You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access Server settings" entry in the Client Access Permissions topic.

This example configures the Autodiscover service and sets the **ExternalURL** property.

```
Set-ActiveSyncVirtualDirectory -Identity "COMPUTERNAME\Microsoft-Server-ActiveSyn
```

This example configures the Exchange ActiveSync server property on the Client Access server.

```
Set-ActiveSyncVirtualDirectory -Identity "COMPUTERNAME\Microsoft-Server-ActiveSyn
```

For more information about syntax and parameters, see Set-ActiveSyncVirtualDirectory.

1.6.2.6.8 Configure Exchange Services for the Autodiscover Service

Configure Exchange Services for the Autodiscover Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Microsoft Exchange services, such as the Availability service, for the Autodiscover service on a Microsoft Exchange Server 2010 Client Access server.

When you enable Outlook Anywhere, you must also configure external client access to Microsoft Exchange services for the Autodiscover service. Other external URLS you must configure include the URLs for the Availability service, Exchange Web Services, Unified Messaging (UM), and the offline address book.

If you don't configure the external URL values, the Autodiscover service information provided to the Microsoft Office Outlook 2007 or Outlook 2010 clients may be incorrect for users who are connecting from outside your network. They may be able to connect to their Exchange mailbox. However, they won't be able to use Exchange features such as Automatic Replies, the Availability service, Unified Messaging, or offline address book downloads.

Generally, the internal URL is configured by Exchange Setup. However, the external URLs must be configured by using the virtual directory cmdlet for each component.

Looking for other management tasks related to the Autodiscover service? Check out Managing the Autodiscover Service.

Use the Shell to configure the Outlook Anywhere external host name for the

Autodiscover service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration (enable, disable, change, view)" entry in the Client Access Permissions topic.

This example sets the external host name for Outlook Anywhere on the Client Access server CAS01.

```
Enable-OutlookAnywhere -Server CAS01 -ExternalHostname "mail.contoso.com" -Defaul
```

For more information about syntax and parameters, see Enable-OutlookAnywhere.

Use the Shell to configure the offline address book external URL for the Autodiscover service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "OAB virtual directory" entry in the Mailbox Permissions topic.

This example sets the external URL for the offline address book virtual directory on the Client Access server CAS01.

```
Set-OABVirtualDirectory -identity "CAS01\OAB (Default Web Site)" -externalurl htt
```

For more information about syntax and parameters, see Set-OABVirtualDirectory.

Use the Shell to configure the Exchange Web Services external URL for the Autodiscover service

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services settings" entry in the Client Access Permissions topic.

This example sets the external URL for the Exchange Web services virtual directory on the Client Access server CAS01.

```
Set-WebServicesVirtualDirectory -identity "CAS01\EWS (Default Web Site)" -externa
```

For more information about syntax and parameters, see Set-WebServicesVirtualDirectory.

Other Tasks

After you configure Exchange services for the Autodiscover service, you may also want to:

- Configure the Autodiscover Service for Internet Access
- Configure the Autodiscover Service to Use Site Affinity

Modify the Time Limit for Autodiscover Operations

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-09-14*

The Cross-Forest Availability service has a time limit for performing an AutoDiscover operation for cross-forest users in the Active Directory directory service. By default, the time-out value is 10 seconds. If the Autodiscover request does not finish in 10 seconds, the Availability service request for the cross-forest user may time out.

To control the time-out value, use the **RecipientResolutionTimeoutInSeconds** property. The **RecipientResolutionTimeoutInSeconds** property is set in the ASP.NET Web.config file. The ASP.NET Web.config file exists in two locations.

Caution:

We recommend that you set this property to a value of no more than 25 seconds.

Change the value of the RecipientResolutionTimeoutInSeconds property

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the Exchange Server configuration settings entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

The ASP.NET Web.config file exists in two locations. Therefore, the same procedure applies to both locations.

1. Locate the Web.config file in the following directory:

   drive:\Program Files\Microsoft\Exchange Server\V14\ClientAccess\exchweb\ews\web.config

2. Copy the existing Web.config file, and then rename the copy file **Web.config.bak1**.
3. Open the Web.config file in Notepad.
4. Look for a section that is named **<appSettings>**. If **<appSettings>** exists, add the following entry to this section between **<appSettings>** and **</appSettings>**:

   ```
   <add key="RecipientResolutionTimeoutInSeconds" value="24"/>
   ```

   If the **<appSettings>** section does not exist, add the following section directly beneath the **<Configuration>** section:

   ```
   <appSettings>
        <add key="RecipientResolutionTimeoutInSeconds" value="24"/>
   </appSettings>
   ```

   Important:

   - This entry is case-sensitive, and must be entered exactly as shown. However, you can change the value from 24 to the value that you want to use. We recommend that you set the value for this property to between 20 and 24 seconds.

- Do not add this section under any other section of the Web.config file. If the new section does not immediately follow **<Configuration>**, it will not work.

1. Save the Web.config file.
2. Locate the Web.config file in the following directory:

   drive:\Program Files\Microsoft\Exchange Server\V14\ClientAccess\Owa\web.config

3. Copy the existing Web.config file, and then rename the copy file **Web.config.bak1**.
4. Open the Web.config file in Notepad.
5. Look for a section that is named **<appSettings>**. If **<appSettings>** exists, add the following entry to this section between **<appSettings>** and **</appSettings>**:

```
<add key="RecipientResolutionTimeoutInSeconds" value="24"/>
```

If the **<appSettings>** section does not exist, add the following section directly under the **<Configuration>** section:

```
<appSettings>
     <add key="RecipientResolutionTimeoutInSeconds" value="24"/>
</appSettings>
```

Important:

- This entry is case-sensitive, and must be entered exactly as shown. However, you can change the value from 24 to the value that you want to use. We recommend that you set the value for this property to between 20 and 24 seconds.
- Do not add this section under any other section of the Web.config file. If the new section does not immediately follow **<Configuration>**, it will not work.

1. Save the Web.config file.

For More Information

Configure the Availability Service for Cross-Forest Topologies

1.6.2.7 Managing the Availability Service

Managing the Availability Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Configure the Availability Service for Network Load Balanced Computers

Configure the Availability Service for Cross-Forest Topologies

Diagnose Availability Service Issues

Configure the Availability Service for Network Load Balanced Computers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Outlook 2007 discovers the Availability service URL using the Autodiscover service. To use network load balancing with the Availability service, you must make changes to your configuration. Specifically, for the Autodiscover and Availability services to work, DNS needs to be configured so that mail.<*domain name*>.com and autodiscover.<*domain name*>.com point to the Network Load Balancing (NLB) array of Client Access servers. In the previous sentence, <*domain name*> is a placeholder for your domain name.

You can configure the Availability service for network load balanced computers using the Exchange Management Shell.

Looking for other management tasks related to managing the Availability service? See Managing the Availability Service.

Prerequisites

Review the section "Availability Service Network Load Balancing" in the topic Understanding the Availability Service.

Use the Shell to configure the Availability service for network load balanced computers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability service permissions" entry in the Client Access Permissions topic.

This example configures the Availability service for load balancing for a domain named Contoso.com.

```
Set-WebServicesVirtualDirectory -Identity "EWS*" -ExternalUrl "Https:// mail.cont
```

Note:

If you have a set of load balanced Client Access servers, you don't have to specify the name of each server when you run this command. You only need to use the name of one of the servers in the set of load balanced servers.

For information about syntax and parameters, see Set-WebServicesVirtualDirectory.

Other Tasks

After you configure the Availability service for network load balanced computers, you may also want to:

- Diagnose Availability Service Issues
- Configure the Availability Service for Cross-Forest Topologies

1.6.2.7.2 Configure the Availability Service for Cross-Forest Topologies

Configure the Availability Service for Cross-Forest Topologies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-23*

The Availability service improves information workers' free/busy information by providing secure, consistent, and up-to-date free/busy information to clients who are running Microsoft Office Outlook 2007. By default, this service is installed with Microsoft Exchange Server 2010. In cross-forest topologies where all connecting clients are running Outlook 2007, the Availability service is the only method of retrieving free/busy information. You can use the Exchange Management Shell to configure the Availability service for cross-forest topologies.

Note:
You can't use the EMC to configure the Availability service for cross-forest topologies.

Note:
The terms *Source forest* and *Target forest* are used in this topic to identify each forest. These terms are defined as follows:

- **Source forest** Exchange forest from which the Availability Service makes the free/busy inquiry
- **Target forest** Exchange forest from which the free/busy information is being retrieved

Looking for other management tasks related to the Availability service? Check out Managing the Availability Service.

Using the Availability Service in Trusted and Untrusted Forests

You can use the Availability service in cross-forest topologies across trusted or untrusted forests. The type of free/busy information that's available depends on if you're using a trusted or untrusted forest.

Trusted Forests In trusted forests, you can configure the Availability service to retrieve free/busy information on a per-user basis. When the Availability service is configured to retrieve free/busy information on a per-user basis, the service can make cross-forest requests on behalf of a particular user. This allows a user in a remote forest to retrieve detailed free/busy information for someone who is not in the same forest.

Untrusted Forests In untrusted forests, you can configure the Availability service only to retrieve free/busy information on an organization-wide basis. When the Availability service makes free/busy cross-forest requests at the organizational level, free/busy information is returned for each user in the organization. In untrusted forests, it isn't possible to control the level of free/busy information that's returned on a per-user basis.

Configure Active Directory for Cross-Forest Topologies

To configure Active Directory in Microsoft Windows for a cross-forest topology, you must install and configure GAL Synchronization (GALSync). For information about how to install and configure the GALSync feature in Microsoft Identity Integration Server (MIIS), see the following resources:

- Microsoft Identity Integration Server 2003 Scenarios
- Microsoft Identity Integration Server 2003

Note:
If you want to use the *PerUserFB* parameter together with the **Add-AvailabilityAddressSpace** cmdlet, GALSync must be configured to synchronize the **msExchMasterAccountSid** attribute for the contacts and mail users that are synchronized to the target forest. This is not required for OrgWideFB.

If you're running Office Outlook 2003 or an earlier version, you must use the Microsoft Exchange Inter-Organization Replication tool to synchronize free/busy information across multiple forests. For more information about the Microsoft Exchange Inter-Organization Replication tool, see Microsoft Exchange Server Inter-Organization Replication.

Note:
To use the Microsoft Exchange Inter-Organization Replication tool, a Microsoft Exchange Server 2003 server or a Microsoft Exchange Server 2007 server must be the target server. The Microsoft Exchange Inter-Organization Replication tool is not supported when a Microsoft Exchange Server 2010 server is the target server.

Note:
Microsoft Exchange Server 2010 Service Pack 2 (SP2) Update Rollup 1 uses the external URL for Exchange Web Services to connect to the target forest. The external URL for Exchange Web Services cannot be returned by the AutoDiscover service if Outlook Anywhere is not enabled in the target forest. In this case, the cross-forest lookup fails. To work around this issue, enable Outlook Anywhere in the target forest, and then verify that the external URL for Exchange Server Web Services is configured correctly.

1. Enable Outlook Anywhere in the target forest. For information about how to enable Outlook Anywhere, see Enable Outlook Anywhere.
2. Configure the external URL for Exchange Web Services for the target forest. To do this, run the following command in Windows PowerShell for Exchange: **Set-WebServicesVirtualDirectory -identity "server_name\EWS (Default Web Site)" -ExternalURL https://mail.contoso.com/ews/Exchange.asmx**

   Note:
   In this command, contoso is a placeholder for the appropriate domain name.
3. Enable Outlook Anywhere for the organization mailboxes that should make incoming remote availability requests.

   Note:
   If an administrator disables Outlook Anywhere on an individual mailbox, that mailbox's information cannot be retrieved by a remote forest because Autodiscover will not return an Exchange Web Services ExternalURL for that mailbox.

Use the Shell to configure per-user free/busy information in a trusted cross-forest topology

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability Service Permissions" entries in the Client Access Permissions topic.

This example configures the Availability service to retrieve per-user free/busy information

on a Client Access server in the target forest.

Target Forest

```
Get-ClientAccessServer | Add-ADPermission -Accessrights Extendedright -Extendedri
EPI-Token-Serialization"  -User "<Remote Forest Domain>\Client Access servers"
```

This example defines the free/busy access method that the Availability service uses on the local Client Access server in the source forest. The local Client Access server is configured to access free/busy information from the <*Target_Forest*>.com forest on a per-user basis. The following example uses the service account to retrieve free/busy information.

Source Forest

```
Add-AvailabilityAddressSpace -Forestname <Target_Forest> -AccessMethod PerUserFB
```

Note:
To configure bidirectional cross-forest availability, repeat these steps in the target forest.

If you choose to configure cross-forest availability with trust, and also choose to use a service account (instead of specifying organization-wide or per-user credentials), you must extend permissions, as shown in the example in the "Use the Shell to configure trusted cross-forest availability with a service account" section. Performing that procedure in the target forest gives Client Access servers in the source forest permission to serialize the original user context.

Use the Shell to configure trusted cross-forest availability with a service account

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability Service Permissions" entries in the Client Access Permissions topic.

This example configures trusted cross-forest availability with a service account in the source forest.

Source Forest

```
$a = Get-Credential (Type the credential  "TargetForest\User"  for organization-w
Add-AvailabilityAddressSpace -ForestName <Target_Forest> -AccessMethod OrgWide -C
```

This example configures trusted cross-forest availability with a service account in the target forest.

Target Forest

```
Set-AvailabilityConfig -OrgWideAccount "TargetForest\User"
```

For detailed information about syntax and parameters, see the following topics:

- Get-ClientAccessServer
- Add-ADPermission
- Add-AvailabilityAddressSpace
- Set-AvailabilityConfig

Use the Shell to configure organization-

wide free/busy information in an untrusted cross-forest topology

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability Service Permissions" entries in the Client Access Permissions topic.

This example sets the organization-wide account on the availability configuration object to configure the access level for free/busy information in the target forest.

Target Forest

```
Set-AvailabilityConfig -OrgWideAccount "TargetForestDomain\User"
```

This example adds the Availability address space configuration object for the source forest.

Source Forest

```
$a = get-credential  (Enter the credentials for organization-wide user in SourceF
Add-AvailabilityAddressspace -Forestname SourceForestDomain -Accessmethod OrgWide
```

Configuring Cross-Forest Availability in Forests that Include Exchange 2003

For Outlook 2007 and Exchange 2010 users to view the free/busy information of Exchange Server 2003 users in another forest, you must configure the Availability service by using the **Add-AvailabilityAddressSpace** cmdlet.

You only have to run this command once on any server in the Exchange 2010 forest. You can run this cmdlet from any computer running Exchange 2007 or Exchange 2010.

Use the Shell to configure cross-forest availability in forests that include Exchange 2003

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability Service Permissions" entries in the Client Access Permissions topic.

This example sets public folder free/busy availability in the source forest.

Source Forest

```
Add-AvailabilityAddressSpace -ForestName SourceForestDomain -AccessMethod PublicF
```

Note:

To replicate free/busy information and public folder content between Exchange organizations you must use the Microsoft Exchange Inter-Organization Replication tool. For more information about the Microsoft Exchange Inter-Organization Replication tool, see Microsoft Exchange Server Inter-Organization Replication.

Cross-Forest Availability with Shared

name space

Important:
When you set up cross forest availability together with a shared name space, the availability services uses the target address on the contacts.

To configure SMTP namespace sharing, you must create an accepted domain that configured as internal relay domain for the SMTP namespace that you want to share. Then, create an SMTP connector that has the address space of the internal SMTP domain. The destination e-mail server must be a Hub Transport Server.

For more information, see Configure Exchange 2010 to Route Messages for a Shared Address Space.

Other Tasks

After you configure the Availability service for cross-forest topologies, you may also want to:

- Diagnose Availability Service Issues
- Configure the Availability Service for Network Load Balanced Computers

1.6.2.7.3 Diagnose Availability Service Issues

Diagnose Availability Service Issues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to diagnose Availability service issues in Exchange Server 2010, as follows:

- For an individual user
- On a Client Access server
- Across different sites

The Autodiscover service provides Microsoft Office Outlook 2007 with configuration information that's needed to connect to Exchange. The **Test-OutlookWebServices** cmdlet verifies whether the Autodiscover service and the Availability service are correctly configured and can service Outlook client requests.

Before you perform these procedures, consider trying to diagnose your Availability service issues using Event Viewer. Specifically, search Event Viewer on your Client Access server for event logs that contain the event source "MSExchange Availability".

Looking for other management tasks related to managing the Availability service? See Managing the Availability Service.

Prerequisites

You must create a test account before you can diagnose Availability service issues using the **Test-OutlookWebServices** cmdlet. To create the test mailbox, log on to the Exchange Server 2007 or Exchange 2010 Mailbox server. Open the Shell, and then locate the **Scripts** directory under the installation path on the Exchange server. For Exchange 2007, the folder is located at C:\Program Files\Microsoft\Exchange Server\Scripts, where C:\ is the directory to which you installed Exchange. For Exchange 2010, the folder is located at C:\Program Files\Microsoft\ExchangeServer\V14\Scripts, where C:\ is the directory to which you installed Exchange 2010. Run the script New-TestCasConnectivityUser.ps1. Repeat this process on each Exchange 2007 or Exchange 2010 Mailbox server that is to be tested.

Use the Shell to diagnose Availability service issues for an individual user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability service permissions" entry in the Client Access Permissions topic.

This example tests access to the Availability service for user User1@Contoso.com.

```
Test-OutlookWebServices -Identity: User1@Contoso.com
```

Use the Shell to diagnose Availability service issues for a Client Access server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability service permissions" entry in the Client Access Permissions topic.

This example tests user access to the Availability service on the Client Access server ClientAccessServer01.

```
Test-OutlookWebServices -ClientAccessServer ClientAccessServer01
```

Use the Shell to diagnose Availability service issues across different sites

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Availability service permissions" entry in the Client Access Permissions topic.

This example tests Availability service connectivity between users in two different Active Directory sites.

```
Test-OutlookWebServices -Identity User1@Site1.Contoso.com -TargetAddress User2@Si
```

For information about syntax and parameters, see Test-OutlookWebServices.

Other Tasks

After you diagnose Availability service issues, you may also want to:

- Configure the Availability Service for Cross-Forest Topologies
- Configure the Availability Service for Network Load Balanced Computers

1.6.2.8 Managing External Client Access

Managing External Client Access

Configure External Client Access Namespaces

Using ISA Server with Outlook Web App

Using ISA Server with Outlook Anywhere

Using ISA Server with Exchange ActiveSync

Using ISA Server with POP3 and IMAP4

1.6.2.8.1 Configuring External Client Access

Configuring External Client Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

By allowing remote access to Microsoft Exchange to users who are based outside the corporate network, an organization enables its employees to take full advantage of the technology their company provides. Remote access lets employees use many types of devices to communicate with their peers and customers from any place and at any time.

When an organization allows access to corporate resources from any location—perhaps with devices that aren't controlled by the organization—it risks the security of the data and services that are accessed. Therefore it's critical to take measures to ensure that the data is accessed securely. This means you must implement technologies such as certificates, implement firewalls, and enforce pre-authentication and device or endpoint validation. This process is known as publishing Exchange.

When you publish Exchange, Microsoft offers two primary software-based options: Microsoft Forefront Threat Management Gateway 2010 (Forefront TMG) and Microsoft Forefront Unified Access Gateway 2010 (Forefront UAG). Both options offer publishing wizards and security features to provide secure access to Exchange when it's accessed from outside the safety of the corporate network. For more information about these two solutions, see Publishing Exchange Server 2010 with Forefront UAG and TMG.

Configuring Client Access Protocols for External Access

In addition to configuring your chosen firewall and security solution, you must configure

the individual Client Access server protocols for external access. For more information about how to configure the various Client Access server protocols for external access, see the following topics.

- Configure External Client Access Namespaces
- Using ISA Server with Outlook Web App
- Using ISA Server with Outlook Anywhere
- Using ISA Server with Exchange ActiveSync
- Using ISA Server with POP3 and IMAP4

1.6.2.8.1.1 Using ISA Server with Outlook Web App

Using ISA Server with Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

Outlook Web App for Microsoft Exchange Server 2010 is designed to take full advantage of the features that are available in Microsoft Internet Security and Acceleration (ISA) Server 2006. Exchange 2010 is also designed to integrate with earlier versions of ISA Server. When you deploy Exchange 2010 in an environment where ISA Server 2006 is being used to help secure your corporate network, the full set of features for Exchange Client Access are available.

Looking for more tasks related to external access? See Managing External Client Access.

Contents

Benefits of Using ISA Server 2006 with Outlook Web Access

The following table lists features in ISA Server 2006 that can help you secure your Exchange messaging environment that includes Outlook Web App.

Using ISA Server 2006 as a reverse proxy server for Outlook Web App

Feature	Description
Link Translation	ISA Server 2006 redirects Outlook Web App requests for internal URLs that are contained in the body of any object in Outlook Web App, such as an e-mail message or calendar

	entry. Users no longer have to remember the external namespaces for internal corporate information that is mapped to an external namespace. For example, if a user sends a link in an e-mail message to an internal namespace such as http://contoso, and this internal URL is mapped to an external namespace such as http://www.contoso.com, the internal URL is automatically translated into the external URL when the user clicks the internal URL.
Web Publishing Load Balancing	ISA Server 2006 can load balance client requests and send them to an array of Client Access servers. When ISA Server 2006 receives a request for a connection to Outlook Web App, it selects a Client Access server and then sends the name of the Client Access server back to the Web browser in a cookie.
HTTP Compression	In the past, if you used forms-based authentication on the ISA Server computer that had Exchange Server 2003 and ISA Server 2004 or ISA Server 2000 installed, it was not possible to use Gzip compression. This was because ISA Server could not decompress and recompress the information correctly. ISA Server 2006 can decompress, inspect, and then recompress data before it sends the data to your Exchange servers. **Note:** Gzip compression is available in ISA Server 2004, Service Pack 2 (SP2).
Exchange server locations are hidden	When you publish an application through ISA Server, you're protecting the server from direct external access because the name and IP address of the server can't be viewed by the user. The user accesses the ISA Server computer. The ISA Server computer then creates a connection to the Client Access server according to the conditions of the server publishing rule.
SSL bridging and inspection	Secure Sockets Layer (SSL) bridging protects against attacks that are hidden in SSL-encrypted connections. For SSL-enabled Web applications, after ISA Server receives the client's request, ISA Server decrypts the request, inspects it, and acts as the endpoint for the SSL connection with the client computer. The Web publishing rules determine how ISA Server communicates the request for the object to the published Web server. When you use SSL bridging, the secure Web publishing rule is configured to forward the request by using Secure HTTP (HTTPS). ISA Server then initiates a new SSL connection with the published server.

	Because the ISA Server computer has become an SSL client, it requires the published Web server to respond with a certificate. An additional advantage of SSL bridging is that an organization has to buy SSL certificates from an external certification authority only for the ISA Server computers. Servers that use ISA Server as a reverse proxy can either not require SSL or use SSL certificates that are generated internally. You can also terminate the SSL connection at the ISA Server computer and continue to the Client Access server with a connection that isn't encrypted. This is known as SSL offloading. If you do this, the internal URL for Outlook Web App must be set to use HTTP and the external URL must be set to use HTTPS. The internal URL and external URL can be configured through the Exchange Management Console, or by using the **Set-OwaVirtualDirectory** cmdlet with the *InternalURL* parameter and *ExternalURL* parameter in the Exchange Management Shell. For more information about how to use the **Set-OwaVirtualDirectory** cmdlet and the EMC to manage Outlook Web App virtual directories, see Set-OwaVirtualDirectory and Managing Outlook Web App Virtual Directories.
Single sign-on	Single sign-on enables users to access a group of published Web sites without being required to authenticate with each Web site. When you use ISA Server 2006 as a reverse proxy server for Outlook Web App, ISA Server 2006 can be configured to obtain the user's credentials and pass them to the Client Access server so that users are prompted for their credentials only one time.

For more information about ISA Server 2006 when it is used with Exchange 2010, see What's New and Improved in ISA Server 2006.

Return to top

Deployment Options

When you deploy ISA Server 2006 together with Exchange 2010, you won't have to do any additional configuration to your Exchange infrastructure. However, ISA Server 2006 can be configured in different ways to enable Exchange client access using Outlook Web App, POP3 or IMAP access, Exchange ActiveSync, and Outlook Anywhere. The configuration options depend on the authentication method that you want to use to access Exchange.

Earlier versions of ISA Server, including ISA Server 2004 and ISA Server 2000 when they are deployed with Exchange 2010, don't have the same deployment options for authentication. Additionally, if you're deploying Exchange 2010 with both ISA Server 2006 and an earlier version of ISA Server, you can use the following authentication options:

- **Basic authentication for Outlook Web App** If you plan to use Basic authentication for Outlook Web App, ISA Server 2006 and earlier versions of ISA Server should all use Web Publishing to publish Outlook Web App.
- **Client certificate authentication** If you plan to use a client certificate-based authentication method, ISA Server will automatically perform authentication on the computer that is running ISA Server. Earlier versions of ISA Server, including ISA Server 2004 and ISA Server 2000, require server publishing to use client certificate authentication. If you use client certificate authentication, you can't use ISA Server to inspect the SSL packets before they are sent to the Client Access server.

For More Information

ISA Server Web site

ISA Server 2006 Features at a Glance

Configure Reverse Proxy Servers for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use ISA Server 2006 as a reverse proxy server for Outlook Web App.

Use ISA Server 2006 to configure a reverse proxy server for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "ISA Server 2006" entry in the Client Access Permissions topic.

1. In the ISA Server 2006 console, use the **Publish Exchange Web Client Access** wizard to publish Outlook Web App.
2. Configure ISA Server to authenticate users when they connect to the Outlook Web App virtual directories (optional).
   For more information about how to configure ISA Server, see ISA Server 2006.

If you've configured the ISA Server computer to authenticate users, it's recommended that you configure the Outlook Web App virtual directories to use either Integrated Windows authentication or Basic authentication, depending on which type of authentication is required by your organization. When you use Basic authentication or Integrated Windows authentication, users are prompted for their sign-in information only one time.

Note:
Integrated Windows authentication prohibits access to documents on Windows file shares or in Windows SharePoint Services document libraries from Outlook Web App. If you must access documents from Outlook Web App, you must use Basic authentication.

Other Tasks

After you configure a reverse proxy server for Outlook Web App, you may also want toConfigure Outlook Web App Virtual Directories to Use SSL.

Deploy ISA Server 2006 for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you deploy ISA Server 2006 for Outlook Web App, you use the New Exchange Publishing Rule wizard on the firewall policy tasks. This wizard shows you the specific settings that you must configure to enable access to Exchange.

Important:
If you have multiple versions of Exchange in your organization, you must create an Exchange publishing rule for each version that you support.

Steps

Here are the basic steps for deploying ISA Server 2006 for Outlook Web App:

Step 1: Create a new Exchange publishing rule

Step 2: Configure additional options

Step 3: Install a server certificate for ISA Server 2006

See the following sections for information about each step.

Step 1: Create a new Exchange publishing rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "ISA Server 2006" entry in the Client Access Permissions topic.

During this process, you must provide the following information:

- **Exchange publishing rule name** Provide a friendly name for your publishing rule, such as "Exchange E-mail Access".
- **Supported client access services** On the **Select Services** page, select the version of Exchange that you're deploying and the client access services that you want to support for your users. By default, when you select Exchange 2010, Outlook Web App is selected.
- **Publishing type** On the **Publishing Type** page, select an option to use

depending on whether you plan to publish a single site or an external load balancer, a Web server farm, or multiple Web sites.

- **Server connection security** This page lets you select whether to use SSL or non-secured connections from the ISA Server computer to Exchange.
- **Internal publishing details** On the **Internal Publishing Details** page, enter the internal site name of Outlook Web App or select the option to use a computer name or IP address to connect to Exchange.
- **Public name details** The **Public name details** page lets you select which domains you will accept requests from. You must also provide a public name, for example, www.contoso.com.
- **Select web listener** The **Select web listener** page lets you specify the listener for the Exchange server to which you're connecting. A listener is used to specify the authentication type that will be used when the client first contacts the ISA Server computer. The listener contains information about how the ISA Server computer accepts requests from clients, such as the encryption, compression, and authentication that's used on the external connection. You can use this page to create a new listener or edit existing listeners.
- **Authentication delegation** The **Authentication delegation** page lets you specify the type of authentication mechanism that the Client Access server should expect from ISA Server. Select from the following:
  - No delegation, but client may authenticate directly
  - Basic authentication
  - NTLM authentication
  - Negotiate (Kerberos/NTLM)
  - Kerberos constrained delegation
- **User sets** The **User sets** page lets you select which users can use this rule to connect to Exchange.

If you have configured the ISA Server computer to authenticate users, you should configure the Outlook Web App virtual directories to use either Integrated Windows authentication or Basic authentication, depending on which type of authentication is required by your organization. When you use Basic authentication or Integrated Windows authentication on the Outlook Web App virtual directories together with ISA Server 2006 authentication, users are prompted for their sign in information only one time.

Note:
If you select forms-based authentication for the ISA Server listener, the user will be prompted to reenter authentication credentials if the Outlook Web App session times out.

However, Integrated Windows authentication disallows access from Outlook Web App to documents on Windows file shares or in Windows SharePoint Services document libraries. If you must access documents from Outlook Web App, you must use Basic authentication on the Outlook Web App virtual directory.

After you complete the wizard, the wizard creates the Exchange publishing rule. The rule you create appears in the **Firewall Policy Rules** list on the **Firewall Policy** tab.

Note:
After you finish creating your publishing rule, you must wait for the settings to take effect. You can monitor ISA Server 2006 publishing rule progress by using the Monitoring node in the ISA Server 2006 Management console.

Step 2: Configure additional options (optional)

You can configure additional features, such as link translation and HTTP compression, for the new rule that you created in the ISA Server 2006 Management console. Additional settings for link translation and HTTP compression are managed under the General node

on the ISA Server 2006 Management console.

- **Configure Link Translation** To configure link translation, you must select the Exchange publishing rule that you created, and then click **Edit Selected Rule** under **Policy Editing Tasks**. On the **Link Translation** tab, you can configure link translation based on the needs of your users.
- **Configure HTTP Compression** The HTTP compression option can be configured in the General node under **Configuration** in the ISA Server 2006 Management console. Click **Define HTTP compression preferences**, and then select the options that you want to support for your users.

After you finish configuring these options, the ISA Server configuration for Exchange is complete.

Step 3: Install a server certificate for ISA Server 2006

To enable an encrypted channel by using SSL between the client computer and the ISA Server computer, you must install a server certificate on the ISA Server computer. This certificate should be issued by a public certification authority (CA) because it will be accessed by users on the Internet. If a private CA is used, the root CA certificate from the private CA must be installed on any computer that has to create an encrypted channel (HTTPS) to the ISA Server computer. Otherwise, users will receive a warning that the certificate isn't trusted.

For more information about how to install a server certificate on ISA Server 2006, see Publishing Exchange Server 2007 with ISA Server 2006.

Other Tasks

After you deploy ISA Server, you may also want to Configure Reverse Proxy Servers for Outlook Web App.

ISA Server 2006 Features at a Glance

1.6.2.8.1.2 Using ISA Server with Outlook Anywhere

Using ISA Server with Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-12*

This topic describes how you can use Microsoft Internet Security and Acceleration (ISA) Server 2006 with Outlook Anywhere. We recommend that you use ISA Server 2006 for all available client access methods in Microsoft Exchange Server 2010. When you publish Outlook Anywhere client access with ISA Server 2006, communications from the Outlook clients located on the Internet to the ISA Server computer and from the ISA Server

computer to the Client Access server are encrypted using Secure Sockets Layer (SSL).

In many organizations, users need to have access to their mailbox when they're away from the office. Outlook Anywhere ensures that users can interact with their Exchange information from any location. To support this client access method, specific paths must be published on the ISA Server computer.

Looking for management tasks related to Outlook Anywhere? See Managing Outlook Anywhere.

Contents

Exchange 2010 Services Used with ISA Server 2006

The following table lists the Exchange services that are supported by ISA Server 2006 for Exchange 2010 and used by Outlook Anywhere clients.

Exchange 2010 services used with ISA Server 2006

Feature	Path	Description
Outlook Anywhere	/rpc/*	Internet-based access to an Exchange deployment by using RPC over HTTP or RPC over HTTPS.
Unified Messaging	/unifiedmessaging/*	Exchange 2010 Unified Messaging puts all e-mail, voice mail, and fax messages into one Exchange 2010 mailbox that can be accessed from a variety of devices.
Offline Address Book	/OAB/*	An offline address book (OAB) is a copy of an address book that's been downloaded so that an Outlook user can access address book information while disconnected from the server.
Exchange Web Services	/ews/*	This virtual directory is used for the Autodiscover service and the Availability service to provide free/busy information.
Autodiscover	/Autodiscover/*	The Autodiscover service provides access to Exchange

		features for Microsoft Office Outlook 2007 clients that are connected to your Exchange messaging environment.

Return to top

ISA Server 2006 Features for Outlook Anywhere Client Access

The following table describes several of the benefits of using ISA Server 2006 to protect client access to your Exchange deployment using Outlook Anywhere.

ISA Server 2006 features for Outlook Anywhere

Feature	Description	More information
Exchange server locations are hidden	When you publish an application through ISA Server, you're protecting the server from direct external access because the name and IP address of the server can't be accessed by the user. The user accesses the ISA Server computer. This computer forwards the request to the server according to the conditions of the server publishing rule.	Publishing Exchange Server 2007 with ISA Server 2006
SSL Bridging and Inspection	SSL bridging protects against attacks that are hidden in SSL-encrypted connections. For SSL-enabled Web applications, after ISA Server receives the client's request, ISA Server decrypts it, inspects it, and ends the SSL connection with the client computer. The Web publishing rules determine how ISA Server communicates the request for the object to the published Web server. If the secure Web publishing rule is configured to forward the request by using secure HTTP (HTTPS), ISA Server initiates a new SSL connection with the published server. Because the ISA Server computer is now an SSL client, it requires the published Web server to respond with a server-side certificate.	Best Practices for Performance in ISA Server 2006

Return to top

ISA Server 2006 Deployment Options for Outlook Anywhere

Before you deploy ISA Server 2006 to help secure communication from Outlook Anywhere clients on the Internet to Exchange Client Access servers, you must verify that you've correctly configured your Exchange deployment to support Outlook Anywhere clients. You will then run the Exchange Publishing Rule wizard to provide Outlook Anywhere access to your Exchange deployment.

Install a Server Certificate for ISA Server 2006

To enable an encrypted channel by using SSL between the client computer and the ISA Server computer, you must install a server certificate on the ISA Server computer. This certificate should be issued by a public certification authority (CA) because it will be accessed by users on the Internet. If a private CA is used, the root CA certificate from the private CA must be installed on any computer that must create an encrypted channel (HTTPS) to the ISA Server computer.

For more information about how to install a server certificate on ISA Server 2006, see Publishing Exchange Server 2007 with ISA Server 2006.

Return to top

How to Deploy ISA Server 2006 for Outlook Anywhere

You can run the Exchange Publishing Rule wizard to provide Outlook Anywhere access to your Exchange deployment by following these steps:

1. **Create a server farm (optional)** When you have more than one Exchange Client Access server, you can use ISA Server to provide load balancing for these servers. The server farm properties determine the following:
   - Servers that are included in the farm
   - Connectivity verification method that ISA Server will use to verify that the servers are functioning
2. **Create a Web listener** When you create a Web publishing rule, you must specify a Web listener to use. The Web listener properties determine the following:
   - IP addresses and ports on the specified networks that the ISA Server computer uses to listen for Web requests (HTTP or HTTPS)
   - Server certificates to use with IP addresses
   - Authentication method to use
   - Number of concurrent connections that are allowed
   - Single sign-on (SSO) settings
3. **Create an Exchange Web client access publishing rule** When you publish an internal Exchange 2010 Client Access server through ISA Server 2006, you protect the Web server from direct external access because the name and IP address of the server can't be accessed by the user. The user accesses the ISA Server computer. The ISA Server computer forwards the request to the internal Web server according to the conditions of your Web server publishing rule. An Exchange Web client access publishing rule is a Web publishing rule that contains default settings appropriate to Exchange client access.

For more information about how to use the Exchange Publishing Rule wizard, see

Publishing Exchange Server 2007 with ISA Server 2006.

Return to top

1.6.2.8.1.3 Using ISA Server with Exchange ActiveSync

Using ISA Server with Exchange ActiveSync

Managing Client Access Servers > Managing External Client Access > Configuring External Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-12*

We recommend that you use Microsoft Internet Security and Acceleration (ISA) Server 2006 to enhance the security of all available client access methods in your Microsoft Exchange Server 2010 deployment. When you configure Microsoft Exchange ActiveSync client access with ISA Server 2006, communications between the Exchange ActiveSync clients and the Exchange server computer pass through an ISA Server computer to add an additional layer of Secure Sockets Layer (SSL) encryption.

Exchange ActiveSync enables information workers to access their Microsoft Exchange messaging data using a mobile device. For more information about Exchange ActiveSync, see the following topics:

- Understanding Exchange ActiveSync
- Managing Exchange ActiveSync

Benefits of Using ISA Server 2006 with Exchange ActiveSync

The following table describes several of the benefits of using ISA Server 2006 to protect client access through Outlook Anywhere to your Exchange deployment.

ISA Server 2006 features for Exchange ActiveSync

Feature	Description
Exchange server locations are hidden	When you publish an application through ISA Server, you are protecting the server from direct external access because the name and IP address of the server can't be viewed by the user. The user accesses the ISA Server computer. The ISA Server computer then forwards the request to the server according to the conditions of the server publishing rule.
SSL Bridging and Inspection	SSL bridging protects against attacks that are hidden in SSL-encrypted connections. For SSL-enabled Web applications, after ISA Server receives the client's request, ISA Server decrypts it, inspects it, and ends the SSL connection with the client computer. The Web publishing rules determine how ISA Server communicates the request for the

	object to the published Web server. If the secure Web publishing rule is configured to forward the request using Secure HTTP (HTTPS), ISA Server initiates a new SSL connection with the published server. Because the ISA Server computer is now an SSL client, it requires the published Web server to respond with a server-side certificate.

ISA Server 2006 Deployment Prerequisites for Exchange ActiveSync

When you deploy ISA Server 2006 to help secure communication from Exchange ActiveSync clients on the Internet to Exchange 2010 computers that have the Client Access server role installed, we recommend that you confirm the following:

- Forms based authentication isn't configured on the Exchange Client Access server. When ISA Server 2006 is being used to publish Exchange client access, we recommend forms-based authentication be configured only on the ISA Server computer.
- A server certificate is installed on the Exchange Client Access server. This certificate can be from an internal certification authority (CA) or a public CA.
- SSL is required on all Exchange Client Access virtual directories.

After you confirm these settings, you can configure ISA Server 2006 to provide Exchange ActiveSync access for your clients.

How to Deploy ISA Server 2006 for Exchange ActiveSync

To enable an encrypted channel between the client computer and the ISA Server computer, you first have to install a server certificate on the ISA Server computer. This certificate should be issued by a public CA because it will be accessed by users on the Internet. If a private CA is used, the root certificate from the private CA must be installed on any computer that requires a secure (HTTPS) connection to the ISA Server computer.

For more information about how to install a server certificate on ISA Server 2006, see Publishing Exchange Server 2007 with ISA Server 2006.

After a server certificate is installed on the ISA Server computer, you can run the New Exchange Publishing Rule Wizard. Running the New Exchange Publishing Rule Wizard to provide Exchange ActiveSync access involves the following steps:

1. **Create a server farm (optional)** When you have more than one Client Access server within your organization, you can use ISA Server to provide load balancing for these servers. The server farm properties determine the following:
   - The specific servers included in the farm.
   - The connectivity verification method that ISA Server will use to verify that the servers are functioning correctly.
2. **Create a Web listener** When you create a Web publishing rule, you must specify a Web listener. The Web listener properties determine the following:
   - The IP addresses and ports on the specified networks the ISA Server computer uses to listen for Web requests (HTTP or HTTPS).
   - Which server certificates to use with IP addresses.
   - The authentication method to use.

- The number of concurrent connections allowed.
- Single sign-on (SSO) settings.

3. **Create an Exchange Web client access publishing rule** When you publish an internal Exchange 2010 Client Access server through ISA Server 2006, you are protecting the Web server from direct external access because the name and IP address of the server can't be viewed by the user. The user accesses the ISA Server computer. The ISA Server computer then forwards the request to the internal Web server according to the conditions of your Web server publishing rule. An Exchange Web client access publishing rule is a Web publishing rule that contains default settings appropriate to Exchange client access.

For more information about how to use the New Exchange Publishing Rule Wizard, see Microsoft ISA Server 2006.

1.6.2.8.1.4 Using ISA Server with POP3 and IMAP4

Using ISA Server with POP3 and IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

You can use Microsoft Internet Security and Acceleration (ISA) Server 2006 with POP3 and IMAP4. We recommend that you use ISA Server 2006 for all your client-to-server connections in Microsoft Exchange Server 2010. When you publish POP3 and IMAP4 client access with ISA Server 2006, communications from the POP3 or IMAP4 clients that are located on the Internet to the ISA Server computer and from the ISA Server computer to the Client Access server are encrypted by using Secure Sockets Layer (SSL).

ISA Server 2006 Features for POP3 and IMAP4 Access

The following table describes several benefits of using ISA Server 2006 to protect POP3 and IMAP4 client access to your Exchange deployment. The links in the "More information" column of the table also apply when you're using ISA Server 2006 with Exchange 2010.

ISA Server 2006 benefits for POP3 and IMAP4

Feature	Description	More information
Exchange server locations are hidden	When you publish an application through ISA Server, you're protecting the server from direct external access, because the name and IP address of the server can't be accessed by the user. The user accesses the ISA Server computer. This computer forwards the request to the Exchange server according to the conditions of the server	Publishing Exchange Server 2007 with ISA Server 2006

	publishing rule.	
SSL bridging and inspection	SSL bridging protects against attacks that are hidden in SSL-encrypted connections. For SSL-enabled Web applications, after ISA Server receives the client's request, ISA Server decrypts it, inspects it, and then ends the SSL connection with the client computer. The Web publishing rules determine how ISA Server communicates the request for the object to the published Web server. If the secure Web publishing rule is configured to forward the request by using secure HTTP (HTTPS), ISA Server initiates a new SSL connection with the published server. Because the ISA Server computer is now an SSL client, it requires the published Web server to respond with a server-side certificate.	Best Practices for Performance in ISA Server 2006

Install a Server Certificate for ISA Server 2006

To enable an encrypted channel using SSL between the client computer and the ISA Server computer, you must install a server certificate on the ISA Server computer. This certificate should be issued by a public certification authority (CA) because it will be accessed by users on the Internet. If a private CA is used, the root certificate from the private CA must be installed on any computer that has to create an encrypted channel (HTTPS) to the ISA Server computer.

For more information about how to install a server certificate on ISA Server 2006, see Publishing Exchange Server 2007 with ISA Server 2006. This information also applies to installing a server certificate on ISA Server 2006 when you're using Exchange 2010.

How to Deploy ISA Server 2006 for POP3 and IMAP4

You can run the Exchange Publishing Rule Wizard to provide POP3 and IMAP4 access to your Exchange deployment by following these steps:

1. **Create a server farm (optional)** When you have more than one Exchange Client Access server, you can use ISA Server to provide load balancing for these servers. The settings you configure allow you to specify the following:
   - The servers that are included in the server farm.
   - The connectivity verification method that ISA Server will use to confirm that the servers are functioning.

2. **Create a Web listener** When you create a Web publishing rule, you must specify a Web listener to use. The settings you configure allow you to specify the following:
   - IP addresses and ports on the specified networks that the ISA Server computer uses to listen for Web requests (HTTP or HTTPS).
   - Server certificates to use with IP addresses.
   - The authentication method to use.
   - The number of concurrent connections that are allowed.
   - Single sign-on settings.
3. **Create an Exchange Web client access publishing rule** When you create an Exchange Web client access publishing rule, you protect the Web server from direct external access because the Web server name and IP address are hidden from the user. The user accesses Exchange through the ISA Server computer. The ISA Server computer forwards the request to the internal Web server according to the conditions of your Web server publishing rule. An Exchange Web client access publishing rule is a Web publishing rule that contains default settings appropriate to Exchange Client Access.

For more information about how to use the New Exchange Publishing Rule Wizard, see Publishing Exchange Server 2007 with ISA Server 2006. This information also applies to publishing Exchange 2010 with ISA Server 2006.

1.6.2.8.1.5 Configure External Client Access Namespaces

Configure External Client Access Namespaces

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-05-19*

When a user has synchronized a mobile phone with their mailbox, the Manage Mobile Device wizard lets you view and manage the mobile phones for that user.

Looking for other management tasks related to Client Access namespaces? Check out Managing External Client Access.

Prerequisites

The Client Access server role has been installed.

What Do You Want to Do?

- Use the EMC to configure external Client Access namespaces
- Use the Shell to configure external Client Access namespaces

Use the EMC to configure external Client Access namespaces

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.

2. In the action pane, click **Configure External Client Access Domain** to open the **Configure External Client Access Domain** wizard.
   - This wizard helps you associate an external DNS address with one or more Client Access servers. The `ExternalURL` property for all services is configured when an external Client Access domain is specified.
3. On the **Configure External Client Access Domain** page, enter the domain name you'll use with your external Client Access servers.
4. Click **Add** to select the Client Access servers that will be associated with this *ExternalURL*.

5. Click **Configure** to complete the **Configure External Client Access Domain** wizard.

Use the Shell to configure external Client Access namespaces

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server settings" entry in the Client Access Permissions topic.

These examples configure the `ExternalURL` property for each Client Access method. Each of these configuration changes is necessary to duplicate the functionality of the **Configure External Client Access Namespace** wizard.

The following example configures the `ExternalURL` property for Exchange ActiveSync virtual directory.

```
Set-ActivesyncVirtualDirectory -Identity "CAS_Server_Name\Microsoft-Server-Active
```

The following example configures the `ExternalURL` property for the Outlook Web App virtual directory.

```
Set-OwaVirtualDirectory -Identity "CAS_Server_Name\OWA (Default Web Site)" -Exter
```

The following example configures the `ExternalURL` property for the Outlook Address Book virtual directory.

```
Set-OABVirtualDirectory -Identity "CAS_Server_name\oab (Default Web Site)" -Exter
```

The following example configures the `ExternalURL` property for the Exchange Web Services virtual directory.

```
Set-WebServicesVirtualDirectory -Identity "CAS_Server_Name\EWS (Default Web Site)
```

The following example configures the `ExternalURL` property for the Outlook Anywhere virtual directory.

```
Enable-OutlookAnywhere -Server CAS01 -ExternalHostname "mail.contoso.com" -Extern
```

For More Information

View or Configure Exchange ActiveSync Virtual Directory Properties

View or Configure Outlook Web App Virtual Directories

Understanding Client Access Server Namespaces

Understanding Client Access Server Publishing

1.6.2.9 Maximum Client Access Service Sessions Per User

Maximum Client Access Service Sessions Per User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-22*

For optimal performance, there is a maximum number of concurrent sessions that a Client Access server can support. Microsoft Exchange Server 2010 imposes limits on the number of concurrent service sessions per user. The limits are set in several different ways. For some client interactions, limits are set for the maximum number of concurrent threads per server or the maximum number of sessions per server. For other client interactions, the limits are set for the maximum number of user sessions per server. Limits are set to improve performance, to prevent users from being locked out of e-mail access, and to prevent service disruption.

Session Limits by Client Type

The following table lists the maximum number of service sessions that are allowed per user for the different client types and services in Exchange 2010.

Client type	Maximum user sessions per server
Exchange ActiveSync	16
Availability Service	16
Exchange Web Services	16
Exchange Management Console	16
RPC Client Access	32
Outlook Web App	16
POP3/IMAP4	16
Unified Messaging	16

1.6.2.10 Using Kerberos with a Client Access Server Array or a Load-Balancing Solution

Using Kerberos with a Client Access Server Array or a Load-Balancing Solution

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-07*

For Microsoft Exchange Server 2010 deployments that have more than one Client Access

server in an Active Directory site, the topology will often require a Client Access server array and a load-balancing solution to distribute traffic among all Client Access servers in the site. For more information about Client Access server arrays, see Understanding RPC Client Access. For more information about load balancing, see Understanding Load Balancing in Exchange 2010.

Using Kerberos Authentication

Typically, mail clients on domain-joined computers inside your network use NTLM authentication. In some circumstances, you might have to use Kerberos authentication. This should only be done if it's required, because Kerberos presents additional challenges in setup and implementation. For more information about Kerberos, see Kerberos Enhancements and Microsoft Kerberos.

Note:

Kerberos can only be used for domain-joined computers inside your network. This includes clients connected by a VPN. For connections outside the network, such as Outlook Anywhere, Kerberos isn't supported.

You may be required to use Kerberos authentication for your Exchange 2010 organization for the following reasons:

- Kerberos authentication is necessary for your local security policy.
- You're encountering or anticipating NTLM scalability issues, for example, when direct MAPI connectivity to the RPC Client Access service causes intermittent NTLM failures.
  In large-scale customer deployments, NTLM can cause bottlenecks on Client Access servers that can result in sporadic authentication failures. Services that use NTLM authentication are more sensitive to Active Directory latency issues. These lead to authentication failures when increases in the rate of Client Access server requests are encountered.

To configure Kerberos authentication, you must be familiar with Active Directory and the setup of Client Access server arrays. And you must have a working knowledge of Kerberos.

Problems with Kerberos and Load-Balanced Client Access Servers

When Client Access servers are load-balanced or are part of a Client Access server array, clients configured with NTLM authentication will connect without a problem. However, using Kerberos requires additional setup and was problematic prior to Exchange 2010 Service Pack 1 (SP1).

In a topology with a load balancer or a Client Access array, a client doesn't connect to an individual server by name, but rather by the array or load balancer name. This impedes Kerberos authentication unless you perform additional configuration steps.

When you use Kerberos, the first configuration step is to set up an array of specific Service Principal Names (SPNs) for the client access services. As soon as the array is set up, e-mail clients that are configured to use Negotiate authentication will try to perform Kerberos authentication. They'll obtain Kerberos service tickets in the context of the array and present those tickets to the Client Access server. However, on any particular Client Access server, Exchange services run in the context of either the local system or network service account and will try to authenticate the Kerberos service tickets in those contexts, rather than in the context of the array. This causes a context mismatch and results in a Kerberos authentication failure. Because of the enhanced security of Kerberos, clients configured to perform Negotiate authentication won't just fall back to NTLM

authentication, but will either default to using Outlook Anywhere, if available, or fail to authenticate and connect.

For Kerberos authentication to succeed, the Client Access server array member must use an alternate credential that's shared by all members of the array. The credential must also be associated with the array-specific SPNs. This shared credential may be either a computer account or a service account and must be known by every Client Access server within the array. Typically, organizations require that account passwords change periodically. This mandates an ongoing task of distributing and updating this shared credential to all Client Access servers. Before Exchange 2010 SP1, neither Windows Server 2008 nor Microsoft Exchange had a solution for this issue.

Note:

Although this discussion refers to a network load balancer and a Client Access server array, any network infrastructure or configuration that doesn't result in the client connecting directly to a specific Client Access server will have these same authentication issues. Other examples of this configuration include Client Access servers with DNS round-robin load balancing and Client Access servers with custom DNS records. The following solution is designed to simplify distribution of the alternate service account credential to members of a Client Access server array or Client Access servers behind a network load balancer. It's not designed to work with configurations where the Client Access servers aren't configured in a Client Access array.

The Solution

To resolve this problem, there must be a shared credential that can be used by all Client Access servers in the array or behind the load balancer. This credential is known as an *alternate service account credential* (ASA credential) and can be either a computer or a user service account. To distribute this alternate service account credential to all Client Access servers, a three-fold solution has been implemented in Exchange 2010 SP1.

The Client Access server service host has been extended to use a shared credential for Kerberos authentication. This service host extension monitors the local machine. When credentials are added or removed, the Kerberos authentication package on the local system and the network service context is updated. As soon as a credential is added to the authentication package, all client access services can use it for Kerberos authentication. The Client Access server will also be able to authenticate service requests addressed directly in addition to being able to use the shared credential. This extension, known as a *servicelet*, runs by default and requires no configuration or action to run.

The shared credential and password can be obtained and set using the Exchange Management Shell. This enables the credential to be set from a remote computer. The credential is set by storing the credential in the target computer's registry for consumption by the service host. You set the credential using the **Set-ClientAccessServer** cmdlet with the new *AlternateServiceAccountCredential* parameter. After the shared credential password has been set, the shared credential allows Client Access services to perform Kerberos authentication for Intranet connected clients. For more information about the **Set-ClientAccessServer** cmdlet, see Set-ClientAccessServer.

A management script has been created to help automate the distribution of the shared credential to all Client Access servers specified within the scope of the script. This script is the recommended way to use and maintain a shared credential for client Access server array Kerberos authentication. The script provides an automated way to use the **Set-ClientAccessServer** cmdlet to facilitate the following tasks:

- **Initial Setup** The ASA credential is set on all Client Access servers within an array or forest.
- **Password Rollover** A new password for the ASA credential is generated and rolled out to all Client Access servers in addition to updating Active Directory.
- **Adding one or more computers to a Client Access server array** The ASA

credential is copied from an existing server and distributed to other servers so they can perform Kerberos authentication with the current credential and password.

- **Ongoing maintenance** A scheduled task is created to regularly roll the password by using an unattended method.

For More Information

For more information about how to configure Kerberos authentication for load-balanced Client Access servers, see Configuring Kerberos Authentication for Load-Balanced Client Access Servers.

For more information about the RollAlternateServiceAccountCredential.ps1 script, see Using the RollAlternateserviceAccountPassword.ps1 Script in the Shell.

1.6.2.10.1 Configuring Kerberos Authentication for Load-Balanced Client Access Servers

Configuring Kerberos Authentication for Load-Balanced Client Access Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-07*

To use Kerberos authentication with a load-balanced array of Client Access servers, several configuration steps must be completed. For more information about how to use Kerberos with a Client Access server array or a load-balancing solution, see Using Kerberos with a Client Access Server Array or a Load-Balancing Solution.

Create the Alternate Service Account Credential in Active Directory

All computers within the Client Access server array must share the same service account. In addition, any Client Access servers that may be called on in a datacenter activation scenario must also share the same service account. In general, it's sufficient to have a single service account per forest. This account is referred to as the alternate service account credential (ASA credential).

Note:

If your deployment is complex and extends beyond the scenarios outlined below, has administrator delegation issues, or has multiple forest segments on different Exchange deployment schedules, you may have to create additional accounts. The **RollAlternateServiceAccountPasswordl**.ps1 script must be run separately for every account created.

Credential Type

You can create a computer account or a user account for the alternate service account. Because a computer account doesn’t allow interactive logon, it may have simpler security policies than a user account and therefore is the preferred solution for the ASA credential. If you create a computer account, the password doesn't actually expire, but we still recommend updating the password periodically. Local group policy can specify a maximum account age for computer accounts and there might be scripts scheduled to periodically delete computer accounts that do not meet current policies. Periodically updating the

password for computer accounts will ensure that your computer accounts aren't deleted for not meeting local policy. Your local security policy will determine when the password needs to be changed.

Credential Name

There are no particular requirements for the name of the ASA credential. You can use any name that conforms to your naming scheme.

Groups and Roles

The ASA credential doesn't need special security privileges. If you are deploying a computer account for the ASA credential this means that the account only needs to be a member of the Domain Computers security group. If you are deploying a user account for the ASA credential, this means that the account only needs to be a member of the Domain Users security group.

Password

The password you provide when you create the account will never actually be used. Instead, the script will reset the password. So when you create the account, you can use any password that conforms to your organization's password requirements.

Cross-Forest Scenarios

If you have a cross-forest or resource-forest deployment, and users are outside the Active Directory forest that contains Exchange, you must configure cross-forest trusts and routing name suffixes across forests. For more information, see Accessing Resources Across Forests and Routing Name Suffixes Across Forests.

Identifying the Service Principal Names That Should Be Associated with the Alternate Service Account Credential

After you create the alternate service account, you must determine the Exchange service principal names (SPNs) that will be associated with the ASA credentials. The list of Exchange SPNs may vary with your configuration, but should include at least the following.

- **http** Use this SPN for Exchange Web Services, Offline Address Book downloads, and the Autodiscover service.
- **exchangeMDB** Use this SPN for RPC Client Access.
- **exchangeRFR** Use this SPN for the Address Book service.
- **exchangeAB** Use this SPN for the Address Book service.

The SPN values must be configured to match the service name being used on the network load balancer, rather than on individual servers.

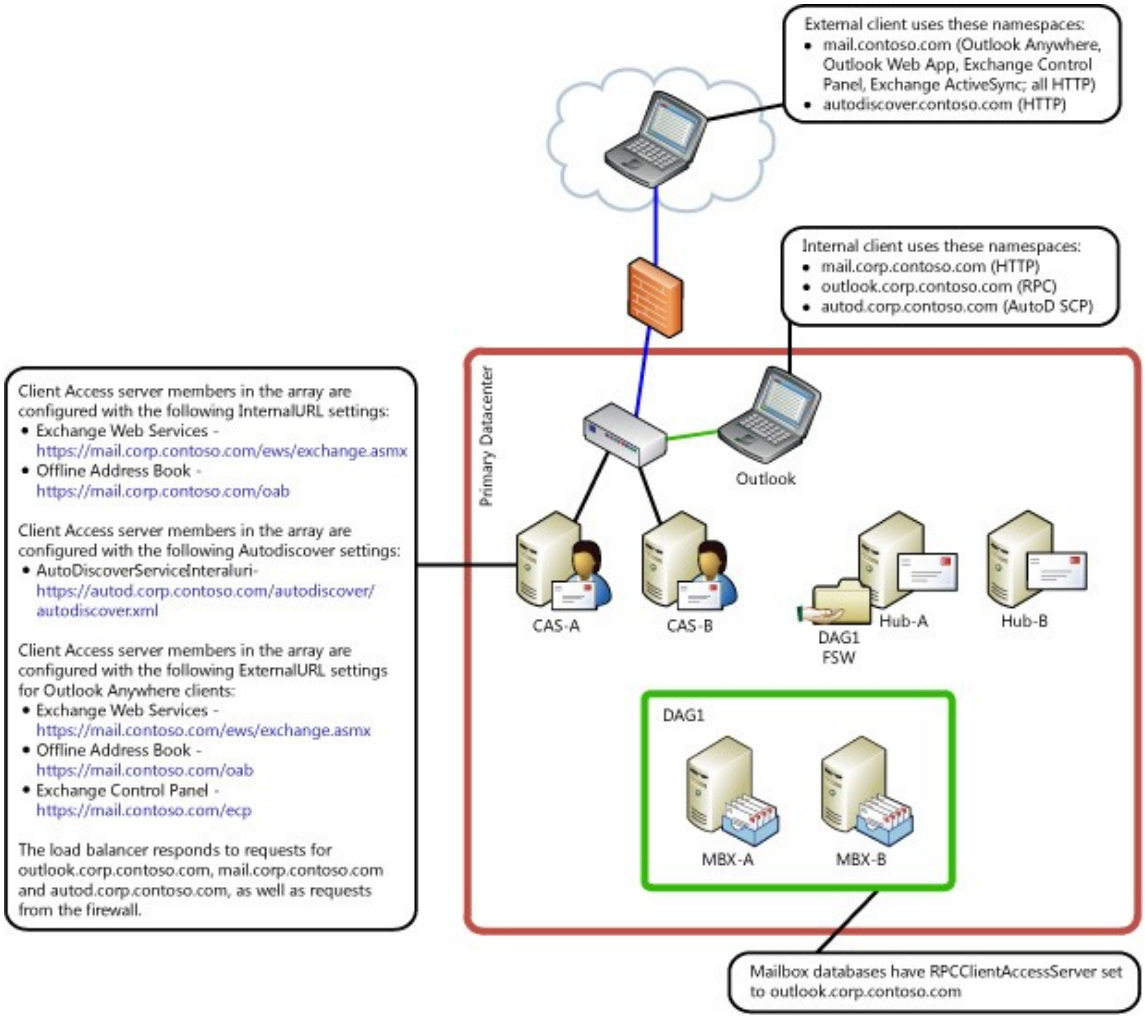
To help plan which SPN values you should deploy, consider the following conceptual scenarios:

1. Single Active Directory Site
2. Multiple Active Directory Sites
3. Multiple Active Directory Sites with DAG Site Resiliency

In each of these scenarios, it's assumed that load-balanced fully qualified domain names have been deployed for the Internal URLs, External URLs, and Autodiscover Internal URI used by the Client Access server members. For more information see Understanding Proxying and Redirection.

Single Active Directory Site

If you have a single Active Directory site, your environment may resemble the one in the following illustration.



Based on the fully qualified domain names that are used by the internal Outlook clients in the previous illustration, the following SPNs would need to be deployed on the ASA credential:

- http/mail.corp.contoso.com
- http/autod.corp.contoso.com
- exchangeMDB/outlook.corp.contoso.com
- exchangeRFR/outlook.corp.contoso.com
- exchangeAB/outlook.corp.contoso.com

External or Internet-based clients that use Outlook Anywhere won't use Kerberos authentication. Therefore, the fully qualified domain names that are used by these clients don't have to be added as SPNs to the ASA credential.

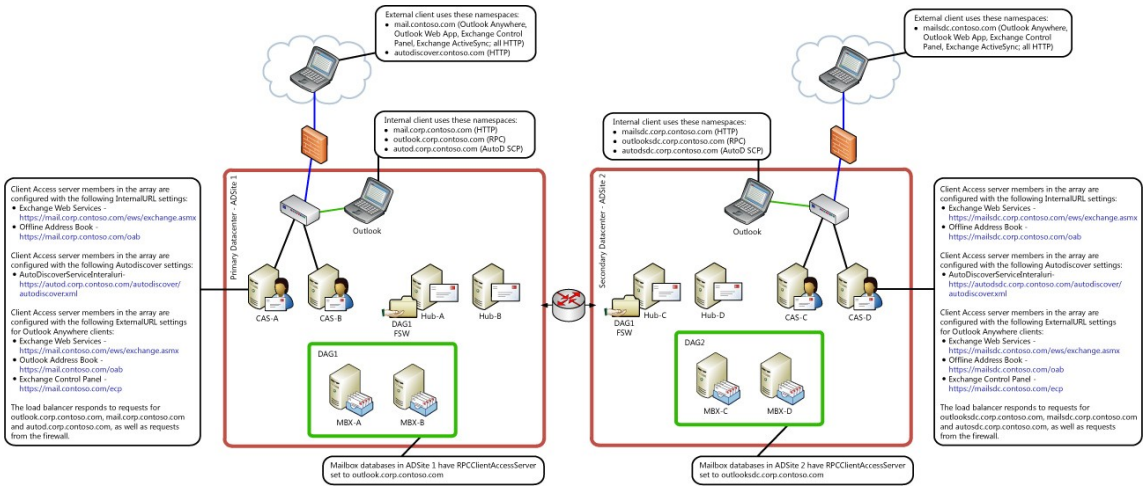
Important:

If you deploy a split DNS infrastructure, external and internal clients use the same fully qualified domain names and those names must be represented as SPNs on the ASA credential.

Multiple Active Directory Sites

If you have multiple Active Directory sites, your environment may resemble the one in the

following illustration.



Based on the fully qualified domain names that are used by the internal Outlook clients in the previous illustration, the following SPNs would have to be deployed on the ASA credential that's used for the Client Access server array with the Active Directory site ADSite1:

- http/mail.corp.contoso.com
- http/autod.corp.contoso.com
- exchangeMDB/outlook.corp.contoso.com
- exchangeRFR/outlook.corp.contoso.com
- exchangeAB/outlook.corp.contoso.com

Based on the fully qualified domain names that are used by the internal Outlook clients in the previous illustration, the following SPNs would need to be deployed on the ASA credential that's used for the Client Access server array within the Active Directory site ADSite2:

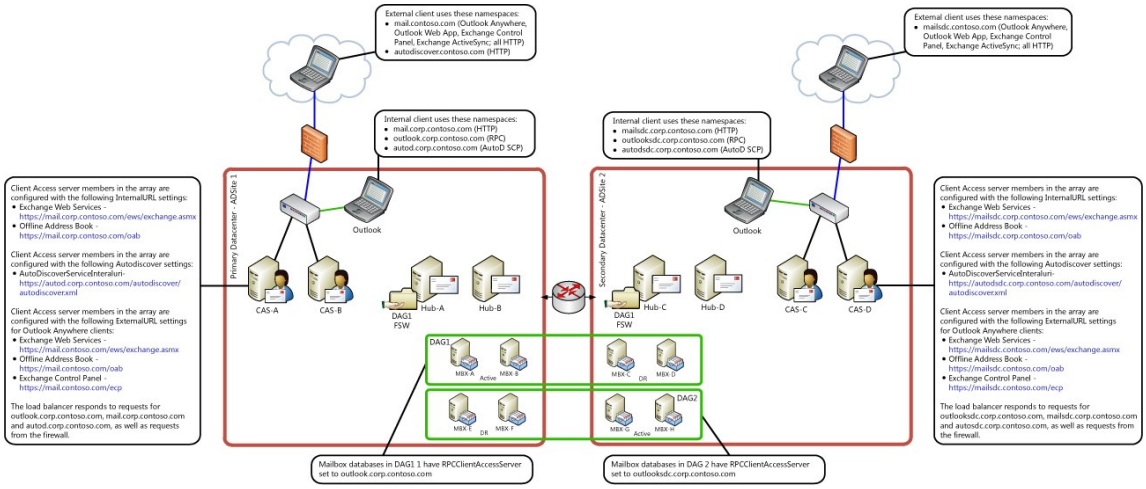
- http/mailsdc.corp.contoso.com
- http/autodsdc.corp.contoso.com
- exchangeMDB/outlooksdc.corp.contoso.com
- exchangeRFR/outlooksdc.corp.contoso.com
- exchangeAB/outlooksdc.corp.contoso.com

Note:

This example shows that you can use multiple ASA credentials for this particular scenario. However, you can use a single ASA credential for all Active Directory sites that host Client Access server arrays where you want to deploy Kerberos authentication.

Multiple Active Directory Sites with DAG Site Resiliency

If you have multiple Active Directory sites with DAG site resiliency, your environment may resemble the one in the following illustration.



Because this architecture includes a Database Availability Group (DAG) that's stretched across both Active Directory sites, you must deploy a single ASA credential for use by members of the Client Access server arrays in ADSite1 and ADSite2. If you don't use a single ASA credential, clients will have Kerberos authentication issues when you perform a datacenter switchover because the secondary datacenter Client Access server array members won't be able to decrypt the Kerberos session ticket. For more information about activating the secondary datacenter, see Datacenter Switchovers.

Based on the fully qualified domain names that are used by the internal Outlook clients in the previous illustration, the following SPNs would need to be deployed on the ASA credential that's in use for the Client Access server arrays in ADSite1 and ADSite2:

- http/mail.corp.contoso.com
- http/autod.corp.contoso.com
- exchangeMDB/outlook.corp.contoso.com
- exchangeRFR/outlook.corp.contoso.com
- exchangeAB/outlook.corp.contoso.com
- http/mailsdc.corp.contoso.com
- http/autodsdc.corp.contoso.com
- exchangeMDB/outlooksdc.corp.contoso.com
- exchangeRFR/outlooksdc.corp.contoso.com
- exchangeAB/outlooksdc.corp.contoso.com

Convert the Offline Address Book Virtual Directory to an Application

Out of the box, the Offline Address Book virtual directory isn't a Web application, so it isn't controlled by the Microsoft Exchange Service Host service. Therefore, Kerberos authentication requests to the Offline Address Book virtual directory can't be decrypted by the ASA credential.

To convert the Offline Address Book virtual directory to a Web application, run the **ConvertOABDir.ps1** script on each Client Access server member. The script will also create a new application pool for the Offline Address Book virtual directory. The script is located in the Exchange 2010 SP2 Scripts directory, or you can download the script here.

Deploying the Alternate Service Account Credential

After you've created the ASA credential, verify the account has replicated to all domain controllers within all Active Directory sites that contain the client Access servers that will use the ASA credential.

You can then run the AlternateServiceAccount credential script in the Exchange Management Shell. For more information, see Using the RollAlternateserviceAccountPassword.ps1 Script in the Shell. After the script has run, we recommend that you verify that all the targeted servers have been updated correctly.

Note:
The script is provided in English only.

For help troubleshooting script errors, see Troubleshooting the RollAlternateServiceAccountCredential.ps1 Script.

The following example output of the RollAlternateServiceAccountPassword.ps1 script uses a computer account that's created as the ASA credential. The account is named contoso/newSharedServiceAccountName. In the following example, the script applies the credential settings to each member of a Client Access server array called outlook.corp.contoso.com.

To run the script, use the following command.

```
RollAlternateServiceAccountPassword.ps1 -ToArrayMembers outlook.corp.contoso.com
```

You should receive the following output after you run the script. There's one prompt that asks you for approval to change the password.

```
========== Started at 08/02/2010 15:48:09 ==========Destination servers that will
```

You'll also see two Event IDs in your event logs. One event is for the start of the script and one is for successful completion. The following is an excerpt from the successful completion event.

```
Log Name:      ApplicationSource:        MSExchange Management ApplicationEvent I
```

Verifying the Deployment of the ASA Credential

In the Exchange Management Shell, run the following command to check the settings on the Client Access servers.

```
Get-ClientAccessServer -IncludeAlternateServiceAccountCredentialStatus | fl name,
```

The result of this command should look like the following.

```
Name                                  : CASAAlternateServiceAccountConfiguration :
```

If you've run the script several times and made changes, the Previous entry will show you when the last change was made.

```
Name                                  : NAE14CASAlternateServiceAccountConfigurati
```

Associating Service Principal Names with the Alternate Service Account Credential

Before you configure the SPNs, verify that the target SPNs aren't already configured on a different account in the forest. The ASA credential must be the only account in the forest with which these SPNs are associated. You can verify that no other account in the forest

has the SPNs associated with it by running the **setspn** command with the *–q* and *–f* parameters from the command line. The following example shows how to run this command. The command should return nothing. If it returns a value, another account is already associated with the SPN you're thinking of using.

Note:

Only Windows Server 2008 supports the duplicate-checking forest wide parameter *(-f)* in the **setspn** command.

```
Setspn -q -f exchangeMDB/outlook.corp.contoso.com
```

The following command provides an example of how to set the SPNs on the shared ASA credential. The setspn command with this syntax must be run once for every target SPN that you identify.

```
Setspn -S exchangeMDB/outlook.corp.contoso.com contoso\newSharedServiceAccountNam
```

When you've set the SPNs, verify that they've been added by using the following command.

```
Setspn -L contoso\newSharedServiceAccountName$
```

Validating Exchange Client Kerberos Authentication

After you've successfully configured Kerberos and deployed the RollAlternateServiceAccountPasswordI.ps1 script, verify that clients can authenticate successfully.

Verifying that the Microsoft Exchange Service Host Service is Running

The Microsoft Exchange Service Host service on the Client Access servers is responsible for managing the ASA credential. If this service isn't running, Kerberos authentication won't be possible. By default, the service is configured to automatically start when the computer is started. Ensure that you've installed Exchange Server 2010 SP1 Rollup 3 or a later version on all Client Access servers in your environment.

Validating Authentication from Outlook

To ensure that Outlook is able to connect to the Client Access servers with Kerberos authentication, follow these steps:

1. Confirm that Outlook is configured to point to the correct load-balanced Client Access server array.
2. Configure the e-mail account server security settings to use logon network security **Negotiate Authentication**. Or, you could configure the client to use **Kerberos Password Authentication**. However, if the SPNs are ever removed, the clients won't be able to authenticate until you change the authentication mechanism back to **Negotiate Authentication**.
3. Confirm that Outlook Anywhere isn't enabled for the client. If Outlook fails to authenticate by using Kerberos, it will try to fall back to Outlook Anywhere, so Outlook Anywhere should be disabled for this test.
4. Restart Outlook.
5. If your desktop computer is running Windows 7, you can run **klist.exe** to see which Kerberos tickets have been granted and are in use. If you're not running Windows 7, you can obtain klist.exe from the Windows Server 2003 Resource Kit.

Validating Using the Test-OutlookConnectivity Cmdlet

To test whether Kerberos is working, use the **Test-OutlookConnectivity** cmdlet. This is the best way to see if TCP connectivity can be established. By default, the cmdlet will use

Negotiate authentication for a TCP connection. So if Kerberos is configured, it will be used. The file klist.exe can be used to view the Kerberos tickets on the computer. This can be run from the Client Access server itself, as well as from an automated monitoring tool such as SCOM. When using the **Test-OutlookConnectivity** cmdlet, ensure that the Mailbox database has the **RPCClientAccessServer** property set to the Client Access server array name. Otherwise the cmdlet won't test the shared ASA credential functionality.

```
Test-OutlookConnectivity -Identity administrator -MailboxCredential $c -Protocol
```

To make sure that the connection is made using Kerberos, view klist.exe to see if there are Kerberos tickets associated with the new SPNs that were added.

Validating Kerberos from the Client Access Server

To confirm that Kerberos is working correctly from the Client Access server, you can examine the protocol logs to verify successful Kerberos connections. You can use these logs in addition to the other validations to confirm that Kerberos is being used.

- On the Client Access server, examine the Address Book protocol logs. These logs are typically located at the following path: C:\Program Files\Microsoft \Exchange server\v14\Logging\AddressBook Service.
- Examine the latest log file and look for the word Kerberos after the script has been run. If you see Kerberos traffic, a connection has been made successfully. The line in the log file should look something like the following.

```
2010-06-11T22:58:49.799Z,9,0,/o=First Organization/ou=Exchange Administ
```

If you see the word Kerberos, then the server is successfully creating Kerberos authenticated connections. For more information about the Address Book service log, see Understanding the Address Book Service.

Troubleshooting Authentication Failures

There are several common problems that may occur when you're configuring Kerberos authentication.

Outlook Clients Configured to use Kerberos Authentication Only Can't Connect

If your Outlook client that's configured to use only Kerberos authentication can't connect, follow these troubleshooting steps:

1. Configure Outlook to use NTLM authentication only, and then verify connectivity. If a connection can't be made, verify that the Client Access server array is available or that network connectivity is stable.
   If NTLM connectivity is successful, but Kerberos is not, verify that the SPNs aren't registered on any other account besides the alternate service account. Make sure that the Exchange SPNs are registered on the account used by the shared alternate service account by using the setSPN query command as described earlier in this topic.
2. Make sure that the password is coordinated between all Client Access servers and Active Directory. To do this, run the script in attended mode and have it generate a new password.
3. Make sure that the Microsoft Exchange Address Book service is running on your Client Access servers.
4. If authentication still isn't successful, make sure that the virtual directories for the services you want to access with Kerberos have Integrated Windows authentication enabled. You can use the Get-VirtualDirectory cmdlets to verify the authentication methods. For more information on virtual directories, see Understanding Outlook Web App Virtual Directories and Understanding Exchange Web Services Virtual Directories.

Autodiscover Service Failures

If you notice the following Autodiscover service failure, it's probably because the Autodiscover service request header contains a large Kerberos authentication ticket that caused the header size to exceed the limit configured by the Internet Information Services (IIS) server. The error will be similar to the following.

```
HTTP/1.1 400 Bad Request
Content-Type: text/html; charset=us-ascii
Server: Microsoft-HTTPAPI/2.0
Date: Tue, 09 Mar 2010 18:06:18 GMT
Connection: close
Content-Length: 346
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN""http://www.w3.org/TR/html4/stri
<HTML><HEAD><TITLE>Bad Request</TITLE>
<META HTTP-EQUIV="Content-Type" Content="text/html; charset=us-ascii"></HEAD>
<BODY><h2>Bad Request - Request Too Long</h2>
<hr><p>HTTP Error 400. The size of the request headers is too long.</p>
</BODY></HTML>
```

To fix this error, increase the IIS header size limit. For more information, see IIS documentation.

Ongoing Maintenance of the ASA Credential

If your local password on the shared ASA credential must be refreshed periodically, see Using the RollAlternateserviceAccountPassword.ps1 Script in the Shell for instructions for setting up a scheduled task to perform regular password maintenance. Be sure to monitor the scheduled task to ensure timely password rollovers and prevent possible authentication outages.

Turning Kerberos Authentication Off

To revert your Client Access server array so that it doesn't use Kerberos, remove the SPNs from the shared service account. If the SPNs are removed, Kerberos authentication won't be attempted by your clients, and clients configured to use Negotiate authentication will use NTLM. Clients configured to use only Kerberos will be unable to connect. Once the SPNs are removed you should also delete the shared service account. You can use the maintenance script to clean out credentials from all Client Access server array members by using the *toEntireForest* parameter and using the -copy from server parameter to specify a server that does not have any Kerberos credentials. In addition, you should eventually restart all client computers to clear the Kerberos ticket cache.

1.6.2.10.2 Troubleshooting the RollAlternateServiceAccountCredential.ps1 Script

Troubleshooting the RollAlternateServiceAccountCredential.ps1 Script

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic provides solutions and information about common errors that may occur when you use the RollAlternateServiceAccountPassword.ps1 script.

One or more of the Client Access servers can't be updated with the password

Problem

When you use the parameters *ToEntireForest* or *ToArrayMembers* with the script, in some instances, one or more of the Client Access servers may not be updated.

Resolution

Verify the servers the script will target all required servers by using the **Get-ClientAccessArray** cmdlet, as shown in the following example.

```
Get-ClientAccessArray | fl members
```

If the server that's failing to update is a member of the Client Access array and is still not updating correctly, rerun Exchange Setup and add the Client Access server role to the server again. You can also specify individual servers to target using the parameter *ToSpecificServers*.

Some servers aren't responding to the script

Problem

In some circumstances, servers might fail to update because of transient errors such as a bad network connection.

Resolution

Verify that the servers in question have network and Active Directory connectivity, and then try the script again.

Some array members are out of service for an extended period of time

Problem

If a server is out of rotation for a longer period of time but is still a member of the array, as determined by the **Get-ClientAccessArray cmdlet**, the script functionality may be impaired when using the parameters *ToArrayMembers* and *ToEntireForest*. The same problem will occur if a server has had a permanent failure but hasn't been cleanly removed from your deployment.

Resolution

To resolve this issue, remove the server from your deployment using Exchange Setup or run the script in attended mode until the server can be removed.

If the server will only be down for a short time, and you don't want to permanently remove Exchange, you can adjust the script to run against specific servers using the

parameter *ToSpecificServers* so that only active servers are targeted. Or, you can remove the RPC Client Access service from the non-responsive server's Active Directory object by using the **Remove-ClientAccessArray** cmdlet, as shown in the following example.

```
Remove-RPCClientAccess -Server Server.Contoso.com
```

After the RPC Client Access service has been removed, the server won't be returned as an array member by Get-ClientAccessArray and the script won't target it. As soon as the server is functional again, you can re-add the RPC Client Access service by using the **New-RpcClientAccess** cmdlet. When the RPC Client Access service is re-added, be sure to restart the Microsoft Exchange Address Book service on the affected server.

Caution:

Before you remove the RPC Client Access service from a server, see the topic Remove-RpcClientAccess.

For More Information

For more information about how to use Kerberos authentication with a Client Access server array or a load-balancing solution, see the following topics:

- Using Kerberos with a Client Access Server Array or a Load-Balancing Solution
- Configuring Kerberos Authentication for Load-Balanced Client Access Servers
- Using the RollAlternateserviceAccountPassword.ps1 Script in the Shell

1.6.2.10.3 Using the RollAlternateserviceAccountPassw ord.ps1 Script in the Shell

Using the RollAlternateserviceAccountPassword.ps1 Script in the Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the RollAlternateServiceAccountPassword.ps1 script in Exchange Server 2010 Service Pack 1 (SP1) to update an alternate service account credential (ASA credential) and distribute the update to specified Client Access servers.

Note:

The Exchange Management Shell doesn't load scripts automatically. You must precede all scripts with "**.**" For example, to run the RollAlternateServiceAccountPassword.ps1 script, type `.\RollAlternateServiceAccountPassword.ps1`.

Note:

This script is provided in English only.

For more information about how to use Kerberos authentication with a Client Access server array or load-balancing solution, see Using Kerberos with a Client Access Server Array or a Load-Balancing Solution and Configuring Kerberos Authentication for Load-Balanced Client Access Servers.

For more information about how to use and write scripts, see Scripting with the Exchange

Management Shell.

```
RollAlternateServiceAccountPassword.ps1 -Scope <Object> -Identity <Object> -
Source <Object> -
```

Detailed Description

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access Security" entry in the Client Access Permissions topic.

Technical Details of the Alternate Service Account Credential Script

This script facilitates setup and maintenance of the ASA credential. After you've created the ASA credential and set the appropriate Service Principle Names, you can use the script to distribute the credential to all targeted Client Access servers.

To use the script, you must identify which servers you want to target and which credential you want to use as your ASA credential.

Server Scope

You can choose to have the script target all the Client Access servers in the forest, all members of a particular Client Access server array, or specific servers. The available parameters are *ToEntireForest*, *ToArrayMembers*, and *ToSpecificServers*. If you target the script to specific servers or to members of a specific server array, the *Identity* parameter must be specified with the servers or server array names you want to target.

Credential Source

The script can copy the alternate service account password from an existing server. Or, you can specify the account you want to use and let the script generate a new password for the account. The available parameters are *GenerateNewPasswordFor* and *CopyFrom*. The *GenerateNewPasswordFor* parameter requires that you specify an account string in the following format: DOMAIN\Account Name. If you're using a computer account, you must append "$" at the end of the account name, for example CONTOSO\ClientServerAcct$. The *CopyFrom* parameter takes the name of an existing Client Access server as the credential source.

Generating a New Password for a Credential

The password is created by the script. No user input is required. The script will try to distribute the password to all target computers, and will then try to update the Active Directory account credential with the newly-generated password.

The newly-generated password is 73 characters long and will satisfy standard strong password requirements. If your password requirements differ, you may need to set the password manually and then copy it to the target servers.

To prevent service interruption, the script examines each Client Access server and maintains the current password in addition to adding the new password. After the script has run, the shared ASA credential will be able to use either of 2 passwords: the current password as stored in Active Directory or the new password that hasn't yet been set in Active Directory.

All passwords that are no longer valid, such as an expired password, will be removed from the destination servers. If the password in Active Directory can't be changed, perhaps because the password has expired, the script will attempt a password reset. This will require the account running the script to have permissions to reset either Active Directory computer account passwords or user account passwords, depending on whether your alternate service account is a computer account or a user account.

If the passwords aren't changed successfully for all target Client Access servers, updating

the Active Directory password can cause an authentication failure. If the script is run in unattended mode, it won't update the Active Directory password with the new password unless all target Client Access servers have been updated successfully. If the script is run in attended mode, you will be asked whether you want to update the password in Active Directory.

Creating a Scheduled Task to Automate Password Maintenance

If you want the script to create a scheduled task to maintain the password on an ongoing basis, use the *CreateScheduledTask* parameter. This parameter requires a string for the name of the task you want to create.

Note:
Run the script and verify that it works correctly in attended mode before you create the unattended scheduled task.

The script creates a .cmd file in the folder where the script is located. It then creates a task to run that .cmd file every three weeks. You can use Windows Task Scheduler to modify the scheduled task, for example, to set it to run more or less often. By default, the task will run as the currently logged-on user. In addition, the script will only run when the user is logged on to the computer. We recommend that you modify the scheduled task to run whether the user is logged on or not. You can also choose to run it under a different account, if that account has Active Directory permissions to reset passwords as well as the Exchange Enterprise Administrator role. When creating a scheduled task, the script will automatically run in unattended mode.

Tasks Out of Scope of the Script

The script won't manage the SPNs of the ASA credential or allow you to remove an alternate service account from a server. To remove an alternate service account from a server, use the **Set-ClientAccessServer** cmdlet. If you have to remove Kerberos authentication, see Using Kerberos with a Client Access Server Array or a Load-Balancing Solution.

Troubleshooting the Script

We recommend that you run the script and verify that it works correctly in attended mode before you create the unattended scheduled task. For troubleshooting information, see Troubleshooting the RollAlternateServiceAccountCredential.ps1 Script.

Validating the Script

The output of the script when you run it interactively with the -verbose flag should indicate what script operations were successful. To confirm that the Client Access servers were updated, you can verify the last modified time stamp on the ASA credential. The following example generates a list of Client Access servers and the last time the alternate service account was updated.

```
Get-ClientAccessServer -IncludeAlternateServiceAccountCredentialstatus |Fl Name,
```

You can also examine the event log on the computer on which the script is run. The event log entries for the script are in the Application Event log and are from the source *MSExchange Management Application*. The following table lists the events that are logged and what the events mean.

Script Event IDs and their explanations

Event	Explanation
14001	Start
14002	Success (information)

14003	Successful but with Warnings. The script encountered some issues but was able to overcome them, or user input confirmed they weren't necessary. If the script is running in interactive mode, read the script output for further warning details.
14004	Failed

If the script runs as a scheduled task, its results are logged to the Exchange server **Logging** folder in a subfolder called **RollAlternateServiceAccountPassword**.

You can use the log to confirm that the task has been running successfully.

Parameters

Parameter	Required	Description
ToEntireForest	Optional	The *ToEntireForest* parameter targets the script to all Client Access servers in the forest.
ToArrayMembers	Optional	The *ToArrayMembers* parameter targets the script to all members of a specific Client Access server array. **Note:** If you're using the *ToArrayMembers* parameter or the *ToSpecificServers* parameter, you must specify the server names or the server array names using the *Identity* parameter.
ToSpecificServers	Optional	The *ToSpecificServers* parameter targets the script to specific servers. **Note:** If you're using the *ToArrayMembers* parameter or the *ToSpecificServers* parameter, you must specify the server names or the server array names using the *Identity* parameter.
Identity	Required	The *Identity* parameter specifies name of the Client Access server array or the names of the specific servers that you're targeting.
GenerateNewPasswordFor<String>	Optional	The *GenerateNewPasswordFor* parameter specifies that the script should generate a new

		password for the ASA. The string value must be the ASA account in the following format: DOMAIN\Account Name. If you're using a computer account, you must append the $ character at the end of the account name.
CopyFrom<String>	Optional	The *CopyFrom* parameter specifies that the credential is copied from another Client Access server. The string value specified is the name of the Client Access server.
Mode	Optional	The *Mode* switch specifies whether the script runs in attended or unattended mode. Unattended mode doesn't prompt for user input and automatically chooses more conservative options, when necessary.
CreateScheduledTask<String>	Optional	The *CreateScheduledTask* parameter tells the script to create a scheduled task to perform the ASA credential update. The string value is the name of the scheduled task that will be created. **Note:** This script creates a .cmd file in the folder where the script is located. The scheduled task will run the .cmd file once every three weeks. You can edit the task directly in Windows Task Scheduler to change the frequency of the task.
WhatIf	Optional	The *WhatIf* switch instructs the command to simulate the actions that it would take on the object. By using the *WhatIf* switch, you can view what changes would occur without having to apply any of those changes. You don't have to specify a value with the *WhatIf* switch.
Confirm	Optional	The *Confirm* switch causes the command to pause processing and requires you to acknowledge what the command will do before processing continues. You

		don't have to specify a value with the *Confirm* switch.
Verbose	Optional	The *Verbose* parameter tells the script to perform verbose logging, so that additional information about the script's actions is written to the log file.
Debug	Optional	The *Debug* parameter tells the script to run in debugging mode. This parameter should be used to determine why the script fails.

Examples

Example 1

This example uses the script to push the credential to all Client Access servers in the forest for first-time setup.

```
.\RollAlternateserviceAccountPassword.ps1 -ToEntireForest -GenerateNewPasswordFor
```

Example 2

This example generates a new password for a user account ASA credential and distributes the password to all members of Client Access server arrays where the name matches *mailbox*.

```
.\RollAlternateserviceAccountPassword.ps1 -ToArrayMembers *mailbox* -GenerateNewP
```

Example 3

This example schedules a once-a-month automated password roll scheduled task called "Exchange-RollAsa". It will update the ASA credential for all Client Access servers in the entire forest with a new, script-generated password. The scheduled task is created, but the script is not run. When the scheduled task is run, the script runs in unattended mode.

```
.\RollAlternateServiceAccountPassword.ps1 -CreateScheduledTask "Exchange-RollAsa"
```

Example 4

This example updates the ASA credential for all Client Access servers in the Client Access server array named CAS01. It obtains the credential from the Active Directory computer account ServiceAc1 in the domain Contoso.

```
.\RollAlternateserviceAccountPassword.ps1 -ToArrayMembers "CAS01" -GenerateNewPas
```

Example 5

This example shows how you can use the script to distribute the ASA to a new computer or to a computer that's being put back into service either because you're increasing the size of your server array or because you're re-introducing array members after maintenance.

You must update the ASA credential before the Client Access server receives traffic. Copy the shared ASA credential from any Client Access server that's already configured correctly. For example, if Server A currently has a working ASA credential and you've just added Server B to the array, you can use the script to copy the credential (including the password) from Server A to Server B. This is useful if Server B was down or not yet a member of the array when the password was rolled the last time.

```
.\RollAlternateServiceAccountPassword.ps1 -CopyFrom ServerA -ToSpecificServers Se
```

1.6.2.11 Managing Client Access Server Virtual Directories

Managing Client Access Server Virtual Directories

Exchange Server 2010 > Client Access > Managing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-18*

Enable or Disable SSL on Exchange Web Services Virtual Directories

Reset Client Access Virtual Directories

Configure ECP Virtual Directory Properties

1.6.2.11.1 Enable or Disable SSL on Exchange Web Services Virtual Directories

Enable or Disable SSL on Exchange Web Services Virtual Directories

Client Access > Managing Client Access Servers > Managing Client Access Server Virtual Directories >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Exchange Web Services virtual directories help you manage calendar sharing and other functionality that's useful for your end users and server applications. An Exchange Web Services virtual directory is created by default on each Exchange computer that's running the Client Access server role. SSL is enabled by default on Exchange Web Services virtual directories. For more information about Exchange Web Services virtual directories, see Understanding Exchange Web Services Virtual Directories.

Important:

SSL should be enabled for each Client Access server in your organization if you don't have an SSL offloading device and want to maintain secure communications between client and server. If you want to enable SSL offloading, you must disable SSL on each Client Access server in your organization for which you want to enable SSL offloading. If your Client Access servers are running Exchange Server 2010 Service Pack 1 (SP1) or a later version, you can disable or enable SSL on an Exchange Web Services virtual directory by making a configuration change in Internet Information Services (IIS) Manager. However, if you're running Exchange 2010 RTM, you must make a configuration change in IIS Manager and also in a configuration file that's located in the Exchange 2010 installation directory.

Looking for other management tasks related to Exchange Web Services virtual directories? Check out the Exchange Web Services virtual directory cmdlets referenced in the Client Access Cmdlets topic.

What Do You Want to Do?

- Disable SSL on an Exchange Web Services virtual directory on a Client Access server running Exchange 2010 SP1 or a later version
- Disable SSL on an Exchange Web Services virtual directory on a Client Access server running Exchange 2010 RTM
- Enable SSL on an Exchange Web Services virtual directory on a Client Access

Disable SSL on an Exchange Web Services virtual directory on a Client Access server running Exchange 2010 SP1 or a later version

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services permissions" entry in the Client Access Permissions topic.

1. Open IIS Manager and turn off SSL on the Exchange Web Services virtual directory using the following steps:
   1.a. In the console tree, click the plus sign (+) next to each of the following folders to show the **EWS** node: **Server Name** > **Sites** > **Default Web Site**.
   1.b. In the console tree, select **EWS**.
   1.c. In the result pane, under **IIS**, double-click **SSL Settings**.
   1.d. Make sure the **Require SSL** check box is cleared.
2. Perform this procedure on each Client Access server in your organization.

Disable SSL on an Exchange Web Services virtual directory on a Client Access server running Exchange 2010 RTM

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services permissions" entry in the Client Access Permissions topic.

1. Open IIS Manager and turn off SSL on the Exchange Web Services virtual directory using the following steps:
   1.a. In the console tree, click the plus sign (+) next to each of the following folders to show the **EWS** node: **Server Name** > **Sites** > **Default Web Site**.
   1.b. In the console tree, select **EWS**.
   1.c. In the result pane, under **IIS**, double-click **SSL Settings**.
   1.d. Make sure the **Require SSL** check box is cleared.
2. Edit the configuration file in the directory in which you installed Exchange 2010.

   Caution:
   Save a copy of the configuration file before you begin the procedure. That way, you can revert to the original file if you make any errors while you're modifying the file.

   2.a. Go to C:\Program Files\Microsoft\Exchange Server\V14\ClientAccess \exchweb\ews, where C:\ is the directory in which you installed Exchange 2010.
   2.b. In Notepad or another .xml editing tool, open the web.config file.
   2.c. Change all occurrences of the term **httpsTransport** to **httpTransport**.
   2.d. Save changes to web.config.
3. Perform this procedure on each Client Access server in your organization.

Enable SSL on an Exchange Web Services

virtual directory on a Client Access server running Exchange 2010 SP1 or a later version

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services permissions" entry in the Client Access Permissions topic.

1. Open IIS Manager and turn on SSL on the Exchange Web Services virtual directory using the following steps:
   1.a. In the console tree, click the plus sign (+) next to each of the following folders to show the **EWS** node: **Server Name** > **Sites** > **Default Web Site**.
   1.b. In the console tree select **EWS**.
   1.c. In the result pane, under **IIS**, double-click **SSL Settings**.
   1.d. Make sure the **Require SSL** check box is selected.
2. Perform this procedure on each Client Access server in your organization.

Enable SSL on an Exchange Web Services virtual directory on a Client Access server running Exchange 2010 RTM

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services permissions" entry in the Client Access Permissions topic.

1. Open IIS Manager and turn on SSL on the Exchange Web Services virtual directory using the following steps:
   1.a. In the console tree, click the plus sign (+) next to each of the following folders to show the **EWS** node: **Server Name** > **Sites** > **Default Web Site**.
   1.b. In the console tree select **EWS**.
   1.c. In the result pane, under **IIS**, double-click **SSL Settings**.
   1.d. Make sure the **Require SSL** check box is selected.
2. Edit the configuration file in the directory to which you installed Exchange 2010.

   Caution:

   Save a copy of the configuration file before you begin the procedure. That way, you can revert to the original file if you make any errors while you're modifying the file.

   2.a. Go to the C:\Program Files\Microsoft\Exchange Server\V14\ClientAccess \exchweb\ews, where C:\ is the directory in which you installed Exchange 2010.
   2.b. In Notepad or another .xml editing tool, open the web.config file.
   2.c. Change all occurrences of the term **httpTransport** to **httpsTransport**.
   2.d. Save changes to web.config file.
3. Perform this procedure on each Client Access server in your organization.

Reset Client Access Virtual Directories

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the Reset Client Access Virtual Directory wizard to reset a virtual directory on an Exchange Server 2010 Client Access server. When you reset a virtual directory, the virtual directory is removed and a new virtual directory with default settings is created.

Important:

Because a new virtual directory with default settings is created when you reset a virtual directory, you need to reconfigure a virtual directory after it's reset. By default, the settings for a virtual directory are copied to the Program Files/Microsoft/Exchange Server/V14 directory.

What Do You Want to Do?

- Use the EMC to reset a Client Access server virtual directory
- Use the Shell to a Client Access server virtual directory

Use the EMC to reset a Client Access server virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Reset Client Access virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, click **Reset Client Access Virtual Directory**.
3. On the **Introduction** page, next to **Virtual directory to be reset**, click **Browse**. Select the virtual directory you want to reset and click **Next**. By default, the following Client Access virtual directories are listed:
   - Autodiscover (Default Web Site)
   - ecp (Default Web Site)
   - EWS (Default Web Site)
   - Microsoft-Server-ActiveSync (Default Web Site)
   - OAB (Default Web Site)
   - owa (default Web Site)
4. After the directory you want to reset is added to the list under **Virtual directory to be reset**, click **Next**.
5. On the **Log Location** page, specify the path and file name for the log file, and click **Next**. The log file includes the settings that exist on the virtual directory you're about to reset. These settings may be helpful if you want to re-create a virtual directory with the same settings. By default, the log file is copied to the Documents folder on the Client Access server.
6. On the **Reset Client Access Virtual Directory** page, click **Reset**.
7. On the **Completion** page, click **Finish**.
8. Restart Internet Information Services (IIS). You can restart IIS by running **iisreset /noforce** from a command prompt window.

Use the Shell to reset a Client Access server virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Reset Client Access virtual directories" entry in the Client Access Permissions topic.

To reset a virtual directory, you must remove the virtual directory and then create a new one.

The cmdlets that you run differ depending on the virtual directory you want to reset.

For example, to reset the Outlook Web App virtual directory on the Client Access server Server01, you need to do the following:

1. Remove the virtual directory by running the following cmdlet.

```
Remove -OwaVirtualDirectory -Identity 'Server01\owa (Default Web Site)
```

2. Create the new virtual directory by running the following cmdlet.

```
New-OwaVirtualDirectory -InternalUrl 'https://<Server01><DomainName>/o
```

3. Restart IIS. You can restart IIS by running **iisreset /noforce** from a command prompt window.

By default, the log file is copied to the Documents folder on the Client Access server. The log file includes the settings that exist on the virtual directory you're resetting. These settings may be helpful if you want to re-create a virtual directory with the same settings.

For more information about syntax and parameters, see the cmdlets that are used to manage the virtual directory that you want to reset.

Virtual directory name	Cmdlet used to create the virtual directory	Cmdlet used to remove the virtual directory
Autodiscover (Default Web Site)	New-AutodiscoverVirtualDirectory	Remove-AutodiscoverVirtualDirectory
ecp (Default Web Site)	New-EcpVirtualDirectory	Remove-EcpVirtualDirectory
EWS (Default Web Site)	New-WebServicesVirtualDirectory	Remove-WebServicesVirtualDirectory
Microsoft-Server-ActiveSync (Default Web Site)	New-ActiveSyncVirtualDirectory	Remove-ActiveSyncVirtualDirectory
OAB (Default Web Site)	New-OABVirtualDirectory	Remove-OABVirtualDirectory
owa (default Web Site)	New-OwaVirtualDirectory	Remove-OwaVirtualDirectory

1.6.2.11.3 Configure ECP Virtual Directory Properties

Configure ECP Virtual Directory Properties

Client Access > Managing Client Access Servers > Managing Client Access Server Virtual Directories >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can view or configure the settings that apply to your Exchange Control Panel (ECP) virtual directory properties.

What Do You Want to Do?

- Use the EMC to configure ECP virtual directory properties
- Use the Shell to configure ECP virtual directory properties

Use the EMC to configure ECP virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Control Panel (ECP) virtual directory settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access** > **Exchange Control Panel**.
2. In the work pane, select **ecp (Default Web site)**, and then, in the action pane, under **ecp (Default Web site)**, click **Properties**. The **ecp (Default Web site) Properties** page will open.
3. On the **General** tab, in the **Internal URL** box, verify that the internal URL is correct for your organization.
4. In the **External URL** box, verify that the external URL is correct for your organization. The external URL isn't configured by default.
5. On the **Authentication** tab, specify the method by which your POP3 users will sign in. ECP uses the same sign-in format as Outlook Web App. By default, **Use forms based authentication** is selected.
   - Select **Use one or more standard authentication methods**, and then select one of the following check boxes if you want to use:
     Integrated Windows authentication
     Digest authentication for Windows domain servers
     Basic authentication (password is sent in clear text)
   - Select **Use forms based authentication** if you want to use forms-based authentication. ECP uses the same sign-in format as Outlook Web App.

Note:
To configure SSL settings for this ECP virtual directory, use Internet Information Services (IIS).

Use the Shell to configure ECP virtual directory properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Control Panel (ECP) virtual directory settings" entry in the Client Access Permissions topic.

This example disables Basic authentication on the default ECP virtual directory on the server named Server01.

```
Set-EcpVirtualDirectory -Identity "Server01\ecp (default web site)" -Basicauthent
```

For more information about syntax and parameters, see Set-EcpVirtualDirectory.

1.6.2.12 Set Message Size Limits for Exchange Web Services

Set Message Size Limits for Exchange Web Services

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-20*

You can modify message size limits to increase or decrease the size of e-mail messages that clients may send or receive.

To configure message size limits, you modify the following parameters on the Send and Receive connectors on the Hub Transport servers:

- **maxReceiveSize**
- **maxSendSize**
- **maxMessageSize**

To view the Send and Receive limits for your Exchange organization, use the following cmdlet:

Get-TransportConfig |fl max*size

To view the Send and Receive limits for individual mailboxes, use the following cmdlets:

Get-Mailbox –id sender |fl max*size

Get-Mailbox –id recipient |fl max*size

To determine whether the sender and recipient have enough room left in their mailboxes, you can run the following Exchange Management Shell cmdlets:

Get-MailboxStatistics –id sender | fl StorageLimitStatus,TotalItemSize

Get-Mailbox sender | fl prohibit*quota

Get-Mailbox sender | foreach {Get-MailboxDatabase –id $_.mailboxdatabase | fl prohibit*quota}

Get-MailboxStatistics –id recipient | fl StorageLimitStatus,TotalItemSize

Get-Mailbox recipient | fl prohibit*quota

Get-Mailbox recipient| foreach {Get-MailboxDatabase –id $_.mailboxdatabase | fl prohibit*quota}

Additionally, you must configure both of the following parameters in the Exchange Web Services (EWS) Web.config file for clients that use Exchange Web Services such as Microsoft Entourage 2008 for Mac, Web Services Edition to submit e-mail messages to Exchange:

- **maxAllowedContentLength** – This setting is used by the Request filtering role service in Internet Information Services 7 (IIS) to protect the Web server from receiving requests that are too large.
  The default values for this parameter are:

  Exchange 2007= 30000000 bytes

  Exchange 2010= 35000000 bytes

Note:
A change to this setting requires a restart of the MSExchangeServicesAppPool application pool. You can verify or modify this setting in the following ways.

- **maxRequestLength** - ASP.NET uses the maxRequestLength setting to determine the maximum amount of data that the Web browser can submit to the Client Access server. This setting is configured initially by Exchange Setup as an entry in the Web.config file for the Exchange Web Services application in IIS.

  Default for Exchange 2007 = 13280 KB

  Default for Exchange 2010 = 2097151 KB

- **maxReceivedMessageSize** – This setting applies only to Microsoft Exchange Server 2010. It indicates the maximum message size that is accepted by EWS. This maximum message size is 35,000,000 bytes, which translates to 25 MB of Base64-encoded data.
  The default values for this parameter are:

  Exchange 2010 RTM = 13600000 Bytes

  Exchange 2010 SP1 = 35000000 Bytes

  Note:
  The values for this limit differ for an on-premise Exchange 2010 deployment.

- **connectionTimeout** - This setting is used to provide a connection time limit. Because this parameter affects traffic to the Web site, we do not recommend changing this value unless you receive HTTP 408 error messages. The recommended method for changing this value is to use the IIS Configuration editor. The Configuration Editor is part of the IIS Administration Pack.

Note:
The size of a message is determined by the size of the message body plus the size of any attached files. For Microsoft Exchange Server 2010 Service Pack 1 (SP1), the default message size restrictions are set to 35 million bytes. This accommodates approximately 25 MB of Base64-encoded data. For Microsoft Exchange Server 2010, the default message size restrictions are set to 13.6 million bytes. This accommodates approximately 10 MB of Base64-encoded data.

Note:
After you set the message size properties for Exchange Web Services, you must stop and then start the Default Web site.

For information about other management tasks that are related to setting up message size limits, see Understanding Message Size Limits.

Use a text editor to modify the Web.config file

To modify the Web.config file, follow these steps:

1. Start Windows Explorer, and then locate the Web.config file. By default, this file is located in the following directory:
   %ProgramFiles%\Microsoft\Exchange Server\V14\ClientAccess\exchweb\ews
2. Create a copy of the file as a backup.
3. Open the Web.config file by using a text editor, such as Notepad.
4. Search for the **maxAllowedContentLength** entry. By default, this entry appears as follows in Microsoft Exchange Server 2010 RTM:

<requestLimits maxAllowedContentLength="13600000" />

5. Change the value for **maxAllowedContentLength** to accommodate the message size that you want to allow. Because message attachments are Base64-encoded before they are transferred, the value must be set high enough to accommodate the desired message size together with the encoding overhead.
   For example, to allow messages of approximately 20 MB, perform the following calculation:
   20971520 bytes * 4/3 for Base64 encoding = 27962027 (rounded up)

   Note:
   In this formula, the fraction 4/3 represents a message that is approximately 33 percent larger than the original. However, message size increase may be much larger, depending on the type of attachment that is sent, the attachment size, whether the attachment is already compressed, and the messaging client from which the message is sent. In some cases, you may experience message size increases of 100 percent after encoding (that is, messages that are twice the size of the original messages).
6. Search for **maxReceivedMessageSize**. This entry is listed after the **EWSServiceBehavior** entries. By default, this entry appears as follows in Exchange 2010 RTM:
   <httpsTransport maxReceivedMessageSize="13600000" authenticationScheme="Anonymous" maxBufferSize="81920" transferMode="Streamed" />
7. Change the value for **maxReceivedMessageSize** to the same value as for **maxAllowedContentLength** to accommodate the desired message size together with the base64 encoding overhead.
8. Save the changes to the Web.config file, and then exit the text editor.
9. Stop and then start the default Web site for the settings to take effect.

   Important:
   You must configure at least the same message size limits on the appropriate transport servers to support the increased message size. For more information, see Understanding Message Size Limits.

1.6.3 Securing Client Access Servers

Securing Client Access Servers

Exchange Server 2010 > Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic summarizes the security and authentication related options available for a computer running Microsoft Exchange Server 2010 that has the Client Access server role installed. The Client Access server role provides access to Outlook Web App, Microsoft Exchange ActiveSync, Outlook Anywhere, Post Office Protocol version 3 (POP3), and Internet Message Access Protocol version 4rev1 (IMAP4). In addition, it supports the Autodiscover service and the Availability service. Each of these protocols and services has unique security needs.

Managing Authentication

One of the most important security-related tasks you can perform for the Client Access server role is to configure an authentication method. The Client Access server role is installed with a default self-signed digital certificate. A digital certificate does two things:

- It authenticates that its holder is who or what the holder claims to be.
- It helps protect data exchanged online from theft or tampering.

Although the default, self-signed certificate is supported for Exchange ActiveSync and Outlook Web App, it isn't the most secure method of authentication. Also, it isn't supported for Outlook Anywhere. For additional security, consider configuring your Exchange 2010 Client Access server to use a trusted certificate from a third-party commercial certification authority (CA) or a trusted Windows public key infrastructure (PKI) CA. You can configure authentication separately for Exchange ActiveSync, Outlook Web App, Outlook Anywhere, POP3, and IMAP4.

For more information about how to configure authentication, see the following topic:

- Setting Up Standard Authentication Methods for Outlook Web App

Enhancing Secure Communications Between the Client Access Server and Other Servers

After you optimize the security of communications between clients and the Exchange 2010 Client Access server, you must optimize the security of the communications between the Exchange 2010 Client Access server and other servers in your organization. By default, HTTP, Exchange ActiveSync, POP3, and IMAP4 communication between the Client Access server and other servers, such as Exchange 2010 servers that have the Mailbox server role installed, domain controllers, and global catalog servers, is encrypted.

For More Information

For more information about how to manage security for the different components of your Client Access server, see the following topics:

- Understanding Security for Exchange ActiveSync
- Understanding Security for Outlook Web App
- Understanding Security for Outlook Anywhere
- Understanding Security for POP3 and IMAP4

1.6.3.1 Managing SSL for a Client Access Server

Managing SSL for a Client Access Server

Exchange Server 2010 > Client Access > Securing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-18*

Understanding Digital Certificates and SSL

Obtain a Server Certificate from a Certification Authority

Install an SSL Certificate on a Client Access Server

Export an Exchange Certificate

Renew an Exchange Certificate

Configure SSL Certificates to Use Multiple Client Access Server Host Names

1.6.3.1.1 Obtain a Server Certificate from a Certification Authority

Obtain a Server Certificate from a Certification Authority

Client Access > Securing Client Access Servers > Managing SSL for a Client Access Server >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-03*

You can obtain a server certificate from a certification authority (CA). This is one step in the process to configure Secure Sockets Layer (SSL) or Transport Layer Security (TLS). You can obtain server certificates from a third-party CA. A third-party CA may require you to provide identification before a certificate can be issued. You can also issue your own server certificates by using an online CA, such as Microsoft Certificate Services.

Note:
Cryptography Next Generation (CNG) certificates are not supported in Microsoft Exchange Server 2010.

For more information about server certificates, see the Windows Server 2003 Internet Information Services (IIS) documentation.

Note:
Microsoft Exchange Server 2010 includes a default self-signed SSL certificate. You can replace this certificate with a third-party certificate from a CA. To do this, you must first delete the self-signed certificate. For more information about how to replace the self-signed certificate, see Install an SSL Certificate on a Client Access Server.

Looking for other management tasks related to SSL? Check out Managing SSL for a Client Access Server.

Prerequisites

Important:
As a security best practice, log on to your computer using an account that isn't in the Administrators group, and then use the **runas** command to run IIS Manager as an administrator. At a command prompt, type **runas /user:***Administrative_AccountName* **"mmc systemroot\system32\inetsrv\iis.msc"**.

Use the Shell to obtain a server certificate from a certification authority

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

The code example below outputs the certificate request in Base64 format to the command-line console. You must send the certificate request to a CA within the organization, a trusted CA outside the organization, or a commercial CA. You can do this

by pasting the certificate request output into an e-mail message or into the appropriate field on the certificate request Web page of the CA. You can also save the certificate request to a file using a text editor such as Notepad.

The certificate that results has the following attributes associated with it:

- Subject name: c=<ES>,o=<Woodgrove Bank>,cn=mail1.woodgrovebank.com
- Subject alternate names: woodgrovebank.com and example.com
- An exportable private key

```
New-ExchangeCertificate -GenerateRequest -SubjectName "c=US, o=Woodgrove Bank, cn
```

Use the procedures specified by your chosen CA to send the certificate request to the CA.

1.6.3.1.2 Install an SSL Certificate on a Client Access Server

Install an SSL Certificate on a Client Access Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to install a Secure Sockets Layer (SSL) certificate on a Microsoft Exchange Server 2010 Client Access server.

Looking for other management tasks related to SSL? Check out Managing SSL for a Client Access Server.

Prerequisites

You've previously requested a certificate from a certification authority by using the **New-ExchangeCertificate** cmdlet and then transmitted that request to a certification authority. The certification authority has returned a certificate file.

Use the Shell to install an SSL certificate on a Client Access server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access Server Security settings" entry in the Client Access Permissions topic.

This example imports an existing certificate and private key from the PKCS #12 file ExportedCert.pfx.

```
Import-ExchangeCertificate -FileData ([Byte[]]$(Get-Content -Path c:\certificates
```

For more information about syntax and parameters, see Import-ExchangeCertificate.

Configure SSL Certificates to Use Multiple Client Access Server Host Names

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure your Secure Sockets Layer (SSL) certificates to use multiple host names.

When you deploy your Microsoft Exchange Server 2010 Client Access servers, you must make sure that all your clients, such as Microsoft Office Outlook Web App and Office Outlook 2007, will be able to connect to the services by using an encrypted session without receiving an error message that states that the certificate isn't trusted.

By using the Shell, you can create a certificate request to include all the DNS host names of the Client Access servers. Then you can enable users to connect to the certificate for services, such as Outlook Anywhere, Autodiscover, POP3 and IMAP4, or Unified Messaging, that are listed in the alternate names attribute. For example, your users may be able to connect to your Exchange services by specifying the name as shown in the following examples:

- https://*CAS01*/owa
- https://*CAS01.FQDN.name*/owa
- https://*CASIntranetName*/owa
- https://autodiscover.*emaildomain*.com

Instead of having to require multiple certificates and maintain the configuration of multiple IP addresses and Internet Information Services (IIS) Web sites for each IP port and certificate combination, you can create a single certificate that enables clients to successfully connect to each host name by using SSL or Transport Layer Security (TLS).

You can create a single certificate by adding all the possible DNS name values to the certificate *Subject Alternative Name* property on the certificate request. A Windows–based Certificate Services certification authority should create a certificate for such a request.

Note:

Third-party or Internet-based certification authorities will issue certificates only for DNS names that you are authorized to use. Therefore, intranet DNS names probably won't be allowed.

To configure your SSL certificates to use multiple Client Access server host names, do the following:

1. Use the **New-ExchangeCertificate** cmdlet to create a certificate request file.
2. Send this file to a Windows Certificate Services certification authority and use the Web server template on the **Certification Authority** page. This will result in a .cer file that can be imported to the Client Access server.
3. Use the **Get-ExchangeCertificate** cmdlet to determine the thumbprint for your certificate.
4. After you've imported the certificate, you can assign it to IIS, IMAP4, and POP3 by using the **Enable-ExchangeCertificate** cmdlet.

Looking for other management tasks related to SSL? Check out Managing SSL for a Client Access Server.

Prerequisites

- You have logged on to your computer using an account that's not in the Administrators group, and then used the **runas** command to run IIS Manager as an administrator. This is a security best practice. To do this, at a command prompt, type **runas /user:***Administrative_AccountName* **"mmc systemroot \system32\inetsrv\iis.msc"**.
- You have read TLS Functionality and Related Terminology in Exchange 2010. This contains information about the many variables you must consider when you configure certificates for SSL or TLS services and how these variables can affect your overall configuration.

Use the Shell to create a certificate request file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

This example creates a text file that contains a certificate request in PKCS#10 format.

```
New-ExchangeCertificate -generaterequest -subjectname "dc=com,dc=contoso,o=Contos
```

Use the Shell to import a certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

This example imports a previously obtained certificate.

```
Import-ExchangeCertificate -path <certificate_file_name>.cer -friendlyname "Conto
```

Use the Shell to determine the thumbprint of your certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

This example determines the thumbprint of a certificate that matches the host name of CAS01.

```
Get-ExchangeCertificate -DomainName "CAS01"
```

Note:
This example will return multiple certificates if there are several certificates that match the host name you specified. Therefore, make sure that you select the thumbprint of the correct certificate for your request.

Use the Shell to assign the certificate to IIS, POP3, and IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

This example assigns the certificate to IIS, POP3, and IMAP4.

```
Enable-ExchangeCertificate -thumbprint <certificate-thumbprint> -services "IIS,PO
```

This example assigns the certificate to a server, which in turn assigns the certificate to all services that are running on the Exchange server.

```
Import-ExchangeCertificate -path <certificate file name> -friendlyname "Contoso C
```

For more information about syntax and parameters for the **Import-ExchangeCertificate**, **Enable-ExchangeCertificate**, **Get-ExchangeCertificate**, and **New-ExchangeCertificate** cmdlets, see Global Cmdlets.

1.6.3.1.4 Export an SSL Certificate

Export an SSL Certificate

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to export a Secure Sockets Layer (SSL) certificate. An SSL certificate is installed on a Microsoft Exchange Server 2010 Client Access server. The SSL certificate enables the Client Access server to encrypt communications with clients by using SSL technology. The SSL certificate installed on the Client Access server can be the default self-signed certificate, a certificate from a Windows public key infrastructure (PKI) certification authority (CA), or a certificate from a trusted commercial third-party CA.

You can export an existing certificate or a certificate request. To install a copy of the SSL certificate on a client computer or a mobile phone, the certificate must be exported by using the **Export-ExchangeCertificate** cmdlet.

Important:

Previous versions of Microsoft Exchange let you use Internet Information Services (IIS) to save a copy of the certificate. Although IIS will still let you save a copy of the certificate in Exchange 2010, we don't recommend that you do this. Use the **Export-ExchangeCertificate** cmdlet to generate a copy of the certificate for importing to another server, client computer, or mobile phone.

After you've exported the SSL certificate in the form of a PKCS #12 file, the file can then be imported by the following:

- Another Exchange 2010 server, by using the **Import-ExchangeCertificate** cmdlet
- A client computer, by using the Certificate Import wizard in the EMC
- A mobile phone, by using desktop ActiveSync

Note:

Not all mobile phones support installation of SSL certificates. For more information, see your mobile phone documentation.

Looking for other management tasks related to SSL? Check out Managing SSL for a Client Access Server.

Use the Shell to export an SSL certificate

The following command uses the **Export-ExchangeCertificate** cmdlet to export certificate data to the variable *$file*.

```
$file = Export-ExchangeCertificate -Thumbprint 5113ae0233a72fccb75b1d019862867533
```

For more information about syntax and parameters, see Export-ExchangeCertificate.

1.6.3.1.5 Export an Exchange Certificate

Export an Exchange Certificate

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Export Exchange Certificate Wizard to export an existing Exchange Secure Sockets Layer (SSL) certificate.

Prerequisites

The Client Access server role has been installed and at least one certificate is installed on your Client Access server.

What Do You Want to Do?

- Use the EMC to export an Exchange certificate
- Use the Shell to export an Exchange certificate

Use the EMC to export an Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

1. In the console tree, click **Server Configuration**.
2. Select the server that contains the certificate, and then select the certificate you want to export.
3. In the action pane, click **Export Exchange Certificate**.
4. On the **Export Exchange Certificate** page, select the certificate you want to export. The services that are checked are currently assigned to the certificate.
5. When you click **Export**, the **Progress Page** will confirm your selections and try to export the certificate.
6. The **Completion** page will display the status of the request together with the syntax of the Shell cmdlet needed to export the certificate.

Use the Shell to export an Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client

Access Permissions topic.

This example exports the Exchange certificate.

```
Export-ExchangeCertificate -Thumbprint 5113ae0233a72fccb75b1d0198628675333d010e -
```

1.6.3.1.6 Renew an Exchange Certificate

Renew an Exchange Certificate

Client Access > Securing Client Access Servers > Managing SSL for a Client Access Server >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-13*

You can use the Renew Exchange Certificate wizard to renew an existing Exchange Secure Sockets Layer (SSL) certificate.

Prerequisites

The Client Access server role has been installed and at least one certificate is installed on your Client Access server.

What Do You Want to Do?

- Use the EMC to renew an Exchange certificate
- Use the Shell to renew an Exchange certificate

Use the EMC to renew an Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

1. In the console tree, click **Server Configuration**.
2. Select the server that contains the certificate, and then select the certificate you want to renew.
3. In the action pane, click **Renew Exchange Certificate**.
4. On the **Renew Exchange Certificate** page, select the services you want to assign to the renewed certificate. The services that are checked are currently assigned to the certificate.
5. When you click **Assign**, the **Progress** page will confirm your selections and try to renew the certificate.
6. Click **Yes** to overwrite the existing certificate with the renewed certificate.
7. The **Completion** page will display the status of the request in addition to the syntax of the cmdlet needed to renew the certificate.

Use the Shell to renew an Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access server security settings" entry in the Client Access Permissions topic.

This example renews the self-signed Exchange certificate by using its thumbprint to identify the certificate.

```
Get- ExchangeCertificate -Thumbprint 'AD19B141228C7CF98B5F78DCED978B7C45E15434' |
```

This example generates a request to renew a certificate issued by a certification authority.

```
Get- ExchangeCertificate -Thumbprint 'AD19B141228C7CF98B5F78DCED978B7C45E15434' |
```

For detailed syntax and parameter information, see **New-ExchangeCertificate**.

Note:

After you generate a certificate request, you must submit it to a certification authority, obtain a signed certificate and install the certificate on the same server. For details, see Obtain a Server Certificate from a Certification Authority and Install an SSL Certificate on a Client Access Server.

1.6.3.2 Managing Exchange ActiveSync Security

Managing Exchange ActiveSync Security

Exchange Server 2010 > Client Access > Securing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

Configure SSL for Exchange ActiveSync

Configure Authentication for Exchange ActiveSync

1.6.3.2.1 Configure SSL for Exchange ActiveSync

Configure SSL for Exchange ActiveSync

Client Access > Securing Client Access Servers > Managing Exchange ActiveSync Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-22*

You can configure Microsoft Exchange ActiveSync virtual directories to use Secure Sockets Layer (SSL). By default, when you install the Client Access server role on a computer that's running Microsoft Exchange Server 2010, an Exchange ActiveSync virtual directory is created on the default Internet Information Services (IIS) Web site on the Exchange server.

