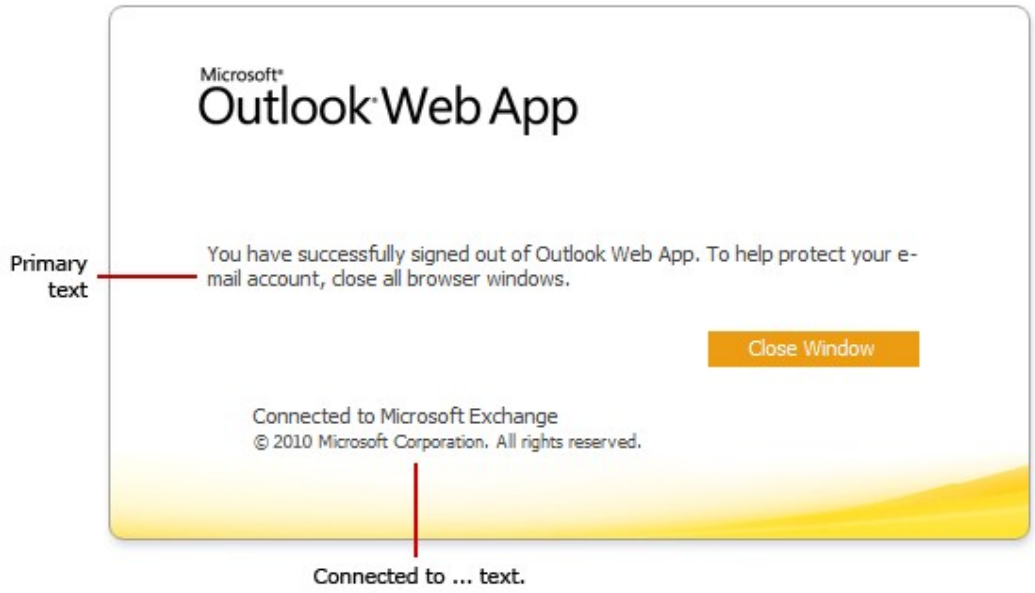
The following figures illustrate the default Outlook Web App sign-in page as it appears if the user clicks **show explanation** and selects **This is a private computer** and **Use the light version of Outlook Web App**. One figure shows how the graphics files that create the page fit together. The other figure shows how the logon.css file determines the colors of the background and text on the sign-in page.





The following figures illustrate the default Outlook Web App sign-out page. One figure shows how the graphic files that create the page fit together. The other shows how the logon.css file determines the colors of the background and text on the sign-out page.





Test changes to the sign-in and sign-out pages

After you've opened the Outlook Web App sign-in or sign-out page in Microsoft Internet Explorer, you can test your changes without having to reset IIS or exit Internet Explorer.

1. Open the Outlook Web App sign-in or sign-out page in Internet Explorer.
2. On the toolbar, click **Tools**, and then click **Internet Options**.
3. On the **General** tab, under **Browsing history**, click **Delete**.

4. Under **Temporary Internet Files**, click **Delete files**, and then click **Yes** when you are asked whether you are sure that you want to delete all temporary Internet Explorer files
5. Click **OK** to close **Internet Options**.
6. Click **Refresh** to see your changes.

Repeat these steps to see your changes every time that you make a change to the sign-in or sign-out page files. If you're making several changes, you can leave the sign-in or sign-out page open and repeat the steps to see your changes.

Change the logo in Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

To customize Outlook Web App, you can change the Outlook Web App logo on the sign-in and sign-out pages to your organization's logo.

1. Create copies of the files that you want to change, and then save them to a safe location so that you can restore the original pages, if it's necessary.
2. Open the lgntopl.gif file by using an image editing tool, and then modify it to create the logo that you want to use.
3. Save your changes, and then click the **Refresh** button to see your changes.

Note:
If you've changed the background color of lgntopl.gif, we recommend that you modify the remaining files that are used to create the sign-in and sign-out pages to match.

Change the font styles and colors

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Text editor" entry in the Client Access Permissions topic.

You can edit the logon.css file to change font styles and some of the colors that are used on the pages. This includes the background color that's behind the controls in the center of the sign-in page and the language selection page. If you've changed the color of these pages, we recommend that you change the background color to match.

To change the background and font colors of the sign-in, language selection, and sign-out pages, you must find the values in the sign-in style sheet (logon.css) and then determine the HTML RGB values for the colors that you want to use. The HTML RGB color values are defined by a seven-character string in the format of the number sign (#) followed by a string of six characters. To find the HTML RGB values for many colors, see the Color Table in the MSDN Library. If you must match a specific color and you can't find a match for the color online, you can use an image editing tool to sample a color and determine its HTML RGB value.

To test your changes, open Internet Explorer and enter the URL for Outlook Web App. If you're testing the changes to the Default Web site on the Client Access server that is hosting the Outlook Web App virtual directory, you can test them by opening Internet Explorer and entering the URL https://localhost/owa.

Note:
The language selection page appears only the first time that a user signs in to Outlook Web App.

The following table lists the elements of the sign-in and sign-out pages and a description for each element.

Sign-in and sign-out page elements and their descriptions

Element to change	String to search for	Description
Background color of the Web browser window	`body{background-color:#FFFFCC`	The background color of the Web browser window. This controls the color of the window that borders the sign-in and sign-out pages.
Background color the sign-in and sign-out pages	`Background: #FFFFCC`	The background color of the sign-in and sign-out pages. If you change the background color of the graphics files, you should change the background color to match.
Warning text	`wrng{color:#ff6c00;`	The color of the warning text that appears when a user selects **This is a private computer**. On the existing Outlook Web App sign-in page, this warning text is orange and stands out well against the white background. If you change the background color of the sign-in page, you may also want to change the color of the warning text so that it's readable.
Primary text color	`select, table {color:#444444;}`	The primary text color is black. It indicates options that can be selected and entry fields on the Outlook Web App sign-in page. Examples include the labels for the user name and password fields, and the text next to the security options. If you've chosen a light color for your sign-in pages, black will still work well for this text.
Show explanation/hide explanation	`a{color:#ff6c00;`	Link on the sign-in page that a user can click to show or hide the explanation of Private and Public sign-ins.
Explanation text	`expl{color:#999999;`	The color of the text that appears when the user clicks **show explanation**.
Description of the light version of Outlook Web App	`disBsc{color:#999999;`	When a user selects **Use the light version of Outlook Web App**, a short explanation about the light version of Outlook Web App is displayed.

After you've decided which elements you want to change the color of and identified the HTML RGB color values that you'll be changing those elements to, use the following procedure to change the color of any element that is defined by a .css file.

Change the color of an element

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Text editor" entry in the Client Access Permissions topic.

1. Open logon.css.
2. Use the table of sign-in and sign-out page elements included earlier in this topic to find the string that matches the element that you want to change.
3. Replace the HTML RGB color value of the element that you want to change with the new HTML RGB color value that you want to use for that element.
4. Save your changes and close logon.css.
5. Test your changes by opening Internet Explorer and entering the URL for the Outlook Web App sign-in page.

Note:

If you've already opened the Outlook Web App sign-in URL, you can test your changes by deleting the temporary Internet files and refreshing Internet Explorer. To do this, click **Tools**, and then click **Internet Options**. On the **General** tab, under **Browsing history**, click **Delete**. Under **Temporary Internet Files**, click **Delete files**, and then click **Yes** when you're asked whether you're sure that you want to delete all temporary Internet Explorer files Click **OK** to close **Internet Options**, and then press F5 to refresh the sign-in page.

1.6.2.2.4.10 Create a Theme for Outlook Web App

Create a Theme for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to create a custom theme for Microsoft Office Outlook Web App. A theme is a collection of media files and cascading style sheets (.css files) that control the appearance of Outlook Web App.

By default, multiple themes are installed when you install the Client Access server role on a computer that's running Microsoft Exchange Server 2010, as follows:

- .css files -- Define colors, gradients, and fonts.
- Image (.png) files -- Provide the icons and other graphic elements. If you edit any of the icons, don't change their size. If you change the size of any graphic elements, test your changes to verify that the elements still fit together correctly.

These files are stored on the Client Access server in the installation directory in \Client Access\OWA\<*version*>\themes. Each theme is stored in a subdirectory of themes. You can create additional themes by copying an existing theme and modifying the copy.

Note:

The light version of Outlook Web App doesn't support themes.

Recommendations

Many elements of an Outlook Web App theme can be changed. To avoid creating instability in Outlook Web App, we recommend that you change only the files directly related to your custom theme.

As a best practice, follow these guidelines:

- Always make backup copies of the original files before you edit them.
- Before you apply upgrades or hotfixes to a Client Access server that has custom themes, make backup copies of those themes.
- Make only one or two changes at a time and test your changes before you make additional changes.
- Don't change files in \Client Access\OWA\<*version*>\themes\resources. Fonts and other settings defined by those files are used by every theme in Outlook Web App. The files can't be changed without affecting every theme.
- Themes are saved on each Client Access server. If you have more than one Client Access server, and you want a custom theme to be available on all servers, you must copy the theme to the themes directory on each Client Access server.

Looking for other management tasks related to customizing the appearance of Outlook Web App? Check out Customize the Outlook Web App Sign-In and Sign-Out Pages.

What Do You Want to Do?

- Create a new Outlook Web App theme
- Name your custom theme
- Create a custom icon for your theme
- Create a custom header
- Use the Internet Explorer Developer Tools to determine colors
- Change colors in a theme
- Change icons and logos in a theme
- Set the default Outlook Web App theme

Create a new Outlook Web App theme

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

1. On the Client Access server that hosts Outlook Web App, open Windows Explorer, and then find the Exchange server installation directory.
2. In \Client Access\OWA\<*version*>\themes, find a theme that uses a color scheme similar to what you want, and then make a copy of it.
3. Give the copy you just created a short name similar to the name you want to give the theme.
4. Create back-up copies of the following files in your new theme folder, in addition to any others that you'll have to change to create your theme. These copies will preserve your original settings if you have to undo your changes:
   - premium.css
   - csssprites.png
   - csssprites2.png
   - headerbgmain.png
   - headerbgright.png
5. Follow the steps in the next sections to modify the files in the new theme folder to create your theme.
6. Restart Internet Information Services (IIS) by using the **iisreset/noforce**

command.
7. Test the new theme by signing in to Outlook Web App and selecting the new theme.

Name your custom theme

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

1. Open the copy of themeinfo.xml that's in the custom theme folder.
2. Find the `displayname` value for the theme, and then change the value to the name you want the theme to have.
   Example: To name your theme Fourth Coffee, the file should read as follows: `theme displayname = "Fourth Coffee"`.
3. Change the `sortorder` value to place your theme where you want it in the theme picker in Outlook Web App.
   Example: To set your theme to appear first, the file should read `sortorder = 1`.
4. Save your changes, and then close themeinfo.xml.
5. Stop and start IIS on the Client Access server by opening a Command Prompt window and using the command **iisreset/noforce**.
6. To test your changes, sign in to Outlook Web App, click **Options**, and then look for your new theme in the theme picker. If you don't see your theme listed, use Internet Options in Microsoft Internet Explorer to delete the temporary files. Then refresh the browser and try again to view the theme picker.

Create a custom icon for your theme

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

To create a custom icon for your theme, you must edit the themepreview.png file. This file is the icon for your theme in the theme picker in Outlook Web App.

1. Open themepreview.png in an image editing tool and make the changes you want. Don't modify the dimensions. The image is 32x32 pixels.
2. To test your changes, sign in to Outlook Web App, click **Options**, and then look for your new theme in the theme picker. If you don't see the new icon, use Internet Options in Internet Explorer to delete the temporary files. Then refresh the browser and try again to view the theme picker.

Create a custom header

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

To change the header in Outlook Web App, you must edit the following files that are used to create the header at the top of Outlook Web App:

- headerbgmain.png
- headerbgright.png
- headerbgmainrtl.png (You only need to edit this file if you support right-to-left languages).

1. Open the .png files in an image editing tool and make the changes you want. Don't modify the dimensions.
2. To change the logo, use an image-editing tool that supports transparent backgrounds, such as Paint.NET or Photoshop, to open and modify csssprites.png. This file has a transparent background. Don't move or change

the size of images in the file because Outlook Web App pulls each icon or logo from a specific location on cssprites.png. When you edit something in the file, you must line up the new image exactly on top of the image you're replacing.

3. After you edit the files, save your changes.
4. To test the changes to your custom theme, sign in to Outlook Web App, click **Options**, and then select your theme from the theme picker. If you don't see your new theme, use Internet Options in Internet Explorer to delete the temporary files. Then refresh the browser and try again to select your custom theme.

Use the Internet Explorer developer tools to determine colors

Internet Explorer 8 and Internet Explorer 9 include developer tools that let you determine the colors and fonts of specific elements and test modifications to those values. You can then use the information from the developer tools to locate those values in the .css files and modify them there to customize a theme.

1. Sign in to Outlook Web App and select any theme.
2. Go to a module that shows the element you want to customize. For example, if you want to customize the highlight color in Mail, go to Mail.
3. In Internet Explorer, go to the program toolbar and select Tools > Developer Tools, or press F12.
4. Arrange your windows so that Outlook Web App and the Developer Tools windows don't overlap.
5. In Developer Tools, click the select arrow at the left of the toolbar or press CTRL+B.
6. Move the pointer over the section of Outlook Web App that you want to customize. You'll see an outline around each element as the pointer passes over it. Click when the element you want to change is outlined.
7. Look in the Developer Tools window. You'll see the code that's used to build the page, and the element you selected will be highlighted in the left window.
8. Look in the right window for the color of that element. It will be an RGB value, which is expressed as a seven-character string starting with a # and followed by six alphanumeric characters. For example, white is expressed as #FFFFCC.
9. If you don't see an RGB value, repeat the preceding steps and try again.
10. When you find an RGB value, change it to the value you want, and then press Enter. The change will show up in Outlook Web App almost immediately. This doesn't change the theme, only the local settings and only for the current session.
11. The right pane of Developer Tools shows you what file the value is in and where to find it in that file.
12. After you find the value that you want to change, you must go the folder for your custom theme on the Client Access server and modify that value in premium.css.

Note:

To find the HTML RGB values for many colors, see the Color Table in the MSDN Library. If you must match a specific color and you can't find a match for the color online, you can use an image-editing tool to sample a color and determine its HTML RGB value. The Developer Tools have a useful color picker tool. Select **Tools** > **Show Color Picker** from the menu. To determine the RGB value of a color you want, position the mouse pointer over an element that has that color.

Change colors in a theme

After you find the color you want to change and determine the RGB value that you want

to change it to, you must find that property in the premium style sheet (premium.css) on the Client Access server and replace the existing value with the new value.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

1. Open the premium.css file in your custom theme by using a text editor such as Notepad.
2. In the file, search for the value that you found using the Internet Explorer tools.
3. Replace the RGB value with the RGB value of the color that you want.
4. To test the changes to your custom theme, sign in to Outlook Web App, click **Options**, and then select your theme from the theme picker. If you don't see your changes, use Internet Options in Internet Explorer to delete the temporary files. Then refresh the browser and try again to select your custom theme.

Change icons and logos in a theme

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Graphics editor" entry in the Client Access Permissions topic.

To change the icons and logos in a theme, use an image editing tool that supports transparent backgrounds, such as Paint.NET or Photoshop, to open and modify csssprites.png and csssprites2.png. These files have a transparent background that must be preserved to correctly display the individual elements. Don't move or change the size of images in the file because Outlook Web App pulls each image from a specific location in the file. When you edit something in the file, you must place the new image in exactly the same location as the image you're replacing.

To change an image:

1. Use an image editing tool that supports transparent backgrounds to open the file that contains the graphic elements you want to change.
2. Edit the element that you want to change, being careful to preserve the location and size of the original element.
3. Save and close the file.
4. To test the changes to your custom theme, sign in to Outlook Web App, click **Options**, and then select your theme from the theme picker. If you don't see your changes, use Internet Options in Internet Explorer to delete the temporary files. Then refresh the browser and try again to select your custom theme.

Set the default Outlook Web App theme

When you set a default theme, only users who haven't previously signed in to Outlook Web App and selected a new theme will be forced to use the default theme.

To force all users to use the default theme, you must disable theme selection in addition to setting a new default theme.

Use the Shell to set the default theme for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example sets the default theme for Outlook Web App where the server name is "FourthCoffee", the virtual directory name is "owa", the Web site name is "Default Web site", and the theme is in the folder named "Custom".

```
set-owavirtualdirectory -identity "fourthcoffee\owa (default web site)" -defaultt
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Use the Shell to disable theme selection for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example disables theme selection in Outlook Web App where the server name is "FourthCoffee", the virtual directory name is "owa", and the Web site name is "Default Web site".

```
set-owavirtualdirectory -identity "fourthcoffee\owa (default web site)" -themesel
```

You can also complete both commands at the same time as shown in the following example:

```
set-owavirtualdirectory -identity "fourthcoffee\owa (default web site)" -defaultt
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Other Tasks

After you create a theme, you may also want toCustomize the Outlook Web App Sign-In and Sign-Out Pages.

1.6.2.2.5 Managing Outlook Web App Mailbox Policies

Remove an Outlook Web App Mailbox Policy from Exchange

Apply an Outlook Web App Mailbox Policy to a Mailbox

1.6.2.2.5.1 Create Outlook Web App Mailbox Policy

Create Outlook Web App Mailbox Policy

Managing Client Access Servers > Managing Outlook Web App > Managing Outlook Web App Mailbox Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-21*

You can create an Outlook Web App mailbox policy to apply a common set of policy settings, such as attachment settings. Outlook Web App mailbox policies are useful for applying and standardizing settings for specific groups of users.

When the Client Access server role is installed, a default Outlook Web App mailbox policy is created. You can create additional Outlook Web App mailbox policies as needed. You apply Outlook Web App mailbox policies by changing the properties of mailboxes.

Looking for other management tasks related to Outlook Web App mailbox policies? Check out Managing Outlook Web App Mailbox Policies.

Prerequisites

The Client Access server role has been installed.

What Do You Want to Do?

- Use the EMC to create an Outlook Web Access mailbox policy
- Use the Shell to create an Outlook Web Access mailbox policy

Use the EMC to create an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Client Access**.
2. In the work pane, click the **Outlook Web App Mailbox Policies** tab.
3. In the action pane, click **New Outlook Web App Mailbox Policy**.
4. In the New UM Mailbox Policy wizard, complete the following fields:
   - **Outlook Web App mailbox policy name** Use this text box to specify a unique name for the Outlook Web App mailbox policy. This is a display name that appears in the Exchange Management Console.
     The Outlook Web App mailbox policy name is required, but it is used for display only. Because your organization may use multiple Outlook Web App mailbox policies, we recommend that you use meaningful names for your Outlook Web App mailbox policies. The maximum length of an Outlook Web App mailbox policy name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Select the features that you want to enable or disable for the Outlook Web App mailbox policy** Select the features that you want to enable or disable, and then click **Enable** or **Disable** to set them.
   - Click **New** to create your policy.
5. On the **Completion** page, confirm whether the Outlook Web App mailbox policy was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New Outlook Web App Mailbox Policy wizard.

Use the Shell to create an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

This example creates an Outlook Web App mailbox policy named `Policy1`:

```
New-OwaMailboxPolicy -Name Policy1
```

For more information about syntax and parameters, see New-OwaMailboxPolicy.

Other Tasks

After you create an Outlook Web App mailbox policy, you may also want to View or Configure Outlook Web App Mailbox Policy Properties.

For More Information

Understanding Outlook Web App Mailbox Policies

1.6.2.2.5.2 View or Configure Outlook Web App Mailbox Policy Properties

View or Configure Outlook Web App Mailbox Policy Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you create an Outlook Web App mailbox policy, you can configure a variety of options to control the features available to users in Outlook Web App. For example, you can enable or disable Inbox rules or create a list of allowed file types for attachments.

Looking for other management tasks related to Outlook Web App? Check out Managing Outlook Web App.

What Do You Want to Do?

- Use the EMC to view or configure Outlook Web App mailbox policies
- Use the Shell to configure Outlook Web Access mailbox policies
- Use the Shell to view Outlook Web App mailbox policies

Use the EMC to view or configure Outlook Web App mailbox policies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client

Access Permissions topic.

1. In the console tree, click **Organization Configuration** > **Client Access**. Click the **Outlook Web App Mailbox Policies** tab.
2. In the work pane, select the Outlook Web App mailbox policy that you want to view or configure, and then click **Properties**.
3. On the **General** tab, you can view and edit the name of the policy and view the modified date.
4. On the **Segmentation** tab, specify the features you want to enable or disable for Outlook Web App users.

Note:
Segmentation settings for mailbox policies override virtual directory settings. You can change segmentation settings for individual users by using the **Set-CASMailbox** cmdlet or by using Outlook Web App policies. For more information, see Managing Outlook Web App Mailbox Policies.

- **Enable** Select a disabled feature in the list, and then click **Enable** to enable that feature.
- **Disable** Select an enabled feature in the list, and then click **Disable** to disable that feature.
- **Feature** The **Feature** column shows the list of features that are potentially available to Outlook Web App users on a virtual directory.
- **Status** The **Status** column shows whether each feature is enabled or disabled.
- **Description** This section displays a description for the selected feature in the list.

5. On the **Public Computer File Access** tab, configure the file access and viewing options available if users select **This is a public computer** while they're signing in to Outlook Web App. File access lets a user open or view any file attached to an e-mail message.
Direct file access
- **Enable direct file access** Select this check box if you want to enable direct file access. Direct file access lets users open files attached to e-mail messages.
- **Customize** After you select **Enable direct file access**, click **Customize** to customize the direct file access settings.

Note:
The direct file access settings are applied to private and public computer file access. Even though the settings can be set from either the **Private Computer File Access** tab or the **Public Computer File Access** tab, you can't have different settings on the two tabs.

In the **Direct File Access Settings** dialog box, specify how files will be allowed, blocked, or handled in Outlook Web App. The Allow list overrides the Block list and the Force Save list. The Block list overrides the Force Save list. Select the following:
Allow Click the **Allow** button to specify which types of files should always be allowed. The Allow list overrides the Block list and the Force Save list.
Block Click the **Block** button to specify which types of files should be blocked. The Block list overrides the Force Save list and is overridden by the Allow list.
Force Save Click the **Force Save** button to specify which types of files the user must save to disk before opening them. The Force Save list is overridden by the Allow and Block lists.
Unknown Files Using the **Unknown Files** list, specify how Outlook Web App will handle unknown files that aren't in the

Allow, Block, or Force Save lists.
When you click **Allow**, **Block**, or **Force Save**, a new window opens in which you can add file name extensions and MIME types to the list you have selected, edit them, or remove them.
After you have selected **Allow**, **Block**, or **Force Save**:
To add a file name extension or MIME type, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (**.**), for example, .exe.
To edit a file name extension or MIME type, select it, and then click **Edit**.
To remove a file name extension or MIME type, select it, and then click **Remove**.
After you finish modifying the lists of file name extensions and MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.

WebReady Document Viewing
WebReady Document Viewing enables Outlook Web App documents to be converted to HTML and displayed in a Web browser. Configure WebReady Document Viewing on the **WebReady Document Viewing Settings** tab. These settings are available for public and private computer file access, and can be different for each:

- **Enable WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a Web browser.
- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a Web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if **Direct File Access** is enabled.
- **Supported** After you select **Enable WebReady Document Viewing**, click **Supported** to select supported document types for **WebReady Document Viewing**.

  Select document types to view from an Internet browser
  To allow all supported document types to be viewed from an Internet browser, select **All supported document types**.
  To allow only specific document types to be viewed, select **Specific document types**.
  Add After you select **Specific document types**, click **Add** to add a document type to the list.
  Remove After you select **Specific document types**, click the document type that you want to remove, and then click the remove icon.
  Select the MIME types of documents Using this list, add the MIME types of documents to the list of types that can be viewed from an Internet browser or remove them from the list.
  Add After you select **Specific document types**, click **Add** to add a MIME type to the list.
  Remove After you select **Specific document types**, click the MIME type that you want to remove, and then click the remove icon.

6. On the **Private Computer File Access** tab, configure the file access and viewing options available if users select **This is a private computer** while they're signing in to Outlook Web App, or if users sign in using an authentication method other than forms-based authentication. File access lets users open any file attached to an e-mail message and files available through Windows file shares and Windows SharePoint Services document libraries.
   Direct file access
   - **Enable direct file access** Select this check box if you want to enable

direct file access. Direct file access lets users open files available through Outlook Web App. This includes files attached to e-mail messages and files in Windows SharePoint Services document libraries and on Windows file shares.

- **Customize** After you select **Enable direct file access**, click **Customize** to customize the direct file access settings.

Note:
The settings for direct file access are divided into public computer file access settings and private computer file access settings. You can configure these settings on either the **Private Computer File Access** tab or the **Public Computer File Access** tab. However, you cannot have different settings for each tab.

In the **Direct File Access Settings** dialog box, specify how files will be allowed, blocked, or handled in Outlook Web App. The Allow list overrides the Block list and the Force Save list. The Block list overrides the Force Save list. Select the following:
Allow Click the **Allow** button to specify which types of files should always be allowed. The Allow list overrides the Block list and Force Save list.
Block Click the **Block** button to specify which types of files should be blocked. The Block list overrides the Force Save list and is overridden by the Allow list.
Force Save Click the **Force Save** button to specify which types of files the user must save to disk before opening them. The Force Save list is overridden by the Allow and Block lists.
Unknown Files Using the **Unknown Files** list, specify how Outlook Web App handles unknown files that aren't in the Allow, Block, or Force Save lists.
When you click **Allow**, **Block**, or **Force Save**, a new window opens in which you can add file name extensions and MIME types to the list you have selected, edit them, or remove them.
After you have selected **Allow**, **Block**, or **Force Save**:
To add a file name extension or MIME type, enter it in the appropriate box, and then click **Add**. File name extensions must be preceded by a period (**.**), for example, .exe.
To edit a file name extension or MIME type, select it, and then click **Edit**.
To remove a file name extension or MIME type, select it, and then click **Remove**.
After you finish modifying the lists of file name extensions and MIME types, click **OK** to save your changes or click **Cancel** to discard your changes and return to the previous window.

WebReady Document Viewing

WebReady Document Viewing enables Outlook Web App documents to be converted to HTML and displayed in a Web browser. Configure WebReady Document Viewing using the **WebReady Document Viewing Settings** tab. These settings are available for public and private computer file access, and can be different for each:

- **Enable WebReady Document Viewing** Select this check box if you want to enable supported documents to be converted to HTML and displayed in a Web browser.
- **Force WebReady Document Viewing when a converter is available** Select this check box if you want to force documents to be converted to HTML and displayed in a Web browser before users can open them in the viewing application. Documents can be opened in the viewing application only if **Direct File Access** is enabled.
- **Supported** After you select **Enable WebReady Document Viewing**, click **Supported** to select supported document types for **WebReady Document Viewing**.

Select document types to view from an Internet browser
To allow all supported document types to be viewed from an Internet browser, select **All supported document types**.
To allow only specific document types to be viewed, select **Specific document types**.
Add After you select **Specific document types**, click **Add** to add a document type to the list.
Remove After you select **Specific document types**, click the document type that you want to remove, and then click the remove icon.
Select the MIME types of documents Using this list, add the MIME types of documents to the list of types that can be viewed from an Internet browser or remove them from the list.
Add After you select **Specific document types**, click **Add** to add a MIME type to the list.
Remove After you select **Specific document types**, click the MIME type that you want to remove, and then click the remove icon.

Use the Shell to configure Outlook Web App mailbox policies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

This example enables calendar access in the default mailbox policy.

```
Set-OwaMailboxPolicy -Identity Default -CalendarEnabled $true
```

For more information about syntax and parameters, see Set-OwaMailboxPolicy.

Use the Shell to view Outlook Web App mailbox policies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "View Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

This example retrieves the properties of the Outlook Web App mailbox policy `Executives` in the organization `Fabrikam`.

```
Get-OwaMailboxPolicy -Identity Fabrikam\Executives
```

For more information about syntax and parameters, see Get-OwaMailboxPolicy.

1.6.2.2.5.3 Remove an Outlook Web App Mailbox Policy from Exchange

Remove an Outlook Web App Mailbox Policy from Exchange

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove a Microsoft Office Outlook Web App mailbox policy from an Exchange organization by using either the EMC or the Shell.

Looking for other management tasks related to Outlook Web App mailbox policies? Check out Managing Outlook Web App Mailbox Policies.

Prerequisites

The Client Access server role has been installed.

Use the EMC to remove an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Client Access**.
2. In the work pane, click the **Outlook Web App Mailbox Policies** tab.
3. Right-click the Outlook Web App mailbox policy you want to remove, and then click **Remove**.
4. In the confirmation window, click **Yes** to remove the mailbox policy, or click **No** to cancel.

Use the Shell to remove an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

This example removes an Outlook Web App mailbox policy named `Policy1`.

```
Remove-OwaMailboxPolicy -Name Policy1
```

For more information about syntax and parameters, see Remove-OwaMailboxPolicy.

1.6.2.2.5.4 Apply an Outlook Web App Mailbox Policy to a Mailbox

Apply an Outlook Web App Mailbox Policy to a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can apply an Outlook Web App mailbox policy to one or more mailboxes or remove one using either the EMC or the Shell.

Looking for other management tasks related to Outlook Web App mailbox policies? Check out Managing Outlook Web App Mailbox Policies.

Prerequisites

The Client Access server role has been installed and the Outlook Web App mailbox policies you want have been created.

Use the EMC to apply an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the work pane, select the mailbox that you want to apply an Outlook Web App mailbox policy to. You can also select multiple mailboxes.
3. Right-click your selection, then click **Properties**.
4. Click the **Mailbox Feature** tab.
5. Click **Outlook Web App**, and then click **Properties** to view the Outlook Web App Properties window.
6. Select the **Outlook Web App mailbox policy** check box, and then click **Browse** to view available Outlook Web App mailbox policies.
7. Click the policy you want to apply and then click **OK**. You'll be taken back to the Outlook Web App mailbox properties window.
8. Click **OK** to apply the policy.
9. If you've selected more than one recipient, you'll see a Bulk Edit Summary. Click **OK** to accept the change, or **Cancel** to cancel.
10. Click **OK** in the mailbox properties window to accept your changes.

Use the EMC to remove an Outlook Web App mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the work pane, select the mailbox that you want to apply an Outlook Web App mailbox policy to. You can also select multiple mailboxes.
3. Right-click your selection, then click **Properties**.
4. Click the **Mailbox Feature** tab.
5. Click **Outlook Web App**, and then click **Properties** to view the Outlook Web App Properties window.
6. Clear the **Outlook Web App mailbox policy** check box.
7. Click **OK** to remove the policy.
8. If you've selected more than one recipient, you'll see a Bulk Edit Summary. Click **OK** to accept the change, or click **Cancel** to cancel.
9. Click **OK** in the mailbox properties window to accept your changes.

Use the Shell to apply an Outlook Web App mailbox policy to an existing mailbox.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access user settings" entry in the Client Access Permissions topic.

This example applies the Outlook Web App mailbox policy named "Calendar" to the

mailbox of the user tony@contoso.com.

```
Set-CASMailbox -Identity tony@contoso.com -OwaMailboxPolicy:Calendar
```

For more information about syntax and parameters, see Set-CASMailbox.

Use the Shell to remove an Outlook Web App mailbox policy from an existing mailbox.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access user settings" entry in the Client Access Permissions topic.

This example removes the Outlook Web App mailbox policy from mailbox of the user tony@contoso.com.

```
Set-CASMailbox -Identity tony@contoso.com -OwaMailboxPolicy:$null
```

For more information about syntax and parameters, see Set-CASMailbox.

1.6.2.2.6 Managing Outlook Web App and Instant Messaging Integration

Managing Outlook Web App and Instant Messaging Integration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-01*

Configure Outlook Web App and Office Communications Server 2007 Integration

Configure Outlook Web App and Lync Server 2010 Integration

1.6.2.2.6.1 Configure Outlook Web App and Office Communications Server 2007 Integration

Configure Outlook Web App and Office Communications Server 2007 Integration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

To enable Microsoft Office Outlook Web App and Microsoft Office Communications Server 2007 integration, you must complete the following steps.

Note:

All references to Communications Server 2007 in this topic refer to Communications

Server 2007 R2.

Prerequisites

You must have:

- Deployed Microsoft Exchange Server 2010 in your organization.
- A working Communications Server 2007 R2 environment.
- A certificate that's trusted by the Communications Server 2007 server and the Client Access server and is issued by the same authority.
- A certificate that has the Client Access server namespace as the subject on the Subject line. The namespace may be the name of a particular Client Access server, or it may be a DNS name that's used for load balancing across multiple Client Access servers.
- The Client Access server namespace must be in the Communications Server 2007 trusted hosts list.
- The fully qualified domain name (FQDN) of the Communications Server 2007 server or the Communications Server 2007 pool.
- Enabled your users to use Communications Server 2007 via the Communications Server 2007 user administration tools.

Download and Install the Web Service Provider

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. On the Client Access server running Windows Server 2008 or a later version, download and install UCMA 2.0 from Unified Communications Managed API 2.0, Core Runtime (64-bit).

   Note:
   UCMA must be version 6907.210 or a later version. If you have installed a previous version of UCMA, you should uninstall it before you install the later version.

2. On the Client Access server, download and extract the CWAOWASSPMain.msi file from: Microsoft Office Communications Server 2007 R2 Web Service Provider.
   2.a. The following files are extracted to the Web Service Provider installer package location:
   CWAOWAASSP.msi
   Donnetfx35setup.exe
   UcamRedist.msi
   Vcredist_x64.exe
3. Double-click **CWAOWASSP.msi** to install the Microsoft Office Communications Server 2007 R2 Web Service Provider.
4. Download and install the hotfix from OCS 2007 R2 Web Service Provider Hotfix version 6907.202.

Use the following checklist to make sure that the installation was successful:

- Look for the **InstantMessaging** key in the registry under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA**. The string under **InstantMessaging** with the name **ImplementationDLLPath** and the value "<Your Exchange Install Path>\ClientAccess\owa\bin\Microsoft.Rtc.UCWeb.dll" should have been created.
- The Microsoft.Rtc.UCWeb.dll file should be present in the directory <install drive>\Program Files\Microsoft\Exchange Server\V14\ClientAccess\Owa\Bin.
- The files SIPEPS.dll and Microsoft.Rtc.Collaboration.dll should be present in the

Microsoft .NET Framework Global Assembly Cache.

Obtain Certificate Information

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Certificate management" entry in the Exchange and Shell Infrastructure Permissions topic.

The Client Access server must be configured to use a certificate that's trusted by Communications Server 2007.

Note:
The certificate on the Client Access server and the Communications Server 2007 server must be from the same issuer.

Note:
If all your Client Access servers are in the same namespace, you can use a single certificate for all of them.

After the certificate is in place on the Client Access server, use the Exchange Management Shell to get the certificate information by running the following command on the Client Access server.

```
get-ExchangeCertificate | fl
```

Locate the certificate you want to use, and then record the *thumbprint*.

When you configure the Communications Server 2007 host authorization list, you'll add the certificate subject as the name of an authorized host.

For information about how to obtain and configure a certificate for a Client Access server, see Obtain a Server Certificate from a Certification Authority.

Select a Communications Server 2007 Pool

Select the same Communications Server 2007 pool you used for the next hop server for Microsoft Office Communicator Web Access server. This server will proxy all SIP requests to the destination pool. For more information about the next hop server, see Creating a Communicator Web Access Virtual Server.

Use the Shell to configure the Communications Server 2007 server used by the Client Access server and to enable integration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures which Communications Server 2007 pool to connect to, the certificate to be used, and enables the Client Access server to use Communications Server 2007 for instant messaging.

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingServerName <na
```

Note:
You may have to restart Internet Information Services (IIS). You can do this by opening a Command Prompt window and using the iisreset/noforce command.

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Configure Communications Server 2007

For information about how to configure Communications Server 2007 to work with Outlook Web App, see Administering Web Service Provider in the Communications Server 2007 documentation.

Other Tasks

After you enable Communications Server 2007 integration on the Client Access server, you may also want to use segmentation or Outlook Web App mailbox policies to enable or disable IM for users.

- Managing Outlook Web App Mailbox Policies
- Set-CASMailbox

1.6.2.2.6.2 Configure Outlook Web App and Lync Server 2010 Integration

Configure Outlook Web App and Lync Server 2010 Integration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

To enable Microsoft Office Outlook Web App and Microsoft Lync Server 2010 integration, you must complete the following steps.

Prerequisites

You must have:

- Deployed Microsoft Exchange Server 2010 in your organization.
- Deployed Lync Server 2010.
- Obtained a certificate that's trusted by the Lync Server 2010 server and the Client Access server and is issued by the same authority. The certificate must have the Client Access server namespace as the subject on the Subject line. The namespace may be the name of a particular Client Access server, or it may be a DNS name that's used for load balancing across multiple Client Access servers.
- Recorded the fully qualified domain name (FQDN) of the Lync Server 2010 server or the Lync Server 2010 pool that the Client Access server will connect to. The server or pool should be geographically close to the Client Access server.
- Enabled your users to use Lync Server 2010 via the Lync Server 2010 user

administration tools.

Step 1: Download and install the Web Service Provider

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. On the Client Access server running Windows Server 2008 or a later version, download and install UCMA 2.0 from Unified Communications Managed API 2.0, Core Runtime (64-bit).

   Note:
   Unified Communications Managed API v. 2.0 (UCMA) must be version 6907.210 or a later version. If you've installed a previous version of UCMA, you should uninstall it before you install the later version.

2. On the Client Access server, download and extract the CWAOWASSPMain.msi file from Microsoft Office Communications Server 2010 R2 Web Service Provider. The following files are extracted to the Web Service Provider installer package location:
   - CWAOWAASSP.msi
   - Donnetfx35setup.exe
   - UcamRedist.msi
   - Vcredist_x64.exe
3. Double-click **CWAOWASSP.msi** to install the Microsoft Office Lync Server 2010 R2 Web Service Provider.
4. Download and install the hotfix from OCS 2007 R2 Web Service Provider Hotfix.

Use the following checklist to make sure that the installation was successful:

- Look for the **InstantMessaging** key in the registry under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA**. The string under **InstantMessaging** with the name **ImplementationDLLPath** and the value "<Your Exchange Install Path>\ClientAccess\owa\bin\Microsoft.Rtc.UCWeb.dll" should have been created.
- The Microsoft.Rtc.UCWeb.dll file should be present in the directory *<installation drive>*\Program Files\Microsoft\Exchange Server\V14\ClientAccess\Owa\Bin.
- The files SIPEPS.dll and Microsoft.Rtc.Collaboration.dll should be present in the Microsoft .NET Framework Global Assembly Cache.

Step 2: Use the Shell to verify certificate information

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Certificate management" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:
If all your Client Access servers are in the same namespace, you can use a single certificate for all of them.

1. Run the following cmdlet on the Client Access server to obtain certificate information for that server:

   ```
   get-ExchangeCertificate | fl
   ```

2. Locate the certificate you want to use, and then record its thumbprint and subject.

When you configure the Lync Server 2010 host authorization list, you'll add the certificate subject as the name of an authorized host.

For detailed syntax and parameter information, see Get-ExchangeCertificate.

For information about how to obtain and configure a certificate for a Client Access server, see Obtain a Server Certificate from a Certification Authority.

Step 3: Use the Shell to set the Lync Server 2010 server used by the Client Access server and to enable integration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

Note:
Step 3 can be performed before or after step 4, but both steps are required.

This example configures which Lync Server 2010 server or pool to connect to, the certificate to be used, and enables the Client Access server to use Lync Server 2010 for instant messaging.

```
Get-OwaVirtualDirectory | Set-OwaVirtualDirectory -InstantMessagingServerName <na
```

Note:
You may have to restart Internet Information Services (IIS). You can do this by opening a Command Prompt window and using the **iisreset/noforce** command.

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Step 4: Configure Lync Server 2010

Note:
Step 3 can be performed before or after step 4, but both steps are required.

This example creates an Outlook Web App pool entry on the Lync Server 2010 server. Use the Lync Server Management Shell on the Lync Server 2010 server to perform the following steps:

1. Run the **Get-CsSite** cmdlet to get the `siteID` for the `siteName` in which you are creating the pool.
2. Run the **New-CsTrustedApplicationPool** cmdlet to create the trusted application pool. This also creates the external service entry in Lync Server 2010.

```
New-CsTrustedApplicationPool -Identity <OwaPoolfqdn same as what is us
```

Note:
Running the cmdlet with these parameters will create a pool with a computer FQDN that's the same as the pool FQDN. This allows you to keep adding new Outlook Web App servers to the Exchange organization without going through this process to add each of them to the Lync server.

1. Run the **New-CsTrustedApplication** cmdlet to add a trusted service port for the application.

```
New-CsTrustedApplication -ApplicationId <ApplicationIDForOWA> -Trusted
```

Note:
The ApplicationID for Outlook Web App can't include spaces, but otherwise it can be any string that allows the Lync Server administrator to recognize the trusted application as Outlook Web App, for example: Outlook Web App Pool.

1. Run the **Enable-CsTopology** cmdlet in the Shell to enable the topology.

```
Enable-CsTopology
```

Other Tasks

After you enable Lync Server 2010 integration on the Client Access server, you may also want to use segmentation or Outlook Web App mailbox policies to enable or disable instant messaging for users.

- Managing Outlook Web App Mailbox Policies
- Set-CASMailbox

1.6.2.3 Managing Outlook Anywhere

Managing Outlook Anywhere

Exchange Server 2010 > Client Access > Managing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-13*

Configure Outlook Anywhere in an Environment with Earlier Versions of Exchange

Enable Outlook Anywhere

Disable Outlook Anywhere

Configure an External Host Name for Outlook Anywhere

Managing Certificates for Outlook Anywhere

Configure Client Access Server Properties

Install the Windows RPC Over HTTP Proxy Component

Test Outlook Anywhere Connectivity

1.6.2.3.1 Configure Outlook Anywhere in an Environment with Earlier Versions of Exchange

Configure Outlook Anywhere in an Environment with Earlier Versions of Exchange

Client Access > Managing Client Access Servers > Managing Outlook Anywhere >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-05-18*

When you deploy the Outlook Anywhere feature (formerly known as RPC over HTTP) on a Microsoft Exchange Server 2010 Client Access server that will provide access to Microsoft Exchange Server 2007 or Exchange Server 2003, you must disable Outlook Anywhere for the earlier versions. You need to do this because Exchange 2003 and Exchange 2007 can't provide access to a mailbox that's hosted on an Exchange 2010 server.

After you enable Outlook Anywhere on Exchange 2010 and disable Outlook Anywhere on Exchange 2003 and Exchange 2007, you should make sure that users who have mailboxes on computers running Exchange 2003 and Exchange 2007 can access their mailboxes through Exchange 2010. To do this, create a test mailbox on each computer running Exchange 2003 and Exchange 2007. Then, perform an Outlook Anywhere (RPC over HTTP) connectivity test on each test mailbox by using Microsoft Exchange Remote Connectivity Analyzer. For more information about testing Outlook Anywhere, see Test Outlook Anywhere Connectivity.

Looking for other management tasks related to Exchange 2010 Outlook Anywhere? Check out Managing Outlook Anywhere.

Looking for other tasks related to upgrading client access from Exchange 2003 to Exchange 2010? Check out Upgrade from Exchange 2003 Client Access.

Looking for other tasks related to upgrading client access from Exchange 2007 to Exchange 2010? Check out Upgrade from Exchange 2007 Client Access.

Configure Outlook Anywhere for Exchange Server 2003

You can configure Outlook Anywhere for the original release version of Exchange 2003 and for Exchange 2003 with Service Pack 1 (SP1) or SP2 by following the configuration steps for RPC over HTTP for these versions of Microsoft Exchange. For detailed steps, see How to Configure Outlook Anywhere with Exchange 2003.

Configure Outlook Anywhere for Exchange Server 2007

Use the EMC or the Shell in Exchange Server 2007 to enable or disable Outlook Anywhere for your organization. For detailed steps, see How to Enable Outlook Anywhere.

Other Tasks

After you configure Outlook Anywhere for earlier versions of Exchange, you may also want to:

- Test Outlook Anywhere Connectivity
- Configure an External Host Name for Outlook Anywhere

1.6.2.3.2 Enable Outlook Anywhere

Enable Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the Enable Outlook Anywhere wizard on the Exchange Server 2010 Client Access server to allow users to connect to their Exchange mailbox from the Internet. Outlook Anywhere eliminates the need for users in remote offices or mobile users to use a virtual private network (VPN) to connect to their Exchange servers.

Outlook Anywhere will be enabled on your Client Access server after a configuration period of approximately 15 minutes. To verify that Outlook Anywhere has been enabled, check the application event log on the Client Access server.

Prerequisites

- Install a valid Secure Sockets Layer (SSL) certificate from a certification authority (CA) that the client trusts.
- Install the Microsoft Windows RPC over HTTP Proxy component if it wasn't already installed by default in Windows Server 2008. For detailed steps, see Install the Windows RPC Over HTTP Proxy Component.
- Enable Outlook Anywhere on the Client Access server.

When you install Exchange 2010, you can install a default SSL certificate that's created by Exchange Setup. However, this certificate isn't a valid SSL certificate that's trusted by the client. To use Outlook Anywhere, you must install an SSL certificate that's trusted by the client.

What Do You Want to Do?

- Use the EMC to enable Outlook Anywhere
- Use the Shell to enable Outlook Anywhere

Use the EMC to enable Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, click **Enable Outlook Anywhere**.
3. In the Enable Outlook Anywhere wizard, type the external host name or URL for your organization in the box under **External host name**.
   This is the URL, for example site.contoso.com, that users will use to connect to the Exchange server by using Outlook Anywhere.
4. Select an available external authentication method. You can select **Basic authentication** or **NTLM authentication**.
   Basic authentication sends the user name and password in clear text. It also requires that users enter domain, user name, and password every time that they connect to the Exchange server. When you use NTLM authentication, the user's credentials are never sent over the network. Instead, the client computer and the server exchange hashed values of the user's credentials. NTLM can also use the current Windows operating system logon information.

Even though it's more secure, NTLM may not work with firewalls that examine and modify traffic. You can use an advanced firewall server such as Microsoft Internet Security and Acceleration (ISA) Server 2006 together with NTLM authentication for Outlook Anywhere.

Caution:

Negotiate Ex authentication is an authentication type that's reserved for future Microsoft use and should not be used. Use of this setting will cause authentication to fail.

5. If you're using an SSL accelerator and you want to use SSL offloading, select the check box next to **Allow secure channel (SSL) offloading**.
   Select this check box if you'll be using a separate server to handle Secure Sockets Layer (SSL) encryption and decryption. When you use SSL offloading, the firewall in front of the Client Access server ends the SSL session and then establishes a new non-SSL session to the Exchange server.

   Important:

   Don't use this option unless you're sure that you have an SSL accelerator that can handle SSL offloading. If you don't have an SSL accelerator that can handle SSL offloading, and you select this option, Outlook Anywhere won't function correctly.

6. Click **Enable** to apply these settings and enable Outlook Anywhere.

7. Click **Finish** to close the Enable Outlook Anywhere wizard.

Use the Shell to enable Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration settings" entry in the Client Access Permissions topic.

In this example, the Client Access server named `Exch1` is enabled for Outlook Anywhere with its external host name as `site.contoso.org`, the default authentication set to Basic, and SSL offloading not selected.

```
Enable-OutlookAnywhere -Server 'Exch1' -ExternalHostname 'site.contoso.org' -Defa
```

This example enables the server named `Server01` for Outlook Anywhere. The external host name is set to `mail.contoso.com`, both Basic and NTLM authentication are used, and SSL offloading is set to `$true`. The `ClientAuthenticationMethod` parameter specifies the authentication method that the Autodiscover service provides to the Outlook Anywhere clients to authenticate to the Client Access server. The authentication method can be set to Basic or NTLM.

```
Enable-OutlookAnywhere -Server:Server01 -ExternalHostname:mail.contoso.com -Clien
```

For more information about syntax and parameters, see Enable-OutlookAnywhere.

Other Tasks

After you enable Outlook Anywhere, you may want to Configure Client Access Server Properties.

1.6.2.3.3 Disable Outlook Anywhere

Disable Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to disable Outlook Anywhere on the Microsoft Exchange Server 2010 Client Access server for your organization.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Prerequisites

If you want to disable Outlook Anywhere access for your whole organization, you must disable it on the Exchange 2010 Client Access server that's enabled for Outlook Anywhere in all sites in your organization. However, you can disable access to Outlook Anywhere on a site-by-site basis by disabling Outlook Anywhere only on each Client Access server in the site in which you want to disable Outlook Anywhere access to Mailbox servers.

Use the EMC to disable Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, click **Disable Outlook Anywhere**.
3. Click **Yes** when you're asked if you want to disable Outlook Anywhere for this server.

Use the Shell to disable Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration" entry in the Client Access Permissions topic.

This example disables Outlook Anywhere on the specified Client Access server.