After you obtain an SSL certificate to use with the Client Access server on the default Web site or on the Web site where you host your Exchange ActiveSync virtual directory, you can configure the Web site to require SSL. You can enable SSL for all Web sites hosted by the Client Access server or enable SSL only for Exchange ActiveSync.

Configuring an Exchange ActiveSync virtual directory to use SSL is just one step in managing security for Exchange ActiveSync. For more information about how to manage security for Exchange ActiveSync, see Managing Exchange ActiveSync Security.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use IIS Manager to configure SSL on the Exchange ActiveSync virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

If you are using IIS 7.0 or a later version, follow these steps:

1. In IIS Manager, select **Default Web site** or the Web site on which you are hosting your **Microsoft-Server-ActiveSync** virtual directory.
2. In the Web site **Home** pane, in the **IIS** area, double-click **SSL Settings**.
3. In **SSL Settings**, select the **Require SSL** check box. **Require 128-bit SSL** is optional. But if it is selected, this option provides greater security.

   Note:

   If you are using an SSL certificate that was created during Exchange Setup, an error message notifies you that the certificate is not a trusted certificate. Make sure that you trust the certification authority (CA) that issued the certificate or use an SSL certificate that is trusted by your CA.

4. Under **Client Certificates**, select **Ignore**.
5. In the action pane, click **Apply** to save your changes.

If you are using a version of IIS earlier than IIS 7, follow these steps:

1. In IIS Manager, select the **Default Web site** or the **Microsoft-Server-ActiveSync** virtual directory, and then click **Properties**.

   Note:

   If you want to configure SSL only for Exchange ActiveSync, select the **Microsoft-Server-ActiveSync** virtual directory under the Default Web site. Otherwise, you'll configure SSL for all virtual directories hosted on the Client Access server.

2. On the **Directory Security** tab, in **Secure Communications**, click **Edit**.
3. In **Secure Communications**, select **Require Secure Channel (SSL)**.
4. After you complete this procedure, your Exchange ActiveSync virtual directory on the Web site will be configured to use SSL. For more information about Exchange ActiveSync, see Managing Exchange ActiveSync Security.

1.6.3.2.2 Configure Authentication for Exchange ActiveSync

Configure Authentication for Exchange ActiveSync

Client Access > Securing Client Access Servers > Managing Exchange ActiveSync Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure Basic authentication for Microsoft Exchange ActiveSync. By default, when you install Microsoft Exchange Server 2010, Exchange ActiveSync is configured to use Basic authentication with Secure Sockets Layer (SSL) encryption. Other standard authentication methods include Digest authentication and Integrated Windows authentication. If you must return Exchange ActiveSync to Basic authentication, you can use the procedures in this topic.

Important:

If you configure Basic authentication for Exchange ActiveSync, we recommend that you require SSL for communications between mobile phones and Exchange ActiveSync. For more information about how to enable SSL, see Configure SSL for Exchange ActiveSync.

Looking for other management tasks related to Exchange ActiveSync? Check out Managing Exchange ActiveSync.

Use the EMC to configure Basic authentication for Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync Security settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the result pane, click the **Exchange ActiveSync** tab.
3. Select the **Microsoft-Server-ActiveSync** virtual directory.
4. In the action pane, under **Microsoft-Server-ActiveSync**, click **Properties**.
5. Click the **Authentication** tab.
6. Select the **Basic authentication (password is sent in clear text)** check box.
7. Click **Apply** to save your changes or click **OK** to save your changes and close the **Microsoft-Server-ActiveSync properties** dialog box.

Use the Shell to configure Basic authentication for Exchange ActiveSync

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange ActiveSync server settings" entry in the Client Access Permissions topic.

This example configures the Exchange ActiveSync virtual directory for basic authentication.

```
Set-ActiveSyncVirtualDirectory -Identity "ExchSrvr\Microsoft-Server-ActiveSync (D
```

For more information about syntax and parameters, see Set-ActiveSyncVirtualDirectory.

1.6.3.3 Managing Outlook Anywhere Security

Managing Outlook Anywhere Security

Exchange Server 2010 > Client Access > Securing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

Configure SSL for Outlook Anywhere

Configure Authentication for Outlook Anywhere

Configure SSL Offloading for Outlook Anywhere

1.6.3.3.1 Configure SSL for Outlook Anywhere

Configure SSL for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-31*

You can configure the /rpc virtual directory to use Secure Sockets Layer (SSL) for Outlook Anywhere. By default, when you install the Microsoft Exchange Server 2010 Client Access server role, a virtual directory named /rpc is created on the default Internet Information Services (IIS) Web site on the Exchange server.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Use IIS to configure SSL on the /rpc virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "SSL for Outlook Anywhere" entry in the Client Access Permissions topic.

If you are using IIS 7.0 or a later version, follow these steps:

1. In IIS Manager, select **Default Web site** or the Web site on which you're hosting your Outlook Web App virtual directories.
2. In the Web site **Home** pane, double-click **SSL Settings** in the **IIS** area.
3. In **SSL Settings**, select the **Require SSL** check box.

Note:
The **Require 128-bit SSL** option is not required. However, if selected, this option helps to provide increased security.

Note:
If you are using an SSL certificate that was created during Exchange Setup, an error message notifies you that the certificate is not a trusted certificate. Make sure that you trust the certification authority (CA) that issued the certificate, or use an SSL certificate that is trusted by your CA.

4. Under **Client Certificates**, select **Ignore**.
5. In the action pane, click **Apply** to save your changes.

If you are using an earlier version of IIS than IIS 7, follow these steps:

1. In IIS, select the **Default Web site** or the **rpc** virtual directory, and then click **Properties**.

Note:
If you want to configure SSL only for Outlook Anywhere, select the **rpc** virtual directory under the **Default Web site**. Otherwise, you'll configure SSL for all virtual directories that are hosted on the Client Access server.

2. On the **Directory Security** tab, in **Secure Communications**, click **Edit**.

3. In **Secure Communications**, select **Require Secure Channel (SSL)**.

After you complete this procedure, your /rpc virtual directory is configured to use SSL.

Other Tasks

After you configure SSL on the /rpc virtual directory, you may also want to:

- Configure SSL Offloading for Outlook Anywhere
- Configure Authentication for Outlook Anywhere

  For more information about CAS security, see Securing Client Access Servers

1.6.3.3.2 Configure Authentication for Outlook Anywhere

Configure Authentication for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure authentication for Outlook Anywhere.

The first time that you run the Enable Outlook Anywhere wizard in the EMC, you can select the authentication method that you want to use for Microsoft Office Outlook 2007, Outlook 2010, or Outlook 2003 clients. However, if you want to configure authentication and you've already run the Enable Outlook Anywhere wizard, you can use the **Set-OutlookAnywhere** cmdlet in the Shell.

Note:

When you specify authentication for Outlook Anywhere, you set the authentication method that will be used by the Outlook client. This authentication method is automatically provided to the client by the Autodiscover service. This authentication method is separate from the authentication method on the /rpc virtual directory that's located on your Microsoft Exchange Server 2010 Client Access servers. By default, the /rpc virtual directory is enabled for Basic authentication, and the authentication method can't be modified.

To choose the correct authentication method, see Understanding Security for Outlook Anywhere.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Use the Shell to configure authentication for Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Anywhere configuration (enable, disable, change, view)" entry in the Client Access Permissions topic.

This example enables Basic authentication for Outlook Anywhere.

```
Set-OutlookAnywhere -Name Server01 -ClientAuthenticationMethod Basic
```

This example enables NTLM authentication Outlook Anywhere.

```
Set-OutlookAnywhere -Name Server01 -ClientAuthenticationMethod NTLM
```

For more information about syntax and parameters, see Set-OutlookAnywhere.

Other Tasks

After you configure authentication for Outlook Anywhere, you may also want to:

- Configure SSL for Outlook Anywhere
- Configure SSL Offloading for Outlook Anywhere

1.6.3.3.3 Configure SSL Offloading for Outlook Anywhere

Configure SSL Offloading for Outlook Anywhere

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure SSL offloading for Outlook Anywhere.

The first time that you run the Enable Outlook Anywhere wizard, you can enable SSL offloading by selecting the check box next to **Allow secure channel (SSL) offloading**. However, if you want to enable SSL offloading and you've already run the Enable Outlook Anywhere wizard without selecting this option, you can use the Shell and the **Set-OutlookAnywhere** cmdlet to set up SSL offloading.

Looking for other management tasks related to Outlook Anywhere? Check out Managing Outlook Anywhere.

Use the EMC to enable SSL offloading for Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "SSL offloading for Outlook Anywhere" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the action pane, click **Enable Outlook Anywhere**.
3. In the Enable Outlook Anywhere wizard, in the box under **External host name**, type the external host name for your organization.
4. Select an available external authentication method. You can select **Basic authentication** or **NTLM authentication**.
5. If you're using an SSL accelerator and you want to do SSL offloading, select the check box next to **Allow secure channel (SSL) offloading**.

Note:

Don't select this option unless you're sure that you have an SSL accelerator that can handle SSL offloading. If you don't have an SSL accelerator that can

handle SSL offloading and you select this option, Outlook Anywhere won't function correctly.

6. Click **Enable** to apply these settings and enable Outlook Anywhere.
7. Click **Finish** to close the Enable Outlook Anywhere wizard.

Use the Shell to configure SSL offloading for Outlook Anywhere

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "SSL offloading for Outlook Anywhere" entry in the Client Access Permissions topic.

This example turns on SSL offloading for the specified Client Access server.

```
Set-OutlookAnywhere -Identity Server01 -SSLOffloading $true
```

For more information about syntax and parameters, see Set-OutlookAnywhere.

Other Tasks

After you configure SSL offloading, you may also want to:

- Configure SSL for Outlook Anywhere
- Configure Authentication for Outlook Anywhere

1.6.3.4 Managing POP3 and IMAP4 Security

Managing POP3 and IMAP4 Security

Exchange Server 2010 > Client Access > Securing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-07*

Configuring TLS and SSL for POP3 and IMAP4 Access

Configuring Authentication for POP3 and IMAP4

1.6.3.4.1 Configuring TLS and SSL for POP3 and IMAP4 Access

Configuring TLS and SSL for POP3 and IMAP4 Access

Client Access > Securing Client Access Servers > Managing POP3 and IMAP4 Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-08*

Transport Layer Security (TLS) and Secure Sockets Layer (SSL) can be used to secure connections between your users and your Microsoft Exchange Server 2010 computers. TLS and SSL are cryptographic protocols that provide security for communications over the

Internet. We strongly recommend that you use TLS and SSL to help secure communications between your POP3 and IMAP4 clients and the Exchange Server 2010 Client Access server.

You can use the Exchange Management Console and the Exchange Management Shell to configure TLS and SSL on the Exchange Server 2010 server that has the POP3 and IMAP4 services enabled.

Looking for more information about securing Client Access servers? See Securing Client Access Servers.

Configuring TLS and SSL

Before you configure TLS and SSL to help secure POP3 and IMAP4 access, make sure that you understand the process for configuring TLS and SSL for the Exchange 2010 Client Access server. For more information about how to help secure communications, see the following topics:

Securing Client Access Servers

Managing SSL for a Client Access Server

Install an SSL Certificate on a Client Access Server

Understanding TLS Certificates

Configuring TLS and SSL for POP3 and IMAP4

You can use either the EMC or the Shell to configure SSL or TLS for POP3 and IMAP4 on an Exchange 2010 Client Access server.

For more information about how to configure SSL and TLS for POP3 and IMAP4, see the following topics:

Configure POP3 to Use TLS or SSL

Configure IMAP4 to Use TLS or SSL

Configuring Ports for POP3 and IMAP4 When Using TLS and SSL

When you use TLS and SSL for POP3 and IMAP4 access, the Exchange 2010 Client Access server uses the ports listed in the following table to communicate with clients.

Ports for POP3 and IMAP4 access when using TLS and SSL

Protocol	Default port
IMAP4/SSL	993 (TCP)
IMAP4 with or without TLS	143 (TCP)
POP3/SSL	995 (TCP)
POP3 with or without TLS	110 (TCP)

By default, the values in this table are used for communicating with clients. You can specify other ports to use with POP3 and IMAP4 clients if you want to disable communication through the default ports. For more information about how to configure ports for Exchange 2010 POP3 and IMAP4 clients, read Configure IP Addresses and Ports for POP3 and IMAP4 Access.

Configure POP3 to Use TLS or SSL

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Exchange Management Console or the Exchange Management Shell to configure POP3 to use Transport Layer Security (TLS) or Secure Sockets Layer (SSL).

Note:
After you've configured POP3 to use TLS or SSL, you must restart the POP3 service for your settings to take effect. For information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure POP3 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **POP3** and then, in the action pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Authentication** tab.
5. In the box under **X.509 certificate name**, enter the name of the certificate.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to configure POP3 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example configures the POP3 service to use TLS or SSL security.

```
Set-PopSettings -server Server01 -X509CertificateName CertificateName01
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you configure POP3 to use TLS or SSL, you may also want to:

- Enable or Disable POP3 Access for a User
- Configure IP Addresses and Ports for POP3 and IMAP4 Access

Configure IMAP4 to Use TLS or SSL

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure IMAP4 to use Transport Layer Security (TLS) or Secure Sockets Layer (SSL).

Note:
After you've configured IMAP4 to use TLS or SSL, you must restart the IMAP4 service. For information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure IMAP4 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Authentication** tab.
5. In the box under **X.509 certificate name**, enter the name of the certificate.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to configure IMAP4 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example configures the IMAP4 service to use TLS or SSL.

```
Set-ImapSettings -server Server01 -X509CertificateName CertificateName01
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you configure IMAP4 to use TLS or SSL, you may also want to:

- Enable or Disable IMAP4 Access for a User
- Configure IP Addresses and Ports for POP3 and IMAP4 Access

Configuring Authentication for POP3 and IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-01*

When you use POP3 and IMAP4 clients, you can set authentication options, such as the ability to use TLS encryption, and configure ports for communication with clients. To successfully use the POP3 or IMAP4 services on your Microsoft Exchange Server 2010 server, you need to configure authentication. You can do this using the Exchange Management Console or the Exchange Management Shell.

Before you configure authentication, make sure you understand the process for configuring Secure Sockets Layer (SSL) for the server that has the Client Access server role installed. For more information about how to help secure communications, read the following topics:

- Securing Client Access Servers
- Managing SSL for a Client Access Server
- Install an SSL Certificate on a Client Access Server

Authentication Options for POP3 and IMAP4

There are three authentication options that you can use with POP3 and IMAP4. These options are configured when you use the EMC or the **Set-PopSettings** and **Set-ImapSettings** cmdlets in the Shell. The default ports to use differ depending on the authentication setting that you're using.

The following table lists the different authentication methods that can be used with POP3 and IMAP4 and the default ports for each method.

Authentication options for POP3 and IMAP4

Authentication method	Value	Default port	Description
PlainTextLogin	1	110 (POP3) 995 (POP3 SSL) 143 (IMAP4) 993 (IMAP4 SSL)	TLS encryption is not required on port 110. User name and password are sent unencrypted unless the underlying connection is encrypted by using TLS or SSL. For IMAP4, this corresponds to using the "login" command to authenticate to the Exchange 2010 computer that has the Mailbox server role installed.

PlainTextAuthentication	2	110 (POP3) 995 (POP3 SSL) 143 (IMAP4) 993 (IMAP4 SSL)	TLS encryption is not required on port 110 and port 143. However, Basic authentication is permitted only on a port that uses TLS or SSL encryption. For IMAP4, this corresponds to using the "authenticate" command to authenticate to the Mailbox server.
SecureLogin	3	110 (POP3) 995 (POP3 SSL) 143 (IMAP4) 993 (IMAP4 SSL)	Connection on port 110 and port 143 must use TLS encryption before authenticating.

Note:
Integrated Windows authentication (NTLM) isn't supported for POP3 or IMAP4 connections in the RTM version of Exchange 2010. Support for NTLM authentication for POP3 and IMAP4 connections was brought back in Exchange 2010 SP1. For more information, see Discontinued Features from Exchange 2007 to Exchange 2010 RTM.

1.6.3.4.2.1 Configure Authentication for POP3

Configure Authentication for POP3

Securing Client Access Servers > Managing POP3 and IMAP4 Security > Configuring Authentication for POP3 and IMAP4 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the EMC and the Shell to configure the authentication options for POP3.

Note:
After you've configured authentication for POP3, you must restart the POP3 service. For information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure POP3 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **POP3** and then, in the action pane, under **POP3**, click **Properties**.
4. On the **POP3 Properties** page, click the **Authentication** tab.
5. Under **Logon Method**, select one of the following:
   5.a. **Plain text logon** (Basic authentication) No TLS connection is required for the client to authenticate to the server.
   5.b. **Plain text authentication logon** (Integrated Windows authentication) No TLS connection is required for the client to authenticate to the server.
   5.c. **Secure logon** A TLS connection is required for the client to authenticate to the server.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to configure authentication for POP3

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example allows Basic authentication on an unsecured port if you won't be using TLS encryption.

```
Set-PopSettings -LoginType PlainTextLogin
```

This example restricts Basic authentication to use only secured ports if you won't be using TLS encryption.

```
Set-PopSettings -LoginType PlainTextAuthentication
```

This example allows authentication after you use TLS encryption.

```
Set-PopSettings -LoginType SecureLogin
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you configure authentication for POP3, you may also want to:

- Configure Ports for POP3 Authentication
- Set Connection Limits for POP3

1.6.3.4.2.2 Configure Authentication for IMAP4

Configure Authentication for IMAP4

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure the authentication options for IMAP4.

Note:

After you've configured authentication for IMAP4, you must restart the IMAP4 service. For

information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure IMAP4 to use TLS or SSL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **IMAP4**, click **Properties**.
4. On the **IMAP4 Properties** page, click the **Authentication** tab.
5. Under **Logon Method**, select one of the following:
   - 5.a. **Plain text logon** (Basic authentication) No TLS connection is required for the client to authenticate to the server.
   - 5.b. **Plain text authentication logon** (Integrated Windows authentication) No TLS connection is required for the client to authenticate to the server.
   - 5.c. **Secure logon** A TLS connection is required for the client to authenticate to the server.
6. Click **Apply**, and then click **OK** to save your changes.

Use the Shell to configure authentication for IMAP4

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example allows Basic authentication on an unsecured port if you won't be using TLS encryption,

```
Set-ImapSettings -LoginType PlainTextLogin
```

This example restricts Basic authentication to use only secured ports if you won't be using TLS encryption.

```
Set-ImapSettings -LoginType PlainTextAuthentication
```

This example allows authentication after you use TLS encryption.

```
Set-ImapSettings -LoginType SecureLogin
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you configure authentication for IMAP4, you may also want to:

- Configure Ports for IMAP4 Authentication
- Set Connection Limits for IMAP4

1.6.3.4.2.3 Configure Ports for POP3 Authentication

Configure Ports for POP3 Authentication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure Exchange to use ports other than the default ports for POP3 authentication.

Note:

After you've configured ports for POP3 authentication, you must restart the POP3 service. For more information about how to restart the POP3 service, see Start and Stop the POP3 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure ports for POP3 authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **POP3**, click **Properties**.
4. On the **Binding** tab, do one of the following:
   - To configure ports for TLS or unencrypted connections, under **TLS or Unencrypted Connections**, click **Edit**. Under **Port to Use**, in the box next to **Port**, enter a port number.
   - To configure ports for SSL connections, under **Secure Sockets Layer (SSL) Connections**, click **Edit**. Under **Port to Use**, in the box next to **Port**, enter a port number.
5. Click **OK** to save your changes.

Use the Shell to configure ports for POP3 authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the port for unencrypted or TLS POP3 connections to a value other than the default port number.

```
Set-PopSettings -UnencryptedOrTLSBindings IPaddress:Port
```

This example sets the port for SSL POP3 connections to a value other than the default port number.

```
Set-PopSettings -SSLBindings IPaddress:Port
```

For more information about syntax and parameters, see Set-PopSettings.

Other Tasks

After you configure ports for POP3 authentication, you may also want to:

- Configure Ports for IMAP4 Authentication

1.6.3.4.2.4 Configure Ports for IMAP4 Authentication

Configure Ports for IMAP4 Authentication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to configure Exchange to use ports other than the default ports for IMAP4 authentication.

Note:

After you've configured ports for IMAP4 authentication, you must restart the IMAP4 service. For information about how to restart the IMAP4 service, see Start and Stop the IMAP4 Service.

Looking for other management tasks related to setting up POP3 and IMAP4? Check out Managing POP3 and IMAP4.

Use the EMC to configure ports for IMAP4 authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration > Client Access**.
2. In the work pane, click the **POP3 and IMAP4** tab.
3. Select **IMAP4** and then, in the action pane, under **IMAP4**, click **Properties**.
4. On the **Binding** tab, do one of the following:
   - 4.a. To configure ports for TLS or unencrypted connections, under **TLS or Unencrypted Connections**, click **Edit**. Under **Port to Use**, in the box next to **Port**, enter a port number.
   - 4.b. To configure ports for SSL connections, under **Secure Sockets Layer (SSL) Connections**, click **Edit**. Under **Port to Use**, in the box next to **Port**, enter a port number.
5. Click **OK** to save your changes.

Use the Shell to configure ports for IMAP4

authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "POP3 and IMAP4" entry in the Client Access Permissions topic.

This example sets the port for unencrypted or TLS IMAP4 connections to a value other than the default port number.

```
Set-ImapSettings -UnencryptedOrTLSBindings IPaddress:Port
```

This example sets the port for SSL IMAP4 connections to a value other than the default port number.

```
Set-ImapSettings -SSLBindings IPaddress:Port
```

For more information about syntax and parameters, see Set-ImapSettings.

Other Tasks

After you configure ports for IMAP4 authentication, you may also want to:

- Configure Ports for POP3 Authentication

1.6.3.5 Managing Outlook Web App Security

Managing Outlook Web App Security

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-25*

This topic describes the authentication methods that you can use to help secure Outlook Web App on computers running Microsoft Exchange Server 2010 that have the Client Access server role installed.

Looking for management tasks related to securing client access? See Securing Client Access Servers.

Contents

Authentication Methods

You can configure the following types of authentication methods on an Exchange 2010 Client Access server:

- Standard
- Forms-based authentication

In addition, you can use the following types of authentication:

- Microsoft Internet Security and Acceleration (ISA) Server forms-based authentication
- Smart card and certificate authentication
- RSA SecurID authentication

Standard and Forms-Based Authentication

You can configure standard and forms-based authentication methods for Outlook Web App by using the Exchange Management Console or the Exchange Management Shell.

- **Standard authentication methods** Standard authentication methods include Integrated Windows authentication, Digest authentication, and Basic authentication. For more information about how to configure standard authentication methods, see Setting Up Standard Authentication Methods for Outlook Web App.
- **Forms-based authentication** Forms-based authentication creates a sign in page for Outlook Web App. Forms-based authentication uses cookies to store encrypted user sign in credentials and password information. For more information about forms-based authentication, see Setting Up Forms-Based Authentication for Outlook Web App.

If you configure multiple authentication methods, Internet Information Services (IIS) uses most restrictive method first. IIS then searches the list of available authentication protocols starting with the most restrictive until an authentication method that is supported by the client and the server is found.

The following table compares the standard and forms-based authentication methods using security level, handling of user sign-in credentials, and client requirements as the criteria.

Comparison of standard and forms-based authentication

Authentication method	Security level	How passwords are sent	Client requirements
Basic authentication	Low (unless Secure Sockets Layer (SSL) is enabled)	Base 64-encoded clear text	All browsers support Basic authentication.
Digest authentication	Medium	Hashed by using MD5.	Microsoft Internet Explorer 5 through Internet Explorer 8.
Integrated Windows authentication	Low (unless SSL is enabled)	Hashed when Integrated Windows authentication is used; Kerberos ticket when Kerberos is used. Integrated Windows authentication includes the Kerberos and NTLM authentication methods.	Internet Explorer 2.0 through Internet Explorer 8 for Integrated Windows authentication. Windows 2000 Server or Windows Server 2008 with Internet Explorer 5 through Internet Explorer 8 for Kerberos.
Forms-based authentication	High	Encrypts user authentication information and stores it in a cookie. Requires SSL to keep	Internet Explorer

		the cookie secure.	

Return to top

Other Authentication Methods

There are other authentication methods that you can use to help secure Outlook Web App. These methods include:

- **ISA Server forms-based authentication** Using ISA Server, you can securely publish Outlook Web App servers by using mail server publishing rules. ISA Server also lets you configure forms-based authentication and control e-mail attachment availability to help protect resources for your organization when they're accessed through Outlook Web App. For more information about how to use ISA Server as an advanced firewall solution, see the Internet Security and Acceleration Server Web site.
- **Smart card and certificate authentication** Certificates can reside either in the certificate store on a client computer or on a smart card. A certificate authentication method uses the Extensible Authentication Protocol (EAP) and Transport Layer Security (TLS) protocols. In EAP-TLS certificate authentication, the client and the server prove their identities to one another. For example, an Outlook Web App client on a user's computer presents its user certificate to the Client Access server, and the Client Access server presents its computer certificate to the Outlook Web App client computer. This provides mutual authentication. For more information about smart card and other certificate authentication methods, see Windows Server 2008 and Windows Server 2008 R2
- **RSA SecurID authentication** You can use the third-party product, RSA SecurID, to configure RSA SecurID authentication methods on the Client Access server. For more information about RSA SecurID, see http://www.rsasecurity.com.

1.6.3.5.1 Configure Outlook Web App Virtual Directories to Use SSL

Configure Outlook Web App Virtual Directories to Use SSL

Client Access > Securing Client Access Servers > Managing Outlook Web App Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Internet Information Services (IIS) Manager to configure Outlook Web App virtual directories to use Secure Sockets Layer (SSL). By default, when you install the Client Access server role, an Outlook Web App virtual directory named \owa is created in the default IIS Web site on the Exchange server. By default, this virtual directory and the default Web site are configured to require SSL.

If you want to use SSL to help secure additional Outlook Web App virtual directories or Web sites that you've created, you must do so manually. To configure a site to use SSL, you must obtain a certificate and configure the Web site or virtual directory to require SSL by using that certificate.

Looking for other management tasks related to security for Outlook Web App? Check out

Managing Outlook Web App Security.

Prerequisites

Identify the SSL certificate that you'll use. For more information about how to obtain and manage SSL certificates, see Managing SSL for a Client Access Server.

Use IIS Manager to configure SSL on Outlook Web App virtual directories

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "IIS Manager" entry in the Client Access Permissions topic.

1. In IIS Manager, select the **Default Web site** or the Web site where you're hosting your Outlook Web App virtual directories.
2. On the web site **Home**, double-click **SSL Settings**.
3. In **SSL Settings**, select **Require SSL**. **Require 128-bit SSL** is optional, but if checked it will provide greater security.

   Note:

   If you're using an SSL certificate that was created during Exchange Setup, an error message will appear to notify you that the certificate isn't a trusted certificate. Make sure that you trust the certification authority (CA) that issued the certificate or use an SSL certificate that's trusted by your CA.
4. Under **Client Certificates**, select **Ignore**.
5. In the action pane, click **Apply** to save your changes.

After you complete this procedure, all Outlook Web App virtual directories on the Web site for which you haven't explicitly disabled SSL will be configured to use SSL.

Other Tasks

After you configure SSL on Outlook Web App virtual directories, you may also want to review:

- Setting Up Forms-Based Authentication for Outlook Web App
- Outlook Web App and S/MIME

1.6.3.5.2 Setting Up Forms-Based Authentication for Outlook Web App

Setting Up Forms-Based Authentication for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-10*

Forms-based authentication enables a sign-in page for Exchange Server 2010 Outlook Web App that uses a cookie to store a user's encrypted sign-in credentials in the Internet browser. Tracking the use of this cookie enables the Exchange server to monitor the activity of Outlook Web App sessions on public and private computers. If a session is inactive for too long, the server blocks access until the user re-authenticates.

Contents

Using Cookies to Control Access

The first time that the user name and password are sent to the Client Access server to authenticate an Outlook Web App session, an encrypted cookie is created that's used to track user activity. When the user closes the Internet browser or clicks **Sign Out** to sign out of their Outlook Web App session, the cookie is cleared. The user name and password are sent to the Client Access server only for the initial user sign-in. After the initial sign-in is complete, only the cookie is used for authentication between the client computer and the Client Access server.

Setting the Value for Cookie Time-Out on Public Computers

By default, when a user selects the **This is a public or shared computer** option on the Outlook Web App sign-in page, the cookie on the computer expires automatically and the user is signed out when they haven't used Outlook Web App for 15 minutes.

Automatic time-out is valuable because it helps protect users' accounts from unauthorized access. To match the security requirements of your organization, you can configure the inactivity time-out values on the Exchange Client Access server.

Although automatic time-out greatly reduces the risk of unauthorized access, it doesn't eliminate the possibility that an unauthorized user might access an Outlook Web App account if a session is left running on a public computer. Therefore, make sure to warn users to take precautions to avoid risks. For example, tell them to sign out from Outlook Web App and close the Web browser when they've finished using Outlook Web App.

For more information about how to configure cookie time-out values for public computers, see Set the Forms-Based Authentication Public Computer Cookie Time-Out Value.

Setting the Value for Cookie Time-Out on Private Computers

When a user selects the **This is a private computer** option on the Outlook Web App sign-in page, the Exchange server allows a longer period of inactivity before automatically ending the Outlook Web App session. The default time-out value for private sign-in is eight hours. Because of the relationship between the recycle time of encryption keys and the time-out value configured on the server, the actual default time-out value for private sign-in can be between eight to twelve hours. For more information, see Understanding Encryption for User Sign-in from Public and Private Computers. The private computer cookie time-out option is intended to benefit Outlook Web App users who are using their own computer or a computer that's on a corporate network.

It's important to warn users about the risks associated with selecting the **This is a private computer** option. A user should select the private computer option only if they are the sole operator of the computer and the computer complies with the security policies for your organization.

For more information about how to configure cookie time-out values for private computers, see Set the Forms-Based Authentication Private Computer Cookie Time-Out

Value.

Return to top

Determining User Activity

After an Outlook Web App session has been inactive for a certain period of time, the Client Access server no longer has the decryption key to read the cookie and the user will be denied access until they authenticate again.

Exchange 2010 uses the following information to determine user activity:

- Interaction between the client computer and the Client Access server that's initiated by the user is considered activity. For example, if a user opens, sends, or saves an item; switches folders or modules; or updates the view or the Web browser window, Exchange 2010 considers this to be activity.

  Note:
  Interaction between the client computer and the server that's automatically generated by the Client Access server isn't considered activity. For example, new e-mail notifications and reminders that are generated by the Client Access server in an Outlook Web App session aren't considered activity.

- In Outlook Web App, any user interaction, including entering text in an e-mail message or meeting request, is considered activity. In the light version of Outlook Web App, any user activity other than entering text is considered activity.

Configuring the Sign-in Prompt Used by Forms-Based Authentication

Instead of a pop-up window, forms-based authentication creates a sign-in page for Outlook Web App. You can configure the sign-in prompt for forms-based authentication using the Exchange Management Console or the Exchange Management Shell. The configuration changes you make change only the text of the sign-in prompt. They don't change the format in which the user must sign in. For example, you can configure the forms-based authentication sign-in page to prompt users to provide their sign-in information in the format domain\user name. However, a user can also enter his or her user principal name (UPN) and the sign-in will be successful.

The following types of sign-in prompts can be used by forms-based authentication on the Outlook Web App sign-in page. Select the prompt that will be easiest for your users to understand and use.

- **Full Domain** The domain and user name of the user in the format domain \user name. For example, Contoso\Kweku.
- **Principal Name** The UPN. The UPN has two parts: the UPN prefix that's the user account name and the UPN suffix that's the DNS domain name. The prefix and the suffix are joined by the at (@) sign to make the complete UPN. For example, Kweku@contoso.com. Users can access Outlook Web App by entering their primary e-mail address or by entering their UPN.
- **User Name** The user name only. The domain name isn't included. For example, Kweku. This sign-in format will work only if the domain name has been configured.

  Note:
  If necessary, you can change the format the user must use to sign in to Outlook Web App by configuring Active Directory and Internet Information Services (IIS). Using Active Directory and IIS to set which user name formats users can enter to be authenticated is independent of the Outlook Web App

forms-based authentication prompt discussed earlier.

Return to top

Understanding Encryption for User Sign-in from Public and Private Computers

Encryption of user sign-in credentials for both public and private Outlook Web App sign-in types involves a set of six Hashed-based Message Authentication Codes (HMACs). HMACs are 160-bit keys that are generated on the Client Access server. HMACs improve sign-in security by combining hashing algorithms with cryptographic functions to encrypt user sign-in credentials. Encryption and decryption of a cookie are performed by the same Client Access server. Only the Client Access server that generated the authentication key has the key to decrypt that cookie.

When forms-based authentication is used, the Client Access server cycles through a set of three keys for each type of sign-in, public and private, at a set rate. This is known as the recycle time. The recycle time for a key is one-half of the time-out value for the sign-in. For example, when the time-out value for the public sign-in is set to 15 minutes, the public key recycle time is 7.5 minutes.

The six sign-in keys are created by the Client Access server when the Outlook Web App virtual directories are started. Three are used with public computer sign-ins, and three are used with private computer sign-ins. When a user signs in, the current key for their sign-in type is used to encrypt the user's authentication information into a cookie.

When the recycle time has passed, the Client Access server moves to the next key. After all three keys for a type of sign-in have been used, the Client Access server deletes the oldest key and creates a new one. The Client Access server always keeps three keys available for each sign-in type: the current key and the two most recent keys. The recycling of keys continues as long as Outlook Web App is running on the Client Access server. The same keys are used for all users.

Any cookie that has been encrypted by using an active key will be accepted. When a user activity request is received by the Client Access server, the cookie for that request is replaced with a new cookie that's been encrypted by using the newest key. A user session is timed out when the cookie associated with it is encrypted by an older key that's been discarded.

Because of the relationship between the recycle time of encryption keys and user time-out configured on the server, the actual time-out period for a user can be between the configured time-out and the configured time-out plus one-half of that value. For example, if the configured time-out is 30 minutes, the actual time-out for any user session may be between 30 minutes and 45 minutes.

The following table provides information about the cookie time-out and authentication key recycling time based on a user sign-in from a public or private computer.

Default cookie time-out and authentication key recycling time for each user sign-in type

Sign-in	Cookie time-out value	Recycle time for authentication key if you use the default time-out value
Public	One minute to 30 days. The default is 15 minutes.	7.5 minutes

Private	One minute to 30 days. The default is 8 hours.	4 hours

Note:
You can configure the cookie time-out value in minutes by using the registry. The recycle time of the authentication key is at least one-third, and not more than one-half, that of the cookie time-out value.

Return to top

Using SSL to Help Secure Outlook Web App

By default, Secure Sockets Layer (SSL) encryption is turned on when you install the Client Access server role. If SSL isn't used, the user name and password will be sent in clear text at initial sign-in. When SSL is used, it encrypts all communications between the client computer and the Client Access server and helps prevent sensitive information, such as user names, passwords, and e-mail messages, from being viewed by third parties.

Return to top

1.6.3.5.2.1 Configure Forms-Based Authentication for Outlook Web App

Configure Forms-Based Authentication for Outlook Web App

Securing Client Access Servers > Managing Outlook Web App Security > Setting Up Forms-Based Authentication for Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure forms-based authentication and the sign-in prompt that's used by forms-based authentication on an Outlook Web App virtual directory on a Client Access server.

Forms-based authentication gives you three options for the default sign-in format. These options change only the text on the Outlook Web App sign-in page. They don't cause a particular format to be required. The user can use any of the standard sign-in formats regardless of the text on the page.

- **FullDomain** This is the domain and user name of the user in the format domain\user name. For example, for a user named Kweku in the domain Contoso, the sign-in would be contoso\kweku.
- **PrincipalName** If user principal name (UPN) sign-in format is specified, the **User Name** field on the Outlook Web App sign-in page guides the user to enter their e-mail address. For example, kweku@contoso.com. Users can access Outlook Web App by entering their primary e-mail address or by entering their UPN.
- **UserName** This is the user name only and doesn't include the domain name. For example, Kweku. If you use the *UserName* sign-in prompt for forms-based authentication, you must also specify the *DefaultDomain* property. The *DefaultDomain* property determines the default domain to use when a user tries to access Outlook Web App. For example, if the default domain is Contoso, and a domain user named Kweku signs in to Outlook Web App, only Kweku must be entered as the user name. The server will use the default

domain Contoso. If the user isn't a member of the Contoso domain, the domain and user name must be entered.

Looking for other management tasks related to forms-based authentication? Check out Setting Up Forms-Based Authentication for Outlook Web App.

Use the EMC to configure forms-based authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, select **Server Configuration**, select **Client Access**, select the server that hosts the Outlook Web App virtual directory, and then click the **Outlook Web App** tab.
2. In the work pane, select the virtual directory that you want to configure to use forms-based authentication, and then click **Properties**.
3. Click the **Authentication** tab.
4. Select **Use forms-based authentication**.
5. Select the sign-in format that you want to use.

Note:

You must restart Internet Information Services (IIS) by using the command `iisreset/noforce` for these changes to take effect.

Use the Shell to configure forms-based authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures forms-based authentication on an Outlook Web App virtual directory in the default IIS Web site on the local Exchange server.

```
Set-owavirtualdirectory -identity "owa (default web site)" -FormsAuthentication:$
```

Use the Shell to configure the default sign-in method used by forms-based authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures a full domain sign-in format,

```
Set-owavirtualdirectory -identity "owa (default web site)" -LogonFormat FullDomai
```

This example configures a UPN sign-in format.

```
Set-owavirtualdirectory -identity "owa (default web site)" -LogonFormat Principal
```

This example configures a user name sign-in format and sets the default domain.

```
Set-owavirtualdirectory -identity "owa (default web site)" -LogonFormat UserName
```

Note:
You must restart IIS by using the command `iisreset/noforce` for these changes to take effect.

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure forms-based authentication for Outlook Web App, you may also want to:

- Configure Outlook Web App Virtual Directories to Use SSL
- Set the Forms-Based Authentication Private Computer Cookie Time-Out Value
- Set the Forms-Based Authentication Public Computer Cookie Time-Out Value

1.6.3.5.2.2 Set the Forms-Based Authentication Public Computer Cookie Time-Out Value

Set the Forms-Based Authentication Public Computer Cookie Time-Out Value

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to configure the cookie time-out values for public computers by using forms-based authentication on an Outlook Web App virtual directory on a Microsoft Exchange Server 2010 Client Access server.

Caution:
Although automatic time-out reduces the risk of unauthorized access, it doesn't completely eliminate the possibility that an unauthorized user might access an Exchange mailbox if a session is left running on a public computer. Therefore, make sure to warn users to take precautions to avoid risks.

Looking for other management tasks related to forms-based authentication? Check out Setting Up Forms-Based Authentication for Outlook Web App.

Prerequisites

Note:
The Outlook Web App virtual directory must be configured to use forms-based authentication.

Caution:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Use Registry Editor to set the cookie time-out values for public computers using forms-based authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Registry Editor" entry in the Client Access Permissions topic.

1. On the Client Access server, sign in by using the Exchange administrator account, and then start Registry Editor (regedit).
2. In Registry Editor, locate the following registry key: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA**
3. On the **Edit** menu, point to **New**, and then click **DWORD Value**. In the details pane, name the new value **PublicTimeout**.
4. Right-click the **PublicTimeout** DWORD value, and then click **Modify**.
5. In **Edit DWORD Value**, under **Base**, click **Decimal**.
6. In the **Value Data** box, type a value in minutes between 1 and 43,200 for a maximum of 30 days. Click **OK**.

Note:

You must restart the Forms-Based Authentication service for the changes to take effect. On the Client Access server, go to **Start** > **Administrative Tools** > **Services**. In Services, right-click **Microsoft Exchange Forms-Based Authentication service**, and then click **Restart**.

Use the Shell to set the cookie time-out values for public computers using forms-based authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App mailbox policies" entry in the Client Access Permissions topic.

This example sets the public computer cookie time-out value.

```
set-ItemProperty 'HKLM:\SYSTEM\CurrentControlSet\Services\MSExchange OWA' -name P
```

Note:

You must restart the Forms-Based Authentication service for the changes to take effect. On the Client Access server, go to **Start** > **Administrative Tools** > **Services**. In Services, right-click **Microsoft Exchange Forms-Based Authentication service**, and then click **Restart**.

This example lets you view the public computer cookie time-out value.

```
get-ItemProperty 'HKLM:\SYSTEM\CurrentControlSet\Services\MSExchange OWA' -name P
```

Other Tasks

After you set the cookie time-out values for public computers using forms-based authentication, you may also want to:

- Configure Outlook Web App Virtual Directories to Use SSL

1.6.3.5.2.3 Set the Forms-Based Authentication Private Computer Cookie Time-Out Value

Set the Forms-Based Authentication Private Computer Cookie Time-Out Value

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can set the cookie time-out values for private computers by using forms-based authentication on an Outlook Web App virtual directory in Microsoft Exchange Server 2010. Private computers are also known as trusted computers.

Caution:

It's important that you warn users of the risks associated with selecting the **This is a private computer** option. A user should select **This is a private computer** only if the user is the sole operator of the computer and the computer complies with your organization's security policies.

Looking for other management tasks related to forms-based authentication? Check out Setting Up Forms-Based Authentication for Outlook Web App.

Prerequisites

The Outlook Web App virtual directory is configured to use forms-based authentication.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Use Registry Editor to set the cookie time-out values for private computers using forms-based authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Registry Editor" entry in the Client Access Permissions topic.

1. On the Exchange Client Access server, sign in by using your Exchange administrator account, and then start Registry Editor (regedit).
2. In Registry Editor, locate the following registry key: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchange OWA**
3. On the **Edit** menu, point to **New**, and then click **DWORD Value**. In the details pane, name the new value **PrivateTimeout**.
4. Right-click the **PrivateTimeout** DWORD value, and then click **Modify**.
5. In **Edit DWORD Value**, under **Base**, click **Decimal**.
6. In the **Value Data** box, type a value in minutes between 1 and 43,200 for a maximum of 30 days. Click **OK**.

Note:

You must restart the Forms-Based Authentication service for the changes to take effect. On the Client Access server, go to **Start** > **Administrative Tools** > **Services**. In Services, right-click **Microsoft Exchange Forms-Based Authentication service** and click **Restart**.

Use the Shell to set the cookie time-out values for private computers using forms-based authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example sets the private computer cookie time-out value.

```
set-ItemProperty 'HKLM:\SYSTEM\CurrentControlSet\Services\MSExchange OWA' -name P
```

Note:

You must restart the Forms-Based Authentication service for the changes to take effect. On the Client Access server, go to **Start** > **Administrative Tools** > **Services**. In Services, right-click **Microsoft Exchange Forms-Based Authentication service** and click **Restart**.

This example lets you view the private computer cookie time-out value.

```
get-ItemProperty 'HKLM:\SYSTEM\CurrentControlSet\Services\MSExchange OWA' -name P
```

Other Tasks

After you set the cookie time-out values for private computers using forms-based authentication, you may also want to:

- Configure Outlook Web App Virtual Directories to Use SSL

1.6.3.5.3 Setting Up Standard Authentication Methods for Outlook Web App

Setting Up Standard Authentication Methods for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Standard authentication methods can help secure Microsoft Exchange Server 2010 Client Access servers for Outlook Web App.

In Exchange 2010, Client Access servers support Integrated Windows authentication and HTTP 1.1 Digest authentication for Exchange 2010 virtual directories. Exchange 2010 virtual directories on a server that's running only the Client Access server role support only Basic and forms-based authentication.

Standard authentication methods include Basic authentication, Digest authentication, and Integrated Windows authentication.

Note:
By default, Exchange 2010 enables forms-based authentication.

Contents

Basic Authentication

Basic authentication is a simple authentication mechanism that's defined by the HTTP specification that encodes a user's sign-in name and password before the user's credentials are sent to the server.

Basic authentication doesn't support single sign-on. Windows Server 2008 authentication enables single sign-on to all network resources. With single sign-on, a user can sign in to the domain one time by using a single password or smart card and authenticate to any computer in the domain.

Basic authentication is supported by all Web browsers but isn't secure unless you require Secure Sockets Layer (SSL) encryption.

Digest Authentication

Digest authentication transmits passwords over the network as a hash value for additional security. Digest authentication can be used only in Windows Server 2008, Windows Server 2003, and Microsoft Windows 2000 Server domains for users who have an account that's stored in Active Directory. For more information about Digest authentication, see the Windows Server 2008 and Internet Information Services (IIS) Manager documentation.

Digest authentication is available only on Exchange 2010 virtual directories.

Important:
If you're using Digest or Basic authentication, when a user uses a kiosk, caching credentials can pose a security risk if the user can't close the browser and end the browser process between sessions. This risk occurs because a user's credentials remain in the cache when the next user accesses the kiosk. To enable Outlook Web App on a kiosk, make sure that the user can close the browser between sessions and end the browser processes. Otherwise, consider using a third-party product that incorporates two-factor authentication, in which the user must present a physical token together with a password to use Outlook Web App on the kiosk.

Integrated Windows Authentication

Integrated Windows authentication requires that users have a valid Windows Server 2008, Windows Server 2003, or Windows 2000 Server user account name and password to access information. Users signed in to the local network aren't prompted for their user names and passwords. Instead, the server negotiates with the Windows security packages that are installed on the client computer. This method enables the server to authenticate users without prompting them for sign-in information. The authentication credentials are protected, but all other communication will be sent in clear text unless SSL is used.

On an Exchange 2010 server on which only the Client Access server role is installed, Integrated Windows authentication can be used only with Exchange 2010 virtual directories. On a server that has both the Client Access and Mailbox roles installed, Integrated Windows authentication can be used with any virtual directory. For more information about Integrated Windows authentication, see the Windows Server 2008 documentation.

Note:
Integrated Windows authentication is supported only on computers that are running a Windows operating system and Internet Explorer. Integrated Windows authentication may work with other Web browsers if they've been configured to pass the user's sign-in credentials to the server that's requesting authentication.

1.6.3.5.3.1 Configure Integrated Windows Authentication

Configure Integrated Windows Authentication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Integrated Windows authentication for Outlook Web App in Microsoft Exchange Server 2010. Integrated Windows authentication enables the server to authenticate users who are signed in to the network without prompting them for their user name and password and without transmitting information that isn't encrypted over the network.

Note:
Integrated Windows authentication can be set only on Exchange 2010 virtual directories on an Exchange 2010 server that has only the Client Access server role installed. Integrated Windows authentication can be set on any Outlook Web App virtual directory on an Exchange 2010 server that has both the Client Access and Mailbox server roles installed.

Looking for other management tasks related to standard authentication for Outlook Web App? Check out Setting Up Standard Authentication Methods for Outlook Web App.

Use the EMC to configure Integrated Windows authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, locate the virtual directory that you want to configure to use Integrated Windows authentication by using the information in step 2 or step 3.
2. Select **Server Configuration**, select **Client Access**, select the server hosting the Outlook Web App virtual directory, and then click the **Outlook Web App** tab.
3. In the work pane, select the virtual directory that you want to configure to use Integrated Windows authentication, and then click **Properties**.
4. Click the **Authentication** tab.

5. Select **Use one or more standard authentication methods**.
6. Select **Integrated Windows authentication**.
7. Click **OK**.

Use the Shell to configure Integrated Windows authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures Integrated Windows authentication on the default Outlook Web App virtual directory in the default Internet Information Services (IIS) Web site on the local Exchange server.

```
Set-OwaVirtualDirectory -Identity "owa (Default Web Site)" -WindowsAuthentication
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure Integrated Windows authentication for Outlook Web App, you may also want toConfigure Outlook Web App Virtual Directories to Use SSL.

1.6.3.5.3.2 Configure Basic Authentication

Configure Basic Authentication

Securing Client Access Servers > Managing Outlook Web App Security > Setting Up Standard Authentication Methods for Outlook Web App >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Windows Basic authentication for Outlook Web App in Microsoft Exchange Server 2010. Basic authentication sends the user's sign-in name and password in clear text and shouldn't be used without using Secure Sockets Layer (SSL) encryption between the client computers and the computer that has the Client Access server role installed.

Looking for other management tasks related to standard authentication for Outlook Web App? Check out Setting Up Standard Authentication Methods for Outlook Web App.

Use the EMC to configure Basic authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, locate the virtual directory that you want to configure to use Basic authentication by using the information in step 2 or step 3.

2. Select **Server Configuration**, select **Client Access**, select the server hosting the Outlook Web App virtual directory, and then click the **Outlook Web App** tab.
3. In the work pane, select the virtual directory that you want to configure to use Basic authentication, and then click **Properties**.
4. Click the **Authentication** tab.
5. Select **Use one or more standard authentication methods**.
6. Select **Basic authentication**.
7. Click **OK**.

Use the Shell to configure Basic authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures Basic authentication on the default Outlook Web App virtual directory in the default Internet Information Services (IIS) Web site on the local Exchange server.

```
Set-OwaVirtualDirectory -Identity "owa (Default Web Site)" -BasicAuthentication <
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Other Tasks

After you configure Basic authentication for Outlook Web App, you may also want to Configure Outlook Web App Virtual Directories to Use SSL.

1.6.3.5.3.3 Configure Digest Authentication

Configure Digest Authentication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Windows Digest authentication for Outlook Web App in Microsoft Exchange Server 2010. Digest authentication transmits passwords over the network as a hash value for additional security. Digest authentication isn't fully secure if the user is unable to close the browser and end the browser process between sessions. This problem may occur if the user is using Outlook Web App on a kiosk. If the browser can't be closed, the user's credentials remain in the cache where the next user may be able to access them.

Note:

Digest authentication can be set only on Exchange 2010 virtual directories.

Looking for other management tasks related to security for Outlook Web App? Check out Managing Outlook Web App Security.

Use the EMC to configure Digest authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, locate the virtual directory that you want to configure to use Digest authentication by using the information in step 2 or step 3.
2. Select **Server Configuration**, select **Client Access**, select the server hosting the Outlook Web App virtual directory, and then click the **Outlook Web App** tab.
3. In the work pane, select the virtual directory that you want to configure to use Digest authentication, and then click **Properties**.
4. Click the **Authentication** tab.
5. Select **Use one or more standard authentication methods**.
6. Select **Digest authentication**.
7. Click **OK**.

Use the Shell to configure Digest authentication for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example configures Digest authentication on the default Outlook Web App virtual directory in the default Internet Information Services (IIS) Web site on the local Exchange server.

```
Set-OwaVirtualDirectory -Identity "owa (Default Web Site)" -DigestAuthentication
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

1.6.3.5.4 Outlook Web App and S/MIME

Outlook Web App and S/MIME

Client Access > Securing Client Access Servers > Managing Outlook Web App Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

S/MIME lets users encrypt outgoing messages and attachments so that only intended recipients who have a digital identification (ID), also known as a certificate, can read them. With S/MIME, users can digitally sign a message, which provides the recipients with a way to verify the identity of the sender and that the message hasn't been tampered with.

Contents

Supporting S/MIME

To support S/MIME in your Exchange organization, you must build a public key infrastructure (PKI).

A PKI is a system of digital certificates, certification authorities (CAs), and registration authorities (RAs) that verify and authenticate the validity of each party that is involved in an electronic transaction by using public key cryptography. When you implement a CA in an organization that uses Active Directory, you provide an infrastructure for certificate life-cycle management, renewal, trust management, and revocation. However, there is some additional cost involved in deploying servers and infrastructure to create and manage Microsoft Windows PKI-generated certificates.

Certificate Services is required to deploy a Windows PKI and can be installed through Add or Remove Programs in Control Panel. You can install Certificate Services on any server in the domain.

If you obtain certificates from a domain-joined Windows CA, you can use the CA to request or sign certificates to issue to the servers or computers on your network. This enables you to use a PKI that resembles a third-party certificate vendor, but is less expensive. Although these PKI certificates cannot be deployed publicly, as other types of certificates can be, when a PKI CA signs the requestor's certificate by using the private key, the requestor is verified. The public key of this CA is part of the certificate. A server that has this certificate in the trusted root certificate store can use that public key to decrypt the requestor's certificate and authenticate the requestor.

A PKI enables organizations to publish their own certificates. Clients can request and receive certificates from a PKI on the internal network. The PKI can renew or revoke certificates.

Requirements to Support S/MIME in Outlook Web App

S/MIME requires that users sign in to Outlook Web App using Microsoft Internet Explorer 7 or Internet Explorer 8. In addition to requiring Internet Explorer 7 or Internet Explorer 8, S/MIME also requires that Secure Sockets Layer (SSL) be used by the /owa virtual directory. S/MIME is not supported in Outlook Web App Light.

Using S/MIME in Outlook Web App

Users must have a digital ID and must install the S/MIME control for Outlook Web App before they can send encrypted and digitally-signed messages using Outlook Web App. They must also have a digital ID and the S/MIME control to read encrypted messages in Outlook Web App. The S/MIME control is necessary to verify the signature on a digitally-signed message.

The S/MIME control for Outlook Web App is installed on a user’s computer by using the SMIME tab in Options. After the user has received a digital ID and the S/MIME control has

been installed on their computer, they can use S/MIME to help secure e-mail mail messages.

Feature Additions and Limitations with S/MIME

When they use S/MIME, users gain additional features that are not otherwise available in Outlook Web App. These features include the ability to do the following:

- Attach messages to messages
- Paste images in messages
- Attach files by using a simpler UI and let users attach multiple files in a single operation.
- When they use S/MIME, users will encounter the following limitations:
- WebReady Document Viewing only works in clear-signed messages. It does not work in encrypted messages or in opaque-signed messages.
- When some content types are sent from Outlook as S/MIME messages, they cannot be displayed in Outlook Web App. Outlook Web App will display a banner in the message header when this happens.
- Most S/MIME features are not available when a user opens a folder in another mailbox or uses explicit sign-in to open another user's mailbox. The only S/MIME feature that is available in those cases is verification of digital signatures.

For More Information

Active Directory Certificate Services and Public Key Management

1.6.3.5.4.1 Enable or Disable S/MIME in Outlook Web App

Enable or Disable S/MIME in Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the EMC and the Shell to enable or disable use of Secure/Multipurpose Internet Mail Extensions (S/MIME) in Microsoft Office Outlook Web App. By default, S/MIME is enabled on the /owa virtual directory.

Looking for other management tasks related to security for Outlook Web App? Check out Managing Outlook Web App Security.

Use the EMC to enable or disable S/MIME in Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. At the top of the work pane, click the server that hosts the Outlook Web App

virtual directory.
3. In the work pane, select **owa (Default Web Site)**, and then, in the action pane, click **Properties**.
4. On the **owa (Default Web Site) Properties** page, click the **Segmentation** tab.
5. In the **Segmentation** window, find the **S/MIME** feature.
6. To enable or disable S/MIME, select **S/MIME**, and then click **Enable** or **Disable**.
7. Click **OK** to save your change, and then close the properties window.

Use the Shell to enable or disable S/MIME in Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Outlook Web App virtual directories" entry in the Client Access Permissions topic.

This example disables S/MIME on the Outlook Web App virtual directory named /owa in the default Internet Information Services (IIS) Web site on the local server.

```
Set-OWAVirtualDirectory -identity "owa (Default Web Site)" -SMimeEnabled $false
```

This example enables S/MIME.

```
Set-OWAVirtualDirectory -identity "owa (Default Web Site)" -SMimeEnabled $true
```

For information about syntax and parameters, see Set-OwaVirtualDirectory.

Note:
Availability of S/MIME in Outlook Web App can be controlled on a per-user basis by using the Set-CASMailbox cmdlet and the `OWASMimeEnabled` parameter.

Other Tasks

After you enable or disable S/MIME in Outlook Web App, you may also want to Manage S/MIME for Outlook Web App.

1.6.3.5.4.2 Manage S/MIME for Outlook Web App

Manage S/MIME for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can edit the registry on a Microsoft Exchange Server 2010 Client Access server so you can manage the behavior of Secure/Multipurpose Internet Mail Extensions (S/MIME) for Outlook Web App.

You can change the registry on an Exchange 2010 server that has the Client Access server role installed to control the behavior of S/MIME in Outlook Web App. These changes are made per server. If you have more than one Client Access server and need the same S/MIME behavior on all Client Access servers, you must make the same changes on each server. Changes to the S/MIME settings in the registry take effect immediately

and will affect Outlook Web App users the next time that they take any action that uses the S/MIME control. You do not have to force users to sign out or to restart any services.

Looking for other management tasks related to Outlook Web App security? Check out Managing Outlook Web App Security.

Prerequisites

If you're unfamiliar with managing public key infrastructures (PKIs) and certificates, we recommend that you start by reviewing the Active Directory Certificate Services and Public Key Management.

S/MIME Control Settings

The following tables list the names, possible values, defaults, and behavior of the registry settings that you can use to control the behavior of the S/MIME control in Outlook Web App.

Check CRL on Send

Exchange 2010 value name and type	CheckCRLOnSend (DWORD)
Exchange 2007 value name and type	CheckCRLOnSend (DWORD)
Exchange 2003 value name and type	CheckCRL (DWORD)
Values and defaults	1=True, 0=False (default)
Explanation	By default, if a certificate revocation list (CRL) distribution point in a sender's certificate chain cannot be accessed during revocation verification when sending signed or encrypted e-mail, Outlook Web App will not display a warning notifying the sender that the certificate cannot be verified. Instead, it allows the e-mail to be sent. When **CheckCRLonSend** is set to true, if a CRL distribution point in a sender's certificate chain cannot be accessed during revocation verification when sending signed or encrypted e-mail, Outlook Web App will indicate a failure and prevent the e-mail message from being sent.

Distribution List Expansion Timeout

Exchange 2010 value name and type	DLExpansionTimeout (DWORD)
Exchange 2007 value name and type	DLExpansionTimeout (DWORD)
Exchange 2003 value name and type	DLExpansionTimeout (DWORD)
Values and defaults	Distribution List Expansion Timeout represents the time that it will take, in milliseconds, before a request to expand a distribution list will time out. The default value is 60000 (60 seconds). The minimum

	value is 0. Setting **DLExpansionTimeout** to 0 disables the ability to send encrypted e-mail to distribution lists. The maximum value is 2147483647. When **DLExpansionTimeout** is set to the maximum value, there is no distribution list expansion time-out and Outlook Web App will wait until the distribution list is expanded, regardless of how long expansion takes.
Explanation	This attribute controls how long Outlook Web App will wait, in milliseconds, for a distribution list in Active Directory to expand when sending encrypted e-mail before the operation fails. When sending encrypted e-mail to a distribution list, Outlook Web App must expand the distribution list to retrieve the encryption certificate of each recipient for use in the encryption operation. The time this operation takes varies depending on the size of the distribution list and the performance of the underlying Active Directory infrastructure. While the distribution list is being expanded, the sender will receive no response from Outlook Web App. This attribute specifies how long Outlook Web App should wait for the full distribution list to be expanded. If the operation has not completed in the time specified by this value, the operation will fail and the mail will not be sent. The sender will be returned to the compose form, which will include an InfoBar that includes the following error message: The action could not be completed. Please try again. If the problem continues, contact technical support for your organization.

Use Secondary Proxies When Finding Certificates

Exchange 2010 value name and type	UseSecondaryProxiesWhenFindingCertificates (DWORD)
Exchange 2007 value name and type	UseSecondaryProxiesWhenFindingCertificates (DWORD)
Exchange 2003 value name and type	CertMatchingDoNotUseProxies (DWORD)
Values and defaults	1=True (default), 0=False
Explanation	Outlook Web App tries to find the correct certificate in Active Directory for a recipient when sending encrypted e-mail. The certificate subject or subject alternative name values can contain an SMTP address as one of its values. Because a recipient can have multiple SMTP proxy addresses in the directory, the subject or subject alternative

	name of the certificate may not match the primary SMTP address. Instead it may match one of the proxy addresses. If **UseSecondaryProxiesWhenFindingCertificates** is set to true, Outlook Web App will accept certificates that do not match the primary SMTP address of the recipient as valid. If **UseSecondaryProxiesWhenFindingCertificates** is set to false, Outlook Web App will accept as valid only certificates that match the primary SMTP address of the recipient.

CRL Connection Timeout

Exchange 2010 value name and type	CRLConnectionTimeout (DWORD)
Exchange 2007 value name and type	CRLConnectionTimeout (DWORD)
Exchange 2003 value name and type	RevocationURLRetrievalTimeout (DWORD)
Values and defaults	CRL Connection Timeout represents the time it will take, in milliseconds, before a CRL connection request will time out. The default value is 60000 (60 seconds). The minimum value is 5000 (5 seconds). A maximum value of 2147483647 can be specified. If **CRLConnectionTimeout** is set to the maximum value, the connection will not time out.
Explanation	CRL Connection Timeout specifies the time, in milliseconds, that Outlook Web App will wait while connecting to retrieve a single CRL as part of a certificate validation operation. Validating a certificate requires retrieving the certification authority's CRL from the CRL distribution point that is specified within the certificate. This operation must be performed for each certificate in the complete certificate chain. When multiple CRLs must be retrieved, this key will apply to each connection. For example, if three CRLs must be retrieved and **CRLConnectionTimeout** is set to 60 seconds, each CRL retrieval operation will have a time-out limit of 60 seconds. If the CRL is not retrieved before the time-out limit that is specified, the operation fails. If **CRLConnectionTimeout** is set to less than 5000, the default value (60000) will be used. If **CRLConnectionTimeout** is set to the maximum, 2147483647, the connection will not time out.

CRL Retrieval Timeout

Exchange 2010 value name and type	CRLRetrievalTimeout (DWORD)
Exchange 2007 value name and type	CRLRetrievalTimeout (DWORD)
Exchange 2003 value name and type	CertURLRetrievalTimeout (DWORD)
Values and defaults	CRL Retrieval Timeout specifies the time, in milliseconds, that Outlook Web App will wait while connecting to complete all of the CRL retrievals for a single message. The default value is 10000 (10 seconds). The minimum value is 0. The maximum value is 2147483647.
Explanation	This attribute resembles CRL Connection Timeout, however it specifies the time, in milliseconds, that Outlook Web App will wait to retrieve all CRLs when validating a certificate. If all CRLs are not retrieved before the time-out limit that is specified, the operation will fail. When you set this value, it is important to remember that, in a certificate validation operation, CRL Connection Timeout is applied to each CRL retrieval and to the overall operation of all CRL retrievals. For example, if three CRLs must be retrieved and **CRLConnectionTimeout** is set to 60 seconds, and **CRLRetrievalTimeout** is set to 120 seconds, each CRL retrieval operation will have a time-out of 60 seconds and the overall operation will have a time-out of 120 seconds. In this example, if any individual CRL retrieval takes more than 60 seconds, the operation will fail. Also, if all the CRL retrievals take more than 120 seconds, the operation will fail.

Disable CRL Check

Exchange 2010 value name and type	DisableCRLCheck (DWORD)
Exchange 2007 value name and type	DisableCRLCheck (DWORD)
Exchange 2003 value name and type	DisableCRLCheck (DWORD)
Values and defaults	1=True, 0=False (default)
Explanation	When set to true, **DisableCRLCheck** prevents CRLs from being checked while certificates are being validated. Disabling CRL checking can increase the time it takes to validate the signatures of signed e-mail. However, it will also show revoked e-mail signed with revoked certificates as valid instead of not valid.

Allow User Choice of Signing Certificate

Exchange 2010 value name and type	AllowUserChoiceOfSigningCertificate (DWORD)
Exchange 2007 value name and type	AllowUserChoiceOfSigningCertificate (DWORD)
Exchange 2003 value name and type	Not available. This was a new feature in Exchange 2007.
Values and defaults	1=True, 0=False (default)
Explanation	When set to true, **AllowUserChoiceOfSigningCertificate** lets users select which signing certificate to use to digitally sign e-mail when they use Outlook Web App with the S/MIME control. This is controlled only from the S/MIME options tab.

Always Sign

Exchange 2010 value name and type	AlwaysSign (DWORD)
Exchange 2007 value name and type	AlwaysSign (DWORD)
Exchange 2003 value name and type	AlwaysSign (DWORD)
Values and defaults	1=True, 0=False (default)
Explanation	When set to true, **AlwaysSign** will force users to digitally sign e-mail when they use Outlook Web App with the S/MIME control. Also, the Options page and the Message Options dialog box will show the "Send signed e-mail" option as selected.

Always Encrypt

Exchange 2010 value name and type	AlwaysEncrypt (DWORD)
Exchange 2007 value name and type	AlwaysEncrypt (DWORD)
Exchange 2003 value name and type	AlwaysEncrypt (DWORD)
Values and defaults	1=True, 0=False (default)
Explanation	When set to true, **AlwaysEncrypt** will force users to encrypt e-mail when they use Outlook Web App with the S/MIME control. Also, the Options page and the Message Options dialog box will display the "Send encrypted e-mail" option as selected.

Clear Sign

Exchange 2010 value name and type	ClearSign (DWORD)
Exchange 2007 value name and type	ClearSign (DWORD)
Exchange 2003 value name and type	ClearSign (DWORD)

Values and defaults	1=True (default), 0=False
Explanation	When set to true, **ClearSign** forces any digitally signed e-mail message that is sent from Outlook Web App to be clear-signed. The default setting for this attribute is true. Setting this value to false will cause Outlook Web App to use an opaque signature. Clear-signed e-mail messages are larger than opaque-signed signatures, but they can be opened and read with most e-mail clients, including clients that do not support S/MIME.

Include Certificate Chain Without Root Certificate

Exchange 2010 value name and type	IncludeCertificateChainWithoutRootCertificate (DWORD)
Exchange 2007 value name and type	IncludeCertificateChainWithoutRootCertificate (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x001)
Values and defaults	1=True, 0=False (default)
Explanation	The default behavior of Outlook Web App is to include only the signing and encrypting certificates, not their corresponding certificate chains, when sending signed or encrypted e-mail. This option may be necessary for interoperating with other clients, or in environments where intermediate certification authorities (CAs) cannot be reached by using the **Authority Information Access** attribute or by having the intermediate CA trusted in the Computer account of the Exchange 2010 mailbox server. When **IncludeCertificateChainWithoutRootCertificate** is set to true, signed or encrypted e-mail will include the full certificate chain, except for the root certificate. This setting increases the size of signed and encrypted messages.

Include Certificate Chain and Root

Exchange 2010 value name and type	IncludeCertificateChainAndRootCertificate (DWORD)
Exchange 2007 value name and type	IncludeCertificateChainAndRootCertificate (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x002)
Values and defaults	1=True, 0=False (default)
Explanation	Include Certificate Chain and Root resembles Include Certificate Chain Without

	Root Certificate, but, when it is set to true, it includes the root certificate and the full certificate chain. When set to true, **IncludeCertificateChainAndRootCertificate** increases the size of signed and encrypted messages more than **IncludeCertificateChainWithoutRootCertificate**.

Encrypt Temporary Buffers

Exchange 2010 value name and type	EncryptTemporaryBuffers (DWORD)
Exchange 2007 value name and type	EncryptTemporaryBuffers (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x004)
Values and defaults	1=True (default), 0=False
Explanation	By default, all client-side temporary buffers that are used to store message data are encrypted by using an ephemeral key and the 3DES algorithm. This setting can be used to enable or disable encrypting the temporary buffers. Disabling encryption of the buffers can increase performance of the Outlook Web App client. However, it leaves information unencrypted in the buffer of the local system. Before you disable this feature, see your organization's security policy.

Signed E-Mail Certificate Inclusion

Exchange 2010 value name and type	SignedEmailCertificateInclusion (DWORD)
Exchange 2007 value name and type	SignedEmailCertificateInclusion (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x008)
Values and defaults	1=True (default), 0=False
Explanation	By default Outlook Web App with the S/MIME control installed includes both signing and encrypting certificates with signed e-mail. When you disable this setting by setting **SignedEmailCertificateInclusion** to false, the size of messages that are sent from Outlook Web App with the S/MIME control will decrease. However, recipients will not have access to the sender's encryption certificate in the received message. They will have to obtain that certificate another way, either by retrieving it from a directory or obtaining it from the sender.

Bcc Encrypted E-Mail Forking

Exchange 2010 value name and type	BccEncryptedEmailForking (DWORD)
Exchange 2007 value name and type	BccEncryptedEmailForking (DWORD)
Exchange 2003 value name and type	SecurityFlags (values 0x040, 0x080)
Values and defaults	0=One encrypted message per Bcc recipient (default) 1=One single encrypted message for all Bcc recipients 2=One encrypted message without Bc forking
Explanation	By default, Outlook Web App will submit a separate encrypted message for each recipient on the Bcc line of an encrypted message. This option provides the most security for Bcc recipients of an encrypted message. By changing the value of **BccEncryptedEmailForking**, you can require Outlook Web App to create a single encrypted message for all Bcc recipients or one encrypted message without a separate message for each Bcc recipient.

Include S/MIME Capabilities in Message

Exchange 2010 value name and type	IncludeSMIMECapabilitiesInMessage (DWORD)
Exchange 2007 value name and type	IncludeSMIMECapabilitiesInMessage (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x100)
Values and defaults	1=True, 0=False (default)
Explanation	When **IncludeSMIMECapabilitiesInMessage** is set to true, Outlook Web App will add attributes to outgoing signed and encrypted messages that indicate which encryption and signing algorithms and key lengths are supported. Enabling this attribute will increase the size of messages. However, enabling it can make it easier for some e-mail clients to interoperate with Outlook Web App.

Copy Recipient Headers

Exchange 2010 value name and type	CopyRecipientHeaders (DWORD)
Exchange 2007 value name and type	CopyRecipientHeaders (DWORD)
Exchange 2003 value name and type	SecurityFlags (value 0x200)
Values and defaults	1=True, 0=False (default)

Explanation	When it is set to true, **CopyRecipientHeaders** puts a copy of the From, To, and Cc recipient headers in the signed part of the message. This allows the recipient to verify that these headers were not tampered with while the message was in transit. Enabling this feature increases the message size.

Only Use Smart Card

Exchange 2010 value name and type	OnlyUseSmartCard (DWORD)
Exchange 2007 value name and type	OnlyUseSmartCard (DWORD)
Exchange 2003 value name and type	SmartCardOnly (DWORD)
Values and defaults	1=True, 0=False (default)
Explanation	When it is set to true, **OnlyUseSmartCard** forces the use of smart card-based certificates for signing and decryption when you use Outlook Web App together with the S/MIME control. Users cannot use certificates not on a smartcard.

Triple Wrap Encrypted Mail

Exchange 2010 value name and type	TripleWrapSignedEncryptedMail (DWORD)
Exchange 2007 value name and type	TripleWrapSignedEncryptedMail (DWORD)
Exchange 2003 value name and type	TripleWrap (DWORD)
Values and defaults	1=True (default), 0=False
Explanation	When **TripleWrapSignedEncryptedMail** is set to true, encrypted e-mail messages that are digitally signed are triple-wrapped. When a message is tripled-wrapped, the digitally-signed message is encrypted, and then the encrypted message is digitally signed. When set to false, the digitally signed message is only encrypted, there is no additional digital signing of the encrypted message. By default, this attribute is set to true. Triple-wrapped messages afford the most security for digitally-signed and encrypted e-mail under the S/MIME standard, but they are larger than messages that are not triple-wrapped.

Use Key Identifier

Exchange 2010 value name and type	UseKeyIdentifier (DWORD)
Exchange 2007 value name and type	UseKeyIdentifier (DWORD)
Exchange 2003 value name and type	UseKeyIdentifier (DWORD)

Values and defaults	1=True, 0=False (default)
Explanation	By default, when encrypting e-mail, Outlook Web App will encode the lockbox where the asymmetrically-encrypted token that is required to decrypt the rest of the message is stored. It encodes the lockbox by indicating the issuer and serial number of each recipient's certificate. This can then be used to locate the certificate and private key for decrypting the message. An alternative way to locate the certificate and private key for decrypting the message is to use a certificate's key identifier by setting **UseKeyIdentifier** to true. Because a key pair can be reused in new certificates, using the key identifier for encrypted e-mail enables users to keep only the most recent certificate and the associated private key, instead of all old certificates, which can only be matched by issuer and serial number. By default, because some e-mail clients do not support finding certificates with a key identifier, Outlook Web App uses the issuer and serial number of each recipient's certificate. However, enabling this feature can make it easier to manage encrypted messages by eliminating the need for users to keep old, expired certificates on their system.

S/MIME Encryption Algorithms

Exchange 2010 value name and type	EncryptionAlgorithms (Reg-SZ)
Exchange 2007 value name and type	EncryptionAlgorithms (Reg-SZ)
Exchange 2003 value name and type	EncryptionAlgorithms (Reg_SZ)
Values and defaults	This key is a semicolon-separated list that represents the symmetric encryption algorithms to use when encrypting messages when using Outlook Web App together with the S/MIME control. List format: {Well-known algorithm ID}[:key length to use]|[,Custom replacement algorithm OID]; {Well-known algorithm ID}[:key length to use]|[,Custom replacement algorithm OID]; … Supported algorithms and their ALG_IDs: • DES6601 • 3DES6603 • RC26602 • AES128660E • AES192660F • AES2566610

	Key length is only applicable to variable-key length algorithms when the key length is not encoded into the algorithm ID itself. RC2 is the only such algorithm in the previous list. Custom replacement algorithm OID You can supply your own algorithm by implementing it within a cryptographic service provider (CSP), assigning it a custom object ID, and specifying the OID by using the **EncryptionAlgorithms** key. An OID must be specified together with a well-known algorithm ID. Outlook Web App needs a well-known algorithm ID so that it can infer how the algorithm should be used. For example, to provide a custom replacement for the 3DES algorithm, you would specify the ALG_ID of 3DES (0x6603) and the custom OID of the replacement algorithm. The values of the registry key should be listed from the longest key length to the shortest because the order reflects priority of use. For example, to list 3DES, RC2-128, RC2-64, DES, RC2-56, and RC2-40, type the value in the following way: 6603;6602:128;6602:64;6601;6602:56;6602:40 If the registry key is present, algorithms that are specified in the key will always be used. If the key is not present, Outlook Web App will fall back to its default internal list. This list begins with AES256 in computers that are running Windows Vista and with 3DES in computers that are running Windows XP. The AES algorithms are only used if the user's computer supports them. AES is not supported on Windows XP and messages that are encrypted by using AES cannot be read on computers that are running Windows XP.
Explanation	Outlook Web App will try to use the strongest algorithm with the longest available key length on the user's computer. If the encryption algorithm or minimum key length is not available on the user's computer, Outlook Web App will not allow encryption.

S/MIME Default Signing Algorithm

Exchange 2010 value name and type	SigningAlgorithms (Reg_SZ)
Exchange 2007 value name and type	SigningAlgorithms (Reg_SZ)
Exchange 2003 value name and type	DefaultSigningAlgorithm (reg_SZ)
Values and defaults	The **SigningAlgorithms** key specifies the list of signing algorithms to use when signing messages using Outlook Web App with the S/MIME control installed. The following table enumerates the

	signing algorithms, their algorithm IDs, and the supported key lengths for each. Format: {Well-known algorithm ID} Well-known algorithm IDs, and key lengths • CALG_SHA_512800E • CALG_SHA_384800D • CALG_SHA_256800C • SHA10x8004 • MD50x8003 If the registry key is present, the algorithm that is specified in the key will always be used. If the key is not present, Outlook Web App will fall back to its internal default list. This list begins with SHA-1. Messages that are digitally signed by using CALG_SHA_256 cannot be verified on computers that are running Windows XP.
Explanation	This attribute specifies the digital signing algorithm to use when digitally signing messages by using Outlook Web App together with the S/MIME control.

Force S/MIME Client Upgrade

Exchange 2010 value name and type	ForceSMIMEClientUpgrade (DWORD)
Exchange 2007 value name and type	ForceSMIMEClientUpgrade (DWORD)
Exchange 2003 value name and type	Not available. This was a new feature in Exchange 2007.
Values and defaults	1=True (default), 0=False
Explanation	When **ForceSMIMEClientUpgrade** is set to true, if the client control version on the user's computer is older than the version on the server, the user must download and install the new control before they can continue to use any S/MIME Read or Compose forms. If this value is set to false, the user will receive a warning if the S/MIME control on their computer is older than the version on the server. However, they will be able to use S/MIME without updating the control.

Use Registry Editor to change the S/MIME control settings for Outlook Web App

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Registry Editor" entry in the Client Access Permissions topic.

Caution:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Start Registry Editor (regedit).
2. Locate the following registry subkey:
   HKLM\System\CurrentControlSet\Services\MSExchange OWA\SMIME
3. Find the key that you want to change.
4. Set the key to the value that's required by your organization.
5. If the key that you need doesn't exist, create a new DWORD with that name, and then set it to the value that's required by your organization.

1.6.3.6 Understanding Extended Protection for Authentication

Understanding Extended Protection for Authentication

Exchange Server 2010 > Client Access > Securing Client Access Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-30*

Extended Protection for Authentication is a feature that helps to protect credentials for network connections that are being authenticated using Integrated Windows authentication. Integrated Windows authentication uses the Negotiate, Kerberos, and NTLM authentication methods. We strongly recommend that you use Extended Protection for Authentication if you're using Integrated Windows authentication.

Exchange Server 2010 Service Pack 1 (SP1) supports Extended Protection for Authentication. However, by default, Extended Protection for Authentication isn't enabled on computers running Exchange 2010.

Contents

Requirements for Extended Protection for Authentication

To use this feature, both the client and the server must be running a Microsoft Windows operating system that includes the Extended Protection for Authentication security update.

Default installations of Windows 7 and Windows Server 2008 R2 operating systems include this security update. However, for client or server computers that are running other versions of Windows (for example Windows Vista or Windows Server 2008 SP2), you must install the update. For detailed information about the operating systems that are supported by default, see Microsoft Knowledge Base article 973811, Microsoft Security

Advisory: Extended protection for authentication.

Exchange 2010 Prerequisite Checking

Exchange 2010 Setup doesn't require that the Extended Protection for Authentication security update be installed before Setup can continue. Instead, when you set up Extended Protection for Authentication for the first time, you'll be prompted to install the security updates referenced in Microsoft Knowledge Base article 968389, Extended Protection for Authentication on your computer if they're not already installed.

For More Information

Microsoft Knowledge Base article 973811, Microsoft Security Advisory: Extended protection authentication for authentication

1.6.4 Troubleshooting Reference for Client Access Servers

Troubleshooting Reference for Client Access Servers

Exchange Server 2010 > Client Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-09-24*

After you've installed the Client Access server role on a computer running Microsoft Exchange Server 2010, you may have to test the functionality of the server or solve problems related to client connectivity. The following information will help you troubleshoot common errors and test to ensure that your Client Access server is configured correctly. This topic will be updated on a regular basis.

Test Client Access Server Connectivity

The Microsoft Exchange Remote Connectivity Analyzer (ExRCA) can help you confirm that connectivity for your Exchange servers is configured correctly and to diagnose any connectivity issues. The Remote Connectivity Analyzer Web site offers tests for Microsoft Exchange ActiveSync, Exchange Web Services, Outlook, and Internet e-mail.

For more information, see Understanding the Remote Connectivity Analyzer.

Outlook Client Connectivity

The following links and information will help you troubleshoot Outlook client connectivity.

Cannot Open Mailbox in Outlook 2007

If you can't open a user's mailbox in Microsoft Office Outlook 2007, but you can open the mailbox in Microsoft Office Outlook Web App, verify the server information by running the following command:

```
Get-MailboxDatabase | fl RPCClientAccessServer
```

If the output of that command is the name of the Exchange 2010 Mailbox server, it's likely that the Client Access server role and the Mailbox server role were installed in the incorrect order. The value of the parameter *RPCClientAccessServer* is set to the Mailbox server instead of the Client Access server. To resolve this issue, run the following command:

```
Get-MailboxDatabase | Set-MailboxDatabase -RPCClientAccessServer <FQDN of the Cli
```

Cannot Open Mailbox in Outlook 2003 and Exchange 2010 RTM

If you're trying to access a mailbox on an Exchange 2010 Mailbox server with Office Outlook 2003, you might receive one of the following error messages:

- Cannot start Microsoft Office Outlook. Unable to open the Office window. The set of folders could not be opened.
- Unable to open your default e-mail folders. The information store could not be opened.

In Exchange 2010, the RPC endpoint is encrypted by default. However, Outlook 2003 doesn't enforce encrypted MAPI connections. When you upgrade your organization to Exchange 2010, your clients that are running Outlook 2007 or later versions will automatically be compatible with the change to RPC Client Access, because they support RPC encryption by default. However, Outlook 2003 doesn't use RPC encryption, and RPC Client Access requires it by default.

Note:

By default, Exchange 2010 Service Pack 1 (SP1) encryption on the RPC endpoint isn't enabled. Therefore, this error shouldn't occur.

To configure Outlook 2003 to use RPC encryption, follow these steps:

1. Click **Tools** > **E-Mail Accounts** > **View or Change an Existing Account**.
2. Select the account and click **More Settings**.
3. Click the **Security** tab.
4. Select the check box **Encrypt data between Microsoft Office Outlook and Microsoft Exchange Server**.
5. Click **OK**.

E-Mail Messages Take a Long Time to Load for Outlook 2003 Clients

UDP notification support was removed from Exchange 2010. As a result, Outlook 2003 can only use polling notifications in online mode. This will result in a slight delay in updates to item status (30 seconds on average with up to a one-minute delay) when changes are made to items in a mailbox accessed with Outlook 2003. There are two workarounds for this issue:

- Use Outlook 2003 in Cached Exchange Mode.
- Adjust the polling interval on the Client Access server. This will impact the performance of the Client Access server.

For more information about this issue, see E-mail messages take a long time to send and receive.

Event ID 106 is logged when you start the RPC Client Access service

If the Microsoft Exchange RPC Client Access service is started on an Exchange 2010 Mailbox server that doesn't have the Client Access server role installed, Event ID 106 is logged in the Application log. This error occurs because the performance counters of the RPC Client Access service aren't installed when the Mailbox server role is installed without the Client Access server role. To resolve this error, install the Client Access server role on the Exchange 2010 server.

DNS Change Prevents User from Signing In to Outlook Web App

When a user tries to sign in to Outlook Web App, he may receive the following error message:

- A server configuration change is temporarily preventing access to your account. Please close all Internet Explorer windows and try again in a few minutes. If the problem continues, contact your helpdesk.

This can happen when the DNS record of the Client Access server is modified and a user tries to sign in to Outlook Web App before the DNS cache in Internet Explorer is refreshed. This can be resolved by the user closing all browser windows to force Internet Explorer to update the DNS cache. See How Internet Explorer uses the cache for DNS host entries for information about the DNS cache in Internet Explorer.

To avoid this, create a second DNS entry for the Client Access server and use the **Set-OwaVirtualDirectory** cmdlet to configure the *FailbackUrl* parameter to match. The *FailbackUrl* parameter specifies the host name Outlook Web App uses to connect to the Client Access server after failback in a site resilience process and requires a separate DNS entry pointing to the original Client Access server's IP address. The *FailbackUrl* parameter must be different from the *ExternalUrl* parameter.

This example configures the *FailbackUrl* parameter.

```
Set-owavirtualdirectory -identity "owa (default web site)" -FailbackUrl "<failbac
```

For more information about syntax and parameters, see Set-OwaVirtualDirectory.

Troubleshoot Certificate Wizard errors

Exchange 2010 uses Microsoft Windows HTTP Services (WinHTTP) to manage all HTTP/HTTPS traffic. Because of this, Exchange 2010 does not use the proxy server settings that may be configured in the web browser. WinHTTP uses Web Proxy Auto-Discover Protocol (WPAD), and requires that a Proxy Access Control (PAC) file be specified through DHCP or DNS.

If the WinHTTP proxy settings are configured incorrectly, the following issues may occur:

1. After you import a valid third-party certificate to an Exchange 2010 CAS, the EMC may report the following status: The certificate status could not be determined because the revocation check failed
2. If you run the **Get-ExchangeCertificate** cmdlet in the Exchange Management Shell, you see the following status for the imported certificate: Status : RevocationCheckFailure

To resolve these issues, follow these steps:

1. To list the WinHTTP proxy settings, type the following command at a command prompt, and then press Enter: **netsh winhttp show proxy**. The response shows the current proxy information that is being used by Exchange. Typically, you receive a response that resembles the following:

   ```
   C:\>netsh winhttp show proxy
   Current WinHTTP proxy settings:
   Direct access (no proxy server)
   ```

2. If the correct server is not identified in the response, configure the proxy setting for WinHTTP by using the netsh command. Also, configure the server FQDN in the bypass-list so that the Exchange Management Shell and the Exchange Management Console can contact Remote PowerShell.
3. To do this, type the following command at a command prompt, and then

press Enter: **netsh winhttp set proxy proxy-server="http=<Proxy_Server_Name>" bypass-list="*.<Exchange_Server_Hostname_Domain>"**

Note:

Replace the *<Proxy_Server_Name>* placeholder by using the proxy server name. Also, replace the *<Exchange_Server_Hostname_Domain>* placeholder by using the second-level domain name and the first-level domain name of the Exchange Server (for example, *microsoft.com*)

4. Close and then open the Exchange Management Console. Check the status of the certificate. If the proxy settings are correct but the certificate status is still incorrect, run the following commands at a command prompt to clear the OCSP/CRL cache:
   certutil -urlcache ocsp delete
   certutil -urlcache crl delete
5. Restart the server, and then open the Exchange Management Console to check the status of the certificate.

1.6.5 Error and Event Reference for Client Access Servers

Error and Event Reference for Client Access Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-01*

Microsoft Exchange Server 2010 Client Access server components, features, and services generate Error events to let you effectively troubleshoot and monitor Client Access servers.

Event Viewer maintains logs about program, security, and system events on your computer. You can use Event Viewer to view and manage the event logs, to gather information about hardware and software problems, and to monitor Microsoft Windows security events. Although Event Viewer is an Windows operating system tool and not a Microsoft Exchange tool, Event Viewer is useful when you troubleshoot problems that affect Exchange. This topic describes the basic concepts related to Event Viewer.

This topic also describes the events that a Client Access server lists in Event Viewer, explains how to use events to monitor Client Access components, and describes the error messages that are generated by a Client Access server.

Address Book Service Errors and Events

The following events are generated by the Address Book service.

Event ID	Event Type	Description
1000	Success	Microsoft Exchange Address Book Service has started successfully.
1001	Success	Microsoft Exchange Address Book Service has stopped successfully.

1002	Error	Failed to register service principal name %1. Failed with error code %2.
1003	Error	Cannot start the service due to Win32 error %1 while removing unnecessary privileges.
1004	Error	An unexpected error occurred while starting the Microsoft Exchange Address Book service.
1005	Error	An unexpected error occurred while stopping the Microsoft Exchange Address Book service.
1007	Error	No RPC endpoints were enabled in the configuration file.
1008	Error	Unable to register the %1 RPC interface. Failed with the error code %2.
1009	Error	%1 was not present or invalid in the configuration file. Protocol logging has been disabled.

Other Client Access Errors and Events

The following additional Client Access errors and events are grouped according to the Client Access feature areas.

- ActiveSync Errors and Events
- Availability Service Errors and Events
- Autodiscover Errors and Events
- Certificate Deployment Errors and Events
- OWA Errors and Events
- RPCHTTPAutoConfig Errors and Events
- ServiceHost Errors and Events

1.6.5.1 ActiveSync Errors and Events

ActiveSync Errors and Events

Exchange Server 2010 > Client Access > Error and Event Reference for Client Access Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 ActiveSync generates events in Event Viewer so that you

can troubleshoot and verify the performance of ActiveSync features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

ActiveSync Errors and Events

The following table provides a list of the ActiveSync events that you can use to troubleshoot and monitor ActiveSync.

ActiveSync events

Event ID	Category	Event type	Value or description
MSExchange ActiveSync 1023	Requests	Warning	Exchange ActiveSync tried to access a mailbox on Mailbox server "%1". It could not access the mailbox because the Mailbox server is offline
MSExchange ActiveSync 1018	Requests	Warning	A user tried to perform a full-text search of their mailbox from their mobile phone, but Content Indexing is not enabled on Mailbox server "%1". If you do not want Exchange ActiveSync users and other Exchange users to be able to search their mailbox data on the server, no user action is required. If you want Exchange ActiveSync users and other Exchange users to be able to search their mailbox data on the server, make sure that the Microsoft Exchange Search service is running on your Mailbox servers. In addition, make sure that you have enabled full-text search on the appropriate database on the Mailbox server.
MSExchange ActiveSync 1008	Requests	Warning	An exception occurred and was handled by

			Exchange ActiveSync. This may have been caused by an outdated or corrupted Exchange ActiveSync device partnership. This can occur if a user tries to modify the same item from multiple computers. If this is the case, Exchange ActiveSync will re-create the partnership with the device. Items will be updated at the next synchronization. URL=%1%2.
MSExchange ActiveSync 1034	Requests	Warning	The proxy request to %1 has timed out.
MSExchange ActiveSync 1038	Requests	Error	The account "%1" doesn't have the appropriate permissions to modify the Exchange ActiveSync service privileges. Please check the assigned permissions for the account running the Exchange ActiveSync ASP.NET process. Error code: "%2".
MSExchange ActiveSync 1022	Requests	Warning	The connection between the Client Access server and Mailbox server "%1" failed. If this event is logged infrequently or only during scheduled downtime for a Mailbox server, no user action is required. If this event occurs repeatedly, check network connectivity using PING or PingPath. Also, check connectivity using the Test-ActiveSyncConnectivity cmdlet. More information: %2
MSExchange ActiveSync 1010	Requests	Warning	Direct Push has detected that the

			configuration value for the maximum heartbeat interval is set to a value higher than the maximum allowed value of "%1" seconds. Therefore, the default maximum heartbeat interval of "%2" seconds and the default minimum heartbeat interval of "%3" seconds will be used until the next time that the computer is restarted. To avoid seeing this message in the future, use Internet Information Services (IIS) Manager to correct this configuration. Reset the value to the default, or use another acceptable value.
MSExchange ActiveSync 1009	Requests	Warning	Direct Push has detected that the configuration value for the minimum heartbeat interval is set to a value higher than the maximum heartbeat interval. Therefore, the default minimum heartbeat interval of "%1" seconds and the default maximum heartbeat interval of "%2" seconds will be used until the next time that the computer is restarted. To avoid seeing this message in the future, use Internet Information Services (IIS) Manager to correct these values. Reset the values to the default, or use other acceptable values.
MSExchange ActiveSync 1032	Requests	Warning	The connection to mailbox "%1" on

			Mailbox server "%2" failed. Examine the event log of Mailbox server "%2". More information%2
MSExchange ActiveSync 1036	Configuration	Error	The Client Access server cannot proxy the Exchange ActiveSync client request to the Exchange server %1. For this to work, Integrated Windows authentication must be configured on the Microsoft-Server-ActiveSync virtual directory on the Exchange server %1.
MSExchange ActiveSync 1015	Server	Error	Exchange ActiveSync experienced a transient error when it tried to access Active Directory information for user "%1". Exchange ActiveSync will try this operation again. If this event occurs infrequently, no user action is required. If this event occurs frequently, check network connectivity using PING or PingPath. You can also use the Test-ActiveSyncConnectivity cmdlet. More information: %2
MSExchange ActiveSync 1016	Server	Error	Exchange ActiveSync has encountered repeated failures when it tries to access data on Mailbox server [%1]. It will temporarily stop making requests to the Mailbox server for [%2] seconds to reduce load on that server. This delay may occur if the Mailbox server is overloaded. If this event is logged

			frequently, review the Application log on this server and the Mailbox server noted above for other events that could indicate the root cause of performance problems. Additional information:"%3".
MSExchange ActiveSync 1033	Configuration	Warning	The setting %1 in the Web.Config file was not valid. The previous value was %2 and has been changed to %3.
MSExchange ActiveSync 1035	Configuration	Warning	The proxy request has failed due to an invalid SSL certificate on %1.
MSExchange ActiveSync 1011	Configuration	Warning	Direct Push has detected that the configuration value for the minimum heartbeat interval is set to a value that is too low. Therefore, the default minimum heartbeat interval of "%1" seconds and the default maximum heartbeat interval of "%2" seconds will be used until the next time that the computer is restarted. To avoid seeing this message in the future, use Internet Information Services (IIS) Manager to correct this configuration. Reset the value to the default, or use another acceptable value.

1.6.5.2 Availability Service Errors and Events

Availability Service Errors and Events

Exchange Server 2010 > Client Access > Error and Event Reference for Client Access Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 Availability generates events in Event Viewer so that you can troubleshoot and verify the performance of the Exchange Availability features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Exchange Availability Service Errors and Events

The following table provides a list of the Availability events that you can use to troubleshoot and monitor the Availability service.

Availability Service events

Event ID	Category	Event type	Logging	Value or description	Class
MSExchange Availability 4018	Availability Service	Error	LogAlways	Process %1: An exception occurred while attempting to locate a Client Access server to handle a request for e-mail address %2. The returned exception is %3.	Availability
MSExchange Availability 4001	Availability Service	Error	LogAlways	Process %1: %2 failed. Exception returned is %3. This event may occur when Availability Service cannot discover an Availability Service in the remote forest.	Availability
MSExchange Availability 4017	Availability Service	Error	LogAlways	Process %1: No Client Access server was found to handle a request for e-mail address %2. This may be due to a	Availability

				misconfigured topology.	
MSExchange Availability 4010	Availability Service Authentication	Error	LogAlways	Process %1: Request from %2 failed security checks.	Availability
MSExchange Availability 4003	Availability Service	Error	LogAlways	Process %1: %2 failed. The exception returned is % 3. The Availability service could not successfully retrieve Schedule+ free/busy data for one or more legacy Exchange mailboxes. To find the root cause of this error, increase the diagnostic logging level of the MSExchange Availability service.	Availability
MSExchange Availability 4006	Availability Service	Error	LogAlways	Process %1: Failed to initialize service, exception returned is % 2	Availability
MSExchange Availability 4002	Availability Service	Error	LogAlways	Process %1: %2 failed. Caller SIDs: % 3. The exception returned is % 4. Make sure that the Active Directory site/ forest that contain the user's mailbox has at least one local Exchange 2010 server running the	Availability

				Availability service. Turn up logging for the Availability service and test basic network connectivity.	
MSExchange Availability 4005	Availability Service	Warning	LogAlways	Process %1: Configuration information for the current forest could not be found in Active Directory. To find the root cause of this error, increase the diagnostic logging level of the MSExchange Availability service.	Availability
MSExchange Availability 4016	Availability Service	Error	LogAlways	Process %1: Unable to logon as network service context for proxying requests. Cross-site and cross-forests requests could fail because of this. Exception is %2.	Availability

1.6.5.3 Autodiscover Errors and Events

Autodiscover Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Autodiscover service events in Event Viewer so that you can troubleshoot and verify the performance of the Autodiscover features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Autodiscover Errors and Events

The following table provides a list of the UM auto attendant events that you can use to troubleshoot and monitor Unified Messaging.

Autodiscover events

Event ID	Category	Event type	Logging	Value or description	Class
MSExchange Autodiscover 1111	Core	Warning	LogAlways	Error "%1" while loading assembly "%2".%nStack Trace:%3. The event is logged when Autodiscover is unable to load an assembly because the assembly file does not have appropriate access permissions (executable and read permissions).	Autodiscover
MSExchange Autodiscover 1201	Provider	Warning	LogAlways	Time:%1, Id: %2, Error Response with the ErrCode:"%3", Message:"%4", DebugData:"%5" was generated for EMailAddress:	Autodiscover

				"%6", LegacyDN:"%7" by "%8".	
MSExchange Autodiscover 1112	Core	Warning	LogAlways	Error "%1" while loading assembly "%2".%nStack Trace:%3. The event is logged when Autodiscover is unable to find an assembly or DLL that Autodiscover is trying to reference.	Autodiscover
MSExchange Autodiscover 1108	Core	Warning	LogAlways	Error "%1" while loading assembly "%2".%nStack Trace:%3. The event is logged because the Microsoft Exchange Autodiscover service found the managed assembly or DLL it was referencing, but failed to load the assembly.	Autodiscover
MSExchange Autodiscover 2	Web	Error	LogAlways	Anonymous Request received from HostAddress:"%1", HostName:"%2". Invalid Autodiscover site configuration. To fix the problem remove Anonymous access.	Autodiscover
MSExchange Autodiscover 1	Web	Error	LogAlways	Unhandled Exception "%1"%nStack trace: %2	Autodiscover

MSExchange Autodiscover 1109	Core	Warning	LogAlways	Error "%1" while loading assembly "%2".%nStack Trace:%3. This event is logged when the loader that Autodiscover is using to load an assembly or DLL has failed because the loader may not be valid.	Autodiscover
MSExchange Autodiscover 101	Core	Error	LogAlways	No providers were found. The Autodiscover service won't be able to process any valid requests.	Autodiscover
MSExchange Autodiscover 1105	Core	Warning	LogAlways	Requested provider for Request Schema:"%1" and Response Schema:"%2" cannot be found.	Autodiscover
MSExchange Autodiscover 1110	Core	Warning	LogAlways	Error "%1" while loading assembly "%2".%nStack Trace:%3. The event is logged when the Autodiscover provider is unable to load the assembly it is referencing because the assembly or DLL could be in an invalid format.	Autodiscover
MSExchange Autodiscover 1106	Core	Warning	LogAlways	Error "%1" while loading the assembly "%2".%nStack	Autodiscover

				Trace:%3. This error may occur because the provider file is corrupt, is in an incorrect format, or has insufficient permissions.	
MSExchange Autodiscover 1113	Core	Warning	LogAlways	Provider "%1" has invalid attribute - "%2". The entry is not added to the table.	Autodiscover

1.6.5.4 Certificate Deployment Errors and Events

Certificate Deployment Errors and Events

Exchange Server 2010 > Client Access > Error and Event Reference for Client Access Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Certificate Deployment events in Event Viewer so that you can troubleshoot and verify the Certificate Deployment features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Certificate Deployment Errors and Events

The following table provides a list of the Certificate Deployment events.

Event ID	Category	Event type	Value or description
MSExchange Certificate Deployment 2009	General	Warning	The federation certificate %1 will expire in less than 15 days. Renew the certificate soon to ensure proper functionality of federation trust services.

1.6.5.5 OWA Errors and Events

OWA Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates Outlook Web App events in Event Viewer so that you can troubleshoot and verify the OWA features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchange OWA Errors and Events

The following table provides a list of OWA errors and events.

Event ID	Category	Event type	Logging	Value or description	Class
MSExchange OWA 39	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to Client Access server "%2". This failed because "%2" didn't respond. Outlook Web App will try to proxy this traffic to Client Access server "%3" in the same Active Directory site.Additional information: %4.	OWA
MSExchange OWA 7	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. You can't define a base experience when you choose to	OWA

				inherit from another forms registry. The base experience of the other forms registry is always used.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 50	ADNotifications	Error	LogAlways	Settings change notifications couldn't be registered in Active Directory for virtual directory "%1" under web site "%2". Exception message:"%3".	OWA
MSExchange OWA 70	Transcoding	Error	LogAlways	The ACL of the temporary folder couldn't be set because the WebReady Document Viewing Manager doesn't have the permissions to set it. The value of the	OWA

				temporary folder is set by a registry key. If the registry key doesn't exist, the default Microsoft Windows temporary folder will be used. The registry key that controls the temporary folder is named HKEY_LOCAL_MACHINE \SYSTEM \CurrentControlSet\Services \MSExchange OWA \WebReadyDocumentViewing \TempFolderLocation. For WebReady Document Viewing to function correctly, the Local System account must have full control permissions assigned to the temporary folder that you have configured.Exception message: "%1".	
MSExchange OWA 16	Configuration	Error	LogAlways	There's an error in your Outlook Web App configurationThe configuration for virtual directory "%1" couldn't be found. This	OWA

				can be fixed using the Get-, Set-, or New-OwaVirtualDirectory cmdlets. Make sure the VirtualDirectory property of the corresponding OwaVirtualDirectory object matches the name of this virtual directory.	
MSExchange OWA 5	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. Expected element = %4.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	OWA
MSExchange OWA 3	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Forms registry %1 specifies %2 as the base experience, but %2 is not defined in the	OWA

				forms registry.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about how to troubleshoot the forms registry.	
MSExchange OWA 24	Themes	Error	LogAlways	Outlook Web App couldn't initialize.It couldn't parse file "%1" in theme folder "%2". The theme ID attribute "%3" wasn't found. Line %4, Position %5.	OWA
MSExchange OWA 37	Configuration	Error	LogAlways	The sign-in to Outlook Web App failed. The Active Directory profile for "%1" doesn't have a primary SMTP address.This may have happened because the user's account wasn't created using the Exchange Management Console or the Exchange command-line tools. The following	OWA

				Exchange Management Shell steps provide one way of correcting the most common cause of the problem. Get-User "%2" | Disable-Mailbox. Get-User "%3" | Enable-Mailbox At the prompt, enter the mailbox database name (normally "Mailbox Store").	
MSExchange OWA 46	Proxy	Error	LogAlways	Client Access server "%1", running Exchange version "%2", is proxying Outlook Web App traffic to Client Access server "%3", which runs Exchange version "%4". To ensure reliable interoperability, the proxying Client Access server needs to be running a newer version of Exchange than the Client Access server it is proxying to. If the proxying Client Access server is running a newer version of Exchange than the Client Access	OWA

				server it is proxying to, the proxying Client Access server needs to have an Outlook Web App resource folder (for example, "<Exchange Server installation path>) \ClientAccess \owa \8.0.498.0" that contains all the same versioned resource files as the Client Access server it is proxying to. If you will be running Outlook Web App proxying with mismatched server versions, you can manually copy this resource folder to the proxying Client Access server. After you copy this resource folder to the proxying Client Access server, you need to restart IIS before proxying will work.	
MSExchange OWA 42	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to Client Access server "%2". This failed	OWA

				because one of these configuration problems was encountered:1. "%2" has been set to use "http://" (not using SSL) instead of "https://" (using SSL). You can modify this by setting the InternalUrl parameter of the Outlook Web App virtual directory this proxy traffic is going to. You can set that parameter using the Set-OwaVirtualDirectory cmdlet in the Exchange Management Shell.2. The destination virtual directory returned an HTTP 403 error code. This usually means it's not configured to accept SSL access. You can change this configuration by using IIS Manager on the Client Access server "%2".If you don't want this proxy connection to use SSL, you need to set the registry key "AllowProxying	

				WithoutSSL" on this Client Access server and to set the InternalUrl and SSL settings for the Outlook Web App virtual directory this proxy traffic is going to accordingly.	
MSExchange OWA 47	Transcoding	Warning	LogAlways	A folder couldn't be created to cache the current Outlook Web App process. Other processes may be using the same directory. To fix this problem, stop the processes that are using the same directory, and then restart Outlook Web App. Exception message: "%1".	OWA
MSExchange OWA 10	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. The value "%4" specified for the MinimumVersion element isn't a valid number.The forms registry is a critical component of Outlook Web App. If this	OWA

				error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about how to troubleshoot the forms registry.	
MSExchange OWA 38	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy or redirect Outlook Web App traffic for mailbox "%2". This failed because one of the service discovery entries returned for the Client Access server to use for this mailbox is malformed. The service discovery URLs should be in the format "http [s]:// hostname [:port]/owa". The malformed entry is stored as "%3".	OWA
MSExchange OWA 40	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to Client Access server "%2". This failed because "%2" didn't respond.Additional information: %	OWA

				3.	
MSExchange OWA 71	Proxy	Error	LogAlways	Microsoft Exchange Client Access server %1 tried to proxy Outlook traffic to Client Access server %2. This failed because the authentication for the connection between the two Client Access servers failed. This may be due to one of these configuration problems: 1. The host name in %2 may not be registered as a Service Principal Name (SPN) with Kerberos on the target Client Access server. This usually happens because you used the IP address, instead of the host name, of the target Client Access server in the "internalURL" configuration for the Outlook Web App virtual directory on the target Client Access server. You can change the "internalURL" configuration for the target Client Access	OWA

				server using the "Set-OwaVirtualDirectory" task. If you don't want to change the "internalURL" configuration for the Outlook Web App virtual directory on the target Client Access server, you can also use the tool "setspn.exe" on the target Client Access server to register additional SPNs for which that Client Access server will accept Kerberos authentication. 2.The server hosting %2 may be configured not to allow Kerberos authentication. It might be set to use Integrated Windows authentication for the Outlook Web App virtual directory, but be configured to only use NTLM (not Kerberos) authentication for Integrated Windows authentication. If you suspect this may be the cause of the failure, see	

				the IIS documentation for additional troubleshooting steps.	
MSExchange OWA 28	SmallIcons	Error	LogAlways	Outlook Web App couldn't initialize.The small icon configuration file named %1 doesn't exist.The small icon configuration file is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about how to troubleshoot the small icon configuration file.	OWA
MSExchange OWA 57	Proxy	Warning	LogAlways	Outlook Web App isn't available for this mailbox. The Client Access server %1, running Exchange version %2, tried to find a Client Access server to proxy Outlook Web App traffic for mailbox %3. It couldn't find the Client Access server in the target Active	OWA

				Directory site.Additional information: %4. If the problem continues, contact your helpdesk.	
MSExchange OWA 21	Themes	Error	LogAlways	Outlook Web App couldn't initialize.File "%1" in theme folder "%2" couldn't be parsed. The attribute "%3" is empty. Line %4, Position %5.	OWA
MSExchange OWA 22	Themes	Error	LogAlways	Outlook Web App couldn't initialize.It couldn't parse file "%1" in theme folder "%2". The attribute "%3" exceeds the maximum length of %4 characters. Line %5, Position %6.	OWA
MSExchange OWA 4	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.More than one forms registry is named %1. Each registry name must be unique. Rename one of the forms registries.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web	OWA

				App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 19	Themes	Error	LogAlways	Outlook Web App couldn't initialize.File "%1" in theme folder "%2" wasn't parsed. The xml element "%3" is missing.	OWA
MSExchange OWA 1	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.The forms registry folder %1 doesn't exist.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about how to troubleshoot the forms registry.	OWA
MSExchange OWA 44	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to Client Access server "%2". This failed for user "%3" because this	OWA

				user is a member of too many groups. Outlook Web App limits group membership when proxying to "%4".	
MSExchange OWA 2	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Forms registry %1 inherits forms registry %2, but forms registry %2 couldn't be found.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	OWA
MSExchange OWA 31	Configuration	Error	LogAlways	The Address Book custom properties couldn't be parsed. RootElementNotFound in "%1" at line number = "%2". Make sure that this file contains "CustomProperties" as the root element. If this error isn't addressed,	OWA

				users won't be able to view the custom properties. The Help and Support Center provides information about how to troubleshoot this issue.	
MSExchange OWA 26	Themes	Error	LogAlways	Outlook Web App couldn't initialize.A base theme couldn't be found. The base theme must be in a folder with name = "%1".	OWA
MSExchange OWA 54	ADNotifications	Error	LogAlways	The Active Directory system configuration session couldn't be retrieved.Exception message:"%1".	OWA
MSExchange OWA 43	Proxy	Warning	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to Client Access server "%2". This failed because the Outlook Web App registry key "AllowInternalUntrustedCerts" is set to "0", but no certificate trusted by "%1" was available for the Secure Sockets Layer (SSL)	OWA

				encryption of the proxy connection.	
MSExchange OWA 30	Configuration	Error	LogAlways	There's an error in your Outlook Web App configuration.The authentication type on the /owa virtual directory is set to Anonymous. This check box must be cleared for Outlook Web App to function correctly.	OWA
MSExchange OWA 45	Proxy	Error	LogAlways	Client Access server "%1" tried to proxy Outlook Web App traffic to "%2". This failed because "%2" couldn't verify that the Active Directory account "%3" used to authenticate has the necessary access rights to send Outlook Web App proxy traffic.Additional information: %4.	OWA
MSExchange OWA 9	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. Message = %4.The forms registry is a	OWA

				critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 15	Configuration		LogAlways	There's an error in your Outlook Web App configurationThe character '%5' isn't valid for file extensions. It was found in character %4 of "%3" in element %2 of the %1 array in the Outlook Web App attachment policy for the %6 virtual directory. This can be corrected using the Exchange Management Console.	OWA
MSExchange OWA 53	ADNotifications	Error	LogAlways	The message classification settings couldn't be read from Active Directory for virtual directory "%1" under web site "%2".Exception	OWA

				message:"%3".	
MSExchange OWA 36	Configuration	Error	LogAlways	The Address Book custom properties couldn't be parsed. An invalid value was provided for the attribute "%1" and in the file "%2" at line number "%3". The values of these attributes can't be null or empty.	OWA
MSExchange OWA 41	Proxy	Error	LogAlways	The Client Access server "%1" attempted to proxy Outlook Web App traffic for mailbox "%2". This failed because no Client Access server with an Outlook Web App virtual directory configured for Kerberos authentication could be found in the Active Directory site of the mailbox. The simplest way to configure an Outlook Web App virtual directory for Kerberos authentication is to set it to use Integrated Windows authentication by using the Set-OwaVirtualDir	OWA

				ectory cmdlet in the Exchange Management Shell, or by using the Exchange Management Console. If you already have a Client Access server deployed in the target Active Directory site with an Outlook Web App virtual directory configured for Kerberos authentication, the proxying Client Access server may not be finding that target Client Access server because it does not have an internalUrl parameter configured. You can configure the internalUrl parameter for the Outlook Web App virtual directory on the Client Access server in the target Active Directory site by using the Set-OwaVirtualDirectory cmdlet.	
MSExchange OWA 11	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number	OWA

				= %2 Position = %3. The value "%4" specified for the ApplicationElement element isn't one of the expected values.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 59	Configuration	Warning	LogAlways	A corrupted calendar configuration was detected (user = %1), The configuration is being reset.	OWA
MSExchange OWA 29	Configuration	Error	LogAlways	There's an error in your configuration.The authentication type specified in the %1web.config file is incorrect. The correct authentication type is "Windows".	OWA
MSExchange OWA 48	Transcoding	Error	LogAlways	WebReady Document Viewing isn't registered. To	OWA

				fix this problem, reinstall Outlook Web App.	
MSExchange OWA 34	Configuration	Error	LogAlways	The Address Book custom properties couldn't be parsed. Invalid element found in "%1" at line number ="%2" position = "%3". The custom properties couldn't be parsed because an invalid element was encountered. The only element that can have attributes in the custom properties file is "customProperty". If this error isn't addressed, users won't be able to view the custom properties. The Help and Support Center provides information about how to troubleshoot this issue.	OWA
MSExchange OWA 49	Transcoding	Warning	LogAlways	WebReady Document Viewing can't be found. To fix this problem, reinstall Outlook Web App.	OWA

MSExchange OWA 33	Configuration	Error	LogAlways	The Address Book custom properties couldn't be parsed. "%1" attribute wasn't found in "%2" at line number = "%3". Having the "%1" as the "%4" attribute in the custom properties file is a requirement for Outlook Web App to parse it and display the values to users. If this error isn't addressed, users won't be able to view the custom properties. The Help and Support Center provides information about how to troubleshoot this issue.	OWA
MSExchange OWA 6	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. Expected attribute = %4.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access	OWA

				Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 20	Themes	Warning	LogAlways	Outlook Web App couldn't initialize.File "%1" in theme folder "%2" wasn't parsed. More than one instance of the attribute "%3" was found. Line %4, Position %5.	OWA
MSExchange OWA 55	FormsRegistry	Error	LogAlways	Outlook Web App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3 The value "%4" specified for the IsRichClient attribute isn't a valid Boolean value. Change this property in the registry to contain True or False.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support	OWA

				Center provides information about how to troubleshoot the forms registry.	
MSExchange OWA 35	Configuration	Error	LogAlways	The Address Book custom properties couldn't be parsed. Invalid file "%1" Line number = %2 Position = %3 Message = "%4". A valid custom property file format is required for Outlook Web App to parse it and display the values to users. If this error isn't addressed, users won't be able to view the custom properties. The Help and Support Center provides information about troubleshooting this issue.	OWA
MSExchange OWA 65	ADNotifications	Error	LogAlways	An error occurred while the Outlook Web App configuration settings were being loaded. Virtual directory: "%1". Web site: "%2".Error message:"%3"	OWA
MSExchange	FormsRegistry	Error	LogAlways	Outlook Web	OWA

OWA 8				App couldn't initialize.Invalid forms registry file %1 Line number = %2 Position = %3. You must either define a base experience or a forms registry to inherit from.The forms registry is a critical component of Outlook Web App. If this error isn't addressed, users might not be able to access Outlook Web App. The Help and Support Center provides information about troubleshooting the forms registry.	
MSExchange OWA 18	Themes	Error	LogAlways	Outlook Web App couldn't initialize.Themes folder "%1" doesn't exist.	OWA
MSExchange OWA 52	ADNotifications	Error	LogAlways	The configuration settings couldn't be read from Active Directory for virtual directory "%1" under Web site "%2".Exception message:"%3".	OWA
MSExchange OWA 61	Configuration	Error	LogAlways	Outlook Web App has encountered	OWA

				an error. This can happen if the mailbox was created using Active Directory Users and Computers instead of the Exchange Management Console or the Exchange Management Shell, or if the version number of the user's mailbox object doesn't match the mailbox version that's configured on the Exchange 2003 server or on the computer running the Mailbox server role. To correct this error, run cmdlet Set-Mailbox -Identity <Mailbox Identity> -ApplyMandatoryProperties.	
MSExchange OWA 60	SmallIcons	Warning	LogAlways	Outlook Web App encountered an error during initialization.The values (%1) defined for the Alt attribute in the small icon configuration file aren't valid.	OWA
MSExchange OWA 25	Themes	Error	LogAlways	Outlook Web App couldn't initialize.It couldn't parse	OWA

				file "%1" in theme folder "%2". There was an error parsing the XML file. Line %3, Position %4.	

1.6.5.6 RPCHTTPAutoConfig Errors and Events

RPCHTTPAutoConfig Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates RPC Over Autonconfig events in Event Viewer so that you can troubleshoot and verify the RPC Over Autonconfig features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

RPC Over HTTP Autoconfig Errors and Events

The following table provides a list of RPC Over Autonconfig errors and events.

Event ID	Category	Event type	Value or description
MSExchangeRPCHTTPAutoconfig 2003	General	Error	The RPC over HTTP Proxy component is not installed or is not properly configured. Use the Windows Component Wizard to add the RPC over HTTP Proxy component to the Networking Services.
MSExchangeRPCHTTPAutoconfig 2008	General	Information	The RPC over HTTP Proxy component is currently disabled. This prevents Outlook Anywhere from being

			configured correctly. Enable the RPC over HTTP Proxy component by setting a registry key %1, value %2 to DWORD 1, or disable Outlook Anywhere.
MSExchangeRPCHTTPAutoconfig 3002	General	Warning	Exchange has added the string "ncacn_HTTP:6004" to the following registry key entry: HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NTDS\Parameters\NSPI Interface Protocol Sequences. You must reboot the server before you can use it for Outlook Anywhere.
MSExchangeRPCHTTPAutoconfig 3003	General	Information	The Outlook Anywhere authentication settings have been updated.Old settings: %1New settings: %2
MSExchangeRPCHTTPAutoconfig 3008	General	Information	The Outlook Anywhere feature has been enabled. The Client Access server resource pool registry setting has been modified to reflect this change.New value: %2

MSExchangeServiceHost 2010	General	Information	Service stopped successfully.
MSExchangeServiceHost 2014	General	Information	The Mailbox server role is installed.
MSExchangeServiceHost 2016	General	Information	The Client Access server role is installed.
MSExchangeServiceHost 2017	General	Information	The Unified Messaging server role is installed.
MSExchangeServiceHost 2018	General	Information	The Hub Transport server role is

			installed.

1.7 Transport

Transport

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-10*

The component of Microsoft Exchange that is responsible for transferring messages is known as Transport. Two server roles are involved:

- **Edge Transport** The mail routing server that typically sits at the perimeter of the topology and routes mail between the Exchange organization and the Internet.
- **Hub Transport** The mail routing server that routes mail within the Exchange organization.

The following topics are gateways to information about Transport in Exchange Server 2010:

Understanding Transport

1.7.1.1 Overview of the Edge Transport Server Role

Overview of the Edge Transport Server Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In Microsoft Exchange Server 2010, the Edge Transport server role is deployed in your organization's perimeter network. Designed to minimize the attack surface, the Edge Transport server handles all Internet-facing mail flow, which provides SMTP relay and smart host services for the Exchange organization. Additional layers of message protection and security are provided by a series of agents that run on the Edge Transport server and act on messages as they're processed by the message transport components. These agents support the features that provide protection against viruses and spam and apply transport rules to control message flow.

The computer that has the Edge Transport server role installed doesn't have access to Active Directory. All configuration and recipient information is stored in Active Directory Lightweight Directory Services (AD LDS). To perform recipient lookup tasks, the Edge Transport server requires data that resides in Active Directory. This data is synchronized to the Edge Transport server using EdgeSync. EdgeSync is a collection of processes that are run on a computer that has the Hub Transport server role installed to establish one-way replication of recipient and configuration information from Active Directory to the AD LDS instance on an Edge Transport server. The Microsoft Exchange EdgeSync service copies only the information that's required for the Edge Transport server to perform anti-spam configuration tasks and the information about the connector configuration that's

required to enable end-to-end mail flow. The Microsoft Exchange EdgeSync service performs scheduled updates so that the information in AD LDS remains current.

You can install more than one Edge Transport server in the perimeter network. Deploying more than one Edge Transport server provides redundancy and failover capabilities for your inbound message flow. You can load-balance SMTP traffic to your organization between Edge Transport servers by defining more than one mail exchange (MX) resource record with the same priority in the Domain Name System (DNS) database for your mail domain. You can achieve consistency in configuration between multiple Edge Transport servers by using cloned configuration scripts.

The message-processing scenarios that you can manage on the Edge Transport server role are described in the following sections.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Internet Mail Flow

Servers that run the Edge Transport server role accept messages that come into the Exchange 2010 organization from the Internet. After the messages are processed by the Edge Transport server, they are routed to Hub Transport servers inside the organization.

All messages that are sent to the Internet from the organization are routed to Edge Transport servers after the messages are processed by the Hub Transport server. You can configure the Edge Transport server to use DNS to resolve MX resource records for external SMTP domains, or you can configure the Edge Transport server to forward messages to a smart host for DNS resolution.

For more information about mail flow, see Understanding Transport Pipeline.

Anti-Spam and Antivirus Protection

In Exchange 2010, the anti-spam and antivirus features provide services to block viruses and spam, or unsolicited commercial e-mail, at the network perimeter. Most viruses use spam-like tactics to gain access to your organization and to entice users to open an e-mail message. If you can filter out most of your spam, you're also more likely to capture viruses before they enter your organization.

Spammers use a variety of techniques to send spam into your organization. Servers that run the Edge Transport server role help prevent users in your organization from receiving spam by providing a collection of agents that work together to provide different layers of spam filtering and protection. Establishing tarpitting intervals on connectors makes e-mail harvesting attempts ineffective.

For more information about the anti-spam and antivirus features in Exchange 2010, see Understanding Anti-Spam and Antivirus Functionality.

Edge Transport Rules

Edge Transport rules are used to control the flow of messages that are sent to or received from the Internet. The Edge Transport rules help protect corporate network resources and data by applying an action to messages that meet specified conditions. These rules are configured for each server. Edge Transport rule conditions are based on data, such as specific words or text patterns in the message subject, body, header, or From address, the spam confidence level (SCL), or attachment type. Actions determine how the message is processed when a specified condition is true. Possible actions include

quarantine of a message, dropping or rejecting a message, appending additional recipients, or logging an event. Optional exceptions exempt particular messages from having an action applied.

For more information about the Edge Transport rules, see Understanding Transport Rules.

Address Rewriting

You use address rewriting to present a consistent appearance to external recipients of messages from your Exchange 2010 organization. You configure the Address Rewriting agent on the Edge Transport server role to enable the modification of the SMTP addresses on inbound and outbound messages. Address rewriting is especially useful when a newly merged organization that has several domains wants to present a consistent appearance of e-mail addresses to external recipients.

For more information about address rewriting, see Understanding Address Rewriting.

1.7.1.2 Overview of the Hub Transport Server Role

Overview of the Hub Transport Server Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Deployed inside your Active Directory forest, the Hub Transport server role handles all mail flow inside the organization, applies transport rules, applies journaling policies, and delivers messages to a recipient's mailbox. Messages that are sent to the Internet are relayed by the Hub Transport server to the Edge Transport server role that's deployed in the perimeter network. Messages that are received from the Internet are processed by the Edge Transport server before they're relayed to the Hub Transport server. If you don't have an Edge Transport server, you can configure the Hub Transport server to relay Internet messages directly or utilize a third-party smart host. You can also install and configure the Edge Transport server agents on the Hub Transport server to provide anti-spam and antivirus protection inside the organization, although this isn't recommended.

You can install the Hub Transport server role on the same hardware with any other internal server role or on a server that's dedicated to the Hub Transport server role. You must deploy a Hub Transport server role in each Active Directory site that contains a Mailbox server role. Deploying more than one Hub Transport server per site provides redundancy. When you install more than one Hub Transport server in an Active Directory site, the connections are distributed.

The message-processing scenarios that you can manage on the Hub Transport server role are described in the following sections.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Internal Mail Flow

The Hub Transport server role processes all messages that are sent inside the Microsoft Exchange Server 2010 organization before the messages are delivered to a recipient's Inbox or are routed to users outside the organization. There are no exceptions to this behavior; messages are always passed through a server that runs the Hub Transport

server role.

Messages are submitted to the Hub Transport server in three ways: through SMTP submission, from the Pickup directory, or when a user inside the organization sends a message, which is picked up from the user's Outbox by the *store driver*. The store driver is a software component of the Hub Transport server that delivers inbound messages to *Exchange stores*, the databases that contain public folder and mailbox stores.

When messages are submitted to the Hub Transport server, they're processed by the categorizer. The *categorizer* is a component of Exchange transport that processes all inbound messages and determines what to do with the messages based on information about the intended recipients. In Exchange 2010, the Hub Transport server uses the categorizer to expand distribution lists and to identify alternative recipients and forwarding addresses. After the categorizer retrieves full information about the recipients, it uses that information to apply policies, route the messages, and perform content conversion. Messages are then delivered locally by the store driver to a recipient's mailbox, or they're delivered remotely by using SMTP to send messages to another transport server. Messages that are sent by users in your organization are picked up from the sender's Outbox by the store driver and are put in the Submission queue on a server that runs the Hub Transport server role. For more information, see Understanding Transport Pipeline.

Messaging Policy and Compliance Features

With a collection of transport agents, you can configure rules and settings that are applied as messages enter and leave the mail flow components. You can create messaging policy and rule settings that are designed to meet different regulations and that can easily be changed to adapt to your organization's requirements. The transport-based messaging policy and compliance features include server-based rules that you configure to enforce your organization's compliance scenarios and the Journaling agent that acts to enforce message retention. For more information, see Planning for Compliance.

Anti-Spam and Antivirus Protection

Exchange 2010 provides anti-spam and antivirus protection for messages. Although these features are designed for use in the perimeter network on the Edge Transport server role, the Edge Transport agents can also be configured on the Hub Transport server. By default, these agents aren't enabled on the Hub Transport server role. To use the anti-spam features on the Hub Transport server, you must register the agents in a configuration file and enable the features that you want to use by running a provided Exchange Management Shell script. You install and enable the antivirus agent in a separate operation. For more information, see Understanding Anti-Spam and Antivirus Functionality.

1.7.1.3 Understanding Accepted Domains

Understanding Accepted Domains

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-23*

An accepted domain is any SMTP namespace for which a Microsoft Exchange organization sends or receives e-mail. Accepted domains include those domains for which the Exchange organization is authoritative. An Exchange organization is authoritative when it handles mail delivery for recipients in the accepted domain. Accepted domains also include domains for which the Exchange organization receives mail and then relays it to an e-mail server that's outside the Active Directory forest for delivery to the recipient.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Configuring Accepted Domains

Accepted domains are configured as global settings for the Exchange organization and on computers that have the Edge Transport server role installed. You must configure every domain for which your Hub Transport servers relay or deliver messages as an accepted domain in your organization. The Edge Transport server requires that all domains for which it accepts and relays messages are configured as accepted domains.

We recommend that you create and manage all accepted domains inside the organization and synchronize that information to the Edge Transport server by creating an Edge Subscription. When you subscribe the Edge Transport server to the Microsoft Exchange Server 2010 organization, all accepted domains that are configured in the organizational settings for the Hub Transport server role are replicated to the Edge Transport server during EdgeSync synchronization. To modify the accepted domain configuration on an Edge Transport server that's subscribed to the Exchange 2010 organization, you must make the change on the Hub Transport server.

There are three types of accepted domains: authoritative, internal relay, and external relay. These accepted domain types are described in the following sections.

Return to top

Authoritative Domains

An organization may have more than one SMTP domain. The set of e-mail domains for an organization are the authoritative domains. In Exchange 2010, an accepted domain is considered authoritative when the Exchange organization hosts mailboxes for recipients in this SMTP domain. The Edge Transport servers should always accept e-mail that's addressed to any of the organization's authoritative domains.

By default, when the first Hub Transport server role is installed, one accepted domain is configured as authoritative for the Exchange organization. The default accepted domain is the fully qualified domain name (FQDN) for your forest root domain. Frequently, the internal domain name differs from the external domain name. For example, your internal domain name may be Contoso.local, although your external domain name is Contoso.com. The Domain Name System (DNS) mail exchange (MX) resource record for your organization

references Contoso.com. Contoso.com is the SMTP namespace that you assign to users when you create an e-mail address policy. You must create an accepted domain to match your external domain name.

By default, no accepted domains are configured on the Edge Transport server role.

Return to top

Relay Domains

When e-mail is received from the Internet by an Edge Transport server and the recipient of the message isn't part of an authoritative domain, the sending server tries to relay through the Exchange server. When a server acts as a relay server that has no restrictions, it can put a large burden on Internet-connected servers. Administrators can prevent this open relay scenario by rejecting all e-mail that isn't addressed to a recipient in the organization's authoritative domains. However, there are scenarios where an organization wants to let partners or subsidiaries relay e-mail through the Exchange servers. In Exchange 2010, you can configure accepted domains as relay domains. Your organization receives the e-mail messages and then relays the messages to another e-mail server.

You can configure a relay domain as an internal relay domain or as an external relay domain. These two relay domain types are described in the following sections.

Internal Relay Domain

When you configure an internal relay domain, some or all of the recipients in this domain don't have mailboxes in this Exchange organization. Mail from the Internet is relayed for this domain through Hub Transport servers in this Exchange organization. This configuration is used in the scenarios that are described in this section.

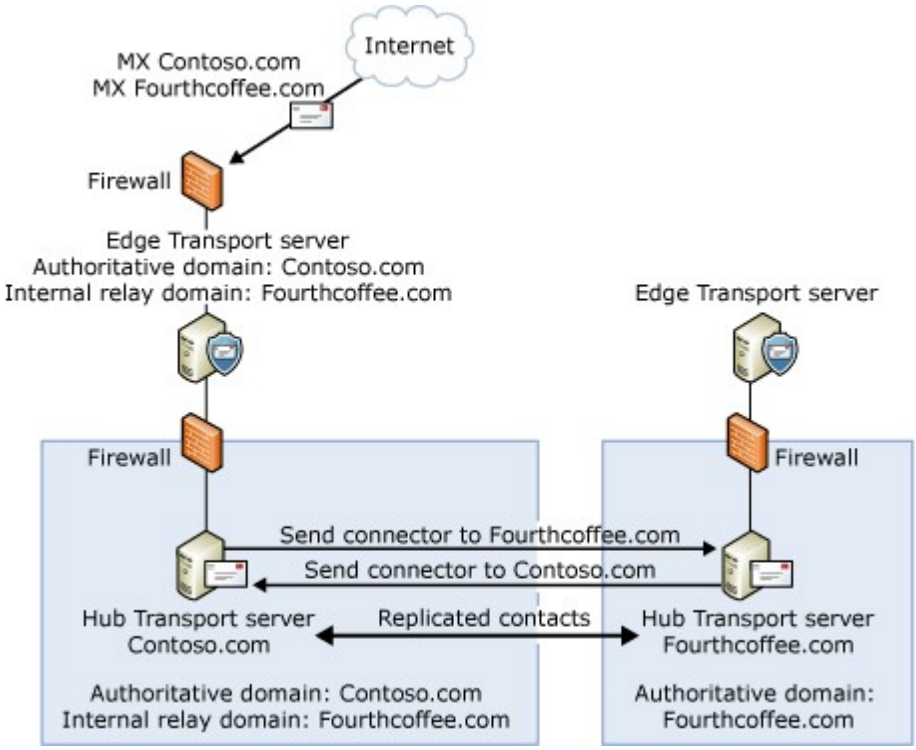
An organization may have to share the same SMTP address space between two or more different e-mail systems. For example, you may have to share the SMTP address space between Microsoft Exchange and a third-party e-mail system, or between Exchange environments that are configured in different Active Directory forests. In these scenarios, users in each e-mail system have the same domain suffix as part of their e-mail addresses.

To support these scenarios, you must create an accepted domain that's configured as an internal relay domain. You must also add a Send connector that's sourced on a Hub Transport server and configured to send e-mail to the shared address space. If an accepted domain is configured as authoritative and a recipient isn't found in Active Directory, a non-delivery report (NDR) is returned to the sender. The accepted domain that's configured as an internal relay domain first tries to deliver to a recipient in the Exchange organization. If the recipient isn't found, the message is routed to the Send connector that has the closest address space match.

If an organization contains more than one forest and has configured global address list (GAL) synchronization, the SMTP domain for one forest may be configured as an internal relay domain in a second forest. Messages from the Internet that are addressed to recipients in internal relay domains are received and processed by the Edge Transport server and then relayed to the Hub Transport servers in the same organization. The receiving Hub Transport servers then route the messages to the Hub Transport servers in the recipient forest. You configure the SMTP domain as an internal relay domain to make sure that e-mail that's addressed to that domain is accepted by the Exchange organization. The connector configuration of your organization determines how messages are routed.

In the following figure, Fourthcoffee.com is configured as an internal relay domain for the

Exchange 2010 organization in the Contoso.com forest. The MX resource records for Fourthcoffee.com reference a public IP address for the Contoso.com organization. A forest trust exists between Fourthcoffee.com and Contoso.com, and GAL synchronization is configured. The Contoso.com Edge Transport server accepts messages for the Fourthcoffee.com SMTP domain from the Internet and then relays those messages to the Hub Transport servers in the Contoso.com Exchange organization. The messages are then routed to the Hub Transport servers in the Fourthcoffee.com Exchange organization. A cross-forest Send connector is configured for routing messages from Contoso.com to Fourthcoffee.com. Messages that are sent from Fourthcoffee.com to external recipients are routed to the Hub Transport servers in the Contoso.com forest. A second cross-forest Send connector is configured for routing messages from Fourthcoffee.com to Contoso.com. When the Hub Transport servers in Contoso.com receive messages from the internal relay domain Fourthcoffee.com, they deliver messages for recipients in authoritative domains and relay messages for Internet recipients to the Edge Transport server for delivery.



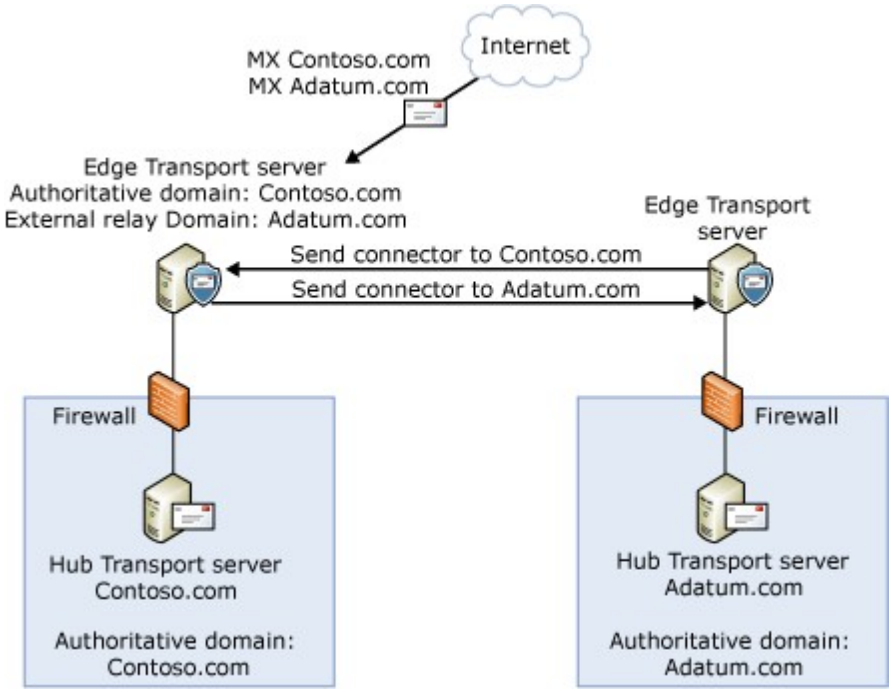
External Relay Domain

When you configure an external relay domain, messages are relayed to an e-mail server that's outside the Exchange organization and outside the organization's network perimeter. The messages are relayed by the Edge Transport server.

In this scenario, the MX resource record for the external relay domain references a public IP address for the Exchange 2010 organization that's relaying messages. The Edge Transport server receives the messages for recipients in the external relay domain and then routes the messages to the e-mail system for the external relay domain. A Send connector from the Edge Transport server to the external relay domain is required in this scenario. The external relay domain may also use your organization's Edge Transport server as a smart host for outgoing mail.

In the following figure, Adatum.com is configured as an external relay domain for the Exchange 2010 organization in the Contoso.com forest. The MX resource record for Adatum.com references a public IP address for the Contoso.com organization. The

Contoso.com Edge Transport server accepts messages for the Adatum.com SMTP domain from the Internet and then relays those messages to the e-mail servers in the Adatum.com organization. Adatum.com also uses the Contoso.com Edge Transport server as a smart host for routing outgoing messages. Messages that are sent from Adatum.com to external recipients are routed to the Edge Transport servers in the Contoso.com organization. When the Edge Transport servers in Contoso.com receive messages from Adatum.com, they deliver messages for recipients in authoritative domains and internal relay domains to the Hub Transport servers and route messages to the Internet.



Return to top

Accepted Domains and E-Mail Address Policies

You must configure an accepted domain before that SMTP address space can be used in an e-mail address policy. When you create an accepted domain, you can use a wildcard character (*) in the address space to indicate that all subdomains of the SMTP address space are also accepted by the Exchange organization. For example, to configure Contoso.com and all its subdomains as accepted domains, enter *.Contoso.com as the SMTP address space. The accepted domain entries are automatically available for use in an e-mail address policy.

If you delete an accepted domain that's used in an e-mail address policy, the policy is no longer valid, and recipients with e-mail addresses in that SMTP domain will be unable to send or receive e-mail.

Return to top

1.7.1.4 Understanding Address Rewriting

Understanding Address Rewriting

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

In Microsoft Exchange Server 2010, address rewriting enables you to modify the addresses of senders and recipients on messages that enter and leave your Exchange 2010 organization.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Why Use Address Rewriting?

You use address rewriting to present a consistent appearance to external recipients of messages from your Exchange 2010 organization. Address rewriting can be valuable to organizations that use third-party vendors to provide e-mail support and services. Customers and partners expect e-mail messages to come from the organization, not a third-party vendor. Similarly, after a merger or acquisition, an organization might want all e-mail messages to appear to come from the single new organization. The address rewriting feature frees organizations to structure their businesses by business requirements instead of by technical requirements or limitations.

You can also use address rewriting to enable appropriate routing of inbound messages from outside your Exchange 2010 organization to internal recipients. Address rewriting enables replies to messages that were rewritten to be correctly routed to the original sender of the rewritten message.

You configure Address Rewriting agents on the Receive connector and Send connector on a computer that has the Edge Transport server role installed.

Return to top

Address Rewriting Scenarios

The following scenarios are examples of how address rewriting can benefit organizations:

- **Group consolidation** Some organizations segment their internal businesses into separate domains that are based on business or technical requirements. However, this configuration can cause e-mail messages to appear as if they come from separate groups or even separate organizations. This appearance might not be desirable to the organization.
  The following example shows how an organization, Contoso, Ltd., could hide its subdomains:
  - Outbound messages from the Northamerica.contoso.com, Europe.contoso.com, and Asia.contoso.com domains are rewritten to appear as if they all originate from a single Contoso.com domain. All messages are rewritten as they pass through Edge Transport servers that provide SMTP connectivity between the whole organization and the Internet.
  - Inbound messages to the Contoso.com domain are passed on by the Edge Transport server to the Hub Transport server role, which then determines the correct recipient. For example, messages to chris@contoso.com are sent to an internal Hub Transport server, which then determines the correct mailbox to send the message to by using the proxy address that's configured on the recipient's e-mail account.
- **Mergers and acquisitions** When organizations merge or are acquired, their technology infrastructure must be modified to match new business and technical requirements. An acquired company may continue to run as a separate business unit, but the e-mail administrator can use address rewriting to make the two organizations appear as if they're one integrated organization.
  The following example shows how Contoso, Ltd. could hide the e-mail domain of the newly acquired company, Fourth Coffee:
  - Contoso, Ltd. wants all outbound messages from Fourth Coffee's Exchange organization to appear as if they originate from Contoso.com. All messages from both organizations are sent through the Edge Transport servers at Contoso, Ltd., where e-mail messages are rewritten from *someone*@fourthcoffee.com to *someone*@contoso.com.
  - Inbound messages to adam@contoso.com are rewritten and routed to his adam@fourthcoffee.com e-mail account. Incoming messages that use his old adam@fourthcoffee.com domain are also accepted, because the domain still exists. Inbound replies to e-mail messages that were rewritten are handled by the Edge Transport servers at Contoso, Ltd., where the Address Rewriting agent rewrites the recipient address so that replies are correctly routed to the appropriate Fourthcoffee.com e-mail address. Replies to e-mail messages that were sent before the merger to Fourthcoffee.com e-mail addresses are routed directly to Fourth Coffee's e-mail servers.
- **Partners** Many organizations use external partners to provide services for their customers, other partners, or the organization itself. To avoid confusion, the organization might replace the e-mail domain of the partner organization with its own e-mail domain.
  The following example shows how Contoso, Ltd. could hide a partner's e-mail domain:
  - Contoso, Ltd. provides support for the larger Wingtip Toys organization. Wingtip Toys wants a unified experience for its customers and requires all messages that originate from support personnel at Contoso, Ltd. to appear as if they were sent from Wingtip Toys. All outbound messages that relate to Wingtip Toys are sent through their Edge Transport servers, and all Contoso.com addresses are rewritten to appear as Wingtiptoys.com addresses.
  - Inbound messages for support@wingtiptoys.com are accepted by Wingtip Toy's Edge Transport servers, rewritten, and then routed to the

support@contoso.com e-mail address.

> **Caution:**
> So that inbound e-mail is appropriately mapped and routed, you must make sure that the user name part of the address is unique across all e-mail organizations that may be affected by address rewriting.

Return to top

SMTP Message Headers

Address Rewriting agents rewrite e-mail addresses by rewriting the SMTP headers on e-mail messages that are sent and received by an Edge Transport server. Address Rewriting agents typically rewrite outbound messages because the organization wants to hide the internal domains and subdomains as effectively as possible and present a single external domain to the Internet. Address Rewriting agents typically rewrite inbound messages to route those messages to their intended recipients. For these reasons, Address Rewriting agents rewrite several SMTP header fields on outbound e-mail messages. Address Rewriting agents rewrite only one SMTP header field on inbound e-mail messages. The following table shows which SMTP header fields are rewritten on outbound and inbound messages.

SMTP header fields rewritten on outbound and inbound messages

SMTP header field	Outbound	Inbound
Envelope From (MAIL FROM)	Rewritten	Not rewritten
Envelope To (RCPT TO)	Not rewritten	Rewritten
Body To	Rewritten	Not rewritten
Body Cc	Rewritten	Not rewritten
Body From	Rewritten	Not rewritten
Body Sender	Rewritten	Not rewritten
Body Reply-To	Rewritten	Not rewritten
Body Return-Receipt-To	Rewritten	Not rewritten
Body Disposition-Notification-To	Rewritten	Not rewritten
Body Resent-From	Rewritten	Not rewritten
Body Resent-Sender	Rewritten	Not rewritten

Return to top

What Address Rewriting Agents Don't Rewrite

Address Rewriting agents don't rewrite several SMTP header fields, because address rewriting would break SMTP functionality. For example, changing these SMTP headers could affect message loop detection, invalidate the signature, or make a rights-protected

message unreadable. The following SMTP header fields aren't modified by the Address Rewriting agents:

- **Return-Path**
- **Received**
- **Message-ID**
- **X-MS-TNEF-Correlator**
- **Content-Type Boundary=string**
- **Headers located inside MIME body parts**

Address Rewriting agents also don't rewrite header fields within e-mail messages that contain domains for which the Hub Transport server isn't authoritative. Rewriting such domains causes an uncontrollable form of message relay.

Address Rewriting agents also don't modify the header fields of messages that are embedded in another message. Senders and recipients expect embedded messages to remain intact and be delivered without modification, as long as the messages don't trigger transport rules that are implemented between the sender and recipient.

Return to top

Considerations for Use of Outbound-Only Address Rewriting

When an e-mail message is outbound from the Exchange 2010 organization, outbound-only address rewriting involves modification of the sender SMTP address only. The Address Rewriting agent is configured only on the Send connector on the Edge Transport server. The following list shows the conditions that are required to configure an outbound-only Address Rewriting agent:

- The resulting addresses must be unique across the organization. For example, if the unique e-mail addresses ed@sales.contoso.com and ed@research.contoso.com are included in a rule to rewrite all addresses to contoso.com, the Address Rewriting agent will rewrite both addresses to ed@contoso.com and will cause a conflict.
- A proxy address must be configured on each mailbox that matches the rewritten e-mail address. This enables those mailboxes to receive replies to e-mail messages in which headers are rewritten.
- When you use wildcard characters, there must be a period between the wildcard character and the domain name.
- You can use wildcard characters only in the internal domain.
- No characters can be in front of the wildcard character.
- Outbound-only address rewriting can't affect the user name or display name part of the address.
- Only literal strings are supported.

Return to top

Considerations for Bidirectional Address Rewriting

Bidirectional address rewriting modifies the sender SMTP address on e-mail messages that are leaving the Exchange organization and the recipient SMTP address on e-mail messages that are entering the Exchange organization. To do this, you configure the Address Rewriting agent on both the Send connector and Receive connector on the Edge Transport server.

The following list shows the conditions that are required when you create a bidirectional Address Rewriting agent:

- You can't use wildcard characters.
- You must use full SMTP addresses when you configure a bidirectional address rewriting rule. For example, the internal address is chris@contoso.com, and the external address is support@contoso.com.
- Only literal strings are supported.
- The address must be unique across the organization. For example, if an e-mail address, bob@contoso.com, already exists, mapping robert@fourthcoffee.com to bob@contoso.com will cause replies to messages from bob@contoso.com to be delivered to the wrong person.

Return to top

Considerations for Rewriting Addresses in Multiple Domains

Before you create an address rewrite entry that rewrites multiple domains, you must prepare your subdomains. Also, before you perform the procedure for creating an address rewrite entry for multiple subdomains that's described in Create an Address Rewrite Entry, you must understand the requirements for rewriting e-mail addresses in multiple domains to a single domain, and the appropriate preconfiguration for the affected mailboxes and contacts.

Important Considerations

When you flatten internal subdomains into a single external domain, you must consider the following factors, which apply only when multiple subdomains are being rewritten:

- **Unique aliases are required** All e-mail aliases, the part of the e-mail address to the left of the at (@) sign, must be unique across all subdomains. For example, if there is a joe@sales.contoso.com, there can't be a joe@marketing.contoso.com.
- **Proxy addresses are required** A proxy address that matches the e-mail address that's produced by the Address Rewriting agent must be configured on every e-mail account that's in the subdomains that are rewritten. For example, if joe@sales.contoso.com is rewritten to joe@contoso.com, the e-mail address joe@contoso.com must be added as a proxy address to Joe's mailbox.
- **Contacts may be required** If you're rewriting e-mail from a non-Exchange 2010 e-mail system, you must create Active Directory mail-enabled contacts for each e-mail address in the non-Exchange 2010 e-mail address that's being rewritten. This mail-enabled contact must contain the original e-mail address and the rewritten e-mail address. For example, if joe@unix.contoso.com is rewritten to joe@contoso.com, you must create a mail-enabled contact in Active Directory with joe@unix.contoso.com as the target SMTP address and joe@contoso.com as the proxy SMTP address.

These factors are important because rewriting addresses in multiple subdomains causes a many-to-one relationship between internal subdomains and the externally visible domain. Because of this many-to-one relationship, the Address Rewriting agent can't determine which subdomain contains the correct recipient when a message that's addressed to the externally visible domain is received.

Important:

Make sure that every e-mail alias that exists across all subdomains is unique. Exchange 2010 doesn't check to verify that every e-mail alias that can be rewritten to a single domain is unique.

Removing Conflicting E-Mail Addresses

To create an address rewrite entry that rewrites multiple subdomains, you must first make sure that all e-mail aliases are unique across all your subdomains. For example, consider the following configuration:

The following users are in the subdomains sales.contoso.com, marketing.contoso.com and research.contoso.com:

- maria@sales.contoso.com
- chris@sales.contoso.com
- david@marketing.contoso.com
- brian@marketing.contoso.com
- chris@research.contoso.com
- adam@research.contoso.com

Each subdomain has two users, and each user has a unique e-mail address. However, you want to rewrite the subdomains sales.contoso.com, marketing.contoso.com, and research.contoso.com into a single domain that's called contoso.com. The following table shows each original e-mail address and its corresponding rewritten e-mail address.

Original e-mail addresses and corresponding rewritten e-mail addresses

Original e-mail address	Rewritten e-mail address
maria@sales.contoso.com	maria@contoso.com
chris@sales.contoso.com	chris@contoso.com
david@marketing.contoso.com	david@contoso.com
brian@marketing.contoso.com	brian@contoso.com
chris@research.contoso.com	chris@contoso.com
adam@research.contoso.com	adam@contoso.com

When the e-mail addresses in each subdomain are rewritten, a conflict occurs between chris@sales.contoso.com and chris@research.contoso.com. Therefore, both e-mail addresses are rewritten to chris@contoso.com. To resolve this situation, you must change the e-mail address of one of the recipient mailboxes to an address that doesn't conflict with the e-mail address in any other subdomain.

Applying Proxy Addresses to Recipient Mailboxes

For internal recipient mailboxes to receive replies to addresses that have been rewritten, you must configure those recipient mailboxes by using a proxy address that matches the rewritten external address.

For example, if a mailbox exists for adam@research.contoso.com, and the rewritten external address is adam@contoso.com, the mailbox must be configured by using a proxy address that's set to adam@contoso.com.

Return to top

Prioritization of Address Rewriting Entries

The rule that best matches the internal and external domain pair is applied. The following prioritization is the exact order of address rewriting entries from highest priority to lowest priority:

1. **Individual e-mail addresses** An example is mapping john@contoso.com to

support@contoso.com.

2. **Specific domain or subdomain mapping** An example is mapping Contoso.com to Northwindtraders.com or Sales.contoso.com to Contoso.com.
3. **Domain flattening** An example is flattening *.contoso.com into Contoso.com. For example, the following two rules are configured on the Edge Transport server:

```
*.contoso.com maps to Contoso.com
Japan.sales.contoso.com maps to contoso.jp
```

If masato@japan.sales.contoso.com sends an e-mail message, the address is rewritten as masato@contoso.jp, because that rule most closely matches the sender's internal domain, even though the *.contoso.com rule is present.

Return to top

Digitally Signed, Encrypted, and Rights-Protected Messages

Address rewriting shouldn't affect most signed, encrypted, or rights-protected messages. If address rewriting were to invalidate a signature, make an encrypted or rights-protected message unreadable, or otherwise change the security status of such messages in any way, address rewriting isn't applied.

Addresses and information in the following message sections can be rewritten, because information in these sections isn't part of message signing, encryption, or rights protection:

- SMTP envelope fields
- Top-level message body headers

Addresses and information in the following message sections isn't rewritten because information in these sections is part of message signing, encryption, or rights protection:

- Headers located inside MIME body parts that may be signed
- The boundary string parameter of the MIME content type

1.7.1.5 Understanding Anti-Spam and Antivirus Functionality

Understanding Anti-Spam and Antivirus Functionality

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

Spammers, or malicious senders, use a variety of techniques to send spam into your organization. No single tool or process can eliminate all spam. Microsoft Exchange Server 2010 builds on the foundation of Exchange Server 2007 to provide a layered, multipronged, and multifaceted approach to reducing spam and viruses. Exchange 2010 includes a variety of anti-spam and antivirus features that are designed to work cumulatively to reduce the spam that enters your organization.

You can reduce the incidences of virus outbreaks and attacks by malicious software, which is also referred to as *malware*, in your organization if you reduce the overall volume of spam that enters your organization. When you eliminate the bulk of the spam at the

computer that has the Edge Transport server role installed, you save processing resources, bandwidth, and storage when the messages are scanned for viruses and other malware further along the mail flow path.

The layered approach to reducing spam refers to the configuration of several anti-spam and antivirus features that filter inbound messages in a specific order. Each feature filters for a specific characteristic or set of related characteristics on the inbound message.

The following sections provide brief descriptions of each default anti-spam and antivirus feature.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Anti-Spam and Antivirus Filters

The anti-spam and antivirus filters are applied in a specific order. For more information, see Understanding Anti-Spam and Antivirus Mail Flow. The following order applies:

1. **Connection filtering** Connection filtering inspects the IP address of the remote server that's trying to send messages to determine what action, if any, to take on an inbound message. The remote IP address is available to the Connection Filter agent as a byproduct of the underlying TCP/IP connection that's required for the SMTP session. Connection filtering uses a variety of IP Block lists, IP Allow lists, as well as IP Block List provider services or IP Allow List provider services to determine whether the connection from the specific IP should be blocked or allowed in the organization.
2. **Sender filtering** Sender filtering compares the sender on the MAIL FROM: SMTP command to an administrator-defined list of senders or sender domains who are prohibited from sending messages to the organization to determine what action, if any, to take on an inbound message.
3. **Recipient filtering** Recipient filtering compares the message recipients on the RCPT TO: SMTP command to an administrator-defined Recipient Block list. If a match is found, the message isn't permitted to enter the organization. The recipient filter also compares recipients on inbound messages to the local recipient directory to determine whether the message is addressed to valid recipients. When a message isn't addressed to valid recipients, the message can be rejected at the organization's network perimeter.
4. **Sender ID** Sender ID relies on the IP address of the sending server and the Purported Responsible Address (PRA) of the sender to determine whether the sender is spoofed or not. PRA is calculated based on the following message headers:
   - Resent-Sender:
   - Resent-From:
   - Sender:
   - From:

For more information about the PRA, see Understanding Sender ID and RFC 4407.

5. **Content filtering** Content filtering uses Microsoft SmartScreen technology to assess the contents of a message. Intelligent Message Filter is the underlying technology of Exchange content filtering. Intelligent Message Filter is based on patented machine-learning technology from Microsoft Research. During its development, Intelligent Message Filter learned distinguishing characteristics of legitimate e-mail messages and spam. Regular updates with Microsoft Exchange Anti-spam Update service ensure that the most up-to-date information is always included when the Intelligent Message Filter runs. Based on the characteristics of millions of messages, Intelligent Message Filter recognizes indicators of both legitimate messages and spam messages. Intelligent Message Filter can accurately assess the probability that an inbound e-mail message is either a legitimate message or spam.
   Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages that are incorrectly classified as spam. Spam quarantine provides a temporary storage location for messages that are identified as spam and that shouldn't be delivered to a user mailbox inside the organization.
   Content filtering also acts on the safelist aggregation feature. Safelist aggregation collects data from the anti-spam safe lists that Microsoft Outlook and Outlook Web App users configure and makes this data available to the Content Filter agent on the computer that has the Edge Transport server role installed in Exchange 2010.
   When an Exchange administrator enables and correctly configures safelist aggregation, the Content Filter agent passes safe e-mail messages to the enterprise mailbox without additional processing. E-mail messages that Outlook users receive from contacts or that those users have added to their Outlook Safe Senders List or have trusted are identified by the Content Filter agent as safe. The result is that messages that are identified as safe aren't classified as spam and unintentionally filtered out of the messaging system.
6. **Sender reputation** Sender reputation relies on persisted data about the IP address of the sending server to determine what action, if any, to take on an inbound message. The Protocol Analysis agent is the underlying agent that implements the sender reputation functionality. A sender reputation level (SRL) is calculated from several sender characteristics that are derived from message analysis and external tests.
   Senders whose SRL exceeds a configurable threshold will be temporarily blocked. All their future connections are rejected for up to 48 hours.
   In addition to the locally calculated IP reputation, Exchange 2010 also takes advantage of IP reputation anti-spam updates, available via Microsoft Update, which provide sender reputation information about IP addresses that are known to send spam.
7. **Attachment filtering** Attachment filtering filters messages based on attachment file name, file name extension, or file MIME content type. You can configure attachment filtering to block a message and its attachment, to strip the attachment and allow the message to pass through, or to silently delete the message and its attachment.
8. **Microsoft Forefront Protection 2010 for Exchange Server** Forefront Protection 2010 for Exchange Server (FPE) is an antivirus software package that's tightly integrated with Exchange 2010 and offers antivirus protection for the Exchange environment. The antivirus protection that's provided by FPE is language independent. However, the setup, administration of the product, and end-user notifications are available in 11 server languages. For more information, see Microsoft Forefront Protection 2010 for Exchange Server.
9. **Outlook junk e-mail filtering** The Outlook junk e-mail filter uses state-of-the-art technology to evaluate whether a message should be treated as a junk e-mail message based on several factors, such as the time that the message was sent, the content and structure of the message, and the

metadata collected by the Exchange Server anti-spam filters. Messages caught by the filter are moved to a special Junk E-mail folder, where the recipient can access them later.

Return to top

Anti-Spam Stamps

Anti-spam stamps help you diagnose spam-related problems by applying diagnostic metadata, or stamps, such as sender-specific information, puzzle validation results, and content filtering results, to messages as they pass through the anti-spam features that filter inbound messages from the Internet. These stamps are visible to the end-user mail client and encode sender-specific information, the version of the spam filter definition file, Outlook puzzle validation results, and content filtering results.

Return to top

Microsoft Update for Anti-Spam Services

Exchange 2010 offers additional services to help keep anti-spam components up to date, taking advantage of the proven Microsoft Update infrastructure.

Microsoft Exchange 2010 Standard Anti-spam Filter Updates offer anti-spam updates every two weeks via Microsoft Update.

The Forefront Security for Exchange Server Anti-spam Update service is a premium service that updates the content filter daily via Microsoft Update. In addition, the premium service includes the spam signature and IP Reputation Service updates that are available on an as-needed basis, up to several times a day. Spam signature updates identify the most recent spam campaigns. IP Reputation Service updates provide sender reputation information about IP addresses that are known to send spam.

Note:

To use the premium service, you must have the Exchange Enterprise client access license (CAL).

Return to top

Using Exchange Hosted Services

Spam filtering is enhanced by or is also available as a service from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

Return to top

Strategy for Anti-Spam Approach

Your strategy for how to configure the anti-spam features and establish the aggressiveness of your anti-spam agent settings requires that you plan and calculate carefully. If you set all anti-spam filters to their most aggressive levels and configure all anti-spam features to reject all suspicious messages, you're more likely to reject messages that aren't spam. On the other hand, if you don't set the anti-spam filters at a sufficiently aggressive level and don't set the spam confidence level (SCL) threshold low enough, you probably won't see a reduction in the spam that enters your organization.

It's a best practice to reject a message when Exchange detects a bad message through the Connection Filter agent, Recipient Filter agent, or Sender Filter agent. This approach is better than quarantining such messages or assigning metadata, such as anti-spam stamps, to such messages. The Connection Filter agent and Recipient Filter agent automatically block messages that are identified by the respective filters. The Sender Filter agent is configurable.

This best practice is recommended because the SCL that underlies connection filtering, recipient filtering, or sender filtering is relatively high. For example, with sender filtering, where the administrator has configured specific senders to block, there's no reason to assign the sender filtering data to such messages and to continue to process them. In most organizations, blocked messages should be rejected. (If you didn't want the messages rejected, you wouldn't have put them on the Blocked Senders List.)

The same logic applies to real-time block list services and recipient filtering, although the underlying confidence isn't as high as the IP Block list. You should be aware that the further along the mail flow path a message travels, the greater the probability of false positives, because the anti-spam features are evaluating more variables. Therefore, you may find that if you configure the first several anti-spam features in the anti-spam chain more aggressively, you can reduce the bulk of your spam. As a result, you'll save processing, bandwidth, and disk resources so that you can process more ambiguous messages.

Ultimately, you must plan to monitor the overall effectiveness of the anti-spam features. If you monitor carefully, you can continue to adjust the anti-spam features to work well together for your environment. With this approach, you should plan on a fairly non-aggressive configuration of the anti-spam features when you start. This approach lets you minimize the number of false positives. As you monitor and adjust the anti-spam features, you can become more aggressive about the type of spam and spam attacks that your organization experiences.

1.7.1.5.1 Understanding Anti-Spam and Antivirus Mail Flow

Understanding Anti-Spam and Antivirus Mail Flow

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-07*

When an external user sends e-mail messages to a server running Microsoft Exchange

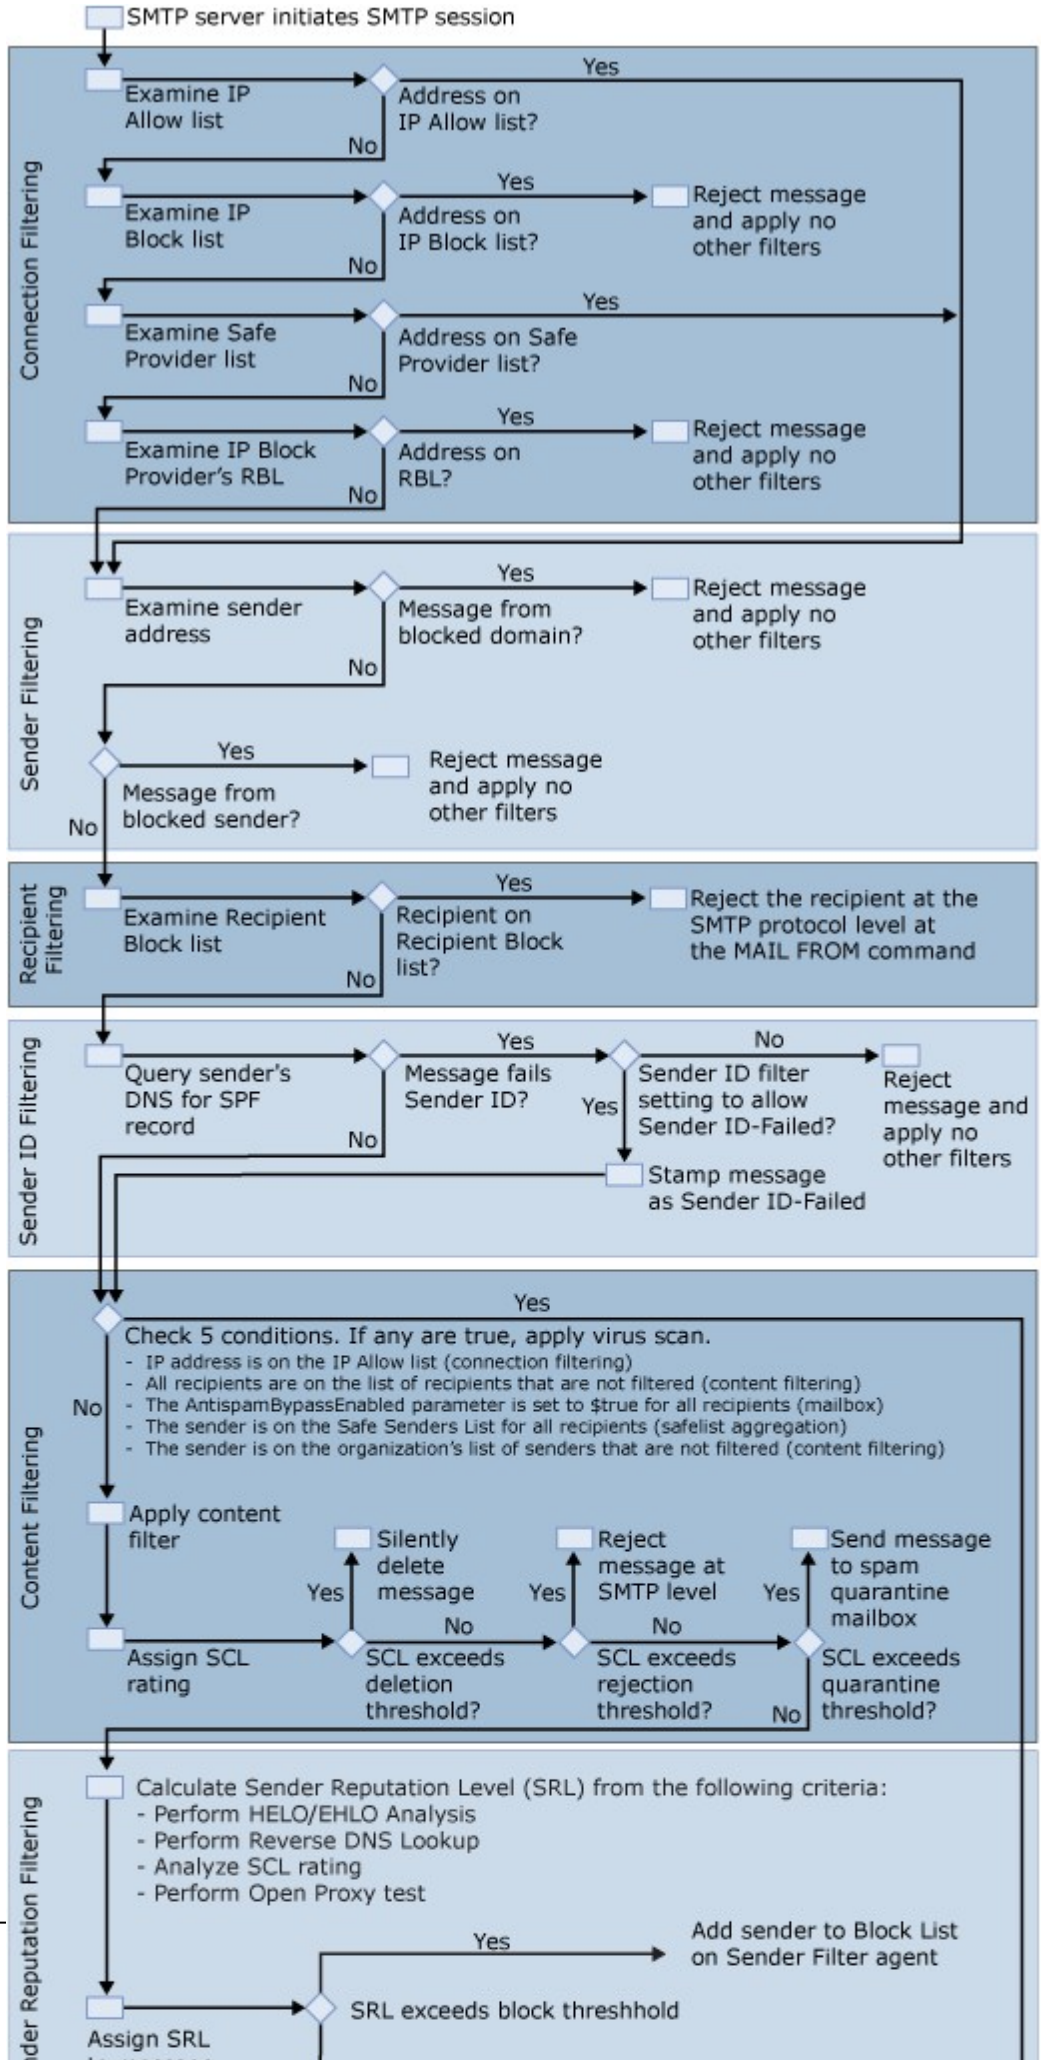
that runs the anti-spam features, the anti-spam features cumulatively evaluate characteristics of inbound messages and either filter out messages suspected to be spam or assign messages a rating based on the probability that the message is spam. This rating is stored with the message as a message property called the *spam confidence level (SCL) rating*. This rating is persisted with the message when the message is sent to other Exchange servers.

The following figure shows the order in which the default anti-spam features and Microsoft Forefront Protection for Exchange Server filter inbound messages from the Internet. By default, the anti-spam and antivirus features are arranged in this order with the filters that use the least resources filtering first, and then the filters that use the greatest resources filtering last.

Note:

The following figures and explanations assume that the Microsoft Exchange Server 2010 Edge Transport server is the first SMTP server to accept inbound messages. In some organizations, the Edge Transport server may be deployed behind a third-party SMTP server. When the Exchange 2010 Edge Transport server is deployed behind a third-party SMTP gateway server, the Exchange 2010 Edge Transport server requires additional configuration. Specifically, you must make sure that all SMTP gateway servers are listed in the **InternalSMTPServer** property of the **TransportConfig** object. For more information, see Set-TransportConfig.

For more information about additional Exchange anti-spam and antivirus features, see Microsoft Forefront Protection 2010 for Exchange Server.



SMTP server initiates SMTP session
Connection Filtering
Examine IP Allow list
Address on IP Allow list?
Yes
No
Examine IP Block list
Address on IP Block list?
Reject message and apply no other filters
Examine Safe Provider list
Address on Safe Provider list?
Examine IP Block Provider's RBL
Address on RBL?
Sender Filtering
Examine sender address
Message from blocked domain?
Message from blocked sender?
Recipient Filtering
Examine Recipient Block list
Recipient on Recipient Block list?
Reject the recipient at the SMTP protocol level at the MAIL FROM command
Sender ID Filtering
Query sender's DNS for SPF record
Message fails Sender ID?
Sender ID filter setting to allow Sender ID-Failed?
Reject message and apply no other filters
Stamp message as Sender ID-Failed
Content Filtering
Check 5 conditions. If any are true, apply virus scan.
- IP address is on the IP Allow list (connection filtering)
- All recipients are on the list of recipients that are not filtered (content filtering)
- The AntispamBypassEnabled parameter is set to $true for all recipients (mailbox)
- The sender is on the Safe Senders List for all recipients (safelist aggregation)
- The sender is on the organization's list of senders that are not filtered (content filtering)
Apply content filter
Assign SCL rating
Silently delete message
SCL exceeds deletion threshold?
Reject message at SMTP level
SCL exceeds rejection threshold?
Send message to spam quarantine mailbox
SCL exceeds quarantine threshold?
Sender Reputation Filtering
Calculate Sender Reputation Level (SRL) from the following criteria:
- Perform HELO/EHLO Analysis
- Perform Reverse DNS Lookup
- Analyze SCL rating
- Perform Open Proxy test
Assign SRL
SRL exceeds block threshhold
Add sender to Block List on Sender Filter agent

As shown in the preceding figure, when an SMTP server connects to Exchange 2010 and initiates an SMTP session, filters are applied in the following order when the Edge Transport server is Internet-facing:

- Connection filtering
- Sender filtering
- Recipient filtering
- Sender ID filtering
- Content filtering
- Sender reputation filtering
- Attachment filtering
- Antivirus scanning
- Outlook junk e-mail filtering

Note:

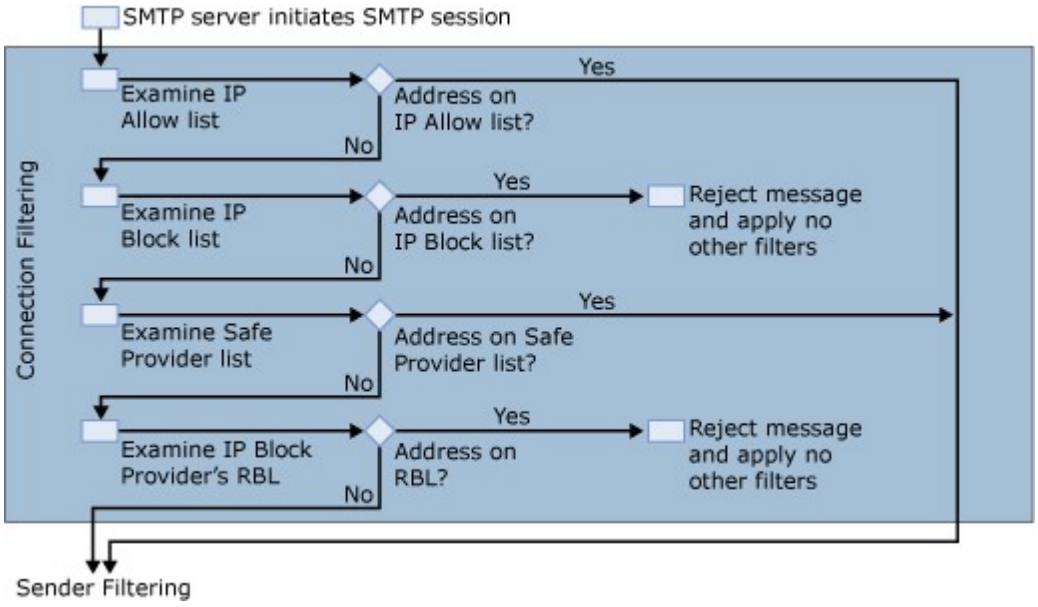
Connection filtering gathers information during two different events. In the first event, connection filtering gathers IP address information from the connection (shown in the preceding figure). In the second event, connection filtering gathers information when the Sender Filter agent parses the message headers to determine the first external IP address (shown in the figure in "Sender Filtering" later in this topic). Agents may monitor multiple events. The preceding figure shows a high-level view of the approximate order in which agents are applied, when all agents are enabled, for the purposes of illustrating message flow. For more information about specific events and which agents monitor which events, see Understanding Transport Agents.

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Contents

Connection Filtering

During the SMTP session, Exchange 2010 applies connection filtering by using the criteria shown in the following figure.



The following process applies:

1. The Connection Filter agent examines the administrator-defined IP Allow list. If the IP address of the sending server is on the administrator-defined IP Allow list, the message is then processed by sender filtering.
2. The Connection Filter agent examines the local IP Block list. If the IP address of the sending server is found on the local IP Block list, the message is automatically rejected, and no other filters are applied.
3. The Connection Filter agent examines the list of allowed IP addresses from any IP Allow List providers that you have. If the IP address of the sending server is on the list of allowed IP addresses from the IP Allow List providers, the message is then processed by sender filtering.
4. The Connection Filter agent examines the real-time block lists of any IP Block List providers that you've configured. If the sending server's IP address is found on a real-time block list, the message is rejected, and no other filters are applied.

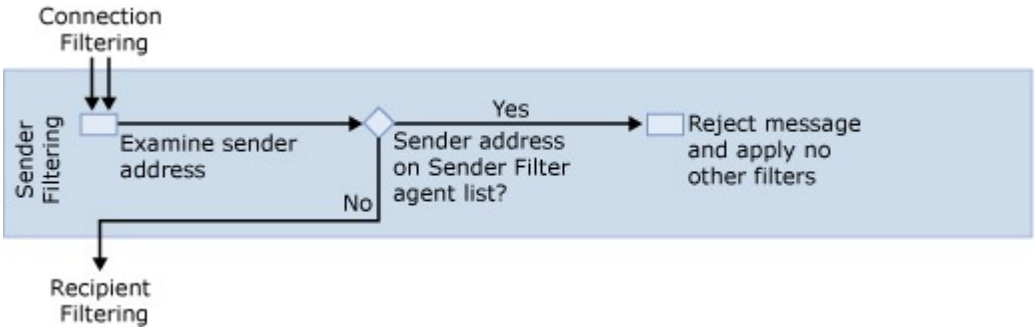
For more information, see Understanding Connection Filtering.

Note:
If the Connection Filter agent is deployed on a computer behind another server that faces the Internet, other filters, such as sender filtering and recipient filtering, are invoked before the Connection Filter agent.

Return to top

Sender Filtering

After connection filtering has been applied, Exchange 2010 examines the sender e-mail address against the list of blocked senders that you configure in sender filtering as shown in the following figure.



The Sender Filter agent then checks the sender's e-mail address contained in the From header fields in the message envelope and the message header. If either From header field matches the address in the Blocked Sender list, Exchange 2010 rejects the message at the protocol level, and no other filters are applied.

Note:
Even if recipients in your organization have put senders on their Microsoft Outlook Safe Senders List, sender filtering on the Edge Transport server will override the recipient's Outlook setting and reject the messages.

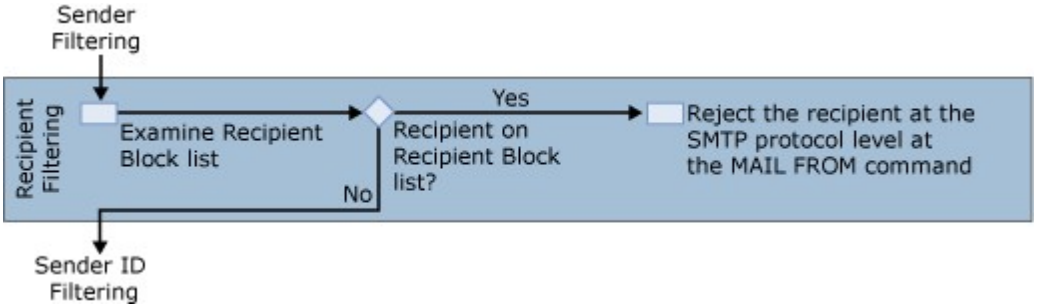
For more information about sender filtering, see Understanding Sender Filtering.

For more information about message envelopes and message headers, see Understanding the Pickup and Replay Directories.

Return to top

Recipient Filtering

If sender filtering doesn't reject the message, Exchange runs connection filtering again. Exchange then applies the Recipient Filter agent as shown in the following figure.



The Recipient Filter agent examines the recipient against the Recipient Block list that you configure in the Recipient Filter agent settings. If the intended recipient matches an e-mail address on your Recipient Block list, Exchange 2010 rejects the message for that particular recipient. In addition, the Recipient Filter agent checks whether the recipient is present in the organization. If the recipient isn't present in the organization, Exchange rejects the message for that particular recipient.

If multiple recipients are listed on the message and all the recipients aren't on the Recipient Block list, the message will continue to process. Otherwise, if the message is bound for only a single blocked recipient, no other filters are applied.

When a message with blocked recipients is processed, the set of blocked recipients are removed from the message, and the message continues into the organization. Protocol-

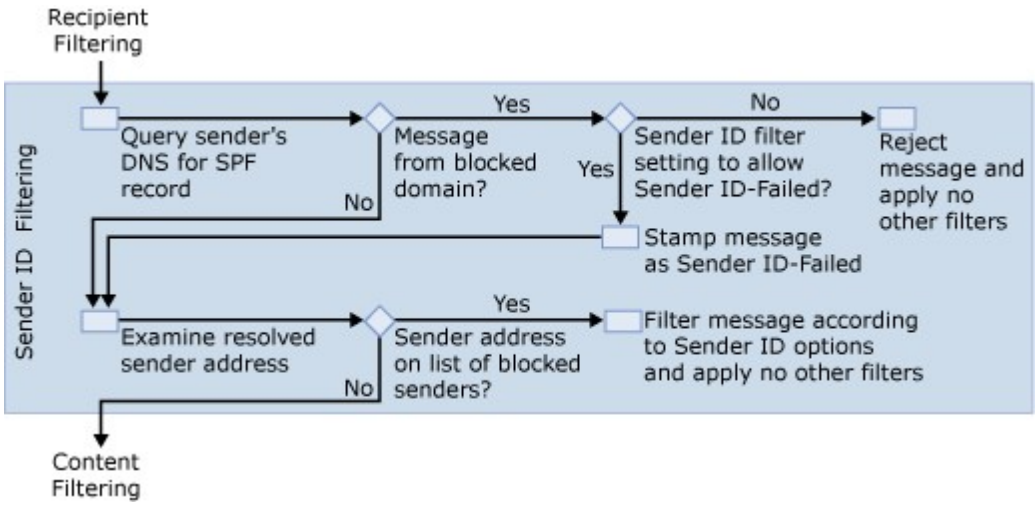
level SMTP rejection responses are sent to the sender for each blocked recipient. The Sender Reputation agent monitors the **OnReject** event to calculate sender reputation level (SRL).

For more information, see Understanding Recipient Filtering.

Return to top

Sender ID Filtering

If the message still contains valid recipients after recipient filtering has been applied, Exchange 2010 runs the Sender ID agent as shown in the following figure.



First, the Sender ID agent determines the Purported Responsible Address (PRA) of the message using the algorithm described in RFC 4407. This step is required to accurately identify the message sender. The PRA is an SMTP address, such as kim@contoso.com. The Sender ID agent then performs a Domain Name System (DNS) lookup against the domain part of the PRA. If that domain has published a sender policy framework (SPF) record, the agent uses the SPF record to evaluate the message according to the specification for RFC 4408. The result of the evaluation is stamped on the message in the anti-spam stamp. If that domain doesn't have a published SPF record, the Sender ID agent stamps a Sender ID result of "None" on the message. For more information about the types of stamps used for Sender ID filtering, see Understanding Anti-Spam Stamps.

If the sender's DNS is from a blocked domain or a blocked address, the following actions may be taken depending on your configuration of Sender ID actions:

- **Reject message** If the Sender ID action is set to **Reject Message**, Exchange rejects the message and sends an SMTP error response to the sending server. The SMTP error response is a 5*xx* level protocol response with text that corresponds to the Sender ID status.
- **Delete message** If the Sender ID action is set to **Delete Message**, Exchange deletes the message without informing the sending server of the deletion. The computer that has the Edge Transport server role installed sends a fake "OK" SMTP command to the sending server, and then deletes the message. Because the sending server assumes that the message was sent, the sending server won't retry sending the message in the same session.
- **Stamp message with Sender ID result and continue processing** Exchange stamps the message with the Sender ID result and continues processing the message. This metadata is evaluated by the Content Filter agent when an SCL is calculated. Additionally, sender reputation uses the message metadata

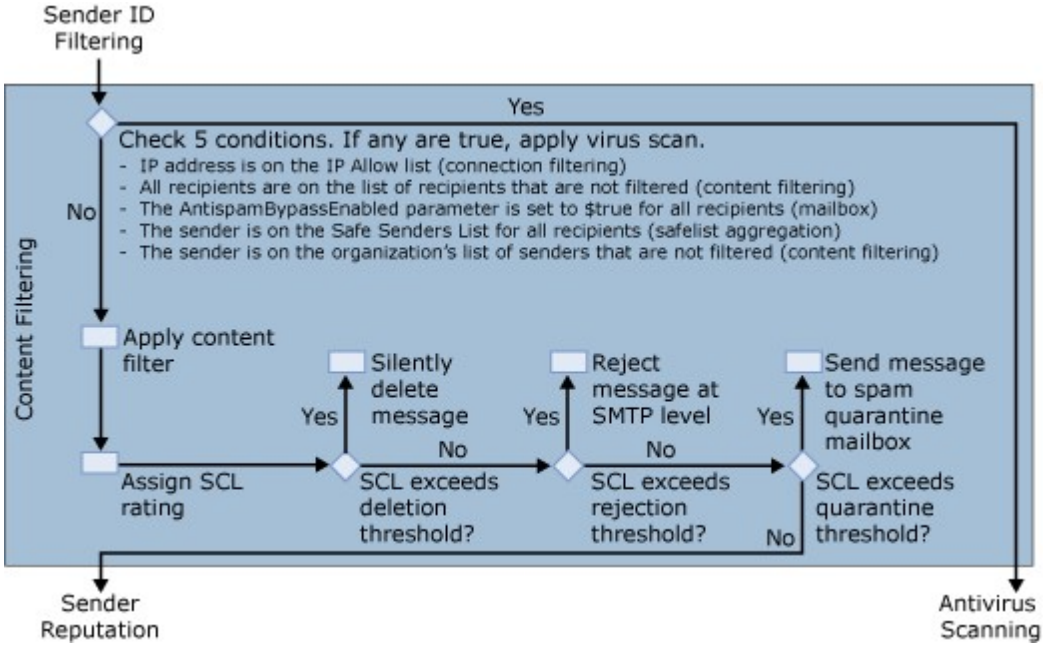
when it calculates an SRL for the sender of the message.

For more information, see Understanding Sender ID.

Return to top

Content Filtering

Before Exchange content filtering calls the Exchange Intelligent Message Filter, it applies sender filtering again. The Exchange server then applies the Content Filter agent as shown in the following figure.



The Content Filter agent checks the following conditions in the message. If any of the conditions are true, the message bypasses content filtering and attachment filtering. These messages then go to antivirus scanning for processing. The following conditions are checked:

- The sender's IP address is on the IP Allow list for connection filtering.
- All recipients are on the exceptions list for content filtering.
- The *AntiSpamBypassEnabled* parameter is set to `$True` on all the recipients' mailboxes.
- All the recipients have added this sender to their Outlook Safe Senders List, which is updated to the Edge Transport server by using safelist aggregation.
- The sender is a trusted partner and on the organization's list of senders that aren't filtered.

In addition to the conditions listed, if the SMTP session has been authenticated as a trusted partner, and if the administrator has granted the Bypass Anti-Spam (Ms-Exch-Bypass-Anti-Spam) permission to partners, the anti-spam agents will be disabled for messages during that session. The Bypass Anti-Spam permission isn't granted to partners by default and must be assigned by an administrator.

If a message doesn't meet any of the conditions described, content filtering is applied. Content filtering assigns an SCL rating to the message. Based on the SCL rating, one of the following actions occurs:

- If the SCL rating on the message is equal to or greater than the SCL delete

threshold, and the SCL delete threshold is enabled, the Content Filter agent deletes the message. There is no protocol-level communication that tells the sending system or sender that the message was deleted. If the SCL rating is lower than the SCL delete threshold value, the Content Filter agent doesn't delete the message. Instead, the Content Filter agent compares the SCL value to the SCL reject threshold.

- If the SCL rating on the message is equal to or greater than the SCL reject threshold, and the SCL reject threshold is enabled, the Content Filter agent rejects the message and sends a rejection response to the sending system. You can customize the rejection response. In some cases, a non-delivery report (NDR) is sent to the original sender of the message. If the SCL rating is lower than the SCL reject threshold value, the Content Filter agent doesn't reject the message. Instead, the Content Filter agent compares the SCL value to the SCL quarantine threshold.
- If the SCL rating on the message is equal to or greater than the SCL quarantine threshold, and the SCL quarantine threshold is enabled, the Content Filter agent sends the message to the spam quarantine mailbox. For more information about how to manage the spam quarantine mailbox, see Understanding Content Filtering. The message then continues to attachment filtering.

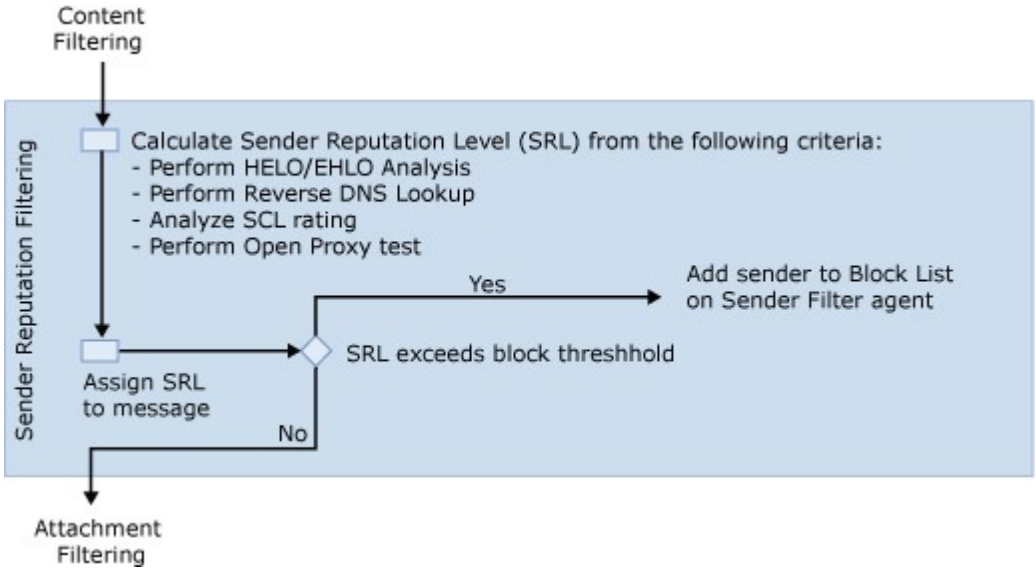
For more information, see the following topics:

- Configure Safelist Aggregation
- Understanding Content Filtering

Return to top

Sender Reputation Filtering

After content filtering has been applied, Exchange applies sender reputation filtering as shown in the following figure.



Sender reputation weighs each of the following message statistics and calculates an SRL for each sender:

- HELO/EHLO analysis
- Reverse DNS lookup
- Analysis of SCL ratings on messages from a specific sender
- Sender open proxy test

The SRL is a number from 0 through 9 that predicts the probability that a specific sender is a spammer or otherwise malicious user. A value of 0 indicates that the sender isn't likely to be a spammer; a value of 9 indicates that the sender is likely to be a spammer.

You can configure an SRL block threshold from 0 through 9 by which sender reputation issues a request to the Sender Filter agent to block the sender from sending a message into the organization. When a sender is blocked, the sender is added to the Blocked Senders list for a configurable period. How blocked messages are handled depends on the configuration of the Sender Filter agent. The following actions are the options for handling blocked messages:

- Reject
- Delete and archive
- Accept and mark as a blocked sender

If a sender is included in the IP Block list or Microsoft IP Reputation Service, the Sender Reputation agent issues an immediate request to the Sender Filter agent to block the sender. To take advantage of this functionality, you must enable and configure the Microsoft Exchange Anti-spam Update Service.

By default, the Edge Transport server sets a rating of 0 for senders that haven't been analyzed. After a sender has sent 20 or more messages, sender reputation calculates an SRL that's based on the statistics listed earlier.

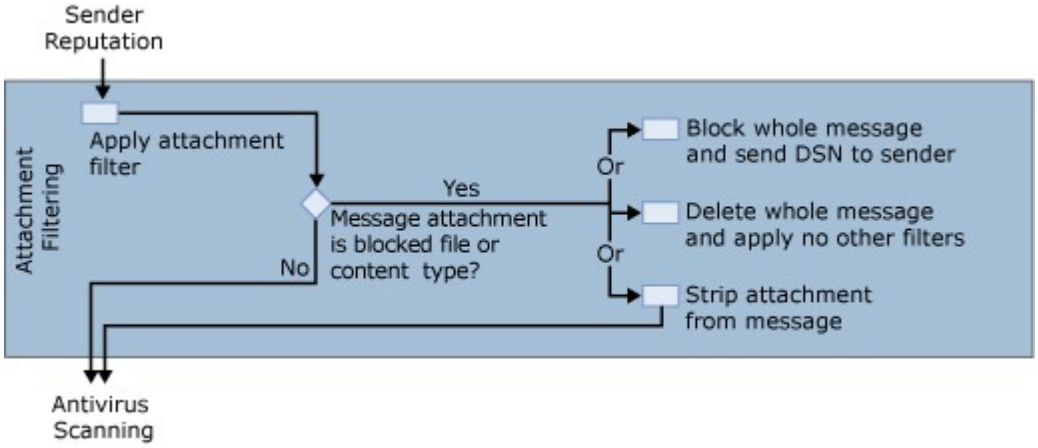
For more information, see the following topics:

- Understanding Sender Reputation
- Configure Sender Reputation Properties

Return to top

Attachment Filtering

After sender reputation filtering has been applied, Exchange applies attachment filtering as shown in the following figure.



You can configure attachment filtering to block attachments based on their MIME content type, file name, or file name extension. If attachment filtering detects a content type or file name that has been blocked, one of the following actions will occur based on your attachment filtering settings:

- **Reject** If the action setting is set to **Reject**, both the e-mail message and attachment are prevented from being delivered to the recipient and the system generates a delivery status notification (DSN) failure message to the

sender. You can customize your rejection response.

- **Silent Delete** If the action setting is set to **Silent Delete**, both the e-mail message and attachment are prevented from being delivered to the recipient. A notification that the e-mail message and attachment were blocked isn't returned to the sender.
- **Strip** If the action setting is set to **Strip**, the attachment is stripped from the e-mail message. This value allows the message and other attachments that don't match an entry on the attachment block list to be delivered to the recipient. A notification that the attachment was blocked is added to the recipient's e-mail message.

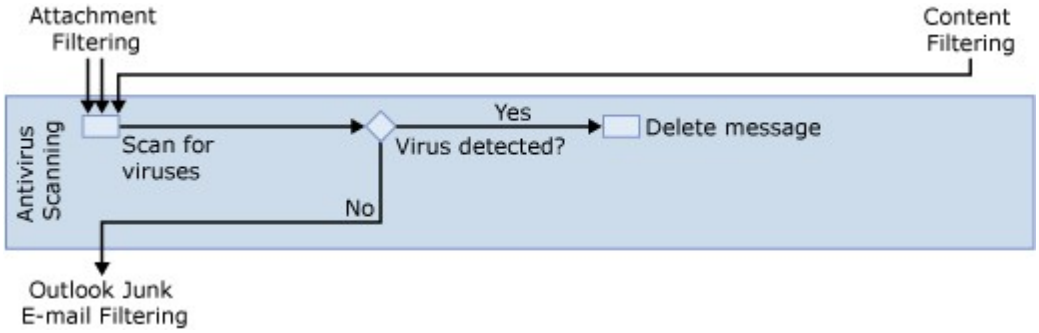
If the message wasn't rejected or deleted, or attachment filtering didn't detect blocked attachment types, the message is then scanned for viruses.

For more information, see Configure Attachment Filtering.

Return to top

Antivirus Scanning

After attachment filtering has been applied, or if the recipients were bypassed in content filtering, Forefront Protection for Exchange Server antivirus scanning is applied as shown in the following figure.



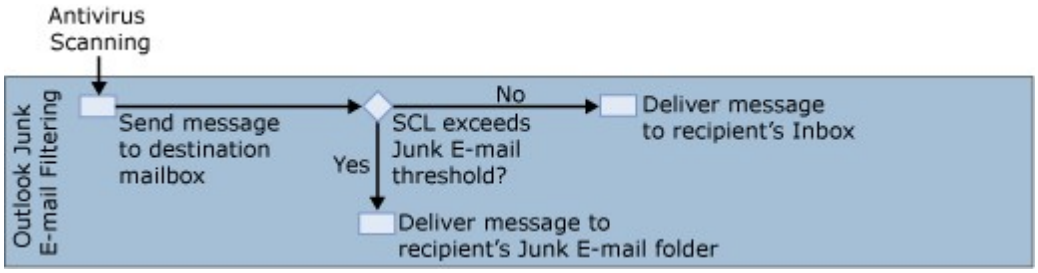
Forefront Protection for Exchange Server is an antivirus software package that's tightly integrated with Exchange 2010 and offers additional antivirus protection for your Exchange environment. When Forefront Protection for Exchange Server detects messages that seem to contain a virus, the system deletes the message, generates a notification message, and sends the notification to the recipient’s mailbox.

For more information, see Microsoft Forefront Protection 2010 for Exchange Server.

Return to top

Outlook Junk E-Mail Filtering

After all the filters are applied and the message has been scanned for viruses, the message is sent to the intended recipient's mailbox and junk e-mail filtering is applied as shown in the following figure.



If the SCL rating for the message is equal to or greater than the SCL Junk E-mail folder threshold, and the SCL Junk E-mail folder threshold is enabled, the Mailbox server puts the message in the Outlook user's Junk E-mail folder. If the SCL value for a message is lower than the values for the SCL delete, reject, quarantine, and Junk E-mail folder thresholds, the Mailbox server puts the message in the user's Inbox. For more information about the SCL thresholds, see Understanding Spam Confidence Level Threshold.

Return to top

1.7.1.5.2 Understanding Anti-Spam Stamps

Understanding Anti-Spam Stamps

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-28*

In Microsoft Exchange Server 2010, anti-spam stamps help you diagnose spam-related problems by applying diagnostic metadata, or stamps, such as sender-specific information, puzzle validation results, and content filtering results, to messages as they pass through the anti-spam features that filter inbound messages from the Internet. There are three anti-spam stamps: the phishing confidence level stamp, the spam confidence level stamp, and the Sender ID stamp.

This topic explains how to view anti-spam stamps and describes the contents of the anti-spam report.

You can use anti-spam stamps as diagnostic tools to determine what actions to take on false-positives and on suspected spam messages that individuals receive in their mailboxes.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Viewing Anti-Spam Stamps

You can view anti-spam stamps by using Microsoft Office Outlook 2007. For more information about how to view anti-spam stamps, see View Anti-Spam Stamps in Outlook 2010 and Outlook 2007.

Understanding the Anti-Spam Report

The anti-spam report is a summary report of the anti-spam filter results that have been applied to an e-mail message. The Content Filter agent applies this stamp to the message

envelope in the form of an X-header as follows.

```
X-MS-Exchange-Organization-Antispam-Report: DV:<DATVersion>;CW:CustomList;PCL:Phi
```

The following table describes the filter information that can appear in an anti-spam report.

Note:
The anti-spam report only displays information from the filters that were applied to the specific message. An anti-spam report doesn't usually contain all the information listed in the following table. For example, you may receive the following anti-spam report: `DV:3.1.3924.1409;SID:SenderIDStatus Fail;PCL:PhishingLevel SUSPICIOUS;CW:CustomList;PP:Presolved;TIME:TimeBasedFeatures`.

Filter information in an anti-spam report

Stamp	Description
SID	The Sender ID (SID) stamp is based on the sender policy framework (SPF) that authorizes the use of domains in e-mail. The SPF is displayed in the message envelope as `Received-SPF`. The Sender ID evaluation process generates a Sender ID status for the message. This status can be returned as one of the following values: • **Pass** Both the IP address and Purported Responsible Address (PRA) passed the Sender ID verification check. • **Neutral** Published Sender ID data is explicitly inconclusive. • **Soft fail** The IP address for the PRA may be in the not permitted set. • **Fail** The IP Address is not permitted; no PRA is found in the incoming mail or the sending domain does not exist. • **None** No published SPF data exists in the sender's DNS. • **TempError** A temporary DNS failure occurred, such as an unavailable DNS server. • **PermError** The DNS record is invalid, such as an error in the record format. The Sender ID stamp is displayed as an X-Header in the message envelope as follows: `X-MS-Exchange-Organization-SenderIdResult:<status>` For more information about Sender ID, see Understanding Sender ID.
DV	The DAT version (DV) stamp indicates the version of the spam definition file that was used when scanning the message.
SA	The signature action (SA) stamp indicates that the message was either recovered or deleted because of a signature that was found in the message.
SV	The signature DAT version (SV) stamp indicates the version of the signature file that was used when scanning the message.
PCL	The phishing confidence level (PCL) stamp displays the rating of the message based on its content and is applied when the message is processed by the Content Filter agent. This status can be returned as one of the following values: • **Neutral** The message's content isn't likely to be phishing. • **Suspicious** The message's content is likely to be phishing. The PCL value can range from 1 through 8. A PCL rating from 1 through 3 returns a status of `Neutral`. This means that the message's content

	isn't likely to be phishing. A PCL rating from 4 through 8 returns a status of `Suspicious`. This means that the message is likely to be phishing. The values are used to determine what action Outlook takes on messages. Outlook uses the PCL stamp to block the content of suspicious messages. The PCL stamp is displayed as an X-header in the message envelope as follows: `X-MS-Exchange-Organization-PCL:<status>`
SCL	The spam confidence level (SCL) stamp of the message displays the rating of the message based on its content. The Content Filter agent uses Microsoft SmartScreen technology to assess the contents of a message and to assign an SCL rating to each message. The SCL value is from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered more likely to be spam. The actions that Exchange and Outlook take depend on your SCL threshold settings. The SCL stamp is displayed as an X-header in the message envelope as follows: `X-MS-Exchange-Organization-SCL:<status>` For more information about SCL thresholds and actions, see Understanding Spam Confidence Level Threshold.
CW	The custom weight (CW) stamp of a message indicates that the message contains an unapproved word or phrase and that the SCL value, or weight, of that unapproved word or phrase was applied to the final SCL score: • Unapproved phrases, or Block phrases, have maximum weight and change the SCL score to 9. • Approved words or phrases, or Allow phrases, have minimum weight and change the SCL score to 0. For more information about how to add approved and unapproved words or phrases to the Content Filtering agent, see Configure Content Filtering Properties.
PP	The presolved puzzle (PP) stamp indicates that if a sender's message contains a valid, solved computational postmark, based on Outlook E-mail Postmark validation functionality, it's unlikely that the sender is a malicious sender. In this case, the Content Filter agent would reduce the SCL rating. The Content Filter agent doesn't change the SCL rating if the E-mail Postmark validation feature is enabled and either of the following conditions is true: • An inbound message doesn't contain a computational postmark header. • The computational postmark header isn't valid. For more information about the postmark validation feature, see Configure Content Filtering Properties.

TIME:TimeBasedFeatures	The TIME stamp indicates that there was a significant time delay between the time that the message was sent and the time that the message was received. The TIME stamp is used to determine the final SCL rating for the message.
MIME:MIMECompliance	The MIME stamp indicates that the e-mail message isn't MIME compliant.
P100:PhishingBlock	The P100 stamp indicates that the message contains a URL that's present in a phishing definition file.
IPOnAllowList	The IPOnAllowList stamp indicates that the sender's IP address is on the IP Allow list. For more information about the IP Allow list, see Understanding Connection Filtering.
MessageSecurityAntispamBypass	The MessageSecurityAntispamBypass stamp indicates that the message wasn't filtered for content and that the sender has been granted permission to bypass the anti-spam filters.
SenderBypassed	The SenderBypassed stamp indicates that the Content Filter agent doesn't process any content filtering for messages that are received from this sender. For more information, see Configure Content Filtering Properties.
AllRecipientsBypassed	The AllRecipientsBypassed stamp indicates that one of the following conditions was met for all recipients listed in the message: • The *AntispamBypassedEnabled* parameter on the recipient's mailbox is set to `$true`. This is a per-recipient setting that can only be set by an administrator. For more information about this setting, see Set-Mailbox. • The message sender is in the recipient's Outlook Safe Senders List. For more information about the Safe Senders List, see Configure Safelist Aggregation. • The Content Filter agent doesn't process any content filtering for messages that are sent to this recipient. For more information about recipient exceptions, see Configure Content Filtering Properties.

1.7.1.5.3 Understanding Anti-Spam Updates

Understanding Anti-Spam Updates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-06*

Microsoft Exchange Server 2010 includes many anti-spam features that depend on downloaded data to determine whether a message can be delivered with confidence that it isn't spam. The following data must be kept up-to-date for the anti-spam features to operate optimally:

- **Content filter updates** These updates contain data about phishing Web sites, Microsoft SmartScreen spam heuristics, and other Intelligent Message Filter updates. Content filter updates generally contain about 6 MB of data that's useful for longer periods of time than other anti-spam update data.
- **Microsoft IP Reputation Service data** The Microsoft IP Reputation Service is an IP Block list service offered exclusively to Exchange 2010 customers. Administrators can decide to implement and use the Microsoft IP Reputation

Service in addition to other real-time block list services.

- **Spam signature data** Spam signatures identify the latest spam campaigns. The spam is hashed into a message digest, or *spam signature*. This data is used by content filtering to assign a higher spam confidence level (SCL) to known spam. The spam signature files are small. A collection of spam signatures is only a few KB. The spam signatures are also time sensitive. Therefore, they're updated more frequently than other anti-spam data sets.

Anti-spam updates contain data only. They don't contain updated binaries or libraries. Anti-spam updates don't require mail flow interruption or service restarts.

Updates with Microsoft Update

By default, anti-spam updates aren't automatic. Instead, the administrator must visit Microsoft Update to download and install the content filter updates. The content filter update data is updated and available for download every two weeks.

Manual updates from Microsoft Update don't include the Microsoft IP Reputation Service or spam signature data. The Microsoft IP Reputation Service and spam signature data is only available when you use the anti-spam features of Microsoft Forefront Protection 2010 for Exchange Server (FPE).

Updates with Forefront Protection 2010 for Exchange Server

Microsoft Forefront Protection 2010 for Exchange Server (FPE) integrates multiple scan engines into a comprehensive, layered solution that helps you protect your Microsoft Exchange server messaging environment from malware, spam, and inappropriate content. FPE prevents the spread of malicious content by scanning all messages in real time with minimal impact on Exchange server performance or message delivery time.

You can enable FPE anti-spam technology in both the Exchange Edge Transport and Exchange Hub Transport roles. However, the Edge Transport role is the preferred location for anti-spam filtering. The technology includes a series of agents that are registered with Exchange and are invoked at specific points in the SMTP pipeline. FPE can also be integrated with Forefront Online Protection for Exchange (FOPE) to provide an additional layer of filtering for your messaging environment.

When you deploy FPE, the anti-spam features that are built in to Exchange are disabled. To learn more about how the FPE anti-spam solution works, see Using Antispam Filtering.

To learn more about how anti-spam updates work when you're using FPE, see Configuring and scheduling updates.

1.7.1.5.4 Understanding Attachment Filtering

Understanding Attachment Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

In Microsoft Exchange Server 2010, you can use attachment filtering to apply filters at the server level to control the attachments that users receive. Attachment filtering is

increasingly important in today's environment, where many attachments contain harmful viruses or inappropriate material that may cause significant damage to the user's computer or to the organization as a whole by damaging important documentation or releasing sensitive information to the public.

Note:

As a best practice, don't remove attachments from digitally signed, encrypted, or rights-protected e-mail messages. If you remove attachments from such messages, you invalidate the digitally signed messages and make encrypted and rights-protected messages unreadable.

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Types of Attachment Filtering in Exchange 2010

You can use the following types of attachment filtering to control attachments that enter or leave your organization:

- **Filtering based on file name or file name extension** You can filter attachments by specifying the exact file name or file name extension to be filtered. An example of an exact file name filter is BadFilename.exe. An example of a file name extension filter is *.exe.
- **Filtering based on file MIME content type** You can also filter attachments by specifying the MIME content type to be filtered. MIME content types indicate what the attachment is, whether it is a JPEG image, an executable file, a Microsoft Office Excel file, or some other file type. E-mail attachments are encoded in e-mail messages as ASCII text. E-mail servers and clients use the information about MIME content type to decode the ASCII text information in an e-mail message and convert it into a usable binary file familiar to the user. Content types are expressed as `type/subtype`. For example, the JPEG image content type is expressed as `image/jpeg`.
  To view a complete list of all file name extensions and content types that attachment filtering can filter on, run the following command.

```
Get-AttachmentFilterEntry | FL
```

If an attachment matches one of these filtering criteria, you can configure one of the following actions to be performed on the attachment:

- **Block whole message and attachment** An attachment that matches an attachment filter together with its whole e-mail message can be blocked from entering the messaging system. If an attachment and e-mail message are blocked, the sender receives a delivery status notification (DSN) message that states that the message contains an unacceptable attachment file name.
- **Strip attachment but allow message through** An attachment that matches an attachment filter can be removed whereas the e-mail message and any other attachments that don't match the filter are allowed through. If an attachment is stripped, it's replaced with a text file that explains why the attachment was removed. This action is the default setting.
- **Silently delete message and attachment** An attachment that matches an attachment filter together with its whole e-mail message can be blocked from entering the messaging system. If an attachment and e-mail message are blocked, neither the sender nor the recipient receives notification.

Caution:

You can't retrieve e-mail messages and attachments that are blocked or

attachments that are stripped. When you configure attachment filters, make sure that you carefully examine all possible file name matches and verify that legitimate attachments won't be affected by the filter.

- **RejectResponse** This parameter specifies the string response included in the non-delivery report (NDR) message if an e-mail message that has a filtered e-mail attachment is returned to the sender.

For more information, see Configure Attachment Filtering.

File Filtering by Using Forefront Protection for Exchange Server

The file filtering functionality provided by Microsoft Forefront Protection 2010 for Exchange Server includes advanced features that are unavailable in the default Attachment Filter agent included with Exchange 2010 Standard Edition.

For example, container files, which are files that contain other files, can be scanned for offending file types. Forefront Protection for Exchange Server filtering can scan the following container files and act upon embedded files:

- PKZip (.zip)
- GNU Zip (.gzip)
- Self-extracting compressed file archives (.zip)
- Compressed files (.zip)
- Java archive (.jar)
- TNEF (winmail.dat)
- Structured storage (.doc, .xls, .ppt, and others)
- MIME (.eml)
- SMIME (.eml)
- UUEncode (.uue)
- UNIX tape archive (.tar)
- RAR archive (.rar)
- MACBinary (.bin)

Note:

The default Attachment Filter agent included with Exchange 2010 Standard Edition detects file types even if they have been renamed. Attachment filtering also makes sure that compressed files with a .zip or .lzh file name extension don't contain blocked attachments by performing a file name extension match against the files in the compressed files. Forefront Protection for Exchange Server file filtering has the additional capability of determining if a blocked attachment has been renamed within a container file.

You can also filter files by file size. Additionally, you can configure Forefront Security for Exchange Server to quarantine filtered files or to send e-mail notifications based on file filter matches.

For more information, see Microsoft Forefront Protection 2010 for Exchange Server.

Understanding Connection Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-22*

The Connection Filter agent is an anti-spam agent enabled on computers running Microsoft Exchange Server 2010 that have the Edge Transport server role installed. The Connection Filter agent relies on the IP address of the remote server that's trying to connect, to determine what action, if any, to take on an inbound message. The remote IP address is available to the Connection Filter agent as a by-product of the underlying TCP/IP connection required for the SMTP session. Because the Connection Filter agent must evaluate the IP address of the remote server that's sending the message to be effective, the Connection Filter agent is typically enabled on the Internet-facing Edge Transport server. However, you may also perform additional configuration to run the Connection Filter agent deeper in the inbound message path.

When you configure anti-spam agents on an Edge Transport server, the agents act on messages cumulatively to reduce the number of unsolicited messages that enter the organization. To reduce redundancy and improve overall system performance and efficiency, you must understand the order in which the agents evaluate inbound messages. Understanding the order in which the filters evaluate inbound messages will help you optimize your configuration of the Edge Transport servers. For more information about how to plan and deploy the anti-spam agents, see Understanding Anti-Spam and Antivirus Functionality.

When you enable the Connection Filter agent, the Connection Filter agent is the first anti-spam agent to run when an inbound message is evaluated.

When an inbound message is submitted to an Edge Transport server on which the Connection Filter agent is enabled, the source IP address of the SMTP connection is checked against IP Allow lists and IP Block lists. If the source IP address is listed on an IP Allow list, the message is sent to the destination without additional processing by other anti-spam agents. If the source IP address is listed on an IP Block list, the SMTP connection is dropped after all RCPT TO headers in the message are processed.

Note:

The timing of when a specific connection is dropped may depend on other anti-spam configurations. For example, you can specify which recipients always receive e-mail messages, even if the source IP address is blocked. Additionally, you may have configured other agents that rely on content from the DATA command to be parsed. The Connection Filter agent always drops blocked connections according to the overall anti-spam configuration.

If the source IP address isn't listed on any IP Allow list or IP Block list, the message continues to flow through other anti-spam agents if other anti-spam agents are configured.

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Contents

Testing IP Block List and IP Allow List Functionality

IP Allow Lists and IP Block Lists

The Connection Filter agent compares the IP address of the server sending a message to any of the following data stores of IP addresses:

- Administrator-defined IP Allow lists and IP Block lists
- IP Block List providers
- IP Allow List providers

For more information about IP Block List providers, see "IP Block List Providers" later in this topic.

You must configure at least one of these data stores of IP addresses for the Connection Filter agent to be operational. If the data stores of IP addresses don't contain the IP addresses on the IP Allow lists or IP Block lists, or if you don't have any IP Block List providers or IP Allow List providers configured, you should disable the Connection Filter agent.

Administrator-Defined IP Allow Lists and IP Block Lists

Administrators of Edge Transport servers maintain administrator-defined lists of IP addresses. You can enter and delete the IP addresses that you want to allow or block by using the Exchange Management Console (EMC) or the Exchange Management Shell. You can add IP addresses individually, by IP address range, or by IP address and subnet mask.

When you add an IP address or IP address range, you must specify the IP address or IP address range as an IP Block list address or an IP Allow list address. Additionally, you can specify an expiration time for each IP Block list entry that you create. When you set the expiration time, the expiration time specifies how long the IP Block list entry is active. When the expiration time duration is reached, the IP Block list entry is disabled.

By using administrator-defined IP Allow lists and IP Block lists, you can configure connection filtering to support the following scenarios:

- To exempt IP addresses from the IP Block lists of IP Block List providers
  You may have to exempt IP addresses from the IP Block lists of IP Block List providers when legitimate senders are unintentionally put on an IP Block List provider's IP Block list. For example, legitimate senders could be unintentionally put on an IP Block list when an SMTP server was unintentionally configured to act as an open relay. In this scenario, the sender will probably try to correct the misconfiguration and remove the IP address from the IP Block List provider's IP Block list.
  For more information about IP Block List providers, see "IP Block List Providers" later in this topic.
- To deny access from IP addresses that are a source of unsolicited e-mail messages but aren't found on an IP Block List provider's IP Block lists
  Sometimes, you may receive a large quantity of unsolicited messages from a source that wasn't yet identified by a *real-time block list* service to which you subscribe.

IP Block List Providers

IP Block List provider services can help you reduce the number of unsolicited e-mail messages that enter your organization.

Note:

IP Block List provider services are frequently referred to as real-time block list services or

RBL services. The EMC refers to real-time block list services as IP Block List provider services. The terms real-time block list services, RBL services, and IP Block List provider services are equivalent.

IP Block List provider services compile lists of IP addresses from which spam has originated in the past. Additionally, some IP Block List providers provide lists of IP addresses for which SMTP is configured for open relay. There are also IP Block List provider services that provide lists of IP addresses that support dial-up access. Internet service providers (ISPs) that provide dial-up access services to their clients assign dynamic IP addresses for each dial-up session. Some ISPs block SMTP traffic from dial-up accounts. These ISPs and the attendant dial-up IP ranges aren't typically added to IP Block lists. However, some ISPs allow clients to send SMTP traffic from dial-up accounts. Malicious users take advantage of ISPs that allow SMTP traffic to send spam on dynamically assigned IP addresses. When the IP address is put on an IP Block list, the malicious users start another dial-up session and receive a new IP address. Frequently, a single IP Block List provider can provide a list of IP addresses that covers all these spam threats.

You can configure multiple IP Block List provider configurations by using the EMC or the Shell. Each service requires a separate IP Block List provider configuration in the EMC or the Shell.

When you configure the Connection Filter agent to use an IP Block List provider, the Connection Filter agent queries the IP Block List provider service to determine whether a match exists with the connecting IP addresses before the message is accepted into the organization.

Before the Connection Filter agent contacts the IP Block List provider to verify an IP address, the IP address is first compared to the administrator-defined IP Allow list and IP Block list. If the IP address doesn't exist on either the administrator-defined IP Allow list or IP Block list, the Connection Filter agent queries the IP Block List provider services according to the priority rating assigned to each provider. If the IP address appears on the IP Block list of an IP Block List provider, the Edge Transport server waits for and parses the RCPT TO header, responds to the sending system with an SMTP 550 error, and closes the connection. If the IP address doesn't appear on the IP Block lists of any one of the IP Block List providers, the next agent in the anti-spam chain processes the connection. For more information about the order in which the default anti-spam and antivirus agents filter inbound messages from the Internet, see Understanding Anti-Spam and Antivirus Functionality.

When you use the Connection Filter agent, it's a best practice to use one or more IP Block List providers to manage access into your organization. The use of an administrator-defined block list to maintain your own IP Block list is time-consuming and may be impossible from a human resource perspective in most organizations. Therefore, we recommend the use of an external IP Block List provider service, whose sole purpose is to maintain IP Block lists.

However, there may be some disadvantages to using an IP Block List provider. Because the Connection Filter agent must query an external entity for each unknown IP address, outages or delays at the IP Block List provider service can cause delays in the processing of messages on the Edge Transport server. In extreme cases, such outages or delays could cause a mail-flow bottleneck on the Edge Transport server.

The other disadvantage of using an external IP Block List provider service is that legitimate senders are sometimes added to the IP Block lists of IP Block List providers by mistake. For example, legitimate senders can be added to the IP Block lists maintained by IP Block List providers as the result of an SMTP misconfiguration, where the SMTP server was unintentionally configured to act as an open relay.

For each IP Block List provider service that you configure, you can customize the SMTP 550

error returned to the sender when the sender IP address is matched to an IP Block List provider service and is subsequently blocked by the Connection Filter agent. It's a best practice to customize the SMTP 550 error to identify the IP Block List provider service that identifies the sender as a blocked IP address. This best practice enables legitimate senders to contact the IP Block List provider service so that they can be removed from the IP Block List provider service's IP Block list.

Different IP Block List provider services may return different codes when the IP address of a remote server sending a message matches an IP address on an IP Block List provider service's IP Block list. Most IP Block List provider services return one of the following data types: bitmask or absolute value. Within these data types, there may be multiple values that indicate the type of list that the submitted IP address is on.

Bitmask Example

This section shows an example of the status codes returned by most Block List providers. For details about the status codes that the provider returns, see the documentation from the specific provider.

For bitmask data types, the IP Block List provider service returns a status code of 127.0.0.*x*, where the integer *x* is any one of the values listed in the following table.

Values and status codes for bitmask data types

Value	Status code
1	The IP address is on an IP Block list.
2	The SMTP server is configured to act as an open relay.
4	The IP address supports a dial-up IP address.

For absolute value types, the IP Block List provider service returns explicit responses based on the cause of the block of the IP address. The following table shows some examples of absolute values and the explicit responses.

Values and status codes for absolute value data types

Value	Explicit response
127.0.0.2	The IP address is a direct spam source.
127.0.0.4	The IP address is a bulk mailer.
127.0.0.5	The remote server sending the message is known to support multistage open relays.

IP Allow List Providers

You can also manage inbound messages by using IP Allow List provider services that provide IP Allow lists. IP Allow lists are sometimes referred to as IP safe lists or white lists elsewhere in the software industry. IP Allow List providers maintain lists of IP addresses that are definitively known not to be associated with any spam activity. When an IP Allow List provider returns an IP Allow match, which indicates that the sender's IP address is more likely to be a reputable or safe sender, the Connection Filter agent relays the message to the next agent in the anti-spam chain.

Return to top

Configuring Connection Filtering for Edge Transport Servers That Aren't the First SMTP Entry Point

In some organizations, the Edge Transport server role is installed on computers that don't process SMTP requests directly on the Internet. In this scenario, the Edge Transport server is behind another front-end SMTP server that processes inbound messages directly from the Internet. In this scenario, the Connection Filter agent must be able to extract the correct originating IP address from the message. To extract and evaluate the originating IP address, the Connection Filter agent must parse the Received headers from the message and compare those headers to the known SMTP server in the perimeter network.

When an RFC-compliant SMTP server receives a message, the server updates the message's Received header with the domain name and IP address of the sender. Therefore, for each SMTP server between the originating sender and the Edge Transport server, the SMTP server adds an additional Received header entry.

When you configure your perimeter network to support Exchange 2010, you must specify all the IP addresses for the SMTP servers in your perimeter network. The IP address data is replicated to Edge Transport servers by EdgeSync. When messages are received by the computer that runs the Connection Filter agent, the IP address in the Received header that doesn't match an SMTP server IP address in your perimeter network is assumed to be the originating IP address.

You must specify all internal SMTP servers on the transport configuration object in the Active Directory forest before you run connection filtering. Specify the internal SMTP servers by using the *InternalSMTPServers* parameter on the Set-TransportConfig cmdlet.

Return to top

Testing IP Block List and IP Allow List Functionality

After you configure an IP Block List provider service or IP Allow List provider service, you can test to make sure that connection filtering is configured correctly for the particular service. Most IP Block List provider services or IP Allow List provider services provide test IP addresses that you can use to test their services. When you run a test against an IP Block List provider service or an IP Allow List provider service, the Connection Filter agent issues a Domain Name System (DNS) query based on the real-time block list IP address that should respond with a specific response. For more information about how to test IP addresses against an IP Block List provider service or an IP Allow List provider service, see Test-IPAllowListProvider and Test-IPBlockListProvider.

Return to top

1.7.1.5.6 Understanding Content Filtering

Understanding Content Filtering

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

The Content Filter agent evaluates inbound e-mail messages and assesses the probability that an inbound message is legitimate or spam. Unlike many other filtering technologies, the Content Filter agent uses characteristics from a statistically significant sample of e-mail messages. The inclusion of legitimate messages in this sample reduces the chance of mistakes. Because the Content Filter agent recognizes characteristics of legitimate messages and spam, its accuracy is increased. Updates to the Content Filter agent are available periodically through Microsoft Update.

Contents

Using the Content Filter Agent

The Content Filter agent is one of several anti-spam agents. When you configure anti-spam agents on a computer that has the Edge Transport server role installed, the agents act on messages cumulatively to reduce the amount of spam that enters the organization. For more information about how to plan and deploy anti-spam agents, see Understanding Anti-Spam and Antivirus Functionality.

The Content Filter agent assigns a spam confidence level (SCL) rating to each message. The SCL rating is a number between 0 and 9. A higher SCL rating indicates that a message is more likely to be spam.

You can configure the Content Filter agent to take the following actions on messages according to their SCL rating:

- Delete message
- Reject message
- Quarantine message

For example, you may determine that messages that have an SCL rating of 7 or higher must be deleted, messages that have an SCL rating of 6 must be rejected, and messages that have an SCL rating of 5 must be quarantined.

You can adjust the SCL threshold behavior by assigning different SCL ratings to each of these actions. For more information about how to adjust the SCL threshold to suit your organization's requirements and about per-recipient SCL thresholds, see Understanding Spam Confidence Level Threshold.

Note:

Messages that are over 11 MB aren't scanned by the Intelligent Message Filter. Instead, they pass through the Content Filter without being scanned. However, the default maximum message size limit configured on Exchange 2010 Receive connectors is 10 MB. Therefore, the 11 MB threshold for the Intelligent Message Filter isn't a practical concern in the default Exchange configuration.

Allow Phrases and Block Phrases

You can customize how the Content Filter agent assigns SCL values by configuring custom words. Custom words are individual words or phrases that the Content Filter agent uses to apply appropriate filter processing. You configure approved words or phrases with Allow phrases and unapproved words or phrases with Block phrases. When the Content

Filter agent detects a preconfigured Allow phrase in an inbound message, the Content Filter agent automatically assigns an SCL value of 0 to the message. Alternatively, when the Content Filter agent detects a configured Block phrase in an inbound message, the Content Filter agent assigns an SCL rating of 9.

You can enter custom words or phrases in any combination of uppercase and lowercase letters. However, when the Content Filter agent evaluates message content, it ignores case. The maximum number of custom words or phrases that can be created is 800.

Outlook E-mail Postmark Validation

The Content Filter agent also includes Microsoft Office Outlook E-mail Postmark validation, a computational proof that Outlook applies to outgoing messages to help recipient messaging systems distinguish legitimate e-mail from junk e-mail. This feature helps reduce the chance of false positives. In the context of spam filtering, a *false positive* exists when a spam filter incorrectly identifies a message from a legitimate sender as spam. When Outlook E-mail Postmark validation is enabled, the Content Filter agent parses the inbound message for a computational postmark header. The presence of a valid, solved computational postmark header in the message indicates that the client computer that generated the message solved the computational postmark.

Computers don't require significant processing time to solve individual computational postmarks. However, processing postmarks for many messages may be prohibitive to a malicious sender. Anyone who sends millions of spam messages is unlikely to invest the processing power that is required to solve computational postmarks for all outbound spam. If a sender's e-mail contains a valid, solved computational postmark, it's unlikely that the sender is a malicious sender. In this case, the Content Filter agent would lower the SCL rating. If the postmark validation feature is enabled and an inbound message either doesn't contain a computational postmark header or the computational postmark header isn't valid, the Content Filter agent would not change the SCL rating.

Bypassing the Recipient, Sender, and Sender Domain

In some organizations, all e-mail to certain aliases must be accepted. This scenario can introduce problems if your organization is in an industry that manages significant volumes of spam.

For example, a company named Woodgrove Bank has an alias named customerloans@woodgrovebank.com that provides e-mail-based support to external loan customers. The Exchange administrators configure the Content Filter agent to set Block phrases that filter out words or phrases that are typically used in spam that is sent by unscrupulous loan agencies. To prevent potentially legitimate messages from being rejected, the administrators set exceptions to content filtering by entering a list of SMTP e-mail recipient addresses in the Content Filter agent configuration.

You can also specify senders and sender domains that you do not want the Content Filter agent to block.

Safelist Aggregation

In Exchange 2010, the Content Filter agent on the Edge Transport server uses the Outlook Safe Senders Lists, Blocked Sender List, Safe Recipients Lists, and trusted contacts from Outlook to optimize spam filtering. *Safelist aggregation* is a set of anti-spam functionality that is shared across Outlook and Exchange 2010. As its name suggests, this functionality collects data from the anti-spam safe lists that Outlook users configure and makes this data available to the anti-spam agents on the Edge Transport server. E-mail messages that Outlook users receive from contacts that those users have added to their Outlook Safe Recipients List, Safe Senders List, or trusted contacts list are identified by the Content Filter agent as safe. The Sender Filter agent also performs per-recipient sender filtering using the Blocked Senders list that users configure. For more information, see Understanding Safelist Aggregation.

Configuring the Content Filter Agent

You configure the Content Filter agent by using the Exchange Management Console or the Exchange Management Shell.

Important:

Configuration changes that you make to the Content Filter agent by using the Exchange Management Console or the Exchange Management Shell are only made to the local computer that has the Edge Transport server role installed. If you have multiple instances of the Edge Transport server role running in your organization, you must make Content Filter configuration changes to each computer.

For more information about how to configure content filtering, see Configure Content Filtering Properties.

Using SCL Value Stamped by the Content Filter Agent in Edge Transport Rules

In Exchange 2010, transport rules that run on Edge Transport servers are applied to messages by the Edge Rule agent on the `OnEndOfData` SMTP transport event. One of the transport rule conditions available on Edge Transport servers is the **with a spam confidence (SCL) rating that is greater than or equal to limit** transport rule condition. By using this transport rule condition, you can apply a transport rule action to a message based on the SCL value stamped on the message. The Content Filter agent stamps an SCL value on the message based on an analysis of the message content and is used to determine whether the message is spam. The Content Filter agent also runs on the `OnEndOfData` SMTP transport event.

Note:

Although the Content Filter agent also runs on other events, the SCL value is stamped on the message by the instance of the Content Filter agent registered on the `OnEndOfData` SMTP transport event.

Because both the Edge Rule agent and the Content Filter agent run on the `OnEndOfData` SMTP transport event, the priority value applied to each transport agent is used to determine which transport agent runs first. By default, the Edge Rule agent runs before the Content Filter agent to reduce the cost of processing messages that may be blocked by the Edge Rule agent. However, because the Edge Rule agent runs before the Content Filter agent and therefore the SCL value has not yet been stamped on the message, you can't use the **with a spam confidence (SCL) rating that is greater than or equal to limit** transport rule condition in the default configuration.

For details about how to configure the Content Filter agent to run before the Edge Rule agent on the `OnEndOfData` SMTP transport event, see Make the SCL Value Available to Edge Transport Rules. This enables the Content Filter agent to stamp an SCL value on a message that can then be read by the **with a spam confidence (SCL) rating that is greater than or equal to limit** transport rule condition.

For more information about transport agents and transport agent priority, see Understanding Transport Agents.

If you configure the Content Filter agent with a higher priority value than the Edge Rule agent, the Edge Transport server may incur additional processing costs because all the messages that are received by the Edge Transport server will be evaluated by the Content Filter agent. This is true even if the message is later rejected by a transport rule that is configured on the Edge Rule agent. Also, you will no longer be able to configure a

transport rule on the Edge Transport server to stamp a message that has an SCL value of –1. This value indicates to the Content Filter agent that the message should not be evaluated.

Forefront Protection 2010 for Exchange Server

Microsoft Forefront Protection 2010 for Exchange Server (FPE) integrates multiple scan engines into a comprehensive, layered solution that helps you protect your Microsoft Exchange server messaging environment from malware, spam, and inappropriate content. FPE prevents the spread of malicious content by scanning all messages in real time with minimal impact on Exchange server performance or message delivery time.

You can enable FPE anti-spam technology in both the Exchange Edge Transport and Exchange Hub Transport roles. However, the Edge Transport role is the preferred location for anti-spam filtering. The technology includes a series of agents that are registered with Exchange and are invoked at specific points in the SMTP pipeline. FPE can also be integrated with Forefront Online Protection for Exchange (FOPE) to provide an additional layer of filtering for your messaging environment.

When you deploy FPE, the anti-spam features that are built in to Exchange are disabled. To learn more about how the FPE anti-spam solution works, see Using Antispam Filtering.

1.7.1.5.7 Understanding Recipient Filtering

Understanding Recipient Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-30*

The Recipient Filter agent is an anti-spam agent enabled on computers running Microsoft Exchange Server 2010 that have the Edge Transport server role installed. The Recipient Filter agent relies on the RCPT TO SMTP header to determine what action, if any, to take on an inbound message.

When you configure anti-spam agents on an Edge Transport server, the agents act on messages cumulatively to reduce the number of unsolicited messages that enter the organization. For more information about how to plan and deploy anti-spam agents, see Understanding Anti-Spam and Antivirus Functionality.

The Recipient Filter agent blocks messages according to the characteristics of the intended recipient in the organization. The Recipient Filter agent can help you prevent the acceptance of messages in the following scenarios:

- **Nonexistent recipients** You can prevent delivery to recipients that aren't in the organization's address book. For example, you may want to stop delivery to frequently misused account names, such as administrator@contoso.com or support@contoso.com.
- **Restricted distribution lists** You can prevent delivery of Internet mail to distribution lists that should be used only by internal users.
- **Mailboxes that should never receive messages from the Internet** You can prevent delivery of Internet mail to a specific mailbox or alias that's typically used inside the organization, such as Helpdesk.

The Recipient Filter agent acts on recipients stored in one or both of the following data sources:

- **Recipient Block list** An administrator-defined list of recipients for which inbound messages from the Internet should never be accepted.
- **Recipient Lookup** Verification that the recipient is in the organization. Recipient Lookup requires access to Active Directory information provided by EdgeSync to Active Directory Lightweight Directory Services (AD LDS).

For more information about Recipient Block lists and Recipient Lookup functionality, see "Recipient Data Sources" later in this topic.

When you enable the Recipient Filter agent, one of the following actions is taken on inbound messages according to the characteristics of the recipients. These recipients are indicated by the RCPT TO header.

- If the inbound message contains a recipient that is on the Recipient Block list, the Edge Transport server sends a "550 5.1.1 User unknown" SMTP session error to the sending server.
- If the inbound message contains a recipient that doesn't match any recipients in Recipient Lookup, the Edge Transport server sends a "550 5.1.1 User unknown" SMTP session error to the sending server.
- If the recipient isn't on the Recipient Block list and the recipient is in Recipient Lookup, the Edge Transport server sends a "250 2.1.5 Recipient OK" SMTP response to the sending server, and the next anti-spam agent in the chain processes the message.

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Contents

Configuring AD LDS for Recipient Lookup

One of the most effective ways to reduce spam is to validate recipients before accepting inbound messages from the Internet. Therefore, it's a good idea to configure the AD LDS instance that runs on the Edge Transport server to synchronize with Active Directory. By default, AD LDS is installed and configured on the Edge Transport server. However, you must configure AD LDS to communicate with an Active Directory domain-joined global catalog server. Most of the time, you must also configure your firewall to enable specific ports to communicate with AD LDS. For more information, see Understanding Edge Subscriptions.

After you configure AD LDS to replicate a Recipient Block list from Active Directory, you must then enable blocking of messages sent to recipients who aren't present in the Exchange organization. You enable message blocking on the **Blocked Recipients** tab of the **Recipient Filtering Properties** page in the Exchange Management Console (EMC). You can also enable message blocking by using the Set-RecipientFilterConfig cmdlet in the Exchange Management Shell. For more information, see Set-RecipientFilterConfig.

Return to top

Recipient Data Sources

As mentioned earlier, the Recipient Filter agent references two data sources when it compares recipients on inbound messages: the Recipient Block list and Recipient Lookup.

Recipient Block List

The Recipient Block list is maintained by the Edge Transport server administrators. The Recipient Block list data is stored in the Edge Transport server instance of AD LDS. You must enter blocked recipients on each Edge Transport server computer.

You can enter the recipients that you want the Recipient Filter agent to block in the EMC on the **Blocked Recipients** tab of the **Recipient Filtering Properties** page. You use the **Set-RecipientFilterConfig** cmdlet in the Shell to enter recipients. For more information about how to configure the Recipient Filter agent, see Configure Recipient Filtering Properties.

Recipient Lookup

One benefit of the Recipient Filter agent is the ability to verify that the recipients on an inbound message are in your organization before Exchange 2010 transmits the message into your organization. The ability to verify recipients in your organization relies on a recipient data source available to the Edge Transport server. Because the Edge Transport server isn't an Active Directory domain-joined computer and could be segregated from the organization by a firewall, you must configure a Recipient Lookup data source for the Edge Transport server to use.

The Edge Transport server role uses AD LDS for configuration and data storage. For more information, see Understanding Edge Subscriptions.

Return to top

Tarpitting Functionality

Recipient Lookup functionality enables the sending server to determine whether an e-mail address is valid or invalid. As mentioned earlier, when the recipient of an inbound message is a known recipient, the Edge Transport server sends back a "250 2.1.5 Recipient OK" SMTP response to the sending server. This functionality provides an ideal environment for a directory harvest attack.

A *directory harvest attack* is an attempt to collect valid e-mail addresses from a particular organization so that the e-mail addresses can be added to a spam database. Because all spam income relies on trying to make people open e-mail messages, addresses known to be active are a commodity that malicious users, or *spammers*, pay for. Because the SMTP protocol provides feedback for known senders and unknown senders, a spammer can write an automated program that uses common names or dictionary terms to construct e-mail addresses to a specific domain. The program collects all e-mail addresses that return a "250 2.1.5 Recipient OK" SMTP response and discards all e-mail addresses that return a "550 5.1.1 User unknown" SMTP session error. The spammer can then sell the valid e-mail addresses or use them as recipients for unsolicited messages.

To combat directory harvest attacks, Exchange 2010 includes tarpitting functionality. *Tarpitting* is the practice of artificially delaying server responses for specific SMTP communication patterns that indicate high volumes of spam or other unwelcome messages. The intent of tarpitting is to slow down the communication process for such e-mail traffic so that the cost of sending spam increases for the person or organization sending the spam. Tarpitting makes directory harvest attacks too costly to automate

efficiently.

If tarpitting isn't configured, Exchange Server immediately returns a "550 5.1.1 User unknown" SMTP session error to the sender when a recipient isn't located in Recipient Lookup. Alternatively, if tarpitting is configured, SMTP waits a specified number of seconds before it returns the "550 5.1.1 User unknown" error. This pause in the SMTP session makes automating a directory harvest attack more difficult and less cost-effective for the spammer. By default, tarpitting is configured for 5 seconds on Receive connectors.

To configure the time before SMTP returns the "550 5.1.1 User unknown" error, use the EMC or the Shell to set the *TarpitInterval* value on the Receive connector. For more information about how to administer and configure Receive connectors, see Understanding Receive Connectors.

Return to top

Configuring the Tarpitting Interval

As explained in Understanding Recipient Filtering, you can configure the Receive connectors that process inbound messages from the Internet to slow down the SMTP response. Make sure that you enable tarpitting functionality on the Receive connectors, especially if you have enabled the Recipient Lookup feature of recipient filtering. If you don't enable tarpitting, and you have enabled the Recipient Lookup feature, you are exposing your organization to a directory harvest attack. A directory harvest attack will likely cause more spam.

When you specify a tarpitting interval time on a Receive connector, tarpitting is enabled. The default value is 5 seconds. We recommend that you start with a value of 5 (seconds). Use caution if you decide to change this value. An overly long interval could disrupt ordinary mail flow, whereas an overly brief interval may not be as effective in thwarting a directory harvest attack. If you change the tarpitting interval value, do so in small increments.

If you are running a version of Exchange Server earlier than Microsoft Exchange Server 2010 Service Pack 2 (SP2), you can set the tarpitting interval on the **Security** tab of the Receive connector property pages in the EMC, or you can use the Set-ReceiveConnector cmdlet in the Exchange Management Shell. For more information about how to use the EMC to configure the tarpitting interval, see Configure Receive Connector Properties.

If you are running Exchange Server 2010 SP2, or a later version, you set the tarpitting interval by using the Set-ReceiveConnector cmdlet in the Exchange Management Shell.

Return to top

Multiple Namespaces

Some organizations accept e-mail messages for multiple domains. For example, one organization may accept messages for both the Contoso.com and the Woodgrovebank.com domains. Sometimes organizations are authoritative for all the domains for which they accept messages. In the context of SMTP, the organization is authoritative for a domain if the organization hosts and manages the mailboxes for that domain. This relationship extends to the Edge Transport server. An Edge Transport server may accept messages for multiple domains, but it may not be authoritative for all the domains. For example, an Edge Transport server can be configured to be authoritative for all recipients in the Contoso.com domain, but the Edge Transport server still accepts and forwards messages for the Woodgrovebank.com domain.

When you enable the Recipient Filter agent, the Recipient Filter agent performs recipient lookups only for the domains specified as authoritative in the transport server

configuration. If an Edge Transport server accepts and forwards messages on behalf of another domain, but the Edge Transport server isn't configured as authoritative, the Recipient Filter agent doesn't perform a recipient lookup. However, if a recipient that's not authoritative is specified in the Recipient Block list, the recipient will still be blocked.

Return to top

1.7.1.5.8 Understanding Safelist Aggregation

Understanding Safelist Aggregation

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-29*

In Microsoft Exchange Server 2010, *safelist aggregation* refers to anti-spam functionality shared across Microsoft Outlook and Exchange. This functionality collects data from the anti-spam Safe Recipients Lists, Safe Senders Lists, Blocked Senders Lists, and contact data that Outlook users configure, and makes this data available to the anti-spam agents on the computer that has the Edge Transport server role installed. Safelist aggregation can help reduce the instances of false-positives in anti-spam filtering performed by the Edge Transport server.

When you enable and correctly configure safelist aggregation, the Content Filter agent passes safe e-mail messages to the enterprise mailbox without additional processing. E-mail messages that Outlook users receive from contacts that those users have added to their Outlook Safe Recipients List or Safe Senders List or have trusted are identified by the Content Filter agent as safe. An Outlook *contact* is a person, inside or outside the user's organization, about whom the user can save several types of information, such as e-mail and street addresses, telephone and fax numbers, and Web page URLs.

In Exchange 2010, the safelist aggregation process also replicates a per-recipient Blocked Senders List to the Edge Transport server. This allows the Sender Filtering agent on the Edge Transport server to block incoming messages from those senders.

Safelist aggregation can help reduce the instances of false-positives in anti-spam filtering performed by the Edge Transport server. A *false-positive* is a positive test or filter result in a subject or body of data that doesn't possess the attribute for which the filter or test is being conducted. In the context of spam filtering, a false-positive occurs when a spam filter incorrectly identifies a message from a legitimate sender as spam.

For organizations that filter hundreds of thousands of messages from the Internet every day, even a small percentage of false-positives means that users might not receive many messages identified incorrectly as spam, which were quarantined or deleted.

Safelist aggregation is likely the most effective way to reduce false-positives. In Office Outlook 2007, users can create *Safe Senders Lists*. Safe Senders Lists specify a list of domain names and e-mail addresses from which the Outlook user wants to receive messages. By default, e-mail addresses in Outlook Contacts and in the Exchange Server global address list are included in this list. By default, Outlook adds all external contacts to which the user sends mail to the Safe Senders List.

Contents

Information Stored in the Outlook User's Safelist Collection

A *safelist collection* is the combined data from the user's Safe Senders List, Safe Recipients List, Blocked Senders List, and external contacts. This data is stored in Outlook and in the Exchange mailbox.

The following types of information are stored in an Outlook user's safelist collection:

- **Safe senders and safe recipients** The From message header indicates a sender. The To field of the e-mail message indicates a recipient. Safe senders and safe recipients are represented by full SMTP addresses, such as masato@contoso.com. Outlook users can add senders and recipients to their safe lists.
- **Blocked senders** Just like safe senders, users can block unwanted senders by adding them to their Blocked Senders Lists.
- **Safe domain** The domain is the part of an SMTP address that follows the @ symbol. For example, contoso.com is the domain in the masato@contoso.com address. Outlook users can add sending domains to their safe lists.

  Important:

  Exchange provides functionality that allows you to specify whether to include the safe domain data for the anti-spam agents on the Edge Transport server by using the **Update-SafeList** cmdlet. In most cases, we don't recommend that you include domains because users may include the domains of large Internet service providers (ISP), which could unintentionally provide addresses that may be used or spoofed by spammers. By default, Exchange doesn't include the domains during safelist aggregation.

- **External contacts** Two types of external contacts can be included in the safelist aggregation. The first type of external contact includes contacts to whom Outlook users have sent mail. This class of contact is added to the Safe Senders List only if an Outlook user selects the corresponding option in the Junk E-mail settings in Outlook 2007.
  The second type of external contact includes the users' Outlook contacts. Users can add or import these contacts into Outlook. This class of contact is added to the Safe Senders List only if an Outlook user selects the corresponding option in the Junk E-mail Filter settings in Outlook 2010 or Outlook 2007.

Return to top

How Exchange Uses the Safelist Collection

The safelist collection is stored on the user's Mailbox server. A user can have up to 1,024 unique entries in a safelist collection. Exchange 2010 has a mailbox assistant, called the Junk E-mail Options mailbox assistant, which monitors changes to the safelist collection for your mailboxes. It then replicates these changes to Active Directory, where the safelist collection is stored on each user object. When the safelist collection is stored on the user object in Active Directory, the safelist collection is aggregated with the anti-spam functionality of Exchange 2010 and is optimized for minimized storage and replication. The Microsoft Exchange EdgeSync service replicates the safelist collection to the Active

Directory Lightweight Directory Services (AD LDS) instance on the Edge Transport server. The Edge Transport servers use the safelist collection data during content filtering.

Important:

Although the safe recipient data is stored in Outlook and can be aggregated into the safelist collection on the AD LDS instance on the Edge Transport server, the content filtering functionality doesn't act on safe recipient data.

Return to top

Hashing of Safelist Collection Entries

Safelist collection entries are hashed (SHA-256) one way before they are stored as array sets across three user object attributes, **msExchSafeSenderHash**, **msExchSafeRecipientHash**, and **msExchBlockedSendersHash**, as a binary large object. When data is hashed, an output of fixed length is produced, and the output is likely to be unique. For hashing of safelist collection entries, a 4-byte hash is produced. When a message is received from the Internet, Exchange hashes the sender address and compares it to the hashes stored on behalf of the Outlook user to whom the message was sent. If the sender matches the safe senders hash, the message bypasses content filtering. If the sender matches the blocked senders hash, the message is blocked.

One-way hashing of safelist collection entries performs the following important functions:

- **Minimizes storage and replication space** Most of the time, hashing reduces the size of the data hashed. Therefore, saving and transmitting a hashed version of a safelist collection entry conserves storage space and replication time. For example, a user who has 200 entries in his or her safelist collection would create about 800 bytes of hashed data stored and replicated in Active Directory.
- **Renders user safelist collections unusable by malicious users** Because one-way hash values are impossible to reverse-engineer into the original SMTP address or domain, the safelist collections don't yield usable e-mail addresses for malicious users who might compromise an Edge Transport server.

Return to top

Enabling Safelist Aggregation

Safelist aggregation is enabled by default in Exchange 2010. Unlike in Exchange Server 2007, you don't need to manually run the **Update-SafeList** cmdlet to hash and write the safelist collection data to Active Directory. In Exchange 2010, this is accomplished behind the scenes by the Junk E-mail Options mailbox assistant.

You can still manually run safelist aggregation by using the **UpdateSafelist** cmdlet. The **Update-SafeList** cmdlet reads the safelist collection from the user's mailbox, hashes each entry, sorts the entries for easy search, and then converts the hash to a binary attribute. Finally, the **Update-SafeList** cmdlet compares the binary attribute that was created to any value stored on the attribute. If the two values are identical, the **Update-SafeList** cmdlet doesn't update the user attribute value with the safelist aggregation data. If the two attribute values are different, the **Update-SafeList** cmdlet updates the safelist aggregation value.

To make the safelist aggregation data in Active Directory available to Edge Transport servers in the perimeter network, you must install and configure the Microsoft Exchange EdgeSync service so that the safelist aggregation data is replicated to AD LDS.

Return to top

Options available in the msexchangemailboxassistants.exe.config file

To activate the options to include safe domains, or to change the maximum values for the default settings, you must change the msexchangemailboxassistants.exe.config file. Specifically, the following settings and values can be changed in the **appsettings** section of the msexchangemailboxassistants.exe.config file:

Setting	Value
IncludeSafeDomains	The value for this setting can be True or False.
UpdateInterval	By default, the value for this setting is 15 minutes. This setting can have a value from 15 minutes through 1 day.
TestUpdateInterval	TestUpdateInterval is used in test environments. This setting can have a value from 10 seconds through 1 hour.
MaxSafeSenders	3*1024
MaxSafeRecipients	2*1024
MaxBlockedSenders	By default, the value for this setting is 500. The maximum value is 1000.

For example, the settings in the **appsettings** section of the msexchangemailboxassistants.exe.config file may be as follows:

```
<configuration>
  <runtime>
    <gcConcurrent enabled="false" />
    <generatePublisherEvidence enabled="false" />
  </runtime>
  <appSettings>
        <add key="IncludeSafeDomains" value="true" />
</appSettings>
</configuration>
```

Return to top

1.7.1.5.9 Understanding Sender Filtering

Understanding Sender Filtering

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-17*

The Sender Filter agent is an anti-spam filter that's enabled on computers that have the

Microsoft Exchange Server 2010 Edge Transport server role installed. The Sender Filter agent relies on the MAIL FROM: SMTP header to determine what action, if any, to take on an inbound e-mail message.

When you configure anti-spam filters on an Edge Transport server, the filters act on messages cumulatively to reduce the number of unsolicited messages that enter the enterprise. For more information about how to plan and deploy the anti-spam features, see Understanding Anti-Spam and Antivirus Functionality.

The Sender Filter agent acts on messages from specific senders outside the organization. Administrators of Edge Transport servers maintain a list of senders who are blocked from sending messages to the organization. As an administrator, you can block single senders (kim@contoso.com), whole domains (*.contoso.com), or domains and all subdomains (*.contoso.com). You can also configure what action the Sender Filter agent should take when a message that has a blocked sender is found. You can configure the following actions:

- The Sender Filter agent rejects the SMTP request with a "554 5.1.0 Sender Denied" SMTP session error and closes the connection.
- The Sender Filter agent accepts the message and updates the message to indicate that the message came from a blocked sender. Because the message came from a blocked sender and it's marked as such, the Content Filter agent will use this information when it calculates the spam confidence level (SCL).

You can use the Exchange Management Console (EMC) or the Exchange Management Shell to designate blocked senders and to define how the Sender Filter agent should act on messages from blocked senders. For more information about how to configure the Sender Filter agent, see Configure Sender Filtering Properties.

Important:

The MAIL FROM: SMTP headers can be spoofed. Therefore, you shouldn't rely on the Sender Filter agent only. Use the Sender Filter agent and the Sender ID agent together. The Sender ID agent uses the originating IP address of the sending server to try to verify that the domain in the MAIL FROM: SMTP header matches the domain that's registered. For more information about the Sender ID agent, see Understanding Sender ID.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Using the Sender Filter Agent to Block Messages

By default, sender filtering is enabled on the computer that has the Edge Transport server role installed for inbound messages that come from the Internet but aren't authenticated. These messages are handled as external messages. You can disable the Sender Filter agent in individual computer configurations by using the EMC or the Shell. For more information, see Enable or Disable Sender Filtering.

When you enable the Sender Filter agent on a computer, the Sender Filter agent filters all messages that come through all Receive connectors on that computer. As noted earlier in this topic, only messages that come from external sources are filtered. *External sources* are defined as non-authenticated sources. These are considered anonymous Internet sources.

For more information about how to configure Receive connectors and how message source categories are determined, see Understanding Receive Connectors.

As a best practice, you shouldn't filter e-mail messages from trusted partners or from inside your organization. When you run anti-spam filters, there's always a chance that the

filters will detect false positives. You should enable anti-spam agents to run only on messages from potentially untrusted and unknown sources. This will reduce the chance that anti-spam filters will mishandle legitimate messages. You can enable and disable the Sender Filter agent to run on messages from any source by using the Shell. For more information, see Set-SenderFilterConfig.

You can configure the Sender Filter agent to block inbound messages that don't specify a sender and domain in the MAIL FROM: SMTP header. You can use this feature to prevent non-delivery report (NDR) attacks on the Exchange server. Most legitimate SMTP messages come from SMTP servers that provide a sender and domain in the MAIL FROM: SMTP command.

Specifying the Block Action

After you've specified blocked senders and domains, you must specify how you want the Sender Filter agent to act on messages from blocked senders and domains. We recommend that you reject the messages. When you use the Sender Filter agent on which all blocked e-mail addresses and domains are specified by the Edge Transport server administrator, the chance of false positives is relatively less than when you use other anti-spam agents. For example, the Content Filter agent is an anti-spam agent that relies on many different variables to determine whether a message is spam.

There are only two scenarios in which legitimate messages may be rejected by the Sender Filter agent:

- If you mistype an e-mail address or domain name, the wrong sender may be blocked.
- If a domain name is reregistered to a legitimate company after you add the domain to your Blocked Senders list, you will unintentionally block legitimate messages.

In either of these cases, it may still make sense to reject the messages.

1.7.1.5.10 Understanding Sender ID

Understanding Sender ID

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-27*

The Sender ID agent is an anti-spam agent that's enabled on computers that have the Microsoft Exchange Server 2010 Edge Transport server role installed. The Sender ID agent relies on the RECEIVED SMTP header and a query to the sending system's DNS service to determine what action, if any, to take on an inbound message.

When you configure anti-spam agents on an Edge Transport server, the agents act on messages cumulatively to reduce the number of unsolicited e-mail messages that enter the organization. For more information about how to plan and deploy the anti-spam agents, see Understanding Anti-Spam and Antivirus Functionality.

Sender ID is intended to combat the impersonation of a sender and a domain, a practice that's frequently called *spoofing*. A *spoofed mail* is an e-mail message that has a sending address that was modified to appear as if it originates from a sender other than the actual sender of the message.

Spoofed mails typically contain a From: address that purports to be from a certain organization. In the past, it was relatively easy to spoof the From: address, in both the SMTP session, such as the MAIL FROM: header, and in the RFC 822 message data, such as From: "Masato Kawai" masato@contoso.com, because the headers weren't validated.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Using Sender ID to Combat Spoofing

In Exchange 2010, Sender ID makes spoofing more difficult. When you enable Sender ID, each message contains a Sender ID status in the metadata of the message. When an e-mail message is received, the Edge Transport server queries the sender's DNS server to verify that the IP address from which the message was received is authorized to send messages for the domain that's specified in the message headers. The IP address of the authorized sending server is referred to as the purported responsible address (PRA).

Domain administrators publish sender policy framework (SPF) records on their DNS servers. SPF records identify authorized outbound e-mail servers. If an SPF record is configured on the sender's DNS server, the Edge Transport server parses the SPF record and determines whether the IP address from which the message was received is authorized to send e-mail on behalf of the domain that's specified in the message. For more information about what an SPF record contains and how to create an SPF record, see Sender ID.

The Edge Transport server updates the message metadata with the Sender ID status based on the SPF record. After the Edge Transport server updates the message metadata, the Edge Transport server delivers the message as it ordinarily would.

Sender ID Status Values

The Sender ID evaluation process generates a Sender ID status for the message. The Sender ID status is used to evaluate the spam confidence level (SCL) rating for the message. This status can be set to one of the following values:

- **Pass** Both the IP address and Purported Responsible Address (PRA) passed the Sender ID verification check.
- **Neutral** Published Sender ID data is explicitly inconclusive.
- **Soft fail** The IP address for the PRA may be in the not permitted set.
- **Fail** The IP Address is not permitted; no PRA is found in the incoming mail or the sending domain does not exist.
- **None** No published SPF data exists in the sender's DNS.
- **TempError** A temporary DNS failure occurred, such as an unavailable DNS server.
- **PermError** The DNS record is invalid, such as an error in the record format.

The Sender ID status is added to the message metadata and is later converted to a MAPI property. The junk e-mail filter in Microsoft Office Outlook uses the MAPI property during the generation of the SCL value.

Outlook neither displays the Sender ID status nor necessarily flags a message as junk at certain Sender ID values. Outlook uses the Sender ID status value only during the calculation of the SCL value.

Besides the seven scenarios that generate the Sender ID statuses, the Sender ID evaluation process may reveal instances where the From: IP address is missing. If the From: IP address is missing, the Sender ID status can't be set. If the Sender ID status can't be set, Exchange continues to process the message without including a Sender ID status on the message. The message isn't discarded or rejected. In this scenario, Sender ID status isn't set, and an application event is logged.

For more information about how the Sender ID status is displayed in messages, see Understanding Anti-Spam Stamps.

Sender ID Options for Handling Spoofed Mail and Unreachable DNS Servers

You can also define how the Edge Transport server handles messages that are identified as spoofed mail and how the Edge Transport server handles messages when a DNS server can't be reached. The options for how the Edge Transport server handles spoofed mail and unreachable DNS servers include the following actions:

- **Stamp the status** This option is the default action. All inbound messages to your organization have the Sender ID status included in the metadata of the message.
- **Reject** This option rejects the message and sends an SMTP error response to the sending server. The SMTP error response is a 5*xx* level protocol response with text that corresponds to the Sender ID status.
- **Delete** This option deletes the message without informing the sending system of the deletion. In fact, the Edge Transport server sends a fake OK SMTP command to the sending server and then deletes the message. Because the sending server assumes the message was sent, it doesn't retry sending the message in the same session.

For more information about how to configure the Sender ID agent, see Configure Sender ID Properties.

Return to top

Updating Your Organization's Internet-Facing DNS to Support Sender ID

The effectiveness of Sender ID depends on specific DNS data. The more organizations that update their Internet-facing DNS servers by using an SPF record, the more effectively Sender ID identifies spoofed e-mail messages.

To support the Sender ID infrastructure, you must update your Internet-facing DNS data by creating an SPF record and hosting the SPF record on your public DNS servers. For more information about how to create and deploy SPF records, see Sender ID.

Return to top

Specifying Recipients and Sender Domains to Exclude From Sender ID

Filtering

You may want to exclude specific recipients and sender domains from Sender ID filtering. To do this, specify the recipients and sender domains in the Exchange Management Shell. You can't specify the recipients and sender domains in the Exchange Management Console.

For more information about how to set recipient and sender domain exclusions for Sender ID, see Set-SenderIdConfig.

1.7.1.5.11 Understanding Sender Reputation

Understanding Sender Reputation

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-07*

Sender reputation is anti-spam functionality that's enabled on computers that have the Microsoft Exchange Server 2010 Edge Transport server role installed to block messages according to many characteristics of the sender. Sender reputation relies on persisted data about the sender to determine what action, if any, to take on an inbound message.

When you configure anti-spam agents on an Edge Transport server, the agents act on messages cumulatively to reduce the number of unsolicited messages that enter the organization. For more information about how to plan and deploy the anti-spam agents, see Understanding Anti-Spam and Antivirus Functionality.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Calculation of the Sender Reputation Level

A sender reputation level (SRL) is calculated from the following statistics:

- **HELO/EHLO analysis** The HELO and EHLO SMTP commands are intended to provide the domain name, such as Contoso.com, or IP address of the sending SMTP server to the receiving SMTP server. Malicious users, or *spammers*, frequently forge the HELO/EHLO statement in various ways. For example, they

type an IP address that doesn't match the IP address from which the connection originated. Spammers also put domains that are known to be locally supported at the receiving server in the HELO statement in an attempt to appear as if the domains are in the organization. In other cases, spammers change the domain that's passed in the HELO statement. The typical behavior of a legitimate user may be to use a different, but relatively constant, set of domains in their HELO statements.

Therefore, analysis of the HELO/EHLO statement on a per-sender basis may indicate that the sender is likely to be a spammer. For example, a sender that provides many different unique HELO/EHLO statements in a specific time period is more likely to be a spammer. Senders who consistently provide an IP address in the HELO statement that doesn't match the originating IP address as determined by the Connection Filter agent are also more likely to be spammers, as are remote senders who consistently provide a local domain name, which is in the same organization as the Edge Transport server, in the HELO statement.

- **Reverse DNS lookup** Sender reputation also verifies that the originating IP address from which the sender transmitted the message matches the registered domain name that the sender submits in the HELO or EHLO SMTP command.

  Sender reputation performs a reverse DNS query by submitting the originating IP address to DNS. The result that's returned by DNS is the domain name that's registered by using the domain naming authority for that IP address. Sender reputation compares the domain name that's returned by DNS to the domain name that the sender submitted in the HELO/EHLO SMTP command. If the domain names don't match, the sender is likely to be a spammer, and the overall SRL rating for the sender is adjusted upward.

  The Sender ID agent performs a similar task, but the success of the Sender ID agent relies on legitimate senders to update their DNS infrastructure to identify all the e-mail-sending SMTP servers in their organization. By performing a reverse DNS lookup, you can help identify potential spammers.
- **Analysis of SCL ratings on messages from a particular sender** When the Content Filter agent processes a message, it assigns a spam confidence level (SCL) rating to the message. The SCL rating is a number from 0 through 9. A higher SCL rating indicates that a message is more likely to be spam. Data about each sender and the SCL ratings that their messages yield is persisted for analysis by sender reputation. Sender reputation calculates statistics about a sender according to the ratio between all messages from that sender that had a low SCL rating in the past and all messages from that sender that had a high SCL rating in the past. Additionally, the number of messages that have a high SCL rating that the sender has sent in the last day is applied to the overall SRL.
- **Sender open proxy test** An *open proxy* is a proxy server that accepts connection requests from anyone anywhere and forwards the traffic as if it originated from the local hosts. Proxy servers relay TCP traffic through firewall hosts to provide user applications transparent access across the firewall. Because proxy protocols are lightweight and independent of user application protocols, proxies can be used by many different services. Proxies can also be used to share a single Internet connection by multiple hosts. Proxies are usually set up so that only trusted hosts inside the firewall can cross through the proxies.

  Open proxies can exist because of either of the following conditions:
  - Unintentional misconfiguration.
  - Malicious Trojan horse programs. A *Trojan horse* program is a program that masquerades as another common program in an attempt to receive information.

  Frequently with insufficient logging, open proxies provide an ideal way for malicious users to hide their true identities and launch denial of service attacks (DoS) or send spam. As more proxy servers are configured to be open by default, open proxies have become more common. Additionally, malicious users

can use multiple open proxies together to hide the sender's originating IP address.
When sender reputation performs an open proxy test, it does so by formatting an SMTP request in an attempt to connect back to the Edge Transport server from the open proxy. If an SMTP request is received from the proxy, sender reputation verifies that the proxy is an open proxy and updates the open proxy test statistic for that sender.

Sender reputation weighs each of these statistics and calculates an SRL for each sender. The SRL is a number from 0 through 9 that predicts the probability that a specific sender is a spammer or otherwise malicious user. A value of 0 indicates that the sender isn't likely to be a spammer; a value of 9 indicates that the sender is likely to be a spammer.

You can configure a block threshold from 0 through 9 at which sender reputation issues a request to the Sender Filter agent, and, therefore, blocks the sender from sending a message into the organization. When a sender is blocked, the sender is added to the Blocked Senders list for a configurable period. How blocked messages are handled depends on the configuration of the Sender Filter agent. The following actions are the options for handling blocked messages:

- Reject
- Delete and archive
- Accept and mark as a blocked sender

If a sender is included in the IP Block list or Microsoft IP Reputation Service, sender reputation issues an immediate request to the Sender Filter agent to block the sender. To take advantage of this functionality, you must enable and configure the Microsoft Exchange Anti-spam Update Service.

By default, the Edge Transport server sets a rating of 0 for senders that haven't been analyzed. After a sender has sent 20 or more messages, sender reputation calculates an SRL that's based on the statistics listed earlier in this topic.

Return to top

Use of the SRL

Sender reputation acts on messages during two phases of the SMTP session:

- **At the MAIL FROM: SMTP command** Sender reputation acts on a message only if the message was blocked or otherwise acted on by the Connection Filter agent, Sender Filter agent, Recipient Filter agent, or Sender ID agent. In this case, sender reputation retrieves the sender's current SRL rating from the sender profile that's persisted about that sender in the Edge Transport server database. After this rating is retrieved and evaluated, the Edge Transport server configuration dictates the behavior that occurs at a particular connection according to the block threshold.
- **After the "end of data" SMTP command** The end of data transfer (**_EOD**) SMTP command is given when all the actual message data is sent. At this point in the SMTP session, many of the anti-spam agents have processed the message. As a by-product of anti-spam processing, the statistics that sender reputation relies on are updated. Therefore, sender reputation has the data to calculate or recalculate an SRL rating for the sender.

For more information, see Configure Sender Reputation Properties.

Return to top

Enabling and Configuring the Detection of

Open Proxy Servers

Sender reputation evaluates several sender characteristics to calculate an SRL. Among the characteristics that sender reputation evaluates are the results of a test for open proxy servers. Frequently, spammers route messages through open proxy servers on the Internet. By routing spam through open proxy servers, spammers can send messages that appear to originate from a different server than their own.

When sender reputation calculates an SRL, sender reputation tries to connect to the sender's originating IP address by using a variety of common proxy protocols, such as SOCKS4, SOCKS5, HTTP, Telnet, Cisco, and Wingate. Sender reputation formats a protocol-specific request in an attempt to connect back to the Edge Transport server from the open proxy server by using an SMTP request. If an SMTP request is received from the proxy server, sender reputation verifies that the proxy server is an open proxy server and adjusts the SRL rating according to this result. By default, detection of open proxy servers is enabled on sender reputation.

For more information about how to enable detection of open proxy servers, see Configure Sender Reputation Properties.

For more information about how to configure detection of open proxy servers, see Configure Outbound Access for Detection of Open Proxy Servers for Sender Reputation.

Return to top

Setting the SRL Block Threshold

The SRL is a number from 0 through 9 that predicts the probability that a specific sender is a spammer or otherwise malicious user. You must set a threshold for sender blocking by SRL. This SRL block threshold defines the SRL value that must be exceeded for sender reputation to block a sender. By default, the SRL is set at 7. You should monitor the effectiveness of the agent at the default level. You may find that you can adjust the value to meet the needs of your organization. If you set other anti-spam agents aggressively, you may be able to set a higher SRL threshold for sender reputation than you would if the other anti-spam agents weren't set aggressively. For more information about how to adjust anti-spam configurations so that they work together to reduce spam, see Understanding Anti-Spam and Antivirus Functionality.

If the SRL block threshold is exceeded for a particular sender, sender reputation adds the sender to the IP Block list on the Connection Filter agent. Sometimes, spammers send batches of spam from a single sender. In this scenario, if sender reputation calculates an SRL that exceeds the SRL block threshold, the sender is added to the Sender Block List for a configurable duration of time. The default duration is 24 hours. After 24 hours, the sender is removed from the Sender Block List and can send messages again.

When a sender is added to the IP Block list, sender reputation deletes the profile for the sender. Sender reputation deletes the profile because the blocked sender's existing profile indicates that the sender's SRL exceeds the SRL block threshold. This would cause the blocked sender to be added to the IP Block list again as soon as the duration for sender blocking ends.

For more information, see Configure Sender Reputation Properties.

Return to top

Understanding Spam Confidence Level Threshold

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-10*

In Microsoft Exchange Server 2010, you can define specific actions according to spam confidence level (SCL) thresholds. For example, you can define different thresholds for rejecting, deleting, or quarantining messages on a server that has the Edge Transport server role installed.

The combination of this SCL threshold configuration on the Edge Transport server and the SCL Junk E-mail folder configuration on the user mailbox helps you implement a more comprehensive and precise anti-spam strategy. This more precise and detailed SCL threshold adjustment functionality in Exchange 2010 can help you reduce the overall cost of deploying and maintaining an anti-spam solution across your Exchange organization.

The SCL threshold configuration is used by the Content Filter agent, one of the default anti-spam agents included with Exchange 2010. The Content Filter agent uses Microsoft SmartScreen technology to assess the contents of a message and to assign an SCL rating to each message.

The Content Filter agent performs this function late in the anti-spam cycle, after other anti-spam agents have processed any inbound messages. Many of the other anti-spam agents that process inbound messages before they're processed by the Content Filter agent are deterministic in how they act on a message. For example, the Connection Filter agent rejects any message sent from an IP address on a real-time block list. The Sender Filter agent and Recipient Filter agent process messages in a similarly deterministic manner.

In Exchange 2010, these deterministic anti-spam agents process messages first and therefore greatly reduce the number of messages that must be processed by the Content Filter agent. For more information about the order in which anti-spam agents process messages, see Understanding Anti-Spam and Antivirus Mail Flow.

Because content filtering isn't an exact, deterministic process, the ability to adjust the action that the Content Filter agent performs on different SCL values is important. By carefully adjusting the SCL threshold configuration, you can minimize the following:

- Size of the spam quarantine storage
- Number of legitimate e-mail messages mistakenly quarantined
- Number of legitimate e-mail messages that reach the Microsoft Outlook user's Junk E-mail folder
- Number of offensive spam e-mail messages that reach the Outlook user's Inbox or Junk E-mail folder
- Number of spam e-mail messages that reach the Outlook user's Inbox

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

SCL Threshold Actions in Exchange 2010

In Exchange 2010, by adjusting SCL threshold actions, you can escalate the content filtering action taken on messages that have a greater risk of being spam. To understand this functionality, it's helpful to understand the different SCL threshold actions and how they're implemented:

- **SCL delete threshold** When the SCL value for a specific message is equal to

or higher than the SCL delete threshold, the Content Filter agent deletes the message. There's no protocol-level communication that tells the sending system or sender that the message was deleted. If the SCL value for a message is lower than the SCL delete threshold value, the Content Filter agent doesn't delete the message. Instead, the Content Filter agent compares the SCL value to the SCL reject threshold.

- **SCL reject threshold** When the SCL value for a specific message is equal to or higher than the SCL reject threshold, the Content Filter agent deletes the message and sends a rejection response to the sending system. You can customize the rejection response. In some cases, a non-delivery report (NDR) is sent to the original sender of the message. If the SCL value for a message is lower than the SCL delete and SCL reject threshold values, the Content Filter agent doesn't delete or reject the message. Instead, the Content Filter agent compares the SCL value to the SCL quarantine threshold.
- **SCL quarantine threshold** When the SCL value for a specific message is equal to or higher than the SCL quarantine threshold, the Content Filter agent sends the message to a quarantine mailbox. E-mail administrators must periodically review the quarantine mailbox. If the SCL value for a message is lower than the SCL delete, reject, and quarantine threshold values, the Content Filter agent doesn't delete, reject, or quarantine the message. Instead, the Content Filter agent sends the message to the appropriate Mailbox server, where the per-recipient SCL Junk E-mail folder threshold value of the message is evaluated.
- **SCL Junk E-mail folder threshold** If the SCL value for a specific message exceeds the SCL Junk E-mail folder threshold, the Mailbox server puts the message in the Outlook user's Junk E-mail folder. If the SCL value for a message is lower than the SCL delete, reject, quarantine, and Junk E-mail folder threshold values, the Mailbox server puts the message in the user's Inbox.

For example, if you set the SCL delete threshold to 8, the SCL reject threshold to 7, the SCL quarantine threshold to 6, and the SCL Junk E-mail folder threshold to 5, all e-mail with an SCL of 5 or lower will be delivered to the user's Inbox.

As you plan and deploy your strategy for adjusting the SCL threshold, it's important to understand that the Content Filter agent and the SCL Junk E-mail folder process the SCL threshold value differently. The Content Filter agent takes action on the SCL threshold value that you configure. The SCL Junk E-mail folder takes action on the SCL threshold value that you configure plus 1. For example, if you configure the Delete action to an SCL of 4 on the Content Filter agent, all messages with an SCL of 4 or greater are deleted. However, if you configure the Delete action to an SCL of 4 on the SCL Junk E-mail folder, all messages with an SCL of 5 or greater are deleted.

To configure the SCL Junk E-mail folder threshold on individual user mailboxes, you must use the Set-Mailbox cmdlet in the Exchange Management Shell. You can configure the SCL delete, reject, and quarantine thresholds in two locations:

- **On the content filter configuration (per-transport server SCL configuration)** We recommend that you set the organization-wide SCL thresholds on the content filter configuration on the Edge Transport server. If you run anti-spam agents on the Hub Transport server, set the organization-wide SCL thresholds on the Hub Transport server. By applying the same SCL thresholds across all transport servers, you can establish a consistent baseline level of SCL functionality across the organization. Over time, as you analyze the spam functionality and metrics provided by the anti-spam logging and reporting features, you can make additional adjustments to these SCL threshold configurations as needed.
- **On user mailboxes (per-recipient SCL configuration)** You can use the **Set-Mailbox** cmdlet to set per-recipient SCL delete, reject, and quarantine thresholds on individual user mailboxes. As mentioned earlier in this topic, you set the SCL Junk E-mail folder threshold on individual user mailboxes by using

the **Set-Mailbox** cmdlet. The per-recipient SCL delete, reject, and quarantine thresholds are stored in Active Directory and are replicated to the Edge Transport servers by the Microsoft Exchange EdgeSync service. The per-recipient SCL threshold configurations are used by the Content Filter agent even if you've set per-transport server SCL configurations. Therefore, if you've set per-recipient SCL thresholds, the Content Filter agent uses the per-recipient SCL thresholds for specific users instead of the SCL configuration on the Content Filter agent.

Note:

Per-recipient SCL thresholds are not enforced on mail received through distribution groups. These types of messages are rejected at the Transport server before the per-recipient threshold settings are applied. Additionally, if you're using Microsoft Forefront Protection 2010 for Exchange Server, any per-recipient SCL threshold settings replicated to the Edge Transport servers by the Microsoft Exchange EdgeSync service will take precedence over the Forefront anti-spam settings.

For more information about how to use the **Set-Mailbox** cmdlet, see Set-Mailbox.

Best Practice for Setting Up and Adjusting SCL Thresholds

We recommend that you set up and adjust the SCL thresholds as follows:

1. Enable the SCL delete, reject, and quarantine thresholds on the content filter configuration on each Edge Transport server.
   We recommend that you enable SCL thresholds at an organization level and that you use the default values for these SCL thresholds. The default values were set by the Exchange Server team according to real-world data from the Microsoft IT messaging department and from Exchange 2010 early adopter feedback. The default values are optimized for large, global enterprise deployments.
   If needed, you can also configure the SCL delete, reject, and quarantine thresholds on a per-recipient configuration to bypass the SCL thresholds configured at the organization level. For more information about how to set the SCL thresholds on the content filter configurations, see Configure Content Filtering Properties.
2. Monitor spam reports and logs closely for the first week after you enable the SCL thresholds.
   You can use several built-in scripts located in the %ExchangeInstallPath%\Scripts folder, such as get-AntispamSCLHistogram.ps1, for gathering filtering result data. If the data indicates that you must make immediate adjustments, reconfigure the SCL thresholds. Otherwise, collect data and analyze the spam reporting to determine whether adjustments are required.

1.7.1.5.13 Understanding Spam Quarantine

Understanding Spam Quarantine

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Many organizations are bound by legal or regulatory requirements to preserve or deliver all legitimate e-mail messages. In Microsoft Exchange Server 2010, spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. Spam quarantine provides a temporary storage location for messages identified as spam that shouldn't be delivered to a user mailbox inside the organization.

Messages identified by the Content Filter agent as spam are wrapped in a non-delivery report (NDR) and delivered to a spam quarantine mailbox inside the organization. You can manage messages delivered to the spam quarantine mailbox and take appropriate actions. For example, you can delete messages or let messages flagged as false positives in anti-spam filtering be routed to their intended recipients. In addition, you can configure the spam quarantine mailbox to automatically delete messages after a designated time period.

For more information about how the anti-spam agents filter inbound messages and the order in which the agents are applied, see Understanding Anti-Spam and Antivirus Functionality.

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Contents

Spam Confidence Level

When an external user sends e-mail messages to a server running Exchange that runs the anti-spam features, the anti-spam features cumulatively evaluate characteristics of the messages and act as follows:

- Those messages suspected to be spam are filtered out.
- A rating is assigned to messages based on the probability that a message is spam. This rating is stored with the message as a message property called the spam confidence level (SCL) rating.

Spam quarantine uses the SCL rating to determine whether mail has a high probability of being spam. The SCL rating is a numeric value from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered most likely to be spam.

You can configure mail that has a certain SCL rating to be deleted, rejected, or quarantined. The rating that triggers any of these actions is referred to as the *SCL quarantine threshold*. Within content filtering, you can configure the Content Filter agent to base its actions on the SCL quarantine threshold. For example, you can set the following conditions:

- SCL delete threshold is set to 8.
- SCL reject threshold is set to 7.
- SCL quarantine threshold is set to 6.
- SCL Junk E-mail folder threshold is set to 5.

Based on the preceding SCL thresholds, all e-mail with an SCL of 6 will be delivered to the spam quarantine mailbox.

For more information, see Configure Content Filtering Properties.

Return to top

Spam Quarantine

When messages are received by the Edge Transport server and all default anti-spam filters are enabled, the anti-spam agents apply their filters. Then the content filter is applied as follows:

- If the SCL rating is greater than or equal to the SCL quarantine threshold but less than either the SCL delete threshold or SCL reject threshold, the message goes to the spam quarantine mailbox.
- If the SCL rating is lower than the spam quarantine threshold, it's delivered to the recipient's Inbox.

The message administrator uses Microsoft Office Outlook 2007 to monitor the spam quarantine mailbox for false positives. If a false positive is found, the administrator can send the message to the recipient's mailbox.

The message administrator can review the anti-spam stamps if either of the following conditions is true:

- Too many false positives are filtered into the spam quarantine mailbox.
- Not enough spam is being rejected or deleted.

For more information, see Understanding Anti-Spam Stamps.

You can then adjust the SCL settings to more accurately filter the spam coming into the organization. For more information, see Understanding Spam Confidence Level Threshold.

To use spam quarantine, you must follow these steps:

1. Enable content filtering.
2. Create a spam quarantine mailbox.
3. Specify the spam quarantine mailbox.
4. Configure the SCL quarantine threshold.
5. Manage the spam quarantine mailbox.
6. Adjust the SCL quarantine threshold as needed.

Enabling Content Filtering

You must enable content filtering before you can apply spam quarantine. By default, the Content Filter agent filters all external messages that come through all Receive connectors on the computer on which the Content Filter feature is enabled.

Important:

Configuration changes that you make to the Content Filter agent by using the Exchange Management Console or the Exchange Management Shell are made only to the local computer that has the Edge Transport server role installed. If multiple instances of the Edge Transport server role are running in your organization, you must apply sender reputation configuration changes to each computer.

For more information, see Enable or Disable Content Filtering.

Creating a Spam Quarantine Mailbox

You must create a spam quarantine mailbox before you can enable the feature. To set up a spam quarantine mailbox, you must follow these steps:

- **Create a dedicated Exchange database** We recommend that you create a dedicated database for the spam quarantine mailbox. The spam quarantine mailbox should have a large database, because if the storage quota limit is reached, messages will be lost. For more information, see Create a Mailbox Database.
- **Create an Active Directory user** We recommend that you create a separate

Active Directory user for the spam quarantine mailbox. You may apply different recipient policies, such as messaging records management and mailbox size, and delegation rights, according to your organization's compliance policies and needs.

- **Create a user mailbox** You must create a mailbox that you can use as the spam quarantine mailbox with an appropriate messaging records management policy that includes mailbox size and the number of days that messages will be saved before they are deleted. For more information, see Messaging Records Management.

  Note:
  If a quarantined message is rejected because of a storage quota, the message will be lost. Exchange doesn't generate NDRs for quarantined messages because the quarantined messages are wrapped as NDRs.

  For more information, see Create a Mailbox.
- **Set up the Outlook account profile** You must configure management or delegation of the Outlook account to meet the needs of your organization. In addition, to help with the account management, we recommend that you configure the Outlook profile to expose the original Sender[#0x0069001E], Recipient[#0x0E04001E], and Bcc[#0x0E02001E] fields in the Message view. For more information, see Release Quarantined Messages from the Spam Quarantine Mailbox.

Specifying the Spam Quarantine Mailbox

After you set up the spam quarantine mailbox, you must specify the spam quarantine mailbox in the content filter configuration. You use the **Set-ContentFilterConfig** cmdlet in the Shell to specify a spam quarantine mailbox. The *QuarantineMailbox* parameter uses the SMTP address of the spam quarantine mailbox.

Important:
You must specify the spam quarantine mailbox on all servers that have the Edge Transport server role installed in Active Directory where user mailboxes are located. To specify the spam quarantine mailbox in Active Directory, run the **Set-ContentFilterConfig** cmdlet on a Hub Transport server. You don't have to have content filtering enabled on the Hub Transport server to specify a spam quarantine mailbox in Active Directory.

For more information, see Specify a Spam Quarantine Mailbox.

Configuring the SCL Quarantine Threshold

The SCL quarantine threshold is the value at which a particular message identified as potential spam is delivered to the spam quarantine mailbox. You can set the SCL quarantine threshold to a value from 0 through 9, where 0 is considered less likely to be spam, and 9 is considered most likely to be spam.

For more information about how to adjust SCL thresholds to suit your organization's requirements and how to adjust per-recipient SCL thresholds, see Configure Content Filtering Properties.

Managing the Spam Quarantine Mailbox

When you manage your spam quarantine mailbox, follow these guidelines:

- Release items that have been sent to the spam quarantine mailbox by using the Send Again feature in Outlook to resend the original message. For more information, see Release Quarantined Messages from the Spam Quarantine Mailbox.
- Monitor the spam quarantine mailbox so that the size of the spam quarantine mailbox remains in an acceptable range. The volume of e-mail messages can change because of a larger set of recipients, the natural trend of larger messages, or the threshold on the SCL quarantine action.
- Monitor the spam quarantine mailbox for false positives. If your spam quarantine mailbox includes many false positives, adjust your SCL quarantine

threshold as described in "Adjusting the SCL Quarantine Threshold" later in this topic. For more information about how to determine why false positives are being delivered to the spam quarantine mailbox, see Understanding Anti-Spam Stamps.

- Use the same Outlook profile to recover quarantined messages from the spam quarantine mailbox. Applying permissions to a different Outlook profile to recover messages isn't supported. You can't use a different Outlook profile to recover or release messages from the spam quarantine mailbox.

Important:

NDRs identified as spam are deleted, even if their SCL rating indicates that they should be quarantined. NDRs aren't delivered to the spam quarantine mailbox. To track such messages, use the agent log or the message tracking log. For more information, see Get-AgentLog and Search Message Tracking Logs.

Adjusting the SCL Quarantine Threshold

After you configure the SCL quarantine threshold, periodically monitor the settings and adjust them based on your organization's needs. For example, if too many false positives are filtered into the spam quarantine mailbox, raise the SCL quarantine threshold to a larger number. For more information about how to adjust the SCL quarantine threshold, see Understanding Spam Confidence Level Threshold.

Return to top

Exchange Hosted Services

Spam filtering and quarantine functionality are enhanced by services available from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

1.7.1.5.14 Using Edge Transport Rules to Manage Viruses

Using Edge Transport Rules to Manage Viruses

Transport > Understanding Transport > Understanding Anti-Spam and Antivirus Functionality >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Edge Rules agent and transport rules in Microsoft Exchange Server 2010 to help protect your organization from viruses.

New viruses threaten organizations every day. To minimize the damage caused by viruses, antivirus vendors and administrators must respond to virus threats as soon as possible. Despite a quick response, there will be a gap between the time that a virus threat appears and the time that a solution becomes available. This gap, when a virus threat remains unknown and unresolved, is called a *zero-day virus threat*.

At the same time, viruses that have been circulating on the Internet for many years also continue to pose a significant threat to organizations. Although the majority of these viruses can be identified by antivirus scanners, antivirus scanners may be taken offline by mistake, updated with out-of-date definitions, or experience other problems that make them unavailable.

The transport rules that run on computers that have the Edge Transport server role installed are designed to help you manage and control zero-day virus threats and preexisting or ongoing virus threats.

For more information about transport rules, see the following topics:

- Overview of Transport Rules
- Understanding How Transport Rules Are Applied

Looking for management tasks related to anti-spam and antivirus functionality? See Managing Anti-Spam and Antivirus Features.

Managing Virus Threats

Most viruses contain unique characteristics that identify them as a virus, such as a specific e-mail address in the From message header field, a specific subject, or an attachment. You can configure transport rules to identify potentially harmful messages by these unique characteristics and perform a specific action on them. Available actions include sending the message to a quarantine mailbox, deleting it completely, or adding a warning to the subject.

Identifying Virus Threats

It's important to maximize the number of infected messages that you identify in your perimeter network on Edge Transport servers to reduce the cost of processing the messages after they have entered the Exchange organization. If you can identify an infected message on Edge Transport servers and either reject or delete it, you don't incur the cost of storing the message on your internal servers or the cost of scanning the message for viruses.

When you create a transport rule to identify virus threats, you should examine the reports published about the virus and look for unique characteristics that identify the virus and that could be used in a transport rule. The following list describes some unique characteristics that a virus may contain:

- Limited number of strings in the subject or message body
- Specific e-mail address in either the From header field or To header field
- Specific message header field that has a specific value

Important:

Although you may be able to identify unique characteristics about a particular virus, you must make sure that these characteristics don't match any content that may exist in legitimate messages.

For more information about the types of message content that can be examined by transport rules on an Edge Transport server, see Transport Rule Predicates.

Controlling Virus Threats with Transport Rules

After you have identified the unique characteristics of a virus, you can create a transport rule to perform actions on it. The actions that you perform on specific messages depend

on your organization's policies.

Caution:

If you decide to drop an SMTP connection, delete a message, or reject a message, you can't retrieve it. If you want to prevent the message from being delivered, but don't want to delete it, configure the rule to deliver the message to a quarantine mailbox.

For more information about the actions available on transport rules on an Edge Transport server, see Transport Rule Actions.

For more information about how to manage and configure transport rules used to identify and perform actions on messages that may be infected with viruses, see the following topics:

- Create a Transport Rule
- View a Transport Rule
- Modify a Transport Rule
- Remove a Transport Rule
- Configure a Disclaimer

The following topics provide additional information that will help you manage and enhance transport rules:

- Transport Rule Predicates
- Transport Rule Actions
- Regular Expressions in Transport Rules

Using Exchange Hosted Services

Transport messaging policies are enhanced by services available from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

1.7.1.6 Understanding Approval Framework

Understanding Approval Framework

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-18*

Approval Framework

Microsoft Exchange uses the *approval framework* for simple decision-making about e-mail messages. For each workflow, the approval framework uses a special mailbox called the *arbitration mailbox*, which is used to store the original message and the decision state during the approval process.

The following workflow is followed by any application that uses the approval framework:

1. The user starts a new workflow process using the workflow application.
2. The workflow application sends an initiation message to the arbitration mailbox.
3. Exchange stores the message in the arbitration mailbox and sends approval requests to the specified decision makers.
4. The specified decision makers either approve or reject the approval request.
5. Exchange marks the decision on the original message that is stored in the arbitration mailbox.
6. The workflow application monitors the arbitration mailbox and acts on the decisions that are marked on the original message.

In Exchange Server 2010, the approval framework is used for the following:

- **Moderated recipients** For more information, see Understanding Moderated Transport.
- **Joining and departing distribution groups** For more information, see step 7 in Configure Distribution Group Properties.

1.7.1.7 Understanding Back Pressure

Understanding Back Pressure

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-02-02*

Back pressure is a system resource monitoring feature of the Microsoft Exchange Transport service that exists on Microsoft Exchange Server 2010 Hub Transport and Edge Transport servers. Exchange transport can detect when vital resources, such as available hard disk space and memory, are under pressure, and take action in an attempt to prevent service unavailability.

Back pressure prevents the system resources from being completely overwhelmed, and Exchange tries to deliver the existing messages. When utilization of the system resource returns to a normal level, the Exchange server gradually resumes normal operation.

In Exchange Server 2007, when a Hub Transport or Edge Transport server is under resource pressure, it rejects incoming connections. In Exchange 2010, incoming connections are accepted, but incoming messages over those connections are either accepted at a slower rate or are rejected. When an SMTP host attempts to make a connection to a Hub Transport or Edge Transport server that's in back pressure, the connection will succeed but when the host issues the MAIL FROM command to submit a message, depending on the resource that's under pressure, Exchange either delays the acknowledgement to the MAIL FROM command or rejects it.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Resources Monitored

The following system resources are monitored as part of the back pressure feature:

- Free space on the hard disk that stores the message queue database.
- Free space on the hard disk that stores the message queue database transaction logs.
- The number of uncommitted message queue database transactions that exist in memory.
- The memory that's used by the EdgeTransport.exe process.
- The memory that's used by all other processes.

For each monitored system resource on a Hub Transport server or Edge Transport server, the following three levels of resource utilization are applied:

- **Normal** The resource isn't overused. The server accepts new connections and messages.
- **Medium** The resource is slightly overused. Back pressure is applied to the server in a limited manner. Mail from senders in the authoritative domain can flow. However, depending on the specific resource under pressure, the server uses tarpitting to delay server response or rejects incoming MAIL FROM commands from other sources.
- **High** The resource is severely overused. Full back pressure is applied. All message flow stops, and the server rejects all new incoming MAIL FROM commands.

The following sections explain how Exchange handles the situation when a specific resource is under pressure.

Free Hard Disk Space for the Message Queue Database

By default, the message queue database is stored at C:\Program Files\Microsoft \Exchange Server\V14\TransportRoles\data\Queue. Exchange monitors the hard disk space utilization for this location. The high level of hard disk space utilization is calculated by using the following formula:

100 * (*hard disk size* - *fixed constant*) / *hard disk size*

The value of *fixed constant* is 500 megabytes (MB).

The results of this formula are expressed as a percentage of the total hard disk space that's being used. The results of the formula are always rounded down to the nearest integer. By default, the medium level of hard disk utilization is 2 percent less than the high level. By default, the normal level of hard disk utilization is 4 percent less than the high level.

For more information about the message queue database, see Understanding Transport Queues.

Free Hard Disk Space for the Message Queue Database Transaction Logs

By default, the message queue database transaction logs are stored at C:\Program Files \Microsoft\ExchangeServer\V14\TransportRoles\data\Queue. Exchange monitors the hard disk space utilization for this location. The EdgeTransport.exe.config file contains a *DatabaseCheckPointDepthMax* parameter that has a default value of 512 MB. This parameter controls the total allowed size of all uncommitted transaction logs that exist on the hard disk. This parameter is used in the formula that calculates hard disk utilization.

Note:

The value of the *DatabaseCheckPointDepthMax* parameter applies to all transport-related Extensible Storage Engine (ESE) databases that exist on the Hub Transport server or Edge Transport server. This would include the message queue database and the IP filter database.

By default, the high level of hard disk utilization is calculated by using the following formula:

100 * (*hard disk size* - Max(5 GB, 3**DatabaseCheckPointDepthMax*)) / *hard disk size*

The results of the formula are always rounded down to the nearest integer. By default, the medium level of hard disk utilization is 2 percent less than the high level. The normal level of hard disk utilization is 4 percent less than the high level.

For more information about the message queue database, see Understanding Transport Queues.

Number of Uncommitted Message Queue Database Transactions in Memory

A list of changes that are made to the message queue database is kept in memory until those changes can be committed to a transaction log. Then the list is committed to the message queue database itself. These outstanding message queue database transactions that are kept in memory are known as *version buckets*. The number of version buckets may increase to unacceptably high levels because of an unexpectedly high volume of incoming messages, spam attacks, problems with the message queue database integrity, or hard disk performance.

When Exchange starts receiving messages, these messages are grouped together in batches and then prepared as version buckets. If an incoming message has a large attachment, it can be separated into multiple batches. These batches that are being processed are known as *batch points*. The number of outstanding batch points can exceed the set thresholds, especially when there's an unexpectedly high volume of incoming messages with large attachments.

When version buckets or batch points are under pressure, the Exchange 2010 transport server will start throttling incoming connections by delaying acknowledgement to incoming messages. Exchange will reduce the rate of inbound message flow by tarpitting, which introduces a delay to the MAIL FROM commands. If the resource pressure condition continues, Exchange will gradually increase the tarpitting delay. After the resource utilization returns to normal, Exchange will gradually start reducing the acknowledgement delay and ease into normal operation. By default, Exchange will start delaying message acknowledgements 10 seconds when under resource pressure. If the resources continue to be under pressure, the delay is increased in 5-second increments up to 55 seconds.

Exchange 2010 keeps a history of version bucket and batch point resource utilization. If the resource utilization doesn't go down to normal level for a specific number of polling intervals, known as the history depth, Exchange will stop the tarpitting delay and start rejecting incoming messages until the resource utilization goes back to normal. By default, the history depths for version buckets and batch points are in 10 and 300 polling intervals respectively.

Memory Used by the EdgeTransport.exe Process

By default, the high level of memory utilization by the EdgeTransport.exe process is calculated by using the following formula:

75 percent of the total physical memory or 1 terabyte, whichever is less

This calculation doesn't include virtual memory that's available on the hard disk in the paging file, or the memory that's used by other processes. The results of this formula are expressed as a percentage of the total memory that's used by the EdgeTransport.exe process. The results of the formula are always rounded down to the nearest integer.

By default, the medium level of memory utilization by the EdgeTransport.exe file is calculated as 73 percent of the total physical memory or 2 percent less than the value of the high level, whichever is less. By default, the normal level of memory utilization by the EdgeTransport.exe file is calculated as 71 percent of the total physical memory or 4 percent less than the value of the high level, whichever is less.

If the memory utilization of the EdgeTransport.exe process is higher than the specified normal level, *garbage collection* is forced. Garbage collection is a process that checks for unused objects that exist in memory, and reclaims the memory that's used by those unused objects.

Exchange 2010 keeps a history of the memory utilization of the EdgeTransport.exe process. If the utilization doesn't go down to normal level for a specific number of polling intervals, known as the history depth, Exchange will start rejecting incoming messages until the resource utilization goes back to normal. By default, the history depth for EdgeTransport.exe memory utilization is 30 polling intervals.

Memory Used by All Processes

By default, the high level of memory utilization by all processes is 94 percent of total physical memory. This value doesn't include virtual memory that's available on the hard disk in the paging file.

When the specified memory utilization level is reached, *message dehydration* occurs. Message dehydration is the act of removing unnecessary elements of queued messages that are cached in memory. Complete messages are cached in memory for enhanced performance. Removal of the MIME content of queued messages from memory reduces the memory that's used at the expense of higher latency because the messages are read directly from the message queue database. By default, message dehydration is enabled.

Actions Taken by Exchange Transport When Under Resource Pressure

The following table summarizes the actions taken by Exchange transport when a specific resource is under pressure.

Back pressure actions taken by Hub Transport and Edge Transport servers when responding to resource pressure

Resource under pressure	Utilization level	Actions taken
Hard disk space for message queue database	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories

Hard disk space for message queue database	High	• Reject incoming messages from other Exchange servers • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only) • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Hard disk space for message queue database transaction logs	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Hard disk space for message queue database transaction logs	High	• Reject incoming messages from other Exchange servers • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only) • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories

Version buckets	Medium	• Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire version bucket history depth, take the following actions:
		  • Reject incoming messages from non-Exchange servers
		  • Reject message submissions from Pickup and Replay directories

Version buckets	High	• Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire version bucket history depth, take the following actions:
		  • Reject incoming messages from other Exchange servers
		  • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only)
		  • Reject incoming messages

		from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Batch point	Medium	• Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire batch point history depth, take the following actions: • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Batch point	High	• Introduce or increment the tarpitting delay to incoming messages. If normal level isn't reached for the entire batch point history depth, take the following actions: • Reject incoming messages from other Exchange servers • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only) • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Memory used by EdgeTransport.exe process	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Force garbage collection
Memory used by EdgeTransport.exe process	High	• Reject incoming messages from other Exchange servers • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only) • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories
Memory used by all processes	Medium	• Reject incoming messages from non-Exchange servers • Reject message submissions

		from Pickup and Replay directories • Force garbage collection
Memory used by all processes	High	• Reject incoming messages from other Exchange servers • Reject message submissions from the store driver on Mailbox servers (Hub Transport server only) • Reject incoming messages from non-Exchange servers • Reject message submissions from Pickup and Replay directories • Flush enhanced Domain Name System (DNS) cache from memory • Start message dehydration

Back Pressure Configuration Options in the EdgeTransport.exe.config File

All configuration options for back pressure are available in the EdgeTransport.exe.config application configuration file. For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File.

Caution:

These settings are listed as a reference only. We strongly discourage any modifications to the back pressure settings in the EdgeTransport.exe.config file. Modifications to the back pressure settings may result in poor performance or data loss. We recommend that you investigate and correct the root cause of any back pressure events that you may encounter.

Back pressure configuration options

Parameter name	Default value
EnableResourceMonitoring	TRUE
ResourceMonitoringInterval	00:00:02
PercentageDatabaseDiskSpaceUsedHighThreshold	0. This value indicates that the default formula will be used.
PercentageDatabaseDiskSpaceUsedMediumThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentageDatabaseDiskSpaceUsedHighThreshold*.
PercentageDatabaseDiskSpaceUsedNormalThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentageDatabaseDiskSpaceUsedMediumThreshold*.
PercentageDatabaseLoggingDiskSpaceUsedHighThreshold	0. This value indicates that the default formula will be used.

PercentageDatabaseLoggingDiskSpaceUsedMediumThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentageDatabaseLoggingDiskSpaceUsedHighThreshold*.
PercentageDatabaseLoggingDiskSpaceUsedNormalThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentageDatabaseLoggingDiskSpaceUsedMediumThreshold*.
PercentagePrivateBytesUsedHighThreshold	0. This value indicates that the default calculation will be used.
PercentagePrivateBytesUsedMediumThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentagePrivateBytesUsedHighThreshold*.
PercentagePrivateBytesUsedNormalThreshold	0. This value indicates that the actual value is 2 percent less than the value of *PercentagePrivateBytesUsedMediumThreshold*.
VersionBucketsHighThreshold	200
VersionBucketsMediumThreshold	120
VersionBucketsNormalThreshold	80
VersionBucketsHistoryDepth	10
BatchPointHighThreshold	4000
BatchPointMediumThreshold	2000
BatchPointNormalThreshold	1000
BatchPointHistoryDepth	300
BatchPointUseCostForPressure	TRUE
BatchPointBatchSize	40
BatchPointBatchTimeout	00:00:00.100
BatchPointItemExpiryInterval	00:05:00
SMTPBaseThrottlingDelayInterval	00:00:00
SMTPMaxThrottlingDelayInterval	00:00:55
SMTPStepThrottlingDelayInterval	00:00:05
SMTPStartThrottlingDelayInterval	00:00:10
PercentagePhysicalMemoryUsedLimit	94
DehydrateMessagesUnderMemoryPressure	TRUE
PrivateBytesHistoryDepth	30

Back Pressure Logging Information

The following list describes the event log entries that are generated by specific back pressure events in Exchange 2010:

- **Event log entry for an increase in any resource utilization level**
  Event Type: Error
  Event Source: MSExchangeTransport
  Event Category: Resource Manager
  Event ID: 15004
  Description: Resource pressure increased from *Previous Utilization Level* to *Current Utilization Level*.
- **Event log entry for a decrease in any resource utilization level**
  Event Type: Information
  Event Source: MSExchangeTransport
  Event Category: Resource Manager
  Event ID: 15005
  Description: Resource pressure decreased from *Previous Utilization Level* to *Current Utilization Level*.
- **Event log entry for critically low available disk space**
  Event Type: Error
  Event Source: MSExchangeTransport
  Event Category: Resource Manager
  Event ID: 15006
  Description: The Microsoft Exchange Transport service is rejecting messages because available disk space is below the configured threshold. Administrative action may be required to free disk space for the service to continue operations.
- **Event log entry for critically low available memory**
  Event Type: Error
  Event Source: MSExchangeTransport
  Event Category: Resource Manager
  Event ID: 15007
  Description: The Microsoft Exchange Transport service is rejecting message submissions because the service continues to consume more memory than the configured threshold. This may require that this service be restarted to continue normal operation.

1.7.1.8 Understanding Content Conversion

Understanding Content Conversion

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-07*

Content conversion is the process of correctly formatting a message for each recipient. The decision to perform content conversion on a message depends on the destination and format of the message being processed. Messages sent to recipients inside the Microsoft Exchange Server organization don't require any content conversion. Only messages sent to external recipients may require content conversion.

In an Exchange Server 2010 organization, content conversion is handled by the categorizer on a server that has the Hub Transport server role installed. Categorization on each message happens after a newly arrived message is put in the Submission queue. In addition to recipient resolution and routing resolution, content conversion is performed on the message before the message is put in a delivery queue. If a single message

contains multiple recipients, content conversion determines the appropriate encoding for each message recipient. On an Edge Transport server, an abbreviated categorization occurs, which doesn't involve content conversion.

Contents

Looking for management tasks related to content conversion? See Managing Transport Servers.

Understanding the Structure of E-mail Messages

To better understand content conversion, you must understand the structure of e-mail messages. An SMTP message is based on plain 7-bit US-ASCII text to compose and send e-mail messages. A standard SMTP message consists of the following elements:

- **Message envelope** The message envelope is defined in RFC 2821. The message envelope contains information required to transmit and deliver the message. Recipients never see the message envelope, because it's generated by the message transmission process and isn't actually part of the message contents.
- **Message contents** The message contents are defined in RFC 2822. The message contents consist of the following elements:
  - **Message header** The message header is a collection of header fields. Header fields consist of a field name, followed by a colon (:) character, followed by a field body, and ended by a carriage return/line feed (CR/LF) character combination.

    A field name must be composed of printable US-ASCII text characters except the colon (:) character. Specifically, ASCII characters that have values from 33 through 57 and 59 through 126 are permitted.

    A field body may be composed of any US-ASCII characters, except for the carriage return (CR) character and the line feed (LF) character. However, a field body may contain the CR/LF character combination when used in *header folding*. Header folding is the separation of a single header field body into multiple lines as described in section 2.2.3 of RFC 2822. Other field body syntax requirements are described in sections 3 and 4 of RFC 2822.
  - **Message body** The message body is a collection of lines of US-ASCII text characters that appears after the message header. The message header and the message body are separated by a blank line that ends with the CR/LF character combination. The message body is optional. Any line of text in the message body must be less than 998 characters. The CR and LF characters can only appear together to indicate the end of a line.

When SMTP messages contain elements that aren't plain US-ASCII text, the message must be encoded to preserve those elements. The MIME standard defines a method of encoding content in messages that isn't text. MIME allows for text in other character sets, attachments without text, multipart message bodies, and header fields in other character

sets. MIME is defined in RFC 2045, RFC 2046, RFC 2047, RFC 2048, and RFC 2077. MIME defines a collection of header fields that specifies additional message attributes. The following table describes some important MIME header fields.

Important MIME header fields

Header field name	Default value	Description
MIME-Version	1.0	This header field is the first MIME header field that appears in a MIME-formatted message. This header field appears after the other standard RFC 2822 header fields, but before any other MIME header fields. MIME-aware e-mail clients use this header field to identify a MIME-encoded message. When this header field is absent, MIME-aware e-mail clients identify the message as plain text.
Content-Type	text/plain	This header field identifies the media type of the message content as described in RFC 2046. A media type consists of a type, a subtype, and one or more optional parameters, such as a *charset*= parameter that defines the MIME character encoding. Types that begin with "x-" aren't standard. Subtypes that begin with "vnd." are vendor-specific. The Internet Assigned Numbers Authority (IANA) maintains a list of registered media types. For more information, see MIME Media Types. The *multipart* media type allows for multiple message parts in the same message by using sections defined by different media types. Some Content-Type field values include text/plain, text/html, multipart/mixed, and multipart/alternative.
Content-Transfer-Encoding	7bit	This header field can describe the following information about a message: • The encoding algorithm used to transform any non-US-ASCII text or binary data that exists in the message body. • An indicator that describes the current condition of the message body. There can be multiple values of the Content-Transfer-Encoding header field in a MIME message. When the Content-Transfer-Encoding header field appears in the message header, it applies to the whole body of the message. When the Content-Transfer-Encoding header field appears in one of the parts of a

		multipart message, it applies only to that part of the message. When an encoding algorithm is applied to the message body data, the message body data is transformed into plain US-ASCII text. This transformation allows the message to travel through older SMTP messaging servers that only support messages in US-ASCII text. The values of the Content-Transfer-Encoding header field that indicate an encoding algorithm was used on the message body are as follows: • **Quoted-printable** This encoding algorithm uses printable US-ASCII characters to encode the message body data. If the original message text is mostly US-ASCII text, Quoted-printable encoding gives somewhat readable and compact results. All printable US-ASCII text characters except the equal sign (=) character can be represented without encoding. • **Base64** This encoding algorithm is based primarily on the privacy-enhanced mail (PEM) standard defined in RFC 1421. Base64 encoding uses the 64-character alphabet encoding algorithm and output padding characters defined by PEM to encode the message body data. A Base64 encoded message is typically 33 percent larger than the original message. Base64 encoding creates a predictable increase in message size and is optimal for binary data and non-US-ASCII text. Typically, you won't see multiple encoding algorithms used in the same message. When no encoding algorithm has been used on the message body, the Content-Transfer-Encoding header field merely identifies the current condition of the message body data. The

		following values of the Content-Transfer-Encoding header field indicate that no encoding algorithms were used on the message body:
		• **7bit** This value indicates that the message body data is already in the RFC 2822 format. Specifically, this means that the following conditions must be true:
		  • All lines of text must be less than 998 characters long.
		  • All characters must be US-ASCII text that have character values from 1 through 127.
		  • The CR and LF characters can only be used together to indicate the end of a line of text.
		The whole message body may be 7bit, or part of the message body in a multipart message may be 7bit. If the multipart message contains other parts that have any binary data or non-US-ASCII text, that part of the message must be encoded using the Quoted-printable or Base64 encoding algorithms.
		Messages that have 7bit bodies can travel between SMTP messaging servers by using the standard DATA command.
		• **8bit** This value indicates that the message body data contains non-US-ASCII characters. Specifically, this means that the following conditions must be true:
		  • All lines of text must be less than 998 characters long.
		  • One or more characters in the message body have values larger than 127.
		  • The CR and LF characters can only be used together to indicate the end of a line of text.
		The whole message body may be 8bit, or part of the message body in a multipart message may be 8bit. If the

		multipart message contains other parts that have binary data, that part of the message must be encoded using the Quoted-printable or Base64 encoding algorithms. Messages that have 8bit bodies can only travel between SMTP messaging servers that support the 8BITMIME SMTP extension as defined in RFC 1652, such as servers running Exchange 2010, Exchange Server 2007, Exchange Server 2003, or Exchange 2000 Server. Specifically, this means that the following conditions must be true: • The 8BITMIME keyword must be advertised in the server's EHLO response. • Messages are still transferred by using the SMTP standard DATA command. However, the BODY=8BITMIME parameter must be added to the end of the MAIL FROM command. • **Binary** This value indicates that the message body contains non-US-ASCII text or binary data. Specifically, this means that the following conditions are true: • Any sequence of characters is allowed. • There is no line length limitation. • Binary message elements don't require encoding. Messages that have Binary bodies can only travel between SMTP messaging servers that support the BINARYMIME SMTP extension as defined in RFC 3030, such as servers running Exchange 2010, Exchange 2007, Exchange 2003, or Exchange 2000. Specifically, this means that the following conditions must be true: • The BINARYMIME keyword

		must be advertised in the server's EHLO response. • The BINARYMIME SMTP extension can only be used with the CHUNKING SMTP extension. *Chunking* enables large message bodies to be sent in multiple, smaller chunks. Chunking is also defined in RFC 3030. The CHUNKING keyword must also be advertised in the server's EHLO response. • Messages are transferred using the BDAT command instead of the standard DATA command. • The *BODY=BINARYMIME* parameter must be added to the end of the MAIL FROM command when the message has a message body. The values 7bit, 8bit, and Binary never exist together in the same multipart message. The values are mutually exclusive. The Quoted-printable or Base64 values may appear in a 7bit or 8bit multipart message body, but never in a Binary message body. If a multipart message body contains different parts composed of 7bit and 8bit content, the whole message is classified as 8bit. If a multipart message body contains different parts composed of 7bit, 8bit, and Binary content, the whole message is classified as Binary.
Content-Disposition	Attachment	This header field instructs a MIME-enabled e-mail client on how it should display an attached file, and is described in RFC 2183. The values of this field may be Inline or Attachment. When the value of this field is Inline, the attachment is displayed in the message body. When the value of this field is Attachment, the attached file appears as a regular attachment separate from the message body. Other parameters are available when the value is Attachment, such as Filename, Creation-date, and Size.

Exchange 2010 and Outlook Message

Formats

The following list describes the basic message formats available in Exchange 2010 and Microsoft Outlook:

- **Plain text** A plain text message uses only US-ASCII text as described in RFC 2822. The message can't contain different fonts or other text formatting. The following two formats can be used for a plain text message:
  - The message headers and the message body are composed of US-ASCII text. Attachments must be encoded by using *Uuencode*. Uuencode represents Unix-to-Unix encoding and defines an encoding algorithm to store binary attachments in the body of an e-mail message by using US-ASCII text characters.
  - The message is MIME-encoded with a Content-Type value of text/plain, and a Content-Transfer-Encoding value of 7bit for the text parts of a multipart message. Any message attachments are encoded by using Quoted-printable or Base64 encoding. By default, when you compose and send a plain text message in Outlook, the message is MIME-encoded with a Content-Type value of text/plain.
- **HTML** An HTML message supports text formatting, background images, tables, bullet points, and other graphical elements. By definition, an HTML-formatted message must be MIME-encoded to preserve these formatting elements.
- **Rich text format (RTF)** RTF supports text formatting and other graphical elements. RTF is synonymous with the Transport Neutral Encapsulation Format (TNEF). TNEF and RTF can be used interchangeably.
  Only Outlook and a few other MAPI e-mail clients understand RTF messages. MAPI is a Microsoft-developed messaging architecture that enables multiple applications to interact with different messaging systems across a variety of hardware platforms. MAPI is built on the Component Object Model (COM) architecture. Outlook uses MAPI to communicate with mailboxes on a computer running Exchange 2010 that has the Mailbox server role installed.
  The rich text message format is completely different from the rich text document format available in Microsoft Word.
- **TNEF** TNEF is a Microsoft-specific format for encapsulating MAPI message properties. A TNEF message contains a plain text version of the message and an attachment that packages the original formatted version of the message. Typically, this attachment is named Winmail.dat. The Winmail.dat attachment includes the following information:
  - Original formatted version of the message, including, for example, fonts, text sizes, and text colors
  - OLE objects, including, for example, embedded pictures or embedded Microsoft Office documents
  - Special Outlook features, including, for example, custom forms, voting buttons, or meeting requests
  - Regular message attachments that were in the original message

  The resulting plain text message can be represented in the following formats:
  - RFC 2822-compliant message composed of only US-ASCII text with a Winmail.dat attachment encoded in Uuencode
  - Multipart MIME-encoded message that has a Winmail.dat attachment

  A MAPI-compliant e-mail client that fully understands TNEF, such as Outlook, processes the Winmail.dat attachment and displays the original message content without ever displaying the Winmail.dat attachment. An e-mail client that doesn't understand TNEF may present a TNEF message in any of the following ways:
  - The plain text version of the message is displayed, and the message contains an attachment named Winmail.dat, Win.dat, or some other generic name such as Att*nnnnn*.dat or Att*nnnnn*.eml where the *nnnnn* placeholder represents a random number.

- The plain text version of the message is displayed. The TNEF attachment is ignored or removed. The result is a plain text message.
- Messaging servers that understand TNEF can be configured to remove TNEF attachments from incoming messages. The result is a plain text message. Moreover, some e-mail clients such as Microsoft Outlook Express may not understand TNEF, but recognize and ignore TNEF attachments. The result is a plain text message.

There are third-party utilities that can help convert Winmail.dat attachments. TNEF is understood by Exchange 2010, Exchange 2007, Exchange 2003, Exchange 2000, and Exchange Server version 5.5. TNEF messages are transferred between SMTP messaging servers by using the standard DATA command verb. TNEF is automatically used by Exchange based on the following situations:

- **Exchange 2003** If the Exchange organization is in mixed mode, TNEF is used for messages transferred between Exchange servers in different routing groups.
- **Exchange 2000** TNEF is used for messages transferred between Exchange servers in different routing groups.

- **Summary Transport Neutral Encapsulation Format (STNEF)** STNEF is equivalent to TNEF. However, STNEF messages are encoded differently than TNEF messages. Specifically, STNEF messages are always MIME-encoded and always have a Content-Transfer-Encoding value of Binary. Therefore, there's no plain text representation of the message, and there's no distinct Winmail.dat attachment contained in the body of the message. The whole message is represented by using only binary data. Messages that have a Content-Transfer-Encoding value of Binary can only be transferred between SMTP messaging servers that support and advertise the BINARYMIME and CHUNKING SMTP extensions as defined in RFC 3030. The messages are always transferred between SMTP messaging by using the BDAT command, instead of the standard DATA command.
  STNEF is understood by Exchange 2010, Exchange 2007, Exchange 2003, and Exchange 2000. STNEF is automatically used by Exchange if the following conditions are true:
  - **Exchange 2010** STNEF is used for all messages transferred between Exchange servers in the organization.
  - **Exchange 2007** STNEF is used for all messages transferred between Exchange servers in the organization.
  - **Exchange 2003** If the Exchange organization is in native mode, STNEF is used for all messages transferred between Exchange servers in the organization.
  - **Exchange 2000** STNEF is used for messages transferred between Exchange servers in the same routing group. An unsupported hotfix also enables Exchange 2000 to use STNEF for messages transferred between Exchange servers in different routing groups.

  Exchange never sends STNEF messages to external recipients. Only TNEF messages can be sent to recipients outside the Exchange organization.

Elements of Content Conversion

Content conversion is the act of correctly formatting a message for each external recipient. This conversion is performed by the categorizer on a Hub Transport server.

The content conversion options that you can set in an Exchange organization can be described in the following categories:

- **TNEF conversion options** These conversion options specify whether TNEF should be preserved or removed from messages that leave the Exchange organization.
- **Message encoding options** These options specify message encoding options, such as MIME and non-MIME character sets, message encoding, and

attachment formats.

These conversion and encoding options are independent of one another. For example, whether TNEF messages can leave the Exchange organization isn't related to the MIME encoding settings or plain text encoding settings of those messages.

You can specify the content conversion at various levels of the Exchange organization as described in the following list:

- **Remote domain settings** Remote domains define the settings for outgoing message transfers between the Exchange 2010 organization and domains outside the Active Directory forest. Even if you don't create remote domain entries for specific domains, there's a predefined remote domain named Default that applies to all remote address spaces (*).
- **Mail user and mail contact settings** Mail users resemble mail contacts—both have external e-mail addresses and contain information about people outside the Exchange organization. The main difference is mail users have security contexts that can be used to log on to the Active Directory domain and access resources to which they have been granted permission.
- **Outlook settings** In Outlook, you can set the message formatting and encoding options described in the following list:
  - **Message format** You can set the default message format for all messages. You can override the default message format as you compose a specific message.
  - **Internet message format** You can control whether TNEF messages are sent to remote recipients or whether they are first converted to a more compatible format. You can also specify various message encoding options for messages sent to remote recipients. These settings don't apply to messages sent to recipients in the Exchange organization.
  - **Internet recipient message format** You can control whether TNEF messages are sent to specific recipients or whether they are first converted to a more compatible format. You can set the conversion options for specific contacts in your Contacts folder, and you can override the conversion options for a specific recipient in the To, Cc, or Bcc fields as you compose a message. These conversion options aren't available for recipients in the Exchange organization.
  - **Internet recipient message encoding options** You can control the MIME or plain text encoding options for specific contacts in your Contacts folder, and you can override the conversion options for a specific recipient in the To, Cc, or Bcc fields as you compose a message. These conversion options aren't available for recipients in the Exchange organization.
  - **International options** You can control the character sets used in messages.

TNEF Conversion Options

You can specify the TNEF conversion options at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Outlook settings, including:
  - Message format
  - Internet message format
  - Internet recipient message format

For detailed information, see TNEF Conversion Options.

Message Encoding Options

You can specify the message options at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Outlook settings, including:

- Message format
- Internet message
- Internet recipient message format
- Message character set encoding options

For detailed information, see Message Encoding Options.

Content Conversion Performed by the Store Driver

The store driver also performs content conversion. The store driver exists on Hub Transport servers to transport messages between mailboxes on Mailbox servers and the Submission queue. Specifically, the store driver transports messages from the sender's Outbox to the Submission queue on the Hub Transport server, and the store driver transports the messages from the Submission queue on the Hub Transport server to the recipient's Inbox. The store driver converts all outgoing messages from MAPI and converts all incoming messages to MAPI. Content conversion tracing captures these store driver conversion failures.

For more information, see Content Conversion Tracing.

1.7.1.8.1 TNEF Conversion Options

TNEF Conversion Options

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The content conversion options that you can set in an Exchange organization can be described in the following categories:

- **TNEF conversion options** These conversion options specify whether Transport Neutral Encapsulation Format (TNEF) should be preserved or removed from messages that leave the Exchange organization.
- **Message encoding options** These options, such as MIME and non-MIME character sets, specify message encoding and attachment formats.

This topic describes the TNEF conversion options that you can specify at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Microsoft Outlook settings
  - Message format
  - Internet message format
  - Internet recipient message format

TNEF Conversion Options for Messages Sent to Remote Domains

When you configure TNEF conversion options for a remote domain, those TNEF conversion options are applied to all messages sent to that domain. For remote domains in your organization, you have the following configuration options for TNEF conversion:

- **TNEF use enabled** TNEF is used for all messages sent to the remote domain.
- **TNEF use disabled** TNEF is never used for any messages sent to the remote domain.
- **Unspecified** TNEF messages aren't specifically allowed or prevented for recipients in the remote domain. Whether TNEF messages are sent to recipients in the remote domain depends on the specific setting on the mail contact or mail user, or the setting specified by the sender in Outlook. This is the default setting.

In Microsoft Exchange 2010, you can set the TNEF conversion options for messages sent to a remote domain in the Exchange Management Shell or on the **Remote Domains** tab in the Exchange Management Console (EMC). For more information about configuring TNEF options for a remote domain, see the following topics:

- Configure Remote Domain Properties
- Set-RemoteDomain

TNEF Conversion Options for Messages Sent to Mail Users and Mail Contacts

When you configure TNEF conversion options for a mail contact or a mail user, those TNEF conversion options are applied to all messages sent to that specific recipient. For mail contacts and mail users in your organization, you have the following configuration options for TNEF conversion:

- **Always** TNEF is used for all messages sent to the recipient.
- **Never** TNEF is never used for any messages sent to the recipient.
- **Use default settings** TNEF messages aren't specifically allowed or prevented for the mail user or mail contact. Whether TNEF messages are sent to the recipient depends on the specific setting for the corresponding remote domain or the setting specified by the sender in Outlook. This is the default setting.

Note:

In both the EMC and the Shell, the TNEF conversion settings are referred to as **MAPI rich text format**.

You can set the TNEF conversion options for messages sent to mail users and mail contacts in the Shell or in the **Recipient Configuration** node in the EMC. For more information about configuring TNEF options for these recipient types, see the following topics:

- Configure Mail Contact Properties
- Configure Mail User Properties
- Set-MailContact
- Set-MailUser

TNEF Conversion Options for Messages Available in Outlook

Senders can control the default TNEF message conversion options for TNEF messages sent to all recipients outside the Exchange organization. These options are called *Internet message format* options. The options only apply to remote recipients, and not to recipients in the Exchange organization.

Note:

The following options define how messages containing Outlook rich text are handled when sent to external recipients. If the message format you're using is HTML or plain text, these settings don’t apply.

You have the following TNEF conversion options in Outlook:

- **Convert to HTML format** This is the default option. Any TNEF messages sent to remote recipients are converted to HTML. Any formatting in the message should closely resemble the original message. MIME-encoded HTML messages are supported by many, but not all, e-mail clients.
- **Convert to Plain Text format** Any TNEF messages sent to remote recipients are converted to plain text. Any formatting in the message is lost.
- **Send using Outlook Rich Text Format** Any TNEF messages sent to remote recipients remain TNEF messages.

These options can be configured in Outlook by navigating to **Tools > Options > Mail Format**, and then clicking **Internet Format**.

Senders can also control the default TNEF message conversion options for TNEF messages sent to specific recipients outside the Exchange organization. These options are called *Internet recipient message format* options. The options only apply to remote recipients stored in your Contacts folder, and not to recipients in the Exchange organization. You have the following TNEF conversion options for remote recipients in your Contacts folder:

- **Let Outlook decide the best sending format** This is the default setting. This setting forces Outlook to use the TNEF conversion option that's specified by the default Internet format. The possible values are **Convert to HTML format**, **Convert to Plain Text format**, or **Send using Outlook Rich Text Format**. Therefore, the TNEF message may be left as TNEF, converted to HTML, or converted to plain text. If you want to make sure that the TNEF message remains TNEF for this recipient, you should change this setting from **Let Outlook decide the best sending forma**t to **Send using Outlook Rich Text format**.
- **Send Plain Text only** Any TNEF messages sent to the recipient are converted to plain text. Any formatting in the message is lost.
- **Send using Outlook Rich Text format** Any TNEF messages sent to remote recipients remain TNEF messages.

These options can be configured for a contact in Outlook by opening that contact and then double-clicking the **E-mail** field and selecting **Internet format**.

Order of Precedence for TNEF Conversion Options

Exchange 2010 uses the order of precedence as described in the following list to determine the TNEF conversion options for outgoing messages sent to recipients outside the Exchange organization:

1. Outlook settings
2. Mail user or mail contact settings
3. Remote domain settings

The list specifies the order of precedence from lowest to highest. A setting made at a higher level overrides a setting made at a lower level.

Exchange never sends Summary Transport Neutral Encoding Format (STNEF) messages to external recipients. Only TNEF messages can be sent to recipients outside the Exchange organization.

1.7.1.8.2 Message Encoding Options

Message Encoding Options

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The content conversion options that you can set in an Exchange organization can be described in the following categories:

- **TNEF conversion options** These conversion options specify whether Transport Neutral Encapsulation Format (TNEF) should be preserved or removed from messages that leave the Exchange organization.
- **Message encoding options** These options specify message encoding options, such as MIME and non-MIME character sets, message encoding, and attachment formats.

This topic describes message encoding options that you can specify at the following levels:

- Remote domain settings
- Mail user and mail contact settings
- Microsoft Outlook settings
  - Message format
  - Internet message format
  - Internet recipient message format
  - Message character set encoding options

Message Encoding Options for Messages Sent to Remote Domains

When you configure message encoding options for a remote domain, the specific settings are applied for all messages sent to that domain. For remote domains in your organization, you have the following configuration options for message encoding:

- **Content type** You can specify the content type for MIME messages sent to the recipients in the remote domain. You can use of the following settings:
  - **MimeHtmlText** All messages are converted to MIME messages that use HTML formatting, unless the original message is a text message. If the original message is a text message, the outgoing message will be a MIME message that uses text formatting. This is the default setting.
  - **MimeText** All messages are converted to MIME messages that use text formatting.
  - **MimeHtml** All messages are converted to MIME messages that use HTML formatting.

  Note:
  You can only configure this setting using the Exchange Management Shell.
- **Line wrap size** You can specify the maximum number of characters that can exist on a single line of text in the body of the e-mail message. Older e-mail client applications may prefer 78 characters per line.
- **MIME character set** The character set that you specify will only be used for MIME messages that don't have their own character set specified. Setting this parameter won't overwrite character sets that are already specified in the outgoing mail. For a list of valid character set names, see Supported Character Sets for Remote Domain Configuration.
- **Non-MIME character set** This parameter is used if either of the following conditions are true:

- Incoming messages from a remote domain are missing the value of the *charset*= parameter in the MIME Content-Type: header field.
- Outgoing messages to a remote domain are missing the value of the MIME character set.

For a list of valid character set names, see Supported Character Sets for Remote Domain Configuration.

In Microsoft Exchange Server 2010, you can set the message encoding options for recipients in remote domains in the Shell or on the **Remote Domains** tab in the Exchange Management Console (EMC). For more information, see the following topics:

- Configure Remote Domain Properties
- Set-RemoteDomain

Message Encoding Options for Mail Users and Mail Contacts

When you configure message encoding options for a mail contact or a mail user, that option is applied to all messages sent to that specific recipient. For mail contacts and mail users in your organization, you have the following configuration options for message encoding:

- **UsePreferMessageFormat** This parameter specifies whether the message format settings configured for the mail contact override the global settings configured for the remote domain. If you disable this setting, Exchange ignores other message encoding options for this recipient and the message encoding is determined by the configuration of the remote domain or the settings configured by the message sender.
- **MessageFormat** This parameter specifies the message format. You can either specify Text or Mime as the message format. The value of this setting is dependent on the *MessageBodyFormat* parameter. If the message body format is Html or TextAndHtml, you must set this parameter to Mime.
- **MessageBodyFormat** This parameter specifies the message body format. You can specify Text, Html, or TextAndHtml. The value of this setting is dependent on the *MessageFormat* parameter. If the message format is Text, you must also set this parameter to Text.
- **MacAttachmentFormat** This parameter specifies the Apple Macintosh operating system attachment format for messages. You can specify BinHex, UuEncode, AppleSingle, or AppleDouble. The value of this setting is dependent on the *MessageFormat* parameter. If the message format is set to Text, you must set this parameter to either BinHex or UuEncode. If the message format is set to Mime, you must set this parameter to BinHex, AppleSingle or AppleDouble.

You must use the Shell to set the message encoding options for mail users and mail contacts. For more information, see the following topics:

- Enable-MailContact
- New-MailContact
- Set-MailContact
- Enable-MailUser
- New-MailUser
- Set-MailUser

Message Encoding Options Available in Outlook

As a sender, you can specify message encoding options in Outlook at any of the following stages:

- By configuring the default message format to be either plain text or HTML.
- By setting the message format as you're composing it to either plain text or HTML using the **Format** area in the **Options** tab.
- By configuring the message encoding options for messages that are sent to all recipients outside the Exchange organization. These options are called *Internet message format* options. The options only apply to remote recipients, and not to recipients in the Exchange organization. These options can be configured in Outlook by navigating to the **Tools > Options > Mail Format**, and clicking **Internet Format**.
- By configuring the message encoding options for messages that are sent to specific recipients outside the Exchange organization. These options are called *Internet recipient message format* options. The options only apply to remote recipients in your Contacts folder, and not to recipients in the Exchange organization. These options can be configured for a contact in Outlook by opening that contact and then double-clicking the **E-mail** field and selecting **Send Options**.

By default, Outlook uses automatic character set message encoding by scanning the whole text of the outgoing message to determine the appropriate encoding to use for the message. This setting applies to messages that you send to Internet recipients and recipients in the Exchange organization. However, you can bypass this and specify a preferred encoding for outgoing messages. These options can be configured in Outlook by navigating to **Tools > Options > Mail Format**, and clicking **International Options.**

Order of Precedence for Message Encoding Options

Exchange 2010 uses the order of precedence as described in the following list to determine the message encoding options for outgoing messages sent to recipients outside the Exchange organization:

1. Remote domain settings
2. Outlook settings
3. Mail user or mail contact settings

The list specifies the order of precedence from lowest to highest. A setting made at a higher level may override a setting made at a lower level.

The following table describes the order of precedence from lowest priority to highest priority for message character set encoding options.

Order of precedence from lowest priority to highest priority for message character set encoding options

Source	Parameter	Values
Set-RemoteDomain	*CharacterSet*	Specified
Set-RemoteDomain	*NonMimeCharacterSet*	Specified
Outlook setting	Message character set encoding	• Auto-select • Specified

The value of the *NonMimeCharacterSet* parameter from the **Set-RemoteDomain** cmdlet is used to assign a character set to the following types of messages:

- Outgoing messages to a configured remote domain that don't contain a specified character set
- Incoming messages from a configured remote domain that don't contain a specified character set

The value of the Windows ANSI code page for the Hub Transport server is used to assign a character set to the following types of messages:

- Internal messages that don't contain a specified character set
- Internal messages that contain a specified character set, but don't contain a specified server code page

If a message contains a specified but invalid character set, the Hub Transport server tries to replace the invalid character set with a valid character set.

The following table describes the order of precedence from lowest priority to highest priority for plain text message encoding options.

Order of precedence from lowest priority to highest priority for plain text message encoding options

Source	Parameter	Values
Set-RemoteDomain	*LineWrapSize*	• From 0 through 132 • unlimited
Outlook settings	Message format	Plain text
Outlook settings	Internet message format	Plain text options: • Encode attachments in UuEncode format when you send a plain text message • Automatically wrap text at *nn* characters
Outlook settings	Internet recipient message format	Plain text format: • Encode attachments in UuEncode attachment format • Use BinHex Mac attachment format
Set-MailUser **Set-MailContact**	*UsePreferMessageFormat*	• `$true` • `$false` If the value is `$false` or if the recipient isn't defined as a mail user or mail contact in the Exchange organization, the mail user or mail contact settings are ignored.
Set-MailUser **Set-MailContact**	*MessageFormat*	Text
Set-MailUser **Set-MailContact**	*MessageBodyFormat*	Text
Set-MailUser **Set-MailContact**	*MacAttachmentFormat*	• BinHex • UuEncode

The following table describes the order of precedence from lowest priority to highest priority for MIME message encoding options.

Order of precedence from lowest priority to highest priority for MIME

message encoding options

Source	Parameter	Values
Set-RemoteDomain	*ContentType*	• `MimeHtmlText` • `MimeText` • `MimeHtml`
Outlook settings	Message format	• Plain text • HTML
Outlook settings	Internet recipient message format	MIME message format • Plain text • Include both plain text and HTML • HTML

Set-MailUser
 	
Set-MailContact
	UsePreferMessageFormat	`$true`
		
		`$false`
		
		If the value is `$false` or if the recipient isn't defined as a mail user or mail contact in the Exchange organization, the mail user or mail contact settings are ignored.

Set-MailUser **Set-MailContact**	*MessageFormat*	• Text • Mime
Set-MailUser **Set-MailContact**	*MessageBodyFormat*	• `Text` • `Html` • `TextAndHtml`
Set-MailUser **Set-MailContact**	*MacAttachmentFormat*	• BinHex • AppleSingle • AppleDouble

1.7.1.8.3 Content Conversion Tracing

Content Conversion Tracing

Transport > Understanding Transport > Understanding Content Conversion >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-06*

Content conversion tracing captures failures in the content conversion that's performed by the store driver on inbound and outbound messages on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role installed.

The categorizer on a Hub Transport server is responsible for the content conversion of all messages sent to external recipients. However, the store driver on a Hub Transport server is responsible for the content conversion of messages sent to and from mailbox recipients. Specifically, the store driver must convert outbound messages from mailbox users from MAPI to MIME. The store driver must also convert inbound messages for mailbox users from MIME to MAPI. Content conversion tracing is responsible for capturing these MAPI conversion failures. Content conversion tracing doesn't capture any content conversion failures that the categorizer encounters as it converts messages sent to

external recipients.

Contents

Configuring Content Conversion Tracing

Content conversion tracing is controlled by the following parameters in the **Set-TransportServer** cmdlet in the Exchange Management Shell:

- *ContentConversionTracingEnabled* This parameter enables or disables content conversion. Valid values for this parameter are `$True` and `$False`. The default value is `$False`. If the Exchange organization contains multiple Hub Transport servers, you must enable content conversion tracing on each Hub Transport server responsible for delivery of messages to Mailbox servers.
- *PipelineTracingPath* Although this parameter is associated with pipeline tracing, it also specifies the root location of the content conversion tracing files. By default, the value of the *PipelineTracingPath* parameter is C:\Program Files\Microsoft\Exchange Server\TransportRoles\Logs\PipelineTracing. The path must be local to the Exchange 2010 computer.

Content conversion creates a folder named ContentConversionTracing inside the path specified by the *PipelineTracingPath* parameter. Inside the ContentConversionTracing folder, content conversion creates two subfolders: InboundFailures and OutboundFailures. The InboundFailures folder contains the information from inbound message content conversion failures. The OutboundFailures folder contains the information from outbound message content conversion failures.

The maximum size for all the files in the InboundFailures folder is 128 megabytes (MB). The maximum size for all the files in the OutboundFailures folder is 128 MB. The content conversion tracing directories don't use circular logging to remove old files, depending on the age or size of the files. As soon as the maximum size for a folder is reached, content conversion tracing stops writing information to the folder. If you want to make sure that the maximum folder size limits aren't exceeded, you can create a scheduled task that periodically moves the content conversion tracing files to a different location.

The permissions required on the folders and subfolders used in content conversion tracing are as follows:

- Administrators: Full Control
- Network Service: Full Control
- System: Full Control

Caution:

Content conversion tracing copies the complete contents of e-mail messages. To avoid unwanted exposure of confidential information, you must set appropriate security permissions on the location of the content conversion tracing files.

Return to top

How Content Conversion Tracing Works

When the content conversion of an inbound message fails, a delivery status notification (DSN) that has the status code 5.6.0 is sent to the message sender. If content conversion tracing is enabled, the failure information is recorded at the time that the 5.6.0 DSN message is generated. Each content conversion error generates two separate files.

A content conversion error that occurs when an inbound message is converted from MIME to MAPI generates the following two files in the InboundFailures folder:

- **<GUID>.eml** This file contains the failed message in text format.
- **<GUID>.txt** This file contains the exception description, conversion results, conversion options, and message size limits imposed on all messages by the store driver.

A content conversion error that occurs when an outbound message is converted from MAPI to MIME generates the following two files in the OutboundFailures folder:

- **<GUID>.msg** This file contains the failed message in the Microsoft Outlook message format.
- **<GUID>.txt** This file contains the exception description, conversion results, conversion options, and message size limits imposed on all messages by the store driver.

The placeholder *<GUID>* is the same in both file names. Each content conversion error generates a different GUID that's used in the file names of the corresponding message and text files. An example of a GUID that's used in the file names is `038b930e-61fd-4bfd-b9b4-0374c18b73f7`.

Return to top

Considerations for Content Conversion Tracing

You can leave content conversion tracing enabled for proactive monitoring. Or, you can enable content conversion tracing to troubleshoot a specific failure event. You can usually reproduce inbound content conversion failures by asking the recipient of the 5.6.0 DSN message to resend the original message.

Inbound content conversion failures are the most common. Some of the reasons for inbound content conversion errors include the following:

- **Violations of message size limits** These message size limits are imposed by the store driver to help prevent denial of service attacks (DoS). These message limits are listed in the *<GUID>*.txt file. These message limits include the following:
  - **MaxMimeTextHeaderLength** This limit specifies the maximum number of text characters that can be used in a MIME header. The value is 2000.
  - **MaxMimeSubjectLength** This limit specifies the maximum number of text characters that can be used in the subject line. The value is 255.
  - **MSize** This limit specifies the maximum message size. The value is 2147483647 bytes.
  - **MaxMimeRecipients** This limit specifies the total number of recipients allowed in the To, Cc, and Bcc fields. The value is 12288.
  - **MaxRecipientPropertyLength** This limit specifies the maximum number of text characters that can be used in a recipient description. The value is 1000.
  - **MaxBodyPartsTotal** This limit specifies the maximum number of message parts that can be used in a MIME multipart message. The value is 250.
  - **MaxEmbeddedMessageDepth** This limit specifies the maximum number of forwarded messages that can exist in a message. The value is 30.

  For more information about configurable message size limits used in Hub

Transport servers or Edge Transport servers, see Understanding Message Size Limits.

- **Failure to convert an inbound iCalendar message to a meeting request** RFC 2445 defines iCalendar as a standard for calendar data exchange. Specific causes of the conversion failure include the following:
  - Incorrect use of iCalendar by the sending agent.
  - Constructs of iCalendar that can't be supported by the Outlook or Exchange calendar schema.

  Conversion failures of iCalendar don't result in the sender receiving a 5.6.0 DSN message. Instead, the message is delivered with an attached .ics file that contains the iCalendar message body.
- **Failures caused by badly formatted MIME messages** Unsolicited commercial e-mail or spam messages may have formatting errors in the message header, such as unmatched quotation marks in recipient descriptions. A much smaller number of failures caused by badly formatted MIME messages are considered bugs.

Outbound content conversion failures are much less common than inbound failures. When outbound failures occur, they are usually caused by Exchange code bugs or corrupted message content.

Return to top

1.7.1.9 Understanding Delivery Agents

Understanding Delivery Agents

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-17*

Delivery agents are responsible for delivering messages addressed to foreign systems that don't use the SMTP protocol. Each delivery agent works with a Delivery Agent connector. When a message is routed to a Delivery Agent connector, the associated delivery agent performs the content conversion and message delivery. Delivery agents are a significant improvement over Foreign connectors in handling non-SMTP messages in your Exchange organization.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Delivery Agents

A delivery agent is a custom agent that can:

- Establish a connection to the foreign system for message delivery.

- Retrieve messages from the remote delivery queues on Hub Transport servers.
- Deliver messages to the foreign system.
- Provide acknowledgement for each successful message delivery.

While the Foreign connector architecture remains in Microsoft Exchange Server 2010, we recommend using delivery agents for routing messages to non-SMTP systems whenever possible. Delivery agents provide the following benefits:

- They allow queue management of messages routed to foreign systems using the familiar queue management tools.
- Because the messages no longer need to be written to and read from the file system, message delivery performance is improved.
- They provide access to message properties with rich events for agent developers.
- Development time for a delivery agent is faster than implementing a Foreign connector because the delivery agent can use the message representation and management features of Exchange.
- You can now be sure that the messages are delivered to the foreign system as opposed to just being written to the Drop directory.
- The usage of Delivery Agent connectors allows service level agreement (SLA) analysis because it's now possible to track the latency of message delivery to the foreign system.

Return to top

Adding Delivery Agents to Your Organization

To use a delivery agent in your organization, you have to complete the following:

- Acquire the delivery agent. Typically, delivery agents are written by third parties. Exchange 2010 comes with only one Delivery Agent connector by default: the Text Messaging Delivery Agent connector.
- Install the delivery agent on your Hub Transport servers that will act as source servers for the Delivery Agent connectors.
- Create a Delivery Agent connector for the specific protocol.

When all of these steps are completed, messages to the foreign systems will be routed through the Delivery Agent connectors and processed by the delivery agent.

Delivery Agent Connectors

Don't confuse the Delivery Agent connectors with the actual delivery agents. Delivery Agent connectors are configured to make routing decisions. The Delivery Agent connectors handle queuing messages to be processed by the delivery agents; much like Send connectors or Routing Group connectors are used for SMTP delivery.

Delivery Agent connectors ensure that the messages destined to the foreign system are inserted into the appropriate queues on the Hub Transport servers that are used for delivering messages to the foreign systems. After the messages are queued, Connection Manager invokes the delivery agent to handle the actual delivery of the message to the foreign system.

Return to top

Events Used by Delivery Agents

Delivery agents act on the following events raised by the Connection Manager

component:

- **OnOpenConnection** This event is raised when there are messages in the queue to be delivered to the foreign system. It notifies the delivery agent to initiate a connection to the foreign system.
- **OnDeliverMailItem** This event notifies the delivery agent to retrieve the next item from the queue.
- **OnCloseConnection** This event is raised when there are no more messages in the queue to be delivered to the foreign system. It notifies the delivery agent to close the connection to the foreign system.

In a typical delivery scenario, the following interaction between Connection Manager and the delivery agent takes place:

1. Connection Manager detects messages queued for delivery to the foreign system.
2. Connection Manager invokes the delivery agent using the **OnOpenConnection** event.
3. The delivery agent establishes a connection with the foreign system. After the connection is established, it notifies Connection Manager using the **RegisterConnection** method.
4. Connection Manager raises the **OnDeliverMailItem** event.
5. The delivery agent retrieves the message from the queue and delivers it to the foreign system. After delivery is complete, it provides acknowledgement to Connection Manager.
6. If there are additional messages in the queue, steps 4 and 5 are repeated until all messages are delivered.
7. Connection Manager raises the **OnCloseConnection** event.
8. The delivery agent closes the connection with the foreign system and notifies Connection Manager using the **UnRegisterConnection** method.

Retry Situations

The following are the situations where messages or the entire Delivery Agent connector queue would end up in the Retry state:

- After Connection Manager raises the **OnOpenConnection** event, if no delivery agents respond with the **RegisterConnection** method, the entire queue for that Delivery Agent connector is put into retry.
- If the delivery agent doesn't provide an acknowledgement for a specific message, that message is put into retry.

Return to top

1.7.1.10 Understanding DSNs and NDRs

Understanding DSNs and NDRs

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-05-20*

This topic describes how to read and interpret non-delivery report (NDR) delivery status notification (DSN) messages in Microsoft Exchange Server 2010.

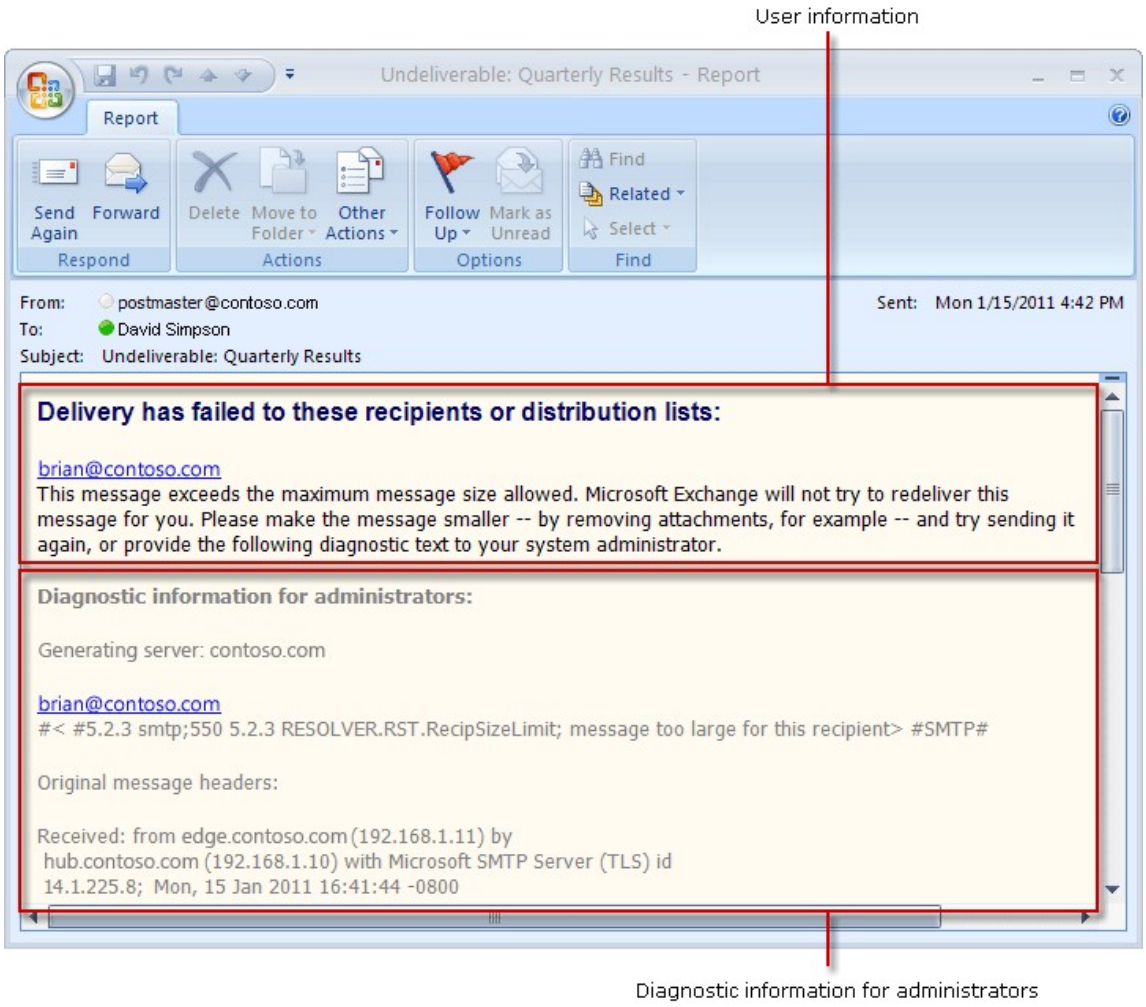
NDR Sections

In Exchange 2010, NDRs have been designed to make them easier to read and understand by both end-users and administrators. Information that is displayed in an NDR

is separated into the following two areas:

- A user information section
- A **Diagnostic information for administrators** section

The information in each section is targeted to the readers of that section. The user information section appears first and contains feedback to help the user understand in nontechnical terms why the delivery of the message failed. The **Diagnostic information for administrators** section provides deeper technical information such as the original message headers, to help e-mail administrators troubleshoot a delivery issue that may exist. The following figure shows the user information section and **Diagnostic information for administrators** section of an NDR.



User Information Section

The user information section of an NDR generated by Exchange 2010 contains information that you want to communicate to an end-user who has sent a message that is later returned with an NDR. The text that is displayed in this section is inserted by the Exchange server that generated the NDR.

The text in the user information section is designed to help the end-user determine why the message was rejected and how to resend the message successfully if the message should be resent. When applicable, the fully qualified domain name (FQDN) of the server that rejected the message is included in the user information section. If delivery fails to more than one recipient, the e-mail address of each recipient is listed and the reason for the failure is included in the space below the recipient's e-mail address.

You can modify the text in the user information section by using the **New-SystemMessage** cmdlet. By creating a custom message, you can provide specific information to end-users, such as a telephone number to use to contact the helpdesk department or a hyperlink to use to obtain self-service support. For more information about how to customize the text that is displayed in the user information section, Create a Custom DSN Message.

Diagnostic Information for Administrators

The **Diagnostic information for administrators** section contains more detailed information about the specific error that occurred during delivery of the message, the server that generated the NDR, and the server that rejected the message. The following fields are present in most NDRs and are visible in the "NDR sections" figure earlier in this topic:

- **Generating server** The generating server is the SMTP server that created the NDR. The generating server takes the enhanced status code that is explained later in this topic. This code creates an easy-to-read NDR. If no remote server is listed below the e-mail address of the sender in the **Diagnostic information for administrators** section, the generating server is also the server that rejected the original e-mail message. If message delivery fails when the message is sent to another recipient in the Exchange organization, the same server typically rejects the original message and generates the NDR.
- **Rejected recipient** The rejected recipient is the e-mail address of the recipient to which delivery of the original message failed. If delivery to more than one recipient has failed, the e-mail address for each recipient is listed. The rejected recipient field also contains the following sub-fields for each e-mail address listed:
  - **Remote server** The remote server field contains the FQDN of the server that rejects delivery of the message during the Simple Mail Transfer Protocol (SMTP) conversation. The remote server field is only populated when delivery has been attempted to a remote server, and that delivery attempt has been rejected before the receiving server successfully acknowledges the message after the message body is sent. If the original message is successfully acknowledged by the receiving server and is then rejected because of content restrictions, for example, the remote server field is not populated.
  - **Enhanced status code** The enhanced status code is the code returned by the server that rejected the original message. The enhanced status code indicates why the original message was rejected. The enhanced status code is not rewritten by Exchange 2007 but is used to determine what text to display in the user information section. The enhanced status codes you're most likely to encounter are listed in "Common Enhanced Status Codes" later in this topic. For a detailed list of enhanced status codes, see RFC 3463.
  - **SMTP response** The SMTP response is the machine readable text returned by the server that rejected the original message. The SMTP response typically contains a short string that provides an explanation of the enhanced status code that is also returned. The SMTP response is not rewritten by Exchange 2010. Additionally, this response is always presented in US-ASCII format.
- **Original message headers** The original message headers section contains the message headers of the rejected message. These headers can provide useful diagnostic information, such as information that can help you determine the path that the message took before it was rejected or whether the **To** field matches the e-mail address that is specified in the rejected recipient field.

Examples of NDR Messages

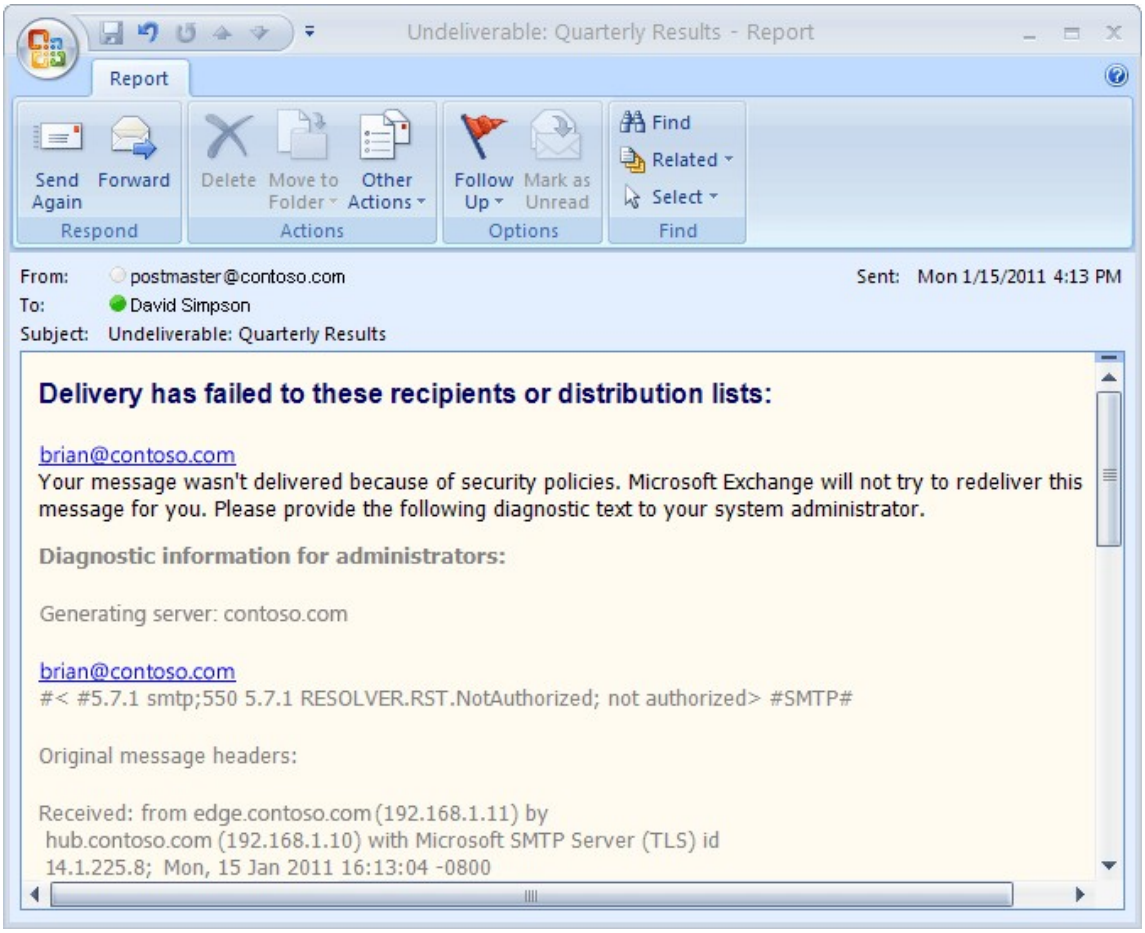
The following sections provide examples of two ways that NDR messages can be

generated:

- By the same server
- By different servers

NDR Generated and Original Message Rejected by the Same Server

The following example shows what happens when a remote e-mail organization accepts delivery of an e-mail message through an Edge Transport server, and then rejects that message because of a policy restriction on the recipient's mailbox. In this case, the sender is not allowed to send messages to the recipient. Edge Transport servers do not perform message size validation so the Edge Transport server in this example accepts the message because it has a valid recipient address and the message does not violate another content restrictions. Because the remote e-mail organization accepts the whole message, including the message contents, the remote e-mail organization is responsible for rejecting the message and for generating the NDR message to be sent to the sender.

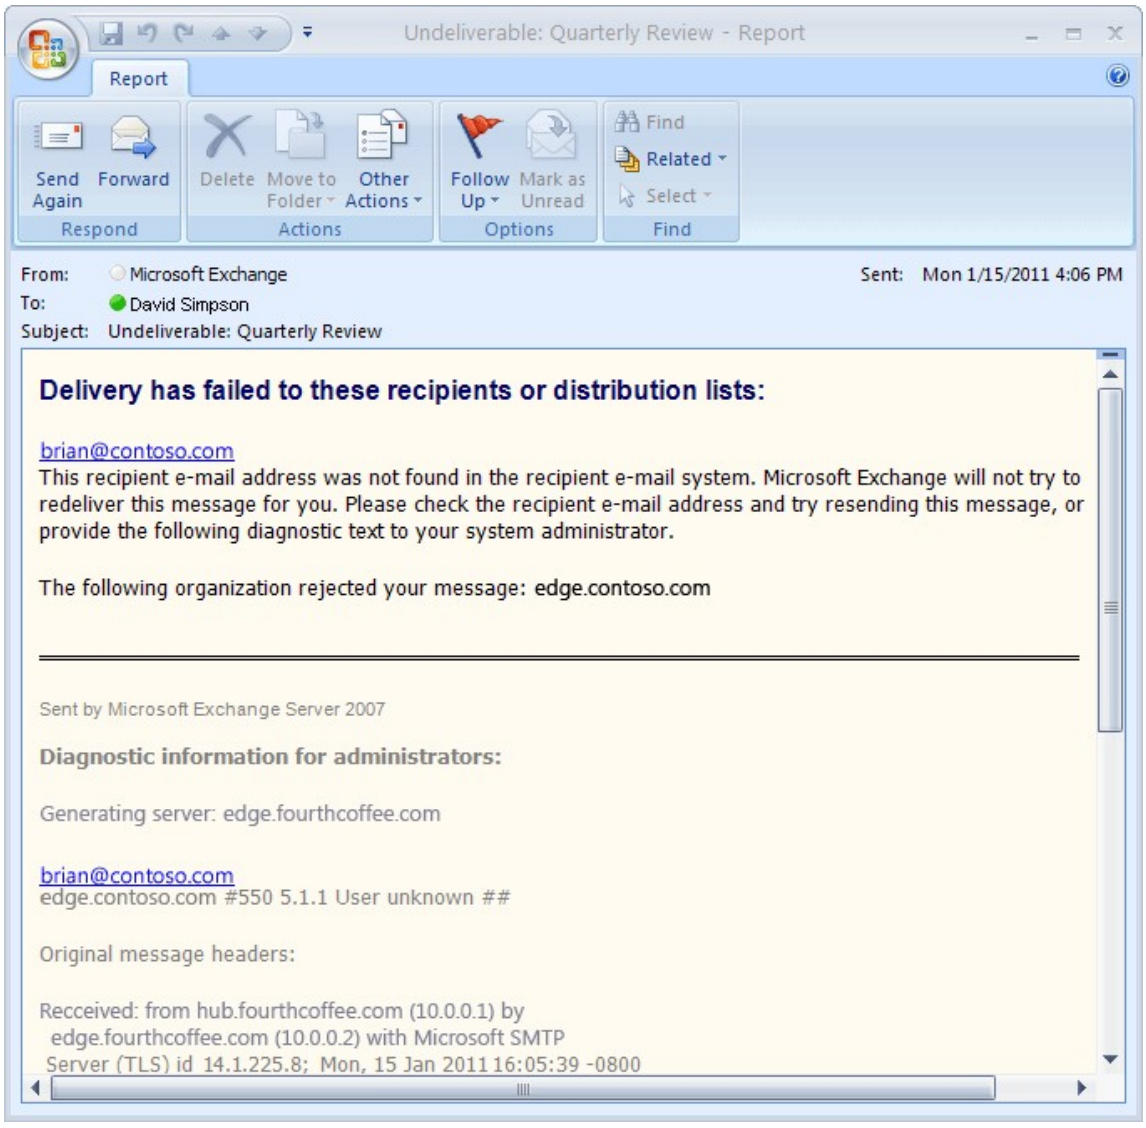


Also, messages that are rejected when they are sent to recipients that are part of the same Exchange 2010 organization are typically rejected by the same e-mail server that generates the NDR message. Messages sent to local recipients can be rejected for various reasons, such as mailboxes that have exceeded their quota, lack of authorization to send messages to the recipient address, or hardware failures that result in an extended loss of connectivity to other servers in the organization.

In both situations, no remote server is included under the e-mail address of the recipients listed in the NDR message.

NDR Generated and Original Message Rejected by Different Servers

The following example shows what happens when a remote e-mail organization rejects delivery of an e-mail message before it ever accepts the message. In this example, the remote server rejects the message and returns an enhanced status code to the local sending server because the specified recipient does not exist. The rejection happens before the receiving server ever acknowledges the message. Because the receiving server doesn't successfully acknowledge the message, the receiving server is not responsible for the message. Therefore, the local sending server generates the NDR message and sends it to the sender of the original message.



Common Enhanced Status Codes

The following table contains a list of the enhanced status codes that are returned in NDRs for the most common message delivery failures.

Enhanced status code	Description	Possible cause	Additional information

4.3.1	Insufficient system resources	An out-of-memory error occurred. A resource problem, such as a full disk, can cause this problem. Instead of getting a disk full error, you might be getting an out-of- memory error.	Ensure that your Exchange server has enough disk storage.
4.3.2	System not accepting network messages	This NDR is generated when a queue has been frozen.	You can resolve this condition by unfreezing the queue.
4.4.1	Connection timed out	The destination server is not responding. Transient network conditions can cause this error. The Exchange server tries automatically to connect to the server again and deliver the mail. If delivery fails after multiple attempts, an NDR with a permanent failure code is generated.	Monitor the situation. This may be a transient problem that may correct itself.
4.4.2	Connection dropped	A connection dropped between the servers. Transient network conditions or a server that is experiencing problems can cause this error. The sending server will retry delivery of the message for a specific time period, and then generate further status reports.	Monitor the situation as the server retries delivery. This may be a transient problem that may correct itself. This situation can also occur when the message size limit for the connection is reached, or if the message submission rate for the client IP address has exceeded the configured limit.
4.4.7	Message expired	The message in the queue has expired. The sending server tried to relay or deliver the message, but the action was not completed before the message expiration time occurred. This message can also indicate that a message header limit has been reached on a remote server, or some other protocol time-out occurred while communicating with the remote server.	This message usually indicates an issue on the receiving server. Check the validity of the recipient address, and determine if the receiving server is configured correctly to receive messages. You may have to reduce the number of recipients in the message header for the host about which you are receiving this error. If you send the message again, it is placed in the queue again. If the receiving server is available, the message is delivered.
5.0.0	HELO / EHLO	This situation is a permanent failure. Possible	Some potential resolutions include:

	requires domain address	causes include: • There is no route for the given address space; for example, an SMTP connector is configured, but this address does not match. • DNS returned an authoritative host that was not found for the domain. • An SMTP error occurred.	• On one or more SMTP connectors, add an asterisk (*) value as the SMTP address space. • Verify that DNS is working.
5.1.0	Sender denied	This NDR is caused by a general failure (bad address failure). An e-mail address or another attribute could not be found in Active Directory. Contact entries without the **targetAddress** attribute set can cause this problem. Another possible cause could be that the **homeMDB** attribute of a user could not be determined. The **homeMDB** attribute corresponds to the Exchange server on which the user's mailbox resides. Another common cause of this NDR is if you used Microsoft Office Outlook to save your e-mail message as a file, and then someone opened the message offline and replied to the message. The message property only preserves the **legacyExchangeDN** attribute when Outlook delivers the message, and therefore the lookup could fail.	Either the recipient address is incorrectly formatted, or the recipient could not be correctly resolved. The first step in resolving this error is to check the recipient address and send the message again.
5.1.1	Bad destination mailbox address	This failure may be caused by the following conditions: • The recipient e-mail address was entered incorrectly by the sender. • No recipient exists in the destination e-mail system.	This error typically occurs when the sender of the message incorrectly enters the e-mail address of the recipient. The sender should check the recipient's e-mail address and send again. This error can also occur if the recipient e-mail address was correct in the past but has changed or has been

		• The recipient mailbox has been moved and the Microsoft Office Outlook recipient cache on the sender's computer has not updated. • An invalid legacy domain name (DN) exists for the recipient mailbox Active Directory.	removed from the destination e-mail system. If the sender of the message is in the same Exchange organization as the recipient, and the recipient mailbox still exists, determine whether the recipient mailbox has been relocated to a new e-mail server. If this is the case, Outlook may not have updated the recipient cache correctly. Instruct the sender to remove the recipient address from sender's Outlook recipient cache and then create a new message. Resending the original message will result in the same failure. Other issues may cause this error, such as an invalid legacy distinguished name (DN) in Active Directory. Examine and correct the legacy DN of the recipient's mailbox. Then instruct the sender to remove the recipient address from sender's Outlook recipient cache and then create a new message. Resending the original message will result in the same failure.
5.1.2	Invalid X.400 address	The recipient has a non-SMTP address that can't be matched to a destination. The address does not appear to be local, and there are no connectors configured with address spaces that contain the recipient's address.	Verify that the recipient's address was entered correctly. If the recipient's address is in a non-SMTP e-mail system that you specifically want to provide mail delivery to, you will need to add the appropriate type of connector to your topology and configure it to provide service to the recipient's e-mail system.
5.1.3	Invalid recipient address	This message indicates that the recipient address appears incorrectly on the message.	Either the recipient address is formatted incorrectly, or the recipient could not be correctly resolved. The first step in resolving this error is to check the recipient address and send the message again.

			Also, examine the SMTP recipient policy and ensure that each mail domain for which you want to accept mail appears correctly.
5.1.4	Destination mailbox address ambiguous	Two or more recipients in the Exchange organization have the same address.	This error typically occurs because of a misconfiguration in Active Directory. Possibly because of replication problems, two recipient objects in Active Directory have the same SMTP address or Exchange Server (EX) address.
5.1.7	Invalid address	The sender has a malformed or missing SMTP address, the **mail** attribute in the directory service. The mail item cannot be delivered without a valid **mail** attribute.	Check the sender directory structure, and determine if the **mail** attribute exists.
5.2.1	Mailbox cannot be accessed	The mailbox cannot be accessed. The mailbox may be offline, disabled, or the message has been quarantined by a rule.	Check to see if the recipient database is online, the recipient mailbox is disabled, or the message has been quarantined.
5.2.2	Mailbox full	The recipient's mailbox has exceeded its storage quota and is no longer able to accept new messages.	This error occurs when the recipient's mailbox has exceeded its storage quota. The recipient must reduce the size of the mailbox or the administrator must increase the storage quota before delivery can be successful. If the recipient resides in the local Exchange 2010 organization, see Configure Storage Quotas for a Mailbox.
5.2.3	Message too large	The message is too large, and the local quota is exceeded. For example, a remote Exchange user might have a restriction on the maximum size of an incoming message.	Send the message again without attachments, or set the server or the client-side limit to allow a larger message size limit.
5.2.4	Mailing list expansion problem	The recipient is a misconfigured dynamic distribution list. Either the filter string or the base DN of the dynamic distribution list is invalid.	Set the categorizer event logging level to at least the minimum level, and send another message to the dynamic distribution list. Check the application event log for a 6025 event or a

			6026 event detailing which attribute is misconfigured on the dynamic distribution list object.
5.3.3	Unrecognized command	When the Exchange remote server reaches capacity of its disk storage to hold mail, it could respond with this NDR. This error usually occurs when the sending server is sending mail with an ESMTP BDAT command. This error also indicates a possible SMTP protocol error.	Ensure that the remote server has enough storage capacity to hold mail. Check the SMTP log.
5.3.4	Message too big for system	The message exceeds a size limit configured on a transport or mailbox database and can't be accepted. This failure can be generated by either the sending e-mail system or the recipient e-mail system.	This error occurs when the size of the message that was sent by the sender exceeds the maximum allowed message size when passing through a transport component or mailbox database. The sender must reduce the size of the message for the message to be successfully delivered. For more information about how to configure message size limits in an Exchange 2010 organization, see Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder.
5.3.5	System incorrectly configured	A mail-looping situation was detected, which means that the server is configured to loop mail back to itself.	Check the configuration of the server's connectors for loops, and ensure that each connector is defined by a unique incoming port. If there are multiple virtual servers, ensure that none are set to "All Unassigned."
5.4.4	Invalid arguments	This NDR occurs if no route exists for message delivery, or if the categorizer could not determine the next-hop destination.	Check that the domain name specified is valid, and that a mail exchanger (MX) record exists.
5.4.6	Routing loop detected	A configuration error has caused an e-mail loop. By default, after 20 iterations of an e-mail loop, Exchange interrupts the loop and generates an NDR to the sender of the message.	This error occurs when the delivery of a message generates another message in response. That message then generates a third message, and the process is repeated, creating a loop. To help protect against exhausting system

			resources, Exchange interrupts the mail loop after 20 iterations. Mail loops are typically created because of a configuration error on the sending mail server, the receiving mail server, or both. Check the mailbox rules configuration of the recipient and sender to determine whether automatic message forwarding is enabled.
5.5.2	Send hello first	A generic SMTP error occurs when SMTP commands are sent out of sequence. For example, a server attempts to send an AUTH (authorization) command before identifying itself with an EHLO command. It is possible that this error can also occur when the system disk is full.	View the SMTP Log or a Netmon trace, and ensure that there is adequate disk storage and virtual memory available.
5.5.3	Too many recipients	The combined total of recipients on the To, Cc, and Bcc lines of the message exceeds the total number of recipients allowed in a single message.	This error occurs when the sender has included too many recipients on the message. The sender must reduce the number of recipient addresses in the message or the maximum number of recipients must be increased to allow the message to be successfully delivered. To configure the maximum number of recipients that can be included in a message, use the *RecipientLimits* parameter on the **Set-Mailbox** cmdlet. For more information, see Set-Mailbox.
5.5.4	Invalid domain name	The message contains either an invalid sender or an incorrect recipient address format. One possible cause is that the recipient address format might contain characters that are not conforming to Internet standards.	Check the recipient address for nonstandard characters.
5.5.6	Invalid message content	This message indicates a possible protocol error.	Check Event Log for possible failures.

5.7.1	Delivery not authorized	The sender of the message is not allowed to send messages to the recipient.	This error occurs when the sender tries to send a message to a recipient but the sender is not authorized to do this. This frequently occurs when a sender tries to send messages to a distribution group that has been configured to accept messages only from members of that distribution group or other authorized senders. The sender must request permission to send messages to the recipient. On an Exchange 2010 server, the following cmdlets accept the *AcceptMessageOnlyFrom* and *AcceptMessagesOnlyFromDLMembers* parameters. These enable you to determine who is authorized to send messages to the recipients that you configure: • Set-Mailbox • Set-MailUser • Set-MailContact • Set-DistributionGroup • Set-DynamicDistributionGroup This error can also occur if an Exchange 2010 transport rule rejects a message because the message matched conditions that are configured on the transport rule. For more information about transport rules, see Understanding Transport Rules.
5.7.1	Unable to relay	The sending e-mail system is not allowed to send a message to an e-mail system where that e-mail system is not the final destination of the message.	This error occurs when the sending e-mail system tries to send an anonymous message to a receiving e-mail system, and the receiving e-mail system does not accept messages for the domain or domains specified in one or more of the recipients. The following are the most common reasons for this error: • A third party tries to use a

			receiving e-mail system to send spam, and the receiving e-mail system rejects the attempt. By the nature of spam, the sender's e-mail address may have been forged and the resulting NDR could have been sent to the unsuspecting sender's e-mail address. It is difficult to avoid this situation. • A domain name service (DNS) mail exchanger (MX) record for a domain points to a receiving e-mail system where that domain is not accepted. The administrator responsible for the specific domain name must correct the DNS MX record or configure the receiving e-mail system to accept messages sent to that domain, or both. For more information about how to accept messages for a domain, see Managing Accepted and Remote Domains. • A sending e-mail system or client that should use the receiving e-mail system to relay messages does not have the correct permissions to do this. For more information

			about transport permissions, see Understanding Permissions.
5.7.1	Client was not authenticated	The sending e-mail system did not authenticate with the receiving e-mail system. The receiving e-mail system requires authentication before message submission.	This error occurs when the receiving server must be authenticated before message submission, and the sending e-mail system has not authenticated with the receiving e-mail system. The sending e-mail system administrator must configure the sending e-mail system to authenticate with the receiving e-mail system for delivery to be successful. This error can also occur if you try to accept anonymous messages from the Internet by using a Hub Transport server that has not been configured to do this. We recommend that you put an Edge Transport server in a perimeter network between the Hub Transport server and the Internet. For more information, see the following topics: Configure Internet Mail Flow Directly Through a Hub Transport Server Configure Internet Mail Flow Through a Subscribed Edge Transport Server
5.7.3	Not Authorized	The sender prohibited reassignment to the alternate recipient.	

1.7.1.10.1 Supported Locales for Use with System Messages

Supported Locales for Use with System Messages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-11*

The following table lists the supported language locales available for use with the **New-SystemMessage** and **Set-SystemMessage** cmdlets.

Supported language locales for system messages

Language	Locale	Language	Locale
Arabic	AR	Japanese	JA
Basque	EU	Kazakh	KK
Bulgarian	BG	Korean	KO
Catalan	CA	Latvian	LV
Chinese (Simplified)	ZH-CHS	Lithuanian	LT
Chinese (Traditional)	ZH-CHT	Malay	MS
Croatian	HR	Norwegian	NB
Czech	CS	Persian	FA
Danish	DA	Polish	PL
Dutch	NL	Portuguese	PT
English	EN	Portuguese	PT-PT
Estonian	ET	Romanian	RO
Filipino (Tagalog)	FIL	Russian	RU
Finnish	FI	Serbian (Cyrillic)	SR-SP-CYRL
French	FR	Serbian (Latin)	SR-SP-LATN
Galician	GL	Slovak	SK
German	DE	Slovenian	SL
Greek	EL	Spanish	ES
Hebrew	HE	Swedish	SV
Hindi	HI	Thai	TH
Hungarian	HU	Turkish	TR
Icelandic	IS	Ukrainian	UK
Indonesian	ID	Urdu	UR
Italian	IT	Vietnamese	VI

You can use the **New-SystemMessage** cmdlet to create customized delivery status notification (DSN) and quota messages in various languages. For more information about creating customized DSNs, see Create a Custom DSN Message.

1.7.1.10.2 DSN Message Identity

DSN Message Identity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-18*

You can identify a customized delivery status notification (DSN) message based on its syntax. The identity is the customized DSN message's GUID or a string that consists of the following values:

- **Locale** This variable specifies the locale of the language that the DSN message is displayed in. For a list of locale codes that you can use with the **New-SystemMessage** command, see Supported Locales for Use with System Messages.
- **Internal or External** This variable specifies whether the DSN message is sent only to senders who are part of the internal Microsoft Exchange Server 2010 organization or also to senders outside the Exchange 2010 organization. You can use the Internal option when you want to include a specific e-mail contact or resolution in DSN messages sent to internal senders, but don't want to expose that information to senders outside your organization.
- **DSN code** This variable specifies the DSN code of the customized DSN message.

The syntax of the DSN message identity is `<Locale>\<Internal or External>\<DSN code>`.

For each DSN code, you can create more than one customized DSN message, which can target internal senders or external senders, and different locales. For example, the following table shows some of the possible configurations for the DSN code 5.1.2 and the corresponding DSN message identities.

Example DSN configurations and identities

DSN configuration	DSN identity
Display DSN messages to internal senders with an English (en) locale	En\Internal\5.1.2
Display DSN messages to external senders with an English (en) locale	En\External\5.1.2
Display DSN messages to internal senders with a Japanese (ja) locale	Ja\Internal\5.1.2
Display DSN messages to external senders with a Japanese (ja) locale	Ja\External\5.1.2

1.7.1.10.3 DSN Message Text

DSN Message Text

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-25*

You can include text in a customized delivery status notification (DSN) message in Microsoft Exchange Server 2010, and you can format that text in HTML.

You can include any information that you want to display to the recipient of the DSN message. For example, you can include a detailed description of the DSN, contact information for your help desk, and a link to your support department's Web site. Each DSN message can contain a maximum of 512 characters.

Because DSN messages can be displayed in HTML, you can embed HTML formatting tags in the DSN text. For example, if you want to make some text in your DSN message bold, enclose the text in <B> and </B> HTML tags. The following table provides some examples of valid HTML tags that can be used in DSN message text.

Valid HTML tags for use in DSN messages

HTML tag	Description
<B>	Bold begin
</B>	Bold end
<A HREF="url">	Hyperlink begin
</A>	Hyperlink end
 	Link break
<EM>	Italic begin
</EM>	Italic end
<P>	Paragraph begin
</P>	Paragraph end

Note:

By default, Exchange 2010 sends HTML DSN messages, but you can configure whether Exchange 2010 sends HTML DSN messages to internal senders, external senders, or both. To configure this behavior, modify the *InternalDsnSendHtml* parameter and the *ExternalDsnSendHtml* parameter with the **Set-TransportServer** command.
If the *InternalDsnSendHtml* parameter is set to `$false`, Exchange 2010 suppresses HTML tags in DSN messages sent to internal senders. If the *ExternalDsnSendHtml* parameter is set to `$false`, Exchange 2010 suppresses HTML tags in DSN messages sent to external senders.

The following characters that Exchange 2010 uses in DSN message text have special meanings:

- Greater than sign (>)
- Less than sign (<)
- Ampersand (&)
- Quotation marks (")

These characters are used to determine where HTML tags begin and end, and where text that should be displayed to senders starts and stops. If you want to display these characters in your DSN messages, you must use the escape codes in the following table.

For example, if you want to display the message `"Please contact the Help Desk at <1234>."`, you must add `"Please contact the Help Desk at <1234>."` to the DSN message text.

DSN message character escape codes

Escape code	Character
<	<
>	>
"	"

&amp;	&

Important:
If you include an HTML tag in your DSN message text that contains quotation marks ("), such as <A HREF="url">, you must use single quotation marks (') around the whole DSN message text. You will receive an error message if you use double quotation marks around the whole DSN message text and around an HTML tag.

1.7.1.11 Understanding DNS Query Failure Sensitivity

Understanding DNS Query Failure Sensitivity

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-23*

You can adjust the DNS query sensitivity for slightly faster message delivery when DNS errors are encountered for the destination domain. However, depending on the DNS errors, this adjustment may cause delivery failures in certain circumstances.

DNS Queries and Remote Message Delivery

In a typical Microsoft Exchange Server 2010 organization, an Edge Transport server that's subscribed to the organization is responsible for delivering messages to external recipients. This Edge Transport server is responsible for accepting the outgoing messages from the Hub Transport server in the organization. The subscribed Edge Transport server must be able to find a destination messaging server that accepts mail for the external recipients. Depending on the destination, the messages are put in one or more remote delivery queues as they await delivery to the remote recipients. For more information about delivery queues, see Understanding Transport Queues.

The Edge Transport server queries the configured external DNS servers to find the DNS records that are required to deliver the message. The DNS servers that are configured for external DNS lookups are queried in the order in which they're listed. If one of the DNS servers is unavailable, the query goes to the next DNS server on the list. The DNS servers are queried for the following information:

- **Mail exchange (MX) records for the domain part of the external recipient** The MX record contains the fully qualified domain name (FQDN) of the messaging server that's responsible for accepting messages for the domain, and a preference value for that messaging server. A lower preference value indicates a preferred messaging server. The preference value is important if the domain has more than one MX record. To optimize fault tolerance, most organizations use multiple messaging servers and multiple MX records that have different preference values.
- **Address (A) records for the destination messaging servers** Every messaging server that's used in an MX record should have a corresponding A record. The A record is used to find the IP address of the destination messaging server. The subscribed Edge Transport server uses the IP address to open an SMTP connection with the destination messaging server. Although it's technically possible to use the FQDN of a canonical name (CNAME) record in an MX record, this practice violates RFC 974, RFC 1034, RFC 1912, and RFC 2181, and is therefore not supported by most messaging servers.
  The required combination of iterative DNS queries and recursive DNS queries

that start with a root DNS server is used to resolve the FQDN of the messaging server that's found in the MX record into an IP address.

In Exchange 2010, there's a DNS query limit that's not configurable of 5 seconds for each DNS server, and a one-minute limit for the entire DNS query.

Potential DNS Problems

Even when the external DNS settings on the Microsoft Exchange Transport server are configured correctly, problems with the DNS records for a specific domain or problems with any of the DNS servers that are used to find the authoritative DNS server for a specific domain may still occur. Generally, these problems are beyond your control and need to be resolved by the parties that own those DNS servers. These DNS-related errors may be caused by one or more of the following conditions:

- Invalid DNS records for the destination domain
- Problems with DNS server utilization
- Problems with DNS server replication

In Exchange 2010, when a DNS query results in errors, the query continues to the next DNS server only if that DNS server hasn't already returned an error for the current query.

Exchange 2010 also includes a parameter in the EdgeTransport.exe.config application configuration file that's named *DnsFaultTolerance*. This parameter has the following values:

- **Lenient** When the DNS query encounters a combination of valid MX records and invalid MX records, the DNS query continues until the DNS query time-out value of one minute is reached. The invalid MX records are discarded, and the valid MX record that has the lowest preference value is used to deliver the message to the destination messaging server.
- **Normal** When the DNS query first encounters an invalid MX record, any resolved MX records that have a preference value that's greater than or equal to the invalid MX records are immediately discarded. The remaining MX record that has the lowest preference value is used to deliver the message to the destination messaging server without waiting for the whole DNS query to time out. Although this behavior may result in faster message delivery, the potential drawback of this behavior is the DNS query may have no valid MX records if the following conditions are true:
  - The invalid MX record is the first MX record for the destination domain.
  - The valid MX records have the same precedence value as the invalid MX records.

The default value of the *DnsFaultTolerance* parameter on a Hub Transport server or Edge Transport server in Exchange 2010 is `Lenient`.

In both `Normal` mode and `Lenient` mode, the results of the DNS query for an invalid MX record are never cached. The next time that a DNS query is executed, it will try to resolve the MX records for the destination domain.

For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File.

1.7.1.12 Understanding Domain Security

Understanding Domain Security

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Domain Security refers to the set of functionality in Microsoft Exchange Server 2010 and Microsoft Office Outlook 2007 that provides a relatively low-cost alternative to S/MIME or other message-level security solutions. The purpose of the Domain Security feature set is to provide administrators a way to manage secured message paths over the Internet with business partners. After these secured message paths are configured, messages that have successfully traveled over the secured path from an authenticated sender are displayed to users as **Domain Secured** in the Outlook and Microsoft Office Outlook Web App interface.

Domain Security uses mutual Transport Layer Security (TLS) authentication to provide session-based authentication and encryption. Mutual TLS authentication differs from TLS as it's usually implemented. Typically, when TLS is implemented, the client verifies that the connection securely connects to the intended server by validating the server's certificate. This is received as part of TLS negotiation. In this scenario, the client authenticates the server before the client transmits data. However, the server doesn't authenticate the session with the client.

With mutual TLS authentication, each server verifies the connection with the other server by validating a certificate that's provided by that other server. In this scenario, where messages are received from external domains over verified connections in an Exchange 2010 environment, Outlook 2007 displays a Domain Secured icon.

Important:

It's beyond the scope of this topic to provide a detailed explanation of cryptography and certificate technologies and concepts. Before you deploy any security solution that uses cryptography and digital certificates, we recommend that you understand the basic concepts of trust, authentication, encryption, and public and private key exchange as they relate to cryptography. For more information, see the references listed at the end of this topic.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Validation of TLS Certificates

To understand the overall security and resulting trustworthiness of any mutual TLS transmission, you must understand how the underlying TLS certificate is validated.

Exchange 2010 includes a set of cmdlets to create, request, and manage TLS certificates. By default, these certificates are self-signed. A self-signed certificate is a certificate that's signed by its own creator. In Exchange 2010, the self-signed certificate is created by the computer running Microsoft Exchange by using the underlying Microsoft Windows Cryptography API (CAPI). Because the certificates are self-signed, the resulting certificates are less trustworthy than certificates that are generated by public key infrastructure (PKI) or a third-party certification authority (CA). Therefore, we recommend that you use self-signed certificates for internal mail only. Alternatively, if the receiving organizations with which you exchange domain-secured e-mail manually add your self-signed certificate to the trusted root certificate store in each of their inbound Edge Transport servers, the self-signed certificates are trusted explicitly.

For connections that traverse the Internet, it's a best practice to generate TLS certificates with a PKI or third-party CA. Generating TLS keys with a trusted PKI or third-party CA reduces the overall management of Domain Security. For more information about the options regarding trusted certificates and Domain Security, see Using PKI on the Edge Transport Server for Domain Security.

You can use the Exchange 2010 certificate cmdlets to generate certificate requests for your own PKI or for third-party CAs. For more information, see Understanding TLS Certificates.

For more information about how to configure Domain Security, see the following:

- Using Domain Security: Configuring Mutual TLS
- Domain Security White Paper

Using Exchange Hosted Services

Message-level security is enhanced by or is also available as a service from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

Best Practices for Implementing a Microsoft Windows Server 2003 Public Key Infrastructure

1.7.1.12.1 Using Domain Security: Configuring Mutual TLS

Using Domain Security: Configuring Mutual TLS

Transport > Understanding Transport > Understanding Domain Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

This topic explains how to configure mutual Transport Layer Security (TLS) for Domain

Security, the set of functionality in Microsoft Exchange Server 2010 and Microsoft Office Outlook 2007 that provides a relatively low-cost alternative to S/MIME and other message-level security solutions.

For the purposes of this scenario, this topic explains how Exchange administrators at a fictitious company, Contoso, configure their Exchange 2010 environment to exchange domain-secured e-mail with their partner, Woodgrove Bank. Contoso administrators want to make sure that all e-mail sent to and received from Woodgrove Bank is protected with mutual TLS. Also, they want to configure Domain Security functionality so that all mail to and from Woodgrove Bank is rejected if mutual TLS can't be used.

Contoso has an internal public key infrastructure (PKI) that generates certificates. The PKI's root certificate has been signed by a major third-party certification authority (CA). Woodgrove Bank uses the same third-party CA to generate their certificates. Therefore, both Contoso and Woodgrove Bank trust the other's root CAs.

To set up mutual TLS, Exchange administrators at Contoso perform the following procedures:

Step 1: Generate a certificate request for TLS certificates

Step 2: Import certificates to Edge Transport servers

Step 3: Configure outbound Domain Security

Step 4: Configure inbound Domain Security

Step 5: Test domain-secured mail flow

Prerequisites

- This topic assumes that you have read and understood Generate Request for Third-Party Certificate Services.
- The Microsoft Exchange EdgeSync service must be fully deployed for Domain Security. Generally, configuration changes that are made to Domain Security functionality that don't use the **ExchangeCertificate** cmdlets are made within the organization and synchronized to Edge Transport servers by using the Microsoft Exchange EdgeSync service.
- Before you can successfully run mutual TLS on an Edge Transport server, you must configure the computer and PKI environment so that certificate validation and certificate revocation list checking are operable. For more information, see Using PKI on the Edge Transport Server for Domain Security.
- Even though individual configuration steps within this scenario can be accomplished with lesser rights, to complete the entire end-to-end scenario tasks, your account needs to be a member of the Organization Management management role group.

Step 1: Generate a Certificate Request for TLS Certificates

Contoso has an internal PKI that's subordinated to a third-party CA. In this scenario, subordination refers to the fact that the CA that's deployed by Contoso in the corporate infrastructure contains a root certificate that has been signed by a public third-party CA. By default, the public third-party CA is one of the trusted root certificates in the Microsoft Windows certificate store. Therefore, any client that includes the same third-party CA in its trusted root store and that connects to Contoso can authenticate to the certificate

that's presented by Contoso.

Contoso has two Edge Transport servers that require TLS certificates: mail1.contoso.com and mail2.mail.contoso.com. Therefore, the Contoso e-mail administrator must generate two certificate requests, one certificate request for each server.

The following example shows the commands that the administrator uses to generate the base64-encoded PKCS#10 certificate requests.

The Contoso administrator must run this command for CN=mail1.contoso.com.