```
disable-OutlookAnywhere -Server:'ServerName'
```

For more information about syntax and parameters, see Disable-OutlookAnywhere.

Other Tasks

After you disable Outlook Anywhere, you may also want to:

- Enable Outlook Anywhere
- Test Outlook Anywhere Connectivity

Configure an External Host Name for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can create an external host name for Outlook Anywhere on a Microsoft Exchange Server 2010 Client Access server.

If you manage more than one Exchange site, we recommend that you create separate external host names for each site that has a Client Access server that's enabled for Outlook Anywhere. When you create a separate external host name for each site, Microsoft Office Outlook 2007 clients automatically use the Client Access server that's closest to their mailbox.

Note:
Users who are using Outlook 2003 must have their profiles manually updated to use the external host name that is closest to their mailbox.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Prerequisites

To successfully complete this procedure, either the Client Access server must be enabled for Outlook Anywhere or the external host name must be specified by using the Enable Outlook Anywhere wizard. To enable Outlook Anywhere, see Enable Outlook Anywhere.

Use the EMC to configure an external host name for Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration (enable, disable, change, view)" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, click **Properties**.
3. On the **Exchange (Default Web Site) Properties** page, click the **Outlook Anywhere** tab.
4. In the text box under **External host name**, enter the external host name to use for this site.
5. Click **OK** to save your changes.

Use the Shell to configure an external host name for Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration (enable, disable, change, view)" entry in the Client Access Permissions topic.

This example configures an external host name for Outlook Anywhere.

```
set-OutlookAnywhere -Identity:'CAS01' -ExternalHostName:'site.contoso.com'
```

For more information about syntax and parameters, see Configure an External Host Name for Outlook Anywhere.

Other Tasks

After you configure an external host name for Outlook Anywhere, you may also want to:

- Configure Authentication for Outlook Anywhere
- Configure SSL for Outlook Anywhere
- Configure SSL Offloading for Outlook Anywhere

1.6.2.3.5 Managing Certificates for Outlook Anywhere

Managing Certificates for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-07*

Configure Outlook Anywhere to Use an SSL Certificate with Redirection

Configure Outlook Anywhere to Use Multiple SSL Certificates

1.6.2.3.5.1 Configure Outlook Anywhere to Use an SSL Certificate with Redirection

Configure Outlook Anywhere to Use an SSL Certificate with Redirection

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you can't use multiple Secure Sockets Layer (SSL) certificates for your Outlook Anywhere deployment, you can set up your Outlook Anywhere deployment to use a single SSL certificate with redirection. Microsoft Office Outlook 2007 and Outlook 2010 clients that aren't joined to your domain or don't have direct access to Active Directory in your Microsoft Exchange Server 2010 forest will be redirected to another Domain Name System (DNS) address to obtain their user profile information by using the Autodiscover service.

For more information about how a single SSL certificate works with redirection in an Outlook Anywhere deployment, see Understanding Redirection for Outlook Anywhere with a Single SSL Certificate.

Looking for other tasks for managing Outlook Anywhere? Check out Managing Outlook Anywhere.

Configure your Outlook Anywhere deployment to use an SSL certificate with redirection

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "SSL for Outlook Anywhere" and "IIS Manager" entries in the Client Access Permissions topic.

1. Configure a valid SSL certificate. You must obtain a valid SSL certificate from a certification authority (CA) that's trusted by the client computer's operating system. For more information, see Obtain a Server Certificate from a Certification Authority. After you obtain a valid SSL certificate, apply the certificate to the default Web site of your Client Access server. For more information, see Install an SSL Certificate on a Client Access Server.
2. Configure the URLs for Exchange services. You must configure the external and internal URLs for your available Exchange services to point to the default Web site, for example, mail.contoso.com. For more information about how to set the URLs for the Exchange services, see Configure Exchange Services for the Autodiscover Service.
3. Configure the service connection point object to use a site dedicated to handling e-mail, for example, mail.contoso.com. You can do this by running the following command:

```
Set-ClientAccessServer -id <CAS01>  -AutoDiscoverServiceInternalUri ht
```

4. Configure the IP address for the default Web site. You must set the default Web site to listen on only one IP address. After you have done this, bind any additional IP addresses to the network adapter, also known as a NIC, for the Client Access server. For more information about how to do this, see your Windows server documentation.
5. Create a new Web site in Internet Information Services (IIS) Manager for the Autodiscover service redirection by doing the following:
   5.a. In IIS Manager, expand your Client Access server name to select and right-click **Sites**, then select **Add Web Site**. Enter your domain name under **Site name**.
   5.b. Under **Physical path**, navigate to %SystemDrive%\inetpub\. Under inetpub, create a new folder called Autodiscover_redirect.

   Note:
   You must allow the **Users** group **Read & execute** access to the Web site that you create.
6. Create the Autodiscover redirect. Use Windows Explorer to locate the folder that you created named Autodiscover_redirect. Create a new folder named Autodiscover in the Autodiscover redirect folder, and then use a text editor, such as Notepad, to create a new blank text file named Autodiscover.xml in the Autodiscover folder.
7. Configure the new Web site to redirect to the site that's dedicated to handling e-mail, for example, mail.contoso.com. In IIS Manager, right-click the Autodiscover.xml file that you created, and then click **Properties**. On the Properties page, select **A redirection to a URL**, and then enter the same URL that you used to configure the server connection point object. For example, https://mail.contoso.com/autodiscover/autodiscover.xml.
8. Test your results to make sure that the site that you're using to handle e-mail, for example, mail.contoso.com, can be resolved internally and externally by using your Outlook 2010 or Outlook 2007 client.

Other Tasks

After you configure Outlook Anywhere to use an SSL certificate with redirection, you may

also want to:

- Configure SSL Offloading for Outlook Anywhere

1.6.2.3.5.2 Configure Outlook Anywhere to Use Multiple SSL Certificates

Configure Outlook Anywhere to Use Multiple SSL Certificates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use multiple Secure Sockets Layer (SSL) certificates for Outlook Anywhere and the Microsoft Exchange services that Microsoft Office Outlook 2007 and Outlook 2010 use, such as Unified Messaging and the offline address book.

After your Outlook Anywhere deployment has been configured correctly to use multiple SSL certificates, your domain-joined clients will contact Active Directory and obtain the site address for the Autodiscover service from the service connection point (SCP) object. Clients that aren't domain joined or that don't have direct access to Active Directory will contact the DNS server to obtain the site address for the Autodiscover service SCP object. After a client connects to the Autodiscover service, the client will receive the URLs for the available Microsoft Exchange services. The client won't be prompted with a certificate warning because a valid certificate is provided at each point during the connection process.

Looking for management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Configure your Outlook Anywhere deployment to use multiple SSL certificates

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "SSL for Outlook Anywhere", "IIS Manager", and "Autodiscover service virtual directory settings" entries in the Client Access Permissions topic.

The following are the steps required to configure your Outlook Anywhere deployment to use multiple SSL certificates.

1. **Obtain two valid SSL certificates** You must obtain two valid SSL certificates from a certification authority (CA) that's trusted by the client's operating system. One SSL certificate will be used for the site that will handle e-mail and the other will be used for the site dedicated to the Autodiscover service. For example, you can create one SSL certificate named mail.contoso.com and another certificate named autodiscover.contoso.com. For more information, see Obtain a Server Certificate from a Certification Authority.
2. **Configure a second IP address** After you've obtained the certificates, you must assign an additional IP address to the network adapter, also known as a NIC, on the Microsoft Exchange Server 2010 Client Access server. This will enable the Client Access server to have two public IP addresses. For more

information, see the Windows Server 2008 documentation about configuring networks and servers.

3. **Create an A record** Create a Host (A) resource record using the DNS manager for the second site that's dedicated to the Autodiscover service, for example, autodiscover.contoso.com, and point it to the new IP address that you created on the Client Access server. For more information, see the Windows Server 2008 DNS documentation about adding resource records.
4. **Create a new Autodiscover Web site** On the Client Access server, use Internet Information Services (IIS) Manager to create a new Web site that points to an empty directory. Then assign this new Web site the IP address for the second site that's dedicated to the Autodiscover service (for example, autodiscover.contoso.com). Follow these steps:
   4.a. From IIS Manager, expand your server name > **Sites**, and select the new Web site
   4.b. In the **Actions** pane, select **Bindings**.
   4.c. From the **Site Bindings** dialog box, in the **Types** column, select **http**, and then click **Edit**.
   4.d. In the **Edit Site Binding** dialog box, assign the dedicated IP address, enter the host name, for example autodiscover.contoso.com, and then click **OK**.
5. **Create a new Autodiscover virtual directory** Use the **New-AutodiscoverVirtualDirectory** cmdlet to create the new Autodiscover virtual directory on this second Web site that's dedicated to the Autodiscover service. For more information, see Create an Autodiscover Virtual Directory.
6. **Remove the Autodiscover virtual directory for the default Web site** You must correctly identify and remove the Autodiscover virtual directory that you created during Exchange Setup by using the **Remove-AutoDiscoverVirtualDirectory** cmdlet. For more information, see Delete the Default Autodiscover Virtual Directory.
7. **Assign the SSL certificates to the correct Web sites** You must assign the first SSL certificate, for example, the certificate for mail.contoso.com, to the default Web site, and then assign the second SSL certificate to the site that's dedicated to the Autodiscover service, for example, the autodiscover.contoso.com Web site. Follow these steps:
   7.a. From IIS Manager, expand your server name > **Sites**, and then select the Web site.
   7.b. In the **action** pane, select **Bindings**.
   7.c. In the **Site Bindings** dialog box, click **Add**.
   7.d. In the **Add Site Bindings** dialog box, set the binding type as **https**.
   7.e. Under SSL certificate, select the SSL certificate to be used for this site, and then click **OK**.
8. **Change the URLs for the Exchange services** You must change the external and internal URLs for your available Exchange services to point to the site that's dedicated to handling e-mail, for example, mail.contoso.com. For more information about how to set the URLs for the Exchange services, see Configure Exchange Services for the Autodiscover Service.
9. **Configure the SCP object** You must configure the SCP object to use the site that's dedicated to the Autodiscover service, for example, autodiscover.contoso.com. This example sets the Active Directory SCP object to direct users to the autodiscover.contoso.com URL using the **Set-ClientAccessServer** cmdlet on CAS1:

```
Set-ClientAccessServer -Identity CAS1 -AutoDiscoverServiceInternalUri
```

10. **Test your results** After you've completed these steps, you must make sure that the sites that are dedicated to handling e-mail and the Autodiscover service can be resolved internally and externally by your Outlook client. For more information, see Test Outlook Anywhere Connectivity and Test Outlook Autodiscover Connectivity.

Other Tasks

After you've configured Outlook Anywhere to use multiple SSL certificates, you may also want to:

- Configure Outlook Anywhere to Use an SSL Certificate with Redirection
- Test Outlook Anywhere Connectivity
- Test Outlook Autodiscover Connectivity

1.6.2.3.6 Configure Client Access Server Properties

Configure Client Access Server Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Outlook Anywhere** tab to configure settings after you enable Outlook Anywhere on your Microsoft Exchange Server 2010 Client Access server.

Looking for other tasks for managing Outlook Anywhere? Check out Managing Outlook Anywhere.

What Do You Want to Do?

- Use the EMC to configure Outlook Anywhere on the Client Access server properties
- Use the Shell to configure Outlook Anywhere on the Client Access server properties

Prerequisites

Outlook Anywhere has been enabled. For detailed steps, see Enable Outlook Anywhere.

Use the EMC to configure Outlook Anywhere on the Client Access server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration settings" entry in the Client Access Permissions topic.

Note:

You can also use the Shell to view general information about a server. For more information, see Get-ExchangeServer.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the work pane, select the server that you want to configure.
3. In the action pane, click **Properties**.

4. On the **General** tab, you can view general information about the server:
   - **Version** This field displays the version of Exchange installed on the server.
   - **Edition** This field displays the Exchange Server edition. The edition is either Standard Edition or Enterprise Edition.
   - **Role(s)** This field displays the Exchange server roles installed on the server.
   - **Product ID** This field displays the product ID for the Exchange server. If you haven't yet entered the product key for the server, the product ID displayed is **Unlicensed**. To license an unlicensed version of Exchange, see Enter Product Key.
   - **Modified** This field displays the last date and time that a configuration change was made on this server.

5. On the **System Settings** tab, view the domain controller servers and global catalog servers. You can also enable an error reporting feature:
   - **Domain controller servers being used by Exchange** This read-only box displays a list of domain controller servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Global catalog servers being used by Exchange** This read-only box displays a list of global catalog servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Automatically send fatal service error report to Microsoft** Select this check box if you want to enable the error reporting feature and automatically send an error report to Microsoft in the event of a fatal error.
     If you enable the error reporting feature, information about fatal service errors is sent to Microsoft over encrypted channels. The information is used to improve Microsoft products. When this feature is enabled and the issue reported has a known solution, the server receives feedback from Microsoft. This feedback contains a link to information that may help resolve the problem.

6. On the **Customer Feedback Options** tab, you can enroll the selected server into the Customer Experience Improvement Program. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.

7. Use the **Outlook Anywhere** tab to view or configure Outlook Anywhere settings. This tab is available only on servers that have the Client Access server role installed.
   - **Status** This read-only field displays whether Outlook Anywhere is enabled or disabled for the server.
   - **External host name** Use this text box to type the external host name or URL for your organization. Users will use this name to connect to the Exchange server by using Outlook Anywhere.
   - **Client authentication method** There are three authentication options available for Outlook Anywhere.
     Basic authentication Click this button to use Basic authentication. Basic authentication sends the user's user name and password in clear text. Basic authentication also requires the user to enter their domain, user name, and password every time they connect to the Client Access server.
     NTLM authentication Click this button to use NTLM authentication. NTLM authentication is also known as Integrated Windows authentication. When NTLM authentication is used, the user's credentials aren't sent over the network. Instead, the client computer and the server exchange hashed

values of the user's credentials. NTLM can also use the current Microsoft Windows operating system logon information.
Even though it is more secure, NTLM may not work with firewalls that examine and modify traffic. For more information about whether you can use NTLM with your firewall, see your firewall manufacturer's documentation. We recommend that you choose NTLM authentication with SSL when you're using an advanced firewall server such as Microsoft Internet Security and Acceleration (ISA) Server 2006. ISA Server 2006 allows NTLM authentication to be used with Outlook Anywhere.
Negotiate Ex authentication Do not click this button. Negotiate Ex authentication is an authentication type reserved for future Microsoft use and shouldn't be used. Use of this setting will cause authentication to fail.

- **Allow secure channel (SSL) offloading** Select this check box if you will be using a separate server to handle Secure Sockets Layer (SSL) encryption and decryption. When you use SSL offloading, the firewall in front of the Client Access server ends the SSL session and then establishes a new non-SSL session to the Client Access server.

Use the Shell to configure Outlook Anywhere on the Client Access server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration settings" entry in the Client Access Permissions topic.

This example sets the client authentication method to NTLM for a Client Access server named CAS01.

```
Set-OutlookAnywhere -Identity:CAS01\Rpc (Default Web Site) -ClientAuthenticationM
```

This example turns on SSL offloading on the Client Access server named CAS01.

```
Set-OutlookAnywhere -Identity:CAS01\Rpc (Default Web Site) -SSLOffloading:$true
```

For more information about syntax and parameters, see Set-OutlookAnywhere.

For More Information

Managing Outlook Anywhere

1.6.2.3.7 Install the Windows RPC Over HTTP Proxy Component

Install the Windows RPC Over HTTP Proxy Component

Client Access > Managing Client Access Servers > Managing Outlook Anywhere >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

For Outlook Anywhere to work correctly, the Windows RPC over HTTP Proxy component must be installed on your Microsoft Exchange Server 2010 Client Access server that's

running Windows Server 2008. If the component isn't installed, follow these steps to install it before you enable Outlook Anywhere. You can install the Windows RPC over HTTP Proxy component using Server Manager or the command line.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Install the RPC over HTTP Proxy component using Server Manager

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "RPC over HTTP Proxy component" entry in the Client Access Permissions topic.

1. Click **Start** > **Administrative Tools** > **Server Manager**.
2. Under Server Manager, right-click **Features**, and then click **Add Features**.
3. In the **Add Features Wizard**, on the **Features** page, select the check box for **RPC over HTTP Proxy**, and then click **Next**.
4. On the **Confirmation** page, click **Install**.
5. On the **Results** page, click **Close**.

Install the RPC over HTTP Proxy component using the command line

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "RPC over HTTP Proxy component" entry in the Client Access Permissions topic.

Open a Command Prompt window, and then type the following command:

```
ServerManagerCmd -i RPC-over-HTTP-proxy
```

Other Tasks

After you install the RPC over HTTP Proxy component, you may also to want to:

- Enable Outlook Anywhere
- Test Outlook Anywhere Connectivity

1.6.2.3.8 Test Outlook Anywhere Connectivity

Test Outlook Anywhere Connectivity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you enable Outlook Anywhere (formerly known as RPC over HTTP) in your Microsoft Exchange Server 2010 organization, you can test for end-to-end client Outlook Anywhere connectivity in either of the following ways:

- Perform the test in the Shell by running the **Test-OutlookConnectivity** cmdlet on the Exchange Client Access server enabled for Outlook Anywhere.

- Run the Outlook Anywhere connectivity test from a Web browser using the Exchange Remote Connectivity Analyzer (ExRCA).

If the cmdlet test fails, the output notes the step that failed. The ExRCA also returns a detailed summary showing where the test failed and what steps you can take to fix issues. Both tests attempt to sign in to the specified user mailbox via Outlook Anywhere after obtaining server settings from the Autodiscover service.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Prerequisites

- Outlook Anywhere must be enabled on the Client Access server. For more information, see Enable Outlook Anywhere.
- Before running the test using the cmdlet, you must create a test user using the New-TestCasConnectivityUser.ps1 script.

Use the Shell to test Outlook Anywhere connectivity

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Test Outlook Anywhere connectivity" entry in the Client Access Permissions topic.

This example tests Outlook Anywhere connectivity by setting the `Protocol` parameter to HTTP.

```
Test-OutlookConnectivity -Protocol:Http -GetDefaultsFromAutoDiscover:$true -verbo
```

Note:

The `verbose` parameter returns a detailed output that notes each action the cmdlet performs.

For more information about cmdlet syntax, parameters, and examples, see Test-OutlookConnectivity.

Use the ExRCA to test Outlook Anywhere connectivity

1. From your Web browser, navigate to the Exchange Remote Connectivity Analyzer Web site.
2. Follow the wizard instructions for testing Outlook Anywhere.

Other Tasks

After you test Outlook Anywhere connectivity, you may also want to:

- Configure Client Access Server Properties
- Test Outlook Autodiscover Connectivity

1.6.2.4 Managing Exchange ActiveSync

Managing Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-17*

Managing the Exchange ActiveSync Virtual Directory

Managing Exchange ActiveSync Users

Managing an Exchange ActiveSync Server

1.6.2.4.1.1 Create an Exchange ActiveSync Virtual Directory

Create an Exchange ActiveSync Virtual Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Exchange Management Shell to create a Microsoft Exchange ActiveSync virtual directory in Microsoft Exchange Server 2010.

By default, when Exchange 2010 is installed, a new virtual directory is created in the default Web site in Internet Information Services (IIS). This virtual directory is named Microsoft-Server-ActiveSync. You can create additional Exchange ActiveSync virtual directories under Web sites other than the default Web site. All Exchange ActiveSync virtual directories you create will have the name Microsoft-Server-ActiveSync.

Note:
You can also use this procedure to create a new Exchange ActiveSync virtual directory if you've removed the virtual directory because it's become corrupted.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use the Shell to create an Exchange ActiveSync virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

This example creates the Exchange ActiveSync virtual directory under the contoso.com Web site.

```
New-ActiveSyncVirtualDirectory -Identity "Contoso.com\Microsoft-Server-ActiveSync
```

For more information about syntax and parameters, see New-ActiveSyncVirtualDirectory.

Other Tasks

After you create an Exchange ActiveSync virtual directory, you may also want to:

- Remove an Exchange ActiveSync Virtual Directory
- View or Configure Exchange ActiveSync Virtual Directory Properties

1.6.2.4.1.2 Remove an Exchange ActiveSync Virtual Directory

Remove an Exchange ActiveSync Virtual Directory

Managing Client Access Servers > Managing Exchange ActiveSync > Managing the Exchange ActiveSync Virtual Directory >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to remove a Microsoft Exchange ActiveSync virtual directory in Microsoft Exchange Server 2010.

By default, when Exchange 2010 is installed, a new virtual directory is created in the default Web site in Internet Information Services (IIS). This virtual directory is named Microsoft-Server-ActiveSync. You can create additional Exchange ActiveSync virtual directories under Web sites other than the default Web site. All Exchange ActiveSync virtual directories you create will have the name Microsoft-Server-ActiveSync. You can remove the default Exchange ActiveSync virtual directory or any additional Exchange ActiveSync virtual directories you create.

Note:
You can also use this procedure to remove an Exchange ActiveSync virtual directory if the virtual directory settings become corrupted.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use the Shell to remove an Exchange ActiveSync virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

This example removes the Exchange ActiveSync virtual directory under the contoso.com Web site.

```
Remove-ActiveSyncVirtualDirectory -Identity "Contoso.com\Microsoft-Server-ActiveS
```

For more information about syntax and parameters, see Remove-ActiveSyncVirtualDirectory.

Other Tasks

After you remove an Exchange ActiveSync virtual directory, you may also want to:

- Create an Exchange ActiveSync Virtual Directory
- View or Configure Exchange ActiveSync Virtual Directory Properties

1.6.2.4.1.3 View or Configure Exchange ActiveSync Virtual Directory Properties

View or Configure Exchange ActiveSync Virtual Directory Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you have installed the Client Access server role on an Exchange Server 2010 computer, Exchange ActiveSync is enabled by default. An Exchange ActiveSync virtual directory is created on the Exchange 2010 Client Access server. You can configure a variety of options on that virtual directory.

Looking for other management tasks related to Exchange ActiveSync virtual directories? Check out Managing the Exchange ActiveSync Virtual Directory.

Prerequisites

The Client Access server role has been installed on an Exchange 2010 computer. For more information, see Install Exchange Server 2010.

What Do You Want to Do?

Use the EMC to view or configure the Exchange ActiveSync virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync virtual directory settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the work pane, click the **Exchange ActiveSync** tab, and then click the **Microsoft-Server-ActiveSync** virtual directory.
3. In the action pane, under click **Microsoft-Server-ActiveSync**, click **Properties**.

4. Use the **General** tab to view display-only information about the Exchange ActiveSync virtual directory and to modify the Internal and External URLs.
   - **Server** This read-only field shows the name of the server the virtual directory is located on.
   - **Web site** This read-only field shows the name of the Web site that holds the virtual directory. Normally, this will be the **Default Web Site**.
   - **SSL Enabled** This read-only field shows the Secure Sockets Layer (SSL) status of the virtual directory. The default is **True**.
   - **Modified** This read-only field shows the date and time that the virtual directory was last modified.
   - **Internal URL** This field shows the `InternalURL` setting for the virtual directory. In most cases, you shouldn't change this setting.
   - **External URL** This field shows the `ExternalURL` setting for the virtual directory. In an Internet-facing Active Directory site, this field will be populated with the external DNS endpoint for Exchange ActiveSync, for example, http://contoso.com/Microsoft-Server-ActiveSync.

5. Use the **Authentication** tab to control the authentication methods for the Exchange ActiveSync virtual directory.
   - **Basic authentication (password is sent in clear text)** Select this check box if you want the mobile device to send the user name and password in clear text.

     Important Because passwords are sent in clear text with Basic authentication, you should configure SSL to encrypt data transferred between your mobile clients and the Exchange ActiveSync virtual directory.
   - **Client Certificate authentication** Select whether you want to ignore, accept, or require client certificate authentication.

     Certificates can reside in the certificate store on a mobile device or on a smart card. A certificate authentication method uses the Extensible Authentication Protocol (EAP) and Transport Layer Security (TLS) protocols. In EAP-TLS certificate authentication, the client and the server prove their identities to each other. For example, an Exchange ActiveSync client presents its user certificate to the Client Access server, and the Client Access server presents its computer certificate to the mobile device to provide mutual authentication.

     Note Requiring client certificates will force you to configure SSL on the Web site that's hosting the Exchange ActiveSync virtual

directory.

6. Exchange ActiveSync clients can access files and Web sites that are located on Windows SharePoint Services and Windows file shares. Use the **Remote File Servers** tab to specify allowed and blocked host names for your Exchange ActiveSync clients. This tab also allows you to configure which domains are treated as internal.
   - **Block List** Click **Block** to configure a list of host names of servers to which clients are denied access.
     The Block list takes precedence over the Allow list. To add a host name to the Block list, type the host name in the **Block List** dialog box, and then click **Add**. To remove a host name from the Block list, select the host name, and then click **Delete** in the **Block List** dialog box.
   - **Allow List** Click the **Allow** button to configure a list of host names of servers from which clients are allowed to access files.
     To add a host name to the Allow list, type the host name in the **Allow List** dialog box, and then click **Add**. To remove a host name from the Allow list, select the name, and then click **Delete** in the **Allow List** dialog box.
     If a host name is specified in the Allow list and the Block list, clients will be blocked from accessing files from that host name.
   - **Unknown Servers** Use this list to specify how to access files from host names that aren't listed in either the Block list or the Allow list. The default value is Allow.
   - **Enter the domain suffixes that should be treated as internal** Use this option to configure specific host names as internal host names. Click **Configure** to add host names to the **Internal Domain Suffix List**.
     When clients try to access files on one of these host names, Exchange ActiveSync uses the internal network to access these files instead of trying to access them over the Internet.

Use the Shell to configure the Exchange ActiveSync virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync virtual directory settings" entry in the Client Access Permissions topic.

This example configures the Exchange ActiveSync virtual directory with Basic authentication and an *External URL* of http://contoso.com/Microsoft-Server-ActiveSync.

```
Set-ActiveSyncVirtualDirectory -Identity "http://contoso/microsoft-server-actives
```

This example configures the Exchange ActiveSync virtual directory with Basic authentication and adds a site to the blocked list.

```
Set-ActiveSyncVirtualDirectory -Identity "contoso\microsoft-server-activesync" -B
```

For syntax and parameter information, see Set-ActiveSyncVirtualDirectory.

Use the Shell to view the Exchange ActiveSync virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync virtual directory settings" entry in the Client Access Permissions topic.

This example returns the settings for the Exchange ActiveSync virtual directory on the server CAS-01.

```
Get-ActiveSyncVirtualDirectory -Server "CAS-01"
```

This example returns the settings for a specific Exchange ActiveSync virtual directory on the server CAS-01.

```
Get-ActiveSyncVirtualDirectory -Server "CAS-01" -Identity "Microsoft-Server-Activ
```

This example returns the settings for the Exchange ActiveSync virtual directory on the server CAS-01, for the domain controller DOM-01.

```
Get-ActiveSyncVirtualDirectory -Server "CAS-01" -DomainController "DOM-01"
```

For syntax and parameter information, see Get-ActiveSyncVirtualDirectory.

Other Tasks

After you configure Exchange ActiveSync virtual directory properties, you may also want to View or Configure Exchange ActiveSync Mailbox Policy Properties.

Configure Synchronization Options for Users

Enable Exchange ActiveSync for a User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a user for Microsoft Exchange ActiveSync. By default, in Microsoft Exchange Server 2010, all new users are enabled for Exchange ActiveSync. If Exchange ActiveSync is disabled for a user, it can be manually enabled.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync Users.

Prerequisites

Exchange ActiveSync is enabled on the Exchange 2010 Client Access server.

Note:

By default, Exchange ActiveSync is enabled on a Client Access server.

Use the EMC to enable a user for Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Select **Properties** from the action pane, or right-click the user's mailbox and then click **Properties**.
3. Click the **Mailbox Features** tab.
4. Select **Exchange ActiveSync**, and then click **Enable**.
5. Click **OK**.

Use the Shell to enable a user for Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

This example enables Exchange ActiveSync for a user.

```
Set-CASMailbox -Identity <SMTP Address of user> -ActiveSyncEnabled $true
```

For more information about syntax and parameters, see Set-CASMailbox.

1.6.2.4.2.2 Disable Exchange ActiveSync for a User

Disable Exchange ActiveSync for a User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable Microsoft Exchange ActiveSync for a user. By default, in Microsoft Exchange Server 2010, users are enabled for Exchange ActiveSync.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync Users.

Prerequisites

Exchange ActiveSync has been enabled on the Exchange 2010 server that has the Client Access server role installed.

Note:

By default, Exchange ActiveSync is enabled on a Client Access server.

Use the EMC to disable Exchange ActiveSync for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Select **Properties** from the action pane, or right-click the user's mailbox and then click **Properties**.
3. Click the **Mailbox Features** tab.
4. Select **Exchange ActiveSync**, and then click **Disable**.
5. Click **OK**.

Use the Shell to disable Exchange ActiveSync for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

This example disables Exchange ActiveSync for a user.

```
Set-CASMailbox -Identity<SMTP Address of user> -ActiveSyncEnabled $false
```

For more information about syntax and parameters, see Set-CASMailbox.

Configure Synchronization Options for Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Windows Mobile to configure synchronization options for users.

Microsoft Exchange ActiveSync can synchronize e-mail messages, contacts, calendar items, and tasks between a user's Microsoft Exchange mailbox and the user's mobile phone. Exchange ActiveSync can't synchronize Microsoft Outlook Notes to a mobile phone.

There are many different phones that use Exchange ActiveSync and synchronize with Microsoft Exchange Server 2010. The steps in this topic are designed for Windows Mobile 6.0.

Note:
For information about how to configure phones that don't use Windows Mobile, or phones that use versions of Windows Mobile other than Windows Mobile 6.0 to synchronize with Exchange, see the documentation for your mobile phone.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync Users.

Prerequisites

- You've reviewed the manufacturer's documentation for the mobile phone you want to configure.
- Exchange ActiveSync is enabled on the Exchange 2010 Client Access server.
- You've established a partnership with the Exchange server. For more information about how to establish a partnership, see Configure a Mobile Phone for Synchronization.

Use ActiveSync on a mobile phone to configure synchronization options

1. On the mobile phone, select **Start**, select **Programs**, and then select **ActiveSync** to start the ActiveSync application.
2. Select **Menu**, and then select **Options** to display the **Options** screen.
3. Select or clear **Contacts**, **Calendar**, **E-mail**, or **Tasks**.
4. To configure options for any of these data types, select the data type, and then select **Settings**.

Use Pocket Outlook on a mobile phone to configure e-mail synchronization options

Note:
The exact steps will vary depending on the version of your mobile phone's software.

1. On the mobile phone, select **Outlook E-mail** to start the Pocket Outlook application.
2. Select **Menu**, select **Tools,** and then select **Manage Folders** to display the

folder list screen.
3. Select or clear the check box next to the folder name. Selecting the check box enables the folder for synchronization. Clearing the check box disables synchronization for that folder.

For more information about how to manage Windows Mobile phones, visit the Windows Mobile Center Web site.

1.6.2.4.3 Managing an Exchange ActiveSync Server

Managing an Exchange ActiveSync Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-18*

Enable Exchange ActiveSync

Disable Exchange ActiveSync

Configure Direct Push to Work Through Your Firewall

Configure Autodiscover for Exchange ActiveSync

Monitor Exchange ActiveSync

Define the SMTP Gateway to the Exchange Server

1.6.2.4.3.1 Disable Exchange ActiveSync

Disable Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable Microsoft ActiveSync. When you disable ActiveSync on a Microsoft Exchange Server 2010 Client Access server, you disable the application pool ActiveSync uses. An application pool is a group of processes that Internet Information Services (IIS) uses to perform a task. For more information, see Understanding Exchange ActiveSync.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Prerequisites

- The IIS component ASP.NET is installed.
- The ASP.NET Web service extension status is set to **Allowed**, not **Prohibited**. You can verify the status of the ASP.NET Web service extension in IIS Manager by expanding the server name and then clicking **Web Service Extensions**. If the **ASP.NET** Web service extension isn't set to **Allowed**, right-click the Web

service extension to change the status.

Use IIS Manager to disable Exchange ActiveSync

To perform these steps you must have Local Administrator permissions on the Client Access server.

Click **Start**, click **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.

1. Double-click to expand the server name, and then double-click to expand the **Application Pools** folder.
2. Right-click **MSExchangeSyncAppPool**, and then click **Stop** to disable ActiveSync.

Note:

If the **Stop** command is unavailable, ActiveSync is already disabled on this server.

1.6.2.4.3.2 Enable Exchange ActiveSync

Enable Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable Microsoft ActiveSync. By default, ActiveSync is enabled when you install the Client Access server role on the computer that's running Microsoft Exchange Server 2010.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Prerequisites

- The Internet Information Services (IIS) component ASP.NET is installed.
- The ASP.NET Web service extension status is **Allowed**, not **Prohibited**. You can verify the status of the ASP.NET Web service extension in IIS Manager by expanding the server name and then clicking **Web Service Extensions**. If the **ASP.NET** Web service extension isn't set to **Allowed**, right-click the Web service extension to change the status.

Use IIS Manager to enable Exchange ActiveSync

To perform the following procedures, you must have Local Administrator privileges on the Client Access server.

1. Click **Start**, click **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.
2. Double-click to expand the server name, and then double-click to expand the **Application Pools** folder.
3. Right-click **MSExchangeSyncAppPool**, and then click **Start** to enable ActiveSync.

Note:
If the **Start** command isn't available, ActiveSync is already enabled on this server.

1.6.2.4.3.3 Configure Direct Push to Work Through Your Firewall

Configure Direct Push to Work Through Your Firewall

Managing Client Access Servers > Managing Exchange ActiveSync > Managing an Exchange ActiveSync Server >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure your firewall to support Direct Push. Direct Push lets your mobile phone stay current with your Microsoft Exchange Server 2010 mailbox.

Direct Push operates by maintaining a long-standing HTTPS request between the mobile phone and the Exchange Client Access server. This request tells the Exchange Client Access server to immediately notify the mobile phone if any items in synchronized folders change during the life of the request. If any items change, the mobile phone issues a synchronization request, synchronizes with the server, and then reissues the HTTPS request. If no items change during the life of the request, the request is reissued.

Configure your firewall for Direct Push

Because the request and the response travel over an HTTPS connection, the only port that you have to open on your firewall is port 443 for HTTPS traffic. No additional ports are required for Direct Push to operate.

To verify that port 443 is open, see your firewall documentation. You should also configure your firewall time-out value to be between 15 and 30 minutes. This ensures that the long-standing HTTPS request can stay open without expiring. The exact steps for this configuration will vary, depending on your firewall hardware and software.

1.6.2.4.3.4 Configure Autodiscover for Exchange ActiveSync

Configure Autodiscover for Exchange ActiveSync

Managing Client Access Servers > Managing Exchange ActiveSync > Managing an Exchange ActiveSync Server >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to enable the Autodiscover service in Microsoft Exchange ActiveSync. You can't configure the Autodiscover service for Exchange ActiveSync using the EMC.

Note:
The ability to use Autodiscover depends on the operating system of the mobile phone.

Not all mobile phone operating systems that support synchronization with Microsoft Exchange Server 2010 support Autodiscover. For more information about operating systems that support Autodiscover, contact the manufacturer of the mobile phone.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use the Shell to configure Autodiscover in Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mobile phone settings" entry in the Client Access Permissions topic.

This example configures Autodiscover for Exchange ActiveSync and sets the **ExternalURL** property.

```
Set-ActiveSyncVirtualDirectory -Identity "COMPUTERNAME\Microsoft-Server-ActiveSyn
```

For more information about syntax and parameters, see Set-ActiveSyncVirtualDirectory.

1.6.2.4.3.5 Monitor Exchange ActiveSync

Monitor Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-03*

The performance of Microsoft Exchange ActiveSync is affected by many factors. These include the number of users who are synchronizing with Exchange ActiveSync, the types of mobile phones that are synchronizing, and how much data each user synchronizes between the Microsoft Exchange server and the mobile phone. By using monitoring, you can understand the factors that affect the performance of Exchange ActiveSync. You can examine Internet Information Services (IIS) log files and use the **Export-ActiveSyncLog** cmdlet to generate reports in comma-separated value format. You can also create several graphs from the data in these reports to analyze traffic and usage patterns.

By monitoring Exchange ActiveSync errors and events, you can understand problems your users encounter when they synchronize their mobile phones with Microsoft Exchange.

For More Information

For more information about how to monitor Exchange ActiveSync, see the following topics:

- Generate Exchange ActiveSync Reports
- Understanding Exchange ActiveSync Reporting Services

Generate Exchange ActiveSync Reports

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to generate a compiled set of reports for Microsoft Exchange ActiveSync. The **Export-ActiveSyncLog** cmdlet compiles a set of Internet Information Services (IIS) logs and processes them to create a series of output files. Each file is a separate report that can help you understand your Exchange ActiveSync deployment.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Prerequisites

You have read-only access to the directory that contains the IIS log files.

Use the Shell to generate Exchange ActiveSync reports

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

This example exports the Exchange ActiveSync log for the date range 06/08/09 to 06/09/09. The times on the report are in Coordinated Universal Time (UTC), and the report is saved in c:\exreports\easreports.

```
Export-ActiveSyncLog -Filename: "c:\Windows\System32\LogFiles\W2SVC1\ex060809.log
```

For more information about syntax and parameters, see Export-ActiveSyncLog.

Other Tasks

After you generate Exchange ActiveSync reports, you may also want to learn about:

- Managing Exchange ActiveSync Devices
- Configuring Exchange ActiveSync Policies

1.6.2.4.3.6 Configure Exchange ActiveSync to Access Windows SharePoint Services Sites and Windows File Shares

Configure Exchange ActiveSync to Access Windows SharePoint Services Sites and Windows File Shares

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to manage the list of Microsoft Windows SharePoint Services sites and Windows file shares that Microsoft Exchange ActiveSync users can access from their mobile phones.

Note:
The lists of Windows SharePoint Services sites and Windows file shares that are allowed and blocked apply to the whole Exchange ActiveSync virtual directory. You can't configure these lists for individual users. But you can disable Windows SharePoint Services sites and Windows file share access for individual users by using Exchange ActiveSync policies.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use the EMC to configure access to Windows SharePoint Services sites and Windows file shares

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

1. Open the EMC.
2. In the console tree, navigate to **Server Configuration** > **Client Access**.
3. Select **Exchange ActiveSync**.
4. In the action pane, under **Microsoft-Server-ActiveSync**, click **Properties**.
5. Click the **Remote File Servers** tab.
6. Click **Block** to add host names of sites that clients are prohibited from accessing.
7. Click **Allow** to add host names of sites that clients are permitted to access.
8. Use the list in the **Unknown Servers** section to specify the default action that should be taken when a client tries to access a file from a server that's not entered in either the Allow List or Block List.
9. Click **Configure** to enter the domain suffixes that should be treated as internal.

   Note:
   If you specify that a domain suffix should be treated as internal, the Exchange ActiveSync client will access the content through an intranet connection instead of an Internet connection.

Use the Shell to configure access to Windows SharePoint Services sites and Windows file shares

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the " Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

This example adds two sites to the Block list and one to the Allow list, specifies an internal domain suffix, and configures the default action to take when a client tries to access a file from a server that's not entered in the Allow or Block lists.

```
Set-ActiveSyncVirtualDirectory -Identity:"ServerName\Microsoft-Server-ActiveSync
```

For more information about syntax and parameters, see Set-ActiveSyncVirtualDirectory.

1.6.2.4.3.7 Define the SMTP Gateway to the Exchange Server

Define the SMTP Gateway to the Exchange Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-30*

Microsoft Exchange Server 2010 uses an SMTP-to-SMS gateway to send text messaging notifications from an Exchange mailbox to a user's mobile phone. This functionality notifies a user by sending them a text message whenever a new e-mail message is received. An SMTP-to-SMS gateway is required for each mobile phone provider. Several common SMTP-to-SMS gateways are included with Exchange 2010 Service Pack (SP1). These SMTP-to-SMS gateways are stored in an XML file and a copy of that file is included on each Client Access server and each Hub Transport server. If your organization requires an SMTP-to-SMS gateway for a mobile phone provider that isn't included in Exchange 2010 SP1, you can create a customized XML file using the instructions included in this topic.

Creating a Customized SMTP Gateway XML File

The SMTP gateway XML file is located in the Exchange Server\V14\Bin folder. The file name is TextMessagingHostingData-System.xml. In order to create your own customized XML file, must create a second customized XML file named TextMessagingHostingData-Site.xml in the same location on the Client Access servers and the Hub Transport servers in your Exchange organization.

Note:
If your Exchange organization includes multiple Client Access servers and Hub Transport servers, you must copy this customized XML file to all of these servers.

As soon as the file has been copied to all applicable servers, the next time your users try to configure SMS notifications in the Exchange Control Panel (ECP), they'll see the new SMTP-to-SMS gateways you have defined.

Note:
Because changes to the customized XML file are visible without a service restart, we recommend that you don't edit the customized XML file in the target location. Copy it to another location for editing, and then copy the completed file to the target folder.

SMTP Gateway XML File Format

The name of customized XML file must be TextMessagingHostingData-Site.xml. Three types of information are stored in this file:

- Country and region information, which is stored in the Regions section of the XML file.
- SMTP gateway carrier information.
- SMTP gateway detailed specifications.

Every SMTP gateway requires both a country or region and a carrier. One carrier can have multiple SMTP gateways, but each SMTP gateway can have only one carrier. Each combination of these three types of information must be unique. Therefore, if you define a

combination in the customized file that's the same as the combination in the default file, the information in the default file will be overwritten.

Regions Section

The Regions section of the XML file is made up of three pieces of information.

- **ISO2 two-letter country code** This is the two-letter code from ISO 3166-1 alpha-2.
- **Country code** This code is obtained from the List of ITU-T Recommendation E.164 Assigned Country Codes.
- **Phone number example** This example format is optional.
- The regions section in the XML file might look like the following:

```
<Regions>
    <Region Iso2="CN">
      <CountryCode>86</CountryCode>
      <PhoneNumberExample>139 0000 0000</PhoneNumberExample>
    </Region>
</Regions>
```

Note:

If the custom XML file tries to define the same region as one contained in the default file, the entry in the default file will be overwritten.

Carriers Section

The carrier information section contains the following two pieces of information:

- **ID** This is a 5-digit number that's unique within the default and customized SMTP configuration XML files.
- **Carrier localized name** Each carrier can have multiple names. This is the localized name for the carrier in the local region. You can specify display names for a variety of localities. An English display name should always be specified as a default.

The carriers section of the XML file might look like the following:

```
<Carriers>
    <Carrier Identity="30344">
        <LocalizedInfo Culture="en">
            <DisplayName>Gold Systems, Inc.</DisplayName>
        </LocalizedInfo>
    </Carrier>
    <Carrier Identity="30345">
        <LocalizedInfo Culture="en">
            <DisplayName>China Mobile</DisplayName>
        </LocalizedInfo>
        <LocalizedInfo Culture="zh">
            <DisplayName>中国移动</DisplayName>
        </LocalizedInfo>
    </Carrier>
</Carriers>
```

Note:

If the XML file contains Unicode text for the localized carrier name, you must save the XML file in a UTF-8 or Unicode encoding format.

Service Section

The service section defines the SMTP gateway specification. Three types of information are included in this section of the XML file.

- **Region ISO** The Region ISO you are specifying must have been previously defined in the Region section of the XML file.
- **Carrier** The Carrier identity must have been previously defined in the Carriers section of the XML file.
- **SMTPToSMSGateway** This section of the file contains the following information:
  - **SMTP address** This is the SMTP address for the message to be routed to

when an SMS notification is generated. There are two keywords in this field. %c is the country code specified in region section and %n is the local phone number.

- **MessageRendering** This container defines how the message is rendered. It includes several parameters. The *Container* parameter can have one of two values. If the value is body, then the SMS message content is stored in the message body. If the value is subject, then the SMS message content is stored in the message subject. The *Capacity* parameter specifies how many characters can be contained in one SMS message. The **CodingScheme** property of the *Capacity* parameter can be either GSMDefault, Unicode, or Euc-KR.

An example service section might look like the following.

```
<Service>
        <RegionIso2>CN</RegionIso2>
        <CarrierIdentity>30345</CarrierIdentity>
        <Type>SmtpToSmsGateway</Type>
        <SmtpToSmsGateway>
            <RecipientAddressing>
                <SmtpAddress>%n@139.com</SmtpAddress>
            </RecipientAddressing>
            <MessageRendering Container="Body">
                <Capacity CodingScheme="GsmDefault">140</Capacity>
                <Capacity CodingScheme="Unicode">50</Capacity>
            </MessageRendering>
        </SmtpToSmsGateway>
    </Service>
```

For a GSM network, GsmDefault capacity should always be specified, while Unicode is optional. When Unicode is not specified, all Unicode characters will be automatically converted to ? in the system.

For a CDMA network, at least one capacity should be specified.

Note:

Typically, the SMTP gateway will use some characters for extra information, such as the from field. Set aside enough buffer when specifying message length for some of this extra information.

XML File Example

This is an example of a complete TextMessagingHostingData-Site.xml file.