```
$Data1 = New-ExchangeCertificate -GenerateRequest -FriendlyName "Internet certifi
Set-Content -Path "C:\Certificates\mail1-request.req" -Value $Data1
```

The Contoso administrator must run this command for CN=mail2.mail.contoso.com.

```
$Data2 = New-ExchangeCertificate -GenerateRequest -FriendlyName "Internet certifi
Set-Content -Path "C:\Certificates\mail2-request.req" -Value $Data2
```

For detailed syntax and parameter information, see New-ExchangeCertificate.

Important:

The specific details of the certificate or certificate request that you create depends on many variables. If you're generating a request, make sure that you work closely with the CA or the PKI administrator who will issue your certificate. For more information about how to create a certificate request for TLS, see Generate Request for Third-Party Certificate Services.

Return to top

Step 2: Import Certificates to Edge Transport Servers

After the Contoso administrator generates the certificate requests, the CA administrator for Contoso then uses the requests to generate the certificates for the servers. The resulting certificates must be issued as either a single certificate or a certificate chain and copied to the appropriate Edge Transport servers.

Important:

Do not use the Certificate Manager snap-in in the Microsoft Management Console (MMC) to import the certificates for TLS on the Exchange server. Using the Certificate Manager snap-in to import certificates on Exchange servers doesn't bind the request that's created in this procedure to the issued certificate. Therefore TLS might fail. You can use the Certificate Manager snap-in to import certificates and keys that are stored as .pfx files into the local computer store.

When you import the certificate to the Edge Transport server, you must also enable the certificate for the SMTP service. The Contoso administrator runs the following command on each Edge Transport server, one time for each respective certificate.

```
Import-ExchangeCertificate -FileData ([Byte[]]$(Get-Content -Path C:\Certificates
```

The preceding example imports and enables the TLS certificate by pipelining the certificate to the **Enable-ExchangeCertificate** cmdlet. You can also enable the certificate after you import it. If you do, you will need to specify the thumbprint of the certificate that you want to enable.

For detailed syntax and parameter information, see the Import-ExchangeCertificate and Enable-ExchangeCertificate topics.

Transporting Certificates and Related Keys

When you receive a certificate from your PKI or CA provider, convert the issued certificate to a .pfx (PKCS#12) file so that you can back it up as part of a disaster contingency. A .pfx file contains the certificate and related keys. In some cases, you may want to transport the certificate and keys to move them to other computers. For example, if you have multiple Edge Transport servers where you expect to send and receive e-mail that's domain secured, you can create a single certificate that will work for all servers. In this case, you must have the certificate imported and enabled for TLS on each Edge Transport server.

As long as you keep a copy of the .pfx file securely archived, you can always import and enable the certificate. The .pfx file contains the private key so it's important to physically protect the file by keeping it on storage media in a secure location.

It's important to understand that the **Import-ExchangeCertificate** cmdlet always marks the imported private key from the .pfx file as non-exportable. This functionality is by design.

When you use the Certificate Manager snap-in in MMC to import a .pfx file, you can specify private key exportability and strong-key protection.

Important:

Do not enable strong-key protection on certificates that are intended for TLS. Strong-key protection prompts the user every time that the private key is accessed. With Domain Security, the user is the SMTP service on the Edge Transport server.

Return to top

Step 3: Configure Outbound Domain Security

You must perform three steps to configure outbound Domain Security:

1. Run the **Set-TransportConfig** cmdlet to specify the domain with which you want to send domain-secured e-mail.
2. Run the **Set-SendConnector** cmdlet to set the **DomainSecureEnabled** property on the Send connector that will send mail to the domain with which you want to send domain-secured e-mail.
3. Run the **Get-SendConnector** cmdlet to verify the following:
   - The Send connector that will send mail to the domain with which you want to send domain-secured e-mail routes mail with Domain Name System (DNS).
   - The FQDN is set to match either the Subject Name or the Subject Alternative Name of certificates that you're using for Domain Security.

Because the changes that you make in these three steps are global, you must make the changes on an internal Exchange server. The configuration changes that you make will be replicated to the Edge Transport servers by using the Microsoft Exchange EdgeSync service.

Step 3a: Specify the Sender Domain in Transport Configuration

It's relatively straightforward to specify the domain with which you want to send domain-secured e-mail. The Contoso administrator runs the following command on an internal Exchange 2010 server.

```
Set-TransportConfig -TLSSendDomainSecureList woodgrovebank.com
```

The *TLSSendDomainSecureList* parameter takes a multivalued list of domain names. The

Set-TransportConfig command replaces the whole value for *TLSSendDomainSecureList* with the new value that's supplied in the cmdlet. Therefore, if you have other domains already configured and want to add a new domain, you need to either include the existing domain in the list or use a temporary variable. The following example shows how to add the woodgrovebank.com domain to the *TLSSendDomainSecureList* parameter without overwriting any existing values.

```
$TransportConfig = Get-TransportConfig
$TransportConfig.TLSSendDomainSecureList += "woodgrovebank.com"
Set-TransportConfig -TLSSendDomainSecureList $TransportConfig.TLSSendDomainSecure
```

For detailed syntax and parameter information, see Set-TransportConfig.

Step 3b: Configure the Default Send Connector

Contoso will use the default DNS-routed Send connector named Internet to send domain-secured e-mail to their partners. Because their default DNS-routed Send connector is a default Internet Send connector, it uses DNS to route mail and doesn't use a smart host. The FQDN is already set to `mail.contoso.com`. Because the certificates that the Contoso administrator created set the *DomainName* parameter of the **New-ExchangeCertificate** to `mail.contoso.com`, the Send connector can use the certificates without additional configuration.

If you've configured a subdomain for testing, you may have to update the FQDN of your Send connector to match the certificate that you've created (for example, subdomain.mail.contoso.com). On the other hand, if you've created a certificate that contains the subdomain in the Subject or Subject Alternative name fields, you don't have to update the FQDN of the Send connector.

Therefore, the only configuration that the Contoso administrator must make to the Send connector is to set the *DomainSecureEnabled* parameter. To do this, the Contoso administrator runs the following command on an internal Exchange 2010 server for the Internet Send connector.

```
Set-SendConnector Internet -DomainSecureEnabled:$true
```

For detailed syntax and parameter information, see Set-SendConnector.

Step 3c: Verify the Send Connector Configuration

After completing the configuration changes, the Contoso administrator needs to verify that the Send connector being used for Domain Security is configured correctly. To do so, the Contoso administrator needs to run the following command.

```
Get-SendConnector Internet | Format-List Name,DNSRoutingEnabled,FQDN,DomainSecure
```

This command will list the relevant parameters configured for Domain Security, allowing the Contoso administrator to verify the configuration.

For detailed syntax and parameter information, see Get-SendConnector.

Return to top

Step 4: Configure Inbound Domain Security

You must perform two steps to enable inbound Domain Security:

1. Run the **Set-TransportConfig** cmdlet to specify the domain from which you want to receive domain-secured e-mail.
2. On the Edge Transport server, use the Exchange Management Shell or the

Exchange Management Console (EMC) to enable Domain Security on the Receive connector from which you want to receive domain-secured e-mail. Because Domain Security requires mutual TLS authentication, TLS must also be enabled on the Receive connector.

Step 4a: Specify the Recipient Domain in Transport Configuration

It's relatively straightforward to specify the domain with which you want to receive domain-secured e-mail. To specify the domain, the Contoso administrator runs the following command in the Shell on an internal Exchange 2010 server or management workstation.

```
Set-TransportConfig -TLSReceiveDomainSecureList woodgrovebank.com
```

The *TLSReceiveDomainSecureList* parameter takes a multivalued list of domain names. The **Set-TransportConfig** command replaces the whole value for *TLSReceiveDomainSecureList* parameter with the new value supplied by the **Set-TransportConfig** cmdlet. Therefore, if you have other domains already configured and want to add a new domain, you need to either include the existing domain in the list or use a temporary variable. The following example shows how to add the woodgrovebank.com domain to the *TLSReceiveDomainSecureList* parameter without overwriting any existing values.

```
$TransportConfig = Get-TransportConfig
$TransportConfig.TLSReceiveDomainSecureList += "woodgrovebank.com"
Set-TransportConfig -TLSReceiveDomainSecureList $TransportConfig.TLSReceiveDomain
```

For detailed syntax and parameter information, see Set-TransportConfig.

Step 4b: Configure the Receive Connector

You must configure the Receive connector on each Edge Transport server that accepts mail from the domain from which you want to receive domain-secured e-mail. The Contoso environment is configured to have a single Internet Receive connector, with an *Identity* parameter value of Internet, on both Edge Transport servers. Therefore, to enable TLS while mail is sent to or received from Woodgrove Bank, the Contoso administrator must make sure that TLS is enabled on the default Internet Receive connector on both Edge Transport servers. To do so, the Contoso administrator runs the following command on both mail1.contoso.com and mail2.mail.contoso.com.

```
Set-ReceiveConnector Internet -DomainSecureEnabled $true -AuthMechanism TLS
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

You can also use the EMC to configure the Receive connector using the following steps.

1. On the Edge Transport server, open the EMC, click **Edge Transport**, and then in the result pane, click the **Receive Connectors** tab.
2. Select the Receive connector that accepts mail from the domain from which you want to receive domain-secured e-mail, the connector Internet in this case, and then click **Properties** in the action pane.
3. On the **Authentication** tab, select **Transport Layer Security (TLS)** and **Enable Domain Security (Mutual Auth TLS)**, and then click **OK**.

Be aware that specifying the authentication mechanism as TLS doesn't force TLS on all inbound connections.

TLS will be forced for connections from Woodgrove Bank for the following reasons:

- Woodgrove Bank is specified in the **Set-TransportConfig** cmdlet on the *TLSReceiveDomainSecureList* parameter.
- The *DomainSecureEnabled* parameter is set to `$true` on the Receive connector.

Other senders that aren't listed on the *TLSReceiveDomainSecureList* parameter in the **Set-TransportConfig** cmdlet will only use TLS if TLS is supported by the sending system.

Return to top

Step 5: Testing Domain-Secured Mail Flow

After you've configured domain-secured e-mail, you can test the connection by reviewing the performance logs and the protocol logs. Messages that have successfully authenticated over the domain-secured mail flow path are displayed in Outlook as Domain Secure messages.

Performance Counters

The Domain Security feature includes the following set of performance counters under **MSExchange Secure Mail Transport**:

- Domain-Secured Messages Received
- Domain-Secured Messages Sent
- Domain-Secured Outbound Session Failures

You can create a new counter log file for domain-secured mail flow with these performance counters to monitor the number of messages sent and received and also to monitor failed mutual TLS sessions. For more information about how to create and configure counter logs, see the Help file that's included with the **Performance Logs and Alerts** MMC snap-in.

Protocol Logs

You can review the send and receive protocol logs to determine whether TLS negotiation has been successful.

To view detailed protocol logs, you must set the protocol logging level to `Verbose` on the connectors that your organization uses to send and receive domain secured e-mail. To accomplish this, the Contoso administrator runs the following on both Edge Transport servers.

```
Set-ReceiveConnector Internet -ProtocolLoggingLevel Verbose
```

To enable protocol logging on the Send connector, the Contoso administrator runs the following on an internal Exchange server or management workstation. The configuration change is then replicated to the Edge Transport servers using the Microsoft Exchange EdgeSync service.

```
Set-SendConnector Internet -ProtocolLoggingLevel Verbose
```

For detailed syntax and parameter information, see the Set-ReceiveConnector and Set-SendConnector topics.

For more information about how to view protocol logs, see Configure Protocol Logging.

Return to top

1.7.1.12.2 Using PKI on the Edge Transport Server for Domain Security

Using PKI on the Edge Transport Server for Domain Security

Transport > Understanding Transport > Understanding Domain Security >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Domain Security relies on mutual Transport Layer Security (TLS) for authentication. Successful mutual TLS authentication relies on a trusted, validated X.509 certificate chain for the TLS certificates that are used for Domain Security.

Therefore, before you can successfully deploy Domain Security, you must configure your Edge Transport server and your X.509 public key infrastructure (PKI) to accommodate certificate trusting and certificate validation.

Important:

It's beyond the scope of this topic to provide a detailed explanation of cryptography and certificate technologies and concepts. Before you deploy any security solution that uses cryptography and X.509 certificates, we recommend that you understand the basic concepts of trust, authentication, encryption, and public and private key exchange as they relate to cryptography. For more information, see the references listed at the end of this topic.

Configuring Root Certification Authorities

To validate a given X.509 certificate, you must trust the root certification authority (CA) that issued the certificate. A root CA is the most trusted CA, which is at the top of a CA hierarchy. The root CA has a self-signed certificate. When you run an application that relies on certificate authentication, each certificate must have a certificate chain that ends in a certificate in the trusted root container of the local computer. The trusted root container contains certificates from root certification authorities.

To successfully send domain-secured e-mail, you must be able to validate the receiving server's X.509 certificate. Similarly, when someone sends domain-secured e-mail to your organization, the sending server must be able to validate your certificate.

There are two types of trusted root CAs that you can use to implement Domain Security: Built-in third-party root CAs and private root CAs.

Third-Party Root Certification Authorities

Microsoft Windows includes a set of built-in third-party root CAs. If you trust the certificates issued by these third-party root CAs, this means you can verify certificates issued by these CAs. If your organization and your partner organizations are using the default Windows installation and trust the built-in third-party root CAs, trust is automatic. In this scenario, additional trust configuration is not required.

Private Trusted Root Certification Authorities

A private trusted root CA is a root CA that has been deployed by a private or internal PKI. For example, when your organization or the organization that you exchange domain-secured e-mail with has deployed an internal PKI with its own root certificate, you must make additional trust configurations.

When private root CAs are used, you must update the Windows trusted root certificate store on the Edge Transport server for Domain Security to function correctly.

You can configure trust in two ways: direct root trust and cross-certification. You must understand that whenever the transport service picks a certificate, it validates the certificate before it uses it. Therefore, if you're using a private root CA to issue your certificates, you must include the private root CA in the trusted root certificate store on each Edge Transport server that sends or receives domain-secured e-mail.

Direct Root Trust

If you want to trust a certificate that has been issued by a private root CA, you can manually add that root certificate to the trusted root certificate store on the Edge Transport server computer. For more information about how to manually add certificates

to the local certificate store, see the Help file for the Certificate Manager snap-in in Microsoft Management Console (MMC).

Cross-Certification

Cross-certification occurs when one CA signs a certificate that is generated by a different CA. Cross-certification is used to build trust from one PKI with another PKI. In the context of Domain Security, if you have your own PKI, instead of using direct manual trust for a root authority of a partner with an internal PKI, you might create a cross-certificate for the partner CA under your root authority. In this case, trust is established because the cross-certificate ultimately chains back to your trusted root.

You must understand that if you have an internal PKI and are using cross-certification, you must manually update the root certificate store on each Edge Transport server that receives domain-secured e-mail so that each Edge Transport server can validate certificates when they receive e-mail from partners that are trusted through cross-certificates.

For more information about how to manually add certificates to the local certificate store, see the Help file for the Certificate Manager snap-in in MMC.

Configuring Access to the Certificate Revocation List

Whenever the Transport service retrieves a certificate, it validates the certificate chain and validates the certificate. Validation of the certificate is a process in which many attributes of the certificate are confirmed. Most of these attributes can be confirmed on the local computer by the application that requests the certificate. For example, the intended use of the certificate, the expiration dates on the certificate, and similar attributes are verifiable outside the context of a PKI. However, verification that the certificate has not been revoked must be validated with the CA that issued the certificate. Therefore, most CAs make a certificate revocation list (CRL) available to the public to validate the revocation status.

To successfully use Domain Security, CRLs for CAs that you use or are used by your partners must be available to the Edge Transport servers that send and receive domain-secured e-mail. If the revocation check fails, the receiving Exchange server issues a temporary protocol rejection of the message. A transient revocation failure can occur. For example, the Web server that is used to publish the CRL can fail. Or, general network connectivity issues between the Edge Transport server and the CRL distribution point could fail the revocation check. Therefore, transient revocation failures only cause temporary mail delivery delays because the sending server will retry later. However, CRL validation is required for successful domain-secured e-mail transmission.

You must enable the following scenarios:

- **Your Edge Transport servers must be able to access CRLs for external CAs** Each partner with which you exchange domain-secured e-mail must have publicly available CRLs that your organization's Edge Transport server can contact. In some cases, CRLs are only available with Lightweight Directory Access Protocol (LDAP). In most cases, with public CAs, CRLs are published via HTTP. Make sure that the appropriate outbound ports and proxies are configured to let the Edge Transport server contact the CRL. You can determine which protocol a given CRL distribution point accepts by opening a certificate in MMC and viewing the **CRL Distribution Points** field.
- **You must make the CRL for the CA that issues your certificates publicly available** You must understand that even when an Edge Transport server retrieves a certificate from your own organization, it validates the certificate chain to validate the certificate. Therefore, the CRL for your CA must be available to your own Edge Transport servers. In addition, all partners that

you exchange domain-secured e-mail with must be able to access the CRL for the CA that issues your certificates.

Configuring Proxy Settings for WinHTTP

Exchange 2010 transport servers rely on the underlying Microsoft Windows HTTP Services (WinHTTP) to manage all HTTP and HTTPS traffic. Both Hub Transport servers and Edge Transport servers may use HTTP to access updates for Microsoft Exchange 2010 Standard Anti-spam Filter Updates and for CRL validation.

For more information, see Configure Proxy Settings for WinHTTP.

Testing the PKI and Proxy Configuration

To verify your PKI and proxy configuration for a specific Edge Transport server, use Certutil.exe to verify the certificate chain for your Edge Transport server certificate. Certutil.exe is a command-line tool that is installed as part of Certificate Services in Windows Server 2008 operating systems. For more information, see Test PKI and Proxy Configuration.

1.7.1.12.3 Test PKI and Proxy Configuration

Test PKI and Proxy Configuration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

To verify your public key infrastructure (PKI) and proxy configuration for a specific Edge Transport server, use Certutil.exe to verify the certificate chain for your Edge Transport server certificate. Certutil.exe is a command-line tool installed as part of Certificate Services in the Windows Server 2008 operating system. For more information, see Certutil.

Before you can run **Certutil** to verify the certificate chain for a specific certificate, the certificate must first be in file (.cer) format. Therefore, you must first export the certificate, but not the private keys, to the DER (.cer) file format.

The first procedure in this topic shows you how to add the Certificate Manager snap-in to the Microsoft Management Console (MMC). The second procedure explains how to use the Certificate Manager to export a certificate. The third procedure shows how you can run the **Certutil** command to verify the certificate chain.

Step 1: Add Certificate Manager to the Microsoft Management Console

To perform this procedure, the account you use must be delegated membership in the local Administrators group.

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. In the **Add/Remove Snap-in** box, click **Add**.
4. In the **Available Snap-ins** list, click **Certificates**, and then click **Add**.
5. Click **Computer Account**, and then click **Next**.
6. Click the **Local computer (the computer this console is running on)** option,

and then click **Finish**.
7. Click **OK**.

Step 2: Export the certificate

To perform this procedure, the account you use must be delegated membership in the local Administrators group.

1. Open the Certificate Manager that you created in Step 1.
2. Expand the **Certificates (Local Computer)** folder and the **Personal** folder, and then click the **Certificates** folder.
3. In the details pane, right-click the certificate that you will use for Domain Security, click **All Task**, and then select **Export**. The Certificate Export Wizard will open.
4. On the **Welcome** page, click **Next**.
5. On the **Export Private Key** page, select **No, do not export the private key**, and then click **Next**.
6. On the **Export File Format** page, select **DER encoded binary X.509 (.CER)**, and then click **Next**.
7. On the **File to Export** page, enter the path and file name where you want to save the exported certificate, and then click **Next**.
8. On the **Finish** page, verify the settings and then click **Finish**.

Step 3: Verify the certificate chain for the certificate

To perform this procedure, the account you use must be delegated membership in the local Administrators group.

On the Edge Transport server, open a Command Prompt window, and type the following command.

```
Certutil -verify c:\CertificateName.cer
```

In this example, `CertificateName` is the Edge Transport server certificate that you exported in the previous procedure.

1.7.1.13 Understanding Edge Subscriptions

Understanding Edge Subscriptions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-02-01*

This topic provides detailed information about Edge Subscriptions and the EdgeSync synchronization process. Edge Subscriptions are used to populate the Active Directory Lightweight Directory Services (AD LDS) instance on the Microsoft Exchange Server 2010 Edge Transport server role with Active Directory data.

In Exchange 2010, the Edge Transport server role is deployed in your organization's perimeter network. Designed to minimize the attack surface, the Edge Transport server handles all Internet-facing mail flow and provides SMTP relay and smart host services for the Exchange organization. Additional layers of message protection and security are provided by a series of agents that run on the Edge Transport server and act on messages as they're processed by the message transport components. These agents

support the features that provide protection against viruses and spam and apply transport rules to control message flow.

Although creating an Edge Subscription is optional, subscribing an Edge Transport server to the Exchange organization provides a simpler management experience for the administrator and enhances the available anti-spam features. You must create an Edge Subscription if you plan to use recipient lookup or safelist aggregation, or if you plan to help secure SMTP communications with partner domains by using mutual Transport Layer Security (TLS).

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Edge Subscription Process

In a typical deployment scenario, the computer that has the Edge Transport server role installed doesn't have access to Active Directory. All the configuration and recipient information that the Edge Transport server has to process messages is stored in AD LDS. Creating an Edge Subscription establishes secure, automatic replication of information from Active Directory to AD LDS. The Edge Subscription process provisions the credentials that are used to establish a secure LDAP connection between Hub Transport servers and a subscribed Edge Transport server. The Microsoft Exchange EdgeSync service that runs on Hub Transport servers then performs periodic one-way synchronization to transfer data to AD LDS and keep that data up to date. This process reduces the administration that you must perform in the perimeter network by letting you perform required configuration on the Hub Transport server role and then write that information to the Edge Transport server.

You subscribe an Edge Transport server to the Active Directory site that contains the Hub Transport servers that will directly exchange messages with your Edge Transport servers. The Edge Subscription process creates an Active Directory site membership affiliation for the Edge Transport server. The site affiliation enables Hub Transport servers in the Exchange organization to relay messages to the Edge Transport server for delivery to the Internet without having to configure explicit Send connectors.

One or more Edge Transport servers can be subscribed to a single Active Directory site. However, an Edge Transport server can't be subscribed to more than one Active Directory site. If you have more than one Edge Transport server deployed, each server can be subscribed to a different Active Directory site. Each Edge Transport server requires an individual Edge Subscription.

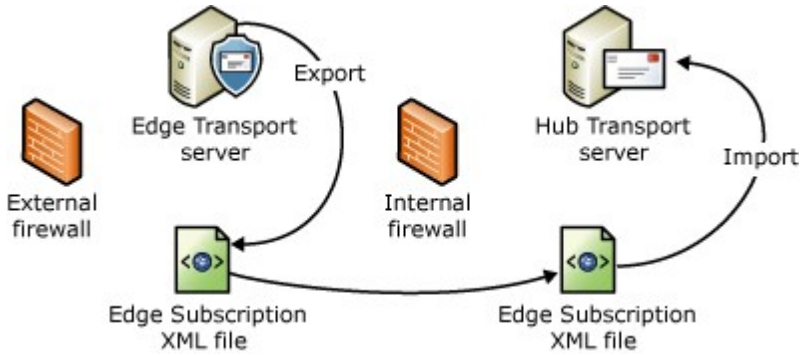
To deploy an Edge Transport server and subscribe it to an Active Directory site, follow these steps:

1. Install the Edge Transport server role.
2. Verify that the Hub Transport servers and the Edge Transport server can locate one another by using Domain Name System (DNS) name resolution.
3. Configure the objects and settings to be replicated to the Edge Transport server.
4. On the Edge Transport server, create and export an Edge Subscription file.

For more information about this step, see Create an Edge Subscription File on an Edge Transport Server.

5. Copy the Edge Subscription file to a Hub Transport server or a file share that's accessible from the Active Directory site that has your Hub Transport servers.
6. Import the Edge Subscription file to your Active Directory site to which you want to subscribe your Edge Transport server. For more information about this step, see Import an Edge Subscription File to an Active Directory Site.

The following figure illustrates the Edge Subscription process.



Configuration Changes Made When a New Edge Subscription Is Created

When you run the **New-EdgeSubscription** cmdlet on the Edge Transport server to create an Edge Subscription file, the following actions occur:

- An AD LDS account is created. This account is called the EdgeSync bootstrap replication account (ESBRA). These credentials are used to authenticate the first EdgeSync connection to the Edge Transport server. The account is configured to expire 1,440 minutes (24 hours) after it's created. Therefore, you must complete the subscription process before that time expires. If the ESBRA expires before the Edge Subscription process is complete, you must run the **New-EdgeSubscription** cmdlet on the Edge Transport server again to create an Edge Subscription file.
- The ESBRA credentials are retrieved from AD LDS and written to the Edge Subscription file. The public key for the Edge Transport server's self-signed certificate is also exported to the Edge Subscription file. The credentials that are written to the Edge Subscription file are specific to the server from which the file is exported.
- Any previously created configuration objects in a class that will now be replicated to AD LDS from Active Directory are deleted from AD LDS and the Exchange Management Shell commands used to configure those objects are disabled. You can still use the cmdlets that let you view those objects. The following cmdlets are disabled on the Edge Transport server when you run the **New-EdgeSubscription** cmdlet:
  - **Set-SendConnector**
  - **New-SendConnector**
  - **Remove-SendConnector**
  - **New-AcceptedDomain**
  - **Set-AcceptedDomain**
  - **Remove-AcceptedDomain**
  - **New-MessageClassification**
  - **Set-MessageClassification**
  - **Remove-MessageClassification**
  - **New-RemoteDomain**
  - **Set-RemoteDomain**
  - **Remove-RemoteDomain**

When you import the Edge Subscription file on the Hub Transport server by running the **New-EdgeSubscription** cmdlet in the Shell or by using the New Edge Subscription wizard in the Exchange Management Console, the following actions occur:

- The Edge Subscription is created, establishing a record of an Edge Transport server that has been joined to an Exchange organization and to which the Microsoft Exchange EdgeSync service will propagate configuration data. This step creates the edge configuration object in Active Directory.
- Each Hub Transport server in the Active Directory site receives notification from Active Directory that a new Edge Transport server has been subscribed. The Hub Transport server retrieves the ESBRA from the Edge Subscription file. The Hub Transport server then encrypts the ESBRA by using the public key of the Edge Transport server's self-signed certificate. The encrypted credentials are then written to the edge configuration object.
- Each Hub Transport server also encrypts the ESBRA by using its own public key and then stores the credentials in its own configuration object.
- EdgeSync replication accounts (ESRAs) are created in Active Directory for each Edge Transport-Hub Transport server pair. Each Hub Transport server stores its ESRA credentials as an attribute of the Hub Transport server configuration object.
- Send connectors are automatically created to relay messages outbound from the Edge Transport server to the Internet, and inbound from the Edge Transport server to the Exchange organization.
- The Microsoft Exchange EdgeSync service that runs on Hub Transport servers uses the ESBRA credentials to establish a secure LDAP connection between a Hub Transport server and the Edge Transport server and performs the initial replication of data. The following data is replicated to AD LDS:
  - Topology data
  - Configuration data
  - Recipient data
  - ESRA credentials
- The Microsoft Exchange Credential Service that runs on the Edge Transport server installs the ESRA credentials. These credentials are used to authenticate and secure later synchronization connections.
- The EdgeSync synchronization schedule is established.

The Microsoft Exchange EdgeSync service that's running on the Hub Transport servers in the Active Directory site to which the Edge Transport server is subscribed will now perform one-way replication of data from Active Directory to AD LDS on a regular schedule. You can also use the **Start-EdgeSynchronization** cmdlet in the Shell to override the EdgeSync synchronization schedule and immediately start synchronization.

For more information about ESRA accounts and how they're used to help secure the EdgeSync synchronization process, see Understanding Edge Subscription Credentials.

Send Connectors Created During Edge Subscription Process

By default, when you complete the Edge Subscription process by importing the Edge Subscription file to a Hub Transport server, the Send connectors that are required to enable end-to-end mail flow between the Internet and the Exchange organization are created automatically. Any existing Send connectors on the Edge Transport server are deleted. Even though that's the recommended method, you can also select to suppress automatic creation of Send connectors and configure Send connectors manually. For more information about manually configuring Send connectors, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync.

The Edge Subscription process provisions the following Send connectors:

- A Send connector that's configured to relay e-mail messages from the Exchange organization to the Internet
- A Send connector that's configured to relay e-mail messages from the Edge

Transport server to the Exchange organization

Also, by subscribing an Edge Transport server to the Exchange organization, you enable Hub Transport servers that are located in the Active Directory site to which the Edge Transport server is subscribed to use the intra-organization Send connector to relay messages to that Edge Transport server.

Automatically Create a Send Connector to Send Messages to the Internet

By default, when you run the **New-EdgeSubscription** cmdlet in the Shell on the Hub Transport server, the *CreateInternetSendConnector* parameter is set to `$true`. This creates the Send connector that's required to send messages to the Internet. The following table shows the default configuration of this Send connector.

Automatic Internet Send connector configuration

Parameter	Value
Name	EdgeSync - <*Site Name*> to Internet
Address Space	SMTP:*;100
Source Servers	Edge Subscription name **Note:** The name of the Edge Subscription is the same as the name of the subscribed Edge Transport server.
Enabled	True
DNS Routing Enabled	True
Domain Secure Enabled (Mutual Auth TLS)	True

If more than one Edge Transport server is subscribed to the same Active Directory site, additional Send connectors to the Internet aren't created. Instead, all Edge Subscriptions are added to the same Send connector as source servers. This configuration causes outbound connections to the Internet to be load balanced between the subscribed Edge Transport servers.

This Send connector is configured to send e-mail messages from the Exchange organization to all remote SMTP domains. It will use DNS routing to resolve domain names to MX resource records. You can modify the configuration of this connector manually. However, if you must route outbound e-mail through a smart host, for example, you can suppress creation of this connector and manually configure a Send connector to the Internet.

Note:

A Send connector that's configured to use a smart host to route e-mail must have the *DNSRoutingEnabled* parameter set to `$false`. If the *DNSRoutingEnabled* parameter is set to `$false`, the *DomainSecureEnabled* parameter must also be set to `$false`.

Automatically Create an Inbound Send Connector

By default, when you run the **New-EdgeSubscription** cmdlet in the Shell on the Hub Transport server, the *CreateInboundSendConnector* is parameter set to `$true`. This creates the Send connector that's required to send messages to the Exchange organization. The following table shows the configuration of this Send connector.

Automatic inbound Send connector configuration

Parameter	Value

Name	EdgeSync - Inbound to *<Site Name>*
Address Space	SMTP:--;1
Source Servers	Edge Subscription name
Enabled	True
DNS Routing Enabled	False
Smart Hosts	--

The **--** placeholder in the address space for the inbound Send connector represents the authoritative and internal relay accepted domains for the Exchange organization and is the literal character displayed. Any messages that the Edge Transport server receives for authoritative and internal relay accepted domains are routed to this Send connector and relayed to the smart hosts.

The **--** placeholder in the list of smart hosts represents all the Hub Transport servers that are located in the subscribed Active Directory site and is the literal character displayed. Hub Transport servers that are added to an Active Directory site after an Edge Subscription has been established don't participate in the EdgeSync synchronization process. However, they are automatically added to the list of smart hosts for the inbound Send connector. If more than one Hub Transport server is located in the subscribed Active Directory site, inbound connections will be load balanced across the smart hosts.

You can't modify the address space or list of smart hosts for the automatically created inbound Send connector. However, you can set the value of the *CreateInboundSendConnector* parameter to `$false` when creating an Edge Subscription, and manually configure a Send connector from the Edge Transport server to the Exchange organization.

Intra-Organization Send Connector

The intra-organization Send connector is an implicit and hidden Send connector that's automatically computed by Exchange 2010 and enables Hub Transport servers in the same organization to relay messages to each other without using explicit Send connectors. Because a configuration object that has an Active Directory site association exists in Active Directory for an Edge Subscription, the intra-organization Send connector will also be used to relay messages to that Edge Transport server.

Only Hub Transport servers that are located in the same Active Directory site to which the Edge Transport server is subscribed can send and receive e-mail directly to or from the subscribed Edge Transport server. If you have a multiple site forest and Exchange 2010 is deployed in more than one site, the Hub Transport servers in non-subscribed sites will route outbound e-mail to the subscribed site. A Hub Transport server in the subscribed site will route outbound e-mail to the Edge Transport server.

Creating Additional Send Connectors After Edge Subscription is Completed

After an Edge Transport server is subscribed to an Active Directory site, the tasks for creating and modifying Send connectors are disabled on the Edge Transport server. If you want to create a Send connector for which the Edge Transport server is a source server, you create the Send connector inside the Exchange organization. You can specify one or more Edge Subscriptions as the source server for a Send connector. You can't specify both Hub Transport servers and Edge Subscriptions as source servers for the same Send connector. The Send connector will be replicated to the AD LDS instance on the Edge Transport server that's configured as a source server the next time that configuration data is synchronized by the EdgeSync synchronization process. If you list more than one Edge Subscription as a source server, connections to that Send connector will be load balanced between the subscribed Edge Transport servers. However, the Edge Transport

servers have to be subscribed to the same Active Directory site for load balancing to occur. If Edge Subscriptions in different Active Directory sites are configured as source servers on the same Send connector, Hub Transport servers will route only to the closest source server.

You have to create Send connectors manually in the following scenarios:

- You've suppressed automatic creation of the Internet or inbound Send connectors.
- You've accepted domains that are configured as external relay domains.

Suppressing Automatic Creation of Send Connectors

Depending on the topology of your Exchange organization, you may decide to suppress automatic creation of Send connectors. The following scenarios provide examples of topologies that require that you suppress automatic creation of Send connectors.

Partitioning Mail Flow

You may decide to partition the inbound and outbound mail processing between two Edge Transport servers. In this scenario, one Edge Transport server is responsible for processing outbound mail flow and a second Edge Transport server is responsible for processing inbound mail flow. To achieve this scenario, you configure the Edge Subscriptions as follows:

- For the Edge Transport server that processes only outbound mail flow, run the following command in the Shell on the Hub Transport server.

```
New-EdgeSubscription -FileData ([byte[]]$(Get-Content -Path "C:\EdgeSer
```

- For the Edge Transport server that processes only inbound mail flow, run the following command in the Shell on the Hub Transport server.

```
New-EdgeSubscription -FileData ([byte[]]$(Get-Content -Path "C:\EdgeSer
```

Routing Outbound E-Mail to a Smart Host

If your Exchange organization routes all outbound e-mail through a smart host, the default automatically created Send connector to the Internet won't have the correct configuration.

In this scenario, you run the following command in the Shell on the Hub Transport server to suppress automatic creation of the Send connector to the Internet.

```
New-EdgeSubscription -FileData ([byte[]]$(Get-Content -Path "C:\EdgeServerSubscri
```

After the Edge Subscription process is complete, manually create a Send connector to the Internet. Create the Send connector inside the Exchange organization and select the Edge Subscription as the source server for the connector. Select the **Custom** usage and configure one or more smart hosts. The Send connector will be replicated to the AD LDS instance on the Edge Transport server the next time that EdgeSync synchronizes configuration data. You can also force EdgeSync synchronization to immediately start by running the **Start-EdgeSynchronization** cmdlet in the Shell on a Hub Transport server.

The following code provides an example of how to use the Shell to configure a Send connector for a subscribed Edge Transport server to route messages for all Internet address spaces through a smart host. This task is run inside the Exchange organization, not on the Edge Transport server.

```
New-SendConnector -Name "EdgeSync - Site-A to Internet" -Usage Custom -AddressSpa
```

Important:

This example doesn't specify any smart host authentication mechanism. Make sure that you configure the correct authentication mechanism and provide all necessary credentials when you create a smart host connector in your own Exchange organization.

Configuring Send Connectors for External Relay Domains

If you've accepted domains in your Exchange organization that are configured as external relay domains, you have to manually create a Send connector for those address spaces. Messages that are being delivered to external relay domains are relayed by the Edge Transport server. The Edge Subscription process doesn't automatically create and configure Send connectors for external relay domains. Therefore, you have to configure Send connectors for those domains and specify one or more Edge Subscriptions as the source server for those Send connectors.

The DNS MX resource record for an external relay domain resolves to your Edge Transport server. Configure a Send connector that relays e-mail to an external relay domain to use a smart host for routing. If you configure the Send connector for an external relay domain to use DNS routing, a routing loop will occur. For more information about external relay domains, see Understanding Accepted Domains.

Return to top

Microsoft Exchange EdgeSync Service

After you subscribe an Edge Transport server to an Active Directory site, the EdgeSync service that runs on the Hub Transport servers will replicate configuration and recipient data to the Edge Transport servers using the Microsoft Exchange EdgeSync service. The service replicates the following data from Active Directory to AD LDS:

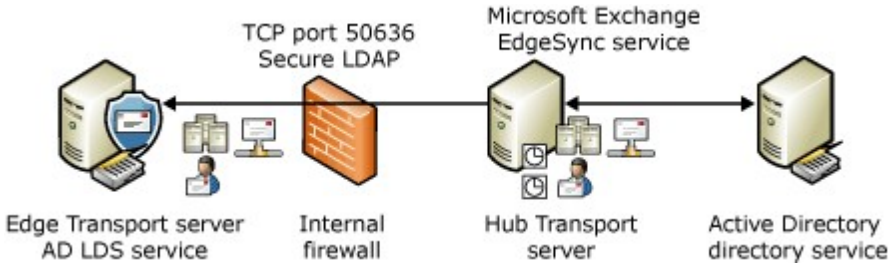
- Send connector configuration
- Accepted domains
- Remote domains
- Message classifications
- Safe Senders Lists
- Blocked Senders Lists
- Recipients
- List of send and receive domains used in domain secure communications with partners
- List of SMTP servers listed as internal in your organization's transport configuration
- List of Hub Transport servers in the subscribed Active Directory site

For more information about the data that's replicated to AD LDS and how it's used, see EdgeSync Replication Data.

The Microsoft Exchange EdgeSync service uses a secure LDAP channel to transfer this data. A mutually authenticated and authorized secure LDAP channel is established from the Hub Transport server to the Edge Transport server.

To replicate data to AD LDS, the Hub Transport server binds to a global catalog server to retrieve updated data. The Microsoft Exchange EdgeSync service initiates a secure LDAP session between a Hub Transport server and the subscribed Edge Transport server over the non-standard TCP port 50636.

The following figure illustrates the EdgeSync synchronization process.



When you first subscribe an Edge Transport server to an Active Directory site, the initial replication that populates AD LDS with data from Active Directory can take some time, depending on the quantity of data in the directory service. After the initial replication is complete, the EdgeSync service only synchronizes the new and changed objects and removes any objects that have been deleted from Active Directory.

Synchronization Schedule

Different types of data synchronize on different schedules. The EdgeSync synchronization schedule specifies the maximum length of time between EdgeSync synchronization intervals. EdgeSync synchronization occurs at the following intervals:

- Configuration data is scheduled to be synchronized at 3-minute intervals.
- Recipient data is scheduled to be synchronized at 5-minute intervals.
- Topology data is reloaded every 5 minutes.

You use the **Set-EdgeSyncServiceConfig** cmdlet to configure the EdgeSync synchronization schedule intervals. If you use the **Start-EdgeSynchronization** cmdlet in the Shell on the Hub Transport server to force Edge Subscription synchronization to occur immediately, you override the timer that determines the next time that EdgeSync synchronization is scheduled to occur.

Selection of Hub Transport Server

A subscribed Edge Transport server is associated with a particular Active Directory site. If more than one Hub Transport server exists in the site, any of them can replicate data to the subscribed Edge Transport servers. To avoid contention among the Hub Transport servers when synchronizing, the selection of the preferred Hub Transport server occurs as follows:

1. The first Hub Transport server in the Active Directory site to perform a topology scan and discover the new Edge Subscription performs the initial replication. Because this discovery is based on the timing of the topology scan, any Hub Transport server in the site may perform the initial replication.
2. The Hub Transport server that performs the initial replication establishes an EdgeSync lease option and sets a lock on the Edge Subscription. The lease option establishes that Hub Transport server as the preferred server to provide synchronization services to that Edge Transport server. The lock prevents the Microsoft Exchange EdgeSync service on another Hub Transport server from taking over the lease option.
3. The EdgeSync lease option lasts for one hour. No other Microsoft Exchange EdgeSync service can take over the option from another Hub Transport server during this one-hour period unless a manual synchronization occurs before this period expires. If the preferred Hub Transport server isn't available to provide the Microsoft Exchange EdgeSync service when manual synchronization is performed, after a five-minute wait, the lock is released and another Microsoft Exchange EdgeSync service takes over the lease option and performs synchronization.
4. If manual synchronization isn't performed, synchronization occurs based on the EdgeSync synchronization schedule. If the preferred server isn't available when scheduled synchronization occurs, after a five-minute wait, the lock is released and another Microsoft Exchange EdgeSync service takes over the lease option and performs synchronization.

This method of locking and leasing prevents more than one instance of the Microsoft Exchange EdgeSync service from pushing data to the same Edge Transport server at the same time.

Note:

If you have both Exchange 2010 and Exchange Server 2007 Hub Transport servers in the Active Directory site to which your Edge Transport server is subscribed, Exchange 2010 Hub Transport servers will always take precedence over Exchange 2007 Hub Transport servers.

Note:

When an Edge Transport server is subscribed to an Active Directory site, all the Hub Transport servers that are installed in that Active Directory site at that time can participate in the EdgeSync synchronization process. If one of those servers is removed, the Microsoft Exchange EdgeSync service that's running on the remaining Hub Transport servers will continue the data synchronization process. However, if new Hub Transport servers are installed in the Active Directory site, they won't participate in the EdgeSync synchronization process automatically. To enable those Hub Transport servers to participate in the EdgeSync synchronization process, you have to subscribe the Edge Transport server again.

The following table lists the EdgeSync properties that are related to the locking and leasing process. You can use the **Set-EdgeSyncServiceConfig** cmdlet to configure these properties.

EdgeSync lease properties

Property name	Value	Description
Lock duration	5 minutes	This setting determines for how long a particular Microsoft Exchange EdgeSync service will acquire a lock. If the Microsoft Exchange EdgeSync service on the Hub Transport server that's holding this lock doesn't respond, it will take five minutes for the Microsoft Exchange EdgeSync service on another Hub Transport server to take over the lease. Forcing EdgeSync synchronization doesn't override this value.
Option duration	1 hour	This setting determines for how long a Microsoft Exchange EdgeSync service can declare a lease option on an Edge Transport server. If the Microsoft Exchange EdgeSync service holding the lease is unavailable and doesn't restart during this option period, no other Microsoft Exchange EdgeSync service will take over the lease option, unless you force EdgeSync

		synchronization.
Lock renewal	1 minute	This setting determines how frequently the lock field is updated when a Microsoft Exchange EdgeSync service has acquired a lock to an Edge Transport server.

Preparing to Run the EdgeSync Service

Before you can subscribe your Edge Transport server to your Exchange organization, you must make sure that your infrastructure and your Hub Transport servers are prepared for the EdgeSync service. The following list summarizes the things you need to do to prepare for EdgeSync synchronization:

- Verify that the perimeter network firewall that separates the Edge Transport server from the Exchange organization is configured to enable communications through the correct ports. The Edge Transport server uses non-standard LDAP ports. You can modify the ports that are used by AD LDS by using the ConfigureAdam.ps1 script that's provided with Exchange 2010 if your environment requires specific ports. For more information, see Modify AD LDS Configuration. However, don't modify the ports after you create the Edge Subscription. If you modify the ports after you create the Edge Subscription, you must remove the Edge Subscription and then create a subscription. By default, the following LDAP ports are used to access AD LDS:
  - **LDAP** Port 50389/TCP is used locally to bind to the AD LDS instance. This port doesn't have to be open on the perimeter network firewall.
  - **Secure LDAP** Port 50636/TCP is used for directory synchronization from Hub Transport servers to AD LDS. This port must be open for successful EdgeSync synchronization.
- Verify that DNS host name resolution is successful from the Edge Transport server to the Hub Transport servers, and from the Hub Transport servers to the Edge Transport server.
- License the Edge Transport server. The licensing information for the Edge Transport server is captured when the Edge Subscription is created and is shown in the EMC for the Exchange organization. For subscribed Edge Transport servers to appear as licensed, they must be subscribed to the Exchange organization after the license key is applied on the Edge Transport server. If the license key is applied on the Edge Transport server after you perform the Edge Subscription process, the licensing information isn't updated in the Exchange organization, and you must resubscribe the Edge Transport server.
- Configure the following settings for propagation to the Edge Transport server role:
  - **Internal SMTP servers** Use the **Set-TransportConfig** cmdlet to configure the *InternalSMTPServers* parameter. This parameter specifies a list of internal SMTP server IP addresses or IP address ranges that should be ignored by Sender ID and connection filtering.
  - **Accepted domains** Configure all authoritative domains, internal relay domains, and external relay domains.
  - **Remote domains** Configure remote domain settings.

Return to top

Managing Edge Subscriptions

This section provides background information about various Edge Subscription management tasks. For step-by-step instructions, see Managing Edge Subscriptions.

Adding an Edge Transport Server

You can subscribe one or more Edge Transport servers to a single Active Directory site. If you deploy additional Edge Transport servers in your perimeter network and subscribe them to the same Active Directory site where an Edge Subscription already exists, the following actions occur:

- A new Edge Subscription object is created in Active Directory.
- Additional ESRA accounts are created for each Hub Transport server in the Active Directory site. These accounts are replicated to AD LDS and used by the EdgeSync synchronization process during synchronization with the new server.
- The new Edge Subscription is added to the source server list of the automatic Send connector to the Internet. Messages submitted to that connector for processing will be load balanced between the subscribed Edge Transport servers.
- An inbound Send connector from the Edge Transport server to the Exchange organization is automatically created.
- EdgeSync synchronization to the Edge Transport server starts.

For detailed steps about creating an Edge Subscription, see the following topics:

- Create an Edge Subscription File on an Edge Transport Server
- Import an Edge Subscription File to an Active Directory Site

Adding or Removing a Hub Transport Server

If a Hub Transport server is added to the Active Directory site to which an Edge Transport server is already subscribed, it doesn't automatically participate in the EdgeSync synchronization process. To enable a newly deployed Hub Transport server to participate in the EdgeSync synchronization process, you must resubscribe each Edge Transport server to the Active Directory site.

Removing a Hub Transport server from an Active Directory site where an Edge Transport server is subscribed won't affect EdgeSync synchronization, unless that Hub Transport server is the last Hub Transport server in that site. If you remove all Hub Transport servers from the Active Directory site where an Edge Transport server is subscribed, the subscribed Edge Transport servers are orphaned.

Resubscribing an Edge Transport Server

Occasionally you may have to resubscribe an Edge Transport server to an Active Directory site. When the Edge Subscription is re-created, new credentials are generated and the complete Edge Subscription process must be followed. This process is used in the following scenarios:

- New Hub Transport servers have been deployed in the subscribed Active Directory site, and you want the new server to participate in EdgeSync synchronization.
- The license key for the Edge Transport server was applied after the Edge Subscription was created. The licensing information for the Edge Transport server is captured when the Edge Subscription is created and is shown in the EMC for the Exchange organization. For subscribed Edge Transport servers to appear as licensed, they must be subscribed to the Exchange organization after the license key is applied on the Edge Transport server. If the license key is applied on the Edge Transport server after you perform the Edge Subscription process, the licensing information isn't updated in the Exchange organization and you must resubscribe the Edge Transport server.
- The ESRA credentials are compromised.

Important:

To resubscribe an Edge Transport server, export a new Edge Subscription file on the Edge Transport server and then import the XML file on a Hub Transport server. You must resubscribe the Edge Transport server to the same Active

Directory site to which it was originally subscribed. You don't have to first remove the original Edge Subscription. The resubscription process will overwrite the existing Edge Subscription.

Removing an Edge Subscription

There are some scenarios where you may have to remove an Edge Subscription from the Exchange organization or from both the Exchange organization and the Edge Transport server. If the Edge Transport server will be resubscribed to the Exchange organization, don't remove the Edge Subscription from the Edge Transport server. When you remove the Edge Subscription from an Edge Transport server, all replicated data is deleted from AD LDS. This can take a long time if you have lots of recipient data.

The following list provides examples of situations that require you to remove the Edge Subscription.

- You no longer want the Edge Transport server to participate in the EdgeSync synchronization process. In this scenario, you must remove the Edge Subscription from both the Edge Transport server and from the Exchange organization.
- An Edge Transport server is being decommissioned. In this scenario, you must remove the Edge Subscription from the Exchange organization only. If you uninstall the Edge Transport server role from the computer, the AD LDS instance and all Active Directory data that's stored in AD LDS is also removed.
- You want to change the Active Directory site association for the Edge Subscription. In this scenario, you must remove the Edge Subscription from only the Exchange organization. After the Edge Subscription is removed from the Exchange organization, you can resubscribe the Edge Transport server to a different Active Directory site.

When you remove the Edge Subscription from the Exchange organization, the effect is as follows:

- Synchronization of information from Active Directory to AD LDS stops.
- The ESRA accounts are removed from both Active Directory and AD LDS.
- The computer that has the Edge Transport server role installed is removed from the source server list of any Send connector.
- The automatic inbound Send connector from the Edge Transport server to the Exchange organization is removed from AD LDS.

When you remove the Edge Subscription from an Edge Transport server, the effect is as follows:

- You can no longer use the Edge Transport server features that rely on Active Directory data.
- Replicated data is removed from AD LDS.
- The tasks that were disabled when the Edge Subscription was created are enabled again to allow for local configuration.

For step-by-step instructions about how to remove an Edge Subscription, see Remove an Edge Subscription.

Verifying EdgeSync Results

You can use the **Test-EdgeSynchronization** diagnostic cmdlet to verify that the edge synchronization is working. This cmdlet provides a report of the synchronization status of subscribed Edge Transport servers. It can be run manually or called by Microsoft System Center Operations Manager 2007. When the task is called by System Center Operations Manager 2007, alerts are generated if an Edge Transport server isn't synchronized.

The output of this cmdlet lets you view which objects haven't been synchronized to the Edge Transport server. The task compares the data that's stored in Active Directory and the data that's stored in AD LDS. Any inconsistencies in data are reported in the results output by this command.

You can use the *ExcludeRecipientTest* parameter with the **Test-EdgeSynchronization** cmdlet to exclude validation of recipient data synchronization. If you include this parameter, only the synchronization of configuration objects is validated. Validating that recipient data is synchronized will take longer than validating only configuration data.

For detailed steps, see Verify EdgeSync Results for a Recipient.

1.7.1.13.1 EdgeSync Replication Data

EdgeSync Replication Data

Transport > Understanding Transport > Understanding Edge Subscriptions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The computer that has the Edge Transport server role installed doesn't have access to Active Directory. To perform recipient lookup and safelist aggregation tasks, and to implement domain security by using mutual Transport Layer Security (TLS) authentication, the Edge Transport server requires data that resides in Active Directory. This data is replicated to the Edge Transport server using the EdgeSync process and the Edge Transport server stores all replicated information in Active Directory Lightweight Directory Services (AD LDS).

This topic focuses on the data that's replicated from Active Directory to the AD LDS instance on a Microsoft Exchange Server 2010 Edge Transport server when the Edge Transport server is subscribed to an Active Directory site. To learn more about the EdgeSync process and Edge Subscriptions, see Understanding Edge Subscriptions.

The following data are replicated from Active Directory to AD LDS:

- Edge Subscription information
- Configuration information
- Recipient information
- Topology information

The following sections describe these types of data and the way they're used by the Edge Transport server.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Edge Subscription Information

Exchange 2010 extends both the Active Directory and AD LDS schemas to provide attributes on the **ms-Exch-ExchangeServer** object to represent the data needed to control the EdgeSync synchronization process. These attributes provide the following three functions that are important to the EdgeSync synchronization process:

- They provide automatic provisioning and maintenance of the credentials that are used to help secure the LDAP connection between a Hub Transport server and a subscribed Edge Transport server.
- They arbitrate the synchronization lock and lease process that makes sure that only one Hub Transport server at a time will try to synchronize with an individual Edge Transport server. For more information about the lock and

lease process, see Understanding Edge Subscriptions.
- They optimize the EdgeSync synchronization process to maintain a record of the current synchronization status and avoid excessive manual synchronization.

The following table lists the schema extensions that are specific to Edge Subscriptions. The values assigned to these attributes are maintained by the Edge Subscription and EdgeSync synchronization process. You shouldn't manually edit these attributes by using editing tools, such as Ldp.exe or Active Directory Service Interfaces (ADSI) Edit.

Edge Subscription schema extensions

Attribute name	Description
ms-Exch-Server-EKPK-Public-Key	This attribute represents the current public key for the certificate being used by the server. This value is stored by both Edge Transport servers and Hub Transport servers. The public key is used to encrypt the credentials that are used to authenticate the server during LDAP and SMTP communication.
ms-Exch-EdgeSync-Credential	This attribute represents the list of credentials that the Microsoft Exchange EdgeSync service uses to establish an authenticated LDAP session to AD LDS. On Hub Transport servers, this attribute contains only the credentials that the Hub Transport server uses to authenticate to the subscribed Edge Transport servers. On Edge Transport servers, this attribute contains the credentials of each Hub Transport server in the subscribed Active Directory site that participates in the EdgeSync synchronization process. This attribute is only present on Hub Transport servers that run the EdgeSync synchronization process and on subscribed Edge Transport servers.
ms-Exch-Edge-Sync-Lease	This attribute is used to arbitrate between Hub Transport servers when more than one Hub Transport server tries to replicate to the same Edge Transport server.
ms-Exch-Edge-Sync-Status	This attribute is only present in AD LDS on the Edge Transport server object. This attribute tracks the status of replication to an AD LDS instance and includes information about replication.

Configuration Information

When you subscribe an Edge Transport server to the organization, you can manage the configuration objects that are common to the Edge Transport server and the Exchange organization from inside the organization. These changes are then replicated to the Edge Transport server by using the Microsoft Exchange EdgeSync service. This process helps maintain a consistent configuration across all servers involved in message processing.

A subset of the configuration data for the Exchange organization must also be maintained on the Edge Transport server. During the EdgeSync synchronization process, the

configuration data that the Edge Transport server needs is written to the configuration partition of AD LDS. The configuration data written to AD LDS includes the following:

- **Hub Transport servers** The fully qualified domain name (FQDN) of each Hub Transport server in the subscribed Active Directory site is made available to the local AD LDS store on the Edge Transport server. This information is used to derive a list of smart host servers for the inbound Send connector.
- **Accepted domains** All authoritative, internal relay, and external relay domains configured for the Exchange organization are written to AD LDS. Having the accepted domains available to the Edge Transport server enables the Exchange organization to perform domain filtering and reject invalid SMTP traffic into their organization as early as possible. For more information about accepted domains, see Understanding Accepted Domains.
- **Message classifications** If message classifications are available on the Edge Transport server, transport agents and content conversion can act on message classifications in the perimeter network. For example, the Attachment Filter agent can apply the Attachment Removed classification when it removes an attachment. Therefore, informational text will be displayed to a Microsoft Outlook user or a Microsoft Office Outlook Web App user to tell the recipient what happened. Agents that are developed for use by third-party applications can use message classifications in a similar manner. Also, message classifications may have to be translated by the Edge Transport server from a GUID in an X-header to Transport Neutral Encapsulation Format (TNEF) as a localized recipient description.
- **Remote domains** All remote domain policies configured for the Exchange organization are written to AD LDS. Remote domain policies control out-of-office message settings and message format settings for a remote domain. For more information about remote domains, see Understanding Remote Domains.
- **Send connectors** By default, Send connectors required to enable end-to-end mail flow between the Exchange organization and the Internet are automatically created. Any existing Send connectors on the Edge Transport server are deleted. If you want to configure additional Send connectors, you configure the Send connector inside the Exchange organization and select the Edge Subscription as the source server for the connector. For more information, see Understanding Edge Subscriptions.
- **Internal SMTP servers** The value for the **InternalSMTPServers** attribute is stored on the **TransportConfig** object for both the Exchange organization and the local Edge Transport server. During the EdgeSync synchronization process, the value that's stored on the local Edge Transport server object is overwritten with the value that's stored on this object for the Exchange organization. This attribute specifies a list of internal SMTP server IP addresses or IP address ranges that should be ignored by Sender ID and connection filtering.
- **Domain Secure lists** The **TLSReceiveDomainSecureList** and the **TLSSendDomainSecureList** attributes are stored on the **TransportConfig** object for both the Exchange organization and the local Edge Transport server. During the EdgeSync synchronization process, the value that's stored on the local Edge Transport server object is overwritten with the value that's stored on this object for the Exchange organization. These attributes specify the list of remote domains that are configured for mutual TLS authentication.

Recipient Information

The recipient information that's replicated to AD LDS includes only a subset of the recipient attributes. Only the data that the Edge Transport server must have to perform certain anti-spam tasks is replicated. The recipient information replicated to AD LDS includes the following:

- **Recipients** The list of recipients in the Exchange organization is replicated to AD LDS. Each recipient is identified by the GUID assigned to it in Active

Directory. If you configure a recipient's user account to deny receipt of mail from outside the organization, the recipient isn't replicated to AD LDS. If you disable or delete the mailbox for a recipient, it isn't replicated to AD LDS.

- **Proxy addresses** All proxy addresses assigned to each recipient are replicated to AD LDS as hashed data. This is a one-way hash that uses Secure Hash Algorithm (SHA)-256. SHA-256 generates a 256-bit message digest of the original data. Storing proxy addresses as hashed data helps secure this information in case the Edge Transport server or AD LDS is compromised. Proxy addresses are referenced when the Edge Transport server performs the recipient lookup anti-spam task.
- **Safe Senders List, Blocked Senders List, and Safe Recipients List** The Safe Senders Lists, Blocked Senders Lists and Safe Recipients Lists that are defined in each recipient's Outlook instance are aggregated and replicated to AD LDS. These settings are stored on the mailbox store where the recipient's mailbox resides. An Outlook user's safelist collection is the combined data from the user's Safe Senders List, Safe Recipients List, Blocked Senders List, and external contacts. Having safelist collection data available in AD LDS enables the Edge Transport server to screen senders appropriately, reducing the operational overhead involved with filtering mail. This information is sent as hashed data.

  Important:
  Although the safe recipient data is stored in Outlook and can be aggregated into the safelist collection on the AD LDS instance on the Edge Transport server, the content filtering functionality doesn't act on safe recipient data.

- **Per recipient anti-spam settings** By using the **Set-Mailbox** cmdlet, you can assign anti-spam threshold settings per recipient that differ from the organization-wide anti-spam settings. If you configure per recipient anti-spam settings, these settings override the organization-wide settings. By replicating these settings to AD LDS, the per recipient settings can be considered before the message is relayed to the Exchange organization. This information is sent as hashed data.

Topology Information

The topology information includes notification of newly subscribed Edge Transport servers or removed Edge Subscriptions. This data is refreshed every five minutes.

1.7.1.13.2 Understanding Edge Subscription Credentials

Understanding Edge Subscription Credentials

Transport > Understanding Transport > Understanding Edge Subscriptions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

This topic explains how the Edge Subscription process provisions the credentials that are used to help secure the EdgeSync synchronization process in Microsoft Exchange Server 2010 and how the Microsoft Exchange EdgeSync service uses those credentials to establish a secure LDAP connection between a Hub Transport server and an Edge Transport server. To learn more about the Edge Subscription process, see Understanding Edge Subscriptions.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Edge Subscription Process

The Edge Transport server is subscribed to an Active Directory site to establish a synchronization relationship between the Hub Transport servers in an Active Directory site and the subscribed Edge Transport server. The credentials that are provisioned during the Edge Subscription process are used to help secure the LDAP connection between a Hub Transport server and an Edge Transport server in the perimeter network.

When you run the **New-EdgeSubscription** cmdlet in the Exchange Management Shell on an Edge Transport server, the EdgeSync bootstrap replication account (ESBRA) credentials are created in the Active Directory Lightweight Directory Services (AD LDS) directory on the local server and then written to the Edge Subscription file. These credentials are used only to establish the initial synchronization and will expire 1,440 minutes (24 hours) after the Edge Subscription file is created. If the Edge Subscription process isn't completed within that time, you must run the **New-EdgeSubscription** cmdlet in the Shell on the Edge Transport server again to create an Edge Subscription file.

The following table describes the data contained in the Edge Subscription XML file.

Edge Subscription file contents

Subscription data	Description
EdgeServerName	The NetBIOS name of the Edge Transport server. The name of the Edge Subscription in Active Directory will match this name.
EdgeServerFQDN	The fully qualified domain name (FQDN) of the Edge Transport server. The Hub Transport servers in the subscribed Active Directory site must be able to locate the Edge Transport server by using Domain Name System (DNS) to resolve the FQDN.
EdgeCertificateBlob	The public key of the Edge Transport server's self-signed certificate.
ESRAUsername	The name assigned to the ESBRA. The ESBRA account has the following format: ESRA.*Edge Transport server name*. ESRA means EdgeSync replication account.
ESRAPassword	The password assigned to the ESBRA. The password is generated by using a random number generator and is stored in the Edge Subscription file in clear text.

EffectiveDate	The creation date of the Edge Subscription file.
Duration	The length of time that these credentials will be valid before they expire. The ESBRA account is valid for only 24 hours.
AdamSslPort	The secure LDAP port to which the EdgeSync service binds when synchronizing data from Active Directory to AD LDS. By default, this is TCP port 50636.
ProductID	The licensing information for the Edge Transport server. After an Edge Transport server is subscribed to Active Directory, the licensing information about the Edge Transport server is displayed in the Exchange Management Console for the Exchange organization. You must license the Edge Transport server before you create the Edge Subscription for this information to be displayed correctly.
VersionNumber	The version number of the Edge Subscription file.
SerialNumber	The version of Exchange Server that is installed on the Edge Transport server.

Important:
The ESBRA credentials are written to the Edge Subscription file in clear text. You must protect this file throughout the subscription process. After the Edge Subscription file is imported to your Exchange organization, you should immediately delete the Edge Subscription file from the Edge Transport server, the network share you used to import the file to your Exchange organization, and any removable media.

Return to top

EdgeSync Replication Accounts

EdgeSync replication accounts (ESRA) are an important part of EdgeSync security. Authentication and authorization of the ESRA is the mechanism used to help secure the connection between an Edge Transport server and a Hub Transport server.

The ESBRA contained in the Edge Subscription file is used to establish a secure LDAP connection during the initial synchronization. After the Edge Subscription file is imported to a Hub Transport server in the Active Directory site to which the Edge Transport server is being subscribed, additional ESRA accounts are created in Active Directory for each Edge Transport-Hub Transport server pair. During initial synchronization, the newly created ESRA credentials are replicated to AD LDS. These ESRA credentials are used to help secure later synchronization sessions.

Each EdgeSync replication account is assigned the properties described in the following table.

Ms-Exch-EdgeSyncCredential properties

Property name	Type	Description
TargetServerFQDN	String	The Edge Transport server

		that will accept these credentials.
SourceServerFQDN	String	The Hub Transport server that will present these credentials. This value is empty if the credential is the bootstrap credential.
EffectiveTime	DateTime (UTC)	When to start using this credential.
ExpirationTime	DateTime (UTC)	When to stop using this credential.
UserName	String	The user name that's used to authenticate.
Password	Byte	The password that's used to authenticate. The password is encrypted by using **ms-Exch-EdgeSync-Certificate**.

The following sections of this topic describe how the ESRA credentials are provisioned and used during the EdgeSync synchronization process.

Provisioning the EdgeSync Bootstrap Replication Account

When the **New-EdgeSubscription** cmdlet is run on the Edge Transport server, the ESBRA is provisioned as follows:

- A self-signed certificate (Edge-Cert) is created on the Edge Transport server. The private key is stored in the local computer store and the public key is written to the Edge Subscription file.
- The ESBRA (ESRA.Edge) is created in AD LDS, and the credentials are written to the Edge Subscription file.
- The Edge Subscription file is exported by copying it to removable media. The file is now ready to import to a Hub Transport server.

Provisioning EdgeSync Replication Accounts in Active Directory

When the Edge Subscription file is imported on a Hub Transport server, the following steps occur to establish a record of the Edge Subscription in Active Directory and to provision additional ESRA credentials.

1. An Edge Transport server configuration object is created in Active Directory. The Edge-Cert certificate is written to this object as an attribute.
2. Every Hub Transport server in the subscribed Active Directory site receives an Active Directory notification that a new Edge Subscription has been registered. As soon as the notification is received, each Hub Transport server retrieves the ESRA.Edge account and encrypts the account by using the Edge-Cert public key. The encrypted ESRA.Edge account is written to the Edge Transport server configuration object.
3. Each Hub Transport server creates a self-signed certificate (Hub-Cert). The private key is stored in the local computer store and the public key is stored in the Hub Transport server configuration object in Active Directory.
4. Each Hub Transport server encrypts the ESRA.Edge account by using the public key of its own Hub-Cert certificate and then stores it in its own configuration object.
5. Each Hub Transport server generates an ESRA for each existing Edge Transport server configuration object in Active Directory (ESRA.Hub.Edge). The account name is generated by using the following naming convention: ESRA.*<Hub Transport server NetBIOS Name>*.*<Edge Transport server NetBIOS Name>*.*<Effective Date UTC Time>*

Example: ESRA.Hub.Edge.01032010
The password for ESRA.Hub.Edge is generated by a random number generator and is encrypted by using the public key of the Hub-Cert certificate. The generated password has the maximum length allowed for Microsoft Windows Server.

6. Each ESRA.Hub.Edge account is encrypted by using the public key of the Edge-Cert certificate and is stored on the Edge Transport server configuration object in Active Directory.

The following sections of this topic explain how these accounts are used during the EdgeSync synchronization process.

Return to top

Authenticating Initial Replication

The ESBRA account, ESRA.Edge, is used only when establishing the initial synchronization session. During the first EdgeSync synchronization session, the additional ESRA accounts, ESRA.Hub.Edge, are replicated to AD LDS. These accounts are used to authenticate later EdgeSync synchronization sessions.

The Hub Transport server that performs the initial replication is determined randomly. The first Hub Transport server in the Active Directory site to perform a topology scan and discover the new Edge Subscription performs the initial replication. Because this discovery is based on the timing of the topology scan, any Hub Transport server in the site may perform the initial replication.

The Microsoft Exchange EdgeSync service initiates a secure LDAP session from the Hub Transport server to the Edge Transport server. The Edge Transport server presents its self-signed certificate and the Hub Transport server verifies that the certificate matches the certificate that's stored on the Edge Transport server configuration object in Active Directory. After the Edge Transport server's identity is verified, the Hub Transport server provides the credentials of the ESRA.Edge account to the Edge Transport server. The Edge Transport server verifies the credentials against the account that's stored in AD LDS.

The Microsoft Exchange EdgeSync service on the Hub Transport server then pushes the topology, configuration, and recipient data from Active Directory to AD LDS. The change to the Edge Transport server configuration object in Active Directory is replicated to AD LDS. AD LDS receives the newly added ESRA.Hub.Edge entries and the Microsoft Exchange Credential Service creates the corresponding AD LDS account. These accounts are now available to authenticate later scheduled EdgeSync synchronization sessions.

Microsoft Exchange Credential Service

The Microsoft Exchange Credential Service is part of the Edge Subscription process. It runs only on the Edge Transport server. This service creates the reciprocal ESRA accounts in AD LDS so that a Hub Transport server can authenticate to an Edge Transport server to perform EdgeSync synchronization. The Microsoft Exchange EdgeSync service doesn't communicate directly with the Microsoft Exchange Credential Service. The Microsoft Exchange Credential Service communicates with AD LDS and installs the ESRA credentials whenever the Hub Transport server updates them.

Return to top

Authenticating Scheduled Synchronization Sessions

After initial EdgeSync synchronization finishes, the EdgeSync synchronization schedule is

established and data that has changed in Active Directory is regularly updated in AD LDS. A Hub Transport server initiates a secure LDAP session with the AD LDS instance on the Edge Transport server. AD LDS proves its identity to that Hub Transport server by presenting its self-signed certificate. The Hub Transport server presents its ESRA.Hub.Edge credentials to AD LDS. The ESRA.Hub.Edge password is encrypted by using the Hub Transport server's self-signed certificate's public key. This means that only that particular Hub Transport server can use those credentials to authenticate to AD LDS.

Return to top

Renewing EdgeSync Replication Accounts

The password for the ESRA account must comply with the local server's password policy. To prevent the password renewal process from causing temporary authentication failure, a second ESRA.Hub.Edge account is created seven days before the first ESRA.Hub.Edge account expires with an effective time that's three days before the first ESRA expiration time. As soon as the second ESRA account becomes effective, EdgeSync stops using the first account and starts to use the second account. When the expiration time for the first account is reached, those ESRA credentials are deleted. This renewal process will continue until the Edge Subscription is removed.

Return to top

1.7.1.14 Understanding Edge Transport Server Cloned Configuration

Understanding Edge Transport Server Cloned Configuration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Microsoft Exchange Server 2010 Edge Transport server role stores its configuration information in Active Directory Lightweight Directory Services (AD LDS). You can install more than one Edge Transport server in the perimeter network and use Domain Name System (DNS) round robin, a simple mechanism that's used by DNS servers to share and distribute loads for network resources, to help balance network traffic among the Edge Transport servers.

To make sure that all Edge Transport servers that you deploy are using the same configuration information, you can use the provided cloned configuration scripts in the Exchange Management Shell to duplicate the configuration of a source server to a target server.

You use *cloned configuration* to deploy new Edge Transport servers based on a configured source server. The configuration information for the source server is duplicated and then exported to an XML file. The XML file is then imported to the target server.

This topic provides an overview of the cloned configuration process. For detailed steps about configuring your Edge Transport servers using cloned configuration, see Configure Edge Transport Server Using Cloned Configuration.

Cloned Configuration and EdgeSync

Run the EdgeSync process after you import the cloned configuration. To perform recipient lookup and message security tasks, the computer that has the Edge Transport server role

installed requires data that resides in Active Directory. *EdgeSync* is a collection of processes that are run on a computer that has the Hub Transport server role installed to establish one-way replication of recipient and configuration information from Active Directory to the AD LDS instance on an Edge Transport server. The Microsoft Exchange EdgeSync service copies only the information that's required for the Edge Transport server to perform anti-spam tasks and the information about the connector configuration that's required to enable end-to-end mail flow. The Microsoft Exchange EdgeSync service performs scheduled updates so that the information in AD LDS remains current.

Cloned configuration doesn't duplicate the Edge Subscription settings of a server. The certificates that are used by the Microsoft Exchange EdgeSync service aren't cloned. You must run the EdgeSync process separately for each Edge Transport server. The Microsoft Exchange EdgeSync service overwrites any settings that are included in both cloned configuration information and in EdgeSync replication information. These settings include Send connectors, Receive connectors, accepted domains, and remote domains.

Cloned Configuration Process

The cloned configuration process consists of three steps:

1. Export the configuration on the source server.
   In this step, you run the ExportEdgeConfig.ps1 script to export the source server's configuration information to an intermediate XML file.
2. Validate the configuration on the target server.
   In this step, you run the ImportEdgeConfig.ps1 script. This script checks the existing information in the intermediate XML file to see whether the settings that were exported are valid for the target server and then creates an answer file. The answer file specifies the server-specific information that's used during the next step when you import the configuration on the target server. The answer file contains entries for each source server setting that isn't valid for the target server. You can modify these settings so that they're valid for the target server. If all settings are valid, the answer file contains no entries.
3. Import the configuration on the target server.
   In this step, the ImportEdgeConfig.ps1 script uses the intermediate XML file and the answer file to clone an existing configuration or to restore the server to a specific configuration.

These steps are described in detail in the following sections.

Step 1: Export the Configuration

After you install and configure the Edge Transport server role, run the ExportEdgeConfig.ps1 script. This script retrieves the source server's configuration information and stores the information in an intermediate XML file.

The following information is exported from the source server and stored in the intermediate XML file:

- Transport server-related information and log file path information. The following file paths are exported:
  - ReceiveProtocolLogPath
  - SendProtocolLogPath
  - MessageTrackingLogPath
  - PickupDirectoryPath
  - RoutingTableLogPath
- Transport agent-related information that includes the status and priority settings of each transport agent.
- All Send connector-related information. If any Send connectors are configured to use credentials, the password is written to the intermediate XML file as an encrypted string. You can use the *-key* parameter with the ImportEdgeConfig.ps1 and ExportEdgeConfig.ps1 scripts to specify the 32-

byte string to use for password encryption and decryption. If you don't use the *-key* parameter, a default encryption key is used.
- Receive connector-related information. To modify the local network binding and port properties, you must modify the configuration information in the answer file that's created in the validate configuration step.
- Accepted domain configuration.
- Remote domain configuration.
- Anti-spam features configuration settings. The following information is exported:
  - IP Allow list information. Only the IP Allow list entries that were manually configured by the administrator are exported.
  - IP Block list information.
  - Content filter configuration.
  - Recipient filter configuration.
  - Address rewrite entries.
  - Attachment filter entries.

Step 2: Validate the Configuration

The target server is an Exchange 2010 server that has a clean installation of the Edge Transport server role. Run the ImportEdgeConfig.ps1 script on the target server to validate the existing information in the intermediate XML file and to create the answer file. The answer file specifies the server-specific information that's used during the next step in the cloned configuration process when you import the configuration on the target server. The answer file contains entries for each source server setting that isn't valid for the target server. You can modify these settings so that they're valid for the target server. If all settings are valid, the answer file contains no entries. The intermediate XML file can be used for different target servers. The answer file is specific to a target server.

The ImportEdgeConfig.ps1 script performs the following tasks during this step:

- The script verifies that the data paths and log paths can be created on the target server. If the paths can't be created, a blank path is inserted into the answer file.
- For each Send connector in the XML file, the script adds a blank entry for the source IP address in the answer file.
- For each Receive connector in the XML file, the script adds a blank entry for the local network bindings in the answer file.

You must manually modify the answer file to provide the following information about server-specific settings:

- Fill in the data paths and log paths. If these paths are left blank in the answer file, the paths that are configured in the intermediate XML file are used in the next step when you import the configuration on the target server.
- For each Send connector entry, fill in the source IP address. If this field is left blank, an error occurs in the import configuration step.
- For each Receive connector entry, fill in the local network bindings. If the local network bindings are left blank, an error occurs in the next step when you import the configuration on the target server.

Step 3: Import the Configuration

Perform this step on any target server to clone the configuration of an existing Edge Transport server or to restore the server to a specific configuration. Run the ImportEdgeConfig.ps1 script to validate and import the new configuration. After you run this script, the target server's configuration matches the settings in the intermediate XML file and the answer file.

Important:

It's a best practice to back up the existing server configuration before you run the import configuration process, so that if the cloning operation fails, the server can be restored to the previous stable state.

This step uses the server-specific information that's provided in the answer file. If a setting isn't specified in the answer file, the data in the intermediate XML file is used. Before the script modifies the configuration, the script validates the data in the intermediate XML file and the answer file.

The following configuration settings of the target server are modified during the import configuration step:

- The transport agent configuration is modified.
- The existing connectors on the target server are removed, and the connectors that are present in the intermediate XML file are added.
- The existing accepted domains are removed, and the accepted domain entries in the intermediate XML file are added.
- The existing remote domains are removed, and the remote domain entries in the intermediate XML file are added.
- The existing IP Allow list entries are removed, and the IP Allow list entries in the intermediate remote domains file are added.
- The existing IP Block list entries are removed, and the IP Block list entries in the intermediate remote domains file are added.
- The following anti-spam configuration is cloned to the target server:
  - Content filter configuration
  - Recipient filter configuration
  - Address rewrite entries
  - Attachment filter entries

Transport Configuration Information

The settings of the transport configuration object define server-wide e-mail transport settings for an Edge Transport server. When you import the intermediate XML file to the target server, all the settings of the transport configuration object except for the following are imported:

- General names and creation dates from the exported XML file
- Send connector information
- Receive connector information
- Attachment filter entries
- The **MaxDumpsterSizePerStorageGroup** attribute entry

After the import process is complete, you may also configure the settings by using the **Set-TransportConfig** cmdlet. For more information, see Set-TransportConfig.

The following table describes the attributes that are associated with the transport configuration object and the default values. You configure this object on both Hub Transport servers and Edge Transport servers. However, many attributes apply only to Hub Transport servers and configuring those attributes on an Edge Transport server will have no effect.

Transport configuration attributes and default values

Attribute	Description	Default value
ClearCategories	This attribute specifies whether to clear Microsoft Office Outlook categories during content conversion.	True
GenerateCopyOfDSNFor	This attribute specifies the delivery status notification (DSN) codes that cause the DSN message to be copied to the postmaster e-mail	5.4.8, 5.4.6, 5.4.4, 5.2.4, 5.2.0, 5.1.4

	address. DSN codes are entered as *x.y.z* and are separated by commas.	
InternalSMTPServers	This attribute specifies a list of internal SMTP server IP addresses or IP address ranges that should be ignored by Sender ID and connection filtering.	Null
JournalingReportNdrTo	This attribute specifies the e-mail address to which journal reports are sent if the journaling mailbox is unavailable. This attribute doesn't apply to the configuration of an Edge Transport server.	Null
MaxDumpsterSizePerStorageGroup	This attribute specifies the maximum size of the transport dumpster on a Hub Transport server. This attribute doesn't apply to the configuration of an Edge Transport server.	18 MB
MaxDumpsterTime	This attribute specifies how long an e-mail message should remain in the transport dumpster on a Hub Transport server. This attribute doesn't apply to the configuration of an Edge Transport server.	7.00:00:00
MaxReceiveSize	This attribute specifies the maximum message size that can be received by recipients in the organization. This attribute doesn't apply to the configuration of an Edge Transport server.	10 MB
MaxRecipientEnvelopeLimit	This attribute specifies the maximum number of recipients that are allowed in a single e-mail message. This attribute doesn't apply to the configuration of an Edge Transport server.	5,000
MaxSendSize	This attribute specifies the maximum message size that can be sent by senders in the organization. This attribute doesn't apply to the configuration of an Edge Transport server.	10 MB

TLSReceiveDomainSecureList	This attribute specifies the remote domains that will use mutual Transport Layer Security (TLS) authentication through Receive connectors configured to support Domain Security. Multiple domains may be separated by commas. The wildcard character (*) isn't supported in the domains that are listed in this attribute.	Null
TLSSendDomainSecureList	This attribute specifies the remote domains that will use mutual TLS authentication when e-mail is sent through a Send connector configured to support Domain Security and the address space of the target domain. Multiple domains may be separated by commas. The wildcard character (*) isn't supported in the domains that are listed in this attribute.	Null
VerifySecureSubmitEnabled	This attribute verifies that e-mail clients that are submitting messages from mailboxes on Mailbox servers are using encrypted MAPI submission. This attribute doesn't apply to the configuration of an Edge Transport server. The valid values for this attribute are `$true` or `$false`.	False
VoicemailJournalingEnabled	This attribute specifies whether Unified Messaging voice mail is journaled by the Journaling agent. This attribute doesn't apply to the configuration of an Edge Transport server.	True
Xexch50Enabled	This attribute specifies whether Xexch50 authentication should be enabled for backward compatibility with Exchange Server 2003 servers.	True

Note:

If the Edge Transport server is subscribed to the Exchange organization later, the value of the **InternalSMTPServers** attribute is overwritten during the EdgeSync process. For more information, see Understanding Edge Subscriptions.

1.7.1.15 Understanding the EdgeTransport.exe.Config File

Understanding the EdgeTransport.exe.Config File

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-09*

The EdgeTransport.exe.config file is an XML application configuration file that is associated with the EdgeTransport.exe file. By default, it's located in the C:\Program Files\Microsoft \Exchange Server\V14\Bin directory.

EdgeTransport.exe and MSExchangeTransport.exe are the executable files that are used by the Microsoft Exchange Transport service. This service runs on every Hub Transport server or Edge Transport server. Changes that are saved to the EdgeTransport.exe.config file are applied after the Microsoft Exchange Transport service is restarted. The default value is enforced if either of the following conditions is true:

- A configuration option is missing.
- A configuration option is present and contains the default value.

The following example shows the typical structure of the EdgeTransport.exe.config file:

```
<configuration>

<runtime>

<gcServer enabled="true" />

</runtime>

<appSettings>

<add key="Configuration Option" value="Value" />

...

</appSettings>

</configuration>
```

You can add new configuration options or modify existing configuration options in the <appSettings> section.

Note:

The parameter names in the <add key=../> section are case sensitive.

1.7.1.16 Understanding Exchange 2010 Support for X.400 Authoritative Domains

Understanding Exchange 2010 Support for X.400 Authoritative Domains

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-18*

This topic describes the support that Microsoft Exchange Server 2010 provides for X.400 domains. Exchange 2010 enables the configuration of one or more X.400 authoritative domain namespaces by using Exchange Management Shell commands.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

X.400 Addresses

An X.400 address is an address that's defined as part of a suite of e-mail standards that are defined by International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T) recommendations. An X.400 address uses a hierarchical naming system and consists of a series of attributes, the sum of which form the X.400 address. Some attributes in the address specify the organization. Other attributes specify the recipient. The sum of all the organizational attributes specifies a unique node in the X.400 address hierarchy.

Exchange 2010 doesn't support the following X.400 scenarios:

- Sharing an X.400 address node with another e-mail system. In Exchange 2010, you can share an SMTP domain namespace by configuring an internal relay accepted domain. You can't use this configuration for an X.400 namespace. Exchange 2010 must be authoritative for the X.400 domain. Alternatively, the X.400 domain must be configured as an external relay subdomain of an authoritative X.400 domain.
- Configuring an X.400 authoritative domain on the Edge Transport server.
- Configuring an X.400 authoritative domain in the Exchange Management Console. You must use the Shell to configure X.400 authoritative domains.
- Routing or relaying directly to an X.400 message transfer agent (MTA). Exchange 2010 must route through a source server that's running Microsoft Exchange Server 2003 and hosting an X.400 connector, or through a third-party Exchange 2010 X.400 connector.

Return to top

Configuring X.400 Authoritative Domains

You configure an X.400 authoritative domain on the Hub Transport server role. When an

organization is configured as authoritative for a particular domain, it's assumed that the organization hosts all the mailboxes for recipients in that domain. After you create an X.400 authoritative domain name, you can create an e-mail address policy that specifies that domain in the e-mail proxy address. The Exchange organization accepts e-mail that's addressed to recipients who have been assigned an X.400 e-mail proxy address that uses the X.400 authoritative domain namespace. Any X.400 recipient addresses in the authoritative namespace that don't resolve to a mailbox or a contact in Active Directory are treated as an error and cause messages to result in a non-delivery report (NDR). If the message that causes the error is a delivery status notification (DSN), such as an NDR, it's deleted.

Exchange 2010 supports non-authoritative X.400 domains if they're a subdomain of an authoritative domain. You use the *X400ExternalRelay* parameter of the **New-X400AuthoritativeDomain** cmdlet to define any exceptions where the Exchange organization isn't authoritative for a subdomain of the authoritative X.400 domain. By default, the value of the *X400ExternalRelay* parameter is set to `$false`. Therefore, a recipient resolution failure for an e-mail message that's sent to a recipient in the X.400 subdomain results in an NDR. If the value of the *X400ExternalRelay* parameter is set to `$true`, Exchange doesn't treat recipient resolution failures as an error and routes messages that are addressed to a recipient in the X.400 subdomain to an external address.

Defining an X.400 Namespace

By default, when you configure an X.400 authoritative domain, the Exchange organization is considered authoritative for all X.400 addresses in the hierarchy.

An X.400 address consists of a series of attributes that define organizational components and specify recipients. The X.400 namespace that's specified in the *X400DomainName* parameter can only include the X.400 organizational components. The following table lists the attributes that you can use to define an X.400 domain namespace in Exchange 2010. The attributes are listed in hierarchical order.

X.400 organizational components

Attribute abbreviation	Organizational component	Required/Optional	Maximum character length
C	**Country** The value of the **Country** attribute is the two-letter country/region designation from International Organization for Standardization (ISO) 3166. This attribute identifies the country or region of the X.400 domain namespace.	Required	2
A	**ADMD** The value of the Administration Management Domain (**ADMD**) typically identifies a public mail service provider. Valid values are decided on a country or regional basis.	Required	16
P	**PRMD** The value of	Optional	16

	the Private Management Domain (**PRMD**)defines the top level domain in the namespace of the Exchange organization.		
O	**Organization** The value of the **Organization** attribute is unique within the context of the **PRMD** or of the **ADMD** if there is no **PRMD**.	Optional	64
OU1	**Organizational unit 1** The value of each organizational unit identifies a unique address element within the scope of the immediately superior address element in the hierarchy.	Optional	64
OU2	**Organizational unit 2** The value of each organizational unit identifies a unique address element within the scope of the immediately superior address element in the hierarchy.	Optional	64
OU3	**Organizational unit 3** The value of each organizational unit identifies a unique address element within the scope of the immediately superior address element in the hierarchy.	Optional	64
OU4	**Organizational unit 4** The value of each organizational unit identifies a unique address element within the scope of the immediately superior address element in the hierarchy.	Optional	64

When you specify the X.400 namespace, the address attributes must be separated by semicolons and the address must be enclosed in quotation marks ("), as in the following example.

```
"C=US;A=ATT;P=Contoso;O=Example"
```

X.400 domain names can only include the following ASCII characters:

- A to Z
- a to z
- 0–9
- These punctuation and special characters: (space) ' () + , - . / : = ?

The inclusion of a wildcard character, such as an asterisk (*), isn't supported in the X.400 authoritative namespace. Each attribute can appear only one time in the X.400 namespace.

Any address in the hierarchy that's subordinate to the defined organizational components must resolve to a recipient or contact in Active Directory, unless an exception has been defined for a subdomain by specifying the *X400ExternalRelay* parameter as `$true`. If the categorizer can't resolve a recipient, an NDR is generated for a message. If the message is a DSN, it's deleted.

For example, if you've configured an X.400 authoritative domain as `"C=US;A=ATT;O=Contoso"`, the Exchange organization is also considered authoritative for the X.400 namespace `"C=US;A=ATT;O=Contoso;OU1=Tailspin Toys"`. If all the recipients for Tailspin Toys are located in another organization, each of those recipients must be represented as a contact in the Active Directory of the Contoso organization. If you can't do this, the Tailspin Toys namespace must be defined as an external relay subdomain.

Return to top

Recipient Resolution and Routing for X.400 Authoritative Domains

To determine how to handle routing of e-mail messages, the Exchange 2010 categorizer compares the recipient addresses to the list of domains for which the Exchange organization is authoritative. This enables the categorizer to determine when to route an X.400 addressed message to an external system and when to generate an NDR for a message if the recipient isn't found in the authoritative namespace. If a message is being sent to a recipient address in an X.400 domain for which the Exchange organization is authoritative, the message is delivered to valid recipients, In addition, an NDR is returned to the sender for any recipient that doesn't appear in Active Directory. If a message is being sent to an X.400 domain for which the Exchange organization isn't authoritative, the message is routed externally through an X.400 connector.

After an X.400 authoritative namespace has been defined, the Exchange organization is assumed to be responsible for message delivery to all recipients that have e-mail proxy addresses that match the namespace. Therefore, X.400 addressed messages that are received by an Exchange 2010 Hub Transport server are processed as follows:

- If the recipient address resolves to a recipient in Active Directory, the message is delivered.
- An NDR is returned to the sender if all the following conditions are true:
  - The recipient address doesn't resolve to a recipient in Active Directory.
  - The recipient address matches an X.400 namespace for which Exchange is authoritative.
  - The e-mail is a message.

- The e-mail is deleted if all the following conditions are true:
  - The recipient address doesn't resolve to a recipient in Active Directory.
  - The recipient address matches an X.400 namespace for which Exchange is authoritative.
  - The e-mail is a DSN.
- The e-mail is routed to an X.400 connector if all the following conditions are true:
  - The recipient address doesn't resolve to a recipient in Active Directory.
  - The recipient address doesn't match an X.400 namespace for which Exchange is authoritative.
  - The e-mail is routed to an X.400 connector.

Although you can configure recipients to receive e-mail that's addressed to an X.400 namespace, Exchange 2010 doesn't provide native transport support for X.400. To send or receive X.400 e-mail messages to or from remote X.400 domains, you must maintain one or more X.400 connectors on an Exchange 2003 server, or configure a Foreign connector to the X.400 backbone.

Exchange 2010 doesn't have an X.400 MTA. Therefore, Exchange 2010 can't convert messages to the X.400 format. An X.400 connector that's hosted on an Exchange 2003 server or a Foreign connector must process the message so that conversion to an X.400 message occurs. To transport X.400 messages, Exchange 2010 routes the message over SMTP as a MIME-encapsulated Transport Neutral Encapsulation Format (TNEF) message.

For more information about how to create an X.400 connector on Exchange 2003, see How to Create an X.400 Connector. For more information about how to create a Foreign connector, see Create a Foreign Connector.

Return to top

1.7.1.17 Understanding Foreign Connectors

Understanding Foreign Connectors

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-26*

A Foreign connector can only be installed on a computer that's running Microsoft Exchange Server 2010 and that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism.

Overview of Foreign Connectors

Exchange 2010 Hub Transport servers require Foreign connectors to deliver messages to foreign gateway servers that don't use SMTP to transmit messages. Third-party fax gateway servers are examples of foreign gateway servers. A Foreign connector controls outbound connections from the Hub Transport server to the foreign gateway server. The outbound messages are put in a Drop directory on the Hub Transport server or in a network file share on a remote server. Each Foreign connector uses its own Drop directory. The foreign gateway server must be configured to obtain messages from the Drop directory that's specified for that Foreign connector.

Foreign connectors that are created on Hub Transport servers are stored in Active

Directory and are available to all Hub Transport servers in the organization. In Active Directory, a Foreign connector is created as an object in the connections container. When a Hub Transport server in the organization routes messages to an address space configured on a Foreign connector, the message is delivered to a source Hub Transport server for that Foreign connector to be relayed to the destination domain. You can specify several different Hub Transport servers in your organization as source servers for a Foreign connector. This provides fault tolerance for the Foreign connector. If a Hub Transport server that contains the Foreign connector is unavailable, the messages that are destined for the Foreign connector's address space are relayed by using any of the other defined and available Hub Transport servers. To provide this fault tolerance, you must make sure that the Drop directory that's specified by the Foreign connector is accessible by all Hub Transport servers that are designated as source servers for that Foreign connector.

Foreign gateway servers can send messages into the Exchange 2010 organization by using the Replay directory that exists on the Hub Transport server. Correctly formatted e-mail message files that you copy to the Replay directory are submitted for delivery.

For more information about the Replay directory, see Understanding the Pickup and Replay Directories.

Defining the Usage of a Foreign Connector by Using Address Spaces and Connector Scope

The address space for a Foreign connector specifies the recipient domains to which the Foreign connector will route e-mail. You can specify SMTP address spaces or non-SMTP address spaces. In Exchange 2010, the complete syntax for specifying an address space is as follows.

```
<AddressSpaceType>:<AddressSpace>;<AddressSpaceCost>
```

You can use the scope of a Foreign connector to control the visibility of the Foreign connector within the Exchange organization. By default, all Foreign connectors that you create are usable by all the Hub Transport servers in the Exchange organization. However, you can limit the scope of any Foreign connector so that it's only usable by other Hub Transport servers that exist in the same Active Directory site.

The connector scope is specified by using the *IsScopedConnector* parameter in the **New-ForeignConnector** cmdlet or the **Set-ForeignConnector** cmdlet. When the value of this parameter is `$false`, the connector can be used by all Hub Transport servers in the Exchange organization. When the value of this parameter is `$true`, the connector can only be used by Hub Transport servers in the same Active Directory site.

Foreign Connector DSN Handling

When a message is sent with a delivery confirmation request to an address that's serviced by a Foreign connector, the sender should be notified if the recipient's messaging server can't correctly process the delivery confirmation request. A Relayed delivery status notification (DSN) notifies the sender that the recipient's messaging system is unable to forward delivery confirmation requests. By default, Relayed DSN messages aren't generated for messages sent to the address spaces that are serviced by a Foreign connector. DSN messages are defined in RFC 1894. For more information about DSN messages, see Managing Delivery Status Notifications.

Delivery Agent Connectors

Exchange 2010 introduces a new feature called Delivery Agent connector, which is also used to route messages to foreign systems that don't use the SMTP protocol. When a message is routed to a Delivery Agent connector, the associated delivery agent performs

the content conversion and message delivery. Delivery Agent connectors allow queue management of Foreign connectors, thereby eliminating the need for storing messages on the file system in a Drop directory. They provide greater control over the message delivery to the foreign systems. To learn more, see Understanding Delivery Agents.

1.7.1.18 Understanding Group Metrics

Understanding Group Metrics

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-07*

Group metrics is the collection of the following data about distribution groups and dynamic distribution groups in your organization:

- Number of members
- Number of members who are external to your organization

Group metrics data is used to support MailTips in Microsoft Exchange Server 2010. MailTips are informative messages displayed to senders while they're composing messages. For more information about MailTips, including a full list of MailTips available in Exchange 2010, see Understanding MailTips.

Group metrics data is used when deciding whether to display the following MailTips:

- **Large Audience** This MailTip is displayed when a sender adds a distribution group whose membership count is considered a large audience as configured in your organization. By default, any message addressed to more than 25 recipients is considered a large audience.
- **External Recipients** This MailTip is displayed when a sender adds a distribution group that has members who are external to your organization.

Determining these characteristics of distribution groups and dynamic distribution groups isn't a simple task. MailTips are evaluated every time a recipient is added to a message composed by a user. Calculating this information while senders compose messages isn't feasible because it would delay the display of MailTips, and it could have an adverse performance impact depending on the size of your organization.

To provide this valuable information to senders without an adverse performance impact, Exchange calculates group metrics data as a background process that can be scheduled to run during nonbusiness hours. When evaluating recipients for MailTips, Exchange reads the group metrics data.

Looking for management tasks related to MailTips? See Managing MailTips.

Group Metrics Generation and Distribution

By default, group metrics data is generated on the same Mailbox server that generates the offline address book (OAB). This is the case even if you explicitly disable group metrics generation on that server using the **Set-MailboxServer** cmdlet. The Mailbox server generates full group metrics data for all distribution groups and dynamic distribution groups every Sunday, and incremental updates for any groups that were modified since the last full generation. The day of the full group metrics data generation is fixed, but you can configure the time it's generated daily. By default, group metrics data is generated daily at a random time within two hours of midnight.

The following files are associated with group metrics:

- **GroupMetrics-<*date*>T<*time*>.bin** This binary file is the main group metrics data file. It contains the membership and external members count for all distribution groups and dynamic distribution groups in your organization. The date and time sections of the file name are separated by hyphens. For example, a group metrics data file created on January 18, 2010 at 20:00 (8:00 P.M.) has the following file name: GroupMetrics-2010-01-18T20-00-00.bin.
- **GroupMetrics-<*servername*>.xml** This XML file contains information about the Mailbox server configured to generate the group metrics data. This file is required by the Microsoft Exchange File Distribution service, and it points to the binary file that needs to be distributed.
- **ChangedGroups.txt** This file contains the list of groups that were updated the last time group metrics data was generated.

Group metrics data won't be generated by default in the following scenarios:

- You don't use OABs in your organization, or you use only public folders for OAB distribution.
- The server responsible for OAB generation is a server running Microsoft Exchange Server 2007 with the Mailbox server role installed.

If any of these scenarios apply to you, you must configure an Exchange 2010 Mailbox server manually to start generating group metrics. For detailed steps, see Configure Group Metrics.

The group metrics data is distributed to the Client Access servers using the Microsoft Exchange File Distribution service. The Microsoft Exchange File Distribution service queries Active Directory for a list of Mailbox servers that have group metrics generation enabled, and then copies the group metrics data from the closest Mailbox server every eight hours.

1.7.1.19 Understanding Header Firewall

Understanding Header Firewall

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-27*

In Microsoft Exchange Server 2010, *header firewall* is a mechanism that removes specific header fields from inbound and outbound messages. Computers that are running Exchange 2010 that have the Hub Transport server role or the Edge Transport server role installed insert custom X-header fields into the message header. An *X-header* is a user-defined, unofficial header field that exists in the message header. X-headers aren't specifically mentioned in RFC 2822, but the use of an undefined header field starting with **X-** has become an accepted way to add unofficial header fields to a message. Messaging applications, such as anti-spam, antivirus, and messaging server applications may add their own X-headers to a message. X-header fields are usually preserved but ignored by messaging servers and clients that don't use them.

The X-header fields contain details about the actions that are performed on the message by the transport server, such as the spam confidence level (SCL), content filtering results, and rules processing status. Revealing this information to unauthorized sources could pose a potential security risk.

Header firewall prevents the spoofing of these X-headers by removing them from inbound messages that enter the Exchange organization from untrusted sources. Header firewall prevents the disclosure of these X-headers by removing them from outbound messages that will go to untrusted destinations outside the Exchange organization. Header firewall

also prevents the spoofing of standard routing headers that are used to track the routing history of a message.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Custom Organization X-Headers and Forest X-Headers That Are Used in Exchange 2010

Organization X-headers start with **X-MS-Exchange-Organization-**. Forest X-headers start with **X-MS-Exchange-Forest-**.

The following table describes some of the organization X-headers and forest X-headers that are used in messages in an Exchange 2010 organization.

Some of the organization X-headers and forest X-headers that are used in messages in an Exchange 2010 organization

X-header	Description
X-MS-Exchange-Forest-RulesExecuted	This X-header lists the transport rules that were performed on the message.
X-MS-Exchange-Organization-Antispam-Report	This X-header is a summary report of the anti-spam filter results that have been applied to the message by the Content Filter agent.
X-MS-Exchange-Organization-AuthAs	This X-header is always present when the security of a message has been evaluated. This X-header specifies the authentication source. The possible values are `Anonymous`, `Internal`, `External`, or `Partner`.
X-MS-Exchange-Organization-AuthDomain	This X-header is populated during Domain Secure authentication. The value is the fully qualified domain name (FQDN) of the remote authenticated domain.
X-MS-Exchange-Organization-AuthMechanism	This X-header specifies the authentication mechanism for the submission of the message. The value is a 2-digit hexadecimal number.
X-MS-Exchange-Organization-AuthSource	This X-header specifies the FQDN of the

	server computer that evaluated the authentication of the message on behalf of the organization.
X-MS-Exchange-Organization-Journal-Report	This X-header identifies journal reports in transport. As soon as the message leaves the transport server, the header becomes X-MS-Journal-Report.
X-MS-Exchange-Organization-OriginalArrivalTime	This X-header identifies the time when the message first entered the Exchange organization.
X-MS-Exchange-Organization-Original-Sender	This X-header identifies the original sender of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-OriginalSize	This X-header identifies the original size of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-Original-Scl	This X-header identifies the original SCL of a quarantined message when it first entered the Exchange organization.
X-MS-Exchange-Organization-PCL	This X-header identifies the phishing confidence level. The possible phishing confidence level values are from 1 through 8. A larger value indicates a suspicious message. For more information, see Understanding Anti-Spam Stamps.
X-MS-Exchange-Organization-Quarantine	This X-header indicates that the message has been quarantined in the spam quarantine mailbox and a delivery status notification (DSN) has been sent. Alternatively, it indicates that the message was quarantined and released by the administrator. This X-header field prevents the released message from being submitted to the spam quarantine mailbox again. For more information, see Release Quarantined Messages from the Spam Quarantine Mailbox.
X-MS-Exchange-Organization-SCL	This X-header identifies the SCL of the message. The possible SCL values are from 0 through 9. A larger value indicates a suspicious message. The special value -1 exempts the message from processing by the Content Filter agent. For more information, see Understanding Content Filtering.
X-MS-Exchange-Organization-SenderIdResult	This X-header contains the results of the Sender ID agent. The Sender ID agent uses the sender policy framework (SPF) to compare the message's source IP address to the domain that's used in the sender's e-mail address. The Sender ID results are used to calculate the SCL of a message. For

	more information, see Understanding Sender ID.

Return to top

Header Firewall for Organization X-Headers and Forest X-Headers

Exchange 2010 applies header firewall to organization X-headers and forest X-headers that exist in messages in the following ways:

- Permissions that can be used to preserve or remove specific X-headers in messages are assigned to Send connectors or Receive connectors.
- Header firewall is automatically implemented for X-headers in messages during other types of message submission.

How Header Firewall Is Applied to Organization X-Headers and Forest X-headers in Messages

Header firewall for organization X-headers and forest X-headers that exist in inbound messages consists of two specific permissions that are assigned to a Receive connector that's configured on a Hub Transport server or an Edge Transport server:

- If the permissions are assigned to the Receive connector, header firewall isn't applied to the message. The organization X-headers or forest X-headers in the message are preserved.
- If the permissions aren't applied to the Receive connector, header firewall is applied to the message. The organization X-headers or forest X-headers are removed from the message.

The following table describes the header firewall permissions for organization X-headers and forest X-headers that are available on a Receive connector.

Header firewall permissions for organization X-headers and forest X-headers that are available on a Receive connector for inbound messages

Permission	By default, the security principals that have the permission assigned	Permission group that has the security principals as members	By default, the usage type that assigns the permission groups to the Receive connector	Description
Ms-Exch-Accept-Headers-Organization	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only	ExchangeServers	Internal	This permission applies to organization X-headers. Organization X-headers start with **X-MS-Exchange-Organization-**. If this permission isn't granted,

				the receiving server removes any organization headers from the message.
Ms-Exch-Accept-Headers-Forest	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only	ExchangeServers	`Internal`	This permission applies to forest X-headers. Forest X-headers start with **X-MS-Exchange-Forest-**. If this permission isn't granted, the receiving server removes any forest headers from the message.

If you want to apply header firewall to organization X-headers and forest X-headers in a custom Receive connector scenario, use any of the following methods:

- Create a Receive connector and select a usage type other than `Internal`. The Receive connector usage type can only be set when you create the connector. For more information, see Create an SMTP Receive Connector.
- Modify an existing Receive connector and remove the ExchangeServers permission group. For more information, see Configure Receive Connector Properties.
- Use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Accept-Headers-Organization permission and the Ms-Exch-Accept-Headers-Forest permission from a security principal that's configured on the Receive connector. This method doesn't work if the permission has been assigned to the security principal by using a permission group. You can't modify the assigned permissions or the group membership of a permission group. For more information, see Remove-ADPermission.
- Use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Accept-Headers-Organization permission and the Ms-Exch-Accept-Headers-Forest permission to a security principal that's configured on the Receive connector. For more information, see Add-ADPermission.

How Header Firewall Is Applied to Organization X-Headers and Forest X-Headers in Outbound Messages

Header firewall for organization X-headers and forest X-headers that exist in outbound messages consists of two specific permissions that are assigned to a Send connector that's configured on a Hub Transport server or an Edge Transport server:

- If the permissions are assigned to the Send connector, header firewall isn't applied to the message. The organization X-headers or forest X-headers in the message are preserved.
- If the permissions aren't applied to the Send connector, header firewall is applied to the message. The organization X-headers and forest X-headers are removed from the message.

The following table describes the header firewall permissions for organization X-headers and forest X-headers that are available on a Send connector.

Header firewall permissions for organization X-headers and forest X-headers that are available on a Send connector for outbound messages

Permission	By default, the security principals that have the permission assigned	By default, the usage type that assigns the security principals to the Send connector	Description
Ms-Exch-Send-Headers-Organization	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers • Exchange Legacy Interop universal security group • Exchange Server 2003 bridgehead servers	`Internal`	This permission applies to organization X-headers. Organization X-headers start with **X-MS-Exchange-Organization-**. If this permission isn't granted, the sending server removes any organization headers from the message.
Ms-Exch-Send-Headers-Forest	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers • Exchange Legacy Interop universal security group • Exchange 2003 bridgehead servers	`Internal`	This permission applies to forest X-headers. Forest X-headers start with **X-MS-Exchange-Forest-**. If this permission isn't granted, the sending server removes any forest headers from the message.