```
<?xml version="1.0" ?>
<TextMessagingHostingData xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" x
<Regions>
    <Region Iso2="CN">
      <CountryCode>86</CountryCode>
      <PhoneNumberExample>139 0000 0000</PhoneNumberExample>
    </Region>
</Regions>
<Carriers>
    <Carrier Identity="30344">
        <LocalizedInfo Culture="en">
            <DisplayName>Gold Systems, Inc.</DisplayName>
        </LocalizedInfo>
    </Carrier>
    <Carrier Identity="30345">
        <LocalizedInfo Culture="en">
            <DisplayName>China Mobile</DisplayName>
        </LocalizedInfo>
        <LocalizedInfo Culture="zh">
            <DisplayName>中国移动</DisplayName>
        </LocalizedInfo>
    </Carrier>
</Carriers>
<Services>
```

```
    <Service>
        <RegionIso2>US</RegionIso2>
        <CarrierIdentity>30344</CarrierIdentity>
        <Type>SmtpToSmsGateway</Type>
        <SmtpToSmsGateway>
            <RecipientAddressing>
                <SmtpAddress>%n@paging.goldsys.com</SmtpAddress>
            </RecipientAddressing>
            <MessageRendering Container="Body">
                <Capacity CodingScheme="GsmDefault">140</Capacity>
            </MessageRendering>
        </SmtpToSmsGateway>
    </Service>
    <Service>
        <RegionIso2>CN</RegionIso2>
        <CarrierIdentity>30345</CarrierIdentity>
        <Type>SmtpToSmsGateway</Type>
        <SmtpToSmsGateway>
            <RecipientAddressing>
                <SmtpAddress>%n@139.com</SmtpAddress>
            </RecipientAddressing>
            <MessageRendering Container="Body">
                <Capacity CodingScheme="GsmDefault">140</Capacity>
                <Capacity CodingScheme="Unicode">50</Capacity>
            </MessageRendering>
            </SmtpToSmsGateway>
    </Service>
</Services>
</TextMessagingHostingData>
```

1.6.2.4.4 Managing Exchange ActiveSync Devices

Managing Exchange ActiveSync Devices

Manage a Mobile Device

1.6.2.4.4.1 Exchange ActiveSync Mobile Phones and Compatible Features

Exchange ActiveSync Mobile Phones and Compatible Features

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-06*

Microsoft Exchange ActiveSync in Microsoft Exchange Server 2010 enables users to synchronize their mobile phones with their Exchange mailbox. Users can synchronize e-mail messages, calendar information, contact and task data, and manage their Deleted Items folder, their e-mail signature, and automatic-reply settings to let people know they're away. This topic provides information about the different types of mobile phones that synchronize with Exchange 2010.

Note:

Although we consistently refer to devices that access Exchange 2010 as mobile phones, there are many personal digital assistant devices that can access Exchange 2010 but don't have cellular phone functionality. The term "mobile phone" in this documentation refers to those devices, as well.

Devices Enabled for Exchange ActiveSync

Users can take advantage of Exchange ActiveSync by selecting mobile phones that are compatible with Exchange ActiveSync. These mobile phones are available from many manufacturers. For more information, see the device documentation.

Mobile phones that are compatible with Microsoft Exchange include the following:

- **Apple** The Apple iPhone, iPod Touch, and iPad all support Exchange ActiveSync.
- **Nokia** Nokia offers Mail for Exchange on their Eseries mobile phones. E-mail, calendar, and contact data can be synchronized over a cellular network or a wireless LAN.
- **Sony Ericsson** Sony Ericsson offers Exchange ActiveSync support on several of their newer smartphones. They also support Direct Push through a third-party program.
- **Palm** Palm offers some models of mobile phones that have the Windows Mobile operating system. These devices support Direct Push.
- **Motorola** Motorola has its own synchronization framework that enables over-the-air synchronization through Exchange ActiveSync on many of its devices.
- **Symbian** Symbian Limited licenses Exchange ActiveSync for use in the Symbian operating system. This operating system is an open standard operating system for mobile phones.
- **Android** Many mobile phones with the Android operating system support Exchange ActiveSync. However, these mobile phones may not support all available Exchange ActiveSync mailbox policies. For more information see Understanding Exchange ActiveSync Mailbox Policies.

Windows Mobile Software Features

Mobile phones that have a version of Windows Mobile software as their operating system offer the greatest functionality when synchronizing with Exchange 2010. The following table shows some features that are available with different versions of Windows Mobile software.

Windows Mobile software features

Operating system	Features
Windows Mobile 6.0 and later versions	• Direct Push • HTML e-mail support • Message flags • Quick message retrieval • Task synchronization • Global address book lookup • Enhanced calendar views • Meeting attendee information • Management of Automatic Replies • Exchange search • Windows SharePoint Services and Windows file share (UNC) document access • Enforcement of Exchange ActiveSync mailbox policies • Remote device wipe • Basic authentication • Integration with Internet Security and Acceleration (ISA) Server • Certificate-based authentication • S/MIME support (with Exchange 2010) • Device storage card encryption • Support for rights management **Important:** Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For a complete list, see Understanding Exchange ActiveSync.

For More Information

For more information about how to manage Windows Mobile phones, see the Windows Mobile Center Web site.

1.6.2.4.4.2 Configure a Mobile Phone for Synchronization

Configure a Mobile Phone for Synchronization

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a mobile phone to synchronize with your Microsoft Exchange Server 2010 mailbox. When you provision a mobile phone, you configure it to synchronize with Microsoft Exchange. Perform this procedure on each mobile phone in your organization.

Looking for other management tasks related to mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

- You've reviewed the manufacturer's documentation for the mobile phone you want to configure.
- Exchange ActiveSync is enabled on the Exchange 2010 Client Access server.

Configure a mobile phone to use Exchange ActiveSync

To configure a mobile phone to use Exchange ActiveSync, you must be able to sign in to the user's Exchange mailbox with the user's credentials.

1. On the mobile phone, from the home screen, click **Start**, and then click **ActiveSync**.
2. Click **Menu**, and then click **Configure Server**.
3. Enter the server address. This is the same address as your Microsoft Office Outlook Web App server address.
4. If you've configured Exchange ActiveSync to require Secure Sockets Layer (SSL), select the **This server requires an encrypted (SSL) connection** check box.
5. Click **Next**.
6. Enter your user name, password, and domain.
7. Select the **Save password** check box.
8. Click **Next**.
9. Select the check box next to each type of information that you want to synchronize with the server, and then click **Finish**.

For more information about how to manage Windows Mobile phones, visit the Windows Mobile Center Web site.

Windows Phone 7 synchronization

If you have Windows Phone 7 mobile phones in your organization, these phones will experience synchronization problems if certain Exchange ActiveSync mailbox policy properties are configured. To allow Windows Phone 7 mobile phones to synchronize with an Exchange mailbox, either set the **AllowNonProvisionableDevices** property to true or only configure the following Exchange ActiveSync mailbox policy properties:

- PasswordRequired
- MinPasswordLength
- IdleTimeoutFrequencyValue
- DeviceWipeThreshold
- AllowSimplePassword
- PasswordExpiration
- PasswordHistory
- DisableRemovableStorage
- DisableIrDA
- DisableDesktopSync
- BlockRemoteDesktop
- BlockInternetSharing

If you have Windows Phone 7 mobile phones in your organization, you can set **AllowNonProvisionalDevices** property to True or you can create a separate Exchange ActiveSync mailbox policy for users with Windows Phone 7 mobile phones. This new Exchange ActiveSync mailbox policy should either have the **AllowNonProvisionalDevices** property set to True or only have the preceding list of policy properties configured. For more information about Exchange ActiveSync Mailbox Policy properties and Windows Phone 7, see Understanding Exchange ActiveSync Mailbox Policies.

Disable a Mobile Phone for Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-09*

Microsoft Exchange Server 2010 lets you restrict access to Exchange ActiveSync by using the device ID. This feature prevents users from synchronizing unauthorized devices with Exchange 2010. You can configure this restriction on each user's mailbox. By default, if Microsoft Exchange ActiveSync is enabled for a user, the user can synchronize their Exchange mailbox with any device. To restrict a user to a specific device, populate the `ActiveSyncAllowedDeviceIDs` parameter from the **Set-CASMailbox** cmdlet. To prevent a single device or set of devices, populate the `ActiveSyncBlockedDeviceIDs` parameter from the **Set-CASMailbox** cmdlet.

The *ActiveSyncBlockedDeviceIDs* parameter accepts a list of device IDs that are restricted from synchronizing with the mailbox.

Note:

When you use the **set-ActiveSyncOrganizationSettings –DefaultAccessLevel** cmdlet, devices can still be blocked if they do not comply with a specific Exchange ActiveSync policy, regardless of whether the device is allowed by the list that is provided to *ActiveSyncAllowedDeviceIDs*.

For more information about the **set-ActiveSyncOrganizationSettings –DefaultAccessLevel** cmdlet, see Set-ActiveSyncOrganizationSettings.

If Exchange ActiveSync isn't enabled for the user, the user won't be able to synchronize any device with Exchange. You can prevent a specific device from synchronizing with Exchange, but only by using the Exchange Management Shell.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Prerequisites

Exchange ActiveSync is enabled for the user.

Use the Shell to disable a device for Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

This example adds the device ID to the `ActiveSyncBlockedDeviceIDs` parameter list to prevent the device from synchronizing with Microsoft Exchange.

```
Set-CASMailbox -Identity: "EmailAlias" -ActiveSyncBlockedDeviceIDs: "<DeviceID_1>
```

Note:

There's no built-in functionality for retrieving the device ID before the user synchronizes with the Exchange server.

This example retrieves the device ID after the user has synchronized the device with the Exchange server.

```
Get-ActiveSyncDeviceStatistics -Mailbox:"<EmailAlias>" |fl DeviceID
```

For more information about syntax and parameters, see Set-CASMailbox.

For more information about how to manage Windows Mobile phones, visit the Windows Mobile Center Web site.

1.6.2.4.4.4 Enable a Device for Exchange ActiveSync

Enable a Device for Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 enables you to restrict access to Microsoft Exchange ActiveSync by using the device ID. This feature prevents users from synchronizing unauthorized mobile phones with Exchange 2010. You can configure this restriction on each user's mailbox. By default, if Exchange ActiveSync is enabled for a user, the user can synchronize the Exchange mailbox with any mobile phone. To restrict a user to a specific mobile phone, populate the `ActiveSyncAllowedDeviceIDs` parameter from the **Set-CASMailbox** cmdlet.

The *ActiveSyncAllowedDeviceIDs* parameter accepts a list of device IDs that are allowed to synchronize with the mailbox. However, devices are not blocked from synchronizing unless this parameter is used together with settings that are defined by the **set-ActiveSyncOrganizationSettings –DefaultAccessLevel** cmdlet.

Note:

When you use the **set-ActiveSyncOrganizationSettings –DefaultAccessLevel** cmdlet, devices can still be blocked if they do not comply with a specific ActiveSync policy, regardless of whether the device is allowed by the list that is provided to *ActiveSyncAllowedDeviceIDs*.

For more information about the **set-ActiveSyncOrganizationSettings –DefaultAccessLevel** cmdlet, see Set-ActiveSyncOrganizationSettings

If Exchange ActiveSync isn't enabled for users, users won't be able to synchronize any mobile phone with Exchange. You can enable a specific mobile phone for Exchange ActiveSync, but only by using the Exchange Management Shell.

Looking for other management tasks related to Exchange ActiveSync mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

Exchange ActiveSync is enabled for the user.

Use the Shell to enable a mobile phone for

Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync Device Settings" entry in the Client Access Permissions topic.

This example adds two mobile phones to a list of allowed mobile phones for the user with the alias *tonysmit*. The mobile phones are added through a property called the *DeviceID*, which is a unique identifier associated with every mobile phone.

```
Set-CASMailbox -Identity: "tonysmit" -ActiveSyncAllowedDeviceIDs: "<DeviceID_1>",
```

Note:
There is no built-in functionality for retrieving the device ID before the user synchronizes with the Exchange server. After the user has synchronized the mobile phone with the Exchange server, this example will enable you to retrieve the device ID: `Get-ActiveSyncDeviceStatistics -Mailbox:"<EmailAlias>" |fl DeviceID`

For more information about syntax and parameters, see Set-CASMailbox.

For more information about how to manage Windows Mobile phones, visit the Windows Mobile Center Web site.

1.6.2.4.4.5 View a List of Devices for a User

View a List of Devices for a User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Users can configure multiple devices for synchronization with Microsoft Exchange Server 2010. You can use the EMC or the Shell to view a list of mobile phones that are associated with a specific user.

Note:
This topic also provides instructions for how to use Microsoft Office Outlook Web App to view a list of mobile phones associated with a user's mailbox. The user must be signed in to Outlook Web App to view a list of devices that are associated with their mailbox.

Looking for other management tasks related to Exchange ActiveSync mobile phones? Check out Managing Exchange ActiveSync Devices.

Use Outlook Web App to view a list of mobile phones for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

1. In Outlook Web App, click **Options**.
2. In the Navigation pane, select **Phone**.
3. Click the **Mobile Phones** tab.
4. The list displays several device statistics including the mobile phone name,

last synchronization time, and status.

Note:
All mobile phones the user has configured for Exchange ActiveSync are displayed in this list. To determine the correct mobile phone, use the device name and the last synchronization time from the list of mobile phones.

Use the EMC to view a list of mobile phones for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Select a user, and then select **Manage Mobile Device** from the action pane. The **Manage Mobile Device** dialog box will display a list of all devices that are configured for synchronization.

Note:
The **Manage Mobile Device** link is only available in the action pane for users who've established a mobile phone partnership with the Exchange server.

Use the Shell to view a list of devices for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync settings" entry in the Client Access Permissions topic.

This example retrieves a list of mobile phones and their associated statistics for a user, where "alias" is the user's alias. These statistics include last synchronization time and identifying mobile phone characteristics such as the name of the mobile phone.

```
Get-ActiveSyncDeviceStatistics -Mailbox:"alias"
```

For more information about syntax and parameters, see Get-ActiveSyncDeviceStatistics.

Other Tasks

After you view a list of devices for a user, you may also want to:

- Perform a Remote Wipe on a Mobile Phone
- Configure Device Password Locking

1.6.2.4.4.6 Configure Device Password Locking

Configure Device Password Locking

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure device password locking. You can require users to lock their mobile phones by using a password. You can also enforce a variety of policy settings that guide the usage of mobile phone passwords. The settings you can configure include the following:

- Enforcing an alphanumeric password.
- Enabling password recovery.
- Requiring encryption on the mobile phone.
- Specifying a minimum password length.
- Specifying a period of inactivity before you must re-enter a password on a mobile phone. This is known as device password locking.

Looking for other management tasks related to managing mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

An Exchange ActiveSync mailbox policy has been created. For detailed steps, see Create a New Exchange ActiveSync Mailbox Policy.

Use the EMC to configure device password locking

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Client Access**.
2. In the work pane, click the **Exchange ActiveSync Mailbox Policies** tab, select an existing mailbox policy, and then click **Properties** in the action pane.
3. Click the **Password** tab.
4. Select the **Require password** check box.
5. Select the **Time without user input before password must be entered (in minutes)** check box.
6. Enter the inactivity time-out value in minutes.
7. Click **OK**.

Use the Shell to configure device password locking

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

This example configures the Exchange ActiveSync mailbox policy named `Default` for device password locking after 15 minutes.

```
Set-ActiveSyncMailboxPolicy -Identity "Default" -DevicePasswordEnabled: $true -Ma
```

For more information about syntax and parameters, see Set-ActiveSyncMailboxPolicy.

Other Tasks

After you configure device password locking, you may also want to:

- Recover a Device Password
- Perform a Remote Wipe on a Mobile Phone

1.6.2.4.4.7 Recover a Device Password

Recover a Device Password

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC, the Shell, or Microsoft Office Outlook Web App to recover a device password.

You can require a device password through Microsoft Exchange ActiveSync policies. A user can configure a device password even if your Exchange ActiveSync policies don't require one. If users forget their password, you can obtain a recovery password using the EMC or the Shell. The recovery password unlocks the device and lets the user create a new password. Users can also recover their device passwords by using Outlook Web App.

Looking for other management tasks related to mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

To use Outlook Web App to recover a user's device password, you must be able to sign in to Outlook Web App using the user's credentials.

Use the EMC to display the device recovery password

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the details pane, select a user, and then select **Manage Mobile Device** from the action pane. The device recovery password is displayed in the **Manage Mobile Device** dialog box.

Use the Shell to display the device recovery password

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

This example displays the recovery password for the mobile phone on the mailbox that belongs to Tony Smith.

```
Get-ActiveSyncDeviceStatistics -Mailbox:"tonysmith" -ShowRecoveryPassword:$true
```

For more information about syntax and parameters, see Get-ActiveSyncDeviceStatistics.

Use Outlook Web App to recover a device password

1. In Outlook Web App, click **Options**.
2. Select **Phones** from the Navigation Pane.
3. Select the mobile phone from the list.

   Note:
   All mobile phones the user has configured for Exchange ActiveSync are displayed in this list. To determine the correct mobile phone, use the device name and the last synchronization time displayed in the list of devices.

4. Click **Display Device Password**.

Other Tasks

After you recover a password, you may also want to:

- Configure Mobile Phones to Synchronize with Exchange Server
- Disable a Mobile Phone for Exchange ActiveSync

1.6.2.4.4.8 Perform a Remote Wipe on a Mobile Phone

Perform a Remote Wipe on a Mobile Phone

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 lets you send a command to a mobile phone to perform a remote device wipe of that phone. This process removes all the information that's stored on the phone. This includes Exchange information. This process then completes a full reset of the device. You can use the EMC or the Exchange Management Shell to perform a remote wipe on a mobile phone.

You can use this procedure to clear data from a stolen phone or to clear data from a phone before you assign it to another user.

Note:
This topic also provides instructions for a user to use Microsoft Office Outlook Web App to perform a remote wipe on a phone. The user must be signed in to Outlook Web App to perform a remote wipe.

Looking for other management tasks related to Exchange ActiveSync device? Check out Managing Exchange ActiveSync Devices.

Use the EMC to perform a remote wipe on a mobile phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Select the user from the **Mailbox** window.
3. In the action pane, click **Manage mobile device**, or right-click the user's mailbox, and then click **Manage mobile device**.
4. Select the mobile phone you want to clear all data from.
5. In the **Actions** section, click **Clear**.
6. Click **Clear** again.

Use Outlook Web App to perform a remote wipe on a mobile phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

1. Open Outlook Web App.
2. Sign in to the device owner's mailbox.
3. Click **Options**.
4. In the Navigation Pane, select **Phone**.
5. Click the **Mobile Phones** tab.
6. Select the ID of the mobile phone that you want to wipe and remove from the list.
7. Click **Wipe device**.
8. Click **OK**.
9. Click **Remove Device**.

Use the Shell to perform a remote wipe on a mobile phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync device settings" entry in the Client Access Permissions topic.

This example obtains the identity of the device.

```
Get-ActiveSyncDeviceStatistics - Mailbox jeffhays | fl Identity
```

This example performs the remote wipe of the device.

```
Clear-ActiveSyncDevice -Identity WM_jeffhayes
```

For more information about syntax and parameters, see Get-ActiveSyncDeviceStatistics and Clear-ActiveSyncDevice.

Install SSL Certificates on a Windows Mobile Phone

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

It is possible to save a digital certificate to a file and install a digital certificate on a Windows Mobile phone. Microsoft Exchange ActiveSync enables a variety of mobile phones to synchronize with an Exchange mailbox. A digital certificate might need to be installed on a user's mobile phone if Exchange ActiveSync is required to use Secure Sockets Layer (SSL) and your organization uses a certificate that isn't from a trusted commercial certification authority (CA).

Instructions for installing a certificate on a Windows Mobile phone are included here. For more information about how to install a certificate on a phone that isn't running Windows Mobile software, see the documentation for the specific phone.

Note:

If your organization uses an SSL certificate from a trusted commercial CA, your users might not have to install the certificate on their phone. Most phones have certificates from several trusted commercial CAs preinstalled in the root store of the phone. For a list of certificates that are preinstalled on Windows Mobile 6.0 and Windows Mobile 5.0 phones, see the Windows Mobile Center Web site.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync Devices.

Prerequisites

To perform the following procedures on a Windows Mobile phone, your users may need an ActiveSync connection between the phone and a desktop or portable computer. For Windows XP, use desktop ActiveSync to form this connection. For Windows Vista computers, use the Windows Mobile Center Web site. Your users must be able to copy the certificate file to the phone before they install the certificate. They can copy the certificate to the phone by using desktop ActiveSync or the Windows Mobile Center web site. Alternatively, your users can copy the certificate to a storage card and access the storage card from the mobile phone.

Use Internet Information Services Manager to save a certificate to a file

1. Right-click the **Default Web Site** or the **Microsoft-Server-ActiveSync** virtual directory, and then click **Properties**.
2. Click the **Directory Security** tab.
3. Under **Secure Communications**, click **View Certificate**.
4. In the **Certificate** dialog box, click the **Details** tab.
5. Click **Copy to File**.
6. In the **Certificate Export Wizard**, click **Next**.
7. Select **No, do not export the private key**, and then click **Next**.
8. Select **DER encoded binary X.509 (.CER)**, and then click **Next**.
9. Type a file name, click **Next**, and then click **Finish**.

After your users have saved their certificate to a file, they can install it on their phone. The procedure for installing the certificate on a phone will vary depending on the operating system of the phone. Choose the procedure that matches the operating system of the phone.

Use ActiveSync to install a certificate on a Windows Mobile 5.0 phone

1. With your user's phone connected to their computer, click **Tools**, and then click **Explore Smartphone**.
2. Drag the .cer file that was created in the previous procedure into a folder on the phone.
3. On the phone, click **Start**, and then click **File Explorer**.
4. Locate the folder that you selected in step 2.
5. Open the .cer file and, when you're prompted, select **Yes**.

Many Windows Mobile 5.0 phones implement a security policy that prevents the installation of certificate files directly from a .cer file. If the previous procedure fails, use the following procedure.

Use the SmartPhoneAddCert tool to install root certificates on a Windows Mobile 5.0 phone

1. Download the SmartPhoneAddcert.exe tool.

   Note:

   Some mobile service providers provide a signed version of this tool. If a signed version is available for the phone, download the signed version from the mobile service provider.

2. Run **SmartPhoneAddCert.exe** and extract the contents to a folder on your user's computer.
3. Copy SmartPhoneAddCert.exe to your user's phone through desktop ActiveSync or the Windows Mobile Center Web site.
4. On your user's phone, create a folder named **Storage**.
5. Copy the .cer file to the **Storage** folder on your user's phone.
6. Run SmartPhoneAddCdert.exe. Select the .cer file that you copied to the **Storage** folder and install the root certificate.

Note:

If you create a .cab file that includes the .cer file, you can also copy this .cab file to your user's phone and run the .cab file to install the certificate.

Use ActiveSync or the Windows Mobile Center Web site to install a certificate on a Windows Mobile 6.0 phone

1. With your user's phone connected to their computer, click **Tools**, and then click **Explore Smartphone**.
2. Drag the .cer file that was created in the previous procedure into a folder on the phone.

3. On the phone, click **Start**, and then click **File Explorer**.
4. Locate the folder that you selected in step 2.
5. Open the .cer file and, when you are prompted, select **Yes**.

Note:
You don't have to use ActiveSync or the Windows Mobile Center Web site to install the certificate on a Windows Mobile 6.0 phone. The certificate file can be copied to a storage card and installed directly from the storage card.

1.6.2.4.4.10 Configure Mobile Phones to Synchronize with Exchange Server

Configure Mobile Phones to Synchronize with Exchange Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a mobile phone, such as a Windows Mobile phone, to use Microsoft Exchange ActiveSync. You should perform this procedure on each mobile phone in your organization.

Looking for other management tasks related to mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

- You have reviewed the manufacturer's documentation for the mobile phone you want to configure.
- Exchange ActiveSync is enabled on the Microsoft Exchange Server 2010 Client Access server.

Configure a mobile phone to use Exchange ActiveSync

To perform these steps, you must be able to sign in to the user's account with their credentials on a mobile phone.

1. On the mobile phone, from the home screen, click **Start**, and then click **ActiveSync**.
2. Click **Menu**, and then click **Configure Server**.
3. Enter the server address. This is the same address as your Outlook Web App server address.
4. If you've configured ActiveSync to require Secure Sockets Layer (SSL), select the **This server requires an encrypted (SSL) connection** check box.
5. Click **Next**.
6. Enter your user name, password, and domain.
7. Select the **Save password** check box.
8. Click **Next**.
9. Select the check box next to each type of information you want to synchronize with the server, and then click **Finish**.

Windows Phone 7 synchronization

If you're configuring a Windows Phone 7 mobile phone to synchronize with an Exchange mailbox using Exchange ActiveSync, synchronization will fail under the following conditions:

- If the **AllowNonProvisionableDevices** property of the Exchange ActiveSync mailbox policy is set to False.
- If any policy properties that aren't included in the following list are configured for the Exchange ActiveSync mailbox policy:
  - PasswordRequired
  - MinPasswordLength
  - IdleTimeoutFrequencyValue
  - DeviceWipeThreshold
  - AllowSimplePassword
  - PasswordExpiration
  - PasswordHistory
  - DisableRemovableStorage
  - DisableIrDA
  - DisableDesktopSync
  - BlockRemoteDesktop
  - BlockInternetSharing

If you have Windows Phone 7 mobile phones in your organization, you can set the **AllowNonProvisionalDevices** property to True or you can create a separate Exchange ActiveSync mailbox policy for users who have Windows Phone 7 mobile phones. This new Exchange ActiveSync mailbox policy should either have the **AllowNonProvisionalDevices** property set to True or only have the preceding list of policy properties configured. For more information about Exchange ActiveSync mailbox policy properties and Windows Phone 7, see Understanding Exchange ActiveSync Mailbox Policies.

1.6.2.4.4.11 Manage a Mobile Device

Manage a Mobile Device

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After a user has synchronized a mobile phone with their mailbox, the Manage Mobile Device wizard lets you view and manage the mobile phones for that user.

Looking for other management tasks related to mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

A user has synchronized a mobile phone with their mailbox.

What Do You Want to Do?

- Use the EMC to manage a mobile phone
- Use the Shell to manage a mobile phone

Use the EMC to manage a mobile phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. Select a mailbox and then, in the action pane, click **Manage Mobile Device** to open the **Manage Mobile Device** wizard.
   - This wizard helps you view mobile phones associated with a user's mailbox and remove a mobile phone from a user's mailbox. To remove a mobile phone from a user's mailbox, select the mobile phone, and then click **Remove Device**.
3. On the **Completion** page, confirm whether the mobile phone has been removed from the user's mailbox.
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
4. Click **Finish** to complete the Manage Mobile Device wizard.

Use the Shell to manage a mobile phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync user settings" entry in the Client Access Permissions topic.

This example removes a mobile phone from Tony Smith's mailbox.

```
Remove-ActiveSyncDevice -Identity iPhone_TonySmith
```

Other Tasks

In addition to using the Manage Mobile Device wizard, you may also want to Perform a Remote Wipe on a Mobile Phone.

For More Information

View a List of Devices for a User

Managing Exchange ActiveSync Devices

1.6.2.4.5 Managing Exchange ActiveSync with Policies

Managing Exchange ActiveSync with Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-12*

Create a New Exchange ActiveSync Mailbox Policy

Add Users to an Exchange ActiveSync Mailbox Policy

View or Configure Exchange ActiveSync Mailbox Policy Properties

1.6.2.4.5.1 Add Users to an Exchange ActiveSync Mailbox Policy

Add Users to an Exchange ActiveSync Mailbox Policy

Managing Client Access Servers > Managing Exchange ActiveSync > Managing Exchange ActiveSync with Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create a Microsoft Exchange ActiveSync mailbox policy, you can add users to that policy. By default, users aren't assigned to an Exchange ActiveSync mailbox policy. You can add a user to only one Exchange ActiveSync mailbox policy at a time. If you add a user to an Exchange ActiveSync mailbox policy, and that user is a member of another Exchange ActiveSync mailbox policy, that user is removed from the original Exchange ActiveSync mailbox policy and added to the new Exchange ActiveSync mailbox policy. You can add users individually or add a filtered group of users to an Exchange ActiveSync mailbox policy.

Prerequisites

The Client Access server role has been installed on a Microsoft Exchange Server 2010 computer.

Use the EMC to add users to an Exchange ActiveSync mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the work pane, right-click the user who you want to assign to a policy, and then click **Properties**.
3. In the user's **Properties** dialog box, click **Mailbox Features**.
4. Click **Exchange ActiveSync**, and then click **Properties**.
5. Select the **Apply an Exchange ActiveSync mailbox policy** check box.
6. Click **Browse** to view the **Select Exchange ActiveSync Mailbox Policy** dialog box.
7. Select an available policy, and then click **OK** three times to apply your changes.
   - **Note** You can add multiple users to a policy at the same time. However, that task must be accomplished by using the Exchange Management Shell.

Use the Shell to add users to an Exchange ActiveSync mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the

Client Access Permissions topic.

This example adds a user with the username TonySmith to an Exchange ActiveSync mailbox policy named Sales.

```
Set-CASMailbox TonySmith -ActiveSyncMailboxPolicy(Get-ActiveSyncMailboxPolicy "Sa
```

This example adds all users to an Exchange ActiveSync mailbox policy named Corporate.

```
Get-Mailbox | Set-CASMailbox -ActiveSyncMailboxPolicy(Get-ActiveSyncMailboxPolicy
```

This example adds a filtered list of users to an Exchange ActiveSync mailbox policy named Contoso.

```
Get-Mailbox | where { $_.CustomAttribute1 -match "Manager"
 } | Set-CASMailbox -activesyncmailboxpolicy(Get-ActiveSyncMailboxPolicy "Contoso
```

Note:

You can substitute `CustomAttribute1` for any of the properties on the **Get-Mailbox** object. To view the full list, type: `Get-Mailbox username |fl`

For more information about syntax and parameters, see Set-CASMailbox.

1.6.2.4.5.2 View or Configure Exchange ActiveSync Mailbox Policy Properties

View or Configure Exchange ActiveSync Mailbox Policy Properties

Managing Client Access Servers > Managing Exchange ActiveSync > Managing Exchange ActiveSync with Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can create an Exchange ActiveSync mailbox policy to configure a variety of security options for users. In addition to password requirements and settings, you can use the **General** tab to specify the types of mobile phones that can connect to the Exchange server and whether attachments can be synchronized.

Looking for other management tasks related to Exchange ActiveSync mailbox policies? Check out Managing Exchange ActiveSync with Policies.

Important:

Windows Phone 7 mobile phones only support a subset of all Exchange ActiveSync mailbox policy settings. For more information, see Understanding Exchange ActiveSync Mailbox Policies.

What Do You Want To Do?

- Use the EMC to view or configure Exchange ActiveSync mailbox properties
- Use the Shell to view Exchange ActiveSync mailbox properties
- Use the Shell to configure Exchange ActiveSync Mailbox properties

Use the EMC to view or configure mailbox user properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Client Access**.
2. In the result pane, click the **Exchange ActiveSync Mailbox Policies** tab, and then select the policy you want to view or configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to specify the types of mobile phones that can connect to the Exchange server and whether attachments can be synchronized.
   - **Allow non-provisionable devices** Select this check box to allow mobile phones that can't be provisioned automatically. These mobile phones may be unable to enforce all the Exchange ActiveSync policy settings. By selecting this box, you're allowing these mobile phones to synchronize even though some policy settings may not be applied.
   - **Refresh interval** Select this check box to force the server to resend the policy to clients at a fixed interval defined in the number of hours between policy refresh events.
5. Use the **Password** tab to set password requirements for Exchange ActiveSync clients.
   - **Require password** Select this checkbox to require a password for the mobile phone. If passwords are required, the following options become available.
   - **Require alphanumeric password** Select this check box to specify that the mobile phone password must include non-numeric characters. Requiring non-numeric characters in passwords increases the strength of password security.
   - **Minimum number of character sets** Use this text box to specify the complexity of the alphanumeric password and force users to use a number of different sets of characters from among the following: lower case letters, upper case letters, symbols and numbers.
   - **Enable password recovery** Select this check box to enable password recovery for the mobile phone. Users can use Outlook Web App to look up their recovery password and unlock their mobile phone. Administrators can use the EMC to look up a user's recovery password.
   - **Require encryption on device** Select this check box to require encryption on the mobile phone. This increases security by encrypting all information on the mobile phone.
   - **Require encryption on storage cards** Select this check box to require encryption on the mobile phone’s removable storage card. This increases security by encrypting all information on the storage cards for the mobile phone.
   - **Allow simple password** Select this check box to allow users to lock their mobile phones with simple passwords such as 1111 or 1234. If you clear this check box, users will be required to use more secure password sequences.
   - **Number of failed attempts allowed** Use this text box to limit the number of failed password attempts a mobile phone accepts before all information on the mobile phone is deleted and the mobile phone is automatically returned to the original factory settings. This reduces the chance of an unauthorized user accessing information on a lost or stolen mobile phone that has a password.
   - **Minimum password length** Use this text box to specify a minimum password length for the mobile phone password. Long passwords can provide increased security. However, long passwords can decrease mobile phone usability. A moderate password length of four to six characters is recommended.
   - **Time without user input before password must be re-entered (in minutes)** When a mobile phone password is required, you can use this

text box to prompt the user for the password after the mobile phone has been inactive for a specified period of time. For example, if this setting is set to 15 minutes, the user must enter the mobile phone password every time that the mobile phone is idle for 15 minutes. If the mobile phone is idle for 10 minutes, the user won't have to re-enter the password.

- **Password expiration (days)** Use this text box to force users to reset their mobile phone's password at a given interval. The interval is set in a number of days.
- **Enforce password history** Select this check box to force the mobile phone to prevent the user from re-using their previous passwords. The number you set determines how many past passwords the user won't be allowed to reuse.

6. Use the **Sync Settings** tab to specify a variety of synchronization-specific settings.
   - **Include past calendar items** Use this drop-down list to select the date range of calendar items to synchronize to the mobile phone. The available options include the following: **All**, **Two Weeks**, **One Month**, **Three Months**, and **Six Months**. If you have to specify other options, use the Shell to configure this setting.
   - **Include past e-mail items** Use this drop-down list to select the date range of e-mail items to synchronize to the mobile phone. The available options include the following: **All**, **One Day**, **Three Days**, **One Week**, **Two Weeks**, and **One Month**. If you have to specify other options, use the Shell to configure this setting.
   - **Limit e-mail size to (KB)** Select this check box to limit the message size that can be downloaded to the mobile phone. After you've selected the check box, use the text box to specify a maximum message size, in kilobytes (KB).
   - **Allow Direct Push when roaming** Select this check box to enable the mobile phone to synchronize as new items arrive when you're roaming with your phone. You're roaming when you're outside your normal service area. Check with your mobile service provider to determine your normal service area. Clearing this check box forces you to manually launch synchronization when you're roaming with the phone and data rates are traditionally higher.
   - **Allow HTML-formatted e-mail** Select this check box to enable e-mail messages that are formatted in HTML to be synchronized to the mobile phone. If this check box isn't selected, all e-mail messages will be converted to plain text before synchronization. Use of this check box doesn't affect whether or not messages are received on the mobile phone.
   - **Allow attachments to be downloaded to device** Select this check box to enable attachments to be downloaded to the mobile phone. If this check box is cleared, the name of the attachment is visible within the e-mail message but can't be downloaded to the mobile phone.
   - **Maximum attachment size (KB)** Select this check box to specify a maximum size for attachments that are downloaded to the mobile phone. After you select the check box, use the text box to enter a maximum attachment size, in KB. If this check box is selected, attachments that are larger than the specified size can't be downloaded to the device.

7. Use the **Device** tab to specify a variety of device-specific settings. All settings that you access on the **Device** tab of the Exchange ActiveSync policy **Properties** page are premium features of Exchange ActiveSync. For these features to be implemented on a mobile phone, the mailbox requires an Exchange Enterprise client access license (CAL).
   - **Allow removable storage** Select this check box to allow storage cards to be accessed from a mobile phone. If this check box isn't selected, storage cards can't be accessed from a mobile phone.
   - **Allow camera** Select this check box to allow the mobile phone camera to

be used.

- **Allow Wi-Fi** Select this check box to allow the mobile phone to use a Wi-Fi connection for Internet access. Direct Push isn't supported over Wi-Fi.
- **Allow infrared** Select this check box to allow the mobile phone to establish an infrared connection with other devices or computers.
- **Allow Internet sharing from device** Select this check box to allow another device to share the Internet connection of the mobile phone. Internet sharing is frequently used when the device functions as a modem for a laptop or desktop computer.
- **Allow remote desktop from device** Select this check box to allow the mobile phone to establish a remote desktop connection to another computer.
- **Allow desktop synchronization** Select this check box to allow the mobile phone to synchronize with a desktop computer through desktop ActiveSync or the Windows Mobile Device Center.
- **Allow Bluetooth** Use this drop-down list to control the Bluetooth functionality of the mobile phone. You can choose to **Allow**, **Disable**, or enable Bluetooth for **Handsfree only**.

8. Use the **Device Applications** tab to enable or disable specific features on a mobile phone. All settings that you access on the **Device Applications** tab of the Exchange ActiveSync policy Properties pages are premium features of Exchange ActiveSync. For these features to be implemented on a mobile phone, the mailbox requires an Exchange Enterprise client access license (CAL).
   - **Allow browser** Select this check box to allow mobile phones to use Pocket Internet Explorer.

     Note:
     This check box doesn't control access to third-party mobile phone browsers.

   - **Allow consumer mail** Select this check box to allow the mobile phone to access e-mail accounts other than Microsoft Exchange accounts. Consumer e-mail accounts include accounts that are accessed through POP3 and IMAP4.

     Note:
     This check box doesn't control access to third-party mobile phone e-mail applications.

   - **Allow unsigned applications** Select this check box to allow unsigned applications to be installed on the mobile phone.
   - **Allow unsigned installation packages** Select this check box to allow unsigned installation packages to be run on the mobile phone.
9. Use the **Other** tab to specify allowed and blocked applications. All settings that you access on the **Other** tab of the Exchange ActiveSync policy Properties pages are premium features of Exchange ActiveSync. For these features to be implemented on a mobile phone, the mailbox requires an Exchange Enterprise client access license (CAL).
   - **Allowed Applications** You can add applications to or remove them from the **Allowed Applications** list. Allowed applications can be installed and run on the mobile phone. Click **Add** to add an application, and click **Delete** to remove an application.
   - **Blocked Applications** You can add applications to or remove them from the **Blocked Applications** list. Blocked applications are prohibited from running on the mobile phone. Click **Add** to add an application, and click **Delete** to remove an application.

Use the Shell to view Exchange

ActiveSync mailbox policy settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

This example returns all the settings for the Exchange ActiveSync mailbox policy named `Sales Policy`.

```
Get-ActiveSyncMailboxPolicy -Identity "SalesPolicy"
```

For more information about syntax and parameters, see Get-ActiveSyncMailboxPolicy.

Use the Shell to configure Exchange ActiveSync mailbox policy settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

This example sets a variety of settings for the Exchange ActiveSync mailbox policy named `MyPolicy`. The settings that are configured include the following:

- Allowing non-provisionable devices
- Requiring an alphanumeric password
- Setting the device password to expire every 12 days
- Allowing password recovery
- Locking the device after 15 minutes of inactivity

```
Set-ActiveSyncMailboxPolicy -Identity MyPolicy -AllowNonProvisionableDevices $tru
```

For more information about syntax and parameters, see Set-ActiveSyncMailboxPolicy.

Other Tasks

After you configure Exchange ActiveSync mailbox policies, you may also want to Perform a Remote Wipe on a Mobile Phone.

1.6.2.4.5.3 Create a New Exchange ActiveSync Mailbox Policy

Create a New Exchange ActiveSync Mailbox Policy

Managing Client Access Servers > Managing Exchange ActiveSync > Managing Exchange ActiveSync with Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the New Exchange ActiveSync Mailbox Policy wizard to create a new Exchange ActiveSync mailbox policy. An Exchange ActiveSync mailbox policy contains a variety of settings, including password settings, attachment settings, and device settings.

Looking for other management tasks related to mobile phones? Check out Managing Exchange ActiveSync Devices.

Prerequisites

The Client Access server role has been installed on an Exchange Server 2010 computer.

What Do You Want to Do?

- Use the EMC to create an Exchange ActiveSync mailbox policy
- Use the shell to create an Exchange ActiveSync mailbox policy

Use the EMC to create an Exchange ActiveSync mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Client Access**.
2. Select the **Exchange ActiveSync Mailbox Policies** tab and then, in the action pane, click **New Exchange ActiveSync Mailbox Policy**.
3. On the **New Exchange ActiveSync Mailbox Policy** page, enter a Mailbox policy name, and then choose from a variety of options including the following:
   - **Allow non-provisionable devices** Select this check box to allow mobile phones that can't be provisioned automatically. These mobile phones may be unable to enforce all the Exchange ActiveSync policy settings. By selecting this box, you are allowing these mobile phones to synchronize even though all policy settings may not be applied.
   - **Allow attachments to be downloaded to device** Select this option to allow attachments to be downloaded to the mobile phone. If selected, files that are attached to synchronized e-mail messages can be downloaded to the mobile phone. Users must select the attachment to mark it for download. After the attachment is selected, it's downloaded at the next scheduled synchronization for users who don't have Direct Push. For users who have Direct Push, the attachment is downloaded immediately.
   - **Require password** Select this option to require users to enter a password to access information on their mobile phones. If you select this option, you can also select a variety of other password options, including settings for password length, password time-out settings, and password recovery.
4. The **Completion** page will confirm whether your new Exchange ActiveSync mailbox policy was successfully created and will also display the syntax for the **New-ActiveSyncMailboxPolicy** cmdlet.

Use the Shell to create an Exchange ActiveSync mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync mailbox policy settings" entry in the Client Access Permissions topic.

This example creates a new Exchange ActiveSync mailbox policy that requires a password of four characters, encryption, and also a new password every 30 days.

```
New-ActiveSyncMailboxPolicy -Name 'All Users' -AllowNonProvisionableDevices $fals
```

Other Tasks

In addition to using the New Exchange ActiveSync Policy wizard, you may also want toPerform a Remote Wipe on a Mobile Phone.

1.6.2.5.1 Start and Stop the POP3 Service

Start and Stop the POP3 Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, POP3 is disabled in Microsoft Exchange Server 2010. After you enable POP3, Exchange 2010 accepts unsecured POP3 client communications on port 110 and over Port 995 using Secure Sockets Layer (SSL).

You can start and stop the POP3 service by using either Microsoft Management Console or net start on the Exchange 2010 Client Access server. You can also check to verify whether the service is running on the Client Access server.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use Microsoft Management Console to start or stop the POP3 service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**.
   - To start the service, in the results pane, right-click **Microsoft Exchange POP3**, and then click **Start**.
   - To stop the service, in the results pane, right-click **Microsoft Exchange POP3**, and then click **Stop**.

Use net start to start or stop the POP3 service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. On the Exchange server that has the Client Access server role installed, open a Command Prompt window.
   - To start the service, at the command prompt, type **net start MSExchangePOP3**, and then press **Enter**.
   - To stop the service, at the command prompt, type **net stop MSExchangePOP3**, and then press **Enter**.
2. Close the Command Prompt window.

Verify that the POP3 service is running

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. On the Exchange Client Access server, open a Command Prompt window.
2. At the command prompt, type **telnet localhost 110**, and then press **ENTER**. POP3 is working correctly if Telnet returns "+OK Microsoft Exchange POP3 server ready".
3. Close Telnet, and then close the Command Prompt window.

Other Tasks

After you start and stop the POP3 service, you may also want to:

- Set Connection Limits for POP3
- Set Connection Time-Out Limits for POP3

1.6.2.5.2 Start and Stop the IMAP4 Service

Start and Stop the IMAP4 Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, IMAP4 is disabled in Microsoft Exchange Server 2010. After you enable IMAP4, Exchange 2010 accepts unsecured IMAP4 client communications on port 143 and over port 993 using Secure Sockets Layer (SSL).

You can start and stop the IMAP4 service by using either Microsoft Management Console or net start on the Exchange 2010 Client Access server. You can also check to verify whether the service is running on the Client Access server.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use Microsoft Management Console to start or stop the IMAP4 service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services**.
   - To start the Microsoft Exchange IMAP4 service, in the results pane, right-click **Microsoft Exchange IMAP4**, and then click **Start**.
   - To stop the Microsoft Exchange IMAP4 service, in the results pane, right-click **Microsoft Exchange IMAP4**, and then click **Stop**.

Use net start to start or stop the IMAP4 service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. On the Exchange server that has the Client Access server role installed, open

a Command Prompt window.
- To start the service, at the command prompt, type **net start MSExchangeIMAP4**, and then press **ENTER**.
- To stop the service, at the command prompt, type **net stop MSExchangeIMAP4**, and then press **ENTER**.

2. Close the Command Prompt window.

Verify that the IMAP4 service is running

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. On the Exchange Client Access server, open a Command Prompt window.
2. At the command prompt, type **telnet localhost 143**, and then press **ENTER**. IMAP4 is working correctly if Telnet returns "+OK Microsoft Exchange IMAP4 server ready."
3. Close Telnet, and then close the Command Prompt window.

Other Tasks

After you start and stop the IMAP4 service, you may also want to:

- Set Connection Time-Out Limits for IMAP4
- Set Connection Limits for IMAP4

Enable POP3 in Exchange 2010

Enable IMAP4 in Exchange 2010

1.6.2.5.3.1 Enable POP3 in Exchange 2010

Enable POP3 in Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you install Microsoft Exchange Server 2010, the POP3 service isn't started. You can set it to start automatically by using the Services snap-in in Microsoft Management Console (MMC) or by using the Shell.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use Microsoft Management Console to enable POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange POP3**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.
4. Under **Service status**, click **Start**, and then click **OK**.

Use the Shell to enable POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables POP3 on the local Client Access server.

1. Run this command to configure the POP3 service to start automatically.

```
Set-service msExchangePOP3 -startuptype automatic
```

2. Run this command to start the POP3 service.

```
Start-service -service msExchangePOP3
```

Other Tasks

After you enable POP3, you may also want to:

- Enable or Disable POP3 Access for a User
- Set Connection Limits for POP3
- Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App

1.6.2.5.3.2 Enable IMAP4 in Exchange 2010

Enable IMAP4 in Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you install Microsoft Exchange Server 2010, the IMAP4 service isn't started. You can set it to start automatically by using the Services snap-in in Microsoft Management Console (MMC) or by using the Shell.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use Microsoft Management Console to enable IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the **Services** snap-in, in the console tree, click **Services (Local)**.
2. In the result pane, right-click **Microsoft Exchange IMAP4**, and then click **Properties**.
3. On the **General** tab, under **Startup type**, select **Automatic**, and then click **Apply**.
4. Under **Service status**, click **Start**, and then click **OK**.

Use the Shell to enable IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables IMAP4 on the local Client Access server.

1. This command configures the IMAP4 service to start automatically.

```
Set-service msExchangeIMAP4 -startuptype automatic
```

2. This command starts the IMAP4 service.

```
Start-service msExchangeIMAP4
```

Other Tasks

After you enable IMAP4, you may also want to:

- Enable or Disable IMAP4 Access for a User
- Set Connection Limits for IMAP4
- Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App

1.6.2.5.4 Enable or Disable POP3 Access for a User

Enable or Disable POP3 Access for a User

Client Access > Managing Client Access Servers > Managing POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable POP3 for a user.

Note:

After you've enabled or disabled POP3 for a user, you must restart the Microsoft Exchange POP3 service. For more information about how to restart the POP3 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to managing user mailboxes? Check out

Managing User Mailboxes.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to enable or disable POP3 for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient provisioning permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the user for whom you want to enable or disable POP3.
3. In the action pane, under the name of the user, click **Properties**.
4. In **<User> Properties**, on the **Mailbox Features** tab, click **POP3**, and then click either **Enable** or **Disable**.
5. Click **OK**.

Use the Shell to enable or disable POP3 for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient provisioning permissions" section in the Mailbox Permissions topic.

This example enables POP3 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -POPEnabled $true
```

This example disables POP3 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -POPEnabled $false
```

For detailed information about syntax and parameters, see Set-CASMailbox.

Other Tasks

After you enable or disable POP3 for a user, you may also want to:

- Enable POP3 in Exchange 2010
- Configure Authentication for POP3

1.6.2.5.5 Enable or Disable IMAP4 Access for a User

Enable or Disable IMAP4 Access for a User

Client Access > Managing Client Access Servers > Managing POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable IMAP4 for a user.

Note:
After you've enabled or disabled IMAP4 for a user, you must restart the Microsoft Exchange IMAP4 service. For more information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to managing user mailboxes? Check out Managing User Mailboxes.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to enable or disable IMAP4 for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient provisioning permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the user for which you want to enable or disable IMAP4.
3. In the action pane, under the name of the user, click **Properties**.
4. In **<User> Properties**, on the **Mailbox Features** tab, click **IMAP4**, and then click either **Enable** or **Disable**.
5. Click **OK**.

Use the Shell to enable or disable IMAP4 for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient provisioning permissions" section in the Mailbox Permissions topic.

This example enables IMAP4 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -IMAPEnabled $true
```

This example disables IMAP4 for the user John Smith.

```
Set-CASMailbox -Identity "John Smith" -IMAPEnabled $false
```

For detailed information about syntax and parameters, see Set-CASMailbox.

Other Tasks

After you enable or disable IMAP4 for a user, you may also want to:

- Enable IMAP4 in Exchange 2010
- Configure Authentication for IMAP4

View or Configure POP3 Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can view or configure the settings that apply to your POP3 users. You can specify the message you want POP3 users to see when they sign in, set connection limits, and make sure that the POP3 service is retrieving messages using the settings you have chosen.

Note:
After you change any settings for the POP3 service by using either the EMC or the Shell, you must restart the POP3 service.

Looking for other management tasks related to POP3? Check out Managing POP3 and IMAP4.

What Do You Want to Do?

- Use the EMC to view or configure POP3 properties
- Use the Shell to configure POP3 properties
- Use the Shell to view POP3 properties

Use the EMC to view or configure POP3 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access** > **POP3 and IMAP4**.
2. In the work pane, select **POP3**, and then, in the action pane, under **POP3**, click **Properties**.
3. On the **General** tab, in the **Banner string** box, specify a banner string for your POP3 clients to see when they log on to their Exchange mailbox. The default banner string for POP3 is "The Microsoft Exchange POP3 service is ready."

   Note:
   After you change a banner string for the POP3 service, you must restart the POP3 service.

4. On the **Binding** tab, specify the IP addresses and TCP ports on the Receive connector that accepts connections from POP3 clients. You can also configure the IP address ranges from which the Receive connector accepts connections from POP3 clients.

   Note:
   If Microsoft Exchange Server 2010 is deployed on a computer running the Windows Server 2008 operating system, enter IP addresses and IP address ranges in the Internet Protocol Version 4 (IPv4) format, Internet Protocol Version 6 (IPv6) format, or both formats. A default installation of Windows Server 2008 enables support for IPv4 and IPv6.

Specify the following:

- **TLS or Unencrypted Connections** In this section, specify the IP addresses and port numbers for POP3 connections that use Transport Layer Security (TLS) or unencrypted connections. For each entry, you must specify a different set of IP addresses or specify all available IP addresses. To add a new IP address or port number, click **Add**. To edit an existing IP address, select the IP address, and then click **Edit**. To remove an existing IP address, select the IP address, and then click  .