If you want to apply header firewall for organization X-headers or forest X-headers in a custom Send connector scenario, use the any of the following methods:

- Create a Send connector and select a usage type other than `Internal` or `Partner`. The Send connector usage type can only be set when you create the connector. For more information, see Create an SMTP Send Connector.
- Remove a security principal that assigns the Ms-Exch-Send-Headers-Organization permission and the Ms-Exch-Send-Headers-Forest permission from the connector. For more information, see Configure Send Connector Properties.
- Use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Send-Headers-Organization permission and the Ms-Exch-Send-Headers-Forest permission

from one of the security principals that's configured on the Send connector. For more information, see Remove-ADPermission.

- Use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Send-Headers-Organization permission and the Ms-Exch-Send-Headers-Forest permission to one of the security principals that's configured on the Send connector. For more information, see Add-ADPermission.

How Header Firewall Is Applied to Organization X-Headers and Forest X-Headers from Other Message Sources

Messages can enter the Exchange 2010 transport pipeline on a Hub Transport server or an Edge Transport server without using Send connectors or Receive connectors. Header firewall for organization X-headers and forest X-headers is applied to messages originating from these other message sources as described in the following list:

- **Pickup directory** The Pickup directory is used by administrators or applications to submit message files. Header firewall for organization X-headers and forest X-headers is always applied to the message files in the Pickup directory. For more information about the Pickup directory, see Understanding the Pickup and Replay Directories.
- **Replay directory** The Replay directory is used to resubmit messages that have been exported from Exchange 2010 message queues. How header firewall for organization X-headers and forest X-headers is applied in these messages is controlled by the `X-CreatedBy:` header field in the message file:
  - If the value of this header field is `MSExchange14`, header firewall isn't applied to the message.
  - If the value of `X-CreatedBy:` isn't `MSExchange14`, header firewall is applied.
  - If the `X-CreatedBy:` header field doesn't exist in the message file, header firewall is applied.

  For more information about the Replay directory, see Understanding the Pickup and Replay Directories.
- **Drop directory** The Drop directory is used by Foreign connectors on Hub Transport servers to send messages to messaging servers that don't use SMTP to transfer messages. Header firewall for organization X-headers and forest X-headers is always applied to message files before they're put in the Drop directory. For more information about Foreign connectors, see Understanding Foreign Connectors.
- **Store driver** The store driver exists on Hub Transport servers to transport messages to and from mailboxes on Mailbox servers. For outgoing messages that are created and submitted from mailboxes, header firewall for organization X-headers and forest X-headers is always applied. For incoming messages, header firewall for organization X-headers and forest X-headers is selectively applied. The X-headers that are specified in the following list aren't blocked by header firewall for inbound messages to mailbox recipients:
  - X-MS-Exchange-Organization-SCL
  - X-MS-Exchange-Organization-AuthDomain
  - X-MS-Exchange-Organization-AuthMechanism
  - X-MS-Exchange-Organization-AuthSource
  - X-MS-Exchange-Organization-AuthAs
  - X-MS-Exchange-Organization-OriginalArrivalTime
  - X-MS-Exchange-Organization-OriginalSize

  For more information about the store driver, see Understanding Transport Pipeline.
- **DSN messages** Header firewall for organization X-headers and forest X-headers is always applied to the original message or the original message header that's attached to the DSN message. For more information about DSN messages, see Managing Delivery Status Notifications.
- **Agent submission** Header firewall for organization X-headers and forest X-headers isn't applied to messages that are submitted by agents.

Return to top

Header Firewall for Routing Headers

Routing headers are standard SMTP header fields that are defined in RFC 2821 and RFC 2822. Routing headers stamp a message by using information about the different messaging servers that were used to deliver the message to the recipient. The available routing headers are described in the following list:

- **Received:** A different instance of this header field is added to the message header by every messaging server that accepted and forwarded the message to the recipient. The `Received:` header typically includes the name of the messaging server and a date-timestamp.
- **Resent-*:** Resent header fields are informational header fields that can be used to determine whether a message has been forwarded by a user. The following resent header fields are available: `Resent-Date:`, `Resent-From:`, `Resent-Sender:`, `Resent-To:`, `Resent-Cc:`, `Resent-Bcc:`, and `Resent-Message-ID:`.
  The Resent fields are used so that the message appears to the recipient as if it was sent directly by the original sender. The recipient can view the message header to discover who forwarded the message.

Routing headers that are inserted into messages can be used to misrepresent the routing path that a message traveled to reach a recipient. Exchange 2010 uses two different ways to apply header firewall to routing headers that exist in messages:

- Permissions are assigned to Send connectors or Receive connectors that can be used to preserve or remove routing headers in messages.
- Header firewall is automatically implemented for routing headers in messages during other types of message submission.

How Header Firewall Is Applied to Routing Headers in Inbound Messages

Receive connectors have the Ms-Exch-Accept-Headers-Routing permission that's used to accept or reject any routing headers that exist in an inbound message:

- If this permission is granted, all routing headers are preserved in the inbound message.
- If this permission isn't granted, all routing headers are removed from the inbound message.

The following table describes the default application of the Ms-Exch-Accept-Headers-Routing permission on a Receive connector.

Default application of the Ms-Exch-Accept-Headers-Routing permission on a Receive connector

By default, the security principals that have the permission assigned	Permission group that has the security principals as members	By default, the usage type that assigns the permission groups to the Receive connector
Anonymous user account	Anonymous	`Internet`
Authenticated user accounts	ExchangeUsers	`Client` (unavailable on Edge Transport servers)
• Hub Transport servers • Edge Transport servers • Exchange Servers	ExchangeServers	`Internal`

Note: Hub Transport servers only • Externally Secured servers		
Exchange Legacy Interop universal security group	ExchangeLegacyServers	Internal
Partner Server account	Partner	• Internet • Partner

The Ms-Exch-Accept-Headers-Routing permission is assigned to all usage types except Custom. If you want to apply header firewall to routing headers in a custom Receive connector scenario, follow these steps:

1. Perform one of the following actions:
   - Create a Receive connector and select the usage type Custom. Don't assign any permission groups to the Receive connector. You can't modify the assigned permissions or the group membership of a permission group.
   - Modify an existing Receive connector, and set the *PermissionGroups* parameter to the value None.
2. Use the **Add-ADPermission** cmdlet to add the appropriate security principals that are required on the Receive connector. Make sure that no security principals have the Ms-Exch-Accept-Headers-Routing permission assigned to them. If it's necessary, use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Accept-Headers-Routing permission to the security principal that you want to configure to use the Receive connector.

For more information, see the following topics:

- Create an SMTP Receive Connector
- Configure Receive Connector Properties
- Add-ADPermission
- Remove-ADPermission

How Header Firewall Is Applied to Routing Headers in Outbound Messages

Send connectors have the Ms-Exch-Send-Headers-Routing permission that's used to allow or remove any routing headers that exist in an outbound message:

- If this permission is granted, all routing headers are preserved in the outbound message.
- If this permission isn't granted, all routing headers are removed from the outbound message.

The following table describes the default application of the Ms-Exch-Send-Headers-Routing permission on a Send connector.

Default application of the Ms-Exch-Send-Headers-Routing permission on a Send connector

By default, the security principals that have the permission assigned	By default, the usage type that assigns the security principals to the Send connector
• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only	Internal

• Externally Secured servers • Exchange Legacy Interop universal security group • Exchange 2003 bridgehead servers	
Anonymous User Account	`Internet`
Partner Servers	`Partner`

The Ms-Exch-Send-Headers-Routing permission is assigned to all usage types except `Custom`. If you want to apply header firewall to routing headers in a custom Send connector scenario, use the any of following methods:

- Create a Send connector and select the usage type `Custom`. The Send connector usage type can only be set when you create the connector. For more information, see Create an SMTP Send Connector.
- Remove a security principal that assigns the Ms-Exch-Send-Headers-Routing permission from the connector. For more information, see Configure Send Connector Properties.
- Use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Send-Headers-Routing permission from one of the security principals that's configured on the Send connector. For more information, see Remove-ADPermission.
- Use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Send-Headers-Routing permission to one of the security principals that's configured on the Send connector. For more information, see Add-ADPermission.

How Header Firewall Is Applied to Routing Headers from Other Message Sources

Messages can enter the Exchange 2010 transport pipeline on a Hub Transport server or an Edge Transport server without using Send connectors or Receive connectors. Header firewall for routing headers is applied to the other message sources that are described in the following list:

- **Pickup directory** The Pickup directory is used by administrators or applications to submit message files. Header firewall for routing headers is always applied to the message files in the Pickup directory. For more information about the Pickup directory, see Understanding the Pickup and Replay Directories.
- **Store driver** The store driver exists on Hub Transport servers to transport messages to and from mailboxes on Mailbox servers. Header firewall for routing headers is always applied to all messages that are sent from mailboxes on Mailbox servers. Header firewall for routing headers isn't applied to incoming messages for delivery to mailbox recipients. For more information about the store driver, see Understanding Transport Pipeline.
- **DSN messages** Header firewall for routing headers is always applied to the original message or the original message header that's attached to the DSN message. For more information about DSN messages, see Managing Delivery Status Notifications.
- **Replay directory, Drop directory, and agent submission** Header firewall for routing headers isn't applied to messages that are submitted by the Replay directory, the Drop directory, or agents.

Return to top

Header Firewall and Earlier Versions of Exchange

Exchange 2003 and earlier versions of Exchange don't use the organization X-headers or forest X-headers. Exchange 2010 treats versions of Exchange earlier than Exchange 2007

as untrusted message sources. Header firewall is applied to all organization X-headers and forest X-headers in messages coming from servers that are running earlier versions of Exchange. Header firewall for organization X-headers and forest X-headers is also applied to messages that are delivered to servers that are running earlier versions of Exchange that exist in the Exchange organization.

Earlier versions of Exchange use the proprietary verb X-EXCH50 to transmit information about messages and recipients that can't be included in the e-mail message. The information is transmitted as the Exch50 binary large object (BLOB). The Exch50 BLOB is a collection of binary data that's stored as a single object. Exch50 contains data such as the SCL, address rewriting information, and other MAPI properties that don't have MIME representation. Because X-EXCH50 is a proprietary Extended Simple Mail Transfer Protocol (ESMTP) verb, Exch50 data can't be propagated by a server that doesn't have Exchange installed. For more information, see Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

Routing group connectors between servers that have Exchange 2010 or Exchange 2003 installed are automatically configured to support sending and receiving Exch50 data. Send connectors and Receive connectors have permissions that enable the Exch50 command.

The following table describes the permissions that allow the Exch50 command on a Receive connector for inbound messages. If one of these permissions isn't granted, and a message is sent that contains the Exch50 command, the server accepts the message, but doesn't include the Exch50 command.

Permissions that allow the Exch50 command on a Receive connector for inbound messages

Permission	By default, the security principals that have the permission assigned	Permission group that has the security principals as members	By default, the usage type that assigns the permission groups to the Receive connector
Ms-Exch-Accept-Exch50	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers	ExchangeServers	`Internal`
Ms-Exch-Accept-Exch50	Exchange Legacy Interop universal security group	ExchangeLegacyServers	`Internal`

If you want to block the Exch50 command in a custom Receive connector scenario, use the any of following methods:

- Create a Receive connector and select a usage type other than `Internal`. The Receive connector usage type can only be set when you create the connector. For more information, see Create an SMTP Receive Connector.
- Modify an existing Receive connector and remove the ExchangeServers permission group. For more information, see Configure Receive Connector Properties.
- Use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Accept-Exch50 permission from a security principal that's configured on the Receive connector.

This method doesn't work if the permission has been assigned to the security principal by using a permission group. You can't modify the assigned permissions or the group membership of a permission group. For more information, see Remove-ADPermission.

- Use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Accept-Exch50 permission to a security principal that's configured on the Receive connector. For more information, see Add-ADPermission.

The following table describes the permission that allows the Exch50 command on a Send connector for outbound messages. If this permission isn't granted and a message is sent that contains the Exch50 command, the server sends the message, but doesn't include the Exch50 command.

Permission that allows the Exch50 command on a Send connector for outbound messages

Permission	By default, the security principals that have the permission assigned	By default, the usage type that assigns the security principals to the Send connector
Ms-Exch-Send-Exch50	• Hub Transport servers • Edge Transport servers • Exchange Servers **Note:** On Hub Transport servers only • Externally Secured servers • Exchange Legacy Interop universal security group • Exchange 2003 bridgehead servers	`Internal`

If you want to block the Exch50 command in a custom Send connector scenario, you can use the any of following methods:

- Create a Send connector and select a usage type other than `Internal`. The Send connector usage type can only be set when you create the connector. For more information, see Create an SMTP Send Connector.
- Remove a security principal that assigns the Ms-Exch-Send-Exch50 permission from the connector.
- Use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Send-Exch50 permission from one of the security principals that's configured on the Send connector. For more information, see Remove-ADPermission.
- Use the **Add-ADPermission** cmdlet to deny the Ms-Exch-Send-Exch50 permission to one of the security principals that's configured on the Send connector. For more information, see Add-ADPermission.

1.7.1.20 Understanding SMTP Failover and Load Balancing in Transport

Understanding SMTP Failover and Load Balancing in Transport

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-13*

When you have multiple Hub Transport servers in your organization, Exchange automatically distributes the mail traffic among all the Hub Transport servers in your organization. The load distribution is successful in distributing the load evenly when all servers are available. However, when one or more servers are unavailable, the load distribution may become uneven among the remaining servers, especially if your organization is distributed across multiple Active Directory sites.

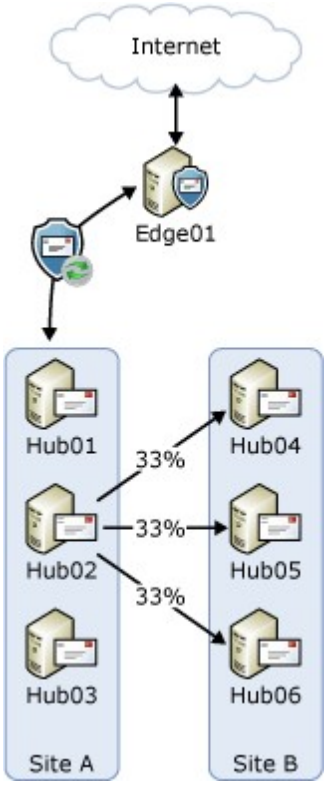
In Microsoft Exchange Server 2010 Service Pack 1 (SP1), several improvements were made to the decision-making mechanism for distributing the load among Hub Transport servers.

Looking for management tasks related to message routing? See Managing Message Routing.

Contents

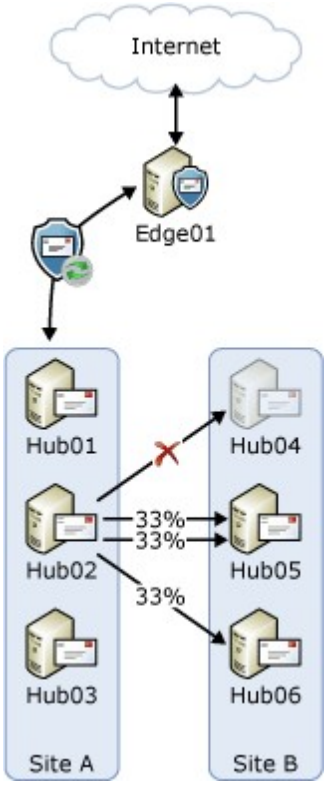
Exchange Server 2010 RTM Behavior

In the release to manufacturing (RTM) version of Exchange 2010, when a transport server needs to route several messages to the same destination, the server initially determines the next hop for those messages. If there are multiple target servers for that next hop, it load balances the connection used to deliver messages equally among the target servers using the round robin manner provided by enhanced Domain Name System (DNS). For example, consider a topology where you have two Active Directory sites with three Hub Transport servers in each (as shown in the following figure). When a Hub Transport server in Site A, for example Hub02, needs to send messages to Site B, the next hop for that message is Site B. There are three possible targets in the next hop: Hub04, Hub05, and Hub06. The server will distribute the number of connections evenly across those three targets as shown in the following figure. This action results in an even distribution of messages across the connections over time.



Similarly, the Hub Transport servers in Site B will distribute the number of messages sent to recipients in Site A evenly across Hub01, Hub02, and Hub03. Also, because Edge01 is subscribed to Site A, the targets for the next hop for messages sent to the Internet are Hub01, Hub02, and Hub03.

A problem arises if one or more of the servers are unavailable in the next hop. For example, assume that Hub04 in Site B is unavailable for scheduled maintenance. The servers in Site A don't maintain availability status of each server in Site B. The servers in Site A will distribute the load destined for Site B among the three Hub Transport servers in that site. However, approximately one third of those connections would be sent to Hub04 but won't succeed. These connections will fail over to the next available server, and one of the Hub Transport servers in Site B will process substantially more load than the other server as shown in the following figure.



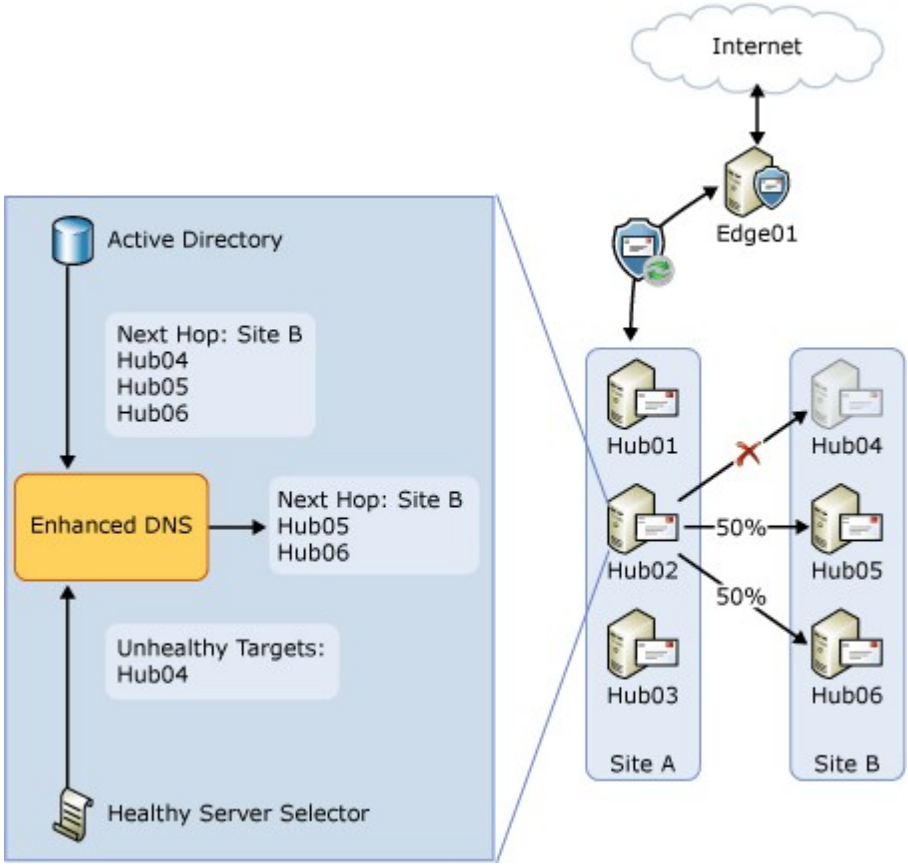
This undesirable behavior may occur whenever there's an unavailable server in the next hop that typically has more than two targets. The next hop could be another Active Directory site as shown in the preceding example, or a connector that has multiple Hub Transport servers listed as the source server (for example, the Send connector to the subscribed Edge Transport server in the topology shown in the preceding figures).

This isn't an issue for mail submissions from Mailbox servers. The mail submission service will detect unavailable Hub Transport servers in a site, and won't attempt to deliver to those servers. In the example shown previously, although one of the Hub Transport servers in Site B may have a heavier load from intersite traffic, the load generated by Mailbox servers in Site B will be evenly split between Hub05 and Hub06.

Return to top

Exchange 2010 SP1 Improvements

To address the issue described in the previous section, a new component called *Healthy Server Selector* was added in Exchange 2010 SP1. Healthy Server Selector maintains a list of servers that are unavailable. This list is used by enhanced DNS to filter out any unavailable servers when applying round robin logic for load balancing. To demonstrate how Healthy Server Selector helps with load balancing, consider the problematic condition shown in the preceding figure. In Exchange 2010 SP1, enhanced DNS will first compile the list of potential targets in the next hop, Site B. It will then ask Healthy Server Selector to filter the list. Healthy Server Selector will report that Hub04 for the next hop Site B is unhealthy. Enhanced DNS will remove Hub04 from the list of potential targets for the next hop Site B, and will use round robin load balancing only between Hub05 and Hub06 as shown in the following figure.



Healthy Server Selector

In its simplest form, Healthy Server Selector tracks servers deemed unhealthy so that those servers aren't included in round robin load balancing. From a Healthy Server Selector perspective, a definition of an unhealthy server is one to which a connection attempt returns any Windows sockets (Winsock) error code.

For each unhealthy server, Healthy Server Selector keeps the following information:

- Server IP address
- Retry count
- Last retry time

Retry Behavior

When a server is marked as unhealthy, Healthy Server Selector will ensure that connections to that specific server are tried again to detect when that server comes online. Healthy Server Selector uses the following settings to determine how frequently connections will be retried to an unhealthy server:

- **QueueGlitchRetryInterval and QueueGlitchRetryCount** These settings determine how many times and at what interval Healthy Server Selector retries connections to a specific server when it's first marked unhealthy. These settings are configured in the EdgeTransport.exe.config file. The default values for these settings are 1 minute and 4 retry attempts. These values mean that a connection to an unhealthy server will be attempted every minute four times in a default configuration.
- **TransientFailureRetryInterval and TransientFailureRetryCount** If the unhealthy server is unavailable, these settings are used by Healthy Server Selector to determine the frequency of the next set of retry attempts. These settings are configured for each transport server. The default values are 5 minutes (10 minutes on an Edge Transport server) and 6 retry attempts. These values mean that a connection to an unhealthy server will be attempted

every five minutes six times after the first four minutes in a default configuration.

- **OutboundConnectionFailureRetryInterval** If the unhealthy server is unavailable, Healthy Server Selector will continue to retry the connection by the frequency specified in this parameter. This setting is configured for each transport server. The default value is 10 minutes (30 minutes on an Edge Transport server). This means that a connection will be attempted to an unhealthy server every 10 minutes after the first 34 minutes in a default configuration.

For step-by-step instructions about how to configure these settings, see Configure Message Retry, Resubmit, and Expiration Intervals.

When it's time to retry a connection, Healthy Server Selector allows only one connection attempt to the unhealthy server. If that connection succeeds, the SMTP outbound component will notify Healthy Server Selector that the connection is successful. At that point, Healthy Server Selector removes the server from the list of unhealthy servers.

Healthy Server Selector and Shadow Redundancy

The shadow redundancy component of transport includes a heartbeat feature. The heartbeat is a simple SMTP connection used to query the status of messages previously submitted to a target server. Healthy Server Selector filtering won't prevent the Shadow Redundancy Manager from issuing heartbeat connection attempts. If a server has shadow messages that were submitted to a server that's unhealthy, it will attempt to make heartbeat connections to that server. If a heartbeat connection succeeds to an unhealthy server, that target server is immediately removed from the list of unhealthy servers by Healthy Server Selector.

To learn more about shadow redundancy and the heartbeat, see Understanding Shadow Redundancy.

Diagnostic Information

In Exchange 2010 SP1, the connectivity logs include diagnostic information for Healthy Server Selector and the enhanced load balancing features. When a server is added to the unhealthy servers list by Healthy Server Selector, the event is logged in the connectivity log. To locate this event, search for the phrase **MarkedUnhealthy** in the connectivity log. On the line that contains this phrase, you can find the following information:

- Target host IP address
- Target host fully qualified domain name (FQDN)
- Winsock error received
- Status: `MarkedUnhealthy`
- Current failure count
- Next retry time

From this entry, you can identify the reason for the failure by evaluating the Winsock error code. For a complete list of Winsock error codes and their definitions, see Windows Sockets Error Codes.

You can also determine how many connection attempts have failed and the next scheduled retry attempt to the target server by analyzing the **Current Failure Count** and **Next Retry Time** fields.

You must have connectivity logging enabled on your transport servers to be able to see this diagnostic information. Connectivity logging is disabled by default on Hub Transport and Edge Transport servers. For more information about configuring connectivity logging, see Configure Connectivity Logging.

Return to top

Windows Network Load Balancing or Third-Party Load Balancing Solutions with Transport Servers

As discussed earlier in this topic, Exchange 2010 automatically load balances all intra-organization message traffic between Edge Transport, Hub Transport, and Mailbox servers using enhanced DNS. However, this functionality doesn't cover the load balancing of messages received from non-Exchange sources such as external mail servers, third-party anti-spam or antivirus solutions, any internal mail servers outside your Exchange organization, line-of-business (LOB) applications, and POP-based or IMAP-based e-mail clients.

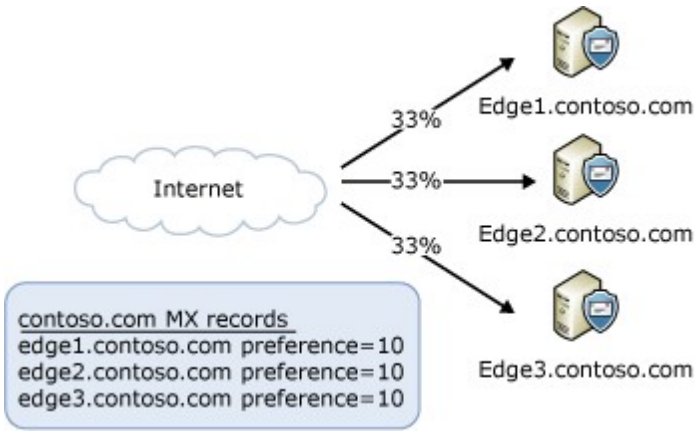
If you have one or more of these mail sources, you may choose to load balance incoming SMTP traffic using a unified SMTP namespace (such as smtp.contoso.com) that distributes external e-mail messages across the transport servers within the organization. Windows Network Load Balancing (NLB) or a hardware-based load balancing solution from a third-party vendor are both supported. For a list of load balancers that have been tested by the vendor and reviewed by Microsoft to meet Exchange 2010 requirements, see Microsoft Unified Communications Load Balancer Deployment.

Important:

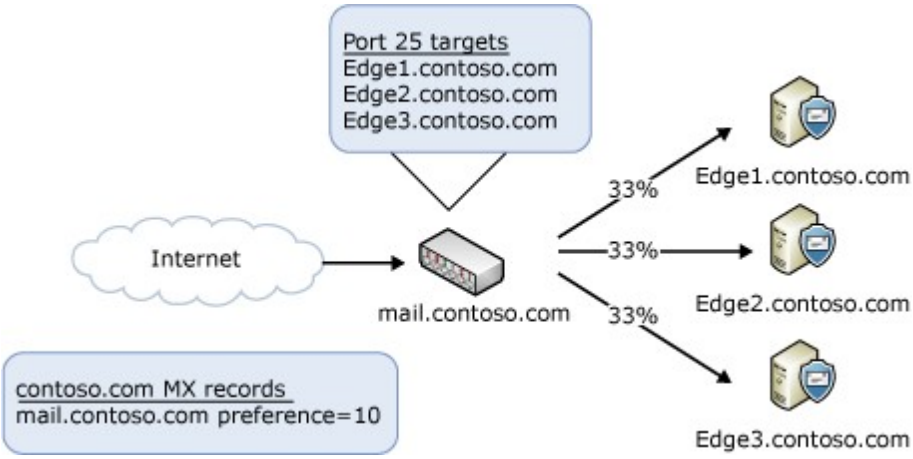
Using a load balancing solution to handle message traffic between the Exchange servers in your organization isn't supported. You must exclude message traffic between Exchange servers from any load balancing solution you deploy in your environment.

Load Balancing Inbound Internet Messages Among Your Edge Transport Servers

The most common situation is handling incoming messages from the Internet. You don't need to deploy a load balancing solution to distribute the load across your Edge Transport servers. You can accomplish this by using DNS round robin and mail exchange records (MX records) that have the same preference value, as shown in the following figure.



If you choose to use Windows NLB or a hardware load balancing solution to distribute incoming Internet messages, you need to publish a single MX record that points to your load balancing solution. The load balancer will distribute incoming messages to all the Edge Transport servers listed in its configuration, as shown in the following figure.

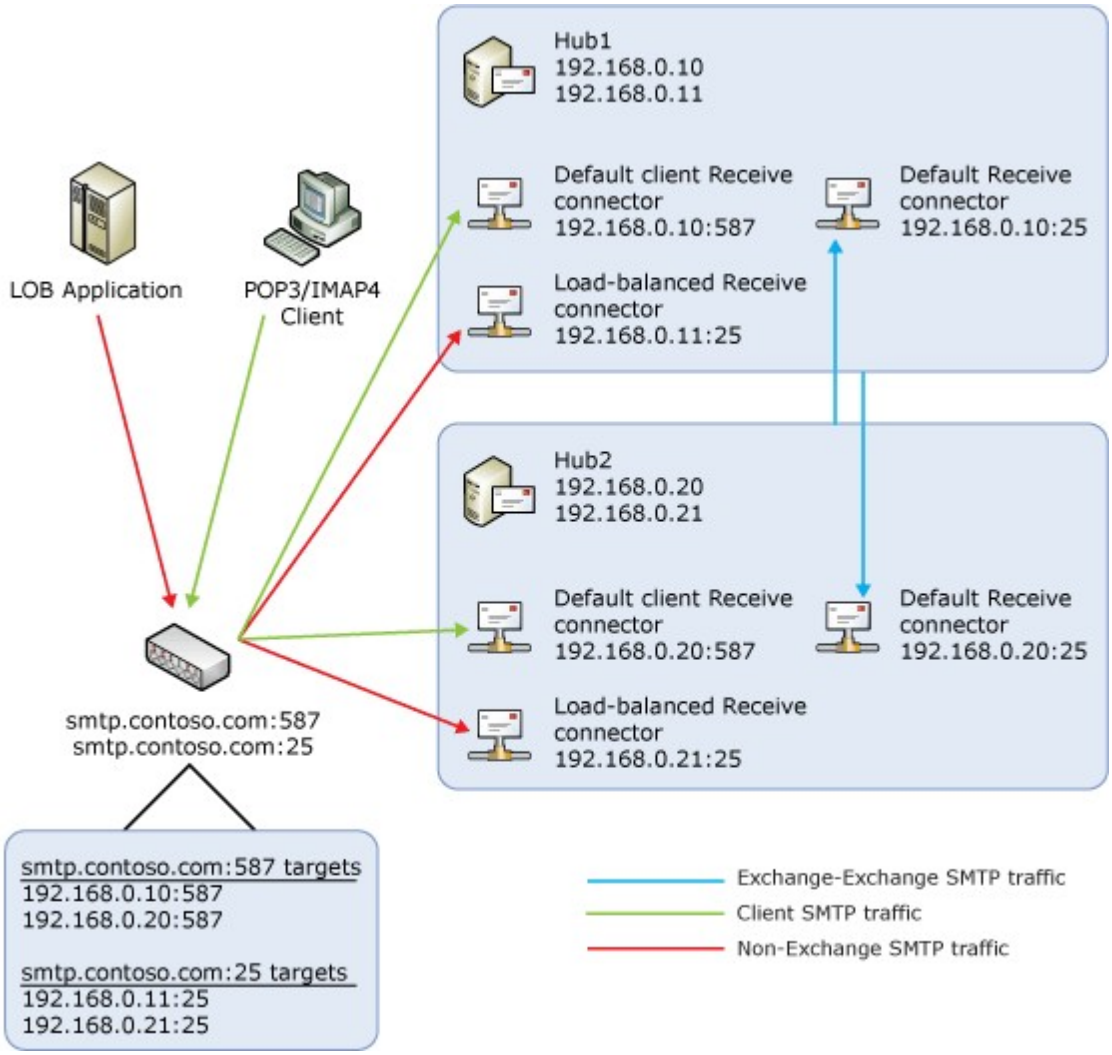


Load Balancing Non-Exchange Messages Among Your Hub Transport Servers

Exchange 2010 uses Receive connectors to accept incoming messages. By default, when an Exchange 2010 Hub Transport server receives an e-mail message via SMTP over TCP port 25, it's processed by the Receive connector named Default Receive connector.

When a POP or IMAP client submits an e-mail message to an Exchange 2010 Hub Transport server, the message is submitted over TCP port 587 by default. This means e-mail messages submitted from POP or IMAP clients are processed by a separate Receive connector named Default Client Receive connector.

If you plan on placing a load balancing solution in front of your Hub Transport servers, you should create a separate Receive connector for that purpose and make sure that only traffic processed by that particular connector is subject to load balancing. This can be achieved by adding an additional IP address to the Hub Transport server and associating this IP address with the new Receive connector. In addition, the **Exchange Server authentication** option should be disabled on the Receive connector to ensure Exchange traffic doesn’t route over it. The following figure shows a configuration where a load balancer is used to distribute messages received from POP3 or IMAP4 clients and non-Exchange SMTP servers among two Hub Transport servers.



Windows Network Load Balancing

Windows NLB is the most common software load balancer used for Exchange servers. There are some limitations associated with deploying Windows NLB with Exchange 2010 Hub Transport servers:

- Windows NLB can't be used on Exchange servers where the Hub Transport and Mailbox server roles coexist and the server also participates in a database availability group (DAG).
  This is because the Windows NLB feature is incompatible with Windows failover clustering. If you use an Exchange 2010 DAG and you want to use Windows NLB, you need to have the Hub Transport server role and the Mailbox server role running on separate computers. In addition, Windows NLB impacts message routing when the DAG member and Hub Transport server role coexist on the same server. To learn more, see Hub Transport and Mailbox Server Roles Coexistence When Using DAGs.
- We don't recommend putting more than eight Hub Transport servers in an array that's load balanced by Windows NLB. If you need to load balance more than eight Hub Transport servers, you should deploy a hardware-based solution.
- Windows NLB doesn't detect service outages.
  It only detects server outages by IP address. If the Exchange Transport service fails, but the server is still functioning, Windows NLB won't detect the failure and will still route incoming e-mail messages to that Hub Transport

server. Manual intervention is required to remove the Hub Transport server experiencing the outage from the load balancing pool.

- Windows NLB configuration can result in port flooding, which can overwhelm networks.
  This is because Windows NLB has been designed in such a way that it simultaneously delivers all incoming client packets to all switch ports. Although this behavior enables Windows NLB to deliver very high throughput, it may cause high switch occupancy.

For detailed steps about configuring Windows NLB, see Configure Windows Network Load Balancing for Hub Transport Servers.

Hardware Load Balancing

If you have more than eight Hub Transport servers for which you want to load balance non-Exchange message traffic, you need a more scalable load balancing solution. Although there are robust software load balancing solutions available, a hardware load balancing solution provides the most capacity.

Unlike Windows NLB, which only detects server outages by IP address, a hardware load balancer can be configured to detect the failure of the Exchange Transport service and can route incoming e-mail messages to other Hub Transport servers without any manual intervention.

For detailed steps about configuring a hardware load balancing solution, see Configure Hardware Load Balancing for Hub Transport Servers.

1.7.1.21 Understanding MailTips

Understanding MailTips

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

MailTips are informative messages displayed to users while they're composing a message. Microsoft Exchange Server 2010 analyzes the message, including the list of recipients to which it's addressed, and if it detects a potential problem, it notifies the user with MailTips prior to sending the message. With the help of the information provided by MailTips, senders can adjust the message they're composing to avoid undesirable situations or non-delivery reports (NDRs).

The following unproductive messaging scenarios are common in any messaging environment:

- NDRs resulting from messages that violate restrictions configured in an organization such as message size restrictions or maximum number of recipients per message.
- NDRs resulting from messages sent to recipients that don't exist, recipients that are restricted, or users whose mailboxes are full.
- Sending messages to users with Automatic Replies configured.

All of these scenarios involve the user sending a message, expecting it to be delivered, and instead receiving a response stating that the message isn't delivered. Even in the best-case scenario, like the automatic reply, these events result in lost productivity. In the case of an NDR, this scenario could result in a costly call to the Help desk.

There are also several scenarios where sending a message won't result in an error, but

can have undesirable, even embarrassing consequences:

- Messages sent to extremely large distribution groups.
- Messages sent to inappropriate distribution groups.
- Messages inadvertently sent to recipients outside your organization.
- Selecting **Reply to All** to a message that was received as a Bcc recipient.

All of these problematic scenarios can be mitigated by informing users of the possible outcome of sending the message as they're composing the message. For example, if senders know that the size of the message they're trying to send exceeds the corporate policy, they won't attempt to send the message. Similarly, if senders are notified that the message they're sending will be delivered to people outside the organization, they're more likely to ensure that the content and the tone of the message are appropriate.

By addressing the scenarios listed earlier, MailTips can help you to:

- Reduce the cost of processing and storing messages by preventing NDRs.
- Reduce the volume of Help desk calls caused by NDRs.
- Increase productivity by avoiding communications that won't succeed, for example, breaking the cycle of sending an e-mail message, receiving an automatic reply, and then redirecting the message.
- Inform your users as they compose e-mail messages about various policies configured in your organization that impose limits on the messages sent.
- Direct your users to the correct distribution groups.
- Reduce the risk of inadvertent disclosure of information to people outside your organization.

Important:
MailTips aren't designed to enforce specific policies. They simply inform the senders about the nature of the message they're composing so they can make necessary adjustments.

Looking for management tasks related to MailTips? See Managing MailTips.

MailTips in Exchange 2010

The following table provides a list of MailTips in Exchange 2010.

Exchange 2010 MailTips

MailTip	Scenario
Invalid Internal Recipient	The Invalid Internal Recipient MailTip is displayed if the sender adds a recipient that appears to be internal to the organization but doesn't exist in Active Directory. This could happen if the sender addresses a message to a user who is no longer with the company but whose address resolves due to name resolution cache or an entry in the sender's Contacts folder. It can also happen if the sender types an SMTP address with a domain for which Exchange is authoritative and the address doesn't resolve to an existing recipient. The MailTip indicates the invalid recipient and gives the sender the option to remove the recipient from the message.
Mailbox Full	The Mailbox Full MailTip is displayed if the sender adds a recipient whose mailbox is full and your

	organization has implemented a Prohibit Receive restriction for mailboxes over a specified size. The MailTip indicates the recipient whose mailbox is full and gives the sender the option to remove the recipient from the message. The MailTip is accurate at the time of display. If the message isn't immediately sent, the MailTip is updated every two hours. This also applies to messages that were saved in the Drafts folder and reopened after two hours.
Automatic Replies	The Automatic Replies MailTip is displayed if the sender adds a recipient who has turned on Automatic Replies. The MailTip indicates the recipient has Automatic Replies turned on and also displays the first 250 characters of the automatic reply configured by the recipient. The MailTip is accurate at the time of display. If the message isn't immediately sent, the MailTip is updated every two hours. This also applies to messages that were saved in the Drafts folder and reopened after two hours. If part of your user mailboxes are hosted on Exchange Online and you're in a coexistence with Exchange Online scenario, the setting on the remote domain object that represents the remote part of your organization has a direct effect on how this MailTip is processed. In Exchange 2010, users can configure different Automatic Replies for internal and external senders. If the remote domain is configured as an internal domain (by setting the *IsInternal* parameter on the remote domain object to `$true`), the internal automatic reply is returned to all users in the organization regardless of where their mailbox resides. However, if the remote domain isn't configured as an internal domain, the internal automatic reply is returned to all users whose mailboxes are in the local domain and the external automatic reply is returned to users whose mailboxes are in the remote domain.
Custom	A custom MailTip is displayed if the sender adds a recipient for whom a customized MailTip is configured. A custom MailTip can be useful for providing specific information about a recipient. For example, you can create a custom MailTip for a distribution group explaining its purpose to reduce its misuse. By default, custom MailTips aren't displayed if the

	sender isn't allowed to send to that recipient. In that case, the Restricted Recipient MailTip is displayed. However, you can change this configuration and have the custom MailTip also display. For more information about configuring custom MailTips, see Configure Custom MailTips for Recipients.
Restricted Recipient	The Restricted Recipient MailTip is displayed if the sender adds a recipient for which delivery restrictions are configured prohibiting this sender from sending messages. The MailTip indicates the recipient to which the sender isn't allowed to send messages and gives the sender the option to remove the recipient from the message. It also clearly informs the sender that the message won't be delivered if sent. If the restricted recipient is an external recipient, or if it's a distribution group that contains external recipients, this information is also provided to the sender. However, the following MailTips, if applicable, are suppressed: • Automatic Replies • Mailbox Full • Custom MailTip • Moderated Recipient • Oversize Message
External Recipients	The External Recipients MailTip is displayed if the sender adds a recipient that's external, or adds a distribution group that contains external recipients. This MailTip informs senders if a message they're composing will leave the organization, helping them make the correct decisions about wording, tone, and content. By default, this MailTip is turned off. You can turn it on using the **Set-OrganizationConfig** cmdlet. For details, see Configure Organizational Settings for MailTips. If part of your user mailboxes are hosted on Exchange Online and you're in coexistence with an Exchange Online scenario, the setting on the remote domain object that represents the remote part of your organization has a direct effect on how this MailTip is processed. If the remote domain is configured as an internal domain (by setting the *IsInternal* parameter on the remote domain object to `$true`), any recipients in this remote domain will be treated as internal and therefore the External Recipients MailTip won't be displayed. However, if the remote domain isn't configured as an internal domain, the recipients in that domain will be considered external and this

	MailTip will be displayed when a message is being composed to those recipients. **Note:** This MailTip isn't evaluated when composing a message to a distribution group in the remote domain.
Large Audience	The Large Audience MailTip is displayed if the sender adds a distribution group that has more than the large audience size configured in your organization. By default, Exchange displays this MailTip for messages to distribution groups that have more than 25 members. For information about configuring the large audience size for your organization, see Configure Organizational Settings for MailTips. The size of distribution groups isn't calculated each time. Instead, the distribution group information is read from the group metrics data. For more information about group metrics, see Understanding Group Metrics.
Moderated Recipient	The Moderated Recipient MailTip is displayed if the sender adds a recipient that's moderated. The MailTip indicates which recipient is moderated and informs the sender that this may result in delay of the delivery. If the sender is also the moderator, this MailTip isn't displayed. It's also not displayed if the sender has been explicitly allowed to send messages to the recipient (by adding the sender's name to the Accept Messages Only From list for the recipient).
Reply-All on Bcc	The Reply-All on Bcc MailTip is displayed if the sender receives a Bcc copy of a message and selects **Reply to All**. When a user selects **Reply to All** to such a message, the fact that the user received a Bcc of that message is revealed to the rest of the audience to which the message was sent. In almost all cases, this is an undesirable situation, and this MailTip informs the user of this condition. **Note:** This MailTip is only supported in Microsoft Office Outlook Web App.
Oversize Message	The Oversize Message MailTip is displayed if the message the sender is composing is larger than configured message size limits in your organization. The MailTip is displayed if the message size violates one of the following size restrictions: • Maximum send size setting on the sender's mailbox

	• Maximum receive size setting on the recipient's mailbox • Maximum message size restriction for the organization • Maximum Request Length setting (for Outlook Web App only) **Note:** Due to the complexity of the implementation, the message size limits on the connectors in your organization aren't taken into account. **Note:** This MailTip isn't displayed in Outlook Web App.

MailTips Architecture

MailTips are implemented as a Web service in Exchange 2010. When a sender is composing a message, the client software makes an Exchange Web service call to the server running Exchange 2010 with the Client Access server role installed to get the list of MailTips. The Exchange 2010 server responds with the list of MailTips that apply to that message, and the client software displays the MailTips to the sender.

The following messaging clients support MailTips:

- Outlook Web App
- Microsoft Outlook 2010

The following actions by the sender trigger MailTips to be evaluated or updated:

- Add a recipient
- Add an attachment
- Reply or reply to all
- Open a message, which is already addressed to recipients, from the Drafts folder

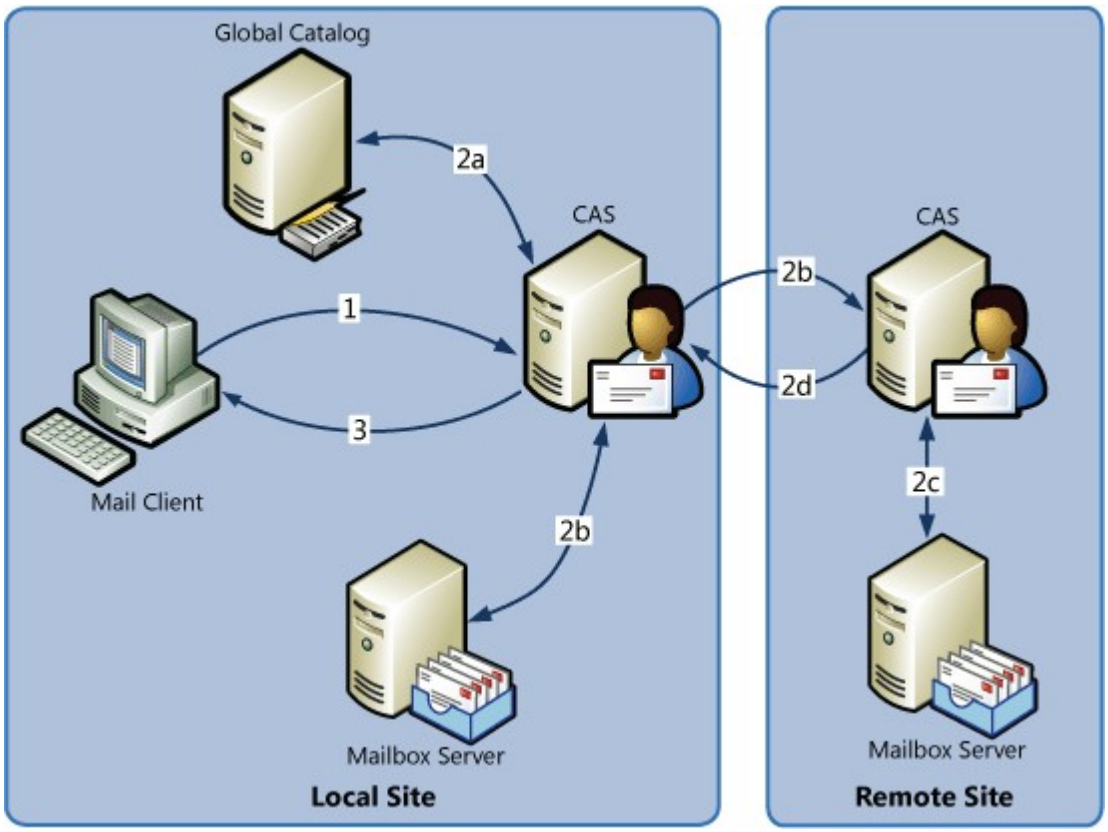
The client caches the MailTips so removing and adding the same recipient won't result in the client querying the Client Access server again.

When the Client Access server is queried, it compiles the list of applicable MailTips and returns them all in one batch. As a result, all MailTips are displayed to the user at the same time and don't arrive one at a time, distracting the sender.

The Client Access server uses the following sources to compile MailTips for a specific message:

- Active Directory
- Recipient mailboxes
- Local group metrics data

Each time a sender adds a recipient to a message, a sequence of events occurs to evaluate MailTips, as shown in the following figure.



As shown in the preceding figure:

1. The mail client queries the Web service on the Client Access server for MailTips that apply to the recipients in the message.
2. The Client Access server gathers MailTip data:
   - 2.a. The Client Access server queries Active Directory and reads group metrics data.
   - 2.b. If the recipient is a mailbox that's located on a Mailbox server in the local site, the Client Access server queries the Mailbox server to gather the Automatic Replies and Mailbox Full MailTips. If the recipient's mailbox is in another site, the Client Access server requests MailTips information from the Client Access server in the remote site.
   - 2.c. The Client Access server in the remote site queries the local Mailbox server for MailTip data.
   - 2.d. The remote Client Access server proxies the results back to the requesting Client Access server.
3. The Client Access server returns MailTip data back to the client.

Limits on MailTips

MailTips are subject to the following restrictions:

- MailTips aren't supported when working in offline mode with Outlook.
- When a message is addressed to a distribution group, the MailTips for individual recipients that are members of that distribution group aren't evaluated. However, if any of the members is an external recipient, the External Recipients MailTip is displayed, which shows the sender the number of external recipients in the distribution group.
- If the message is addressed to more than 200 recipients, individual mailbox MailTips aren't evaluated due to performance reasons.
- Custom MailTips are limited to 250 characters.
- If the sender starts composing a message and leaves it open for an extended

period of time, the Automatic Replies and Mailbox Full MailTips are evaluated every two hours.

MailTips in Complex Topologies

MailTips that rely on the recipients' mailbox data are evaluated by making a connection to the Mailbox servers that hold those recipients. The Mailbox Full and Automatic Replies MailTips are in this category. For these MailTips, the Client Access server directly queries the Mailbox server using RPC, but only if the recipients are in the same site. For recipients that reside in other sites or forests, this information is gathered via server-to-server Web requests between Client Access servers.

MailTips over Organization Relationships

Microsoft Exchange Server 2010 Service Pack 1 (SP1) allows you to configure organization relationships with Exchange Online or other organizations. Establishing an organization relationship allows you to enhance the user experience when dealing with the other organization with features including sharing free/busy data between the two organizations, configuring secure message flow, and enabling message tracking across the two organizations. For more information about organization relationships, see Understanding Federation.

When MailTips are enabled over an organization relationship, the local Client Access servers will proxy the Client Access servers in the remote organization. The behavior is similar to how mailbox-specific MailTips are handled for users in remote Active Directory sites. The one difference is the Client Access servers will proxy all MailTips types over an organization relationship, not just the mailbox-specific MailTips.

You have granular control over which MailTip types are returned over an organization relationship in addition to just allowing or preventing returning MailTips. The following two sections explain these settings in detail.

Controlling the MailTips Access Level

There may be many reasons to establish an organization relationship. Depending on the specific situation, you may want to restrict certain types of MailTips. Specifically, you can either allow all MailTips to be returned or only a limited set that would prevent NDRs. You can configure this setting with the *MailTipsAccessLevel* parameter of the **Set-OrganizationRelationship** cmdlet. The following table shows which MailTips are returned over the organization relationship.

MailTip	All	Limited
Large Audience	Yes	No
Automatic Replies	Yes If the remote domain of the recipient is specified as internal, the internal automatic reply is displayed. Otherwise, the external automatic reply is displayed.	Yes The external automatic reply is displayed.
Moderated Recipient	Yes	No
Oversize Message	Yes	Yes
Restricted Recipient	Yes	Yes
Mailbox Full	Yes	No
Custom MailTips	Yes	No
External Recipients	Yes	Yes

	If the remote domain of the recipient is specified as internal, this MailTip is suppressed. Otherwise, the external MailTip is returned.	If the remote domain of the recipient is specified as internal, this MailTip is suppressed. Otherwise, the external MailTip is returned.

For detailed steps about how to configure MailTips access levels, see Configure Organizational Settings for MailTips.

Controlling the MailTips Access Scope

When you enable MailTips over an organization relationship and set the access level to All, the recipient-specific MailTips, Mailbox Full, Automatic Replies, and custom MailTips, are returned for all users. However, you may only want to allow these MailTips for a specific set of users. For example, if you set up an organization relationship with a partner, you may want to allow these MailTips only for the users that work with that partner.

To achieve this, you need to first create a group and add all users for whom you want to share recipient-specific MailTips to that group. You can then specify that group on the organization relationship.

After you implement this restriction, your Client Access servers will first verify whether the recipient for whom they received a MailTips query is part of this group. If the recipient is a member of this group, the Client Access servers will proxy back all MailTips including the recipient-specific MailTips. Otherwise they won't include the recipient-specific MailTips in their response.

For detailed steps about how to configure MailTips access levels, see Configure Organizational Settings for MailTips.

Performance and Scalability

The following table lists some of the common performance concerns regarding MailTips and how these concerns are addressed.

Common performance concerns for MailTips

Performance concerns	Mitigation of concern
Discovering the size of distribution groups and dynamic distribution groups, and whether they include external recipients, seems like an expensive operation.	Distribution groups and dynamic distribution groups aren't evaluated when a message is being composed. This information is calculated daily by the group metrics generation service and is distributed to all Client Access servers. For more information, see Understanding Group Metrics.
Discovering the delivery restrictions for all recipients in a message with a large number of recipients can be resource- intensive.	Delivery restrictions aren't evaluated if a message has more than 200 recipients. Also, delivery restrictions aren't evaluated for the members of distribution groups and dynamic distribution groups. This is done only for recipients that are explicitly added to the message. If a user expands a distribution group, delivery restrictions for all members will be

	evaluated, as long as the total number of recipients doesn't exceed 200.
It may take a long time to collect information from various sites in complex topologies.	If the requested information isn't returned within 10 seconds, the operation times out. Exchange won't display any new MailTips to the sender after 10 seconds.

1.7.1.22 Understanding Message Routing

Understanding Message Routing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-12*

The primary task of Hub Transport and Edge Transport servers in your organization is to route messages received from users and external sources to their ultimate destinations. This topic explains how Microsoft Exchange Server 2010 routes messages in your organization.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Overview of Message Routing in Exchange 2010

Routing decisions are made during message categorization. The categorizer is a component of the Microsoft Exchange Transport service that processes all incoming messages and determines what to do with the messages based on information about the intended recipients. The categorizer processes messages in several dependent phases and also uses other components of the Microsoft Exchange Transport service during message processing. After a message is received by an Exchange 2010 transport server, and after the preliminary processing that occurs during SMTP Receive is complete, the message is delivered to the Submission queue. Messages move from the Submission

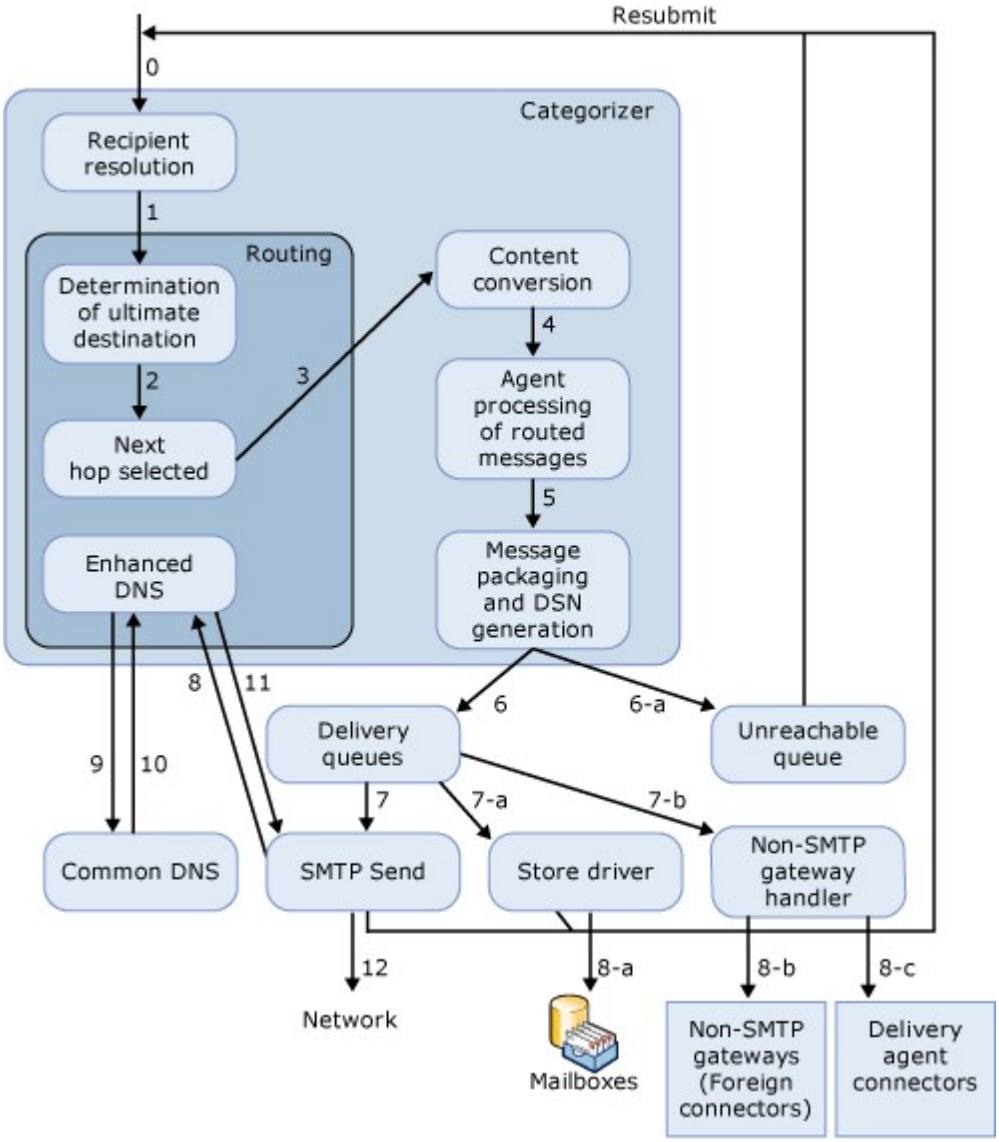
queue through the categorizer in the following phases:

1. **Agent processing of submitted messages** Some agent processing on the Hub Transport server occurs when the message is received for categorization. The agents that are applied during this phase include the optional Microsoft Forefront Protection for Exchange Server antivirus agent and the Journaling agent.
2. **Recipient resolution** During this phase, the recipient's e-mail address is resolved to determine whether the recipient has a mailbox in the Exchange organization or an external e-mail address.
3. **Routing** After information about the recipient is resolved, the routing component of the categorizer determines the ultimate destination for the message and the route to that destination, selects the next segment, or hop, for message relay, and resolves the next hop information to a list of physical servers and IP addresses.
4. **Content conversion** Before a message is relayed to its next hop, content conversion occurs so that the message is sent in a format that's readable by the recipient. *Content conversion* transforms e-mail messages from one format to another format for mail flow or storage, such as MAPI to MIME, or UUENCODE to base64 encoded, or for appropriate rendering that's specific to an e-mail client, such as HTML, rich text format (RTF), or plain text.
5. **Agent processing of routed messages** After the routing decisions for a particular message are made, the Transport Rules agent and the Journaling agent are applied on the Hub Transport server. The Journaling agent is applied both when the message is submitted and when it's routed so that any changes that are made to the message by the Transport Rules agent, for example, when it modifies a delivery address or applies a message-specific journaling requirement, don't bypass the Journaling agent.
6. **Message packaging and DSN generation** The final categorized message is assembled and moved to a delivery queue. A delivery status notification (DSN) may also be generated during this phase.

Messages are next processed by SMTP Send, the store driver, delivery agents, or the foreign gateway connection handler. The component that's used depends on the ultimate destination. A delivery queue is dynamically generated for each hop. The messages are queued in these delivery queues after a routing decision is made. If a route can't be found for a recipient, the messages are queued to the Unreachable queue.

The following figure shows how message processing occurs in the different routing phases and how messages are queued for delivery to the next hop destination.

Routing context in mail flow



Return to top

Routing Components

To make routing decisions, Exchange 2010 must access configuration information that's stored in Active Directory. On an Edge Transport server, configuration information is stored in and accessed from the Active Directory Lightweight Directory Services (AD LDS) instance on the local server. Microsoft Windows and Exchange 2010 services work together to create mappings of the configuration data. These mappings are cached in routing tables. Exchange 2010 references these tables when it makes routing decisions. The cache is updated when the routing topology changes. The Exchange services that are used during message transport are common to both the Hub Transport server role and the Edge Transport server role. However, the Edge Transport server role doesn't cache information about the Active Directory topology.

The following configuration and service components are important to message routing:

- **Active Directory sites** An Active Directory site represents the routing boundary for Hub Transport servers. A Hub Transport server delivers directly

to Mailbox servers, distribution group expansion servers, and to source servers for connectors in the local Active Directory site and to Edge Transport servers subscribed to that site. However, a Hub Transport server must relay messages to another Hub Transport server for recipients, expansion servers, and connectors that are located in remote Active Directory sites. The Hub Transport server role must be deployed in every Active Directory site that contains other Exchange 2010 server roles.

- **Active Directory IP site links** Active Directory IP site links define logical paths between Active Directory sites. Exchange 2010 references the IP site link objects to determine the least-cost routing path of remote Active Directory sites.
- **Send connectors** Send connectors are used for sending messages to other SMTP hosts. The address space configuration on Send connectors are used to make routing decisions. When a message is delivered to an external domain, the routing destination is typically a Send connector. An Exchange organization that accepts messages for more than one e-mail domain may decide to create Send connectors that are dedicated to each address space. For more information about Send connector selection for routing messages to external domains, see External Message Routing.
- **Delivery agents** Delivery agents are used to route messages to foreign systems that don't use SMTP protocol for message transfer. The address space and protocol configuration of delivery agents are used when making routing decisions.
- **Foreign connectors** Foreign connectors use drop directories to send messages to foreign systems that don't use SMTP protocol for message transfer. Exchange uses the configuration of Foreign connectors when making routing decisions.
- **Routing groups** Routing groups represent a routing boundary for Exchange Server 2003. If Exchange 2010 is deployed in an existing Exchange 2003 organization, routing must consider the location of servers within routing groups to deliver a message to a mailbox or a connector that resides on Exchange 2003. To implement compatibility with Exchange 2003, all computers running Exchange 2010 deployed in the organization belong to a single, global routing group.
- **Routing group connectors** Routing group connectors define logical paths between Exchange routing groups. If Exchange 2010 is deployed in an existing Exchange 2003 organization, messages are routed between server versions through routing group connectors. When the first Hub Transport server is deployed, the setup process prompts you to create a routing group connector from the global Exchange 2010 routing group to a legacy routing group. For more information about message routing in an environment where more than one version of Exchange is deployed, see Internal Message Routing.
- **Microsoft Exchange Transport service** The Microsoft Exchange Transport service is the SMTP provider for Exchange 2010 and controls every component of message processing, from SMTP IN to SMTP OUT. A series of configurable SMTP Receive agents are triggered at various SMTP events. The Microsoft Exchange Transport service enables these agents to process messages as they pass through SMTP transport and perform anti-spam, antivirus, and other tasks before messages are submitted to the categorizer. The Microsoft Exchange Transport service also uses the topology discovery module for Exchange topology discovery.
- **Microsoft Exchange Active Directory Topology service** The Microsoft Exchange Active Directory Topology service is responsible for locating the domain controllers and global catalog servers that Exchange 2010 can use to retrieve configuration and recipient data from Active Directory. The Microsoft Exchange Active Directory Topology service is also responsible for keeping Active Directory site affinity for an Exchange 2010 server up to date.
- **Routing tables** The routing tables hold the information that the routing component uses to make routing decisions. The routing table is composed of a

map of topology components and their relationship to one another.

- **DNS** Exchange 2010 uses an enhanced Domain Name System (DNS) client, a component of the Microsoft Exchange Transport service, to resolve the next hop selection to a list of target server names. The standard DNS client is used to resolve that list of server names to IP addresses. Enhanced DNS also provides load-balancing functionality for Exchange 2010 transport servers by using round robin.
- **SMTP** SMTP is used for communication when messages are relayed between SMTP servers. An SMTP server can be a Hub Transport server, Edge Transport server, Exchange 2003 server, or a smart host. A Hub Transport server uses remote procedure call (RPC) to deliver messages directly to Mailbox servers that have the same Active Directory site membership as the Hub Transport server.

Return to top

Using Active Directory Sites for Routing

An Active Directory site is a logical configuration component that's based on the physical aspects of the network. The primary purpose for creating an Active Directory site is to define which subnets in the network are connected in a way that optimizes control of Active Directory replication traffic. The Active Directory site represents a routing boundary for Exchange 2010. Computers that have the Hub Transport server role installed make routing decisions based on the Active Directory site topology.

Determining Site Membership

By default, an Active Directory forest contains only one Active Directory site. The default name for this Active Directory site is Default-First-Site-Name. If no other Active Directory sites are created, all domain member computers in the forest are members of Default-First-Site-Name. You don't have to configure a subnet-to-site association. If additional Active Directory sites are created, you must specify the subnets that are assigned to that Active Directory site.

Each Active Directory site is associated with one or more IP subnets. An administrator assigns Active Directory site membership to computers that are configured as domain controllers and global catalog servers. Other domain member computers, such as Exchange servers, are assigned Active Directory site membership automatically when they're configured to use an IP address that's in an IP subnet that's associated with an Active Directory site. Computers that have the same Active Directory site membership are presumed to have good network connectivity. A server is always a member of a single Active Directory site.

When an application can determine the Active Directory site membership of the computer where it's installed and of other computers in the forest, and then use that information to control communication flow, it's a site-aware application. When site-aware applications must use the services of another server, such as a domain controller or global catalog server, priority is given to the servers that have the same Active Directory site membership as the computer that's requesting those services.

Exchange 2010 is a site-aware application and uses the Active Directory topology for message routing and to communicate with the services that are running on computers that have other Exchange 2010 server roles installed. The Active Directory site isn't only the routing boundary. It's also the service discovery boundary.

Determining site membership for a domain member computer depends on a series of DNS queries to compare the local IP address to defined subnets and then determine the appropriate site membership association. To reduce the overhead that's associated with DNS queries, the Exchange 2010 Active Directory schema additions include the **msExchServerSite** attribute for the Exchange server object. The value of this attribute is

the distinguished name of the Active Directory site of an Exchange server. This attribute is a property of each Exchange server object. When site membership affinity is stored as an attribute of the server object, the current topology can be read directly from Active Directory instead of relying on DNS queries and a site membership association is enabled for a non-domain computer, such as a subscribed Edge Transport server.

The value for the **msExchServerSite** attribute is populated and kept up to date by the Microsoft Exchange Active Directory Topology service. When a Windows-based computer starts, the Net Logon service determines site membership for the computer. The Net Logon service uses that information to locate domain controllers that are located in the same Active Directory site as the local computer and then directs authorization and authentication requests to those servers. The Microsoft Exchange Active Directory Topology service uses the DsGetSiteName API call to retrieve the site membership value from the Net Logon service and writes the Active Directory site's distinguished name to the **msExchServerSite** attribute for the Exchange server object in Active Directory.

The following table shows how an organization might define Active Directory sites. In this example, three Active Directory sites are defined, and each Active Directory site is associated with more than one IP subnet.

Example of an Active Directory site-to-subnet association

Active Directory site name	Associated IP subnets
Site A	192.168.1.0/24 192.168.2.0/24
Site B	192.168.3.0/24 192.168.4.0/24
Site C	192.168.5.0/24 192.168.6.0/24

If a server named HubTransportA has the IP address of 192.168.1.1, it's a member of Site A. By changing the IP address of a server, you may change its site membership. If you change the IP address of HubTransportA to 192.168.2.1, it won't change the server's Active Directory site membership because that subnet is also associated with Site A. However, if you move the server and the IP address changes to 192.168.3.1, the server would be considered a member of Site B.

A change in site membership can also occur if you change the association of subnets to Active Directory sites. For example, if you remove the subnet 192.168.3.0 from association with Site B and associate it with Site A, the site membership of a server that has the IP address of 192.168.3.1 also changes to Site A. Whenever a change in site membership occurs, Exchange 2010 must update its configuration data so that the change is considered when Exchange 2010 makes routing decisions. Some latency occurs between the time that a change in an Active Directory site membership occurs and the topology change is fully propagated. The following communication must occur in the following order to propagate topology changes:

1. The change in site membership is written to a domain controller. The updated information replicates between the domain controllers in each Active Directory site in the forest. The time that's required for the change to propagate fully throughout the forest depends on the Active Directory replication topology and schedule as defined by site links.
2. The Net Logon service runs on all Windows-based computers and polls frequently for changes in Active Directory site membership. The Net Logon service polls at five-minute intervals. Therefore, the change is detected by

the Net Logon service within five minutes of the local domain controller receiving the update.

3. The Microsoft Exchange Active Directory Topology service queries the Net Logon service at 15-minute intervals to determine the Active Directory site membership of the local Exchange server. If a change is detected, the Microsoft Exchange Active Directory Topology service updates the **MsExchServerSite** attribute.
4. The changed site attribute value of the Exchange server configuration object is then replicated throughout the organization. The Exchange servers in the organization detect this change. Then the routing tables are updated with the new Active Directory site membership attribute value.

Some latency occurs between the time that an Active Directory site membership change takes effect and the time that the updated information is available to another Exchange 2010 server. For more information about how Exchange 2010 handles these types of configuration changes, see "Rerouting and the Unreachable Queue" later in this topic.

IP Site Links

Site links are logical paths between Active Directory sites. A site link object represents a set of sites that can communicate at a uniform cost through a specified intersite transport. Site links don't correspond to the actual path taken by network packets on the physical network. However, the cost assigned to the site link by the administrator typically relates to the underlying network reliability, speed, and available bandwidth. For example, the Active Directory administrator would assign a lower cost to a network connection with a speed of 100 megabits per second (Mbps) than to a network connection with a speed of 10 Mbps.

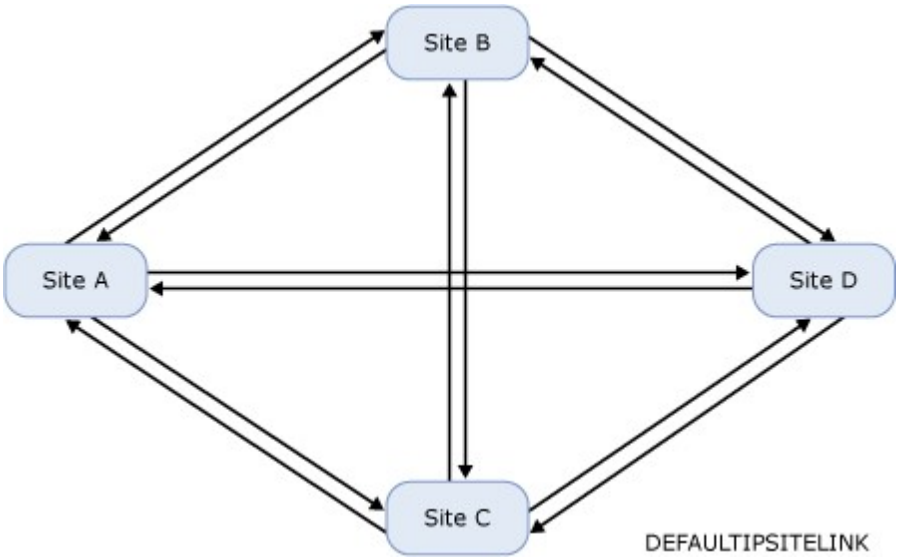
By default, all site links are transitive. This means that if Site A has a link to Site B, and Site B has a link to Site C, Site A is transitively linked to Site C. The transitive link between Site A and Site C is also known as a *site-link bridge*.

An Active Directory site link can be configured to use either IP or SMTP as the transport protocol for communication. An SMTP site link is limited in the types of data that can be replicated by using that protocol and is designed to provide a store and forward mechanism for replication between Active Directory sites that don't have a reliable network link. An IP site link isn't limited in the types of data that can be replicated across it. Exchange 2010 uses only IP site links to determine its routing topology. The cost that's assigned to the IP site link will be considered by the routing component of Exchange 2010 when calculating a routing table. These costs are used to calculate the least-cost routing path to the ultimate destination for a message.

Every Active Directory site must be associated with at least one IP site link. There is a single default IP site link named DEFAULTIPSITELINK. When you create an Active Directory site, you must associate that site to an IP site link. You can create additional IP site links to implement the desired topology, or you can associate every Active Directory site to the DEFAULTIPSITELINK. Each Active Directory site that's part of an IP site link can communicate directly with every other site in that link at a uniform cost.

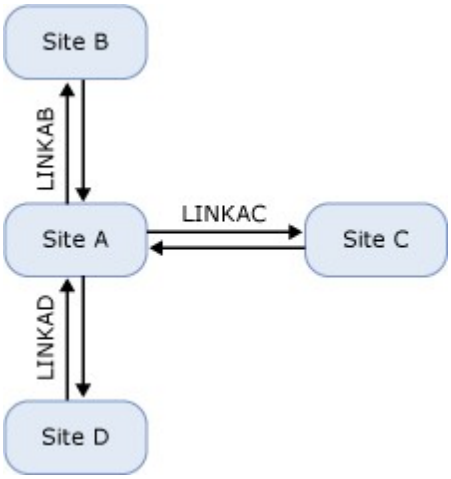
In the following figure, four Active Directory sites are configured in the forest. Every site has been associated with the DEFAULTIPSITELINK. Therefore, each Active Directory site communicates directly with every other site by using the same cost metric. More than one communication path is indicated, but only a single IP site link is defined.

Full mesh topology with a single IP site link



In the following figure, four Active Directory sites are configured in the forest. In this topology, the administrator has configured IP site links to create a *hub-and-spoke topology* of Active Directory sites. Each spoke site can communicate directly with the central site, and the spoke sites can communicate with one another by using the transitive IP site links.

Hub-and-spoke topology of Active Directory IP site links



It's important to note that Exchange uses site links only when determining the least-cost path, but will always try to deliver messages directly to the destination Hub Transport server. For example, if a user in Site B in the topology shown in the preceding figure sends a message to another user in Site C, the Hub Transport server in Site B will connect directly to the Hub Transport server in Site C. If you want to force messages to go through Site A, you must enable that site as a hub site. For more information about hub sites, see "Implementing Hub Sites" later in this topic.

An Active Directory administrator implements the topology that best represents the connectivity and communication requirements of the forest. Because the same topology is used by Exchange 2010, you must make sure that the current topology supports efficient messaging communication.

The default cost for a site link is 100. A valid site link cost can be any number from 1

through 99,999. If you specify redundant links, the link with the lowest cost assignment is always preferred. An Exchange organization administrator can assign an Exchange-specific cost to an IP site link. If an Exchange cost is assigned to an IP site link, it will be used by Exchange 2010. Otherwise, the Active Directory cost is used. For more information about how to set an Exchange cost on an IP site link, see "Controlling IP Site Link Costs" later in this topic. An administrator who has membership in the Enterprise Administrators group can create additional IP site links.

For more information about Active Directory site configuration, see Designing the Site Topology.

Controlling IP Site Link Costs

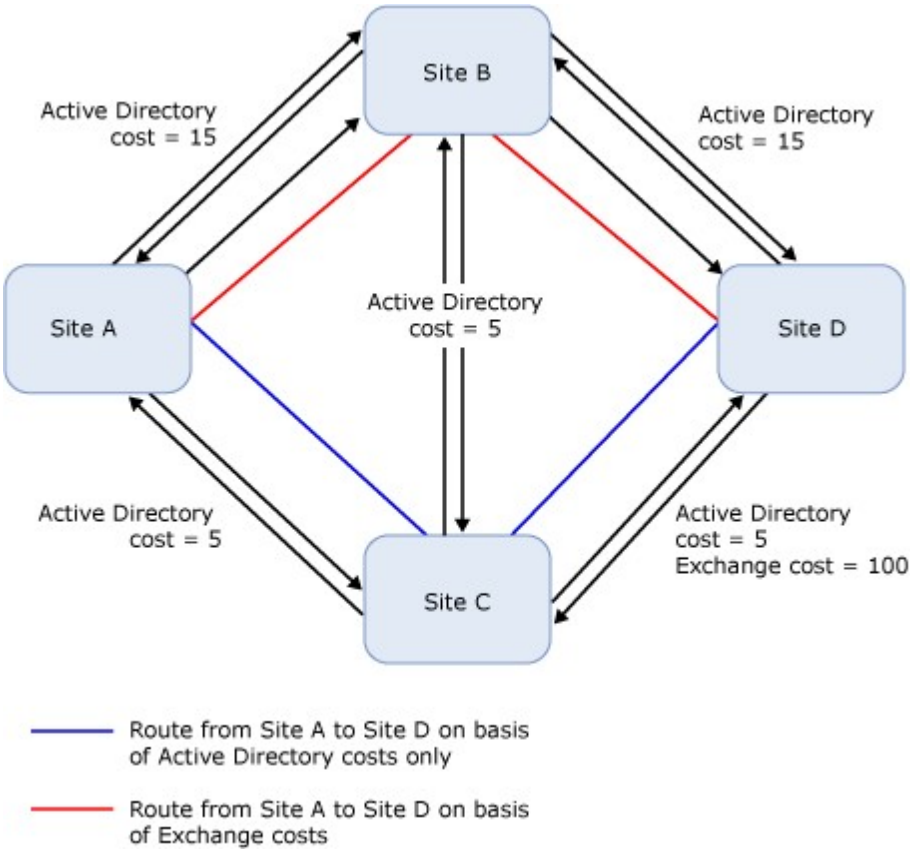
Active Directory IP site links costs are based on relative network speed compared to all network connections in the WAN and are designed to produce a reliable and efficient replication topology. Therefore, in most cases, the existing IP site link costs should work well for Exchange 2010 message routing. However, if after documenting the existing Active Directory site and IP site link topology, you verify that the Active Directory IP site link costs and traffic flow patterns aren't optimal for Exchange 2010, you can make adjustments to the costs evaluated by Exchange. Changing the cost assigned to the IP site link by using Active Directory tools would impact the entire environment. Instead, use the **Set-AdSiteLink** cmdlet in the Exchange Management Shell to assign an Exchange-specific cost to the IP site link. For example, to set a different cost on the IP site link SITELINKAB for message routing purposes, run the following command in the Shell.

```
Set-AdSiteLink -Identity SITELINKAB -ExchangeCost 25
```

When an Exchange cost is assigned to an IP site link, the Exchange cost overrides the Active Directory cost for message routing purposes, and routing only considers the Exchange cost when it evaluates the least-cost routing path.

Adjusting IP site link costs can be useful when the message routing topology has to diverge from the Active Directory replication topology. Exchange costs can be used to force all message routes to use a hub site. Exchange costs can also be used to control where messages are queued when communication to an Active Directory site fails. The following figure shows an Active Directory topology with four sites.

Topology with Exchange costs configured on IP site links



In the preceding figure, the network connection between Site C and Site D is a low bandwidth connection that's only used for Active Directory replication and shouldn't be used for message routing. However, the Active Directory IP site link costs cause that link to be included in the least-cost routing path from any other Active Directory site to Site D. Therefore, messages are delivered to the Site D queue in Site C. The Exchange administrator prefers that the least-cost routing path include Site B instead so that if Site D is unavailable, the messages will queue at Site B. Configuring a high Exchange cost on the IP site link between Site C and Site D prevents that IP site link from being included in the least-cost routing path to Site D.

Exchange 2010 provides support for configuration of a maximum message size limit on an Active Directory IP site link. By default, Exchange 2010 doesn't impose a maximum message size limit on messages that are relayed between Hub Transport servers in different Active Directory sites. If you use the **Set-AdSiteLink** cmdlet to configure a maximum message size on an Active Directory IP site link, routing generates a non-delivery report (NDR) for any message that has a size larger than the maximum message size limit that's configured on any Active Directory site link in the least-cost routing path. This configuration is useful for restricting the size of messages that are sent to remote Active Directory sites that must communicate over low-bandwidth connections. For more information, see Understanding Message Size Limits.

Implementing Hub Sites

In your Exchange organization, you may have to force all message delivery to be relayed through a particular Active Directory site. In this scenario, connectivity may prevent direct SMTP relay between sites. Therefore, messages must be relayed through an interim site before they're sent to their destination. Because of an Exchange organization's internal policies, an administrator may also want to relay all messages through a particular site. You can use Shell cmdlets to designate an Active Directory site as a hub site. By designating an Active Directory site as a hub site, you cause additional overall overhead

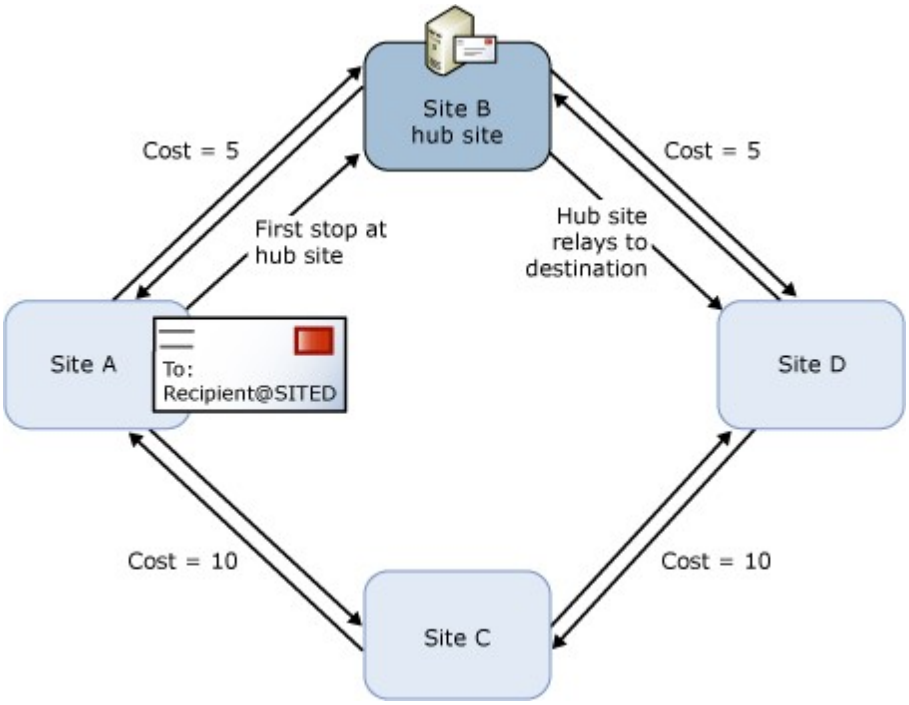
because more servers are involved in message delivery. For example, consider a message that's sent from Site A to Site E. If the least-cost routing path is Site A-Site B-Site C-Site D-Site E, and you designate Site C as a hub site, the message is relayed from Site A to Site C and then relayed from Site C to Site E.

You use the **Set-AdSite** cmdlet to specify an Active Directory site as a hub site. Whenever a hub site exists along the least-cost routing path for message delivery, the messages queue and are processed by the Hub Transport servers in the hub site before they're relayed to their ultimate destination.

After the least-cost routing path is chosen, routing determines whether there's a hub site along that routing path. If a hub site is configured, messages stop at a Hub Transport server in the hub site before they're relayed to the target destination. If there's more than one hub site along the least-cost routing path, messages stop at each hub site along the routing path.

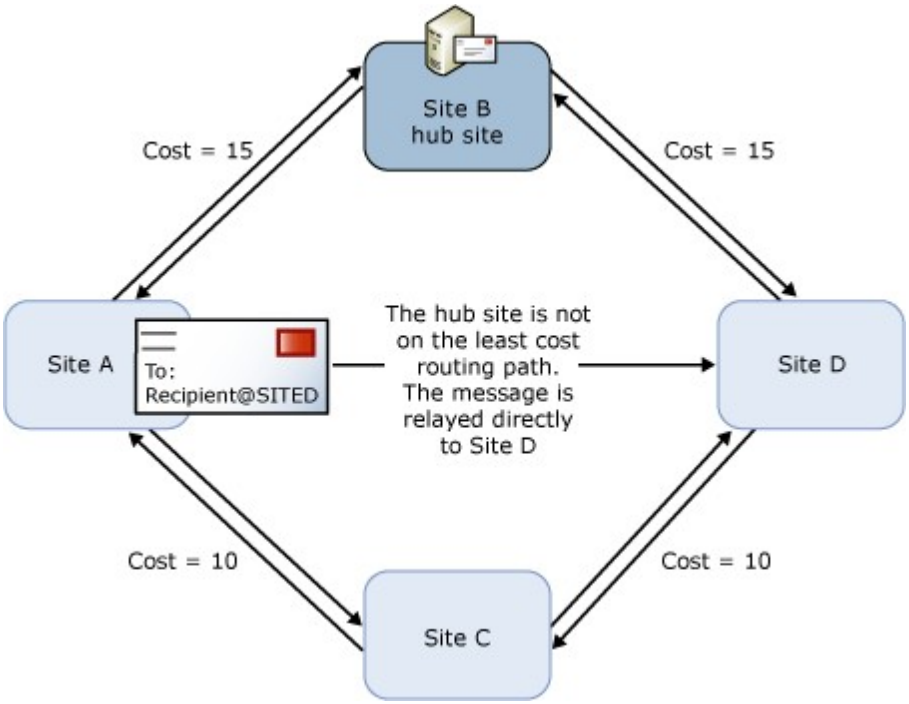
This variation to direct relay routing only is in effect when the hub site is located along the least-cost routing path. The following figure shows the correct use of a hub site. In this diagram, Site B is configured as a hub site. Messages that are relayed from Site A to Site D are relayed to Site B before they're delivered to Site D.

Message delivery with a hub site



The following figure shows how IP site link costs affect routing to a hub site. In this scenario, Site B has been designated as a hub site. However, because it doesn't exist along the least-cost routing path between any other sites, queuing at Site B before delivery to the destination doesn't occur. An Active Directory site is never used as a hub site if it isn't on the least-cost routing path between two other sites.

Misconfigured hub site



You can configure any Active Directory site as a hub site. However, for this configuration to work correctly, you must have deployed at least one Hub Transport server in the hub site.

Topology Discovery

The Exchange 2010 topology relies on the Active Directory site topology and doesn't have its own configuration. The Active Directory topology is made available to Exchange 2010 by the following required elements:

- The Microsoft Exchange Active Directory Topology service
- The topology discovery module inside the Microsoft Exchange Transport service

The Microsoft Exchange Active Directory Topology service runs on all Exchange 2010 server roles, except the Edge Transport server role. These Exchange 2010 servers use the Microsoft Exchange Active Directory Topology service to discover the domain controllers and global catalog servers that can be used by the Exchange servers to read and write Active Directory data. Exchange 2010 binds to the identified directory servers whenever Exchange has to read from or write to Active Directory.

The topology discovery module is part of the Microsoft Exchange Transport service and provides information about the Active Directory topology to Exchange servers. This API discovers the Exchange servers and roles in the organization and determines their relationship to the Active Directory configuration objects. Configuration data is retrieved from Active Directory and then cached so that it can be accessed by the Exchange services that are running on that computer.

The topology discovery module performs the following steps to generate an Exchange routing topology:

1. Data is read from Active Directory. All the following objects are retrieved:
   - Active Directory sites.
   - IP site links.
   - All Exchange servers. This includes information about the Exchange 2010 server roles deployed on those servers.
2. The data that's retrieved in step 1 is used to create the initial topology and

to begin linking and mapping the related configuration objects.
3. Exchange servers are matched to Active Directory sites by retrieving the site attribute value from the Exchange server object that's stored in Active Directory.
4. Routing tables are updated with the collection of information retrieved.

This process makes every Exchange 2010 server aware of the other Exchange servers in the organization and of how close the Exchange servers are to one another.

Return to top

Exchange 2010 Routing Tables

When the Microsoft Exchange Transport service starts, it calculates a set of routing tables that's based on the snapshot of information that's retrieved from Active Directory or, on an Edge Transport server, from AD LDS. The configuration information that's stored in AD LDS includes available connectors and accepted domains, but doesn't include topology data.

The routing component refers to the routing tables to determine how to route messages to recipients. When configuration changes are made, the routing tables are rebuilt. The new routing tables are used to route new incoming messages. Messages in remote delivery queues are also rerouted if the routing component determines that they're affected by the configuration changes. For more information about message rerouting, see "Rerouting and the Unreachable Queue" later in this topic.

The following configuration data is retrieved from Active Directory and made available to the routing component of Hub Transport servers:

- Active Directory sites
- Active Directory IP site links
- Exchange servers and their relationship to Active Directory sites
- SMTP connectors
- Non-SMTP connectors

  Note:
  Non-SMTP connectors include Exchange 2010 delivery agent connectors, Foreign connectors, and in coexistence scenarios, any non-SMTP connectors hosted by Exchange 2003.

- Routing groups
- Routing group connectors
- Mailbox stores (private message databases (MDBs))
- Public folder stores (public MDBs)
- Public folder hierarchies

Based on this data, the routing component of the Microsoft Exchange Transport service populates routing tables to help streamline routing decisions. The routing table correlates the data to create a topology map. This topology map contains the following elements:

- **Linked connectors map** This map correlates the identifiers of Receive connectors on the local server to the linked Send connector.
- **Server map** All Exchange 2010 and Exchange 2007 Hub Transport servers, Edge Transport servers, Mailbox servers, and Exchange 2003 servers in the organization are contained in the server map. This map correlates the distinguished name of each Exchange server to server routing data. This includes the total cost to reach that server.
- **Legacy server map** All Exchange Server 2007 Hub Transport servers, Edge Transport servers, Mailbox servers, and Exchange 2003 servers in the organization are contained in the legacy server map. This map correlates the legacy distinguished name of each Exchange server to server routing data.

This includes the total cost to reach that server. This map supports store override functionality. Store override functionality is specific to public folders. For more information, see "Routing to Public Folders" in Internal Message Routing.

- **MDB map** All MDBs in the organization are contained in the MDB map. This map correlates the distinguished name of each MDB to server routing data. This includes the total cost to reach that server.
- **Active Directory site map** This map correlates each Active Directory site to a structure that contains the least-cost routing path from the local site to every other site. The map includes any hub sites along the least-cost routing path. Each routing path hop also identifies all Hub Transport servers in that site that will be used by the enhanced DNS component.
- **Routing groups map** This map associates the total cost and first hop routing group connector for the least-cost routing path from the Exchange 2010 routing group to each legacy routing group.
- **Send connectors map** This map identifies the Send connectors configured in the organization and the source servers for each connector.

The routing tables are built every time that a transport server is started and recalculated when configuration changes are received. Configuration changes can be detected in any of the following ways:

- **Active Directory change notifications** There is a delay between the time that a notification is received and the time that the change is written to the routing tables. This delay lets the routing component batch the changes and process more than one change in a single operation. By default, each notification causes the routing component to delay processing by five seconds. For example, if five notifications are received exactly one second after the previous notification, routing delays processing the change for a total of nine seconds.
- **Configuration reloading caused by service control commands** The routing component reloads the configuration data when the Microsoft Exchange Transport service is restarted.
- **Periodic reload to track changes that aren't supported by Active Directory notifications** By default, routing will periodically reload the configuration data to make sure that all changes are tracked. The configuration reload occurs at six-hour intervals.

The information in the routing tables is logged to routing logs. By default, these logs are located in the C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\Routing folder. A new log is generated every time that the routing tables are calculated. If for some reason the Hub Transport server is unable to contact Active Directory, routing continues to make routing decisions based on the currently cached data, even though that data may not be up to date. For more information, see Understanding Routing Table Logging.

Return to top

Receiving Messages for Routing

A message can arrive at a Hub Transport server in any of the following ways:

- E-mail is received from an Internet-facing SMTP server for delivery to a recipient in the Exchange organization or to a recipient in an internal relay accepted domain.
- E-mail is received from another Hub Transport server in the Exchange organization for delivery to a recipient mailbox that's located on a Mailbox server in that Active Directory site.
- E-mail is received from SMTP clients. These are typically POP3 or IMAP4 users that may exist in your environment.
- E-mail is received from Pickup and Replay directories on a Hub Transport

server. These directories are typically used by Foreign connectors to transmit messages to your Exchange infrastructure.
- E-mail is retrieved from an Exchange 2010 Mailbox server by the Hub Transport server.
- E-mail is received from an Exchange 2007 or Exchange 2003 server for delivery to a recipient mailbox that's located on an Exchange 2010 Mailbox server.

Processing of all e-mail that's received by a Hub Transport server for categorization begins in the Submission queue.

Receiving Messages from Edge Transport Servers, Other Exchange Hub Transport Servers, and SMTP Clients

In this scenario, messages are received from Edge Transport servers, Hub Transport servers, or other third-party SMTP hosts by using standard SMTP connections. The remote host initiates an SMTP connection and transfers the messages to the Hub Transport server. Hub Transport servers use Receive connectors for accepting incoming SMTP connections. Each Hub Transport server has two Receive connectors created during setup. One of these connectors is used to receive authenticated SMTP connections from other Exchange servers. The second one is used to receive SMTP connections from SMTP clients used by POP3 or IMAP4 users in your organization. These two Receive connectors have different permissions configured that are appropriate for their intended use. To learn more about Receive connectors, see Understanding Receive Connectors.

By default, Hub Transport servers don't accept unauthenticated anonymous connections. If you need to enable this functionality, we recommend that you create a separate Receive connector to handle the anonymous connections. For more information, see Allow Anonymous Relay on a Receive Connector.

Collecting Messages from Pickup and Replay Directories

Messaging systems that don't use SMTP as the transfer protocol can be connected to your Exchange organization using Foreign connectors. When a message is sent to an Exchange user from a remote system, the Foreign connector writes that message to a special directory on the Hub Transport server called the Pickup directory. The Hub Transport server periodically checks the Pickup directory for new messages. When it detects a new message, the Hub Transport server then converts the message to an Exchange e-mail message and routes it as a regular message. To learn more about how the Pickup and Replay directories are used, see Understanding the Pickup and Replay Directories.

Retrieving Messages from a Mailbox Server

In this scenario, the Microsoft Exchange Mail Submission service that runs on Mailbox servers notifies a Hub Transport server that's located in the same Active Directory site that messages are ready for retrieval from a sender's outbox. Each Mailbox server maintains a list of Hub Transport servers that are located in the same Active Directory site. This list of Hub Transport servers is known as the submission server list. The server discovery process repeats every ten minutes to keep the list up to date.

If more than one Hub Transport server is located in the same Active Directory site as the Mailbox server that's submitting a notification that mail is ready for retrieval, the following process is used to select the server:

- If the local Mailbox server is also running the Hub Transport server role and it is not participating in a database availability group (DAG), the local server is notified. If the local Microsoft Exchange Transport service isn't running or the local Hub Transport server can't process new mail submissions because of back pressure, another available Hub Transport server is notified. For more information about back pressure, see Understanding Back Pressure.
- If the local Mailbox server is also running the Hub Transport server role and is also participating in a DAG, it first tries to notify any Hub Transport server in the site before notifying the local Hub Transport server. This is done to avoid having redundant copies of messages on the same server hardware. To learn

more about coexisting Mailbox and Hub Transport server roles when using DAGs, see Hub Transport and Mailbox Server Roles Coexistence When Using DAGs.

- If the local Mailbox server isn't running the Hub Transport server role, notifications are load balanced among Hub Transport servers by using round robin.
- If the selected Hub Transport server can't be contacted, the Microsoft Exchange Mail Submission service fails over to a different Hub Transport server in the same Active Directory site. The failing server is marked as inactive, and the next Hub Transport server in the submission server list is selected. If no Hub Transport servers in the local Active Directory site are available, the submission server list is empty. In this case, an event is logged and mail submission notifications are temporarily stopped. Hub Transport servers that are marked as inactive are retried after five minutes.

By default, the Microsoft Exchange Mail Submission service load balances notification events across the Hub Transport servers in a site so that each Hub Transport server receives an equal distribution of notification events to process. In some circumstances, providing an equal distribution may not be an optimal solution. Not all Hub Transport servers have the same capacity, and some messages require additional processing. For example, a message that has a large attachment or many recipients takes longer for a Hub Transport server to process than a small message that's addressed to only one recipient. If you want to create a static list of Hub Transport servers that a Mailbox server should notify, you can use the **Set-MailboxServer** cmdlet in the Shell. Use the *SubmissionServerOverrideList* parameter to specify a list of Hub Transport servers that the local Mailbox server will notify when it has mail for retrieval. For more information about how to configure this setting, see Set-MailboxServer.

After a Hub Transport server receives a mail submission notification from a Mailbox server, it uses the store driver to retrieve the message from the mailbox database and put it in the Submission queue on the Hub Transport server. The transfer of the message from the Mailbox server to the Hub Transport server happens by using Exchange RPC.

Receiving Messages from Legacy Exchange Servers

Due to the changes made to the Exchange Server Object (XSO) model in Exchange 2010, Exchange 2010 Hub Transport servers can't pick up messages from and deliver messages to Exchange 2007 Mailbox servers. Similarly Exchange 2007 Hub Transport servers can't communicate with Exchange 2010 Mailbox servers. All messages sent from Exchange 2007 recipients are first picked up from the Mailbox servers by Exchange 2007 Hub Transport servers and are then relayed to Exchange 2010 Hub Transport servers. To learn more about message routing when coexisting with Exchange 2007, see Upgrade from Exchange 2007 Transport.

As opposed to Active Directory sites, Exchange 2003 uses routing groups to route messages. Routing groups are connected to each other using routing group connectors. To support coexistence between these two routing topologies, all Exchange 2010 servers are automatically added to a single routing group when Exchange 2010 is installed in an Exchange 2003 organization. All messages that originate on Exchange 2003 mailboxes are delivered to the Exchange 2010 environment through the routing group connectors between the Exchange 2010 routing group and the Exchange 2003 routing groups. To learn more about message routing when coexisting with Exchange 2003, see Upgrade from Exchange 2003 Transport.

Return to top

Routing Messages

After a Hub Transport server or an Edge Transport server receives a message, it determines the ultimate destination and uses the Exchange topology and connector

configurations to determine the least-cost routing path. After the routing path is determined, the message is delivered to the next hop on the routing path.

Although this topic explains how Exchange makes routing decisions in general, the following two topics provide additional information about specific routing scenarios. The internal message routing topic discusses message delivery to Mailbox servers, public folders, and legacy servers. The external message routing topic discusses routing messages to recipients that are outside your Exchange organization. The topic also discusses the roles of Send connectors, delivery agent connectors, and Foreign connectors.

- Internal Message Routing
- External Message Routing

Determining the Ultimate Destination

The previous section described the various sources from which a Hub Transport server can receive messages. When a message is received by a Hub Transport server, the message must be categorized. The first phase of message categorization is recipient resolution. After the recipient has been resolved, the ultimate destination can be determined. The next phase, routing, determines how to best reach that destination. A single, deterministic route is selected. That route isn't recalculated unless the routing configuration changes.

From the perspective of the sending server, each delivery queue represents the destination for a particular message. When the Hub Transport server or Edge Transport server selects the destination for a message, the destination is stamped on the recipient as the **NextHopSolutionKey** attribute. If a single message is being sent to more than one recipient, each recipient has the **NextHopSolutionKey** attribute. The receiving server also performs message categorization and queues the message for delivery. After a message is queued, you can examine the delivery type for a particular queue to determine whether a message will be relayed again when it reaches the next hop destination.

The destination for a message can be classified as one of the following delivery types:

- **DNS connector delivery** The messages are queued for delivery to an external recipient by using an SMTP Send connector for which the local server is a source server. The connector is configured to use DNS to resolve the recipient addresses.
- **Smart host connector delivery** The messages are queued for delivery to an external recipient by using an SMTP Send connector for which the local server is a source server. The connector is configured to use a smart host for delivery.
- **SMTP relay in an Active Directory site to an Edge Transport server** The messages are queued for delivery to an external recipient by using an SMTP Send connector for which the source server is an Edge Transport server that's subscribed to the local Active Directory site.
- **SMTP relay in an Active Directory site to a Hub Transport server** The messages are queued for delivery to a Hub Transport server that's located in the same Active Directory site as the local server. The destination server can be an Exchange 2007 Hub Transport server, the source server for a Send connector, a delivery agent connector or Foreign connector, the source server of a routing group connector, or a distribution group expansion server.
- **SMTP relay to a remote Active Directory site** The messages are queued for delivery to a Hub Transport server that's located in a remote Active Directory site. The ultimate destination server in the remote Active Directory site can be any of the following:
  - The source server for a connector that's configured to transport messages for external recipients
  - The source server for a routing group connector
  - A distribution group expansion server
  - A Mailbox server that's located in the remote Active Directory site

The messages are delivered to one of the Hub Transport servers in the destination site. The receiving server relays the message within the Active Directory site if it's necessary.

- **SMTP relay to a legacy routing group** The messages are queued for delivery to the first hop routing group connector used to reach an Exchange 2003 routing group. The ultimate destination server can be any of the following:
  - The source server for a connector
  - An expansion server
  - An Exchange 2003 bridgehead server that delivers messages addressed to mailbox recipients that are located in the routing group
- **MAPI delivery** The messages are queued for delivery to a recipient's mailbox, a public folder, or a public folder store that's located on a Mailbox server that's located in the local Active Directory site.
- **Non-SMTP gateway delivery** The messages are queued for delivery to an external recipient by using a delivery agent connector or Foreign connector for which the local server is a source server. This delivery type is used only when the messages are being delivered to delivery agent connectors or the Foreign connector drop directory on the local server.
- **Unreachable** A route to the recipient couldn't be determined and the messages are located in the Unreachable queue.

Determining the Least-Cost Routing Path

The least-cost routing path to the remote Active Directory site is determined by the calculation of all the costs assigned to the Active Directory IP site links that exist between the two sites. The links are bridged, and a direct connection occurs. Exchange 2010 Hub Transport servers always select a single, deterministic least-cost routing path. Availability of the underlying connection or destination server is never a consideration in routing path selection, and no alternative routing path is considered.

The least-cost routing path calculation is used to determine a backoff path when message delivery to the next hop fails. In Exchange 2010, *backoff* is a mechanism used to deliver messages at an interim hop along the least-cost routing path when direct relay fails for any reason, such as network issues or servers going offline. The routing component tries to deliver messages as close to the destination as possible by backing off, hop by hop, along the least-cost routing path until a connection is made. First, a connection attempt is made to each Hub Transport server in the destination Active Directory site. If no Hub Transport servers in the Active Directory site respond, the least-cost routing path is checked to determine how to start backing off from the delivery site. The goal is to deliver the message as close as possible to the destination and queue it at a Hub Transport server in that Active Directory site.

Depending on the individual message routing scenario, the following factors may influence the selection of a least-cost routing path:

- **Linked connectors** If the Receive connector that the message is received on is linked to a Send connector, messages are routed to that Send connector regardless of cost. This configuration always takes precedence.
- **The cost assigned to the IP site links and routing group connectors that must be traversed to reach the destination** If more than one routing path exists between a source server and a destination server, the routing path with the lowest aggregate cost is selected.
- **The address space assigned to a Send connector** The Send connector with the most specific address space match to the destination is selected.
- **The cost assigned to the address space configured on a Send connector** If more than one Send connector is assigned the same address space, the routing component compares the cost assigned to the address space. The Send connector with the lowest cost is selected.
- **Connector scope** A connector may be limited to use by Exchange 2010 servers that are located in the same Active Directory site as the source transport servers for the connector. In earlier versions of Exchange, the

connector scope could be limited to servers that have the same routing group membership.

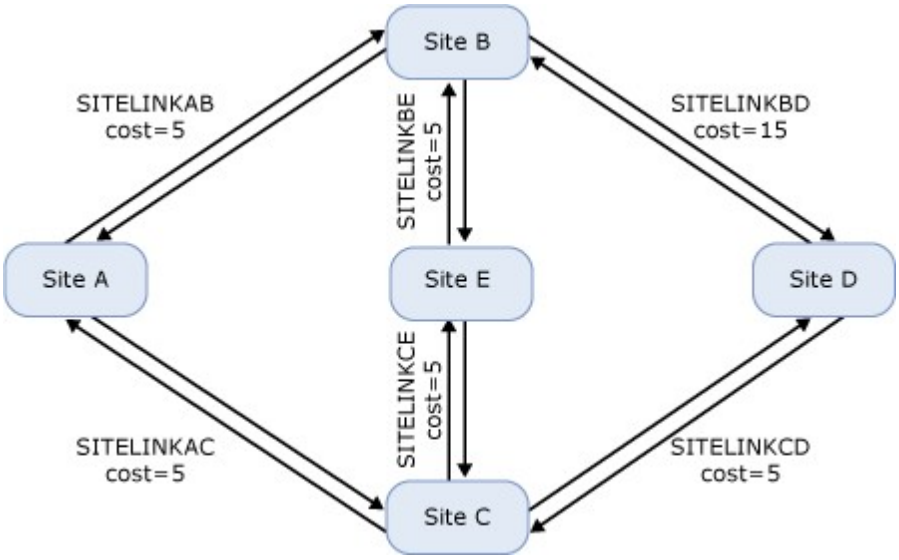
- **Message size restrictions** The message size constraint specified on a connector must be larger than the size of the message being routed. Connectors with a message size restriction that's less than the size of the message are eliminated from routing consideration.
- **The proximity of the destination to the sending server** Routing will prefer the server that's closest, in this order: local server, server in the same Active Directory site, or server in a remote Active Directory site or routing group.
- **The name assigned to an Active Directory site** If more than one routing path results in the same aggregate cost, the routing component makes an alphanumeric comparison of the name of the Active Directory sites that precede the target site along each routing path. The routing path where the Active Directory site nearest to the destination is lowest in alphanumeric order is used.
- **The name assigned to a routing group connector** If more than one routing path results in the same aggregate cost, the routing component makes an alphanumeric comparison of the name of the routing group connectors that come before the target destination along each routing path. The routing path where the routing group connector nearest to the destination is lowest in alphanumeric order is used.
- **The connector state** The Exchange 2010 routing component only considers enabled connectors when it calculates the routing path. However, earlier versions of Exchange don't consider connector state.

The following logic is used to select the routing path:

1. First, calculate the least-cost routing path by adding the cost of the IP site links and of any routing group connectors that must be traversed to reach the destination. If the destination is a connector, the cost assigned to the address space is added to the cost to reach the selected connector. If multiple routing paths are possible, only the routing path with the lowest aggregate cost is used.
2. If more than one routing path has the same aggregate cost, the number of hops in each path is evaluated and the routing path with the least number of hops is used.
3. If more than one routing path is still available, the name assigned to the Active Directory sites or routing group connectors before the destination are considered. The routing path where the Active Directory site nearest the destination is lowest in alphanumeric order is used. If the site nearest the destination is the same for all routing paths being evaluated, an earlier site name is considered.

The following figure shows the routing topology for an Exchange organization. This topology is used in the following examples to demonstrate the logic used by the routing algorithm to select the least-cost routing path.

Exchange 2010 routing topology



Example 1 A message that's being relayed from Site A to Site D can follow two possible routing paths: Site A-Site B-Site D and Site A-Site C-Site D. The costs assigned to the IP site links in each routing path are added to determine the total cost to route the message. In this example, the routing path Site A-Site B-Site D has an aggregate cost of 20. The routing path Site A-Site C-Site D has an aggregate cost of 10. Routing selects path Site A-Site C-Site D.

Example 2 A message is being relayed from Site B to Site D. There are three possible routing paths: Site B-Site D with a cost of 15, Site B-Site E-Site C-Site D with a cost of 15, and Site B-Site A-Site C-Site D with a cost of 15. Because more than one routing path results in the same cost, routing selects the routing path Site B-Site D. This has the least number of hops.

Example 3 A message is being relayed from Site A to Site E. There are two possible routing paths: Site A-Site B-Site E with a cost of 10, and Site A-Site C-Site E with a cost of 10. Both routing paths have the same cost and same number of hops. The alphanumeric order of the Active Directory sites immediately before Site E is compared. Site B has a lower alphanumeric value than Site C. Therefore, routing selects the routing path Site A-Site B-Site E.

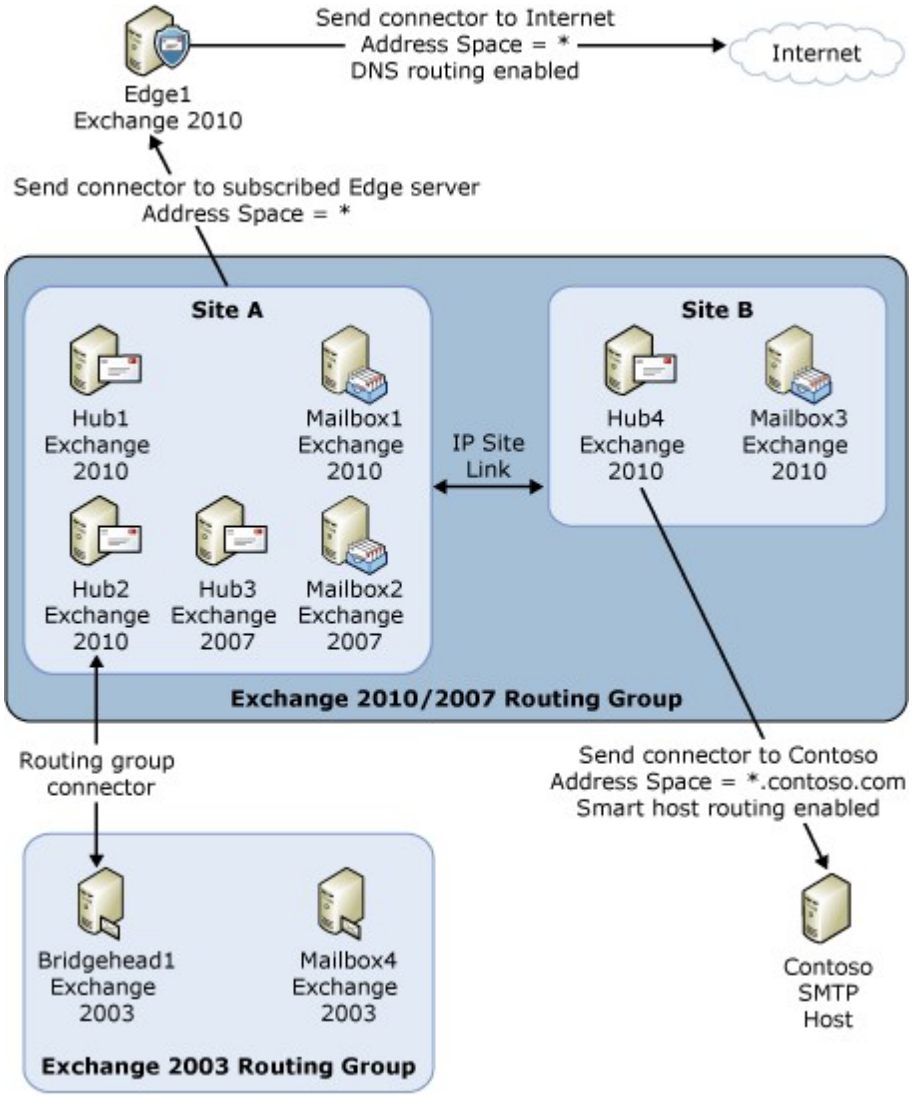
After the least-cost routing path has been determined, the Exchange 2010 routing component doesn't consider alternative routing paths.

Next Hop Selection

Exchange 2010 Hub Transport servers don't relay to each Active Directory site along the least-cost routing path. After the routing path is determined, the message is relayed directly from the source server to the next hop. The next hop selection tries to deliver the messages as close as possible to the ultimate destination. Additional intrasite relay may be required to arrive at the ultimate destination. When routing to legacy routing groups, direct relay to the Active Directory site where the source server for the first hop routing group connector resides occurs. After the message is relayed to the legacy environment, standard legacy routing occurs.

The following figure shows a simple Exchange topology and illustrates many of the Exchange routing components.

Exchange topology and routing components



Using the preceding figure as a reference, a message that's sent from Mailbox1 in Site A, to the external recipient joe@contoso.com is processed as follows:

1. The Microsoft Exchange Mailbox Submission service that's running on Mailbox1 notifies an Exchange 2010 Hub Transport server that's located in the same Active Directory site of the new mail item for transport.
2. Using RPC, the store driver component on an Exchange 2010 Hub Transport server in the same Active Directory site retrieves the message and puts it in the Submission queue on the local server.
3. From the Submission queue, the message moves through categorization. The categorizer first performs recipient resolution and determines that joe@contoso.com is an external recipient.
4. The routing component selects the best connector through which to route the message and calculates the least-cost routing path to that connector. In this example, a Send connector has the address space *.contoso.com and is the connector selected by the routing component. All the source servers for this Send connector are located in Site B.
5. The routing component determines the next hop required to reach a source server for the Send connector. The Hub Transport server in Site A queues the message for SMTP delivery to Site B.
6. If the receiving server in Site B is a source server for the Send connector, it

queues the message for delivery to that Send connector. If the receiving server isn't a source server for the *.contoso.com Send connector, the message is relayed by using SMTP to a Hub Transport server in Site B that's the source server for the connector.

The following table provides additional examples of the next hop selection for several recipients based on the topology shown in the preceding figure. It isn't a complete list of all routing possibilities. It simply provides examples that are most common in a topology like the one shown in the preceding figure.

Examples of next hop selection in the preceding figure

Receiving server	Ultimate destination	Next hop	Queue delivery type
Hub1	Mailbox1	Mailbox1	MAPI delivery
Hub1	Mailbox2	Hub3	SMTP relay in an Active Directory site
Hub1	Mailbox3	Site B	SMTP relay to a remote Active Directory site
Hub1	Mailbox4	Routing group connector	SMTP relay to a legacy routing group
Hub1	Recipient@fourthcoffee.com	Edge1	SMTP relay to Edge Transport
Hub3	Mailbox1	Hub1 or Hub2	SMTP relay in an Active Directory site
Hub4	Mailbox1	Site A	SMTP relay to a remote Active Directory site
Hub4	Mailbox4	Site A	SMTP relay to a remote Active Directory site
Hub4	Recipient@contoso.com	Contoso SMTP Host	Smart host delivery
Hub4	Recipient@fourthcoffee.com	Site A	SMTP relay to a remote Active Directory site
Edge1	Recipient@fourthcoffee.com	Fourth Coffee SMTP Host	DNS delivery

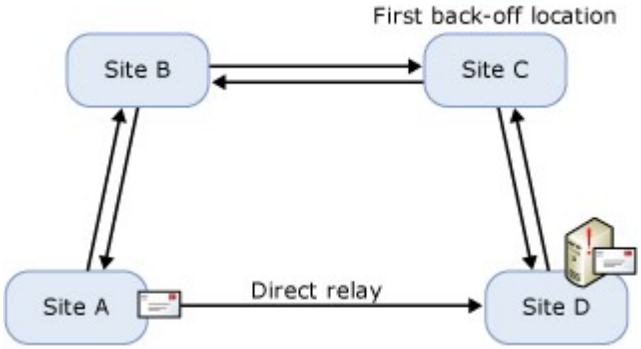
After the least-cost routing path has been calculated and the next hop destination has been chosen, Exchange 2010 routing tries to relay the message directly to the destination, unless a hub site is configured along the least-cost routing path.

Queue at Point of Failure

The least-cost routing path calculation is used to determine a backoff path when message delivery to the next hop fails. Exchange 2010 tries to deliver messages as close to the destination as possible by backing off, hop by hop, along the least-cost routing path until a connection is made. This behavior is known as *queue at point of failure*. When the messages are queued at the point in the delivery path where communication failed, it not only speeds up delivery after the problem is resolved, but it will also help you determine why the message delivery failed.

In the topology shown in the following figure, if a message is being delivered from Site A to Site D, the least-cost routing path may be Site A-Site B-Site C-Site D. Delivery will first be tried directly from Site A to Site D. If no Hub Transport server in Site D responds, delivery will be tried to the Hub Transport servers in Site C. This process continues until a Hub Transport server accepts the message. If all intermediate sites are unavailable, the message will be queued at the source site. If the message is queued in Site C, you can start investigating the failure at the Hub Transport servers in Site D or the network connectivity between Site C and Site D.

Queue at point of failure



When the message is queued at the point of failure, the queue is put in a retry state and delivery attempts continue based on the message retry intervals until delivery succeeds or the message expires. The queue is automatically resubmitted for categorization again after a default interval of 12 hours. Queues that have a connector as the next hop destination aren't automatically resubmitted unless a configuration change that causes resubmission occurs. For more information, see Message Rerouting and the Unreachable Queue.

You can use the Mail Flow Troubleshooter to help diagnose problems with mail flow. This tool is a component of the Microsoft Exchange Troubleshooting Assistant and can be run from the Toolbox of the Exchange Management Console.

In more complex topologies, the least-cost routing path between two Active Directory sites can contain many intermediate Active Directory sites. If a network issue occurs somewhere early along the routing path, it may be too inefficient to back off site by site from the end and try to deliver to every one of the intermediate sites. If the routing path is longer than four hops, binary backoff is implemented until four or fewer sites are remaining. *Binary backoff* means that the next connection attempt is made at the halfway point in the routing path. For example, if the least-cost routing path from Active Directory Site A to Site G is A - B - C - D - E - F - G and the network failure occurs at the link between Site B and Site C, the first connection attempt is made to all Hub Transport servers in Site G. When the connection attempt fails, the next attempt is made to all Hub Transport servers in Site D. This is halfway to Site G. When that connection attempt fails, connection attempts are made to Site C, and Site B because they're closer than four links to the source site. The message will eventually be queued on a Hub Transport server in Site B until the B-C link connectivity is restored.

Delayed Fan-Out

A single e-mail message can be addressed to more than one recipient. These recipients may have internal mailboxes, or they may be external recipients. To route a single message to more than one recipient, the following steps occur:

1. **Recipient resolution** Each recipient of the message is resolved to a delivery destination.
2. **Routing** The least-cost routing path for each recipient is determined. This includes whether a hub site is configured.

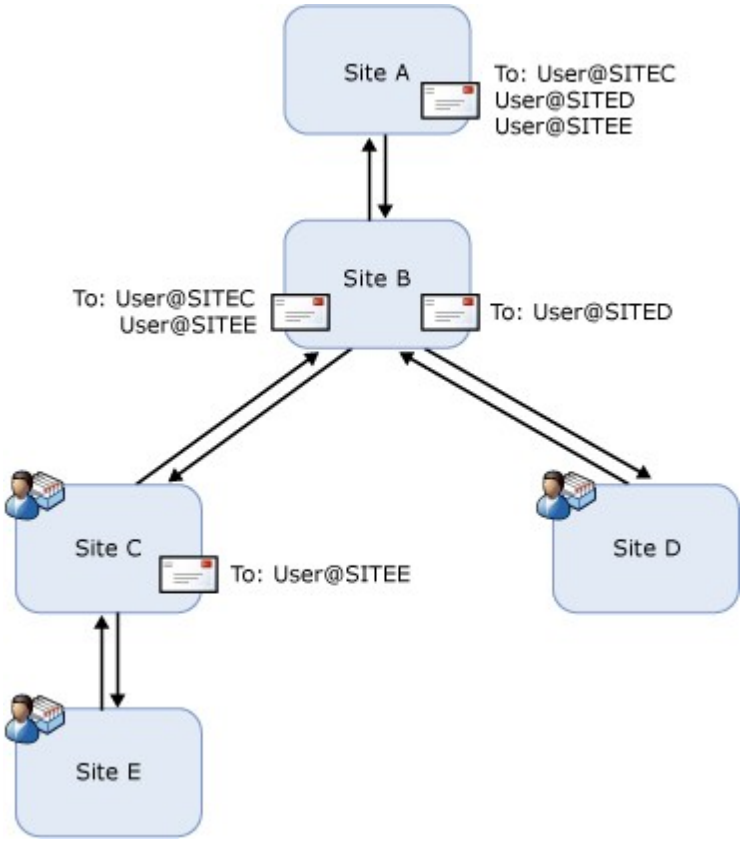
3. **Message splitting** To route the message to recipients that have different delivery locations, the message must be split into multiple copies.

After each recipient has been resolved and a routing path to each delivery destination is determined, Exchange 2010 compares the routing path for each recipient. To preserve bandwidth, the bifurcation, or splitting of the message into multiple copies, doesn't occur until a fork in the routing path is encountered.

For example, if multiple recipients of a single message share part or all of the least-cost routing path, a single copy of the message is sent until the message reaches the point in the routing path where a fork occurs. When the divergence in routing paths occurs, the message splits to create a separate copy for each recipient.

In the following figure, a single message is sent from Site A to recipients in Site C, Site D, and Site E. The least-cost routing path is shared until the message reaches Site B. In this scenario, a single copy of the message that contains all recipients is relayed to Site B. This represents the first fork in the routing path. From Site B, a single message copy is routed to the recipient in Site D, and a single copy is relayed to Site C. In Site C, the message splits again. A copy of the message is delivered to the recipient in Site C. And, a copy of the message is relayed to Site E for delivery to the recipient in that site.

Delayed message fan-out



Return to top

Rerouting and the Unreachable Queue

If routing is unable to determine a route for a valid recipient for any reason, the messages are put in the Unreachable queue. Messages in this queue are rerouted when

configuration changes are processed and routing tables are recalculated. Messages aren't rerouted in the following scenarios. Instead, an NDR is returned to the sender. The following scenarios result in a message being routed to the Unreachable queue:

- The recipient is a non-SMTP address and a matching connector for the address space can't be found.
- The message doesn't meet the message size restrictions of any matching connector.