  The following options are available in the **TLS or Unencrypted Connection Settings** dialog box:

  Use all IP addresses available on this server Select this option to use all IP addresses associated with this computer.

  Specify an IP address Select this option if the following conditions are true:

  * More than one IP address is associated with the computer.
  * You want to bind the Receive connector to a specific IP address.

  Then, in the text box, type the IP address on which this server accepts connections.

  Note:
  You must specify a local IP address that's valid for the Client Access server that's providing POP3 access.

  Port This text box identifies the TCP port number on which this Receive connector listens for incoming mail. TCP port 110 is the default port used for POP3.

  Note:
  After you configure IP addresses and ports for the Receive connector to accept connections from POP3 clients, you must restart the POP3 service.

- **Secure Sockets Layer (SSL) Connections** Using this list, specify the IP address or IP address range for POP3 connections that use SSL. For each entry, you must specify a different set of IP addresses or specify all available IP addresses. To add a new IP address or port number, click **Add**. To edit an existing IP address, select the IP address, and then click **Edit**. To remove an existing IP address, select the IP address, and then click  .

  The following options are available in the **SSL Connection Settings** dialog box:

  Use all IP addresses available on this server Select this option to use all IP addresses associated with this computer.

  Specify an IP address Select this option if the following conditions are true:

  * More than one IP address is associated with the computer.
  * You want to bind the Receive connector to a specific IP address.

  Then, in the text box, type the IP address on which this server accepts connections.

  Note:
  You must specify a local IP address that's valid for the Client Access server that's providing POP3 access.

  Port This text box identifies the TCP port number on which this Receive connector listens for incoming mail. SSL port 995 is the default port used for POP3.

  Note:
  After you configure IP addresses and ports for the Receive connector to accept connections from POP3 clients, you must restart the POP3 service.

5. On the **Authentication** tab, specify the method by which your POP3 users will log on.
   - **Plain text logon (Basic authentication)** Select this option if you want to send user names and passwords in clear text. Using this option enables user names and passwords to be sent to the server without a TLS or SSL connection.
   - **Plain text authentication logon (Integrated Windows authentication)** Select this option if you want to use Integrated Windows authentication without a TLS or SSL connection.
   - **Secure logon** Select this option if you want to require a TLS or SSL connection.
   - **X.509 certificate name** Use this text box to specify the X.509 certificate name to use for a TLS or SSL session.

   Note:
   After you configure the authentication settings, you must restart the POP3 service.

6. On the **Connection** tab, configure the time-out settings, connection limit settings, and the proxy target port for POP3.
   - **Time-out Settings** Configure the following settings:
     Authenticated time-out (seconds) In this text box, specify the amount of time to wait before closing idle authenticated connections. The default setting is 1800 seconds, and the valid input range is 30 to 86400 seconds.
     Unauthenticated time-out (seconds) In this text box, specify the amount of time to wait before closing idle unauthenticated connections. The default setting is 60 seconds, and the valid input range is 30 to 3600 seconds.
   - **Connection Limits** Configure the following settings:
     Maximum connections In this text box, specify the total number of connections the Client Access server will accept. This includes authenticated and unauthenticated connections. The default value is 2000, and the valid input range is 1 to 25000.
     Maximum connections from a single IP address In this text box, specify the number of connections that the Client Access server will accept from a single IP address. The default value is 2000, and the valid input range is 1 to 25000.
     Maximum connections from a single user In this text box, specify the maximum number of connections the Client Access server will accept from a particular user. The default value is 16, and the valid input range is 1 to 25000.
     Maximum command size In this text box, specify the maximum size of a single command. The default value is 45 bytes, and the valid input range is 40 to 1024.
   - **Command Relay** In the **Proxy target port** text box, specify the port on the Microsoft Exchange Server 2003 back-end server for which POP3 will relay commands. The default port is 110. The valid input range is from 0 through 65535. Using a value of 0 will disable proxying commands to the Exchange 2003 back-end server.

   Note:
   After you configure connection settings for the POP3 service, you must restart the POP3 service.

7. On the **Retrieval Settings** tab, specify the message and calendar retrieval settings for your POP3 clients:
   - **Message Retrieval** Configure the following settings:
     Message MIME format Using this drop-down list, specify the

format of the messages retrieved by the Client Access server. You can select from one of the following message format options:
* Text
* HTML
* HTML and alternative text
* Enriched text
* Enriched text and alternative text
* Best body format
* TNEF

Message sort order Using this drop-down list, select the message sort order. You can select **Ascending** or **Descending**.

- **Calendar Retrieval** Configure the following settings:

  iCalendar Configure this setting so users can use the iCalendar standard for calendar items. The iCalendar standard is a standard for exchanging calendar information.
  Intranet URL Specify an internal URL for users to use to access their calendar information.
  Internet URL Specify an external URL for users to use to access their calendar information.
  Custom Specify the URL of the Outlook Web App server for users to use to access their calendar information.
  URL of Outlook Web App server Specify the Outlook Web App server for custom Outlook Web App calendar items. If you've selected the custom setting for Calendar retrieval, you must specify the Outlook Web App server URL.

Note:
After you configure the message retrieval settings for the POP3 service, you must restart the POP3 service.

Use the Shell to configure POP3 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 settings" entry in the Client Access Permissions topic.

This example sets the IP address for communication over a TLS-encrypted connection or a connection that isn't encrypted on a Client Access server named CAS01.

```
Set-PopSettings -Server "CAS01" -UnencryptedOrTLSBindings IPaddress:953
```

For syntax and parameter information, see Set-PopSettings.

Use the Shell to view POP3 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 settings" entry in the Client Access Permissions topic.

This example returns the POP3 settings for the server CAS01.

```
Get-POPSettings -Server CAS01
```

For syntax and parameter information, see Get-POPSettings.

1.6.2.5.7 View or Configure IMAP4 Properties

View or Configure IMAP4 Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can view or configure the settings that apply to your IMAP4 users. You can specify the message you want IMAP4 users to see when they sign in, set connection limits, and make sure that the IMAP4 service is retrieving messages using the settings you have chosen.

Note:

After you change any settings for the IMAP4 service by using either the EMC or the Shell, you must restart the IMAP4 service.

Looking for other management tasks related to IMAP4? Check out Managing POP3 and IMAP4.

What Do You Want to Do?

- Use the EMC to view or configure IMAP4 properties
- Use the Shell to configure IMAP4 properties
- Use the Shell to view IMAP4 properties

Use the EMC to view or configure IMAP4 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IMAP4 settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access** > **POP3 and IMAP4**.
2. In the work pane, select **IMAP4**, and then, in the action pane, under **IMAP4**, click **Properties**. The **IMAP Properties** page will open.
3. On the **General** tab, in the **Banner string** box, specify a banner string for

your IMAP4 clients to see when they log on to their Exchange mailbox. The default banner string for IMAP4 is "The Microsoft Exchange IMAP4 service is ready."

Note:
After you change a banner string for the IMAP4 service, you must restart the IMAP4 service.

4. On the **Binding** tab, specify the IP addresses and TCP ports on the Receive connector that accepts connections from IMAP4 clients. You can also configure the IP address ranges from which the Receive connector accepts connections from IMAP4 clients.

Note:
If Microsoft Exchange Server 2010 is deployed on a computer running the Windows Server 2008 operating system, enter IP addresses and IP address ranges in the Internet Protocol Version 4 (IPv4) format, Internet Protocol Version 6 (IPv6) format, or both formats. A default installation of Windows Server 2008 enables support for IPv4 and IPv6.

Specify the following:

- **TLS or Unencrypted Connections** In this section, specify the IP addresses and port numbers for IMAP4 connections that use Transport Layer Security (TLS) or unencrypted connections. For each entry, you must specify a different set of IP addresses or specify all available IP addresses. To add a new IP address or port number, click **Add**. To edit an existing IP address, select the IP address, and then click **Edit**. To remove an existing IP address, select the IP address, and then click  .

  The following options are available in the **TLS or Unencrypted Connection Settings** dialog box:

  Use all IP addresses available on this server Select this option to use all IP addresses associated with this computer.

  Specify an IP address Select this option if the following conditions are true:

  * More than one IP address is associated with the computer.
  * You want to bind the Receive connector to a specific IP address.

  Then, in the text box, type the IP address on which this server accepts connections.

  Note:
  You must specify a local IP address that's valid for the Client Access server that's providing IMAP4 access.

  Port This text box identifies the TCP port number on which this Receive connector listens for incoming mail. TCP port 143 is the default port used for IMAP4.

  Note:
  After you configure IP addresses and ports for the Receive connector to accept connections from IMAP4 clients, you must restart the IMAP4 service.

- **Secure Sockets Layer (SSL) Connections** Using this list, specify the IP address or IP address range for IMAP4 connections that use SSL. For each entry, you must specify a different set of IP addresses or specify all available IP addresses. To add a new IP address or port number, click **Add**. To edit an existing IP address, select the IP address, and then click **Edit**. To remove an existing IP address, select the IP address, and then click  .

  The following options are available in the **SSL Connection Settings** dialog box:

  Use all IP addresses available on this server Select this option to use all IP addresses associated with this computer.

Specify an IP address Select this option if the following conditions are true:
* More than one IP address is associated with the computer.
* You want to bind the Receive connector to a specific IP address.
Then, in the text box, type the IP address on which this server accepts connections.

Note:
You must specify a local IP address that's valid for the Client Access server that's providing IMAP4 access.

Port This text box identifies the TCP port number on which this Receive connector listens for incoming mail. SSL port 993 is the default port used for IMAP4.

Note:
After you configure IP addresses and ports for the Receive connector to accept connections from IMAP4 clients, you must restart the IMAP4 service.

5. On the **Authentication** tab, specify the method by which your IMAP4 users will log on.
   - **Plain text logon (Basic authentication)** Select this option if you want to send user names and passwords in clear text. Using this option enables user names and passwords to be sent to the server without a TLS or SSL connection.
   - **Plain text authentication logon (Integrated Windows authentication)** Select this option if you want to use Integrated Windows authentication without a TLS or SSL connection.
   - **Secure logon** Select this option if you want to require a TLS or SSL connection.
   - **X.509 certificate name** Use this text box to specify the X.509 certificate name to use for a TLS or SSL session.

     Note:
     After you configure the authentication settings, you must restart the IMAP4 service.

6. On the **Connection** tab, configure the time-out settings, connection limit settings, and the proxy target port for IMAP4.
   - **Time-out Settings** Configure the following settings:
     Authenticated time-out (seconds) In this text box, specify the amount of time to wait before closing idle authenticated connections. The default setting is 1800 seconds, and the valid input range is 30 to 86400 seconds.
     Unauthenticated time-out (seconds) In this text box, specify the amount of time to wait before closing idle unauthenticated connections. The default setting is 60 seconds, and the valid input range is 30 to 3600 seconds.
   - **Connection Limits** Configure the following settings:
     Maximum connections In this text box, specify the total number of connections the Client Access server will accept. This includes authenticated and unauthenticated connections. The default value is 2000, and the valid input range is 1 to 25000.
     Maximum connections from a single IP address In this text box, specify the number of connections the Client Access server will accept from a single IP address. The default value is 2000, and the valid input range is 1 to 25000.
     Maximum connections from a single user In this text box, specify the maximum number of connections the Client Access

server will accept from a particular user. The default value is 16, and the valid input range is 1 to 25000.
Maximum command size In this text box, specify the maximum size of a single command. The default value is 10240 bytes, and the valid input range is 1024 to 16384.

- **Command Relay** In the **Proxy target port** text box, specify the port on the Microsoft Exchange Server 2003 back-end server for which IMAP4 will relay commands. The default port is 143. The valid input range is from 0 through 65535. Using a value of 0 will disable proxying commands to the Exchange 2003 back-end server.

Note:
After you configure connection settings for the IMAP4 service, you must restart the IMAP4 service.

7. On the **Retrieval Settings** tab, specify the message and calendar retrieval settings for your IMAP4 clients.
   - **Message Retrieval** Configure the following settings:
     Message MIME format Using this drop-down list, specify the format of the messages retrieved by the Client Access server. You can select from one of the following message format options:
     * Text
     * HTML
     * HTML and alternative text
     * Enriched text
     * Enriched text and alternative text
     * Best body format
     * TNEF
   - **Calendar Retrieval** Configure the following settings:
     iCalendar Configure this setting so users can use the iCalendar standard for calendar items. The iCalendar standard is a standard for exchanging calendar information.
     Intranet URL Specify an internal URL for users to use to access their calendar information.
     Internet URL Specify an external URL for users to use to access their calendar information.
     Custom Specify the URL of the Outlook Web App server for users to use to access their calendar information.
     URL of Outlook Web App server Specify the Outlook Web App server for custom Outlook Web App calendar items. If you've selected the custom setting for Calendar retrieval, you must specify the Outlook Web App server URL.

Note:
After you configure the message retrieval settings for the IMAP4 service, you must restart the IMAP4 service.

Use the Shell to configure IMAP4 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IMAP4 settings" entry in the Client Access Permissions topic.

This example sets the IP address for communication over a TLS-encrypted connection or a connection that isn't encrypted on a Client Access server named CAS01.

```
Set-ImapSettings -Server "CAS01" -UnencryptedOrTLSBindings IPaddress:953
```

For syntax and parameter information, see Set-ImapSettings.

Use the Shell to view IMAP4 properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IMAP4 settings" entry in the Client Access Permissions topic.

This example returns the IMAP4 settings for the server CAS01.

```
Get-IMAPSettings -Server CAS01
```

For syntax and parameter information, see Get-IMAPSettings.

1.6.2.5.8 Enable POP3 and IMAP4 Users to Use Default Protocol Settings

Enable POP3 and IMAP4 Users to Use Default Protocol Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable POP3 and IMAP4 users to use the default protocol settings on the Microsoft Exchange Server 2010 Client Access server that has the IMAP4 service or POP3 service enabled.

Using the Exchange Management Shell to Enable POP3 and IMAP4 Users to Use the Default Protocol Settings

In addition to using the **Set-PopSettings** or **Set-ImapSettings** cmdlets to manage POP3 and IMAP4 settings for all your users, you can also use the **Set-CASMailbox** cmdlet to specify individual POP3 and IMAP4 settings for your users. You can also use the **Set-CASMailbox** cmdlet to enable a user to use the default protocol settings for a server when you use the **Set-PopSettings** or **Set-ImapSettings** cmdlets.

The following table shows the parameters to use to configure a POP3 or IMAP4 user to use the protocol default settings as specified on the Client Access server.

POP3 and IMAP4 parameters for the Set-CASMailbox cmdlet

Parameter	Value	Description
PoPopUseProtocolDefaults	• $true • $false	This parameter lets you use the default protocol settings as specified by the **Set-PopSettings** cmdlet.
ImImapUseProtocolDefaults	• $true • $false	This parameter lets you use the default protocol settings as specified by the **Set-ImapSettings** cmdlet.

For more information about the **Set-CASMailbox** cmdlet, see Set-CASMailbox.

Looking for other management tasks related to setting up POP 3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the Shell to enable a POP3 user to use the default protocol settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables a POP3 user to use the default protocol settings for the server CAS01:

```
Set-CASMailbox -Identity CAS01 -PopProtocolDefaults $true
```

This example disables the default protocol settings for a POP3 user on the server CAS01:

```
Set-CASMailbox -Identity CAS01 -PopProtocolDefaults $false
```

Use the Shell to configure an IMAP4 user to use the default protocol settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables an IMAP4 user to use the default protocol settings for the server CAS01.

```
Set-CASMailbox -Identity CAS01 -ImapProtocolDefaults $true
```

This example disables the default protocol settings for an IMAP4 user on the server CAS01.

```
Set-CASMailbox -Identity CAS01 -ImapProtocolDefaults $false
```

For more information about syntax and parameters, see Set-CASMailbox.

Other Tasks

After you enable POP3 and IMAP4 users to use the default protocol settings, you may also want to:

- Configure IP Addresses and Ports for POP3 and IMAP4 Access
- Enable IMAP4 in Exchange 2010
- Enable POP3 in Exchange 2010

1.6.2.5.9 Configure Calendar Options for POP3

Configure Calendar Options for POP3

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to set the calendaring options that are available on the Microsoft Exchange Server 2010 server that has the POP3 service enabled.

The following table describes the `CalendarItemRetrievalOption` parameter for your POP3 users.

POP3 calendar options for Exchange 2010

Setting	Value	Description
iCalendar	0	This setting lets users use the iCalendar standard for calendar items. The iCalendar standard is a standard for exchanging calendar information.
IntranetUrl	1	This setting lets you specify an internal URL for users to use to access their calendar information.
InternetUrl	2	This setting lets you specify an external URL for users to use to access their calendar information.
Custom	3	This setting lets you specify an Outlook Web App server for users to use to access their calendar information.

Note:

After you've specified the calendar options for POP3, you must restart the POP3 service. For information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out

Managing POP3 and IMAP4.

Use the EMC to set the calendar options for POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. In the action pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Retrieval Settings** tab.
5. Under **Calendar Retrieval**, select one of the following options:
   - iCalendar
   - Intranet URL
   - Internet URL
   - Custom
6. To apply the calendar retrieval option that you selected, click **Apply**, and then click **OK**.

Use the Shell to set the calendar options for POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables POP3 to use iCalendar.

```
Set-PopSettings -Identity CAS01 -CalendarItemRetrievalOption 0
```

This example enables POP3 users to access internal calendar information from an internal server.

```
Set-PopSettings -Identity CAS01 -CalendarItemRetrievalOption 1 -IntranetUrl "Serv
```

This example enables POP3 users to access calendar information from the Internet on an external server.

```
Set-PopSettings -CalendarItemRetrievalOption 2 InternetUrl "https://Server01"
```

This example enables POP3 users to access calendar information by using Outlook Web App.

```
Set-PopSettings -CalendarItemRetrievalOption 3 -OwaServerUrl "https://OwaServer01
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you set the calendar options for POP3, you may also want to:

- Configure POP3 and IMAP4 Message Retrieval Format Options
- Set Connection Time-Out Limits for POP3

Configure Calendar Options for IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to set the calendaring options that are available on the Microsoft Exchange Server 2010 server that has the IMAP4 service enabled.

These settings allow you to set different calendar options for your organization when you're using IMAP4 as the e-mail protocol for your users. You can use the `CalendarItemRetrievalOption` parameter for the Set-ImapSettings cmdlet in the Shell to set different calendar options.

The following table describes the `CalendarItemRetrievalOption` parameter for IMAP4 users.

IMAP4 calendar options for Exchange 2010

Setting	Value	Description
iCalendar	0	This setting lets users use the iCalendar standard for calendar items. The iCalendar standard is a standard for exchanging calendar information.
IntranetUrl	1	This setting lets you specify an internal URL for users to access their calendar information.
InternetUrl	2	This setting lets you specify an external URL for users to access their calendar information.
Custom	3	This setting lets you specify an Outlook Web App server for users to access their calendar information.

Note:

After you've specified the calendar options for IMAP4, you must restart the IMAP4 service. For information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to set the calendar options for IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions

topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. In the action pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Retrieval Settings** tab.
5. Under **Calendar Retrieval**, select one of the following options:
   - iCalendar
   - Intranet URL
   - Internet URL
   - Custom
6. To apply the calendar retrieval option that you selected, click **Apply**, and then click **OK**.

Use the Shell to set the calendar options for IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables IMAP4 to use iCalendar.

```
Set-ImapSettings -Identity CAS01 -CalendarItemRetrievalOption 0
```

This example enables IMAP4 users to access internal calendar information from an internal server.

```
Set-ImapSettings -Identity CAS01 -CalendarItemRetrievalOption 1 -IntranetUrl "Ser
```

This example enables IMAP4 users to access calendar information from the Internet on an external server.

```
Set-ImapSettings -CalendarItemRetrievalOption 2 InternetUrl "https://Server01"
```

This example enables IMAP4 users to access calendar information by using Outlook Web App.

```
Set-ImapSettings -CalendarItemRetrievalOption 3 -OwaServerUrl "https://OwaServer0
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you set the calendar options for IMAP4, you may also want to:

- Configure POP3 and IMAP4 Message Retrieval Format Options
- Set Connection Time-Out Limits for IMAP4

1.6.2.5.11 Configure POP3 and IMAP4 Message Retrieval Format Options

Configure POP3 and IMAP4 Message Retrieval Format Options

Client Access > Managing Client Access Servers > Managing POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can manage message retrieval format options for users on a Microsoft Exchange Server 2010 Client Access server that has the POP3 service or the IMAP4 service enabled.

You can use the EMC or the Shell to manage the message retrieval options for IMAP4 and POP3 access for an individual user's mailbox. The following table describes the format options available for POP3 and IMAP4 users.

Note:

After you've specified message retrieval format options for POP3 or IMAP4, you must restart whichever service you're using: POP3 or IMAP4. For more information about how to restart the POP3 and IMAP4 services, see Start and Stop the POP3 Service and Start and Stop the IMAP4 Service.

Message retrieval format options for POP3 and IMAP4

Setting	Value	Description
PopMessagesRetrievalMimeFormat	• 0:Text Only • 1:HTML Only • 2:HTML and Alternative Text • 3:Enriched Text Only • 4:Enriched Text and Alternative Text • 5:Best Body Format • 6:TNEF	This setting lets you set the POP3 message retrieval format for an individual user.
ImapMessagesRetrievalMimeFormat	• 0:Text Only • 1:HTML Only • 2:HTML and Alternative Text • 3:Enriched Text Only • 4:Enriched Text and Alternative Text • 5:Best Body Format • 6:TNEF	This setting lets you set the IMAP4 message retrieval format for an individual user.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to set the message retrieval format for a POP3 user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **POP3** and then, in the result pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Retrieval Settings** tab.
5. Under **Message Retrieval**, select a message format from the drop-down list under **Message MIME format**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set the message retrieval format for a POP3 user

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "POP3 and IMAP4 Permissions" section in the Client Access Permissions topic.

This example sets the message retrieval format for POP3 access for USER01.

```
Set-CASMailbox -Identity USER01 -PopMessagesRetrievalMimeFormat value
```

Use one of the message retrieval format options listed in the Value column in the "Message retrieval format options for POP3 and IMAP4" table.

For more information about syntax and parameters, see Set-CASMailbox.

Use the EMC to set the message retrieval format for an IMAP4 user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the result pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Retrieval Settings** tab.
5. Under **Message Retrieval**, select a message format from the drop-down list under **Message MIME format**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set the message retrieval format for an IMAP4 user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4 Permissions" section in the Client Access Permissions topic.

This example sets the message retrieval format for IMAP4 access for USER01.

```
Set-CASMailbox -Identity USER01 -ImapMessagesRetrievalMimeFormat value
```

Use one of the message retrieval format options listed in the Value column in the "Message retrieval format options for POP3 and IMAP4" table.

For more information about syntax and parameters, see Set-CASMailbox.

Other Tasks

After you set the message retrieval format for IMAP4 and POP3 users, you may also want to:

- Enable or Disable POP3 Access for a User
- Enable or Disable IMAP4 Access for a User
- Configure Calendar Options for IMAP4
- Configure Calendar Options for POP3

Set Connection Time-Out Limits for POP3

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure the connection time-out limits for idle authenticated and unauthenticated POP3 connections.

Note:

After you've set the connection time-out limits for POP3, you must restart the POP3 service for the settings to take effect. For information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to set connection time-out limits for POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **POP3** and then, in the action pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Connection** tab.
5. Under **Time-out Settings**, do one of the following:
   - To set the connection time-out limit for idle authenticated connections, enter a number between 1 and 18,000 in the box next to **Authenticated time-out (seconds)**.
   - To set the connection time-out limit for idle unauthenticated connections, enter a number between 1 and 200 in the box next to **Unauthenticated time-out (seconds)**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set connection time-out limits for POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the connection time-out limit for idle authenticated connections.

```
Set -PopSettings -Identity CAS01 -AuthenticatedConnectionTimeout TimeValue
```

This example sets the connection time-out limit for idle unauthenticated connections.

```
Set -PopSettings -Identity CAS01 -PreAuthenticatedConnectionTimeout TimeValue
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you set connection time-out limits for POP3, you may also want to:

- Enable POP3 in Exchange 2010
- Set Connection Limits for POP3

1.6.2.5.13 Set Connection Time-Out Limits for IMAP4

Set Connection Time-Out Limits for IMAP4

Client Access > Managing Client Access Servers > Managing POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure the connection time-out limits for idle authenticated and unauthenticated IMAP4 connections.

Note:

After you've set the connection time-out limits for IMAP4, you must restart the IMAP4 service. For information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to set connection time-out limits for IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Connection** tab.
5. Under **Time-out Settings**, do one of the following:
   - To set the connection time-out limit for idle authenticated connections, enter a number between 1 and 18,000 in the box next to **Authenticated time-out (seconds)**.
   - To set the connection time-out limit for idle unauthenticated connections, enter a number between 1 and 200 in the box next to **Unauthenticated time-out (seconds)**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set connection time-out limits for IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions

topic.

This example sets the connection time-out limit for idle authenticated connections.