Not all configuration changes require resubmission of the messages in the queue. For example, a change to the list of smart hosts for a connector doesn't cause messages to be rerouted. For more information about how messages are rerouted, see Message Rerouting and the Unreachable Queue.

1.7.1.22.1 External Message Routing

External Message Routing

Transport > Understanding Transport > Understanding Message Routing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Microsoft Exchange Server 2010 handles the routing of messages to external recipients. An external recipient is any message recipient that doesn't have a mailbox in the Exchange organization. Exchange uses Send connectors to route messages to external SMTP domains. If the external recipient isn't on an SMTP messaging system, a Delivery Agent connector or a Foreign connector is used instead.

For more information about how Exchange makes routing decisions, see Understanding Message Routing.

Looking for management tasks related to message routing? See Managing Message Routing.

Contents

Send Connectors

To route messages to external SMTP domains, you must configure at least one Send connector to relay messages to the Internet. You can configure a Send connector and define the address space as the asterisk (*) wildcard character. The * character indicates

that the Send connector can be used to relay messages to all external SMTP addresses. You can also configure Send connectors to relay messages to specific address spaces when Send connector restrictions, such as message size, vary for those external domains.

When you configure a Send connector, you must select at least one source server for that Send connector. The source servers are the transport servers associated with that connector to handle message delivery. The source server for a Send connector can be a Hub Transport server, an Edge Transport server, or an Edge server subscribed to an Active Directory site. You can configure more than one source server for a Send connector to provide load balancing and fault tolerance for the address spaces defined on that Send connector. However, each Exchange 2010 source transport server you specify must be in the same Active Directory site.

For more information about how to configure your Exchange organization to send and receive Internet e-mail, see Managing Message Routing.

When Exchange is processing a message sent to an external recipient, the routing component of the Microsoft Exchange Transport service must select the best Send connector through which to route the message, and then calculate the least cost routing path to reach that Send connector.

To learn more about Send connectors, see Understanding Send Connectors.

Return to top

Delivery Agent Connectors

Delivery Agent connectors are used to route messages addressed to messaging systems that don't use SMTP. When a message is routed to a Delivery Agent connector, the associated delivery agent performs the content conversion and message delivery. Delivery Agent connectors allow queue management for non-SMTP messages, thereby eliminating the need for storing messages on the file system in the Drop and Pickup directories. For more information, see Understanding Delivery Agents.

Return to top

Foreign Connectors

Foreign connectors are used to send messages to third-party messaging systems. Each Foreign connector uses a Drop directory configured on the source Hub Transport servers for receiving messages. The foreign gateway server must be configured to obtain messages from the Drop directory specified for that Foreign connector. For more information about Foreign connectors, see Understanding Foreign Connectors.

Return to top

Connector Considerations

Restrictions applied to the connectors may eliminate a specific connector from routing consideration. The following configuration options on connectors can determine whether those connectors are considered when making routing decisions. For more information about configuring connectors, see Managing Connectors.

Connector State

You can disable and enable any connector in your organization. If a connector is disabled, it's not considered when routing messages. For example, if an Exchange 2010 Send connector is disabled, messages aren't routed to that connector.

Note:
Exchange Server 2003 doesn't detect the disabled state of connectors. Therefore, if Exchange 2003 is deployed in the same organization, it may route to that connector.

Connector Scope

Routing only considers connectors in scope for the sending server. By default, no scope limitation is applied to connectors, and they are available to all Hub Transport servers in the organization. However, you can specify a local scope for a connector. If you configure a connector as scoped, the availability of that connector is limited to Hub Transport servers located in the same Active Directory site as the source servers for the connector. Scoped connectors aren't considered when routing by Hub Transport servers in other Active Directory sites.

Address Space

The address space for a connector specifies the following:

- Recipient domains to which this connector routes e-mail
- Address space type
- Cost assigned to the address space for that connector

When you create a Send connector, the address space type is always configured as SMTP by default. Even though you can also specify a non-SMTP address space for a Send connector, the messages are still sent using SMTP. If you need to use a different transport protocol for transmitting messages to their destination, you must use a Delivery Agent connector or a Foreign connector.

When the Microsoft Exchange Transport service selects a connector for routing, it only considers connectors that have a matching address space for the destination domain. You can use the wildcard character * in an address space to indicate all domains, all domains that have a particular top-level domain, such as *.com, or a second-level domain and all its subdomains, such as *.contoso.com. When you configure a connector for a particular domain, e-mail sent to that domain is always routed through that connector.

If more than one connector matches the address space for the destination recipient domain, the connector with the more precise address match is selected. For example, if Send connector C1 is configured to have the address space *.contoso.com and Send connector C2 is configured to have the address space northamerica.contoso.com, e-mail addressed to *user*@europe.subdomain.contoso.com is routed to Send connector C1 and e-mail addressed to *user*@northamerica.contoso.com is routed to Send connector C2. Even though the latter address matches the address spaces on both connectors, the address space of C2 is a better match.

Message Size Restrictions

A message size restriction on a connector may also remove that connector from consideration during routing path selection if the message being routed is larger than the size restriction configured on that Send connector.

Cost

Connector cost is used to set selection priority when more than one connector is configured for the same address space. During routing, when the connector selection is made, the lowest cost routing path to the destination is selected. By adjusting connector costs, you can control the preferred routing path for mail flow in your organization and to the Internet. When you create a connector, the default cost is set to 1.

Return to top

Selecting the Routing Path to an External Recipient

When a message is sent to an external recipient, Exchange 2010 will always select a single connector through which to send the message. The selected connector must meet the message size constraints. After Exchange 2010 has eliminated all connectors whose message size restrictions are less than the size of the message being routed, routing applies the following criteria to determine which connector it will select:

1. From the list of all the connectors configured in the Exchange organization, Exchange narrows the list to connectors that satisfy all the following criteria:
   - In the scope for the local server
   - Enabled
   - With an address space that matches the recipient's e-mail domain
2. From the resulting list, Exchange selects the connector with the most specific address space match.

If more than one connector meets the address space match criteria, Exchange 2010 routing evaluates the following criteria to select a connector:

1. **Connector cost** The cost of the connector is the sum of the cost assigned to all the IP site links between the source Active Directory site and the Active Directory site that contains the source servers for the connector, and the cost assigned to the connector. The connector with the lowest aggregate cost is selected. If more than one connector has the same cost, the selection process continues to the next step.
2. **Proximity** The source server that has the closest proximity to the routing server is selected. This means that the local server is chosen over another Hub Transport server in the same Active Directory site, and a server in the local Active Directory site is chosen over a source server in a remote Active Directory site. If more than one connector matches the criteria, the selection process continues to the next step.
3. **Alphanumerically lower connector name** If more than one routing path has the same cost and proximity, the connector with the name that has the lowest alphanumeric value is selected.

Routing Path Selection When Coexisting with Exchange 2003

In a coexistence scenario, the selection varies slightly depending on whether the source server for the selected connector is an Exchange 2010 or Exchange 2003 server.

If more than one connector meets the address space match criteria, and they are all are hosted on servers running Exchange 2003, the following selection method is used:

1. **Connector cost** The cost of the connector is the sum of the cost assigned to all the routing group connectors between the routing server and the routing group that contains the source servers for the connector and the cost assigned to the connector.
2. **Alphanumerically lower connector name** If more than one routing path has the same cost and proximity, the connector with the name that has the lowest alphanumeric value is selected.

If more than one connector meets the address space match criteria, and they are spread across Exchange 2010 and Exchange 2003, Exchange 2010 will always prefer Exchange 2010 connectors.

When a connector is selected, if there are legacy servers listed as source servers as well as Exchange 2010 servers, messages are routed to the Exchange 2010 servers. When all things are equal, Exchange 2010 will always route the messages to other Exchange 2010 servers.

After a connector is selected by using the previous criteria, there may be more than one routing path to reach the Active Directory site where the source server for the selected connector is located. In this case, the lowest cost routing path to the connector is calculated by using the logic used for intra-organizational routing. For more information, see Internal Message Routing.

Handling Messages That Can't Be Routed

If no connector satisfies all criteria required to select a connector according to the logic described earlier, one of the following actions occurs:

- If there is no matching connector for an SMTP address space, the recipient is marked as unreachable and the message is routed to the Unreachable queue.
- If the message size exceeds the connector size restriction for all connectors, a non-delivery report (NDR) is returned to the sender.
- If there is no matching connector for a non-SMTP address space, an NDR is returned to the sender.

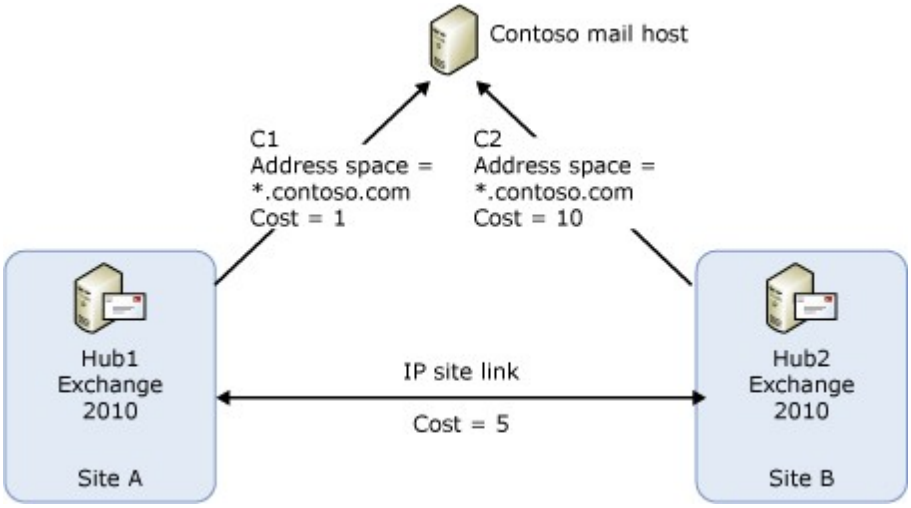
Return to top

Routing Examples

The following examples illustrate how messages are routed to external recipients.

Example 1: Selecting a Connector Based on Address Space Match

In this topology, a message is being routed from Active Directory Site A to the external recipient, john@subdomain.contoso.com. The following figure shows that two connectors can route messages to this address space.



The following table shows the configuration of two Send connectors in an Exchange 2010 topology.

Examples of Send connector configurations

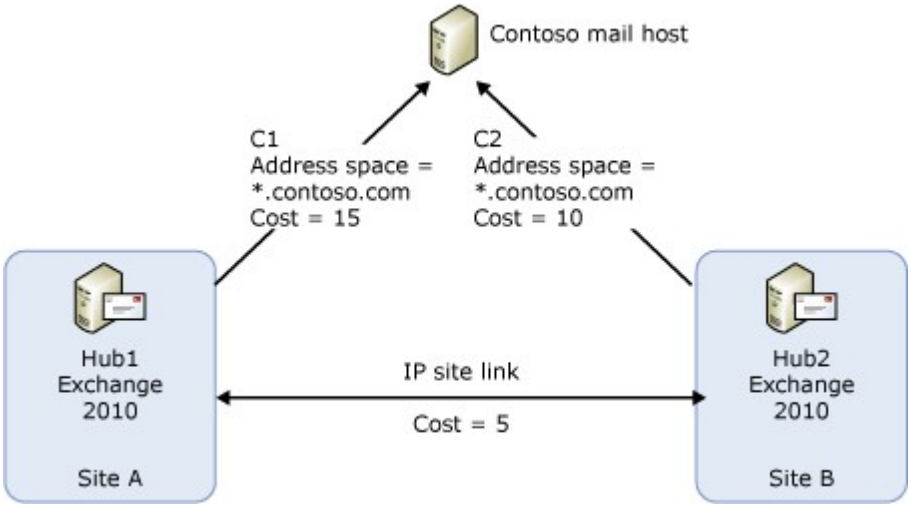
Send connector name	Address space	Connector cost	Source servers	Message size restrictions
C1	*.contoso.com	1	Hub Transport servers in Active Directory Site A	None
C2	subdomain.contoso.com	10	Hub Transport servers in Active Directory Site B	None

In this scenario, the message is routed by using C2 because the most specific address space match is chosen. C1 has a lower routing cost, and the source servers are located in

the same site as the Hub Transport server processing the message. However, the address space match takes priority over the other factors.

Example 2: Selecting a Connector Based on Proximity

In this scenario, a message is being routed by a Hub Transport server located in Active Directory Site A to the external recipient, john@subdomain.contoso.com, as shown in the following figure.



The following assumptions apply:

- The routing server isn't listed as a source server for any Send connector.
- The IP site link between Site A and Site B is assigned a cost of 5.
- Two Send connectors can route messages to the address space. The following table shows the connector configuration.

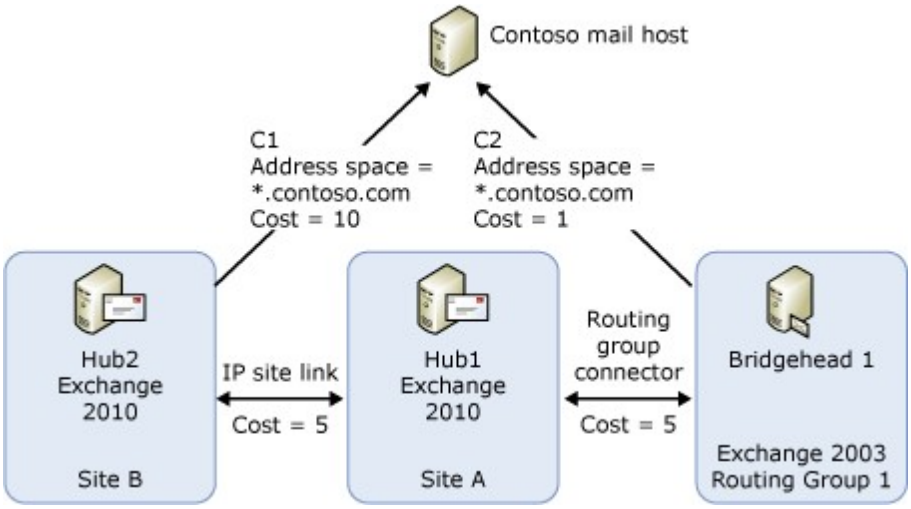
Alternative Send connector configuration

Send connector name	Address space	Address space cost	Source servers	Message size restrictions
C1	subdomain.contoso.com	15	Hub Transport servers in Active Directory Site A	None
C2	subdomain.contoso.com	10	Hub Transport servers in Active Directory Site B	None

Because both connectors have the same address space match, the connector cost is evaluated next. The cost assigned to connector C2 is added to the cost of the IP site link between Active Directory Site A and Site B, for a combined cost of 15. The source servers for connector C1 are located in the local Active Directory site. Therefore, the IP site link cost to reach the connector is 0, for a total cost of 15. In this scenario, both connectors match the address space equally and have an equal cost. Routing selects connector C1 because it has a closer proximity.

Example 3: Selecting a Connector Based on Exchange Version

In the next example, a message is being relayed from Active Directory Site A to the external recipient, john@contoso.com, as shown in the following figure.



The following assumptions apply:

- There are two Send connectors that match the destination address space equally.
- The source servers for the routing group connector between Exchange 2003 and Exchange 2010 are located in Site A.
- The routing group connector has a routing cost of 5.
- The IP site link between Site A and Site B is assigned a cost of 5.
- The source server for one of the Send connectors is an Exchange 2003 server located in routing group 1. The following table shows the connector configuration.

Connectors configured on different versions of Exchange

Connector name	Address space	Address space cost	Source servers	Message size restrictions
C1	*.contoso.com	10	Hub Transport servers in Active Directory Site B	None
C2	*.contoso.com	1	Exchange 2003 bridgehead servers in routing group 1	None

In this scenario, the aggregate cost of using connector C1 is 15, which is the sum of the IP site link cost and the Send connector cost. The aggregate cost of using connector C2 is 6, which is the sum of the routing group connector cost and the Send connector cost. However, even though C1 has a lower routing cost, Exchange will still route the message to the Exchange 2010 connector.

1.7.1.22.2 Message Rerouting and the Unreachable Queue

Message Rerouting and the Unreachable Queue

Transport > Understanding Transport > Understanding Message Routing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

In Microsoft Exchange Server 2010, there are message routing scenarios where a message that isn't delivered is put in the Unreachable queue or rerouted.

The decision to put a message in the Unreachable queue is made during the routing phase of categorization. If a routing path can't be calculated for a message during the routing phase, the message is sent to the Unreachable queue.

The decision to reroute a message occurs during the message delivery phase in the SMTP Send connector process. If there are configuration changes that require a message in the queue to be resubmitted, the message is resubmitted for categorization in the message delivery phase and rerouted with the new configuration information. Depending on the type of configuration change, some or all resubmitted messages may be sent to the Unreachable queue or to a different delivery queue.

For more information about how the least-cost routing path is computed, see Understanding Message Routing. For more information about how the categorizer works, see Understanding Transport Pipeline.

Looking for management tasks related to message routing? See Managing Message Routing.

Message Rerouting

There are two types of message delivery in Exchange:

- *Local delivery* refers to delivery of messages sent to a recipient with a mailbox in the same Active Directory site as the Hub Transport server on which categorization occurred.
- *Remote delivery* refers to delivery of messages to recipients in other Active Directory sites of the Exchange organization and to external recipients. Remote delivery queues are the main focus of message rerouting. Remote delivery can be affected by configuration changes in various ways.

The routing component of the categorizer tries to detect whether messages in a queue must be rerouted during enhanced Domain Name System (DNS) resolution. During enhanced DNS resolution, routing tries to detect if a queue has to be rerouted. In this phase, the **NextHopSolutionKey** attribute is resolved to a list of targets. This enables routing to automatically detect any configuration changes that invalidate or modify the **NextHopSolutionKey** attribute. If routing detects that configuration changes require rerouting of messages in a queue, the messages in the affected queue are resubmitted to the categorizer and the least cost path is recalculated, taking the new configuration changes into account.

The store driver, which delivers inbound messages to the Exchange databases, may also reroute messages. It resubmits a message for rerouting if either of the following conditions is true:

- The message is in a MAPI delivery queue, and the next hop has been selected, but the message hasn't been delivered.
- The destination mailbox is moved to another Mailbox server.

If a Mailbox server is unavailable when the store driver tries to deliver the messages to that Mailbox server, the store driver puts the message queue in a retry state. If continued attempts to contact the Mailbox server are unsuccessful, when the retry interval expires, all messages in the queue are resubmitted to the categorizer.

If a message is located in a non-SMTP gateway delivery queue (a queue being routed to a

Delivery Agent connector or a Foreign connector), the foreign gateway connection handler determines whether the configuration change requires rerouting. The foreign gateway connection handler is a component of the Microsoft Exchange Transport service that manages delivery of messages to Delivery Agent connector queues and Foreign connector Drop directories. For example, deleting or disabling a Foreign connector requires rerouting messages to another connector.

The following list summarizes the types of configuration changes that affect message routing. Each configuration change is discussed in detail later in this topic:

- **Invalid next hop** The next hop for the message has been deleted or modified, therefore invalidating the previously calculated routing path. The next hop for a message may be an Active Directory site, a connector, or a transport server (either a Hub Transport server or Edge Transport server).
- **Changes to next hop** The configuration of the next hop has changed in a way that affects connectivity. For example, changes to the list of Hub Transport servers in the remote Active Directory site cause the next hop connection to be modified.
- **Less preferred routing paths** When configuration changes occur along a previously computed routing path, messages already routed are delivered if the routing path is reachable. But new messages are rerouted with the updated configuration changes.
- **Unavailable next hop** Network connectivity or target server availability cause the next hop to be unavailable for connectivity. However, the next hop doesn't change. An example is when the Hub Transport servers in an Active Directory site are offline.
- **Additional scenarios where rerouting occurs** In some cases, configuration changes may be caused when DNS MX resource record resolution fails for a DNS connector or a smart host connector.
- **Configuration changes that cause message rerouting or delay** When specific configuration changes are detected during the message delivery phase, routing actions occur, and messages are rerouted or delivery is delayed.

Invalid Next Hop

Configuration changes can invalidate a previously calculated next hop. In these circumstances, the routing component of the categorizer can detect the configuration change and reroute to compensate for that change.

Delivery to an SMTP Connector on the Local Computer

When a message is being delivered to an SMTP connector on the local computer, the server that received the message for relay to its destination is also the source server for the Send connector through which the message is routed. This kind of delivery occurs when either of the following conditions is true:

- The message was received on a linked Receive connector.
- The recipient has an external address, and a source server for the selected connector is the local computer.

If the Send connector selected by the routing component of the categorizer is deleted or disabled, the configuration change is detected during the message delivery phase. This causes all messages in the queue to be categorized again.

If the configuration of the Send connector is changed to remove the local server as a source server of the connector, the configuration change is detected during the message delivery phase, and all messages in the queue are categorized again.

A change of the address resolution method of the Send connector causes the queue to be rerouted. A Send connector can be configured to use DNS to resolve MX records and route messages automatically or it can be configured to route all messages through one or

more smart hosts. If you change the address resolution of a Send connector, the messages routed through that Send connector are rerouted.

SMTP Relay in an Active Directory Site

SMTP message relay in an Active Directory site occurs in the following scenarios:

- The recipient has an external address, and at least one of the source servers for the Send connector is an Exchange 2010 Hub Transport server located in the local Active Directory site.
- The recipient has an external address, and at least one of the source servers for the Send connector is an Exchange 2010 Edge Transport server subscribed to the local Active Directory site.
- The recipient's mailbox is located on a server that runs Exchange Server 2007 in the local Active Directory site.
- The recipient's mailbox is located on a server that runs Exchange Server 2003, and at least one of the source servers for the selected routing group connector is an Exchange 2010 Hub Transport server in the local Active Directory site.
- The recipient is a distribution group, and the expansion server for the group is an Exchange 2010 Hub Transport server in the local Active Directory site.

In the first four scenarios, if the Send connector is deleted or disabled, the configuration change is detected during the message delivery phase, and the queue is resubmitted.

In the last scenario, the messages are queued for delivery to an expansion server and the **NextHopSolutionKey** attribute contains the fully qualified domain name (FQDN) of the expansion server for the distribution group. If the Hub Transport server role is uninstalled from the specified expansion server, that configuration change is detected during the message delivery phase, and the queue is resubmitted.

SMTP Relay to a Remote Active Directory Site

When a message is being delivered to a remote Active Directory site, the next hop is a different Active Directory site than the Hub Transport server processing the message. This kind of delivery occurs in the following scenarios:

- The recipient is a resolved user, mailbox database, or public folder, and the destination computer is an Exchange 2010 server in a remote Active Directory site.
- The recipient is an external address, and the source servers of the Send connector selected for that address are Exchange 2010 servers in a remote Active Directory site.
- The recipient is an external address, and the source servers of the Foreign connector selected by the routing component of the categorizer are Exchange 2010 servers in a remote Active Directory site.
- The recipient is a distribution group, and the expansion server is an Exchange 2010 Hub Transport server in a remote Active Directory site.
- The recipient's mailbox is located on an Exchange 2003 server, and the closest Hub Transport server listed as a source server for the selected routing group connector is located in a remote Active Directory site.

In these scenarios, if the remote Active Directory site is deleted, the configuration change is detected during the message delivery phase, and the queue is resubmitted.

SMTP Relay to an Exchange 2003 Server

When a message is being delivered to an Exchange 2003 server, the Exchange 2010 Hub Transport server relays the message through a routing group connector to an Exchange 2003 server. This delivery type occurs in the following scenarios:

- The recipient is a resolved user, mailbox database, or public folder located on an Exchange 2003 server.
- The recipient is an external address, and the source servers for the SMTP connector selected for that address are Exchange 2003 servers.

- The recipient is an external address, and the source servers for the selected Foreign connector for that address are Exchange 2003 servers.
- The recipient is a distribution group, and the designated expansion server is an Exchange 2003 server.

In these scenarios, if the routing group connector is deleted, the configuration change is detected during the message delivery phase, and the queue is resubmitted.

Changes to Next Hop

In some scenarios, the next hop isn't invalidated. However, it's modified in a way that affects the connection to a next hop target. Such configuration changes are automatically detected during the message delivery phase, and messages are delivered to the new targets.

The following types of changes cause an update of the list of next hop targets:

- Changes to the target server list of a routing group connector.
- Changes to the list of Hub Transport servers in the remote Active Directory site.
- Changes to the list of Hub Transport servers or Edge Transport servers in the local Active Directory site.
- The introduction of hub sites along a previously calculated routing path. When this change is detected during the message delivery phase, the IP address list returned to the resolve request is adjusted so that the message is sent to the hub site.

Less Preferred Routing Paths

If a configuration change causes the previously calculated routing path to become less preferred or removes the routing path from consideration, the routing path is still reachable and the messages can still be delivered along the previously calculated routing path. The following configuration changes are in this category:

- Message size restrictions are added along the routing path. This causes messages that exceed the size limit to be routed along a different routing path.
- A routing path with better cost or proximity is created.
- The address space of the connector changes.
- Other connector-related changes occur, such as the enabling of a connector or modification of the scope for a connector. For example, if a connector whose scope is changed from global to scoped is in the local Active Directory site, the change has no effect. If the connector is in a remote Active Directory site, the change isn't detected during the message delivery phase because the messages are queued to the remote Active Directory site instead of to the connector.
- As the routing path tries to SMTP-relay to a Mailbox server in the remote Active Directory site, the Mailbox server moves from a remote Active Directory site to a local Active Directory site.
- The routing path is trying to reach the expansion server for a distribution group when it's no longer an expansion server.

In these scenarios, existing messages are delivered along the already calculated routing path. Because the routing path exists and is reachable, messages already routed are unaffected by these configuration changes. However, newly submitted messages are routed by using the updated configuration.

Unavailable Next Hop

In this scenario, a configuration change or network connectivity change doesn't invalidate the next hop to which messages are routed but a configuration change or network connectivity change makes the next hop unavailable. This means that an SMTP connection can't be established to the next hop target for some reason. Possible reasons are as follows:

- An attempt is made to establish an SMTP connection with a currently offline Hub Transport server in the local site.
- A remote Active Directory site has unavailable or offline Hub Transport servers.
- A remote routing group has unavailable or offline Exchange 2003 bridgehead servers.
- Remote domains are unavailable because of network connectivity issues.

Message delivery failures caused by network connectivity problems aren't detected by the routing component of the categorizer. When an SMTP connection can't be established to the next hop target, the SMTP Send connector retries the queue. The *MaxIdleTimeBeforeResubmit* parameter, which is located in the EdgeTransport.exe.config file, has a default value of 12 hours. After the configurable retry interval (*MaxIdleTimeBeforeResubmit*) has expired without successfully establishing a connection, all messages from the delivery queue are resubmitted to the Submission queue. If the connectivity problem still exists, this process is repeated. If the connectivity problem is resolved, messages are delivered as soon as message retry is successful. Or, a configuration change that modifies the next hop destination may resolve the problem. For example, if the problem is caused by all the Hub Transport servers in a destination site being offline, and you move mailboxes to a server in a different site, the next hop would change to the new site.

Note:

The automatic resubmission from the message delivery queue to the Submission queue only happens for queues that aren't connector queues. Connector queues remain in retry mode until the problem is fixed, or the messages expire and a non-delivery report (NDR) is sent.

Additional Scenarios Where Rerouting Occurs

In addition to the scenarios described earlier in this section, the following scenarios cause messages to be rerouted during the message delivery phase:

- DNS MX resolution fails for a DNS connector. If the DNS MX resolution fails because the authoritative host for the MX record wasn't found, an NDR for the messages in the queue is sent immediately. If other types of failures exist, the queue is put into retry mode until a connection is established or the messages expire.
- DNS MX resolution fails for a smart host connector. The queue is put into retry mode until the messages expire.

Configuration Changes That Cause Message Rerouting or Delay

The following table summarizes the routing actions taken when specific configuration changes are detected during the message delivery phase, and messages are rerouted or delivery is delayed.

Configuration changes that cause message rerouting and delay

Routing scenario	Configuration change and routing action	
Message is routed to a DNS connector configured on the local server.	**Configuration change**	**Routing action**
	The connector is deleted.	The queue is resubmitted.
	The connector is changed to a smart host connector.	The queue is resubmitted.
	The connector is modified to remove the local server from the source server list.	The queue is resubmitted.

	A fatal DNS MX resolution failure occurs.	An NDR is sent.
	A DNS MX resolution failure that isn't fatal occurs.	The queue is retried until messages expire.
	The connector is disabled.	The queue is resubmitted.
Message is routed to a smart host connector configured on the local server.	**Configuration change**	**Routing action**
	The connector is deleted.	The queue is resubmitted.
	The connector is modified to remove the local server from the source server list.	The queue is resubmitted.
	The connector is changed to a DNS connector.	The queue is resubmitted.
	The smart host list for the connector is modified.	The updated smart hosts list is automatically detected and used during the message delivery phase.
	Any DNS MX resolution failure occurs.	The queue is retried until messages expire.
	The connector is disabled.	The queue is resubmitted.
	The SMTP server is offline or the destination isn't running an SMTP server.	The queue is retried until messages expire.
Message is routed to a connector with a source Hub Transport server or Edge Transport server in the local Active Directory site.	**Configuration change**	**Routing action**
	The connector is deleted.	The queue is resubmitted.
	The source server list for the connector is modified to remove or add Hub Transport or Edge Transport servers in the local Active Directory site.	Changes to source servers in the local site are automatically detected and used during the message delivery phase.
	The source server list for the connector is modified to remove all	The queue is resubmitted.

	Hub Transport or Edge Transport servers in the local Active Directory site.	
Message is routed to an expansion server for a distribution group in the local Active Directory site.	**Configuration change**	**Routing action**
	The server is no longer configured for the Hub Transport server role.	The queue is resubmitted.
Message is routed to a transport server in the local Active Directory site.	**Configuration change**	**Routing action**
	The server is offline or the Microsoft Exchange Transport service isn't running.	The queue is resubmitted after an interval.
Message is routed to a remote Active Directory site.	**Configuration change**	**Routing action**
	The remote Active Directory site is deleted.	The queue is resubmitted.
	The link to the remote Active Directory site is deleted. Therefore, the site is unreachable from the local site.	The queue is resubmitted.
	The list of Hub Transport servers in the remote Active Directory site changes.	Changes are automatically detected and used during the message delivery phase.
	All Hub Transport servers in the remote Active Directory site are removed.	The queue is resubmitted.
	Hub sites are introduced along the routing path of the destination Active Directory site.	Changes are automatically detected and used during the message delivery phase so that the messages are relayed to the hub site.
	All Hub Transport servers in the remote Active Directory site are offline.	The queue is resubmitted after an interval.
	The remote site is the delayed fan-out point, and all Hub Transport	The queue is resubmitted after an interval.

</table>

Unreachable Queue

The Unreachable queue contains messages that can't be routed to their destinations. Typically, an unreachable destination is caused by misspelled e-mail addresses, or configuration changes that have modified the routing path for delivery. Regardless of destination, all messages that have unreachable recipients reside in this queue.

The decision to put a message in the Unreachable queue is made during the routing phase of categorization. If a routing path can't be calculated for a message during the routing phase, the message is sent to the Unreachable queue. Messages in the Unreachable queue are rerouted after configuration changes are processed. There is only one Unreachable queue for each Exchange 2010 transport server.

During categorization, messages are put in the Unreachable queue when the following conditions are true:

- The recipient is a valid Active Directory recipient object. However, a routing path can't be calculated for that recipient.
- The recipient is an external SMTP address and a matching connector can't be found for the address space. A matching connector may also be ignored by the routing component of the categorizer because it's disabled or configured incorrectly.
- The recipient is a distribution group. The expansion server for the distribution group is invalid or doesn't have the Hub Transport server role installed.
- The recipient is an SMTP address recipient of a message received on a Receive connector linked to a Send connector that's ignored by the routing component of the categorizer because it's disabled or configured incorrectly in some way.

In the following scenarios, messages aren't put in the Unreachable queue, and NDRs are sent instead:

- The routing path can't be calculated for a recipient because constraints, such as message size restrictions, prevent delivery of the message using the single, deterministic route calculated by the categorizer.
- The recipient is a non-SMTP address and a matching connector can't be found. Or the matching connector is disabled or configured incorrectly.
- The recipient is a non-SMTP address recipient received on a Receive connector linked to a Send connector that's ignored by the routing component of the categorizer because the Send connector is disabled or configured incorrectly.

Messages in the Unreachable queue are resubmitted to the categorizer when the routing tables are rebuilt because of configuration changes. The old routing tables and new routing tables are compared. The Unreachable queue is resubmitted only if the old routing tables and new routing tables aren't the same.

Scenarios Where Messages Are Put in the Unreachable Queue

This section describes some scenarios where messages are put in the Unreachable queue.

Routing group connector between an Exchange 2010 organization and Exchange 2003 organization doesn't exist

A routing group connector between the Exchange 2010 routing group and Exchange 2003 routing groups hasn't been configured, or the last routing group connector between the Exchange 2010 routing group and Exchange 2003 routing groups has been removed. No routing group connector exists to provide a routing path to the Exchange 2003 recipients. To resolve this problem, first verify that the routing group connector is missing. If that's the case, you can create a routing group connector. For more information, see Create Additional Routing Group Connectors from Exchange 2010 to Exchange 2003. If a routing group connector does exist, the message is in the Unreachable queue for some other reason. Check the configuration of the routing group connector.

Destination Active Directory site doesn't have Hub Transport servers

The destination Active Directory site has no Hub Transport servers. In this scenario, messages to recipients in that site are sent to the Unreachable queue. To resolve this problem, deploy a Hub Transport server in the Active Directory site. For more information, see Overview of the Hub Transport Server Role.

Active Directory site link doesn't exist between two Active Directory sites

An Active Directory site link has been removed and as a result, a disconnected Active Directory site contains Exchange 2010 servers. To resolve this problem, create an Active Directory site link by using Active Directory Sites and Services.

Other issues

When a message is put in the Unreachable queue, the last error message specifies why the message was placed in the Unreachable queue. If more than one recipient of the same message is routed to the Unreachable queue, but for different reasons, the last error available on each recipient specifies the reason for each. When inconsistencies are found during routing table computation, events are logged in the Application log of Windows Event Viewer. The last error message and these events can help you determine the configuration error and make corrections so that messages in the Unreachable queue can be routed successfully.

You can also manually force the messages in queues to be resubmitted. For more information, see Resubmit Messages in Queues.

1.7.1.22.3 Internal Message Routing

Internal Message Routing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Internal message delivery involves a routing process that relays e-mail in the following ways:

- From a server running Microsoft Exchange Server 2010 that has the Hub Transport server role installed to an Exchange Server 2007 or Exchange 2010 Hub Transport server in a different Active Directory site
- From an Exchange 2010 Hub Transport server to an Exchange 2010 Mailbox server located in the same Active Directory site
- From an Exchange 2010 Hub Transport server to a Hub Transport server running Exchange 2007 for delivery to a recipient mailbox located on an Exchange 2007 server
- From an Exchange 2010 Hub Transport server to a server running Exchange Server 2003 for delivery to a recipient mailbox located on an Exchange 2003 server
- From an Exchange 2010 Hub Transport server to an Exchange 2010 Mailbox server for delivery to a mail-enabled public folder

For more information about how Exchange makes routing decisions, see Understanding Message Routing.

Looking for management tasks related to message routing? See Managing Message Routing.

Contents

Routing Messages for Delivery to Exchange 2003 Servers

Routing to Public Folders

Routing Messages for Delivery to Exchange 2010 Servers

In Exchange 2010, after a message is received by the Hub Transport server, the message is added to the Submission queue. Messages move from the Submission queue through the categorizer. When the message is categorized, a recipient's e-mail address is resolved to an object in Active Directory. This query determines the mailbox associated with that e-mail address and which Mailbox server is hosting that mailbox.

After information about the recipient is resolved, the next step is resolving the Mailbox server to an Active Directory site. This Active Directory site information is stamped on the message as the **NextHopSolutionKey** attribute. The enhanced DNS component of the Microsoft Exchange Transport service accesses the topology information to determine which Hub Transport servers are located in the same site as the destination Mailbox server. A list of Hub Transport servers in the Active Directory site is then referenced to determine where to route the message. If the destination Mailbox server is located in the same site as the querying Hub Transport server, that Hub Transport server queues the message for local delivery. If the destination Mailbox server is located in a different site, the local Hub Transport server queues the message for remote delivery to that Active Directory site.

A message queued for local delivery is submitted to the destination mailbox store by the store driver. The message is transferred from the Hub Transport server to the Mailbox server by using an Exchange remote procedure call (RPC).

A message queued for delivery to a remote Active Directory site is transferred by using SMTP. Before the message is relayed, the routing component of the categorizer selects the least cost routing path. The method for determining the least-cost routing path is explained in detail in "Determining the Least-Cost Routing Path" in Understanding Message Routing.

Return to top

Routing Messages for Delivery to Exchange 2007 Servers

Due to the changes made to the Exchange Server Object (XSO) model in Exchange 2010, Exchange 2010 Hub Transport servers can't pick up messages from and deliver messages to Exchange 2007 Mailbox servers. Similarly, Exchange 2007 Hub Transport servers can't communicate with Exchange 2010 Mailbox servers. As a result, to have both Exchange 2010 and Exchange 2007 in the same Active Directory site, you must maintain both versions of Hub Transport servers in that site.

When a Hub Transport server queries Active Directory to determine the Mailbox server hosting the destination mailbox, it also retrieves the version of the Mailbox server. If the Mailbox server is an Exchange 2007 server that's in the same site as the Hub Transport server, the Hub Transport server will relay the message to an Exchange 2007 Hub Transport server in the same Active Directory site. The process of using the version information to make routing decisions is called *versioned routing* and is explained in detail in Upgrade from Exchange 2007 Transport.

If the Mailbox server is in a different Active Directory site, the message is queued for delivery to that remote site and is transferred by using SMTP.

Return to top

Routing Messages for Delivery to Exchange 2003 Servers

The routing topology and components of Exchange 2010 differ significantly from those of Exchange 2003 but generally correlate in the following ways:

- The Active Directory site in Exchange 2010 correlates to routing groups in Exchange 2003.
- IP site links in Exchange 2010 correlate to the concept of routing group connectors in Exchange 2003.
- The functionality of the Hub Transport server role in Exchange 2010 correlates to the functionality of a dedicated bridgehead server in Exchange 2003.

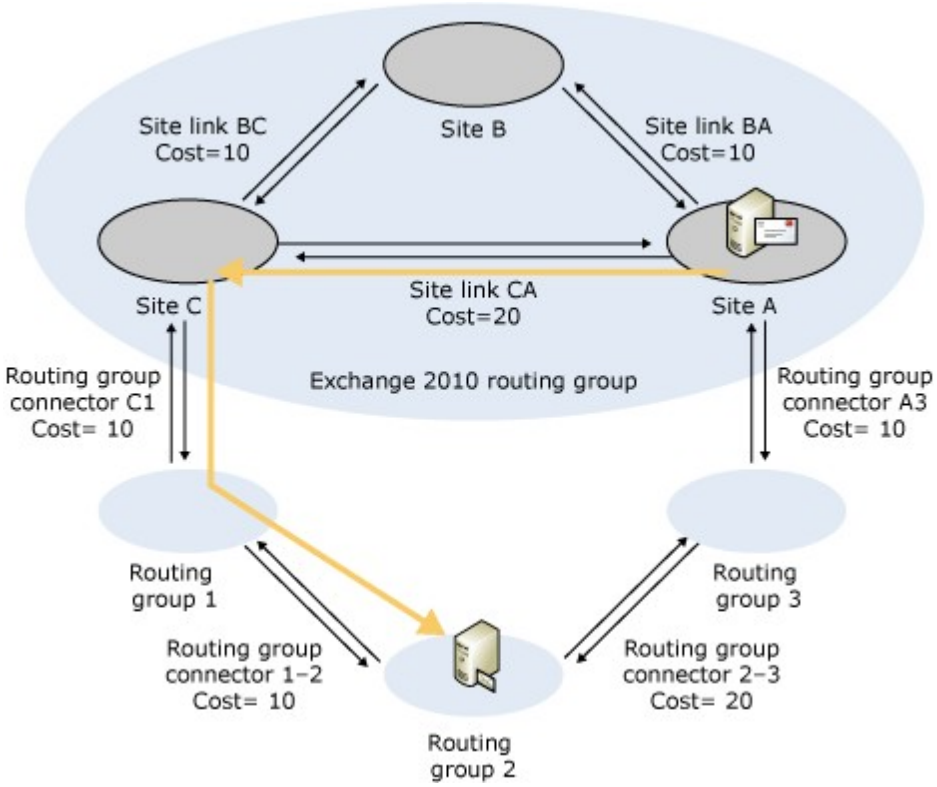
However, each Exchange version differs in the method used to determine routing paths. For more information about the routing differences, see Upgrade from Exchange 2003 Transport.

A message relayed from a Hub Transport server to an Exchange 2003 server for delivery to a recipient mailbox located on an Exchange 2003 server must be relayed across a routing group connector. All Exchange 2010 servers are associated with a single routing group named Exchange Routing Group (DWBGZMFD01QNBJR) for the purposes of routing to earlier versions of Exchange when Exchange 2010 coexists in the same organization with Exchange 2003. Placement of Exchange 2010 and earlier versions of Exchange in the same routing group isn't supported. Therefore, at least one routing group connector will always separate Exchange 2010 servers from Exchange 2003 servers.

When an Exchange 2010 Hub Transport server determines the least-cost routing path to an Exchange 2003 server, the routing component of the Microsoft Exchange Transport service uses the following algorithm to select the least-cost routing path to a computer running Exchange 2003:

1. Examine all possible routing paths across routing group connectors and select the routing path that has the least total cost.
2. If more than one routing path has the same cost, examine all possible routing paths across IP site links to reach the first routing group connector and select the routing path that has the lowest total IP site link cost.
3. If more than one routing path has the same routing group cost and has the same IP site link cost, select the routing path that includes the least number of hops.
4. If more than one routing path has the same routing group cost, the same IP site link cost, and the same number of hops, select the routing path where the name of the last Active Directory site before the destination site has the lowest alphanumeric value.

The following figure shows an example of a routing topology where Exchange 2010 and Exchange 2003 coexist.

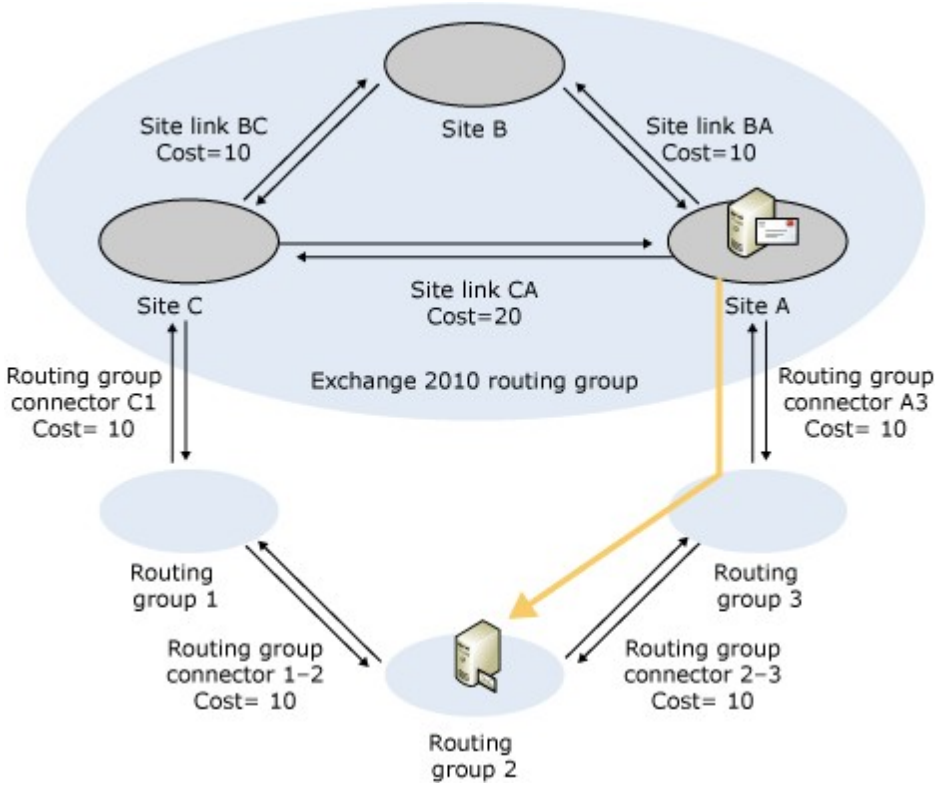


In this example, a message is being routed from a Hub Transport server in Site A to an Exchange 2003 server located in routing group 2. Two possible routing paths exist to reach routing group 2:

- Option 1: From routing group connector A3 at a cost of 10, to routing group connector 2-3 at a cost of 20. This routing path has a total cost of 30.
- Option 2: From routing group connector C1 at a cost of 10, to routing group connector 1-2 at a cost of 10. This routing path has a total cost of 20.

In this example, Option 2 has a lower total routing group connector cost, and the message is routed from the Hub Transport server in Site A, to a Hub Transport server in Site C where it's queued for delivery by using routing group connector C1.

The previous example shows how the routing decisions may not result in optimal routing due to the assigned costs on the routing group connectors. To maintain optimal routing, you may need to modify the routing group connector costs you have in your organization. The following figure shows the same topology, but with the cost of routing group connector 2-3 changed to 10.



Again, two possible routing paths are available to reach routing group 2:

- Option 1: From routing group connector A3 at a cost of 10, to routing group connector 2-3 at a cost of 10. This routing path has a total cost of 20.
- Option 2: From routing group connector C1 at a cost of 10, to routing group connector 1-2 at a cost of 10. This routing path has a total cost of 20.

In this scenario, both options have the same total routing group connector cost. Routing next evaluates the cost of the IP site links that must be crossed to reach the first routing group connector. From Site A, the IP site link cost to reach routing group connector A3 is zero, and the cost to reach routing group connector C1 is 20. Therefore, the routing path described in Option 1 is selected.

Return to top

Routing to Public Folders

Public folders can be mail-enabled in Exchange. Users can send messages to mail-enabled public folders just like any other recipient. When a Hub Transport server receives a message sent to a mail-enabled public folder, the following routing process applies:

1. The categorizer must determine which public folder hierarchy in which the public folder resides.
2. The categorizer looks up the **homeMDB** attribute for the public folder. The **homeMDB** attribute identifies the public folder hierarchy where the destination public folder is located.
3. Based on the routing table calculations performed by the Microsoft Exchange Transport service, and described in "Selecting the Destination Public Folder Database" later in this topic, the preferred public folder database is used to determine which public folder hierarchy contains a replica of the destination public folder.
   If the preferred public folder database is located in the same Active Directory

site as the routing Hub Transport server, message processing proceeds as described in step 4 in this section.
If the preferred public folder database is located in a remote Active Directory site, the message is relayed to that site by using the least cost routing path. The message categorization process described in step 1 and step 2 earlier in this section are repeated by the Hub Transport server that receives the message in the remote site.
If the preferred public folder database is located on an Exchange 2007 or Exchange 2003 server, the message is relayed to the Exchange 2007 Hub Transport server or the Exchange 2003 bridgehead server, and message delivery is determined by the earlier version of Exchange.

4. The Hub Transport server establishes a connection to the store driver on the Mailbox server that contains the preferred public folder database. The public folder database is queried to determine whether content for the public folder is available. The identity of the destination folder is referenced by the **legacyExchangeDN** attribute, and content availability is determined by the value of the **IsContentAvailable** attribute. The store driver either accepts the message for delivery, or if the folder contents aren't available locally, the store driver responds with a list of alternative servers that contain a replica of that public folder.
   The behavior of returning an alternative list of servers is known as *store override*. The alternative list of servers that contain the public folder replica is listed in the same order provided in client folder referrals, and the top entry is chosen by transport. This referral is provided to routing as the destination to which the message should be routed. For more information about client folder referrals, see Configure Public Folder Referrals.
5. If store override occurs, the Hub Transport server uses the routing table to determine the least cost routing path to the server that contains the preferred public folder replica and routes the message to that destination.
6. The message is delivered to the public folder store.

Selecting the Destination Public Folder Database

Public folders are stored in databases created on Mailbox servers. For efficiency and fault tolerance, you can replicate the content in your public folders to multiple Mailbox servers. Public folder content exists only in Exchange databases configured to have a replica of a specific folder, whereas the hierarchy is replicated to all public folder databases. Content and hierarchy information are replicated separately.

Public folder hierarchies are retrieved when routing tables are calculated. The top-level hierarchy object has a list of all the public folder databases to which that hierarchy is replicated. This list of public folder databases is stored as the **msExchOwningPFTreeBL** attribute in Active Directory. The **msExchOwningPFTreeBL** attribute always lists the most recently added public folder databases at the top of the list.

In Exchange 2010, the preferred public folder hierarchy database is selected by using the following criteria:

1. **Ranking by the age of the public folder database** By default, public folder databases that have an age threshold of less than two days aren't considered unless the age of all public folder databases is less than the threshold or the age is unknown.
2. **Proximity** Thelocal server is preferred. If the local server doesn't contain a replica of the public folder database, a server in the same Active Directory site is preferred. If the local Active Directory site doesn't contain a replica of the public folder database, a server in a remote Active Directory site or routing group is selected as the preferred destination.
3. **Cost** If more than one remote Active Directory site or routing group contains a replica of the public folder database, the server in the Active Directory site or routing group that has the least cost routing path from the local Active Directory site is selected as the preferred destination.

If more than one server still meets the criteria, the first server in the replica list returned by Active Directory is selected.

After the hierarchy is read, Exchange then determines which public folder databases have replicas of the content. To make sure that correct message delivery can occur to the public folder replica, a preferred public folder database is selected by the routing component of the Microsoft Exchange Transport service from the **msExchOwningPFTreeBL** list. This selection is made by using the following evaluation process:

1. If only a single instance of a public folder database exists, the server that hosts that database is selected.
2. If the list contains any public folder databases located on servers running Exchange 2007 or Exchange Server 2003, these public folder databases are removed from consideration as the preferred public folder database if a replica also exists on an Exchange 2010 Mailbox server.
3. If more than one Exchange 2010 public folder database is available, the following criteria are used to select a preferred public folder database:
   3.a. **Ranking by the age of the public folder database** The older a public folder database is, the more likely it is to have a replica of the target public folder. Therefore, all public folder databases listed in the **msExchOwningPFTreeBL** list are ranked according to their date of creation by using a configurable number of days as a baseline. The age ranking for each public folder database can be one of the following, listed from best to worst:
      - More than baseline days old
      - Less than baseline days old
      - Unknown

      The public folder database that has the best age rating is selected as the preferred public folder database. By default, the baseline age for public folder replicas is two days (48 hours). You can modify this value by editing the **PFReplicaAgeThreshold** key in the EdgeTransport.exe.config file. This file is located in the *%ProgramFiles%*\Microsoft \Exchange Server\V14\Bin directory on a computer running Exchange 2010.
   3.b. **Proximity** If more than one public folder database has the best age rating, the Mailbox server that has the best proximity rating is selected. The proximity rating for each public folder database can be one of the following, listed from best to worst:
      - **Local server** If the local server contains a replica of the public folder database, it's selected as the preferred destination for routing to public folders contained in that hierarchy.
      - **Server located in the local Active Directory site** If more than one server on the list is located in the local Active Directory site, the first server on the list is selected as the preferred destination for routing to public folders contained in that hierarchy.
      - **Server located in a remote Active Directory site** If the list contains servers from multiple remote Active Directory sites, the server in the Active Directory site that has the least cost routing path from the local Active Directory site is selected as the preferred destination for routing to public folders contained in that hierarchy. If there is more than one server in that site that has a replica of the public folder database, the first server on the list is selected. If more than one remote Active Directory site has the same value for the least cost routing path, the first server on the list is selected.
4. If no public folder database replica is located on an Exchange 2010 Mailbox server, a public folder database located on an Exchange 2007 server is

selected as the preferred destination. If there are no Exchange 2007 servers, a public folder database located on an Exchange 2003 computer is selected as the preferred destination for routing to public folders contained in that hierarchy. In either case, the destination public folder database is selected by the age ranking of the public folder database. The age ranking is determined by using the same method as for an Exchange 2010 server. If more than one public folder database has the same age ranking, the first server on the list is selected.

1.7.1.22.4 Using Exchange 2010 Transport to Relay Application Server SMTP Traffic

Using Exchange 2010 Transport to Relay Application Server SMTP Traffic

Transport > Understanding Transport > Understanding Message Routing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-16*

In Microsoft Exchange Server 2010, the Receive connector and load-balancing concepts remain the same as in Exchange Server 2007. Here's a quick review of those concepts. In Exchange 2007, Receive connectors are used to accept incoming messages. By default, when an Exchange Server 2007 Hub Transport server receives an e-mail message via SMTP over TCP port 25, it's processed by the Receive connector named "Default Receive connector".

In addition, Exchange 2007 automatically load-balances all intra-organization message traffic between Edge Transport, Hub Transport, and Mailbox servers using enhanced DNS. However, this functionality doesn't cover the load-balancing of messages received from non-Exchange sources, such as external mail servers, third-party anti-spam or antivirus solutions, any internal mail servers outside your Exchange organization, line-of-business (LOB) applications, and POP-based or IMAP-based e-mail clients.

For more information about how you configure load balancing for messages received from non-Exchange sources, see Understanding SMTP Failover and Load Balancing in Transport.

If you place a load-balancing solution in front of your Hub Transport servers, you need to create a separate Receive connector for that purpose and make sure that only traffic processed by that specific connector is subject to load balancing. This is achieved by adding an additional IP address to the Hub Transport server and associating this IP address with the new Receive connector.

Changes in Behavior with Exchange 2010

Exchange 2010 introduces the *shadow redundancy* feature which provides redundancy for messages for the entire time they're in transit. With shadow redundancy, the deletion of a message from the transport databases is delayed until the transport server verifies that all of the next hops for that message have completed delivery.

Because shadow redundancy is an Exchange 2010 feature, shadow redundancy is only supported by Exchange 2010 servers. If an Exchange 2010 transport server receives messages from a previous version of Exchange Server or a non-Exchange source, the source server can't send the expected XSHADOW command. Therefore, shadow redundancy isn't used. Non-Exchange sources include external mail servers, third-party

anti-spam or antivirus solutions, any internal mail servers outside your Exchange organization or line-of-business (LOB) applications the source server.

However, when an Exchange 2010 transport server receives a message from a non-Exchange 2010 source, Exchange attempts to achieve shadow redundancy by delaying the acknowledgement to the sending server until it verifies that the message has been successfully delivered to all next hops internally. This way, if the Exchange 2010 server fails, the sending server assumes that the message was never delivered to Exchange and attempts delivery again.

The delayed acknowledgement time-out is controlled by the MaxAcknowledgementDelay attribute of each Receive connector. The default value is 30 seconds.

For more information about shadow redundancy, see Understanding Shadow Redundancy.

Customers who have upgraded from Exchange 2007 to Exchange 2010 and use dedicated Receive connectors for the purpose of relaying messages from sources such as line-of-business (LOB) applications may see a significant decrease in SMTP throughput. This decrease in throughput is because of the default delayed acknowledgement time-out of 30 seconds configured for a Receive connector. To increase the SMTP throughput for the relay Receive connector, we recommend you either lower the time-out value for the delayed acknowledgement attribute or disable it completely. Whether you should lower or disable the time-out value depends on the amount of messages that go through the relay Receive connector. A good approach is to first lower the value and then verify whether SMTP throughput still suffers and, if it does, then disable the feature completely.

Important:

Although disabling delayed acknowledgements for a Receive connector increases SMTP throughput, it also means that you no longer benefit from the features provided by shadow redundancy. For this reason, we recommend the use of storage hardware redundancy for transport servers for which delayed acknowledgements are disabled.

Use the Shell to configure the maximum acknowledgement delay on a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Note:

You can't use the Exchange Management Console to configure the maximum acknowledgement delay on a Receive connector.

This example lowers the time-out value for a Receive connector named “SMTP Application relay” from 30 to 15 seconds.

```
Set-ReceiveConnector "SMTP Application relay" -MaxAcknowledgementDelay 15
```

This example disables delayed acknowledgement on the Receive connector.

```
Set-ReceiveConnector "SMTP Application relay" -MaxAcknowledgementDelay 0
```

Important:

It isn’t possible to disable shadow redundancy for a Receive connector. Instead, you must do this on the Exchange organization level. For detailed syntax and parameter information, see Set-TransportConfig.

Message Throttling Policy Considerations

When relaying application server SMTP traffic through an Exchange 2010 transport server,

there are Receive connector specific message throttling policy options that may need to be adjusted, so the overall SMTP throughput doesn't suffer. For example, the *MessageRateLimit* parameter specifies the maximum number of messages that a Receive connector accepts from a single IP address per minute. On Hub Transport servers, this parameter is set to a value of Unlimited, which means SMTP throughput won't be affected. But, for an Edge Transport server, it's set to accept 600 messages per minute. Depending on the relay application server SMTP traffic in your specific environment, you may need to raise this limit.

This example raises the message rate limit for a Receive connector named "SMTP Application relay" from 600 to 2000.

```
Set-ReceiveConnector "SMTP Application relay" -MessageRateLimit 2000
```

Another Receive connector specific option that can have an impact on overall SMTP throughput from a relay application server is expressed in the value of the *MessageRateSource* parameter. With this parameter, you specify how the message submission rate is calculated. It can be set to None, IPAddress, User, or All. By default, the parameter is set to IPAddress, which means the message submission rate is calculated for sending hosts. If this parameter has a negative impact on SMTP throughput from your relay application servers, you should consider setting the value to None.

This example disables the *MessageRateSource* parameter for a Receive connector named "SMTP Application relay".

```
Set-ReceiveConnector "SMTP Application relay" -MessageRateSource None
```

If you're planning to use a dedicated transport server for relay application server SMTP traffic, you should also consider increasing the maximum number of connections that a Receive connector will serve at the same time from a single IP address. This is done using the *MaxInboundConnectionPercentagePerSource* parameter. The value for this parameter is expressed as the percentage of available remaining connections on a Receive connector. By default, the value is set to 2 percent.

This example changes the value of MaxInboundConnectionPercentagePerSource for a Receive connector named "SMTP Application relay" from 2 to 30 percent.

```
Set-ReceiveConnector "SMTP Application relay" - MaxInboundConnectionPercentagePer
```

For detailed syntax and parameter information for the above Receive connector specific parameters, see Set-ReceiveConnector.

1.7.1.23 Understanding Message Size Limits

Understanding Message Size Limits

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can apply message size limits to individual messages that move through the Microsoft Exchange Server 2010 organization. You can restrict the total size of a message or the size of the individual components of a message, such as the message header, the message attachments, and the number of recipients. You can apply limits globally for the whole Exchange 2010 organization, or specifically for a particular connector or user object.

As you plan the message size limits for your Exchange 2010 organization, consider the following questions:

- What size limits should I impose on all incoming messages?
- What size limits should I impose on all outgoing messages?
- Does my Exchange 2010 organization have a mailbox quota?
- How do the message size limits that I have chosen relate to the mailbox quota size?
- Are there users in my Exchange 2010 organization who must send or receive messages that are larger than the specified allowed size?
- Does my Exchange 2010 network topology include other messaging systems or distinctly separate business units that have different message size limits?

This topic provides guidance to help you answer these questions.

Looking for management tasks related to Transport servers? See Managing Transport Servers.

Types of Message Size Limits

Following are the basic categories of the size limits available for individual messages:

- **Message header size limits** These limits apply to the total size of all message header fields that are present in a message. The size of the message body or attachments isn't considered. Because the header fields are plain text, the size of the header is determined by the number of characters in each header field and by the total number of header fields. Each character of text consumes 1 byte.

  Note:
  Some third-party firewalls or proxy servers apply their own message header size limits. These third-party firewalls or proxy servers may have difficulty processing messages that contain attachment file names that are greater than 50 characters or attachment file names that contain non-US-ASCII characters.

- **Message size limits** These limits apply to the total size of a message, which includes the message header, the message body, and any attachments. Message size limits may be imposed on incoming messages or outgoing messages. For internal message flow, Exchange 2010 uses the custom `X-MS-Exchange-Organization-OriginalSize:` message header to record the original message size of the message as it enters the Exchange 2010 organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing.
- **Attachment size limits** These limits apply to the maximum allowed size of a single attachment within a message. The message may contain many attachments that greatly increase the overall size of the message. However, an attachment size limit applies to the size of an individual attachment only.
- **Recipient limits** These limits apply to the total number of message recipients. When a message is first composed, the recipients exist in the `To:`, `Cc:`, and `Bcc:` header fields. When the message is submitted for delivery, the message recipients are converted into `RCPT TO:` entries in the message envelope. A distribution group is counted as a single recipient during message submission.

Scope of Limits

Following are the basic categories for the scope of the limits available for individual messages:

- **Organizational limits** These limits apply to all Exchange 2010 and Exchange 2007 servers that exist in the organization. The specified message limits apply to all Exchange 2010 and Exchange 2007 servers that have the Hub Transport server role installed. On an Edge Transport server, the specified limits apply to the specific server.
- **Global limits** Global limits are used when Exchange Server 2003 servers coexist with your Exchange 2010 deployment. The global limits are stored in a different location in Active Directory than the organizational limits and are primarily used by Exchange Server 2003 servers. In an environment where you have both Exchange 2010 and Exchange Server 2003 servers in the same organization, changes that you make to the organizational limits are automatically copied to the corresponding global limits. In Exchange 2010, you can modify the organizational limits by using the **Set-TransportConfig** cmdlet in the Exchange Management Shell, or by configuring the Hub Transport server organization configuration properties in the Exchange Management Console.
- **Connector limits** These limits apply to any messages that use the specified Send connector, Receive connector, Delivery Agent connector, or Foreign connector for message delivery. Connectors are defined on Hub Transport servers or Edge Transport servers.
- **Active Directory site links** Hub Transport servers use Active Directory sites and the costs that are assigned to the Active Directory IP site links to determine the least-cost routing path from each Hub Transport server in the organization to every other Hub Transport server in the organization. You can assign specific message size limits to the Active Directory site links in your organization. For example, you may want to apply a lower message size limit to an Active Directory site link that represents a connection to a remote office with a low-bandwidth connection. Any messages that exceed the maximum message size limit on any Active Directory site link included in the least-cost routing path won't be delivered and will generate a delivery status notification (DSN) with a value of 5.3.4. For more information about message routing in Exchange 2010, see Planning to Use Active Directory Sites for Routing Mail.
- **Routing group connectors** A routing group connector is used to send and receive messages between Exchange 2010 Hub Transport servers and Exchange Server 2003 bridgehead servers when the organization is running more than one version of Microsoft Exchange. Any messages that exceed the maximum message size limit on any routing group connector won't be delivered. They will generate a DSN with the value of 5.3.4. For more information about routing group connectors, see Upgrade from Exchange 2003 Transport.
- **Server limits** These limits apply to a specific Hub Transport server or Edge Transport server. You can set the specified message limits independently on each Hub Transport server or Edge Transport server.
  If you are using Outlook Web App, the maximum HTTP request size limit setting on the Client Access servers also controls the size of messages that Outlook Web App users can send. For more information, see Configure Maximum Message Size in Outlook Web App.
- **User limits** These limits apply to a specific user object, such as a mailbox, contact, distribution group, or public folder.

Organizational Limits

The following table shows the organizational limits, including information about how to configure the limits in the Exchange Management Shell or the Exchange Management Console (EMC).

Organizational limits

Size limit	Default value in Exchange 2010	Shell configuration	EMC configuration
Maximum size for	10 MB	Cmdlet: **Set-TransportConfig**	Organization

messages received		Parameter: *MaxReceiveSize*	Configuration > Hub Transport > Global Settings > Transport Settings > General tab
Maximum size for messages sent	10 MB	Cmdlet: **Set-TransportConfig** Parameter: *MaxSendSize*	Organization Configuration > Hub Transport > Global Settings > Transport Settings > General tab
Maximum number of recipients per message **Note:** When a message is first processed by a Hub Transport server, an X-header named `X-MS-Exchange-Organization-OriginalSize:` is inserted into the message header. Any Hub Transport servers that are involved in the future delivery of the message will use this value for the message size. Conversion encoding and agent processing can increase the size of the message as it flows through the Exchange organization.	5000	Cmdlet: **Set-TransportConfig** Parameter: *MaxRecipientEnvelopeLimit*	Organization Configuration > Hub Transport > Global Settings > Transport Settings > General tab
Maximum attachment size in Transport rules that apply to all Hub Transport servers in the organization	Not configured	Cmdlets: **New-TransportRule**, **Set-TransportRule** Parameter: *AttachmentSizeOver*	Organization Configuration > Hub Transport > Transport Rules New Transport Rule wizard or Edit Transport Rule wizard

Global Limits

The following table shows the global limits, including information about where to configure the limits in Exchange System Manager in Exchange Server 2003.

Global limits

Size limit	Default value	Exchange System Manager configuration
Maximum size for messages received	10240 KB (10 MB)	• *delivContLength* in Active Directory • **Incoming message size** in

		Exchange System Manager **Global Settings**
Maximum size for messages sent	10240 KB (10 MB)	• *submissionContLength* in Active Directory • **Outgoing message size** in Exchange System Manager **Global Settings**
Maximum number of recipients per message	5000	• *msExchRecipLimit* in Active Directory • **Maximum number of recipients** in Exchange System Manager **Global Settings**

Connector Limits

The following table shows the connector limits, including information about how to configure the limits in the Exchange Management Shell or the Exchange Management Console (EMC).

Connector limits

Size limit	Default value	Shell configuration	EMC configuration
Maximum header size through a Receive connector	64 KB	Cmdlets: **New-ReceiveConnector**, **Set-ReceiveConnector** Parameter: *MaxHeaderSize*	N/A
Maximum message size through a Receive connector	10 MB	Cmdlets: **New-ReceiveConnector**, **Set-ReceiveConnector** Parameter: *MaxMessageSize*	Server Configuration > Hub Transport > Receive Connectors > Receive Connector properties > General tab Edge Transport > Receive Connectors > Receive Connector properties > General tab
Maximum number of recipients per message through a Receive connector	200 for the Default Client Receive connector 5,000 for the Default Receive connector on Hub Transport servers 200 for the Default Receive connector on Edge Transport servers **Note:** If the number of recipients is exceeded for an anonymous	Cmdlets: **New-ReceiveConnector**, **Set-ReceiveConnector** Parameter: *MaxRecipientsPerMessage*	N/A

	sender, the message is accepted for the first 200 recipients. Most SMTP messaging servers detect that a recipient limit is in effect. The SMTP messaging server continues to resend the message in groups of 200 recipients until the message is delivered to all recipients.		
Maximum message size through a Send connector	10 MB	Cmdlets: **New-SendConnector**, **Set-SendConnector** Parameter: *MaxMessageSize*	Organization Configuration > Hub Transport > Send Connectors > Send Connector properties > General tab Edge Transport > Send Connectors > Send Connector properties > General tab
Maximum message size through an Active Directory site link	Unlimited	Cmdlet: **Set-AdSiteLink** Parameter: *MaxMessageSize*	N/A
Maximum message size through a routing group connector	Unlimited	Cmdlet: **Set-RoutingGroupConnector** Parameter: *MaxMessageSize*	N/A
Maximum message size through a delivery agent connector	Unlimited	Cmdlets: **New-DeliveryAgentConnector**, **Set-DeliveryAgentConnector** Parameter: *MaxMessageSize*	N/A
Maximum message size through a foreign connector	Unlimited	**Cmdlet: Set-ForeignConnector** Parameter: *MaxMessageSize*	N/A

Server Limits

The following table shows the server limits, including information about how to configure the limits in the Exchange Management Shell or the Exchange Management Console (EMC).

Server limits

Size limit	Default value	Shell configuration	EMC configuration
Transport rule on an Edge Transport server that only applies to the specific server	Not configured	Cmdlets: **New-TransportRule**, **Set-TransportRule** Parameter: *AttachmentSizeOver*	Edge Transport > Transport Rules New Transport Rule wizard or Edit Transport Rule wizard
Maximum header size for messages in the pickup directory	64 KB	Cmdlet: **Set-TransportServer** Parameter: *PickupDirectoryMaxHeaderSize*	Not applicable
Maximum number of recipients per message for messages in the pickup directory	100	Cmdlet: **Set-TransportServer** Parameter: *PickupDirectoryMaxRecipientsPerMessage*	Not applicable

In addition, you can configure the maximum HTTP request length on your Client Access servers that service Microsoft Office Outlook Web App clients. The value configured for this setting will also affect the message size users can submit. For example, if you set this value lower than other message size limits in your organization, your users will not be able to send large messages using Outlook Web App even though they can send the same message using Outlook.

You can configure this setting by modifying the *maxRequestLength* parameter in the web.config file on your Client Access servers. By default, this file is located in the <Exchange install directory>\V14\ClientAccess\Owa folder. The default value is 30000 KB.

User Limits

The following table shows message size limits that you can configure at the recipient level, including information about how to configure the limits in the Exchange Management Shell or the Exchange Management Console (EMC).

User limits

Size Limit	Default value	Shell configuration	EMC configuration
Maximum message size that can be sent by this recipient	Unlimited	Cmdlets: **Set-DistributionGroup** **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailUser** **Set-MailPublicFolder**	For mailboxes: Recipient Configuration > Mailbox Properties > Mail Flow Settings tab For mail public folders: Public Folder Management Console > Public Folder properties > Mail Flow Settings tab **Note:** This setting isn't

		Parameter: *MaxSendSize*	configurable using the EMC for other recipient types.
Maximum message size that can be sent to this recipient	Unlimited	Cmdlets: **Set-DistributionGroup** **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailUser** **Set-MailPublicFolder** Parameter: *MaxReceiveSize*	For all recipient types except Mail Public Folders: Recipient Configuration > Recipient Properties > Mail Flow Settings tab For Mail Public Folders: Public Folder Management Console > Public Folder properties > Mail Flow Settings tab
Maximum number of recipients per message sent by this recipient	Unlimited	Cmdlets: **Set-Mailbox**, **Set-MailUser** Parameter: *RecipientLimits* Cmdlet: **Set-MailUser** Parameter: *MaxRecipientsPerMessage*	N/A

Order of Precedence for Message Size Limits

You can set different message size limits at different levels in the Exchange organization. As a message is routed through your Transport infrastructure, it may be subjected to several different message size restrictions. You should plan your message size restrictions in a way that makes sure that messages in the transport pipeline are rejected as early as possible if they violate message size limits. Generally speaking, you should set more restrictive limits at the points where messages enter your infrastructure. For example, any message size restrictions on your Edge server Receive connectors that receive messages from the Internet should be less than or equal to the message size restrictions you configure for your internal Exchange organization. It would be a waste of system resources for the Edge Transport server to accept and process a message from the Internet that would be rejected by your Hub Transport servers. Make sure that your organization, server, and connector limits are configured in a way that minimizes any unnecessary processing of messages.

One exception to this approach is the user limits. User level limits take precedence over other message size restrictions. Therefore, you can configure a user to exceed the default

message size limits for your organization. For example, you can allow a specific group of user mailboxes to send larger messages than the rest of the organization by configuring custom send and receive limits for those users.

The exceptions for the user limits only apply to message exchanges between authenticated users. If a message is sent to or received by a recipient on the Internet, the organizational limits will be applied. For example, assume that you have an organizational message size restriction of 10 MB, but you have configured the users in your marketing department to send and receive messages up to 50 MB. These users will be able to exchange large messages with each other, but they still won't be able to receive large messages from Internet users because such messages will be coming from unauthenticated senders.

Messages Exempt from Size Limits

The following list shows the types of messages generated by a Hub Transport server or an Edge Transport server and exempted from all message size limits:

- System messages
- Agent-generated message
- Delivery status notification (DSN) messages
- Journal report messages
- Quarantined messages

However, these messages are still subject to the organizational value for maximum number of recipients in a message. This value is set by the *MaxRecipientEnvelopeLimit* parameter that you can configure by using the **Set-TransportConfig** cmdlet in the Shell.

Differences in Message Size Limits Between Exchange 2003 and Exchange 2010

The primary difference in message size limits between Exchange Server 2003 and Exchange Server 2010 is in the handling of recipient limits. Exchange 2003 treats each member of an expanded distribution list as one recipient. Exchange 2010 treats a distribution group as one recipient. This change was implemented to avoid the partial message delivery scenarios that may occur in Exchange 2003.

Partial message delivery occurs in Exchange 2003 if the number of individual recipients and the recipients that are contained within the distribution list exceeds the specified recipient limit. The total number of message recipients isn't known until after distribution list expansion. Message delivery occurs as the distribution list is expanded until the number of recipients reaches the specified limit. The remaining recipients do not receive the message, but at least the sender receives a non-delivery report (NDR) for each unsuccessful delivery. However, if delivery failure reporting is disabled for the distribution list, the remaining recipients wouldn't receive the message, and the sender would not know who did not receive the message.

1.7.1.24 Understanding Message Throttling

Understanding Message Throttling

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-07*

This topic explains the message throttling options that are available in Microsoft Exchange Server 2010. It also describes enhancements to the message throttling functionality that are included in Service Pack 1 (SP1) of Microsoft Exchange Server 2010. *Message throttling* refers to a group of limits that are set on the number of messages and connections that can be processed by a computer that is running Exchange 2010 with either the Hub Transport server role or the Edge Transport server role installed. These limits prevent the accidental or intentional exhaustion of system resources on the transport server.

For more information about management tasks related to managing transport servers, see Managing Transport Servers.

Contents

Message Throttling Scope

Message throttling involves a variety of limits on message processing rates, SMTP connection rates, and SMTP session time-out values. These limits work together to protect a Hub Transport server or Edge Transport server from being overwhelmed by accepting and delivering messages. Although a large backlog of messages and connections may be waiting to be processed, the message throttling limits enable the transport server to process the messages and connections in an orderly manner.

In addition to message throttling, with Exchange 2010 you can also put size limits on the individual components of messages, such as the number of recipients, the size of the message header, or the size of individual attachments. For more information about message size limits, see Understanding Message Size Limits.

Another Exchange 2010 feature that helps avoid overwhelming the system resources of an Exchange 2010 transport server is *back pressure*. Back pressure is a system resource monitoring feature on Hub Transport servers and Edge Transport servers. When a monitored system resource, such as hard disk utilization or memory utilization, exceeds the specified threshold, the Exchange transport server reduces the rate at which it accepts new connections and messages, and focuses on delivering existing messages. When the utilization of the monitored system resources returns to normal levels, the Exchange transport server slowly increases the rate at which it accepts new connections and then establishes a normal level. For more information, see Understanding Back Pressure.

Message Throttling Enhancements in Exchange 2010 SP1

Exchange 2010 SP1 includes additional features that enhance the message throttling functionality. These enhancements address the following issues that administrators may experience in a messaging environment:

- Because more resources are required to send messages that have large attachments or that are sent to multiple recipients, other message delivery operations may experience increased latency.
- A high rate of mailbox delivery operations may reduce the user interactive mailbox experience. For example, users may experience slow refresh or update times when they access their mailboxes.
- No centralized method is available to control how a specific user may inadvertently affect the resources of a Transport server. Such an effect may occur if the user sends messages that have high delivery costs in terms of number of recipients or total message size or both.

To provide more consistent message throughput and predictable message delivery latency, Exchange 2010 SP1 establishes an accumulated cost for messages. This cost is based on the following criteria:

- Message size
- Number of recipients
- Frequency of transmission

Transport servers that run on Exchange 2010 SP1 track the average delivery cost of messages that are sent by individual users. By using message costs, Exchange 2010 SP1 provides a group of settings that can control the effect that a user or connection has on an Exchange organization. This group of settings is known as a *throttling policy*. When a user repeatedly sends costly messages, such as messages that have large attachments or messages that are sent to many recipients, the Exchange 2010 SP1-based transport servers use a throttling policy to assign a lower priority to higher-cost messages from the user while continuing to deliver lower-cost messages. This new behavior adds a "quality of service" aspect to the message throttling functionality in Exchange 2010.

Note:

Message throttling doesn't affect the message priority from a user's perspective. Messages still retain the original priority set by the user. For example, messages retain a setting of Important or Urgent, and so on.

To support this new functionality, Exchange 2010 SP1 uses the following mechanisms:

- **Internal prioritization agent** This agent is triggered on the **OnResolvedMessage** event and assigns a lower priority to messages from the same sender that have a high accumulated cost. This cost is measured over a period of one minute and affects messages that have more than 500 P1 and P2 recipients or that are larger than 1 megabyte (MB).
- **Quota-based priority queuing for the MapiDelivery queue type** This mechanism causes Exchange to deliver messages in a normal-priority queue more frequently than messages in a low-priority queue. By default, the normal-to-low message ratio is 20:1. However, new messages from a lower priority queue are never delivered sooner than new items from a higher priority queue. For example, consider the following scenario:
  .1.Twenty normal priority messages are delivered. By default, the next delivered message is a lower priority message.
  .2.Two new messages are received by the Transport server: One message from a higher priority queue and one message from a lower priority queue.
  In this scenario, the message from the higher priority queue is delivered first. Then, the message from the lower priority queue is delivered.
- **Throttle concurrent connections based on messaging database health** This mechanism monitors the health of the Exchange messaging database (MDB) health and throttles concurrent connections to Exchange transport servers based on an assigned Health Measure value. The MDB is monitored by the Resource Health Monitor API on the Hub Transport server and is assigned a health value from -1 through 100. This value is based on the RPC performance

statistics that are included with each RPC response from the Store.exe process. The Resource Health framework uses both the **Requests/Second** rate performance counter and the **Average RPC Latency** performance counter to calculate a health value for the database. To help maintain a consistent interactive user experience, Exchange reduces the number of concurrent connections as the health value decreases. The following health value ranges are available:

.1. **-1:** This value indicates that the MDB health state is unknown. This value is assigned when the database starts. In this scenario, the database is considered healthy.
.2. **0:** This value is assigned if the database is in an unhealthy state. In this state, the database should not be contacted.
.3. **1 through 99:** These values represent a fair health state. A lower value represents a less healthy database.
.4. **100:** This value represents a healthy database.

The Microsoft Exchange Throttling service in Exchange 2010 SP1 provides the framework for mail flow throttling. This service is installed when you install the Mailbox Server role. The Exchange 2010 Throttling service keeps track of mail flow throttling settings for a specific user and caches the throttling information in memory. Mail flow throttling settings are also known as a *budget*. Restarting the Exchange 2010 Throttling service also resets mail flow throttling budgets.

You can use the throttling policy cmdlets that are available in Exchange 2010 SP1 to configure individual budget settings for a throttling policy. A budget is the amount of access that a user or application may have for a specific setting. A budget represents how many connections a user may have or how much activity a user may be permitted for each one-minute period. For example, a budget may be configured to set the amount of time that a user may spend using a specific feature in Exchange, such as ActiveSync, Outlook Web App, or Exchange Web Services. This threshold is stored in a throttling policy and defines the budget.

Time settings for a budget are set as a percentage of one minute. Therefore, a threshold of 100 percent represents 60 seconds. For example, assume that you want to specify Outlook Web App policy settings that limit the amount of time during which a user may run Outlook Web App code on a Client Access server and the amount of time the user may communicate with the Client Access server to 600 milliseconds over a one-minute period. To accomplish this, you need to set the value to 1 percent of one minute (600 milliseconds) for both of the following parameters:

- **OWAPercentTimeInCAS:** 1
- **OWAPercentTimeInMailboxRPC:** 1

A user who has this policy applied has a budget of OWAPercentTimeInCAS of 600 milliseconds and of OWAPercentageTimeInMailboxRPC of 600 milliseconds. In this scenario, when the user is logged into Outlook Web App, the user can run Client Access code for up to 600 milliseconds. After the 600 millisecond-period, the connection is considered over budget and the Exchange server doesn't allow any further Outlook Web App action until one minute after the budget limit is reached. After the one-minute period, the user can run Outlook Web App client access code for another 600 milliseconds.

These Exchange 2010 SP1 features, together with the features in the release to manufacturing (RTM) version of Exchange 2010, let an Exchange administrator maintain a consistent user experience without having to deploy more servers than are required to meet the normal workload.

Message Throttling Options on Transport Servers

You can set the message throttling options at the following locations:

- On the transport server
- On a Send connector
- On a Receive connector

You can set all the message throttling options that are available on Hub Transport servers or Edge Transport servers in the Exchange Management Shell. You can also set some of the same options by configuring the transport server properties in the Exchange Management Console (EMC).

The following table shows the message throttling options that are available on Hub Transport servers or Edge Transport servers.

Message throttling options on Hub Transport or Edge Transport servers

Source	Parameter	Description
Set-TransportServer	*MaxConcurrentMailboxDeliveries*	This parameter specifies the maximum number of delivery threads that the Hub Transport server can have open at the same time to deliver messages to mailboxes. The store driver on the Hub Transport server is responsible for delivering messages to and from Mailbox servers. This limit applies to the delivery of messages to any mailboxes in the Exchange organization. The default value of the *MaxConcurrentMailboxDeliveries* parameter is 20.
Set-TransportServer	*MaxConcurrentMailboxSubmissions*	This parameter specifies the maximum number of delivery threads that the Hub Transport server can have open at the same time to accept messages from mailboxes. The store driver on the Hub Transport server is responsible for delivering messages to and from Mailbox servers. This limit applies to the acceptance of new messages from any mailboxes in the Exchange organization. The default value of the *MaxConcurrentMailboxSubmissions* parameter is 20.
Set-TransportServer	*MaxConnectionRatePerMinute*	This parameter specifies the maximum rate at which new inbound connections can be opened to the Hub Transport server or the Edge Transport

		server. These connections are opened to any Receive connectors that exist on the server. The default value for the *MaxConnectionRatePerMinute* parameter is 1200 connections per minute.
Set-TransportServer or Transport server properties	*MaxOutboundConnections*	This parameter specifies the maximum number of concurrent outbound connections that the Hub Transport server or Edge Transport server can have open at the same time. The outbound connections occur by using the Send connectors that exist on the server. The value that's specified by the *MaxOutboundConnections* parameter applies to all the Send connectors that exist on the transport server. The default value of the *MaxOutboundConnections* parameter is 1000. If you enter a value of `unlimited`, no limit is imposed on the number of outbound connections. This value can also be configured using the EMC.
Set-TransportServer or Transport server properties	*MaxPerDomainOutboundConnections*	This parameter specifies the maximum number of connections that an Internet-facing Hub Transport server or Edge Transport server can have open to any single remote domain. The outbound connections to remote domains occur by using Send connectors that exist on the server. The default value of the *MaxPerDomainOutboundConnections* parameter is 20. If you enter a value of `unlimited`, no limit is imposed on the number of outbound connections per domain. This value can also be configured using the EMC.
Set-TransportServer	*PickupDirectoryMaxMessagesPerMinute*	This parameter specifies the rate of message processing for both the Pickup directory

		and Replay directory. Each directory can independently process message files at the rate that's specified by the *PickupDirectoryMaxMessagesPerMinute* parameter. By default, the Pickup directory can process 100 messages per minute, and the Replay directory can process 100 messages per minute at the same time. The Pickup directory and the Replay directory scan for new message files once every 5 seconds, or 12 times per minute. This 5-second polling interval isn't configurable. This means the maximum number of messages that can be processed during each polling interval is the value that you assign to the *PickupDirectoryMaxMessagesPerMinute* parameter divided by 12 (*PickupDirectoryMaxMessagesPerMinute*/12). By default, a maximum of just over eight messages can be processed during each 5-second polling interval.

For more information, see the following topics:

- Configure Edge Transport Server Properties
- Configure Hub Transport Server Properties
- Set-TransportServer

Message Throttling Option on Send Connectors

The following table shows the message throttling option that's available on Send connectors that are configured in your organization or an Edge Transport server. You must use the Shell to configure this option.

Message throttling option available on Send connectors

Source	Parameter	Description
Set-SendConnector	*ConnectionInactivityTimeOut*	This parameter specifies the maximum time that an open SMTP connection with a destination messaging server can remain idle before the connection is closed. The default value is 10 minutes.

For more information, see Set-SendConnector.

Message Throttling Options on Receive Connectors

The following table shows the message throttling options that are available on Receive connectors that are configured on a Hub Transport server or an Edge Transport server. You must use the Shell to configure these options.

Message throttling options available on Receive connectors

Source	Parameter	Description
Set-ReceiveConnector	*ConnectionInactivityTimeOut*	This parameter specifies the maximum time that an open SMTP connection with a source messaging server can remain idle before the connection is closed. The default value for a Receive connector that's configured on a Hub Transport server is 5 minutes. The default value for a Receive connector that's configured on an Edge Transport server is 1 minute.
Set-ReceiveConnector	*ConnectionTimeOut*	This parameter specifies the maximum time that an SMTP connection with a source messaging server can remain open, even if the source messaging server is transmitting data. The default value for a Receive connector that's configured on a Hub Transport server is 10 minutes The default value for a Receive connector that's configured on an Edge Transport server is 5 minutes. The value specified by the *ConnectionTimeout* parameter must be larger than the value specified by the *ConnectionInactivityTimeout* parameter.
Set-ReceiveConnector	*MaxInboundConnection*	This parameter specifies the maximum number of inbound SMTP connections that this Receive connector allows at the same time. The default value is 5000.
Set-ReceiveConnector	*MaxInboundConnectionPercentagePerSource*	This parameter specifies the maximum number of SMTP

		connections that a Receive connector allows at the same time from a single source messaging server. The value is expressed as the percentage of available remaining connections on a Receive connector. The maximum number of connections that are permitted by the Receive connector is defined by the *MaxInboundConnection* parameter. The default value of the *MaxInboundConnectionPercentagePerSource* parameter is 2 percent.
Set-ReceiveConnector	*MaxInboundConnectionPerSource*	This parameter specifies the maximum number of SMTP connections that a Receive connector allows at the same time from a single source messaging server. The default value is 100.
Set-ReceiveConnector	*MaxProtocolErrors*	This parameter specifies the maximum number of SMTP protocol errors that a Receive connector allows before the Receive connector closes the connection with the source messaging server. The default value is 5.
Set-ReceiveConnector	*TarpitInterval*	This parameter specifies the delay that's used in *tarpitting*. Tarpitting is the practice of artificially delaying SMTP responses for specific SMTP communication patterns that indicate a directory harvest attack or other unwelcome messages. A *directory harvest attack* is an attempt to collect valid e-mail addresses from a particular organization to use as a target for unsolicited commercial e-mail. The delay that's specified by the *TarpitInterval* parameter only applies to anonymous connections. The default value of the *TarpitInterval* parameter is 5 seconds. For more information, see Understanding Recipient Filtering.

For more information, see Set-ReceiveConnector.

Message Throttling Policies

In Exchange 2010 SP1, each mailbox has a ThrottlingPolicy setting. The default value for this setting is $Null. You can use the **Set-Mailbox** command together with the *ThrottlingPolicy* parameter to configure a throttling policy for a mailbox.

A default throttling policy exists to provide a default set budget configuration for users who connect to Exchange. To configure customized budget settings for one or more users, create a new throttling policy. Then, apply the policy to the appropriate user or group.

Important:
We recommend that you do not modify the default throttling policy.

You can set all the message throttling options that are available on Mailbox servers in the Exchange Management Shell. The following cmdlets are available to manage throttling policies:

- **Get-ThrottlingPolicy**
- **Remove-ThrottlingPolicy**
- **New-ThrottlingPolicy**
- **Set-ThrottlingPolicy**

For more information, see Understanding Client Throttling Policies.

You can use the **New-ThrottlingPolicy** and **Set-ThrottlingPolicy** cmdlets to configure how much activity a user can perform against Exchange over a specific connection or time period. These settings make up a user's budget. You can establish throttling policies to control access to the following Exchange features:

- Exchange ActiveSync
- Exchange Web Services
- Outlook Web App
- Unified Messaging
- IMAP4
- POP3
- Outlook client connections (MAPI or RPC connections)
- Mail flow settings
- PowerShell commands
- CPU usages

For more information about the policy settings available for use with the throttling policy cmdlets, see New-ThrottlingPolicy and Set-ThrottlingPolicy.

For more information about how to configure Transport servers, see the following topics:

- Configure Edge Transport Server Properties
- Configure Hub Transport Server Properties
- Set-TransportServer

1.7.1.25 Understanding Moderated Transport

Understanding Moderated Transport

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-05*

Using the moderated transport feature in Microsoft Exchange Server 2010, you can require all e-mail messages sent to specific recipients be approved by moderators. You can configure any type of recipient as a moderated recipient, and Exchange 2010 Hub Transport servers will ensure that all messages sent to those recipients go through an approval process.

In any type of organization, you may need to restrict access to specific recipients. The most common scenario is the need to control messages sent to large distribution groups. Depending on your organization's requirements, you may also need to control the messages sent to executive mailboxes or partner contacts. You can use moderated recipients to accomplish these tasks.

Note:

Previous versions of Exchange don't support moderated recipients. If a message sent to a moderated distribution group is expanded on a Hub Transport server running Exchange Server 2007, it will be delivered to all members of that distribution group, bypassing the moderation process. If you have Exchange 2007 Hub Transport servers in your Exchange 2010 organization, and you want to use moderated distribution groups, you must designate an Exchange 2010 Hub Transport server as the expansion server for the moderated distribution groups. Doing this ensures that all messages sent to the distribution group are moderated.

Moderated transport relies on the Exchange 2010 approval framework. For more information about the approval framework, see Understanding Approval Framework.

Looking for management tasks related to transport servers? See Managing Transport Servers.

Moderated Transport

The moderated transport application consists of the following components:

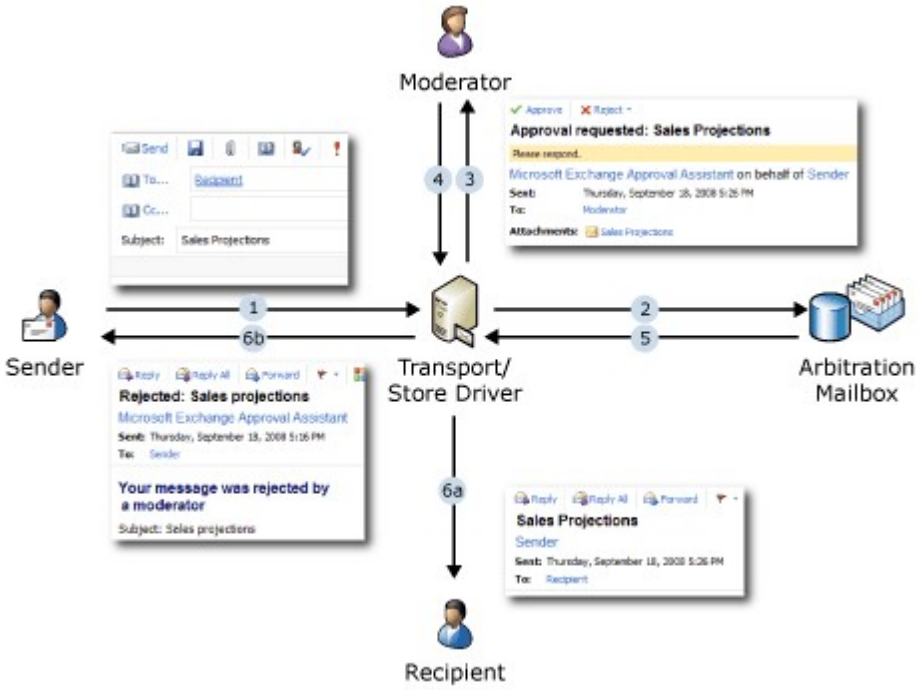
- **Categorizer** The transport categorizer initiates the approval process. When the categorizer detects a moderated recipient while processing a message, it reroutes the message to the arbitration mailbox.
- **Store driver** The store driver processes the messages that the categorizer marks for moderation. When the store driver encounters such a message, it stores the original message in the arbitration mailbox and sends approval requests to the moderators. When a moderator responds with a decision, the store driver marks that decision on the message that's stored in the arbitration mailbox. If an approved message is submitted again by the Information Assistant, the store driver removes the approval workflow wrappers so the message that's delivered is identical to the original message submitted by the sender.
- **Information Assistant** The Information Assistant process monitors the arbitration mailbox. The Information Assistant resubmits any approved messages to the submission queue for delivery to the intended recipients, or it deletes rejected messages. The Information Assistant is also responsible for sending rejection notifications to the sender. In addition, it cleans up the arbitration mailbox by deleting any stale or orphaned messages from the arbitration mailbox. For example, if a moderator simply deletes an approval

request instead of making a decision, the corresponding message waiting for approval in the arbitration mailbox needs to be removed by the Information Assistant.

- **Arbitration mailbox** The arbitration mailbox is used to store the original message that's awaiting approval. By default, one arbitration mailbox is created for moderated transport during setup. It's used for all moderated recipients. You can add additional arbitration mailboxes for load balancing purposes. If you're using multiple arbitration mailboxes, you need to specify which mailbox to use for each moderated recipient.

Message Flow for Moderated Recipients

When a user sends a message to a recipient for whom message moderation is enabled, the message follows a path to its destination, as shown in the following figure and described in the following steps.



1. The sender creates a message and sends it to the moderated recipient.
2. The categorizer intercepts the message, marks it for moderation, and then reroutes it to the arbitration mailbox.
3. The store driver stores the message in the arbitration mailbox and sends an approval request to the moderator.
4. The moderator uses the buttons in the approval request to either accept or reject the message.
5. The store driver marks the moderator's decision on the original message stored in the arbitration mailbox.
6. The Information Assistant reads the approval status on the message stored in the arbitration mailbox, and then processes the message depending on the moderator's decision:
   6.a. If the moderator has approved the message, the Information Assistant resubmits the message to the submission queue, and the message is delivered to the recipient.
   6.b. If the moderator has rejected the message, the Information Assistant deletes the message from the arbitration mailbox and notifies the sender that the message was rejected.

Note:
If the moderator doesn't respond to the message within five days, the Information Assistant will delete the message from the arbitration mailbox and notify the sender that their message has expired.

Handling Multiple Moderated Recipients

It's possible to send a message to a group of recipients that includes both moderated recipients and recipients that aren't moderated. In this case, a separate approval process occurs for each moderated recipient.

Consider a message that's sent to 12 recipients, one of which is a moderated distribution group. The categorizer splits this message into two messages. One message is delivered immediately to the 11 recipients that aren't moderated, and the second message is submitted to the approval process for the moderated distribution group.

If a message is intended for more than one moderated recipient, a separate copy is created for each moderated recipient and is submitted to the approval process.

A moderated distribution group may contain other moderated recipients. In this case, after the message to the distribution group is approved, a separate approval process occurs for each moderated recipient that's a member of the distribution group. However, you can also enable the automatic approval of the distribution group members after the message to the moderated distribution group is approved. To do this, you set the *BypassNestedModerationEnabled* parameter of the moderated distribution group to `$true`. For more parameter and syntax information, see Set-DistributionGroup.

Bypassing Moderation

Messages from moderators are delivered to the moderated recipient immediately, bypassing the approval process. By definition, a moderator has the authority to determine what messages are appropriate for a moderated recipient.

Moderation is also bypassed for owners of distribution groups and dynamic distribution groups. The owner of a distribution group can be responsible for managing the distribution group membership, but may not be able to moderate messages sent to it. For example, the account provisioning staff may be the owners of a distribution group called All Employees, but only specific people in human resources may have moderator rights for the same distribution group.

1.7.1.26 Understanding the Pickup and Replay Directories

Understanding the Pickup and Replay Directories

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

By default, the Pickup and Replay directories exist on every computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed. Correctly formatted e-mail message files that you copy to the Pickup or Replay directories are submitted for delivery. The Pickup directory is used by administrators for mail flow testing, or by applications that must create and submit their own messages. The Replay directory receives messages from foreign gateway servers and can also be used to resubmit messages that administrators export from the queues of Exchange 2010 servers.

Looking for management tasks related to Pickup and Relay directories? See Managing Connectors.

Contents

Anatomy of an E-Mail Message File

A standard SMTP e-mail message consists of a *message envelope* and message content. The message envelope contains information required for transmitting and delivering the message. The message content contains message header fields (collectively called the *message header*) and the message body. The message envelope is described in RFC 2821, and the message header is described in RFC 2822.

When a sender composes an e-mail message and submits it for delivery, the message contains the basic information required to comply with SMTP standards, such as a sender, a recipient, the date and time that the message was composed, an optional subject line, and an optional message body. This information is contained in the message itself and, by definition, is contained in the message header.

The sender's messaging server generates a message envelope for the message by using the sender and recipient information found in the message header and transmits the message to the Internet for delivery to the recipient's messaging server. Recipients never see the message envelope, because it's generated by the message transmission process and isn't actually part of the message.

Each server involved in the transmission of the message may insert message header fields related to the server's role in delivering the message or other application-specific message header fields into the message header. When the recipient opens the message by using an e-mail client, the e-mail client displays some of the more relevant information from the message header, such as the sender, the recipients, and the subject together with the message body.

Return to top

How the Pickup Directory Processes Messages

A correctly formatted .eml message file copied to the Pickup directory is processed for submission in the following steps:

1. The Pickup directory is checked for new message files every five seconds. You can't modify this polling interval. You can adjust the rate of message file processing by using the *PickupDirectoryMaxMessagesPerMinute* parameter on the **Set-TransportServer** cmdlet. The default value is 100 messages per minute. Files that can't be opened are left in the Pickup directory and are reevaluated at the next poll.

2. Limits put on message files in the Pickup directory, such as the maximum header size and the maximum number of recipients, are checked. By default, the maximum header size is 64 kilobytes (KB), and the maximum number of recipients is 100. You change these limits by using the **Set-TransportServer** cmdlet.
3. The file is renamed from *<filename>*.eml to *<filename>*.tmp. If the *<filename>*.tmp file already exists, the file is renamed as *<filename><datetime>*.tmp. If the file renaming fails, an event log error is generated, and the pickup process proceeds to the next file.
4. After the .tmp file is successfully converted into an e-mail message, a **delete on close** command is issued to the .tmp file. The .tmp file appears to remain in the Pickup directory, but the file can't be opened.
5. After the message is successfully queued for delivery, a **close** command is issued, and the .tmp file is deleted from the Pickup directory. If the deletion fails, an event log error is generated. If the Microsoft Exchange Transport service is restarted when there are .tmp files in the Pickup directory; all .tmp files are renamed as .eml files and are reprocessed. This could lead to duplicate message transmission.

Requirements for Message Files in the Pickup Directory

A message file copied to the Pickup directory must meet the following requirements for successful delivery:

- The message file must be a text file that complies with the basic SMTP message format. MIME message header fields and content are supported.
- The message file must have an .eml file name extension.
- At least one e-mail address must exist in the Sender or From message header fields in the message header. If a single e-mail address exists in both the Sender and From fields, the e-mail address in the From field is used as the originator of the message in the message envelope.
- Only one e-mail address can exist in the Sender field. Multiple e-mail addresses aren't allowed. The Sender field is optional if only one e-mail address exists in the From field.
- Multiple e-mail addresses are allowed in the From field, but a single e-mail address must also exist in the Sender field. The address in the Sender field is then used as the originator of the message in the message envelope.
- At least one e-mail address must exist in the To, Cc, or Bcc fields.
- A blank line must exist between the message header and the message body.

This example shows a plain text message that uses acceptable formatting for the Pickup directory.

```
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Message subject
This is the body of the message.
```

MIME content is also supported in Pickup directory message files. MIME defines a broad range of message content that includes languages that can't be represented in 7-bit ASCII text, HTML, and other multimedia content. A complete description of MIME and its requirements is beyond the scope of this topic. This example shows a simple MIME message that uses acceptable formatting for the Pickup directory.

```
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Message subject
MIME-Version: 1.0
Content-Type: text/html; charset="iso-8859-1"
Content-Transfer-Encoding: 7bit
<HTML><BODY>
<TABLE>
<TR><TD>cell 1</TD><TD>cell 2</TD></TR>
<TR><TD>cell 3</TD><TD>cell 4</TD></TR>
```

```
</TABLE>
</BODY></HTML>
```

Modifications to the Message Header That Are Made to Message Files in the Pickup Directory

The Pickup directory removes any of the following message header fields from the message header:

- `Received`
- `Resent-*`
- `Bcc`

Note:

Any e-mail addresses found in the optional Bcc message header fields in the message header are correctly processed. After the Bcc recipients are promoted to invisible message envelope recipients, they are removed from the message header to protect their identity. If a message contains only Bcc recipients, the value of **Undisclosed Recipients** is added to the To field in the message header.

The Pickup directory adds its own Received header field to a message as part of the message submission process. The Received header field is applied in the following format.

```
Received: from localhost by Pickup with Microsoft SMTP Server id <ExchangeServerV
```

The Pickup directory modifies the following message header fields if they're missing or malformed:

- **Message-Id** If the Message-Id field is missing or empty, the Pickup directory adds a Message-Id field by using the format *<GUID>*@*<defaultdomain>*.
- **Date** If the Date field is missing or malformed, the Pickup directory adds the date and time of message processing by the Pickup directory.

Failures in Pickup Directory Message Processing

A message file copied to the Pickup directory may not be successfully queued for delivery. The following categories of message submission failure can occur:

- **Delivery failures** A correctly formatted message file together with a valid sender that can't be successfully submitted for delivery by the Pickup directory generates a non-delivery report (NDR). Malformed content or Pickup directory message restriction violations could also cause the Pickup directory to generate an NDR. When an NDR is generated during Pickup directory message processing, the original message file is attached to the NDR message, and the message file is deleted from the Pickup directory.

  Note:

  A correctly formatted message submitted by the Pickup directory may later experience a delivery failure and be returned to the sender with an NDR. This kind of failure may be caused by transmission issues unrelated to the Pickup directory, such as messaging server failures or routing failures along the delivery path of the message.

- **Badmail** A message classified as *badmail* has serious problems that prevent the Pickup directory from submitting the message for delivery. The other condition that causes badmail is when the message is formatted correctly, but the recipients aren't valid, and an NDR message can't be sent to the sender because the sender isn't valid.
  Message files determined to be badmail are left in the Pickup directory and are renamed from *<filename>*.eml to *<filename>*.bad. If the *<filename>*.bad file already exists, the file is renamed to *<filename><datetime>*.bad. If badmail exists in the Pickup directory, an event log error is generated, but the same badmail messages don't generate repeated event log errors.

  Note:

Always compose and save message files in a different location before you copy them into the Pickup directory for delivery. The Pickup directory polls for new messages every five seconds. Therefore, if you try to compose and save the message files in the Pickup directory itself, the Pickup directory may try to process the message files before you finish composing them.

Return to top

How the Replay Directory Processes Messages

A correctly formatted .eml message file copied to the Replay directory is processed for submission in the following steps:

1. The Replay directory is checked for new message files every five seconds. You can't modify this polling interval. You can adjust the rate of message file processing by using the *PickupDirectoryMaxMessagesPerMinute* parameter on the **Set-TransportServer** cmdlet. The default value is 100 messages per minute. Files that can't be opened are left in the Replay directory and are reevaluated at the next poll.
2. The file is renamed from *<filename>*.eml to *<filename>*.tmp. If the *<filename>*.tmp file already exists, the file is renamed as *<filename><datetime>*.tmp. If the file renaming fails, an event log error is generated, and the Replay process proceeds to the next file.
3. After the .tmp file is successfully converted into an e-mail message, a **delete on close** command is issued to the .tmp file. The .tmp file appears to remain in the Replay directory, but the file can't be opened.
4. After the message is successfully queued for delivery, a **close** command is issued, and the .tmp file is deleted from the Replay directory. If the deletion fails, an event log error is generated. If the Microsoft Exchange Transport service is restarted when there are .tmp files in the Replay directory, all .tmp files are renamed as .eml files and are reprocessed. This could lead to duplicate message transmission.

Requirements for Message Files in the Replay Directory

The Replay directory is used to resubmit exported Exchange messages and to receive messages from foreign gateway servers. These messages are already formatted for the Replay directory. There is little or no need for an administrator or other application to compose and submit new message files by using the Replay directory. The Pickup directory should be used to create and submit new message files.

The Replay directory messages make extensive use of *X-Headers*. X-Headers are user-defined, unofficial message header fields that exist in the message header. X-Headers aren't specifically mentioned in RFC 2822, but the use of an undefined message header field starting with "X-" has become an accepted way to add unofficial message header fields to a message. The Exchange 2010-specific X-Headers used in the message files in the Replay directory can actually set delivery information that normally exists in the message envelope. This feature is required to preserve original message information when you use the Replay directory to process exported messages from another Exchange server.

A message file copied to the Replay directory must meet the following requirements for successful delivery:

- The message file must be a text file that complies with the basic SMTP message format. MIME message header fields and content are supported.
- The message file must have an .eml file name extension.
- X-Headers must occur before all regular header fields.
- A blank line must exist between the header fields and the message body.

The X-Headers described in the following list are required by messages in the Replay directory:

- **X-Sender** This X-Header replaces the From message header field requirement in a typical SMTP message. One X-Sender field that contains one e-mail address must exist. The Replay directory ignores the From message header field if it's present, although the recipient's e-mail client displays the value of the From message header field as the sender of the message. Other parameters usually exist in the X-Sender field, as shown in the following example.

```
X-Sender: <bob@fabrikam.com> BODY=7bit RET=HDRS ENVID=12345ABCD auth=<s
```

Note:

These parameters are message envelope values that are ordinarily generated by the sending server. You may see parameters similar to this in exported message files.
RET specifies whether the whole message or only the headers should be returned to the sender if the message can't be delivered. RET can have a value of HDRS or FULL. ENVID is a message envelope identifier. BODY specifies the text encoding of the message. auth specifies an authentication mechanism to the messaging server as described in RFC 2554.

- **X-Receiver** This X-Header replaces the To message header field requirement in a typical SMTP message. At least one X-Receiver field that contains one e-mail address must exist. Multiple X-Receiver fields are allowed for multiple recipients. The Replay directory ignores the To message header fields if they're present, although the recipient's e-mail client displays the values of the To message header fields as the recipients of the message. Other optional parameters may exist in the X-Receiver fields, as shown in the following example.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER ORcpt=mary@contoso.com
```

Note:

These parameters are message envelope values that are ordinarily generated by the sending server. You may see parameters similar to this in exported message files. These parameters are related to delivery status notification (DSN) messages as described in RFC 1891.
NOTIFY can have a value of NEVER, DELAY, or FAILURE. ORcpt preserves the original recipient of the message.

The X-Headers described in the following list are optional for message files in the Replay directory:

- **X-CreatedBy** Used for header firewall functionality. If this X-Header exists, it must not be blank. If the X-CreatedBy field doesn't exist, it's added with a value of Unspecified. Typically, the value of this field is MSExchange14, but it also may contain the non-SMTP address space type set on a Send connector, such as Notes.
- **X-EndOfInjectedXHeaders** Size in bytes of all the X-Headers present. This X-Header may be used as a marker to indicate the last X-Header before the regular message header fields start.
- **X-ExtendedMessageProps** Extended message properties for the message.
- **X-HeloDomain** HELO/EHLO domain string presented during the initial SMTP protocol conversation.
- **X-LegacyExch50** Used to preserve custom properties generated by Exchange Server 2003 if Exchange 2003 servers are present.
- **X-Source** Used by Queue Viewer under the **MessageSourceName** column. If

the value of this X-Header isn't specified, the value of `Replay` is used. Other possible values for this X-Header are `Smtp Receive Connector` and `Smtp Send Connector`.

- **X-SourceIPAddress** IP address of the sending server. This field is 0.0.0.0 if no IP address is specified.

This example shows a plain text message that uses acceptable formatting for the Replay directory.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER ORcpt=mary@contoso.com
X-Sender: <bob@fabrikam.com> BODY=7bit ENVID=12345AB auth=<someAuth>
Subject: Optional message subject
This is the body of the message.
```

MIME content is also supported in Replay directory message files. MIME defines a broad range of message content that includes languages that can't be represented in 7-bit ASCII text, HTML, and other multimedia content. A complete description of MIME and its requirements is beyond the scope of this topic. This example shows a simple MIME message that uses acceptable formatting for the Replay directory.

```
X-Receiver: <mary@contoso.com> NOTIFY=NEVER ORcpt=mary@contoso.com
X-Sender: <bob@fabrikam.com> BODY=7bit ENVID=12345ABCD auth=<someAuth>
To: mary@contoso.com
From: bob@fabrikam.com
Subject: Optional message subject
MIME-Version: 1.0
Content-Type: text/html; charset="iso-8859-1"
Content-Transfer-Encoding: 7bit
<HTML><BODY>
<TABLE>
<TR><TD>cell 1</TD><TD>cell 2</TD></TR>
<TR><TD>cell 3</TD><TD>cell 4</TD></TR>
</TABLE>
</BODY></HTML>
```

Modifications to the Message Header That Are Made to Message Files in the Replay Directory

The Replay directory deletes the Bcc message header field from the message file.

The Replay directory adds its own Received message header field to a message as part of the message submission process. The Received message header field is applied in the following format.

```
Received: from <ReceivingServerName> by Replay with <ExchangeServerVersion><DateT
```

The Replay directory modifies the following message header fields in the message header:

- **Message-ID** If this message header field is missing or empty, the Replay directory adds a Message-ID message header field by using the format *<GUID>*@*<defaultdomain>*.
- **Date** If this message header field is missing or malformed, the Replay directory adds the Date message header field using the date and time of message processing by the Replay directory.

Failures in Replay Directory Message Processing

Any problems converting a message file into an e-mail message causes the Replay directory to consider the message undeliverable (badmail). A badmail message file has serious problems, such as a missing sender, missing recipients, or formatting problems. Message files determined to be badmail are left in the Replay directory and are renamed from *<filename>*.eml to *<filename>*.bad. If the *<filename>*.bad file already exists, the file is renamed to *<filename><datetime>*.bad. If badmail exists in the Replay directory, an event log error is generated, but the same badmail messages don't generate repeated event log errors.

Return to top

Security Considerations for the Pickup and Replay Directories

The following list describes security concerns that are common to the Pickup directory and the Replay directory:

- Any security checks configured on a Receive connector, such as anti-spam, antivirus, sender filtering, or recipient filtering actions, aren't performed on messages submitted through the Pickup directory or the Replay directory.
- A compromised Pickup directory or Replay directory can act as an open relay. This enables messages to be resubmitted or *relayed* by using a different server to mask the true source of the messages.

The following list describes additional security concerns that apply to the Replay directory:

- The X-Headers used by the Replay directory allow for the manual creation of the message envelope. The information in the X-Sender and X-Receiver fields can be completely different from the To or From message header fields displayed by e-mail clients. Such an impersonation of a sender and a domain is frequently called *spoofing*. A *spoofed mail* is an e-mail message that has a sending address that was modified to appear as if it originates from a sender other than the actual sender of the message.
- If the X-CreatedBy field has the value of `MSExchange14`, the destination is considered trustworthy, and a header firewall isn't applied. A header firewall is a way for Exchange to preserve X-Headers in messages transmitted between trusted Exchange 2010 servers or to remove potentially revealing X-Headers from messages transmitted to untrusted destinations outside the Exchange organization. These X-Headers can be used to share Exchange 2010 information such as spam confidence level (SCL), message signing, or encryption between authorized Exchange 2010 servers. Revealing this information to unauthorized sources could pose a potential security risk.

Tighter security should be applied to the Replay directory because of the additional security risks associated with the Replay directory. Users or applications that must generate and submit messages can be granted access to the Pickup directory, but they shouldn't require access to the Replay directory.

Both the Pickup directory and the Replay directory are enabled by default on all Hub Transport servers and Edge Transport servers. If the Pickup directory or the Replay directory isn't required on a specific Hub Transport server or Edge Transport server in your organization, you can disable the Pickup directory or the Replay directory on that server. For more information, see the following topics:

- Configure the Pickup Directory
- Configure the Replay Directory

Return to top

Permissions for the Pickup and Replay Directories

The following permissions are required on the Pickup and Replay directories:

- Administrator: Full Control
- System: Full Control
- Network Service: Read, Write, and Delete Subfolders and Files

By default, the Microsoft Exchange Transport service uses the security credentials of the Network Service user account to manage the location and permissions of the Pickup and Replay directories. The Network Service account requires these permissions on the Pickup directory so that .eml files can be opened, renamed to .tmp and deleted, or renamed to .bad if the message is classified as badmail.

You can move the location of these directories by using the *PickupDirectoryPath* and *ReplayDirectoryPath* parameters on the **Set-TransportServer** cmdlet. Successfully changing the location of the Pickup directory depends on the rights granted to the Network Service account at the new directory locations, and whether the new directories already exist. If the directory doesn't exist, and the Network Service account has the rights required to create folders and apply permissions at the new location, the directory is created, and the correct permissions are applied to it. If the new directory already exists, the existing folder permissions aren't checked. Whenever you move the directory locations by using the *PickupDirectoryPath* or *ReplayDirectoryPath* parameter with the **Set-TransportServer** cmdlet, always verify that the new directory exists and that the new directory has the correct permissions applied to it.

Return to top

1.7.1.27 Understanding Priority Queuing

Understanding Priority Queuing

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-25*

Priority queuing is a feature of Microsoft Exchange Server 2010 that enables the sender-defined priority of a message to influence the processing of the message by a server running Exchange that has the Hub Transport server role installed.

The message priority is assigned by the sender in Microsoft Outlook when the sender creates and sends the message. The sender can set any of the following message priority values in Outlook:

- Low importance
- Normal importance
- High importance

The default priority for a message created in Outlook or Microsoft Office Outlook Web App is Normal priority. The message priority is stored in the `X-Priority` header field in the message header.

Every message sent or received in an Exchange 2010 organization must be categorized on a Hub Transport server before it can be routed and delivered. The categorizer on a Hub Transport server picks up one message at a time from the Submission queue and performs recipient resolution, routing resolution, and content conversion on the message before putting the message in a delivery queue. For more information, see Understanding Transport Pipeline.

Delivery queues are dynamically created based on the destination of a message. Mailbox delivery queues are created for messages destined for Mailbox servers that exist in the same Active Directory site as the Hub Transport server. Remote delivery queues are created for messages destined for Mailbox servers that exist in a different Active Directory site than the Hub Transport server, and for remote domains. For more information, see

Understanding Transport Queues.

All messages that have the same destination are put in the same delivery queue. Priority queuing affects the transmission of messages from a delivery queue to the destination messaging server. When priority queuing is enabled, High priority messages are transmitted to their destinations before Normal priority messages, and Normal priority messages are transmitted to their destinations before Low priority messages. The prioritized delivery of messages based on the message priority can help you define specific service level agreement (SLA) requirements for message delivery times.

Options for Configuring Priority Queuing

All configuration options for priority queuing are available in the EdgeTransport.exe.config application configuration file located in the C:\Program Files\Microsoft\Exchange Server \V14\Bin directory. For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File. Many configuration options available are unrelated to priority queuing. Any configuration options that don't involve back pressure are outside the scope of this topic.

Enabling or Disabling Priority Queuing

The *PriorityQueuingEnable* parameter enables or disables priority queuing on a Hub Transport server. The default value is `False`. To enable priority queuing, set the *PriorityQueuingEnable* parameter value to `True` in the EdgeTransport.exe.config file and restart the Microsoft Exchange Transport service.

Configuring the Maximum Size of a High Priority Message

The *MaxHighPriorityMessageSize* parameter controls the maximum allowed size of a High priority message. The default value is 250 kilobytes (KB). If a High priority message is larger than the value of the *MaxHighPriorityMessageSize* parameter, the message is automatically downgraded from High priority to Normal priority.

When you enter a value, qualify the value with one of the following units:

- KB (kilobytes)
- MB (megabytes)
- GB (gigabytes)

The value of the *MaxHighPriorityMessageSize* parameter should be significantly less than the value of the *MaxMessageSize* parameter on the **Set-TransportConfig** cmdlet. The default value of the *MaxMessageSize* parameter is 10 MB. A smaller value in the *MaxHighPriorityMessageSize* parameter helps ensure consistent and predictable delivery times for High priority messages.

Configuring the Delay Notification Time-Out Based on the Message Priority

After each message delivery failure, the Hub Transport server generates a delay delivery status notification (DSN) message and queues it for delivery to the sender of the undeliverable message. This delay DSN message is sent only after a specified delay notification time-out interval, and only if the failed message wasn't successfully delivered during that time. This delay prevents the sending of unnecessary delay DSN messages that may be caused by temporary message transmission failures.

The following table shows the delay DSN notification time-out options based on the message priority.

Delay DSN notification time-out options based on the message priority

Parameter name	Default value

LowPriorityDelayNotificationTimeout	8:00:00 (8 hours)
NormalPriorityDelayNotificationTimeout	4:00:00 (4 hours)
HighPriorityDelayNotificationTimeout	00:30:00 (30 minutes)

To specify a value for a delay notification time-out, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. If the value is less than 1 day, you can omit the day part of the time span.

Configuring the Message Expiration Time-Out Based on the Message Priority

The *message expiration time-out* specifies the maximum length of time that a Hub Transport server tries to deliver a failed message. If the message can't be successfully delivered before the expiration time-out interval has passed, a non-delivery report (NDR) that contains the original message or the message headers is delivered to the sender.

The following table shows the message expiration time-out options based on the message priority.

Message expiration time-out options based on the message priority

Parameter name	Default value
LowPriorityMessageExpirationTimeout	2.00:00:00 (2 days)
NormalPriorityMessageExpirationTimeout	2.00:00:00 (2 days)
HighPriorityMessageExpirationTimeout	8:00:00 (8 hours)

To specify a value for a message expiration time-out, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. If the value is less than 1 day, you can omit the day part of the time span.

Configuring the Maximum Number of Connections Per Domain Based on the Message Priority

The maximum number of connections per domain specifies the maximum number of connections that a Hub Transport server can have open to any single remote domain. The outgoing connections to remote domains occur by using the remote delivery queues and Send connectors that exist on the Hub Transport server.

The following table shows the maximum number of connections per domain options based on the message priority.

Maximum number of connections per domain options based on the message priority

Parameter name	Default value
MaxPerDomainLowPriorityConnections	2
MaxPerDomainNormalPriorityConnections	15
MaxPerDomainHighPriorityConnections	3

The sum of the *MaxPerDomainLowPriorityConnections* parameter, the *MaxPerDomainNormalPriorityConnections* parameter, and the *MaxPerDomainNormalPriorityConnections* parameter should be less than or equal to the value of the *MaxPerDomainOutboundConnections* parameter on the **Set-TransportServer**

cmdlet. The default value of the *MaxPerDomainOutboundConnections* parameter is 20.

How Priority Queuing Affects Other Message Limits on Hub Transport Servers

All messages that pass through a Hub Transport server are subject to a variety of message retry, resubmit, and expiration limits. For more information, see Understanding Transport Queues.

Some message limits available in the **Set-TransportServer** cmdlet have corresponding priority queuing message limits available in the EdgeTransport.exe.config configuration file. The following table shows these corresponding message limits.

Message limits in the Set-TransportServer cmdlet that correspond to priority queuing message limits in the EdgeTransport.exe.config configuration file

Source	Parameter	Default value
Set-TransportServer	*DelayNotificationTimeOut*	4:00:00 (4 hours)
EdgeTransport.exe.config	*NormalPriorityDelayNotificationTimeout*	4:00:00 (4 hours)
Set-TransportServer	*MessageExpirationTimeOut*	2.00:00:00 (2 days)
EdgeTransport.exe.config	*NormalPriorityMessageExpirationTimeout*	2.00:00:00 (2 days)

When priority queuing is disabled, all the priority queuing message limits that exist in the EdgeTransport.exe.config configuration file are ignored. All the message limits on the **Set-TransportServer** cmdlet apply to all messages that travel through the Hub Transport server.

When priority queuing is enabled, the priority queuing message limits in the EdgeTransport.exe.config configuration file override the corresponding message limits in the **Set-TransportServer** cmdlet. All other message limits in the **Set-TransportServer** cmdlet still apply to Low priority, Normal priority, and High priority messages that travel through the Hub Transport server.

User Settings for Priority Queuing

The **Set-Mailbox** cmdlet in the Exchange Management Shell has the *DowngradeHighPriorityMessagesEnabled* parameter. The default value is `False`. When this parameter is set to `True`, any High priority messages sent from the mailbox are automatically downgraded to Normal priority. For more information, see Set-Mailbox.

1.7.1.28 Understanding Receive Connectors

Understanding Receive Connectors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Receive connectors are configured on computers that are running Microsoft Exchange Server 2010 and that have the Hub Transport server role or Edge Transport server role installed. Receive connectors represent a logical gateway through which all inbound messages are received. This topic provides an overview of Receive connectors and how the configuration of Receive connectors affects individual message processing.