```
Set -ImapSettings -Identity CAS01 -AuthenticatedConnectionTimeout Timespan
```

This example sets the connection time-out limit for idle unauthenticated connections.

```
Set -ImapSettings -Identity CAS01 -PreAuthenticatedConnectionTimeout Timespan
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you set authentication time-out limits for IMAP4, you may also want to:

- Enable IMAP4 in Exchange 2010
- Set Connection Limits for IMAP4

1.6.2.5.14 Configure IP Addresses and Ports for POP3 and IMAP4 Access

Configure IP Addresses and Ports for POP3 and IMAP4 Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure Microsoft Exchange to use ports other than the default ports on the Microsoft Exchange Server 2010 server that has the POP3 and IMAP4 services enabled.

Note:
Enter IP addresses and IP address ranges in the Internet Protocol Version 4 (IPv4) format, Internet Protocol Version 6 (IPv6) format, or both formats. A default installation of Windows Server 2008 enables support for IPv4 and IPv6.

Note:
After you configure IP addresses and ports for POP3 and IMAP4 access, you must restart the POP3 or IMAP4 service. For information about how to restart the POP3 and IMAP4 services, see Start and Stop the POP3 Service and Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure IP addresses and ports for POP3 and IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select either **POP3** or **IMAP4**, and then under **POP3** or **IMAP4**, click

Properties in the action pane.
4. On the **Binding** tab, under **TLS or Unencrypted Connections**, click **Add**.
5. On the **TLS or Unencrypted Connection Settings** page, under **IP address to Use**, do one of the following:
   - To use all available IP addresses for a server, select **Use all IP addresses available on this server**.
   - To manually specify an address, select **Specify an IP address**, and then enter an IP address in the dialog box.
6. Under **Port to Use**, in the box next to **Port**, enter a port number, or accept the default port.
7. Click **OK** to save your changes.

Use the Shell to configure IP addresses and ports for POP3 and IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the IP address and port for communicating with Exchange by using POP3 with Secure Sockets Layer (SSL).

```
Set-PopSettings -SSLBindings: IPaddress:Port
```

This example sets the IP address and port for communicating with Exchange by using POP3 with no encryption or Transport Layer Security (TLS) encryption.

```
Set-PopSettings -UnencryptedOrTLSBindings IPaddress:Port
```

This example sets the IP address and port for communicating with Exchange by using IMAP4.

```
Set-ImapSettings -SSLBindings: IPaddress:Port
```

This example sets the IP address and port for communicating with Exchange by using IMAP4 with no encryption or TLS encryption.

```
Set-ImapSettings -UnencryptedOrTLSBindings IPaddress:Port
```

For more information about syntax and parameters, see the following topics:

- Set-PopSettings
- Set-ImapSettings

Other Tasks

After you configure IP addresses and ports for POP3 and IMAP4, you may also want to:

- Enable POP3 and IMAP4 Users to Use Default Protocol Settings
- Enable IMAP4 in Exchange 2010
- Enable POP3 in Exchange 2010

1.6.2.5.15 Set Connection Limits for POP3

Set Connection Limits for POP3

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to set the connection limits on the computer running Microsoft Exchange Server 2010 that has the POP3 service enabled.

When you specify connection limits for POP3, you can select connection limits for the server, IP address, or a specific user. The following table describes the three settings for connection limits.

Descriptions of commands for setting connection limits for POP3

Command	Description	Default value	Limits
`MaxConnections`	Specifies the total number of connections the specified server will accept. This includes authenticated and unauthenticated connections.	2,000	1-25,000
`MaxConnectionsFromSingleIP`	Specifies the number of connections that the server will accept from a single IP address.	2000	1-25,000
`MaxConnectionsPerUser`	Specifies the maximum number of connections that the server will accept from a particular user.	16	1-25,000

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Note:
After you set connection limits, you must restart the POP3 service. For information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Use the EMC to set POP3 connection limits for a server, an IP address, or a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **POP3** and then, in the action pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Connection** tab.
5. Under **Connection Limits**, specify the following:
   - To set the connection limit for a server, enter a value between 1 and 25,000 in the box next to **Maximum connections**.
   - To set the connection limit for an IP address, enter a value between 1 and 25,000 in the box next to **Maximum connections from a single IP address**.
   - To set the connection limit for a single user, enter a value between 1 and 25,000 in the box next to **Maximum connections from a single user**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set POP3 connection limits for a server, an IP address, or a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the connection limit for a server.

```
Set-PopSettings -Identity CAS01 -MaxConnections Value
```

This example sets the connection limit for an IP address.

```
Set-PopSettings -Identity CAS01 -MaxConnectionsFromSingleIP Value
```

This example sets the connection limit for a user.

```
Set-PopSettings -MaxConnectionsPerUser Value
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you set POP3 connection limits for a server, IP address, or a user, you may also want to:

- Enable POP3 in Exchange 2010
- Set Connection Time-Out Limits for POP3

1.6.2.5.16 Set Connection Limits for IMAP4

Set Connection Limits for IMAP4

Client Access > Managing Client Access Servers > Managing POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to set the connection limits on a computer running Microsoft Exchange Server 2010 that has the IMAP4 service enabled.

When you specify connection limits for IMAP4, you can select connection limits for the server, IP address, or a specific user.

The following table describes the three settings for connection limits.

Descriptions of commands for setting connection limits for IMAP4

Command	Description	Default value	Limits
MaxConnections	Specifies the total number of	2,000	1-25,000

	connections the specified server will accept. This includes authenticated and unauthenticated connections.		
MaxConnectionsFromSingleIP	Specifies the number of connections that the server will accept from a single IP address.	2000	1-25,0000
MaxConnectionsPerUser	Specifies the maximum number of connections that the server will accept from a particular user.	16	1-25,000

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Note:

After you set connection limits, you must restart the IMAP4 service. For information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Use the EMC to set IMAP4 connection limits for a server, an IP address, or a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Connection** tab.
5. Under **Connection Limits**, specify the following:
   - To set the connection limit for a server, enter a value between 1 and 25,000 in the box next to **Maximum connections**.
   - To set the connection limit for an IP address, enter a value between 1 and 25,000 in the box next to **Maximum connections from a single IP address**.
   - To set the connection limit for a single user, enter a value between 1 and 25,000 in the box next to **Maximum connections from a single user**.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to set IMAP4 connection limits for a server, an IP address, or a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the connection limit for a server.

```
Set-ImapSettings -Identity CAS01 -MaxConnections Value
```

This example sets the connection limit for an IP address.

```
Set-ImapSettings -Identity CAS01 -MaxConnectionsFromSingleIP Value
```

This example sets the connection limit for a user.

```
Set-ImapSettings -MaxConnectionsPerUser Value
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you set IMAP4 connection limits for a server, IP address, or a user, you may also want to:

- Enable IMAP4 in Exchange 2010
- Set Connection Time-Out Limits for IMAP4

1.6.2.5.17 Configure Protocol Logging for POP3 and IMAP4

Configure Protocol Logging for POP3 and IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure protocol logging settings for POP3 and IMAP4 on a Microsoft Exchange Server 2010 Client Access server. By default, protocol logging isn't enabled. You can use protocol logging to review the POP3 and IMAP4 connections in your Exchange environment. This can be useful if you're troubleshooting issues related to POP3 or IMAP4 performance. For more information, see Understanding Protocol Logging for POP3 and IMAP4.

You can enable, disable, and modify protocol logging options by using the Exchange Management Shell.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the Shell to enable protocol logging for POP3 or IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example enables protocol logging for IMAP4 or POP3 on the Client Access server CAS01.

```
Set-IMAPSettings -Server "CAS01" -ProtocolLogEnabled $true
Set-POPSettings -Server "CAS01" -ProtocolLogEnabled $true
```

You must restart the POP3 service or the IMAP4 service after you change these settings. The settings will take effect as soon as you restart the service.

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

Use the Shell to disable protocol logging for POP3 or IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example disables protocol logging for IMAP4 or POP3 on the Client Access server CAS01.

```
Set-IMAPSettings -Server "CAS01" -ProtocolLogEnabled $false
Set-POPSettings -Server "CAS01" -ProtocolLogEnabled $false
```

You must restart the POP3 service or the IMAP4 service after you change these settings. The settings will take effect as soon as you restart the service.

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

Use the Shell to modify protocol logging for POP3 or IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

To modify POP3 or IMAP4 logging settings, run the **Set-IMAPSettings** or **Set-POPSettings** cmdlets with one or more of the following parameters. You must restart the POP3 service or the IMAP4 service after you change these settings. The settings will take effect as soon as you restart the service.

- *LogFileLocation* This parameter specifies the location for the POP3 or IMAP4 protocol log files. By default, POP3 protocol log files are located in the C:\Program Files\Microsoft\Exchange Server\V14\Logging\Pop3 directory. This example turns on POP3 protocol logging on the Client Access server CAS01. It also changes the POP3 protocol logging directory to C:\Pop3Logging.

  ```
  Set-POPSettings -Server "CAS01" -ProtocolLogEnabled $true -LogFileLocat
  ```

- *LogFileRollOverSettings* This parameter defines how frequently POP3 or IMAP4 protocol logging creates a new log file. By default, a new log file is created every hour. The possible values are:
  Hourly
  Daily
  Weekly
  Monthly
  This setting applies only when the value for the parameter *LogPerFileSizeQuota* is set to 0. This example changes the POP3 protocol logging on the Client

Access server CAS01 to create a new log file every hour.

```
Set-POPSettings -Server "CAS01" -LogPerFileSizeQuota 0 -LogFileRollOver
```

- *LogPerFileSizeQuota* This parameter defines the maximum size of a POP3 or IMAP4 protocol log file in bytes. By default, this value is set to 0. When this value is set to zero, a new protocol log file is created at the frequency specified by the *LogFileRollOverSettings* parameter.
  This example changes the POP3 protocol logging on the Client Access server CAS01 to create a new log file when a log file reaches 2 MB.

```
Set-POPSettings -Server "CAS01" -LogPerFileSizeQuota 2000000
```

This example changes the POP3 protocol logging on the Client Access server CAS01 to use the same log file regardless of its creation date and size.

```
Set-POPSettings -Server "CAS01" -LogPerFileSizeQuota unlimited
```

For detailed syntax and parameter information, see Set-ImapSettings and Set-PopSettings.

Other Tasks

After you configure protocol logging settings for POP3 and IMAP4, you may also want to do the following:

- Start and Stop the IMAP4 Service
- Start and Stop the POP3 Service

1.6.2.5.18 Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App

Allow POP3, IMAP4, and SMTP Server Settings to be Viewed By End Users in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-10*

If you have users who use POP3 or IMAP4 to connect to their Microsoft Exchange Server 2010 mailboxes, they have to know the correct server settings to connect to these mailboxes. You can configure Exchange so that your users can look up their own settings.

POP and IMAP e-mail programs require that users enter their incoming POP3 or IMAP4 server settings and their outgoing SMTP server settings. You can allow your users to connect from inside the corporate network (using internal server settings) or over the Internet (using external server settings).

Note:

After a default Exchange 2010 installation, your users can look up their internal POP3 and IMAP4 server settings using Microsoft Office Outlook Web App. However, you must make changes to the settings on your Exchange server if you want users to be able to look up their own external POP3 and IMAP4 server settings or their internal or external SMTP server settings.

For more information about how to manage POP3 and IMAP4, see Managing POP3 and IMAP4.

Use the Shell to allow POP3, IMAP4, and SMTP server settings to be viewed by end users in Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 settings" and "IMAP4 settings" entries in the Client Access Permissions topic and "Receive connectors" entry in the Transport Permissions topic.

This example allows external POP3 server settings to be viewed by end users.

```
set-popsettings -ExternalConnectionSettings {CAS01:995:SSL}
```

For detailed syntax and parameter information, see Set-PopSettings.

This example allows external IMAP4 server settings to be viewed by end users.

```
set-imapsettings -ExternalConnectionSettings {CAS01:993:SSL}
```

For detailed syntax and parameter information, see Set-ImapSettings.

This example allows internal and external SMTP server settings to be viewed by end users using Outlook Web App. **Client CAS01** is the send connector.

```
Set-ReceiveConnector "Client CAS01" -advertiseclientsettings $true
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

After you run these commands, your users can look up their server settings in Outlook Web App, as follows:

- If you're running Exchange 2010 SP1, your users can look up their external POP3, IMAP4, and SMTP server settings by clicking **Options** > **All Options** > **Account** > **My Account** > **Settings for POP, IMAP, and SMTP access**.
- If you're running the RTM version of Exchange 2010, your users can look up their external POP3, IMAP4, and SMTP server settings by clicking the drop-down arrow next to the Help question mark, and then clicking **About**.
- If you're running Exchange 2010 SP1 or Exchange 2010 RTM, your users can look up their internal POP3, IMAP4, and SMTP server settings in Outlook Web App by clicking the drop-down arrow next to the Help question mark, and then clicking **About**.

Other Tasks

After you make it possible for end users to view their POP3, IMAP4, and SMTP settings, you may also want to:

- Enable or Disable POP3 Access for a User
- Enable or Disable IMAP4 Access for a User

1.6.2.6 Managing the Autodiscover Service

Managing the Autodiscover Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-13*

1.6.2.6.1 Create an Autodiscover Virtual Directory

Create an Autodiscover Virtual Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to create a new Autodiscover virtual directory for Microsoft Exchange Server 2010. This can't be done using the EMC. The Autodiscover virtual directory provides the internal and external URLs that connecting Outlook clients require to access Exchange services, including the Availability service, the offline address book, and Unified Messaging.

Note:

The ability to use the Autodiscover service on a mobile phone depends on the operating system that's running on the mobile phone. Not all mobile phone operating systems that support synchronization with Exchange 2010 also support the Autodiscover service. For more information, contact the manufacturer of your mobile phone.

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Use the Shell to create a new Autodiscover virtual directory

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Autodiscover virtual directory settings" entry in the Client Access Permissions topic.

This example creates an Autodiscover virtual directory under the Default Web Site in the Internet Information Services (IIS) Manager, with client authentication set to allow Basic and Integrated Windows authentication.

```
New-AutodiscoverVirtualDirectory -Websitename <websitename> -BasicAuthentication:
```

For more information about syntax and parameters, see New-AutodiscoverVirtualDirectory.

Other Tasks

After you create a new Autodiscover virtual directory, you may also want to:

- Delete the Default Autodiscover Virtual Directory
- Configure the Autodiscover Service for Internet Access

1.6.2.6.2 Delete the Default Autodiscover Virtual Directory

Delete the Default Autodiscover Virtual Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to delete the default Autodiscover virtual directory for Microsoft Exchange Server 2010. You can't use the EMC to do this.

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Use the Shell to delete the default Autodiscover virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Autodiscover virtual directory settings" entry in the Client Access Permissions topic.

This example removes the default Autodiscover virtual directory.

```
Remove-AutodiscoverVirtualDirectory -Identity "MyServer\autodiscover(autodiscover
```

For more information about syntax and parameters, see Remove-AutodiscoverVirtualDirectory.

Other Tasks

After you delete the default Autodiscover virtual directory, you may also want to:

- Create an Autodiscover Virtual Directory
- Configure the Autodiscover Service for Internet Access

1.6.2.6.3 Test Outlook Autodiscover Connectivity

Test Outlook Autodiscover Connectivity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to verify that the Autodiscover service settings for Outlook clients are configured correctly.

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Use the Shell to test Autodiscover connectivity

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Test Autodiscover service connectivity" entry in the Client Access Permissions topic.

This example tests that the Outlook provider settings for the Autodiscover service are configured correctly on the Client Access server CASServer01.

```
Test-OutlookWebServices -ClientAccessServer "CASServer01"
```

For detailed syntax and parameter information, see the Test-OutlookWebServices reference topic.

Other Tasks

After you test connectivity for the Autodiscover service, you may also want toTest Outlook Anywhere Connectivity.

1.6.2.6.4 Configure the Autodiscover Service for Internet Access

Configure the Autodiscover Service for Internet Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the Autodiscover service for Internet access on a Microsoft Exchange Server 2010 Client Access server.

If you've deployed Exchange 2010 in your messaging environment, you can let the Autodiscover service automatically configure Microsoft Office Outlook 2007 or Outlook

2010 clients for features such as the Availability service, Unified Messaging, and Outlook Anywhere. If you plan to allow external access to the Autodiscover service for Outlook 2007 or Outlook 2010 clients that connect from the Internet, you must configure a valid Secure Sockets Layer (SSL) certificate from a certification authority (CA) that's trusted by the client computer's operating system.

You can create a separate Internet Information Services (IIS) Web site to host Autodiscover traffic. Consider hosting the Autodiscover service on a separate IIS Web site if either of the following is true:

- Your primary Web site is visited frequently
- Your primary Web site hosts your e-mail traffic

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Configure Internet access to the Autodiscover service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Autodiscover service virtual directory settings" entry in the Client Access Permissions topic.

To allow external access to the Autodiscover service for Outlook 2010 or Outlook 2007 clients that are connected from the Internet, we recommend that you perform these steps in the following order.

1. **(Optional) Configure a separate IIS Web site on a Client Access server to host the Autodiscover service** You can create a separate site to host Autodiscover service traffic by using the **New-AutodiscoverVirtualDirectory** cmdlet. This step is recommended if the domain in the Simple Mail Transfer Protocol (SMTP) address is the same as the corporate Web site address and your corporate Web site is visited frequently. For example, if the corporate Web site is www.contoso.com, the e-mail SMTP domain is contoso.com, and the corporate Web site (www.contoso.com) is visited frequently, we recommend that you create a separate site and host the Autodiscover service on autodiscover.contoso.com. For more information, see Create an Autodiscover Virtual Directory.

   Note:
   You must use one IP address per site.

2. **(Required) Configure a valid SSL certificate** You must configure a valid SSL certificate from a CA that the client computer trusts. We recommend that you use the Exchange 2010 Certificate wizard to configure a valid SSL certificate. For information about how to create an SSL certificate, see Create a New Exchange Certificate. If you've decided to host the Autodiscover service on a separate Web site, see Configure SSL Certificates to Use Multiple Client Access Server Host Names.
3. **(Optional) Update the SCP Object** You only need to perform this step if you want internal Exchange clients to connect to the Autodiscover service through the Internet. Service connection points (SCPs) are only used for internal Exchange clients. If you've created a separate IIS Web site for the Autodiscover service, you must update the SCP object in Active Directory to specify which Client Access server and Autodiscover virtual directory you want clients to connect to. For more information about how to configure SCP objects, see Publishing with Service Connection Points.
4. **(Required) Configure the firewall and SSL certificate** You should configure the firewall for the address space and configure the SSL certificate for the Autodiscover service. For more information, check your firewall documentation. If your firewall server is ISA Server 2006, see Publishing

Exchange Server 2007 with ISA Server 2006. For information about how to configure Outlook Anywhere to use multiple SSL certificates, see Configure Outlook Anywhere to Use Multiple SSL Certificates.

5. **(Optional) Create a new Web site for the Autodiscover service** Follow these steps:
   5.a. In IIS Manager, expand your Client Access server name, select and right-click **Sites**, and then select **Add Web Site**. Enter your SMTP domain name under **Site name**.
   5.b. Under **Physical path**, navigate to %SystemDrive%\inetpub\. Under inetpub, create a new folder called Autodiscover.

   Note:
   You must allow the **Users** group **Read & execute** access to the Web site that you create.

6. **(Optional) Create an Autodiscover virtual directory for the new Web site** You can use the Shell to create an Autodiscover virtual directory for the new Web site in IIS by running the following command.
   You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Autodiscover virtual directory settings" entry in the Client Access Permissions topic.

   ```
   New-AutodiscoverVirtualDirectory -Websitename <websitename> -BasicAuth
   ```

   Note:
   A Web site that uses SSL requires that you use a unique IP address.

   For more information about syntax and parameters, see New-AutodiscoverVirtualDirectory.
7. **(Optional) Configure a trusted third-party SSL certificate on the new Web site** If you created a new Web site to host the Autodiscover service, configure a trusted third-party SSL certificate on the Web site. We recommend that you use the Exchange 2010 Certificate wizard to configure a valid SSL certificate. For information about how to create an SSL certificate, see Create a New Exchange Certificate. For more information, see Understanding Digital Certificates and SSL.

Other Tasks

After you configure a new Web site for the Autodiscover service, you may also want to:

- Configure Exchange Services for the Autodiscover Service
- Configure the Autodiscover Service for Multiple Forests

1.6.2.6.5 Configure the Autodiscover Service for Multiple Forests

Configure the Autodiscover Service for Multiple Forests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure the Autodiscover service when your Microsoft Exchange deployment has two or more trusted forests.

To configure the Autodiscover service when your deployment has two or more trusted forests, you must update Active Directory so that users who are running Microsoft Office

Outlook 2007 or Outlook 2010 in one forest can access the Client Access servers in the remote (or target) forest to use the Autodiscover service. To do this, you run the **Export-AutodiscoverConfig** cmdlet in each forest that contains the Client Access servers that provide the Autodiscover service against the target forests. This configures the service connection point (SCP) information for the Autodiscover pointer in Active Directory.

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Use the Shell to configure the Autodiscover service for multiple forests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Autodiscover service virtual directory settings" entry in the Client Access Permissions topic.

The procedures in the following examples must be performed on an Exchange 2010 Client Access server in the source forest.

This example retrieves the credentials from the Client Access server in the target forest. Use the target server's credentials to run the cmdlet **Export-AutodiscoverConfig**.

```
$a = Get-Credential
```

This example updates a service connection point for an Autodiscover service pointer on the Client Access server in the source forest for the target Exchange forest.

```
Export-AutoDiscoverConfig -DomainController <FQDN> -TargetForestDomainController
```

For more information about syntax and parameters, see Export-AutoDiscoverConfig.

Other Tasks

After you configure the Autodiscover service for multiple forests, you may also want to:

- Configure the Autodiscover Service to Use Site Affinity

1.6.2.6.6 Configure the Autodiscover Service to Use Site Affinity

Configure the Autodiscover Service to Use Site Affinity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure site affinity for the Autodiscover service on the Microsoft Exchange Server 2010 Client Access server. When you configure site affinity on the Client Access server, you enable clients using Outlook 2007 and Outlook 2010 to get Autodiscover information from the closest Active Directory site. This provides Autodiscover information to the Outlook clients more quickly than if site affinity hasn't been set.

To configure the Autodiscover service to use site affinity, use the **Set-ClientAccessServer**

cmdlet.

Use the Shell to configure site affinity for the Autodiscover service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Autodiscover service site affinity" entry in the Client Access Permissions topic.

This example sets the Autodiscover URL for Outlook clients in the specified Active Directory site to get Autodiscover information.

```
Set-ClientAccessServer -Identity "ServerName" -AutodiscoverServiceInternalURI "ht
```

For more information about syntax and parameters, see Set-ClientAccessServer.

Other Tasks

After you configure site affinity for the Autodiscover service, you may also want to:

- Configure Exchange Services for the Autodiscover Service
- Configure the Autodiscover Service for Internet Access

1.6.2.6.7 Configure Exchange ActiveSync Autodiscover Settings

Configure Exchange ActiveSync Autodiscover Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Autodiscover service to provision mobile phones for users. The Autodiscover service returns an XML file that's used to provision a user's phone when the user's e-mail address and password are supplied. The Autodiscover service returns the address to a Microsoft Exchange Server 2010 Client Access server. By default, the Autodiscover service is enabled. You can use the Shell to enable the Autodiscover service in Microsoft Exchange ActiveSync.

Note:

The ability to use the Autodiscover service depends on the mobile phone operating system that you're using. Not all mobile phone operating systems that support synchronization with Exchange 2010 support Autodiscover. For more information about mobile phone operating systems that support Autodiscover, contact the manufacturer of your mobile phone.