Overview of Receive Connectors

Exchange 2010 transport servers require Receive connectors to receive messages from the Internet, from e-mail clients, and from other e-mail servers. A Receive connector controls inbound connections to the Exchange organization. By default, the Receive connectors that are required for internal mail flow are automatically created when the Hub Transport server role is installed. The Receive connector that's capable of receiving mail from the Internet and from Hub Transport servers is automatically created when the Edge Transport server role is installed. However, end-to-end mail flow is possible only after the Edge Transport server has been subscribed to the Active Directory site by using the Edge Subscription process. Other scenarios, such as an Internet-facing Hub Transport server or an unsubscribed Edge Transport server, require manual connector configuration to establish end-to-end mail flow.

In Exchange 2010, the Receive connector is a *receive listener*. This means that the connector is listening for inbound connections that match the settings of the Receive connector. A Receive connector listens for connections that are received through a particular local IP address and port, and from a specified IP address range. You create Receive connectors when you want to control which servers receive messages from a particular IP address or IP address range, and when you want to configure special connector properties for messages that are received from a particular IP address, such as a larger message size, more recipients per message, or more inbound connections.

Receive connectors are scoped to a single server and determine how that specific server listens for connections. When you create a Receive connector on a Hub Transport server, the Receive connector is stored in Active Directory as a child object of the server on which it's created. When you create a Receive connector on an Edge Transport server, the Receive connector is stored in Active Directory Lightweight Directory Services (AD LDS).

If you need additional Receive connectors for specific scenarios, you can create them by using the Exchange Management Console (EMC) or the Exchange Management Shell. Each Receive connector must use a unique combination of IP address bindings, port number assignments, and the remote IP address ranges from which mail will be accepted by this connector.

Default Receive Connectors Created During Setup

Certain Receive connectors are created by default when you install a Hub Transport or Edge Transport server role.

Default Receive Connectors Created on a Hub Transport Server

When you install the Hub Transport server role, two Receive connectors are created. No additional Receive connectors are needed for typical operation, and in most cases the default Receive connectors don't require a configuration change. The usage type and configuration of these connectors are described in the following table.

Default Receive connector configuration on Hub Transport servers

Connector name and usage type	Configuration

Client Servername This Receive connector accepts SMTP connections from all non-MAPI clients, such as POP and IMAP.	• Status: Enabled. • Protocol logging level: None. • Connector fully qualified domain name (FQDN): *Servername.forestroot.extension* • Bindings: All available IP addresses. The server accepts mail received through any network adapter on the Hub Transport server. • Port: 587. This is the default port for receiving messages from all non-MAPI clients for SMTP relay. • Remote server IP address range: 0.0.0.0–255.255.255.255 IPv4 and 0000:0000:0000:0000:0000:0000:0.0.0.0–ffff:ffff:ffff:ffff:ffff:ffff:255.255.255.255 IPv6. The Hub Transport server accepts mail that's sent from any IP address. • Available authentication methods: Transport Layer Security (TLS), Basic authentication, Exchange Server authentication, Integrated Windows authentication. • Permission groups: Exchange users.
Default Servername This Receive connector accepts connections from other Hub Transport servers and any Edge Transport servers you have.	• Status: Enabled. • Protocol logging level: None. • Connector FQDN: *Servername.forestroot.extension* • Local server Receive connector bindings: All available IP addresses. The server accepts mail received through any network adapter on the Hub Transport server. • Port: 25. • Remote server IP address range: 0.0.0.0–255.255.255.255 IPv4 and 0000:0000:0000:0000:0000:0000:0.0.0.0–ffff:ffff:ffff:ffff:ffff:ffff:255.255.255.255 IPv6.. The Hub Transport server accepts mail that's sent from any IP address. • Available authentication methods: TLS, Basic authentication, Integrated Windows authentication. • Permission groups: Exchange users, Exchange servers, Legacy Exchange servers.

Note:

Any Receive connector that's responsible for accepting connections from Edge Transport servers or other Hub Transport servers must have the Exchange Server authentication method assigned to it. The Exchange Server authentication method is the default authentication method when you create a Receive connector that has the Internal usage type.

Default Receive Connector Created on an Edge Transport Server

During installation, one Receive connector is created. This Receive connector is configured

to accept SMTP communications from all IP address ranges and is bound to all IP addresses of the local server. It's configured to have the Internet usage type, and therefore, the connector accepts anonymous connections. In a typical installation, no additional Receive connectors are required. If you use EdgeSync, you don't need to make any configuration changes because the Edge Subscription process automatically configures permissions and authentication mechanisms. Anonymous sessions and authenticated sessions are granted different permission sets.

If you don't use EdgeSync, we recommend that you modify the settings of this Receive connector and create an additional Receive connector of the Internal usage type. To complete Receive connector configuration, follow these steps:

1. **Modify the settings of the default Receive connector** Set the local network bindings to the IP address of only the Internet-facing network adapter.
2. **Create a Receive connector** Select Internal as the connector usage type. Set the local network bindings to the IP address of only the organization-facing network adapter. Configure the remote network settings to receive mail from the remote IP addresses that are assigned to the Hub Transport servers.

   Note:

   Any Receive connector that's responsible for accepting connections from Edge Transport servers or other Hub Transport servers must have the Exchange Server authentication method assigned to it. The Exchange Server authentication method is the default authentication method when you create a Receive connector that has the Internal usage type.

3. **Determine whether Basic authentication is desired** If you want to support Basic authentication, create a local user account and grant the necessary permissions by using the Add-ADPermission cmdlet.

For more information, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync.

Receive Connector Usage Types

The usage type determines the default security settings for the connector.

The security settings for a Receive connector specify the permissions that are granted to sessions that connect to the Receive connector and the supported authentication mechanisms.

When you use the EMC to configure a Receive connector, the New SMTP Receive Connector wizard prompts you to select the usage type for the connector. You can use two different methods to specify the usage type:

- Use the *Usage* parameter with the desired value, such as *Usage* `Custom`. There are other required parameters based on the usage type that you specify. If you don't specify the required parameters in the **New-ReceiveConnector** command, the command will fail.
- Use the switch parameter for the desired usage type, such as *Custom*. There are other required parameters based on the usage type that you specify. If you don't specify the required parameters in the **New-ReceiveConnector** command, you're prompted for the missing parameter values so the command can continue.

Permission Groups

A permission group is a predefined set of permissions that's granted to well-known security principals and assigned to a Receive connector. Security principals include users, computers, and security groups. A security principal is identified by a security identifier (SID). Permission groups are only available for Receive connectors. The use of permission groups simplifies the configuration of permissions on Receive connectors. The

PermissionGroups property defines the groups or roles that can submit messages to the Receive connector and the permissions that are assigned to those groups. The set of permission groups is predefined in Exchange 2010. This means that you can't create additional permission groups. Also, you can't modify the permission group members or the associated permissions.

The following table lists the available permission groups and identifies the security principals and the permissions that are granted when that permission group is configured for a Receive connector.

Receive connector permission groups

Permission group name	Associated security principals (SIDs)	Permissions granted
Anonymous	Anonymous user account	• Ms-Exch-SMTP-Submit • Ms-Exch-SMTP-Accept-Any-Sender • Ms-Exch-SMTP-Accept-Authoritative-Domain-Sender • Ms-Exch-Accept-Headers-Routing
ExchangeUsers	Authenticated user accounts	• Ms-Exch-SMTP-Submit • Ms-Exch-SMTP-Accept-Any-Recipient • Ms-Exch-Bypass-Anti-Spam • Ms-Exch-Accept-Headers-Routing
ExchangeServers	• Hub Transport servers • Edge Transport servers • Exchange Servers (Hub Transport server only) • Externally Secured servers	• Ms-Exch-SMTP-Submit • Ms-Exch-SMTP-Accept-Any-Sender • Ms-Exch-SMTP-Accept-Any-Recipient • Ms-Exch-Accept-Authoritative-Domain-Sender • Ms-Exch-Bypass-Anti-Spam • Ms-Exch-SMTP-Accept-Authentication-Flag • Ms-Exch-Bypass-Message-Size-Limit • Ms-Exch-Accept-Headers-Routing • Ms-Exch-Accept-Exch50 • Ms-Exch-Accept-Headers-Organization **Note:** This permission isn't granted to Externally Secured servers. • Ms-Exch-Accept-Headers-Forest **Note:** This permission isn't

		granted to Externally Secured servers.
ExchangeLegacyServers	Exchange Legacy Interop security group	• Ms-Exch-SMTP-Submit • Ms-Exch-SMTP-Accept-Any-Sender • Ms-Exch-SMTP-Accept-Any-Recipient • Ms-Exch-Accept-Authoritative-Domain-Sender • Ms-Exch-Bypass-Anti-Spam • Ms-Exch-SMTP-Accept-Authentication-Flag • Ms-Exch-Bypass-Message-Size-Limit • Ms-Exch-Accept-Headers-Routing • Ms-Exch-Accept-Exch50
Partner	Partner Server account	• Ms-Exch-SMTP-Submit • Ms-Exch-Accept-Headers-Routing

Receive Connector Usage Types

The usage type determines the default permission groups that are assigned to the Receive connector and the default authentication mechanisms that are available for session authentication. A Receive connector always responds to a request from a sender to use TLS. The following table describes the available usage types and default settings.

Receive connector usage types

Usage type	Default permission groups	Default authentication mechanism
Client (unavailable on Edge Transport servers)	ExchangeUsers	TLS Basic authentication plus TLS Integrated Windows authentication
Custom	None	None
Internal	ExchangeServers ExchangeLegacyServers (This permission group is unavailable on Edge Transport servers.)	Exchange Server authentication
Internet	AnonymousUsers Partner	None or Externally Secured
Partner	Partner	Not applicable. This usage type is selected when you establish mutual TLS with a remote domain.

The Receive connector permissions and authentication mechanisms are discussed later in this topic.

Receive Connector Usage Scenarios

Each usage type is appropriate for a specific connection scenario. Select the usage type that has the default settings most applicable to the configuration that you want. You can modify permissions by using the **Add-ADPermission** and **Remove-ADPermission** cmdlets. For more information, see the following topics:

- Add-ADPermission
- Remove-ADPermission

The following table lists common connection scenarios and the usage type for each scenario.

Receive Connector usage scenarios

Connector scenario	Usage type	Comment
Edge Transport server receiving e-mail from the Internet	Internet	A Receive connector that's configured to accept e-mail from all domains is created automatically when the Edge Transport server role is installed.
Hub Transport server receiving e-mail from the Internet	Internet	This isn't a recommended configuration. For more information, see Configure Internet Mail Flow Directly Through a Hub Transport Server.
Edge Transport server receiving e-mail from an Exchange Server 2003 bridgehead server	Internal	In this scenario, the Exchange 2003 bridgehead server is configured to use the Edge Transport server as a smart host for a Send connector.
Hub Transport server receiving e-mail submissions from a client application that uses POP3 or IMAP4	Client	This Receive connector is automatically created on every Hub Transport server when the role is installed. By default, this Receive connector is configured to receive e-mail through TCP port 587.
Hub Transport server receiving e-mail from a Hub Transport server	Internal	You don't have to configure Receive connectors between Hub Transport servers within the same organization. This usage type can be used to configure a cross-forest Receive connector.
Hub Transport server receiving e-mail from an Exchange 2003 bridgehead server in the same forest	Internal	This is an optional configuration. Transport between Exchange 2010 and earlier versions of Exchange is accomplished through two-way routing group connectors. If you create SMTP connectors to Exchange 2003 routing groups, a routing group connector must also exist. For more information, see Create Additional Routing Group Connectors from Exchange 2010 to Exchange 2003.
Edge Transport server	Internal	A Receive connector that's configured

receiving e-mail from a Hub Transport server		to accept e-mail from all domains is created automatically when the Edge Transport server role is installed. You can create another connector and configure it to receive e-mail only from the Exchange organization.
Cross-forest Receive connector for a Hub Transport server in one forest receiving e-mail from a Hub Transport server in a second forest	Custom	For detailed configuration steps, see Configure Cross-Forest Connectors.
Cross-forest Receive connector for a Hub Transport server in one forest receiving e-mail from an Exchange 2003 bridgehead server in a second forest	Custom	For detailed configuration steps, see Configure Cross-Forest Connectors.
Hub Transport server receiving e-mail from a third-party message transfer agent (MTA)	Internal	Specify the IP address range from which messages will be accepted and set the authentication mechanism to either Basic authentication or Externally Secured.
Edge Transport server receiving e-mail from a third-party MTA	Custom	Use the **Add-ADPermission** cmdlet to set the extended rights. Specify the IP address range from which messages will be accepted and set the authentication mechanism to Basic authentication. You can also select the Internal usage type and set Externally Secured as the authentication method. No additional permissions configuration is required if you select this option.
Edge Transport server receiving e-mail from an external relay domain	Custom	The Edge Transport server can accept e-mail from an external relay domain and then relay to the destination recipient domain. Specify the IP address range from which messages will be accepted, set the appropriate authentication mechanism, and use the **Add-ADPermission** cmdlet to set the extended rights.
Edge Transport server receiving e-mail from a domain to which you have established mutual TLS authentication	Partner	Mutual TLS authentication functions correctly only if the following conditions are true: • The value of the *DomainSecureEnabled* parameter is set to `$true`. • The value of the *AuthMechanism* parameter contains `TLS` and doesn't contain `External`.

		• The *TLSReceiveDomainSecureList* parameter in the Transport configuration contains at least one domain that's serviced by this Receive connector. The wildcard character (*) isn't supported in domains that are configured for mutual TLS authentication. The same domain must also be defined on the corresponding Send connector, and in the value of the *TLSSendDomainSecureList* parameter in the Transport configuration. For more information, see Set-ReceiveConnector.
Edge Transport server receiving connections from Microsoft Exchange Hosted Services server	Custom	The Exchange Hosted Services server can act as an externally authoritative server. To use the Externally Secured authentication mechanism, use the **Set-ReceiveConnector** cmdlet to set the *PermissionGroup* parameter to `ExchangeServers`.
Hub Transport server receiving connections from an Exchange Hosted Services server	Custom	The Exchange Hosted Services server can act as an externally authoritative server. To use the Externally Secured authentication mechanism, use the **Set-ReceiveConnector** cmdlet to set the *PermissionGroup* parameter to `ExchangeServers`.

Receive Connector Permissions

Receive connector permissions are assigned to security principals when you specify the permission groups for the connector. When a security principal establishes a session with a Receive connector, the Receive connector permissions determine whether the session is accepted and how the received messages are processed. The following table describes the permissions that can be assigned on a Receive connector to security principals. You can set Receive connector permissions by using the EMC or by using the *PermissionGroups* parameter with the **Set-ReceiveConnector** cmdlet in the Shell. To modify the default permissions for a Receive connector, you can also use the **Add-ADPermission** cmdlet.

Receive connector permissions

Receive connector permission	Description
ms-Exch-SMTP-Submit	The session must be granted this permission or it will be unable to submit messages to this Receive connector. If a session doesn't have this permission, the MAIL FROM and AUTH commands will fail.

ms-Exch-SMTP-Accept-Any-Recipient	This permission allows the session to relay messages through this connector. If this permission isn't granted, only messages that are addressed to recipients in accepted domains are accepted by this connector.
ms-Exch-SMTP-Accept-Any-Sender	This permission allows the session to bypass the sender address spoofing check.
ms-Exch-SMTP-Accept-Authoritative-Domain-Sender	This permission allows senders that have e-mail addresses in authoritative domains to establish a session to this Receive connector.
ms-Exch-SMTP-Accept-Authentication-Flag	This permission allows Exchange 2003 servers to submit messages from internal senders. Exchange 2010 will recognize the messages as being internal. The sender can declare the message as trusted. Messages that enter your Exchange system through anonymous submissions will be relayed through your Exchange organization with this flag in an untrusted state.
ms-Exch-Accept-Headers-Routing	This permission allows the session to submit a message that has all received headers intact. If this permission isn't granted, the server will strip all received headers.
ms-Exch-Accept-Headers-Organization	This permission allows the session to submit a message that has all organization headers intact. Organization headers all start with **X-MS-Exchange-Organization-**. If this permission isn't granted, the receiving server will strip all organization headers.
ms-Exch-Accept-Headers-Forest	This permission allows the session to submit a message that has all forest headers intact. Forest headers all start with **X-MS-Exchange-Forest-**. If this permission isn't granted, the receiving server will strip all forest headers.
ms-Exch-Accept-Exch50	This permission allows the session to submit a message that contains the XEXCH50 command. This command is needed for interoperability with Exchange 2003. The XEXCH50 command provides data such as the spam confidence level (SCL) for the message.
ms-Exch-Bypass-Message-Size-Limit	This permission allows the session to submit a message that exceeds the message size restriction configured for the connector.
Ms-Exch-Bypass-Anti-Spam	This permission allows the session to bypass anti-spam filtering.

Local Network Settings

In the EMC, you use the local network settings for a Receive connector to specify the IP address and port through which the transport server accepts connections. In the Shell, use the *Bindings* parameter to specify the local IP address and port of the transport server through which the Receive connector accepts connections. These settings bind the Receive connector to a particular network adapter and TCP port on the transport server.

By default, a Receive connector is configured to use all available network adapters and TCP port 25. If a transport server has multiple network adapters, you may want a Receive connector to be bound to a particular network adapter, or to accept connections through an alternative port. For example, you may want to configure one Receive connector on the Edge Transport server to accept anonymous connections through the external network adapter. A second Receive connector can be configured to accept connections from only Hub Transport servers through the internal network adapter.

Note:

If you choose to bind a Receive connector to a specific local IP address, that IP address must be valid for the Hub Transport server or Edge Transport server on which the Receive connector is located. If you specify an invalid local IP address, the Microsoft Exchange Transport service may fail to start when the service is restarted. Instead of binding the Receive connector to a specific IP address, you can bind the Receive connector to all available IP addresses on the Hub Transport server or Edge Transport server.

Specify the IP address of the network adapter when you configure Receive connector bindings. If the Receive connector is configured to accept connections through a port other than the default, the sending client or server must be configured to send to that port and any firewalls between the message sender and the receiving server must allow network traffic through that port.

The **Local Network Settings** page of the New SMTP Receive Connector wizard in the EMC includes an option to **Specify the FQDN this connector will provide in response to HELO or EHLO**. In the Shell, this property is set by using the *Fqdn* parameter with the **Set-ReceiveConnector** cmdlet. After an SMTP session is established, an SMTP protocol conversation starts between a sending e-mail server and a receiving e-mail server. The sending e-mail server or client sends the EHLO or HELO SMTP command and its FQDN to the receiving server. In response, the receiving server sends a success code and provides its own FQDN. In Exchange 2010, you can customize the FQDN that's provided by the receiving server if you configure this property on a Receive connector. The FQDN value is displayed to connected messaging servers whenever a destination server name is required, as in the following examples:

- In the default SMTP banner of the Receive connector
- In the most recent `Received:` header field in the incoming message when the message enters the Hub Transport server or Edge Transport server
- During TLS authentication

Note:

Don’t modify the FQDN value on the default Receive connector named Default *<Server Name>* that's automatically created on Hub Transport servers. If you have multiple Hub Transport servers in your Exchange organization and you change the FQDN value on the Default *<Server Name>* Receive connector, internal mail flow between Hub Transport servers will fail.

Remote Network Settings

In the EMC, you use the remote network settings for a Receive connector to specify the IP address ranges from which this Receive connector accepts connections. In the Shell, you use the *RemoteIPRanges* parameter to specify the IP address ranges from which this Receive connector accepts connections. By default, Receive connectors are created on Hub Transport servers and Edge Transport servers that allow connections from 0.0.0.0–255.255.255.255, or from every IP address.

Note:
In Exchange 2010 , the IPv6 address range 0000:0000:0000:0000:0000:0000:0.0.0.0–ffff:ffff:ffff:ffff:ffff:ffff:255.255.255.255 also exists in the default Receive connectors on a Hub Transport server.

If you're configuring a Receive connector for a specific scenario, set the remote network settings to only the IP addresses of the servers that should be allowed the permissions and configuration settings for the Receive connector. Multiple Receive connectors can have overlapping remote IP address ranges as long as one range is completely overlapped by another. When remote IP address ranges overlap, the remote IP address range that has the most specific match to the connecting server's IP address is used.

The IP address or IP address range for the remote servers from which the Receive connector will accept inbound connections is entered in one of the following formats:

- **IP address** 192.168.1.1
- **IP address range** 192.168.1.10-192.168.1.20
- **IP address together with subnet mask** 192.168.1.0(255.255.255.0)
- **IP address together with subnet mask by using Classless Interdomain Routing (CIDR) notation** 192.168.1.0/24

Receive Connector Authentication Settings

In the EMC, you use the authentication settings for a Receive connector to specify the authentication mechanisms that are supported by the Exchange 2010 transport server. In the Shell, you use the *AuthMechanisms* parameter to specify the supported authentication mechanisms. You can configure more than one authentication mechanism for a Receive connector. For the authentication mechanisms that are automatically configured for each usage type, see the table labeled "Receive connector usage types" earlier in this topic. The following table lists the available authentication mechanisms for a Receive connector.

Receive connector authentication mechanisms

Authentication mechanism	Description
None	No authentication.
TLS	Advertise STARTTLS. Requires availability of a server certificate to offer TLS.
Integrated	NTLM and Kerberos (Integrated Windows authentication).
BasicAuth	Basic authentication. Requires an authenticated logon.
BasicAuthRequireTLS	Basic authentication over TLS. Requires a server certificate.
ExchangeServer	Exchange Server authentication (Generic Security Services application programming interface (GSSAPI) and Mutual GSSAPI).
ExternalAuthoritative	The connection is considered externally secured by using a security mechanism that's external to Exchange. The connection may be an Internet Protocol security (IPsec) association or a virtual private network (VPN). Alternatively, the servers may reside

	in a trusted physically controlled network. The `ExternalAuthoritative` authentication method requires the `ExchangeServers` permission group. This combination of authentication method and security group permits the resolution of anonymous sender e-mail addresses for messages that are received through this connector. This replaces the **Resolve anonymous senders** function in Exchange Server 2003.

Additional Receive Connector Properties

The property configuration for a Receive connector defines how e-mail is received through that connector. Not all properties are available in the EMC. For more information about the properties that can be configured by using the Shell, see Set-ReceiveConnector.

Using a Receive Connector for Anonymous Relay

Anonymous relay on Internet SMTP messaging servers is a serious security deficiency that could be exploited by unsolicited commercial e-mail senders, or spammers, to hide the source of their messages. Therefore, restrictions are placed on Internet-facing messaging servers to prevent relaying to unauthorized destinations.

In Exchange 2010, relaying is typically handled by using accepted domains. Accepted domains are configured on the Edge Transport server or Hub Transport server. The accepted domains are additionally classified as internal relay domains or external relay domains. For more information about accepted domains, see Understanding Accepted Domains.

You can also restrict anonymous relay based on the source of the incoming messages. This method is useful when an unauthenticated application or messaging server must use a Hub Transport server or an Edge Transport server as a relay server.

When you create the Receive connector that's configured to allow anonymous relay, you should place the following restrictions on the Receive connector:

- **Local network settings** Restrict the Receive connector to listen only on the appropriate network adapter on the Hub Transport server or Edge Transport server.
- **Remote network settings** Restrict the Receive connector to accept connections only from the specified server or servers. This restriction is necessary, because the Receive connector is configured to accept relay from anonymous users. Restricting the source servers by IP address is the only measure of protection that's allowed on this Receive connector.

To grant the relay permission to anonymous users on the Receive connector, you can use either of the strategies described later in this topic. Each strategy has advantages and disadvantages. For step by step instructions for both approaches, see Allow Anonymous Relay on a Receive Connector.

Granting Relay Permission to Anonymous Connections

This strategy involves the following tasks:

- Creating a Receive connector with the usage type set to `Custom`.
- Adding the Anonymous permission group to the Receive connector.

- Assigning the relay permission to the Anonymous Logon security principal on the Receive connector.

The Anonymous permission group grants the following permissions to the Anonymous Logon security principal on the Receive connector:

- Ms-Exch-Accept-Headers-Routing
- Ms-Exch-SMTP-Accept-Any-Sender
- Ms-Exch-SMTP-Accept-Authoritative-Domain-Sender
- Ms-Exch-SMTP-Submit

However, to allow anonymous relay on this Receive connector, you must also grant the following permission to the Anonymous Logon security principal on the Receive connector:

- Ms-Exch-SMTP-Accept-Any-Recipient

The advantage of this strategy is that it grants the minimum required permissions to relay to the specified remote IP addresses.

The disadvantages of this strategy are as follows:

- Additional configuration steps are required to grant the necessary permissions.
- The messages that originate from the specified IP addresses are treated as anonymous messages. Therefore, the messages don't bypass anti-spam checks, don't bypass message size limit checks, and anonymous senders can't be resolved. The process of resolving anonymous senders forces an attempted match between the anonymous sender's e-mail address and the corresponding display name in the global address list (GAL).

Configuring the Receive Connector as Externally Secured

This strategy involves the following tasks:

- Creating a Receive connector with the usage type set to `Custom`.
- Adding the ExchangeServers permission group to the Receive connector.
- Adding the `ExternalAuthoritative` authentication mechanism to the Receive connector.

The ExchangeServers permission group is required when you select the `ExternalAuthoritative` authentication mechanism. This combination of authentication method and permission group grants the following permissions to any incoming connection that's permitted on the Receive connector:

- Ms-Exch-Accept-Headers-Routing
- Ms-Exch-SMTP-Accept-Any-Sender
- Ms-Exch-SMTP-Accept-Authoritative-Domain-Sender
- Ms-Exch-SMTP-Submit
- Ms-Exch-Accept-Exch50
- Ms-Exch-Bypass-Anti-Spam
- Ms-Exch-Bypass-Message-Size-Limit
- Ms-Exch-SMTP-Accept-Any-Recipient
- Ms-Exch-SMTP-Accept-Authentication-Flag

The advantages of this strategy are as follows:

- Ease of configuration
- The messages that originate from the specified IP addresses are treated as authenticated messages. The messages bypass anti-spam checks, bypass message size limit checks, and can resolve anonymous senders.

The disadvantage of this strategy is that the remote IP addresses are considered completely trustworthy. The permissions that are granted to the remote IP addresses allow the remote messaging server to submit messages as if they originated from internal senders within your Exchange organization.

New Features in Exchange 2010 Service Pack 1

In Service Pack 1 (SP1) for Exchange Server 2010, new functionality was added to Receive connectors. This section provides an overview of these new features.

Bare Line Feed Control

When a mail server establishes an SMTP session, it issues SMTP commands to send messages. After specifying the sender and recipient information, the sending server transmits the contents of the message using the DATA command. The content that is transmitted after issuing the DATA command is known as the data stream. The data stream is terminated by a special sequence of characters: a carriage return line feed (CRLF), followed by a period, followed by another CRLF.

Line feed (LF) characters that aren't immediately preceded by carriage return (CR) characters are known as bare line feeds. Bare line feeds aren't allowed in SMTP communications. Although it may be possible for a message containing a bare line feed to be delivered successfully, such messages don't adhere to the SMTP protocol standards and may cause problems with messaging servers.

In Exchange 2010 SP1, you can configure your Receive connectors to reject any messages that contain bare line feeds in their data stream. This behavior is controlled by the *BareLineFeedRejectionEnabled* parameter of the **Set-ReceiveConnector** cmdlet. By default, this setting is disabled to maintain backwards compatibility. For more information about configuring this parameter, see Set-ReceiveConnector.

Extended Protection Capability

Windows offers channel binding to protect NTLM authentication over encrypted channels from authentication relay attacks. In Exchange 2010, all services provided by Exchange have been updated to support Extended Protection for Authentication. To support this feature in Transport, the Receive connectors have been updated. You can allow, require, or disable Extended Protection for Authentication on your Receive connectors.

You can use the *ExtendedProtectionPolicy* and *ExtendedProtectionTlsTerminatedAtProxy* parameters of the **Set-ReceiveConnector** cmdlet to control how your Transport servers handle extended protection. You can configure a Receive connector to allow or require extended protection. When you configure a Receive connector to require extended protection, any incoming connections from hosts that don't support extended protection will be rejected. To maintain backwards compatibility, the extended protection is disabled by default. For more information about configuring extended protection on your Receive connectors, see Set-ReceiveConnector.

To learn more about extended protection, see the following resources:

- Microsoft Knowledge Base article 973811, Microsoft Security Advisory: Extended protection for authentication
- MSDN Library topic, Integrated Windows Authentication with Extended Protection

1.7.1.29 Understanding Recipient Resolution

Understanding Recipient Resolution

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-25*

Recipient resolution is the process of expanding and resolving all the recipients in a message. The act of resolving the recipients matches a recipient to the corresponding Active Directory object in the Microsoft Exchange organization. The act of expanding the recipients expands all distribution groups into a list of individual recipients. Recipient resolution allows message limits and alternative recipients to be applied correctly to each recipient.

In a Microsoft Exchange Server 2010 organization, recipient resolution is performed by the categorizer on a server that has the Hub Transport server role installed. Categorization on each message happens after a newly arrived message is put in the Submission queue. Recipient resolution, in addition to content conversion and routing, is performed on the message before the message is put in a delivery queue. The categorizer performs recipient resolution before routing. The component of the categorizer that's responsible for recipient resolution is frequently called the *resolver*.

Contents

Top-Level Resolution

Top-level resolution is the first stage of recipient resolution. Top-level resolution associates each recipient in an incoming message to a matching recipient object in Active Directory. During top-level resolution, the categorizer creates a list that contains the sender and the initial, unexpanded recipient e-mail addresses that exist within the message. The categorizer then uses that list of e-mail addresses to query Active Directory to find any mail-enabled objects that have matching e-mail address attributes. When a match is found, the properties of matching Active Directory objects are cached for later use. Any sender message restrictions are also enforced.

Recipient E-mail Addresses

Top-level resolution begins with a message and the initial, unexpanded list of recipients from the *message envelope*. The message envelope contains the commands that are used to transmit messages among SMTP messaging servers. The sender's e-mail address is contained in the MAIL FROM: command. Each recipient's e-mail address is contained in a separate RCPT TO: command. The envelope sender and envelope recipients are typically created from the sender and recipients in the To:, From:, Cc:, and Bcc: header fields in the message header. However, this isn't always true. The To:, From:, Cc:, and Bcc: header fields in a message are easily forged and may not match the actual sender or recipient e-mail addresses that were used to transmit the message.

Encapsulated E-mail Addresses

Standard SMTP e-mail addresses follow the specifications of RFC 2821 and RFC 2822, such as chris@contoso.com, for example. However, an e-mail address can also be a non-SMTP e-mail address that's encapsulated inside a valid SMTP address. Exchange 2010 supports encapsulated addresses that use the Internet Mail Connector Encapsulated Address (IMCEA) encapsulation method.

This encapsulation method requires the encoding of any characters that are invalid in SMTP e-mail addresses. Alphanumeric characters, the equal sign (=) and the hyphen (-) don't require encoding. Other characters use the following encoding syntax:

- A forward slash (/) is replaced by an underscore (_).
- Other US-ASCII characters are replaced by a plus sign (+) and the two digits of its ASCII value are written in hexadecimal. For example, the space character has the encoded value +20.

The IMCEA encapsulation method uses the following syntax: `IMCEA<Type>-<address>@<domain>`

The placeholder <*Type*> identifies the type of non-SMTP address, for example EX, X400, or FAX.

Note:
Although SMTP and X500 are theoretically valid values for <*Type*>, Exchange 2010 recipient resolution rejects any IMCEA-encoded addresses that use either of these types.

The placeholder <*address*> is the encoded original address. The placeholder <*domain*> represents the SMTP domain that's used to encapsulate the non-SMTP address, for example, contoso.com

With the IMCEA encapsulation method, addresses are unencapsulated only when the domain matches the default authoritative domain in the Exchange organization. For more information about accepted domains, see Understanding Accepted Domains.

The maximum length for an SMTP e-mail address in Exchange 2010 is 571 characters. This limit includes the following:

- 315 characters for the name part of the address
- 255 characters for the domain name
- The at sign (@) character that separates the name part of the address from the domain name

Currently, Exchange 2010 doesn't support messages that are encoded with the IMCEA encapsulation method when the name part of the address exceeds 315 characters.

Address Resolution

For each message, the sender e-mail address and all recipient e-mail addresses are added to a list that's used to query Active Directory. Any encapsulated addresses are unencapsulated before they're added to the list of e-mail addresses. The Active Directory query is performed on up to 20 e-mail addresses at a time. If the Active Directory query encounters any transient errors, the message is returned to the Submission queue and deferred for the time that's specified by the *ResolverRetryInterval* parameter in the EdgeTransport.exe.config application configuration file. The default value is 30 minutes.

The following table describes the recipient objects that are found in Active Directory. For more information about Exchange 2010 recipient types, see Understanding Recipients.

Recipient objects in Active Directory

Active Directory recipient type	Description
DistributionGroup	Any mail-enabled group object. The distribution group object types are as follows: • **MailUniversalDistributionGroup** A

	universal distribution group object • **MailUniversalSecurityGroup** A universal security group (USG) object that has an e-mail address • **MailNonUniversalGroup** A local security group object or global security group object that has an e-mail address
DynamicDistributionGroup	An object that has the Active Directory class **msExchDynamicDistributionList**. For more information, see Create a Dynamic Distribution Group.
Mailbox	A user object that has an e-mail address and a defined *Database* parameter
MailUser	A user object that has an e-mail address without a defined *Database* parameter. For more information, see Create a Mail User.
MailContact	A contact object that has an e-mail address. Typically, a mail contact is used for recipients outside the Exchange organization. A mail contact is also used in cross-forest Exchange environments. For more information, see Create a Mail Contact.
MailPublicFolder	A public folder object that has an e-mail address.
MicrosoftExchangeRecipient	An object that has the Active Directory class **msExchExchangeServerRecipient**. For more information about the Exchange recipient object, see Understanding the Microsoft Exchange Recipient.
PublicDatabase	An object that has the Active Directory class **msExchPublicMDB**.
SystemAttendantMailbox	An object that has the Active Directory class **exchangeAdminService**. There should be only one system attendant mailbox in the Exchange 2010 organization.
SystemMailbox	A user object that has an e-mail address and that's located in the Microsoft Exchange System Objects container. There should be one system mailbox for each mailbox database in the Exchange 2010 organization.

An object that contains missing or malformed critical properties is classified by the Active Directory query as an invalid object. For example, a dynamic distribution group object without an e-mail address is considered invalid. Messages that are sent to recipients that are classified as invalid objects generate a non-delivery report (NDR).

For each e-mail address, a single initial query is performed for all possible recipient properties, such as the recipient identifiers, recipient type, message limits, e-mail addresses, and alternative recipients. The applicable properties for the recipient are cached for later use. Recipient resolution classifies the recipients based on similarities in how the recipients are resolved, and the similarity of the applicable recipient properties.

The LDAP filter that's used for address resolution is described as follows:

- For the EX e-mail address type, the LDAP filter is based on the recipient **legacyExchangeDN** Active Directory attribute or the recipient **proxyAddresses** Active Directory attribute. The **legacyExchangeDN** Active Directory attribute takes precedence.
- For all other e-mail addresses types, the recipient **proxyAddresses** Active Directory attribute is used as the LDAP filter.

If the e-mail address that's used in the message doesn't match the primary SMTP address of the corresponding Active Directory object, the categorizer rewrites the e-mail address in the message to match the primary SMTP address. The original e-mail address is saved in the *ORCPT*= parameter in the RCPT TO: command in the message envelope.

Sender Message Restrictions

The size that's used for the sender message size restriction is the value of the `X-MS-Exchange-Organization-OriginalSize:` header field in the message header. Exchange 2010 uses this header field to record the original message size of the message when it entered the Exchange 2010 organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing. If this header field doesn't exist, it's created by using the current message size value. If the message is too large, an NDR is generated and additional message processing is stopped.

The sender recipient limit is only enforced on the first Hub Transport server that processes the message. The original, unexpanded message envelope recipient count is compared to the sender recipient limit. The original, unexpanded message envelope recipient count is used to avoid the partial message delivery problems that occur in Microsoft Exchange Server 2003 when nested distribution lists used remote expansion servers.

The message sender and all recipients are marked as resolved by stamping an extended property in the message. This extended property allows the message to bypass top-level resolution if the message must go through recipient resolution again. A message may have to go through recipient resolution again because the Microsoft Exchange Transport service restarted.

Return to top

Expansion

Expansion occurs after top-level resolution. Expansion completely expands nested levels of recipients into individual recipients. Expansion may require multiple trips through the expansion process to expand all recipients. Not all recipients have to be expanded. However, all recipients must go through the expansion process. The expansion process also enforces recipient message restrictions for all kinds of recipients.

The following list describes the kinds of recipients that require expansion:

- **Distribution groups and dynamic distribution groups** Distribution groups are expanded based on the **memberOf** Active Directory property. Dynamic distribution groups are expanded by using the Active Directory query definition. If the *ExpansionServer* parameter is set on the group, the group isn't expanded by the current server. The distribution group is routed to the specified server for expansion.

Note:

If you select a specific Hub Transport server in your organization as the expansion server, the distribution group usage becomes dependent on the availability of the expansion server. If the expansion server is unavailable, any messages that are sent to the distribution group can't be delivered. If you plan to use specific expansion servers for your distribution groups, to

reduce the risk of service interruption, you should consider implementing high availability solutions for these servers.

- **Alternative recipients** The *ForwardingAddress* parameter may be set on mailboxes and mail-enabled public folders. The *ForwardingAddress* parameter redirects all messages to the specified alternative recipient. This is known as a *forwarded recipient*. When an alternative delivery address is specified in the *ForwardingAddress* parameter and the *DeliverToMailboxAndForward* parameter is set to `$true`, the message is delivered to the original recipient and the alternative recipient. This is known as *delivered and forwarded recipient*.
- **Contact chains** A *contact chain* is a mail user or mail contact that has the *ExternalEmailAddress* parameter set to the e-mail address of another recipient in the Exchange organization.

Detection of Recipient Loops

As the distribution groups, alternative recipients, and contacts chains are expanded, the categorizer checks for *recipient loops*. A recipient loop is a recipient configuration problem that causes message delivery to the same recipients in an endless circle. The following list describes the different types of recipient loops:

- **Harmless recipient loop** A harmless recipient loop results in successful message delivery. The following list describes two scenarios when harmless recipient loops occur:
  - When two distribution groups contain one another as members.
  - When mailboxes or mail-enabled public folders are set to deliver and forward to one another. This happens when the *DeliverToMailboxAndForward* parameter of both recipients is set to `$true` and the *ForwardingAddress* parameter is set to one another.

  When a harmless recipient loop is detected, the message is delivered to the recipient, but no additional attempts are made to deliver the message to the same recipient.
- **Broken recipient loop** A broken recipient loop can't result in successful message delivery. An example of a broken recipient loop is when mailboxes or mail-enabled public folders have the *ForwardingAddress* parameter set to one another. When the categorizer detects a broken recipient loop, expansion activity for the current recipient stops, and an NDR is generated for the recipient.

Detection of recipient loops doesn't prevent duplicate message delivery. For example, Distribution Group C will experience duplicate message delivery if the following conditions are true:

- Distribution Group B and Distribution Group C are members of Distribution Group A.
- Distribution Group C is also a member of Distribution Group B.

Delivery Report Redirection for Distribution Groups

When a distribution group is expanded, the message type is checked to determine whether it's a delivery report message. If the message is a delivery report, the redirection settings of the distribution group are checked to determine whether redirection of the delivery report is required. You may want to suppress the delivery reports because the delivery reports may disclose unwanted information about the distribution group and its membership.

The following list describes the delivery report redirection settings that are available for distribution groups and dynamic distribution groups:

- **ReportToManagerEnabled** This parameter enables delivery reports to be sent to the distribution group manager. Valid values are `$true` or `$false`. The default value is `$false`. For a distribution group, the manager is controlled by the *ManagedBy* parameter in the **Set-Group** cmdlet. For a dynamic distribution group, the manager is controlled by the *ManagedBy* parameter in the **Set-**

DynamicDistributionGroup cmdlet.

- **ReportToOriginatorEnabled** This parameter enables delivery reports to be sent to the sender of e-mail messages that are sent to this distribution group. Valid values are `$true` or `$false`. The default value is `$true`.

Note:

The values of the *ReportToManagerEnabled* parameter and *ReportToOriginatorEnabled* parameter can't both be `$true`. If one parameter is set to `$true`, the other must be set to `$false`. The values of both parameters can be `$false`. This suppresses all redirection of all delivery report messages.

The following list describes the available delivery report messages:

- **Delivery receipt (DR)** This report confirms that a message was delivered to its intended recipient.
- **Delivery status notification (DSN)** This report describes the result of an attempt to deliver a message. For more information about DSN messages, see Managing Delivery Status Notifications.
- **Message disposition notification (MDN)** This report describes the status of a message after it has been successfully delivered to a recipient. A read notification (RN) and a non-read notification (NRN) are both examples of an MDN message. MDN messages are defined in RFC 2298 and are controlled by the `Disposition-Notification-To:` header field in the message header. MDN settings that use the `Disposition-Notification-To:` header field are compatible with many different message servers. MDN settings can also be defined by using MAPI properties in Microsoft Outlook and Exchange.
- **Non-delivery report (NDR)** This report indicates to the message sender that the message couldn't be delivered to the specified recipients.
- **Non-read notification (NRN)** This report indicates that a message was deleted before it was read.
- **Out of office (OOF)** This report indicates that the recipient won't respond to e-mail messages. The acronym OOF dates back to the original Microsoft messaging system where the corresponding notification was named "out of facility."
- **Read notification (RN)** This report indicates that a message was read.
- **Recall Report** This report indicates the status of a recall request for a specific recipient. A recall request is when a sender tries to recall a sent message by using Outlook.

When a delivery report message is sent to a distribution group, the following settings cause the report message to be deleted:

- Report redirection isn't set. Alternatively, report redirection is set to the message sender.
- Report redirection is set to the distribution group manager, and the delivery report message isn't an NDR.

When a delivery report message is sent to a distribution group, the following setting causes the delivery report message to be delivered to the distribution group manager:

- Report redirection is set to the distribution group manager, and the report message is an NDR.

When a message that isn't a delivery report message is sent to a distribution group, the message is delivered to the distribution group members. The report request settings are summarized in the following list:

- If report redirection is set to the message sender, the report request settings aren't modified.
- If report redirection isn't set, all report request settings are suppressed. The *NOTIFY=NEVER* parameter is added to RCPT TO: for each recipient in the message envelope.

- If report redirection is set to the distribution group manager, all report request settings are suppressed except NDR messages that are sent to the distribution group manager.

Message Restrictions on Recipients

The expansion process also enforces any message restrictions that are configured for recipients. These restrictions may be configured individually for each recipient or organizationally for all Hub Transport servers in the Exchange organization. The following table describes the message restrictions that are configured for recipients.

Message restrictions on recipients

Source	Parameter	Description
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailPublicFolder** **Set-MailUser** **Set-TransportConfig**	*MaxReceiveSize*	The *MaxReceiveSize* parameter specifies the size that's used for message restrictions that are configured for recipients is the value of the `X-MS-Exchange-Organization-OriginalSize:` header field in the message header. Exchange 2010 uses this header field to record the original message size of the message when it entered the Exchange 2010 organization. Whenever the message is checked against the specified message size limits, the lower value of the current message size or the original message size header is used. The size of the message can change because of content conversion, encoding, and agent processing. If this header field doesn't exist, it's created by using the current message size value. If the message is too large, an NDR is generated and additional message processing is stopped.
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailPublicFolder** **Set-MailUser**	*RequireSenderAuthenticationEnabled*	The *RequireSenderAuthenticationEnabled* parameter requires that all messages that are sent to the recipient come from authenticated senders. When the value of this parameter is set to `$true`, messages from unauthenticated senders are rejected. All senders who send messages to the System and System Attendant mailboxes must be

		authenticated.
Set-DistributionGroup **Set-DynamicDistributionGroup** **Set-Mailbox** **Set-MailContact** **Set-MailPublicFolder** **Set-MailUser**	*AcceptMessagesOnlyFrom* *AcceptMessagesOnlyFromDLMembers* *RejectMessagesFrom* *RejectMessagesFromDLMembers*	The *AcceptMessagesOnlyFrom* parameter specifies the senders who can send e-mail messages to the recipient. The *AcceptMessagesOnlyFromDLMembers* parameter specifies the distribution groups that can send e-mail messages to the recipient. The *RejectMessagesFrom* parameter specifies the senders that can't send e-mail messages to this recipient. The *RejectMessagesFromDLMembers* parameter specifies the distribution groups that can't send e-mail messages to the distribution group. The categorizer checks the recipient permission in two passes. The first pass determines whether the sender is present in the *AcceptOnlyMessagesFrom* or *RejectMessagesFrom* parameter. If the sender isn't found in either parameter, the recipients in the *AcceptMessagesOnlyFromDLMembers* and *RejectMessagesFromDLMembers* parameters are fully expanded. This complete expansion of distribution groups may take some time. We recommend that you minimize the depth of nested distribution groups in the *AcceptMessagesOnlyFromDLMembers* parameter and the *RejectMessagesFromDLMembers* parameters.

Certain types of messages that are sent by authenticated senders are exempt from restrictions. The following list describes the messages that are exempt from recipient restrictions:

- **All messages that are sent by the Microsoft Exchange recipient** These messages include DSN messages, journal reports, quota messages, and other system-generated messages that are sent to internal message senders. For more information about the Microsoft Exchange recipient, see Understanding

the Microsoft Exchange Recipient.

- **Public folder replication messages** These messages are sent by a public database sender.
- **All messages that are sent by the external postmaster address** These messages include DSN messages and other system-generated messages that are sent to external message senders. For more information about the external postmaster address, see Configure the External Postmaster Address.

Certain types of messages are blocked when they are sent from the Exchange organization to external domains. The settings are controlled by the following parameters in the **Set-RemoteDomain** cmdlet:

- *AllowedOOFType*
- *AutoForwardEnabled*
- *AutoReplyEnabled*
- *DeliveryReportEnabled*
- *NDREnabled*

For more information, see Understanding Remote Domains.

Return to top

Bifurcation and Controlling Recipient Expansion

Because the complete list of message recipients is expanded and resolved by recipient resolution, there are occasions when different copies of the same message must be created. These occasions are described by the following scenarios:

- **When message recipients require different message settings** Message properties such as read receipts may have to be enabled for some recipients and blocked for other recipients. Creating a new version of the message that has slightly different properties than the original message is called *bifurcation*.
- **To limit the number of envelope recipients in a single message** The recipient expansion process can generate thousands of individual recipients when large distribution groups are expanded. In Exchange 2010, instead of creating a single copy of the message that has thousands of envelope recipients, multiple copies of the same message that have a limited number of envelope recipients are created.

Bifurcation

Recipient resolution bifurcates a message if the following conditions are true:

- When the message sender in MAIL FROM:, in the message envelope, is updated. An example is when the *ReportToManagerEnabled* parameter on a distribution group has a value of `$true`.
- When auto-response messages, such as DSNs, OOF messages, and recall reports must be suppressed.
- When alternative recipients are expanded.
- When a `Resent-From:` header field must be added to the message header. Resent header fields are informational header fields that can be used to determine whether a message has been forwarded by a user. Resent header fields are used so that the message appears to the recipient as if it was sent directly by the original sender. The recipient can view the message header to discover who forwarded the message. Resent header fields are defined in section 3.6.6 of RFC 2822.
- When the history of the expansion of the distribution group must be transmitted.

Controlling Recipient Expansion

When the number of expanded recipients is too large, the categorizer splits the message into multiple copies. This is performed to reduce system resource use during message expansion. The maximum number of envelope recipients in a message is controlled by the *ExpansionSizeLimit* parameter in the EdgeTransport.exe.config application configuration file. The default value is 1000.

Caution:

We recommend that you don't modify the value of the *ExpansionSizeLimit* parameter on an Exchange transport server in a production environment.

Return to top

Recipient Resolution Diagnostics

Reporting and diagnostic information for recipient resolution is provided by performance counters, message tracking log entries, and recipient resolution logging. These sources can help you identify and diagnose problems with recipient resolution.

Recipient Resolution Performance Counters

The following table describes the performance counters that are available for recipient resolution.

Recipient resolution performance counters

Counter name	Display name	Description
AmbiguousRecipientsTotal	Ambiguous Recipients	This is the total number of ambiguous recipients that were detected during recipient resolution. Ambiguous recipients are different recipients that have matching **legacyExchangeDN** Active Directory attributes or matching **proxyAddresses** Active Directory attributes.
AmbiguousSendersTotal	Ambiguous Senders	This is the number of ambiguous senders that were detected during recipient resolution. Ambiguous senders are different senders that have matching **legacyExchangeDN** Active Directory attributes or matching **proxyAddresses** Active Directory attributes.
FailedRecipientsTotal	Failed Recipients	This is the number of failed recipients that were detected during recipient resolution.
LoopRecipientsTotal	Loop Recipients	This is the number of recipients that failed recipient resolution because of recipient loops.
MessagesChippedTotal	Messages Chipped	This is the total number of copies of the same message that were created during

		recipient resolution to control the number of envelope recipients in a single message. In Exchange 2010, this process is referred to as *chipping*.
MessagesCreatedTotal	Messages Created	This is the number of messages that were created during recipient resolution.
MessagesRetriedTotal	Messages Retried	This is the number of messages that were scheduled for retry during recipient resolution.
UnresolvedOrgRecipientsTotal	Unresolved Org Recipients	This is the number of unresolved recipients from an authoritative domain that were detected during recipient resolution.
UnresolvedOrgSendersTotal	Unresolved Org Senders	This is the number of unresolved senders from an authoritative domain that were detected during recipient resolution.

Recipient Resolution Events That Are Written in the Message Tracking Log

The following table describes the recipient resolution events that are written in the message tracking log.

Recipient resolution events in the message tracking log

Message tracking event	Description
EXPAND	This event indicates that a distribution group was expanded.
REDIRECT	This event indicates that a message sent to a mailbox recipient or a mail-enabled public folder recipient was redirected to an alternative recipient as specified by the *ForwardingAddress* parameter.
RESOLVE	This event indicates that a recipient e-mail address was changed to the primary SMTP e-mail address of the corresponding Active Directory recipient object.
TRANSFER	This event indicates that message bifurcation or chipping occurred.

For more information about message tracking, see Understanding Message Tracking.

Recipient Resolution Logging

Recipient resolution logging is controlled by the *ResolverLogLevel* parameter in the EdgeTransport.exe.config application configuration file. The valid values for this parameter are `Disabled`, `Enabled`, and `FullContent`. The default value is `Disabled`. When the *ResolverLogLevel* parameter is set to `Enabled`, only message envelope data is logged.

When the *ResolverLogLevel* parameter is set to `FullContent`, message envelope data and message header data is logged.

1.7.1.30 Understanding Remote Domains

Understanding Remote Domains

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can create remote domain entries to define the settings for message transfer between the Microsoft Exchange Server 2010 organization and domains outside your Active Directory forest. When you create a remote domain entry, you control the types of messages that are sent to that domain. You can also apply message format policies and acceptable character sets for messages that are sent from users in your organization to the remote domain. The settings for remote domains are global configuration settings for the Exchange organization.

The remote domain settings are applied to messages during categorization. When recipient resolution occurs, the recipient domain is matched against the configured remote domains. If a remote domain configuration blocks a specific message type from being sent to recipients in that domain, the message is deleted. If you specify a particular message format for the remote domain, the message headers and content are modified. Information about the remote domain configuration is stored in Active Directory. The settings apply to all messages that are processed by the Exchange organization.

Note:

If you configure message settings per user, the per-user settings override the organizational configuration.

By default, there's a single remote domain entry. The domain address space is configured as an asterisk (*). This represents all domains. If you don't create additional remote domain entries, all messages that are sent to all recipients in all remote domains have the same settings applied to them.

When you configure remote domains, you can prevent certain types of messages from being sent to that domain. These message types include out-of-office messages, auto-reply messages, non-delivery reports (NDRs), and meeting forward notifications. If you have a multiple forest environment, you may want to allow the sending of those types of messages to those domains. However, if you have identified a domain from which spam originates, you may want to block sending of those types of messages to those remote domains.

Message Format

You can specify the message format and the character set to use for e-mail messages that are sent to remote domains. These settings can be useful to make sure that e-mail sent by senders in your domain to the remote domain is compatible with the receiving e-mail system. For example, if you know that the remote domain's messaging system is Exchange, you can specify to always use Exchange rich text format (RTF). For more information, see Understanding Content Conversion.

Automatic Replies Settings

Automatic replies, formerly known as out-of-office replies, have changed substantially starting with Exchange Server 2007. In Exchange 2010 and Exchange 2007, users can specify different automatic replies for internal and external recipients. Furthermore, the types of automatic replies available in your organization also depend on the Microsoft Outlook version in use.

In Exchange 2010, there are three types of automatic replies:

- **External** Supported by Exchange 2010 and Exchange 2007. Can only be set by Outlook 2010 or Office Outlook 2007, or using Microsoft Office Outlook Web App.
- **Internal** Supported by Exchange 2010 and Exchange 2007. Can only be set by Outlook 2010 or Outlook 2007, or using Outlook Web App.
- **Legacy** Supported by Exchange 2010, Exchange 2007, and Exchange Server 2003. Can be set by Office Outlook 2003 or earlier.

The following table describes various client and server combinations and the types of automatic replies that can be used in each scenario.

Client and server support for automatic replies

Client version	Exchange version	Automatic replies supported
Outlook 2010 or Outlook 2007	Exchange 2010 Exchange 2007	Internal, External
Outlook Web App	Exchange 2010 Exchange 2007	Internal, External
Outlook 2003	Exchange 2010 Exchange 2007	Legacy
Outlook 2010, Outlook 2007, or Outlook 2003	Exchange 2003	Legacy
Outlook Web Access	Exchange 2003	Legacy

For a remote domain, you can specify one of the following options for sending automatic replies:

- **Allow none** If you select this option, no automatic replies are sent to recipients in the remote domain.
- **Allow external out-of-office messages only** If you select this option, only External automatic replies are sent to the remote domain.
- **Allow external out-of-office messages and legacy out-of-office messages (configured by using Outlook 2003 or earlier clients, or configured on Exchange 2003 mailboxes)** If you select this option, both External and Legacy automatic replies are sent to the remote domain.
- **Allow internal out-of-office messages, and legacy out-of-office messages (configured by using Outlook 2003 or earlier clients, or configured on Exchange 2003 mailboxes)** If you select this option, both Internal and Legacy automatic replies are sent to the remote domain.

Controlling NDR Information

As mentioned at the beginning of this topic, you can prevent NDRs from being sent to a remote domain. By blocking NDRs to a remote domain, you can prevent the information contained within the NDR message from leaving your organization, thereby limiting the knowledge a malicious user can obtain about your organization. However, this also

prevents legitimate senders from receiving NDRs, resulting in confusion and lost productivity.

Exchange 2010 SP1 provides you with more granular control over the contents of an NDR destined for a remote domain. With Exchange 2010 SP1, you can now allow NDRs to a remote domain, while stripping any diagnostic information. This way, you can still prevent information about your Exchange deployment from leaving your organization while at the same time providing NDR notifications to external senders.

This feature is controlled with the new *NDRDiagnosticInfoEnabled* parameter of the **Set-RemoteDomain** cmdlet. Because this setting is configurable for each remote domain, you can have different settings based on your needs. For example, you can choose to remove the NDR diagnostic information for the default remote domain, but allow full NDR diagnostic information for the remote domains that represent your partners.

For more information about this new settings, see Set-RemoteDomain.

Remote Domains in Cross-Premises Deployments

Exchange 2010 SP1 supports cross-premises deployments where your Exchange organization is split between your on-premises servers and a cloud-based service such as Microsoft Office 365. In this deployment scenario, a remote domain object represents the part of your organization that exists in the cloud-based service. This remote domain is different from all the other remote domains you may have because it's considered an internal remote domain.

You can use either the Shell or the EMC to designate a remote domain as your Office 365 deployment. For detailed steps, see Configure Remote Domain Properties.

1.7.1.31 Understanding Send Connectors

Understanding Send Connectors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Send connectors are configured on computers that are running Microsoft Exchange Server 2010 and that have the Hub Transport server role or Edge Transport server role installed. The Send Connector represents a logical gateway through which outbound messages are sent. This topic provides an overview of Send connectors and explains how the configuration of Send connectors affects the processing of individual messages.

Overview of Send Connectors

Exchange 2010 transport servers require Send connectors to deliver messages to the next hop on the way to their destination. A Send connector controls outbound connections from the sending server to the receiving server or destination e-mail system. By default, no explicit Send connectors are created when the Hub Transport server role or the Edge Transport server role is installed. However, implicit and invisible Send connectors that are automatically computed based on the Active Directory site topology are used to route messages internally between Hub Transport servers. End-to-end mail flow is only possible after the Edge Transport server has been subscribed to the Active Directory site

by using the Edge Subscription process. Other scenarios, such as an Internet-facing Hub Transport server or an unsubscribed Edge Transport server, require manual configuration of connectors to establish end-to-end mail flow. For more information, see Transport Server Post-Deployment Tasks.

Send connectors that are created on Hub Transport servers are stored in Active Directory and are available to all Hub Transport servers in the organization. If a Send connector is configured to send messages to an external domain, any Hub Transport server in the organization will route a message for that domain to a source server for that connector to be relayed to the destination domain.

The Send connector that's used to route messages to a recipient is selected during the routing resolution phase of message categorization. For more information, see Understanding Message Routing.

Selecting the Usage Type for a Send Connector

When you use the Exchange Management Console (EMC) to create a Send connector, the New SMTP Send Connector wizard prompts you to select a usage type for the connector. The usage type determines the default permission sets that are assigned on the connector and grants those permissions to trusted security principals. Security principals include users, computers, and security groups. A security principal is identified by a security identifier (SID).

You can also specify a usage type when you create a Send connector by using the **New-SendConnector** cmdlet in the Exchange Management Shell. However, the *Usage* parameter isn't required. If you don't specify a usage type when you run the **New-SendConnector** cmdlet, the default usage type is set to Custom. The following table describes the Send connector usage types and their default settings.

Send connector usage types

Type	Default permissions	SID that's granted the default permissions	Default smart host authentication mechanism
Custom	None	None	None
Internal	• ms-Exch-Send-Headers-Organization • ms-Exch-SMTP-Send-Exch50 • ms-Exch-Send-Headers-Routing • ms-Exch-Send-Headers-Forest	• Hub Transport servers • Edge Transport servers • Exchange Servers (on Hub Transport servers only) • Externally Secured servers • Exchange Legacy Interop universal security group • Exchange Server 2003 and Exchange 2000 Server bridgehead servers	Exchange Server Authentication

Internet	Ms-Exch-Send-Headers-Routing	Anonymous User Account	None
Partner	Ms-Exch-Send-Headers-Routing	Partner Servers	Not applicable. This usage type is selected when you establish mutual Transport Layer Security (TLS) authentication with a remote domain.

Note:
If Domain Name System (DNS) resolution delivery is selected for a Send connector instead of a smart host, no smart host authentication mechanism is configured.

The Send connector permissions and smart host authentication mechanisms are discussed in detail later in this topic.

Send Connector Usage Scenarios

Each usage type is appropriate for a specific connection scenario. Select the usage type that has the default settings most applicable to the configuration that you want. You can modify permissions by using the **Add-ADPermission** and **Remove-ADPermission** cmdlets. For more information, see the following topics:

- Add-ADPermission
- Remove-ADPermission

The following table lists common connection scenarios and the usage type for each scenario.

Connector usage scenarios

Connector scenario	Usage type	Comment
Edge Transport server that sends e-mail to the Internet	Internet	A Send connector that's configured to send e-mail to all domains is created automatically when the Edge Transport server is subscribed to the Exchange organization.
Hub Transport server that sends e-mail to the Internet	Internet	This isn't a recommended configuration.
A subscribed Edge Transport server that sends e-mail to a Hub Transport server	Internal	This connector is automatically created by the Edge Subscription process.
Edge Transport server that sends e-mail to an Exchange 2003 bridgehead server	Internal	The Exchange 2003 bridgehead server is configured as a smart host for the Send connector.
Edge Transport server that sends e-mail to a	Custom	When the Edge Subscription process isn't used, a manual connector must

Hub Transport server		be created. Use the **Add-ADPermission** cmdlet to set the extended rights. Set the authentication mechanism as Basic authentication or Externally Secured.
Cross-forest Send connector for a Hub Transport server in one forest that sends e-mail to an Exchange 2010 or Exchange 2007 Hub Transport server in a second forest	Custom	For detailed configuration steps, see Configure Cross-Forest Connectors.
Cross-forest Send connector for a Hub Transport server in one forest that sends e-mail to an Exchange 2003 bridgehead server in a second forest	Custom	For detailed configuration steps, see Configure Cross-Forest Connectors.
Hub Transport server that sends e-mail to a third-party smart host	Custom	Use the **Add-ADPermission** cmdlet to set the extended rights. Route all messages to a smart host and set the authentication mechanism to either Basic authentication or Externally Secured.
Edge Transport server that sends e-mail to a third-party smart host	Custom	Use the **Add-ADPermission** cmdlet to set the extended rights. Route all messages to a smart host and set the authentication mechanism to either Basic authentication or Externally Secured.
Edge Transport server that sends e-mail to an external relay domain	Custom	The Edge Transport server can accept e-mail for an external relay domain and then relay the messages to the authoritative e-mail system for that domain. Route all messages to a smart host, set the appropriate authentication mechanism, and use the **Add-ADPermission** cmdlet to set the extended rights.
Edge Transport server that sends e-mail to a domain to which you have established mutual TLS authentication	Partner	Mutual TLS authentication functions correctly only if the following conditions are true: • The value of the *DomainSecureEnabled* parameter must be `$true`. • The value of the *DNSRoutingEnabled* parameter must be `$true`. • The value of the *IgnoreStartTLS* parameter must be `$false`.

		For more information, see Set-SendConnector.

Send Connector Permissions

You assign Send connector permissions to a security principal. When a security principal establishes a session with a Send connector, the Send connector permissions determine the types of header information that can be sent with the e-mail message. If an e-mail message includes header information that isn't allowed by the Send connector permissions, those headers are stripped from the message when it's sent. The following table describes the permissions that can be assigned on a Send connector to security principals. You can't set Send connector permissions by using the EMC. To modify the default permissions for a Send connector, you must use the **Add-ADPermission** cmdlet in the Shell.

Send connector permissions

Send connector permission	Description
ms-Exch-Send-Exch50	This permission allows the session to send a message that contains the EXCH50 command. If this permission isn't granted, and a message is sent that contains the EXCH50 command, the server sends the message, but doesn't include the EXCH50 command.
Ms-Exch-Send-Headers-Routing	This permission allows the session to send a message that has all received headers intact. If this permission isn't granted, the server removes all received headers.
Ms-Exch-Send-Headers-Organization	This permission allows the session to send a message that has all organization headers intact. Organization headers all start with **X-MS-Exchange-Organization-**. If this permission isn't granted, the sending server removes all organization headers.
Ms-Exch-Send-Headers-Forest	This permission allows the session to send a message that has all forest headers intact. Forest headers all start with **X-MS-Exchange-Forest-**. If this permission isn't granted, the sending server removes all forest headers.

Address Spaces and Connector Scope

The address space for a Send connector specifies the recipient domains to which the Send connector will route e-mail. You can specify SMTP address spaces or non-SMTP address spaces on Send connectors that are configured on Hub Transport servers. You can only specify SMTP address spaces on Send connectors that are configured on Edge Transport servers. If you use a non-SMTP address space type, you must use a smart host to route e-mail.

Note:
Although you can configure non-SMTP address spaces on a Send connector on a Hub Transport server, the Send connector uses SMTP as the transport mechanism to send

messages to other messaging servers. Delivery Agent connectors and foreign connectors on Hub Transport servers are used to send messages to non-SMTP local messaging servers, such as third-party fax gateway servers. For more information, see Understanding Delivery Agents and Understanding Foreign Connectors.

The following table lists valid entries for the SMTP address space of a Send connector.

Valid entries for the SMTP address space of a Send connector

Address space entry	Send connector routes mail to:
*	All domains that don't have an explicit address space entry on another Send connector entry or that aren't an included subdomain of an address space on another Send connector.
Contoso.com	All recipients with e-mail addresses in the Contoso.com domain.
*.Contoso.com	All recipients with e-mail addresses in the Contoso.com domain or any subdomain of Contoso.com. In the EMC, select **Include all subdomains** to set this configuration.
--	This address space is only used on Send connectors configured on Edge Transport servers for sending messages to the Hub Transport servers. When you use this address space, all messages addressed to your accepted domains are routed through this connector.

During routing resolution, a Send connector, to which e-mail is routed for delivery to the destination address space, is selected. The Send connector whose address space most closely matches the recipient's e-mail address is selected. For example, an e-mail message addressed to Recipient@marketing.contoso.com would be routed through the connector that's configured to use the *.Contoso.com address space. When you configure a Send connector for a particular address space, e-mail sent to that address space is always routed through that connector. Also, the configuration settings for that connector are always applied to e-mail sent to that address space.

You can use the scope of a Send connector to control the visibility of the Send connector within the Exchange organization. By default, all Send connectors that you create are usable by all the Hub Transport servers in the Exchange organization. However, you can limit the scope of any Send connector so that it's only usable by other Hub Transport servers that exist in the same Active Directory site.

In Exchange 2010, the complete syntax for specifying an address space is as follows:

<AddressSpaceType>:*<AddressSpace>*;*<AddressSpaceCost>*

You can use the following methods to specify the scope of the Send connector:

- In the EMC, use the **Scoped Send connector** property in the **Address Space** page of the New SMTP Send Connector wizard, or in the **Address Space** tab in the properties of an existing Send connector.
  When **Scoped Send connector** is selected, the connector can only be used by Hub Transport servers in the same Active Directory site. When **Scoped Send connector** isn't selected, the connector can be used by all Hub Transport servers in the Exchange organization.

- In the Shell, use the *IsScopedConnector* parameter in the **New-SendConnector** cmdlet or the **Set-SendConnector** cmdlet.
  When the value of this parameter is `$true`, the connector can only be used by Hub Transport servers in the same Active Directory site. When the value of this parameter is `$false`, the connector can be used by all Hub Transport servers in the Exchange organization.

Network Settings

You can set Send connectors so that they deliver e-mail by using DNS address resolution or by routing the e-mail to a smart host.

Using DNS to Route E-Mail

When the Send connector is set to use DNS MX resource records to route mail automatically, the DNS client on the source server must be able to resolve public DNS records. By default, the DNS server that's configured on the source server's internal network adapter is used for name resolution. You can configure a specific DNS server to use for internal and external DNS lookups by using the EMC to modify the DNS settings on the Exchange server properties. You can also use the Shell to configure the parameters in the **Set-TransportServer** cmdlet.

If you configure a specific DNS server on the transport server to use for external DNS lookups, you must select **Use the external DNS lookup settings on the transport server** on the **Network Settings** page of the New SMTP Send Connector wizard or, in the Shell, on the **Set-TransportServer** cmdlet, set the *UseExternalDNSServersEnabled* parameter to `$true`. The *DnsRoutingEnabled* parameter on the Send connector must also be set to `$true`.

For more information, see the following topics:

- Configure Edge Transport Server Properties
- Configure Hub Transport Server Properties
- Set-TransportServer

Using a Smart Host to Route E-Mail

If you select the Internal usage type for the Send connector, you must specify a smart host. When you route mail through a smart host, the smart host handles delivery to the next hop in the delivery destination. You can use an IP address or the fully qualified domain name (FQDN) of the smart host to specify the smart host identity. The smart host identity can be the FQDN of a smart host server, an MX record, or an A (address) resource record. If you configure an FQDN as the smart host identity, the source server for the Send connector must be able to use DNS name resolution to locate the smart host server.

The smart host for a Send connector with the Internet usage type may be a server that's hosted by your Internet service provider. The smart host for a Send Connector with the Custom or Internal usage types may be another e-mail server in your organization or an e-mail server in a remote domain.

Smart Host Security Settings

When you route mail through a smart host, you must specify how the source server will authenticate to the smart host computer. You can't require security settings for a Send connector unless a smart host destination is specified. For example, an Internet-facing connector can't be set to require TLS.

The following table lists the smart host authentication mechanism that you can configure for a Send connector.

Smart host authentication mechanisms

Security setting	Description

None	Anonymous access is allowed.
Basic authentication	Basic authentication requires that you provide a user name and password. Basic authentication sends credentials in clear text. All smart hosts with which this Send connector is authenticating must accept the same user name and password.
Basic authentication over TLS	Select TLS to encrypt the transmission of the credentials. The receiving server must have a server certificate. The exact FQDN of the smart host, MX record, or A record that's defined on the Send connector as the smart host identity must also exist in the server certificate. The Send connector will attempt to establish the TLS session by sending the STARTTLS verb to the destination server and will only perform Basic authentication after the TLS session has been established. A client certificate is also required to support mutual TLS authentication.
Exchange Server authentication	Exchange Server authentication (Generic Security Services application programming interface (GSSAPI) and Mutual GSSAPI)
Externally Secured (for example, with IPsec)	The network connection is secured using a method that's external to the Exchange server.

Source Server

You must select at least one source server for a Send connector. The source server is the transport server to which messages are routed for delivery through the selected Send connector. You can set more than one source server on a Send connector that's configured for the Exchange organization. When you specify more than one source server, you provide load balancing and redundancy if a server fails. The source servers associated with Send connectors that are configured for the Exchange organization can be Hub Transport servers or subscribed Edge Transport servers.

FQDN

The **General** tab of the Send connector properties in the EMC includes the option **Specify the FQDN this connector will provide in response to HELO or EHLO**. In the Shell, this property is set by using the *Fqdn* parameter with the **Set-SendConnector** cmdlet. After an SMTP session is established, an SMTP protocol conversation starts between a sending e-mail server and a receiving e-mail server. The sending e-mail server or client sends the EHLO or HELO SMTP command and its FQDN to the receiving server. In response, the receiving server sends a success code and provides its own FQDN. In Exchange 2010, you can customize the FQDN that's provided by the sending server if you configure this property on a Send connector. The value of the *Fqdn* parameter is displayed to connected messaging servers whenever a source server name is required, as in the following examples:

- In the most recent Received: header field of the message that's added to the message by the next hop messaging server after the message leaves the Hub Transport server or Edge Transport server
- During TLS authentication

If the Send connector is configured on a Hub Transport server that also has the Mailbox server role installed, any value that you specify for the *Fqdn* parameter isn't used. Instead, the FQDN of the server that's displayed by using the **Get-ExchangeServer** cmdlet is always used.

For servers that have both the Hub Transport server role and the Mailbox server role installed, the only way to remove the server name from the Received: headers of the outgoing message is to use the **Remove-ADPermission** cmdlet to remove the Ms-Exch-Send-Headers-Routing permission from the security principals that use the connector. This action will remove all the Received: headers from the message as the message leaves the Hub Transport server. We recommend that you don't remove the Received: headers for internal messages, because the Received: headers are used for maximum hop count calculations. For more information about the **Remove-ADPermission** cmdlet and the **Get-ExchangeServer** cmdlet, see the following topics:

- Remove-ADPermission
- Get-ExchangeServer

New Features in Exchange 2010 Service Pack 1

In Service Pack 1 (SP1) for Exchange Server 2010, new functionality was added to Send connectors. This section provides an overview of these new features.

Support for Downgrading Connection Failures

You may have dedicated Send connectors that are responsible for transmitting messages over well-defined communication channels that are expected to always be available, such as a Send connector dedicated to send messages to Microsoft Office 365 or to one of your partners over a private channel. On such connections, many of the typical errors that are possible on ordinary destinations on the Internet aren't expected. In this scenario, you may want to treat any communication errors as transient as opposed to issuing non-delivery reports (NDRs). With Exchange 2010 SP1, you can configure a Send connector to downgrade authentication and name resolution errors, which would normally result in an NDR, to transient errors. In these cases, Exchange will attempt delivery again instead of issuing an NDR.

Downgrading connection failures over reliable connections give you an opportunity to troubleshoot and resolve problems without impacting your users.

Important:

This feature should only be enabled for Send connectors that transmit messages over well-defined and reliable networks. You shouldn't enable this feature for your Send connectors to the Internet.

To configure this feature, you use the *ErrorPolicies* parameter of the **Set-SendConnector** cmdlet. You can choose to downgrade authentication failures, DNS failures or both for any Send connector. For more information about configuring this property, see Set-SendConnector.

Support for TLS Domain Validation

Exchange 2010 SP1 provides support for domain validation for outbound TLS connections. Domain validation is an additional security feature that reduces the risk of malicious users impersonating a receiving server. When you enable domain validation on a Send connector, the Transport server performs the following security checks on the outbound connection:

- The communication channel is encrypted using TLS.
- The certificate of the receiving server is validated and revocation list checks are performed.
- The Transport server verifies that the FQDN on the certificate of the receiving

server matches the domain configured in the Send connector properties.

When you enable domain validation on a Send connector, you also have to specify the domain name to validate against. Both of these properties are configurable using the *TlsAuthLevel* and *TlsDomain* parameters of the **Set-SendConnector** cmdlet. For more information about configuring this feature, see Set-SendConnector.

1.7.1.32 Understanding Shadow Redundancy

Understanding Shadow Redundancy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-19*

High availability strategies for Exchange have focused on the availability and recoverability of data stored in mailbox databases. When you implement a highly available solution for your Mailbox servers, the e-mail messages won't be lost, and they can easily be recovered after a failure, after they arrive in a mailbox.

However, these strategies didn't extend to messages while they're in transit. If a Hub Transport server fails while processing messages and can't be recovered, data loss could occur. As the volume of messages processed by Hub Transport servers increases, potential data loss becomes an increasing concern for administrators.

Microsoft Exchange Server 2007 introduced the transport dumpster feature for the Hub Transport server role. An Exchange 2007 Hub Transport server maintains a queue of messages delivered recently to recipients whose mailboxes are on a clustered mailbox server. When a failover is experienced, the clustered mailbox server automatically requests every Hub Transport server in the Active Directory site to resubmit mail from the transport dumpster queue. This prevents mail from being lost during the time taken for the cluster to fail over. While this does provide a basic level of transport redundancy, it's only available for message delivery in a cluster continuous replication (CCR) environment and doesn't address potential message loss when messages are in transit between Hub Transport and Edge Transport servers.

Exchange Server 2010 introduces the *shadow redundancy* feature to provide redundancy for messages for the entire time they're in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport databases is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting back successful delivery, the message is resubmitted for delivery to that next hop.

Shadow redundancy provides the following benefits:

- It eliminates the reliance on the state of any specific Hub Transport or Edge Transport server. As long as redundant message paths exist in your routing topology, any transport server becomes disposable.
- If a transport server fails, you can remove it from production without emptying its queues or losing messages.
- If you want to upgrade a Hub Transport or Edge Transport server, you can bring that server offline at any time without the risk of losing messages.
- It eliminates the need for storage hardware redundancy for transport servers.
- It consumes less bandwidth than creating duplicate copies of messages on multiple servers. The only additional network traffic generated with shadow

redundancy is the exchange of *discard status* between transport servers. Discard status is the information each transport server maintains. It indicates when a message is ready to be discarded from the transport database.
- It provides resilience and simplifies recovery from a transport server failure.

Shadow redundancy is implemented by extending the SMTP service. The service extensions allow SMTP hosts to negotiate shadow redundancy support and exchange discard status for shadow messages.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Shadow Redundancy Components

The following table provides descriptions of all the components of shadow redundancy.

Shadow redundancy components

Component	Description
Primary message	The original message submitted to transport for delivery.
Shadow message	The copy of a message that a transport server retains until it confirms that all the next hops for that message have successfully delivered it.
Primary server	The transport server that's currently processing a message.
Shadow server	The transport server that holds shadow copies of a message after delivering the message to the primary server.
Shadow queue	The queue that a transport server uses to store shadow messages. A transport server will have separate shadow queues for each hop to which it delivered the primary message.
Discard status	The information a transport server maintains for shadow messages that indicate when a message is ready to be discarded.
Discard notification	The response a shadow server receives from a primary server indicating a message is ready to be discarded.
Shadow Redundancy Manager	The transport component that manages shadow redundancy.
Heartbeat	The process of transport servers verifying the availability of each other.

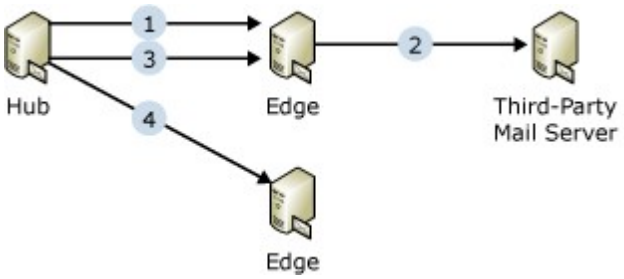
Return to top

Shadow Redundancy Message Flow

To illustrate the mail flow with shadow redundancy enabled, consider the simple scenario

where a Hub Transport server sends a message to a third-party mail server via an Edge Transport server in the perimeter network.

Message flow with shadow redundancy



In this scenario, the message flow goes through following stages:

1. The Hub Transport server delivers a message to the Edge Transport server.
   - 1.a. The Hub Transport server opens an SMTP session with the Edge Transport server.
   - 1.b. The Edge Transport server advertises shadow redundancy support.
   - 1.c. The Hub Transport server notifies the Edge Transport server to track discard status.
   - 1.d. The Hub Transport server submits the message to the Edge Transport server.
   - 1.e. The Edge Transport server acknowledges the receipt of the message and records the Hub Transport server identity for sending discard information for the message.
   - 1.f. The Hub Transport server moves the message to the shadow queue for the Edge Transport server and marks the Edge Transport server as the primary server. The Hub Transport server becomes the shadow server.
2. The Edge Transport server delivers the message to the next hop.
   - 2.a. The Edge Transport server submits the message to a third-party mail server.
   - 2.b. The third-party mail server acknowledges the receipt of the message.
   - 2.c. The Edge Transport server updates the discard status for the message as delivery complete.
3. The Hub Transport server queries the Edge Transport server for discard status (success case).
   - 3.a. At the end of each SMTP session with the Edge Transport server, the Hub Transport server queries the Edge Transport server for discard status on messages previously submitted. If the Hub Transport server hasn't opened any SMTP sessions with the Edge Transport server after the initial message submission, it will open an SMTP session with the Edge Transport server just to query for the discard status after a specific amount of time.
   - 3.b. The Edge Transport server checks the local discard status and sends back the list of messages that have been delivered, and removes the discard information.
   - 3.c. The Hub Transport server deletes the list of messages from its shadow queue.
4. The Hub Transport server queries the Edge Transport server for the discard status and resubmits the message (failure case).
   - 4.a. If the Hub Transport server can't contact the Edge Transport server, the Hub Transport server resumes the primary server role and resubmits the messages in the shadow queue.
   - 4.b. Resubmitted messages are delivered to another Edge Transport server and the workflow starts from stage 1.

Note:

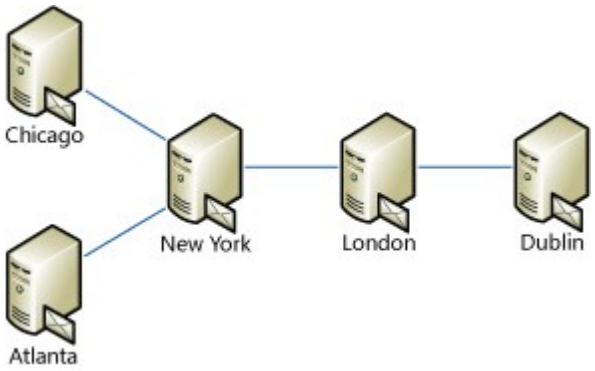
If there are no alternative routes available for a shadow message (such as the second Edge Transport server shown in

the preceding figure), it won't be resubmitted, but remain in the shadow queue.

For more information about message flow in various different scenarios, see Shadow Redundancy Mail Flow Scenarios.

Multiple Hop Scenario

If a message travels through multiple servers that support shadow redundancy, the shadow messages are retained on a server only until the next server in the message path confirms delivery. To illustrate how this works, consider an organization that has five Active Directory sites with Hub Transport servers installed. The sites are connected to each other as shown in the following figure. The organization has New York and London sites configured as hub sites, so the messages from Chicago or Atlanta need to go through Hub Transport servers in the New York and London sites to get to the Dublin site.



Assume that a message is sent by a user in the Chicago site to a user in the Dublin site. This message will need to travel through the New York and London sites to get to Dublin. In this case, the following occurs:

1. The Hub Transport server in Chicago will send the message to the Hub Transport server in New York, and it will retain a shadow copy of the message.
2. The New York Hub Transport server will send the message to the Hub Transport server in London and queue a discard status for the Chicago hub.
3. The Chicago hub queries the New York hub for discard status and receives the discard notification for the message. At this time, it can remove the shadow message from its database. Whether the message was delivered from London to Dublin doesn't have an impact on when the Chicago server deletes the shadow message.

Shadow Redundancy Protection when Hub Transport and Mailbox Server Roles Coexist with DAGs

When using database availability groups (DAGs), the messages that are already committed to mailbox databases are protected with the DAG architecture. For any message delivered to a mailbox database that's part of a DAG, the shadow copy for that message is retained in the transport dumpster until that message is replicated to all DAG members. Similarly, any message submitted to Hub Transport servers from a DAG member has two copies, one in the Hub Transport server queue waiting for delivery, and a shadow copy in the sender's Sent Items folder. This approach is a key component of shadow redundancy.

However, when the Hub Transport and Mailbox server roles coexist on the same server, and you have mailbox databases that are part of a DAG, Hub Transport servers may have to route a message through an extra hop to avoid having the primary message and the shadow message on the same server hardware. Specifically, the Hub Transport server role attempts to avoid the following two scenarios because a failure of a single server

may result in the loss of both the primary and shadow messages:

- **During message delivery, where the active mailbox database of the message recipient and the transport dumpster containing the shadow copy of the message are on the same server** To avoid this scenario, the Hub Transport server routes the message through another Hub Transport server within the site to ensure that the shadow message ends up on different server hardware. However, if no other Hub Transport servers are available, it delivers the message directly.
- **During message submission, where the transport queue holding the primary message and the shadow message in the Sent Items folder of the sender are on the same server** To avoid this scenario, the store driver prefers other Hub Transport servers in the site for message submission. However, if no other Hub Transport servers are available in the site, it submits the message to the local Hub Transport server.

For more information about Hub Transport and Mailbox server role coexistence when using DAGs, see Hub Transport and Mailbox Server Roles Coexistence When Using DAGs.

Interoperability

Whether shadow redundancy will be used or not is decided while establishing a new SMTP connection. If both servers in an SMTP connection support shadow redundancy, the workflow mentioned previously is used. However, there will be situations where Exchange 2010 transport servers exchange messages with mail servers that don't support shadow redundancy. These could be third-party mail servers, earlier versions of Exchange, or an Exchange 2010 organization that hasn't enabled shadow redundancy.

When an Exchange 2010 transport server that supports shadow redundancy establishes a connection with a server that doesn't support shadow redundancy, the following events take place:

1. Exchange establishes an SMTP connection to the target server.
2. The target server doesn't advertise shadow redundancy support.
3. Because the target server doesn't support redundancy, Exchange will perform the following for each message:
   3.a. Deliver the message to the target server.
   3.b. Shadow Redundancy Manager will mark that the message is delivered to the next hop.
   3.c. Delete the message after it's delivered to all of the next hops.

When a server that doesn't support shadow redundancy establishes a connection with an Exchange 2010 server, the following events take place:

1. The sending server establishes an SMTP connection with Exchange.
2. Exchange advertises shadow redundancy support.
3. The sending server doesn't support shadow redundancy and therefore it won't use it. It will deliver messages to the Exchange server.
4. For each message Exchange receives, it will do the following:
   4.a. Deliver the message to the next hop, or make a shadow copy of it.
   4.b. Send acknowledgement to the sending server.

Delayed Acknowledgement

The main principle behind shadow redundancy is maintaining a copy of the message on the previous hop until the server verifies that it has successfully delivered it to all the next hops. This isn't possible when an Exchange 2010 transport server is receiving a message from a mail server that doesn't support shadow redundancy. This mail server can be an Exchange server running an older version of Exchange, a standard SMTP client, or a non-Exchange mail server on the Internet. In this case, Exchange attempts to achieve shadow redundancy by delaying the acknowledgement to the mail server until it verifies that the message has been successfully delivered to all the next hops internally. This way, if the Exchange 2010 server fails, the sending mail server will assume that the message was never delivered to Exchange and will attempt delivery again.

However, the delivery of the message to the next hops may take a long time due to the complexity of your routing infrastructure, or failure of one of the next hops. In this case, to prevent the SMTP session from timing out, the Exchange 2010 transport server will send an acknowledgement to the sending mail server. In this case, the mail redundancy isn't guaranteed, but it's a best effort. For example, a message may be lost in the following scenario: An Internet mail server transmits a message to an Edge Transport server. The Edge Transport server can't communicate with the Hub Transport server due to a network problem and acknowledges the receipt of the message to the Internet mail server. The Edge Transport server then fails and can't be recovered before the network problem is resolved. At this point, the message is lost.

The delayed acknowledgement time-out value is controlled by the *MaxAcknowledgementDelay* attribute of each Receive connector. The default value is 30 seconds. To learn more about configuring this attribute, see Configure Shadow Redundancy.

Bypassing Delayed Acknowledgement

There are cases where it's unlikely a message will be delivered before the delayed acknowledgement time-out is reached. In these cases, the transport server uses one of the following methods to handle messages:

- **Skipping delayed acknowledgement** By default, the transport server skips the delayed acknowledgement to maintain SMTP receive throughput. In essence, the transport server issues an acknowledgment before the time-out is reached.
- **Shadow redundancy promotion** In Microsoft Exchange Server 2010 Service Pack 1 (SP1), instead of skipping the delayed acknowledgement, the transport server can be configured to relay the message to any other transport server in the site. This effectively inserts the message into the shadow redundancy pipeline, thereby protecting the message. This process is called *shadow redundancy promotion*. This approach minimizes the number of unprotected messages in the organization when compared to the skipping delayed acknowledgement method. By default, this feature is disabled. To enable shadow redundancy promotion, an administrator must edit the Edgetransport.exe.config file, change the **shadowredundancypromotionenabled** key to **true**, save the changes to the file, and then restart the Microsoft Exchange Transport service (MSExchangeTransport.exe). For more information about how to do this, see the "Enable Shadow Redundancy Promotion" section in the Configure Shadow Redundancy topic.

The following table lists different scenarios ion which a transport server bypasses delayed acknowledgement, and describes how an Exchange 2010 server handles that scenario.

Scenario	Exchange 2010 default behavior (skipping delayed acknowledgement)	Exchange 2010 SP1 with shadow redundancy promotion enabled
The target queue for the message is either in suspended or retry state.	The receiving transport server skips the delayed acknowledgement.	The receiving transport server immediately uses shadow redundancy promotion.
The target queue enters retry state after the message is added to it.	The receiving transport server skips the delayed acknowledgement for subsequent messages until the target queue returns to ready state.	The receiving transport server uses shadow redundancy promotion for subsequent messages until the target queue returns to ready state.
An administrator suspends	If the administrator suspends	If the administrator suspends

either the target queue or the message.	the target queue, the receiving transport server skips the delayed acknowledgement until the target queue returns to ready state. If the administrator suspends the message, the receiving transport server handles subsequent messages normally.	the target queue, the receiving transport server uses shadow redundancy promotion until the target queue returns to ready state. If the administrator suspends the message, the receiving transport server handles subsequent messages normally.
The target queue for the message has more than 100 messages.	The receiving transport server skips the delayed acknowledgement until the target queue size falls below 100.	If the target queue has any messages in it, the receiving transport server uses shadow redundancy promotion for subsequent messages until the queue clears.

Return to top

Shadow Redundancy Manager

Shadow Redundancy Manager is the core component of an Exchange 2010 transport server that's responsible for managing shadow redundancy.

Shadow Redundancy Manager is responsible for maintaining the following information for all the primary messages that a server is currently processing:

- The shadow server for each primary message being processed.
- The discard status to be sent to shadow servers.

Shadow Redundancy Manager is responsible for the following for all the shadow messages that a server has in its shadow queues:

- Maintaining the list of primary servers for each shadow message.
- Checking the availability of each primary server for which a shadow message is queued.
- Processing discard notifications from primary servers.
- Removing the shadow messages from the database after all expected discard notifications are received.
- Deciding when the shadow server should take ownership of shadow messages, becoming a primary server.

In addition, Shadow Redundancy Manager is also responsible for managing performance counters related to shadow redundancy.

Heartbeat

Shadow Redundancy Manager uses heartbeat to determine the availability of the servers for which shadow messages are queued. During the SMTP session between two servers that both support shadow redundancy, the server that initiates the connection queries the target server for discard status of messages previously submitted to that server. The initiating server accomplishes this by issuing an XQUERYDISCARD command. In response, the target server returns the discard notifications. This exchange between the two servers is used as the heartbeat for shadow redundancy.

There is a time-out value for the heartbeat. If no connections are established to a server for which Shadow Redundancy Manager is maintaining a shadow queue for that duration, the server will attempt to establish an SMTP connection with the primary server

specifically to query the discard status and reset the timer. The time-out value is controlled by the *ShadowHeartbeatTimeoutInterval* parameter of the **Set-TransportConfig** cmdlet. The default value for this parameter is 300 seconds in the release to manufacture (RTM) version of Exchange 2010, and 900 seconds in Exchange 2010 SP1.

If the server can't establish a connection to a primary server when the time-out value is reached, it will reset the timer and try again. If the time-out value is reached twelve times in a row (three times in a row in Exchange 2010 RTM), the server will conclude that the primary server has failed and will assume ownership of the shadow messages and begin to generate discard notifications for them to send to the primary server that failed. The number of time-outs a server will wait before deciding a primary server has failed is controlled by the *ShadowHeartbeatRetryCount* parameter of the **Set-TransportConfig** cmdlet.

To learn more about configuring the shadow redundancy heartbeat, see Configure Shadow Redundancy.

Return to top

Message Processing After an Outage

Shadow redundancy minimizes message loss due to server outages. When a transport server comes back online after an outage, there are two scenarios:

- **The server comes back online with a new transport database** In this scenario, the transport database is unrecoverable due to data corruption or hardware failure. In this case, because the transport server will have a new database ID, it will be recognized as a new route by the other transport servers in the organization. This also applies to the situation where a server couldn't be recovered, and a new server was provisioned as a replacement.
- **The server comes back online with the same transport database** In this scenario, the particular transport server didn't fail, but was offline for an extended period of time. For example, a network card failure, or a long maintenance on the server would cause this scenario.

The following table summarizes how transport reacts to these two scenarios when shadow redundancy is enabled. For clarity, assume that the server that had an outage is named Hub01.

Message processing in recovery scenarios

Recovery scenario	Actions taken for messages that have alternative routes	Actions taken for messages with no alternative routes
Hub01 comes back online with a new database.	When Hub01 becomes unavailable, each server that has shadow messages queued for Hub01 will assume ownership of those messages and resubmit them. The messages then get delivered to their destinations using alternative routes. The total delay for messages is equal to the product of the heartbeat time-out interval and the heartbeat retry count configured in your	These messages remain in the shadow queue on each server that has shadow messages queued for Hub01. When Hub01 comes back online with a new database ID, the shadow servers detect that it's a new database and resubmit the messages that are in the shadow queue to Hub01. This is equivalent to suddenly discovering an alternative route for these messages. The total delay for the

	organization.	messages depends on the duration of the outage.
Hub01 comes back online with the same database.	Hub01 will deliver the messages in its queues. This will result in duplicate delivery of these messages. Exchange mailbox users won't see duplicate messages due to duplicate message detection. However, recipients on foreign systems may receive duplicate copies. The total delay for messages is equal to the product of the heartbeat time-out interval and the heartbeat retry count configured in your organization.	Hub 01 will deliver the messages in its queues and then send discard notifications to the shadow servers. The total delay for the messages depends on the duration of the outage.

Return to top

Extended Rights Required for Shadow Redundancy

Exchange 2010 introduces the following two extended rights, which are required for shadow redundancy:

- ms-Exch-SMTP-Accept-XSHADOW
- ms-Exch-SMTP-Send-XSHADOW

When an SMTP connection is established to an Exchange 2010 transport server, it will advertise shadow redundancy support if the ms-Exch-SMTP-Accept-XSHADOW extended right exists on the Receive connector being used. In addition, the authentication mechanism on the Receive connector should be either Exchange Server authentication or Externally Secured.

When an Exchange 2010 transport server establishes an SMTP connection to another server that advertises shadow redundancy support, it will issue an XSHADOW command only if the session has been granted the ms-Exch-SMTP-Send-XSHADOW extended right.

By default, these extended rights are granted to the Exchange Servers group on all internal Send connectors and Receive connectors.

Note:

Shadow redundancy can be enabled or disabled for the entire organization using the *ShadowRedundancyEnabled* parameter of the **Set-TransportConfig** cmdlet. This setting overrides the extended rights described in this section. If shadow redundancy is disabled for the organization, Exchange will never advertise shadow redundancy support or issue XSHADOW commands even if the necessary extended rights are granted to the SMTP session.

1.7.1.32.1 Shadow Redundancy Mail Flow Scenarios

Shadow Redundancy Mail Flow Scenarios

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

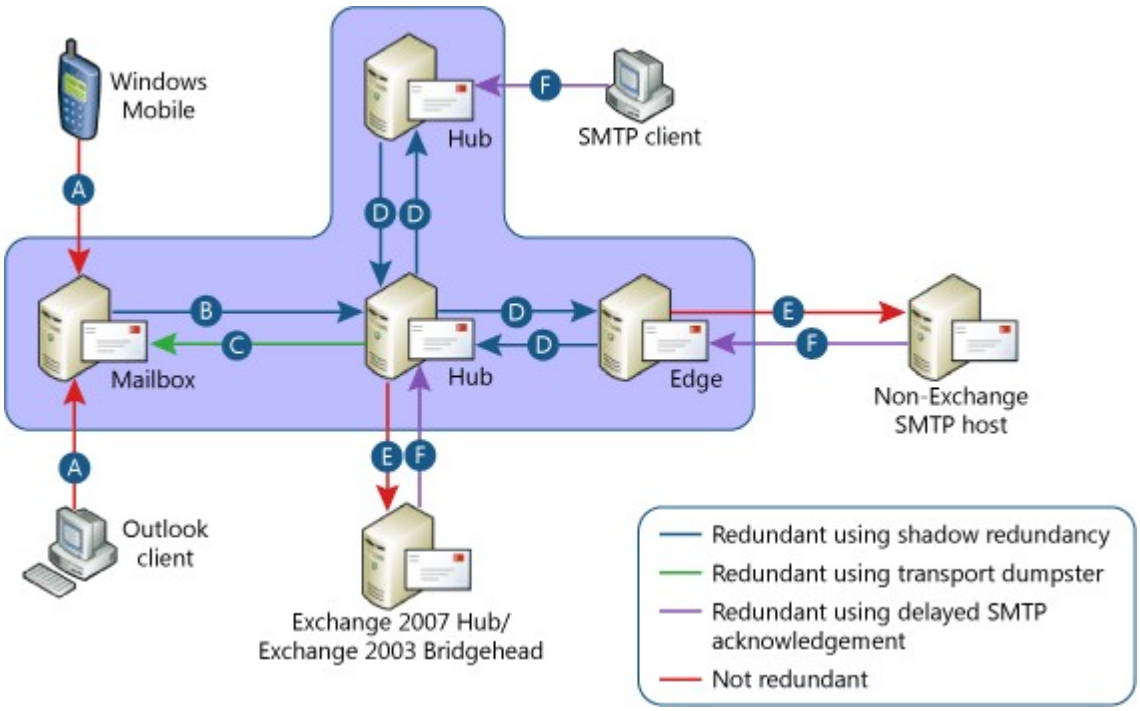
Topic Last Modified: *2010-06-07*

The shadow redundancy feature in Microsoft Exchange Server 2010 provides redundancy for messages for the entire time they're in transit. The general message flow is explained in Understanding Shadow Redundancy. This topic explains in detail what happens for each specific message flow scenario that can involve Exchange.

Mail Flow Scenarios

The following figure shows each possible redundancy scenario in an Exchange organization and how message redundancy is achieved in each scenario. The shaded area shows where shadow redundancy is in effect. Exchange 2010 shadow redundancy prevents data loss while messages are in transit within the shaded area.

Note:
Client Access servers are omitted from the figure for simplicity.



As can be seen from the preceding figure, all mail flow paths possible in an Exchange organization fit into one of the following scenarios:

A. MAPI/Windows Mobile Client Submission

B. Mail Flow from Mailbox Server to Hub Transport Server

C. Message Delivery from Hub Transport Server to Mailbox Server

D. Mail Flow Between Exchange 2010 Transport Servers

E. Mail Flow from Exchange 2010 Transport Servers to Mail Servers That Don't Support Shadow Redundancy

F. Mail Flow from Mail Servers That Don't Support Shadow Redundancy to Exchange 2010 Transport Servers

The following sections explain what happens for each mail flow scenario.

A. MAPI/Windows Mobile Client Submission

Message submissions from MAPI or Windows Mobile clients aren't redundant. After the message is successfully stored on the Mailbox server, Exchange high availability features can take effect and help prevent data loss. This scenario provides a complete picture of message flow, from beginning to end.

Return to the list of mail flow scenarios

B. Mail Flow from Mailbox Server to Hub Transport Server

The following actions take place when an Exchange 2010 Mailbox server submits messages to an Exchange 2010 Hub Transport server.

Important:

Exchange 2010 Mailbox servers can't communicate with transport servers running previous versions of Exchange. Therefore, this topic only discusses mail flow from an Exchange 2010 Mailbox server to an Exchange 2010 Hub Transport server.

1. The mail submission service notifies the Hub Transport server that there is a new message.
2. The Hub Transport server picks up the message from the Outbox of the mailbox submitting the message and stores it in its database.
3. If the message has recipients on Mailbox servers that are in the same Active Directory site, the Hub Transport server delivers the message to the destination mailboxes, following the steps listed in scenario C. For all other recipients, the Hub Transport server delivers the message to the next hop.
4. After delivery to the next hop is complete, the Hub Transport server notifies the Mailbox server that it has finished processing the message and assumed ownership of the message. After this notification, the message is deleted from the Outbox.
5. If none of the other hops for the message support shadow redundancy, the Hub Transport server deletes the message. Otherwise, it converts the message to a shadow message by storing it in the shadow queues for the hops to which it delivered the message.

Return to the list of mail flow scenarios

C. Message Delivery from Hub Transport Server to Mailbox Server

The following actions take place when an Exchange 2010 Hub Transport server delivers messages to an Exchange 2010 Mailbox server.

Important:

Exchange 2010 Hub Transport servers can't communicate with Mailbox servers running previous versions of Exchange. Therefore, this topic only discusses mail flow from an Exchange 2010 Hub Transport server to an Exchange 2010 Mailbox server.

1. The Hub Transport server delivers the message to the destination mailboxes.
2. After the message is delivered to all the destination mailboxes, the Hub Transport server adds the message to the transport dumpster.
3. The Hub Transport server queues discard notifications to the hop from which it has received the message. These discard notifications are created when

the hop queries the Hub Transport server.
4. The previous hop deletes the corresponding shadow message.

Return to the list of mail flow scenarios

D. Mail Flow between Exchange 2010 Transport Servers

The mail flow process is identical for all message exchanges between transport servers running Exchange 2010, whether it's between two Hub Transport servers or between a Hub Transport server and an Edge Transport server. The following actions take place when a message is transferred from one Exchange 2010 transport server to another. For clarity purposes, assume that the server that's sending the message is called Hub01 and the server that's receiving the message is called Edge01.

1. Hub01 establishes an SMTP connection to Edge01.
2. Edge01 advertises shadow redundancy support.
3. Hub01 requests shadow redundancy in the SMTP session by issuing an **XSHADOW** command. The process is similar to establishing Transport Layer Security (TLS) on an SMTP session.
4. For each message that Hub01 needs to send to Edge01:
   4.a. Hub01 transmits the message to Edge01.
   4.b. Edge01 marks the message as shadowed by Hub01.
   4.c. Hub01 marks Edge01 as the primary server and adds it to its shadow queue for Edge01.
   4.d. Hub01 prepares discard notifications for the message to be sent to the hop from which it received the message.
5. Hub01 queries Edge01 for discard status of messages it has previously submitted to Edge01.
6. Edge01 sends all discard notifications that it has prepared for Hub01. These could be for messages that are sent in the same SMTP session or for those that were sent during previous SMTP sessions.
7. Hub01 deletes all shadow messages for which Edge01 has sent a discard notification.

Return to the list of mail flow scenarios

E. Mail Flow from Exchange 2010 Transport Servers to Mail Servers That Don't Support Shadow Redundancy

Neither Exchange Server 2007 transport servers nor Exchange Server 2003 bridgehead servers support shadow redundancy. Therefore, if you have a coexistence scenario with previous versions of Exchange, Exchange 2010 redundancy features can guarantee message delivery only until the legacy Exchange hop, and not all the way to its destination. The same applies to the scenario where Exchange 2010 Edge Transport servers send messages to non-Exchange mail servers.

The following actions take place when an Exchange 2010 Hub Transport server sends a message to an Exchange transport server running a previous version of Exchange, or an Exchange 2010 Edge Transport server sends a message to a non-Exchange mail server. For clarity, assume that an Exchange 2010 Hub Transport server called Hub01 is sending a message to an older Exchange transport server called Legacy01.

1. Hub01 establishes an SMTP connection to Legacy01.
2. Legacy01 doesn't advertise shadow redundancy support.
3. Because Legacy01 didn't advertise shadow redundancy, Hub01 doesn't initiate shadow redundancy on the SMTP session.
4. Hub01 delivers the message to Legacy01.
5. Hub01 deletes the message.
6. Hub01 prepares discard notifications for the hop from which it received the message.

Return to the list of mail flow scenarios

F. Mail Flow from Mail Servers That Don't Support Shadow

Redundancy to Exchange 2010 Transport Servers

There are four entry points to an Exchange organization where a mail server that doesn't support shadow redundancy may establish an SMTP connection to an Exchange 2010 transport server and send messages.

- An Exchange 2010 Unified Messaging (UM) server connecting to an Exchange 2010 Hub Transport server.
- An Exchange transport server that's running Exchange 2007 or Exchange 2003 connecting to an Exchange 2010 Hub Transport server.
- A non-Exchange mail server on the Internet connecting to an Exchange 2010 Edge Transport server.
- A non-Exchange mail server in the organization, such as a UNIX server, or an SMTP client that's submitting messages to an Exchange 2010 Hub Transport server.

In this scenario, Exchange 2010 achieves shadow redundancy using a feature called *delayed acknowledgement*. When an Exchange 2010 transport server receives a message from a mail server that doesn't support shadow redundancy, it delays sending an acknowledgement to the sending mail server until it has confirmed that the message has been successfully delivered to its destination. For more information about delayed acknowledgement, see Understanding Shadow Redundancy.

To illustrate this scenario, assume that an Exchange 2010 Edge Transport server called Edge01 is receiving a message from a non-Exchange mail server on the Internet called Internet01. In this example, the following actions take place:

1. Internet01 establishes an SMTP connection to Edge01.
2. Edge01 advertises shadow redundancy support.
3. Because Internet01 doesn't support shadow redundancy, it simply sends the message to Edge01.
4. Edge01 marks the message as a delayed acknowledgement message.
5. Edge01 delivers the message to the next hops using the steps outlined in scenario D.
6. Edge01 queries the next hops for the discard status of the message.
7. After Edge01 receives discard notifications from all of the next hops, it sends the acknowledgement to Internet01.
8. Edge01 deletes the message from its database.

Note:
If Edge01 can't verify successful delivery of the message to all of the next hops within 30 seconds, it will time out and send an acknowledgement to Internet01. This time-out value is controlled by the value of the *MaxAcknowledgementDelay* attribute of the Receive connector.

1.7.1.32.2 Hub Transport and Mailbox Server Roles Coexistence When Using DAGs

Hub Transport and Mailbox Server Roles Coexistence When Using DAGs

Transport > Understanding Transport > Understanding Shadow Redundancy >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-19*

Microsoft Exchange Server 2007 doesn't support Hub Transport and Mailbox server roles on the same server hardware when high availability features such as single copy cluster

(SCC) or cluster continuous replication (CCR) are used. A minimum high availability deployment in Exchange 2007 requires four servers: two nodes for mailbox high availability and two Hub Transport servers for message transfer redundancy.

To reduce the number of servers required to provide a high availability solution, Exchange Server 2010 supports Hub Transport and Mailbox server roles on the same server hardware when using database availability groups (DAGs). Exchange 2010 provides a feature called *shadow redundancy*, which protects against data loss while messages are in transit. When used together, DAGs and shadow redundancy offer a highly resilient messaging infrastructure.

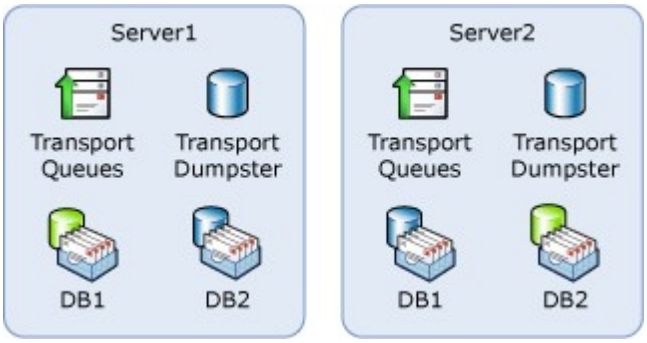
This topic focuses on how the Exchange 2010 Hub Transport server role behaves when deployed on the same server hardware as a Mailbox server that participates in a DAG. To learn more about DAGs, see Understanding Database Availability Groups.

Message Submission and Delivery

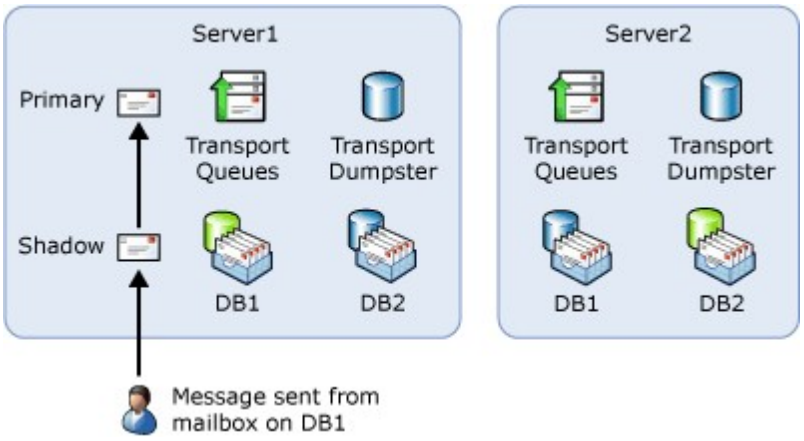
Shadow redundancy prevents data loss while messages are in transit by keeping a duplicate copy of the message along the message path. If a message is lost in transit due to a failure, the shadow copy of the message is resubmitted by the Transport component. For detailed information about how shadow redundancy is implemented, see Understanding Shadow Redundancy.

Mailbox servers are involved during initial message submission, when a user clicks **Send**, and during final delivery, when the message is saved to the Inbox of the recipient. When a message is submitted to Transport, the primary copy of that message is in the queues of the Hub Transport server to which the message was submitted. The shadow copy of that message is the item stored in the Sent Items folder of the sender. When a message is delivered, the primary copy is in the recipient's Inbox and the shadow copy of the message is stored in the transport dumpster.

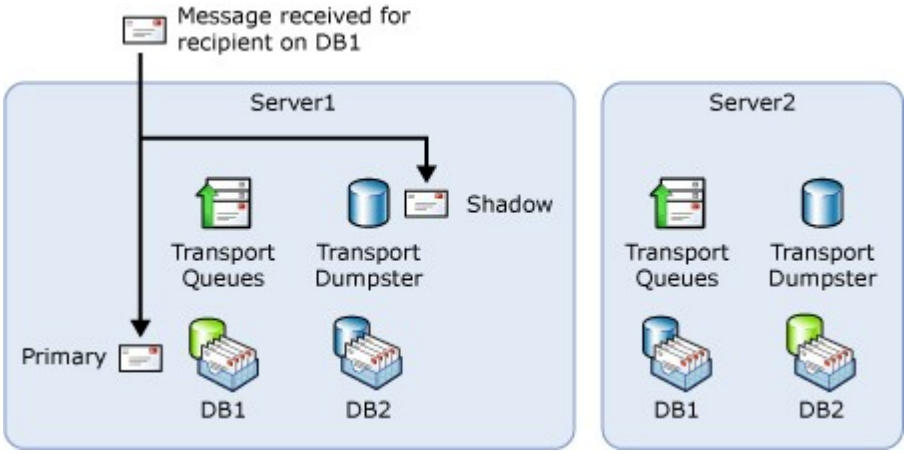
In a high availability scenario where Hub Transport and Mailbox server roles coexist on the same server hardware, it's crucial to try to avoid having both copies of a message reside on the same server. Consider the deployment scenario shown in the following figure. The topology consists of two Exchange servers participating in a DAG with the Hub Transport server role installed. The databases DB1 and DB2 are part of the DAG. Active databases are shown in green, and passive databases are shown in blue.



In this topology, assume that a user whose mailbox is on DB1 sends a message. If that message is submitted to the Hub Transport server role on Server1, both the primary and shadow messages will be physically stored on Server1. The primary messages will be in the Hub Transport server queues, and the shadow messages will be in the Sent Items folder of the sender, as shown in the following figure.



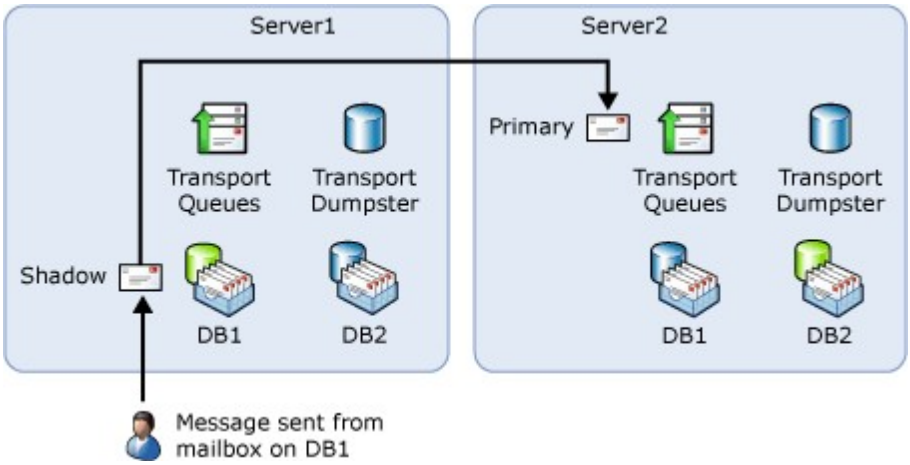
Similarly, if the Hub Transport server role on Server1 receives a message destined to a user on DB1, the message is delivered directly, and both the primary and shadow messages will be physically stored on Server1. The primary messages will be in the Inbox of the recipient, and the shadow messages will be in the transport dumpster, as shown in the following figure. If a server failure occurs at either of those instances, there's a chance that the message can be lost.



To avoid these scenarios where message loss can occur, Exchange attempts to submit or deliver messages over a route that ensures that the primary and shadow copies of messages are stored on different physical servers. The modified message submission and delivery behaviors are discussed in the following section.

Message Submission Behavior

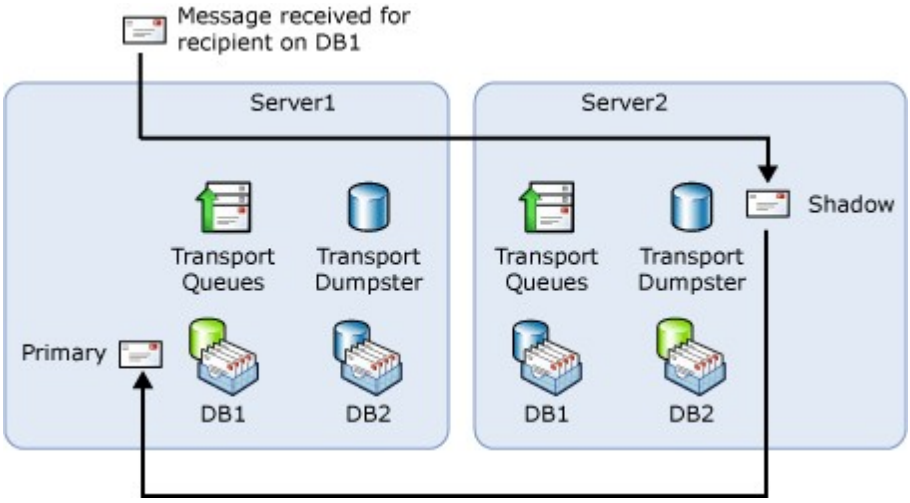
When a user whose mailbox is in a database that's a member of a DAG sends a message, the mail submission service gives preference to remote Hub Transport servers if it detects that the Hub Transport server is also installed on the local server. As shown in the figure "Two server high availability topology with Hub Transport and Mailbox server roles", if a user whose mailbox is on DB1 sends a message, the mail submission service will attempt to use the Hub Transport server installed on Server2 for message submission. The following figure shows this preferred message submission path.



In the case where no other Hub Transport servers are available in the site (for example, if Server2 is unavailable due to scheduled maintenance), the message submission service will fall back to submitting the message to the local Hub Transport server. Even though this is an undesirable submission path for redundancy, Exchange won't delay delivery of messages. This fallback submission path is desirable for availability and low delivery latency.

Message Delivery Behavior

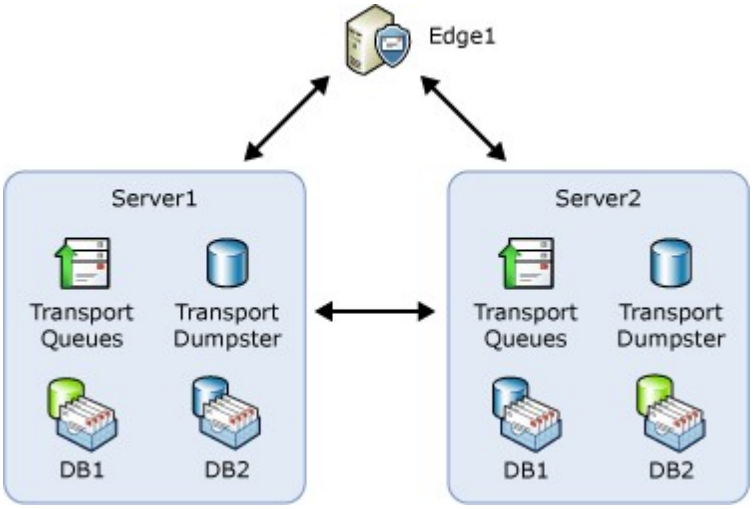
The message routing and delivery behavior doesn’t change in most cases. For example, if Server1 shown in the figure "Two server high availability topology with Hub Transport and Mailbox server roles" receives a message for a recipient on DB2, it will deliver the message normally because that database is active on a different server. The only scenario when a Hub Transport server will process an incoming message differently is when the target mailbox is on a database that's part of a DAG and is also active on the local server. Because a direct delivery in this situation would result in both the delivered message and the copy in the transport dumpster being on the same server, the Hub Transport server will instead reroute this message to another Hub Transport server within the same site. The following figure shows the message delivery path in this scenario.



In the case where no other Hub Transport servers are available in the site, the Hub Transport server will fall back to local delivery even though it's an undesirable delivery path for redundancy. Again, this fallback delivery path is desirable for availability and low delivery latency.

Message Flow Scenarios

This section explains in detail what happens in various message flow scenarios when Hub Transport and Mailbox server roles coexist on the same server. The topology shown in the following figure is used to illustrate various possible message flow scenarios.



The following table shows how the Hub Transport server role on Server1 processes messages in various scenarios. In all of these cases, Server1 is considered the entry point.

Sender location	Recipient location	Normal message path	High availability scenarios
DB1, active on Server1	DB1, active on Server1	1. Submission service on Server1 submits a message to the Hub Transport server role on Server2. 2. Hub Transport server role on Server2 delivers the message to DB1 on Server1 and adds the message to the transport dumpster on Server2.	• If Server1 fails before the message submission completes, the message in the sender's Outbox may be lost. • If Server2 fails before the message submission completes, the message is submitted to the Hub Transport server role on Server1. • If Server1 fails after the message submission to the Hub Transport server role on Server2 completes, DB1 will become active on

			Server2. The message will be queued on Server2 until DB1 is mounted, and then the Hub Transport server role delivers the message locally. • If Server2 fails after the message submission to Hub Transport server role on Server2 completes, the shadow message in DB1 is resubmitted to the Hub Transport server role on Server1, which delivers the message locally. • If Server1 fails after the message delivery is completed, DB1 will become active on Server2. If the delivered message hasn't yet been committed to the database, it's redelivered from the transport dumpster on Server2.
DB1, active on Server1	DB2, active on Server2	1. Submission service on Server1 submits the message to the Hub Transport server role on Server2. 2. Hub Transport server role on Server2 reroutes the message to the Hub Transport server role on Server1. 3. Hub Transport server role on Server1 delivers	• Any server failures prior to the completion of message submission are handled in the same manner as described in the previous row. • If Server1 fails after the message submission to the Hub Transport server role on Server2

		the message to DB2 on Server2 and adds the message to the transport dumpster on Server1.	completes, the Hub Transport server role on Server2 will deliver the message locally. • If Server2 fails after the message submission to the Hub Transport server role on Server2 completes, DB2 will become active on Server1. After the Hub Transport server role on Server1 detects that the Hub Transport server role on Server2 is unavailable, it will resubmit the shadow message. After DB2 is mounted on Server1, the message will be delivered locally. • If Server1 fails after the message is rerouted to Server1 for delivery, the Hub Transport server role on Server2 will resubmit the shadow message after it detects the Hub Transport server role on Server1 is unavailable. It will then deliver the message locally. • If Server2 fails after the message is rerouted to Server1 for delivery, DB2 will become active on Server1. The message will remain queued

			on Server1 until DB2 is mounted on Server1 and then it's delivered locally. • If Server2 fails after the message delivery is completed, DB2 will become active on Server1. If the delivered message hasn't yet been committed to the database, it's redelivered from the transport dumpster on Server1.
External	DB1, active on Server1	1. Hub Transport server role on Server1 reroutes the message to the Hub Transport server role on Server2. 2. Hub Transport server role on Server2 delivers the message to DB1 on Server1 and adds the message to the transport dumpster on Server2.	• If Server1 fails before it completes receiving the message from Edge1, Edge1 will attempt delivery to the Hub Transport server role on Server2. • If Server1 fails after it completes receiving the message from Edge1, Edge1 will resubmit the message to the Hub Transport server role on Server2 after it detects that the Hub Transport server role on Server1 is unavailable. The Hub Transport server role on Server2 will then deliver the message locally after DB1 is mounted on Server2. • All other failure scenarios are

			handled in the same manner as described in the first row.
External	DB2, active on Server2	1. Hub Transport server role on Server1 delivers the message to DB2 on Server2, and adds the message to the transport dumpster on Server1.	• If Server1 fails before it completes receiving the message from Edge1, Edge1 will attempt delivery to the Hub Transport server role on Server2. • If Server1 fails after it completes receiving the message from Edge1, but before delivering to DB2 on Server2, Edge1 will resubmit the shadow message to the Hub Transport server role on Server2. This is because Server1 won't send an acknowledgement to Edge1 until it successfully delivers the message to DB2. Because Edge1 hasn't received an acknowledgement, it will resubmit the message after it detects that Server1 is unavailable. • If Server2 fails after message delivery is completed, DB2 will become active on Server1. If the delivered message hasn't yet been committed to the database, it's redelivered from

			the transport dumpster on Server1.

The preceding table focuses on the minimum scenario where there are only two Hub Transport servers in a site that both coexist with Mailbox server roles that participate in DAGs. In more complex deployments where additional dedicated Hub Transport servers are available, those servers are also used when making routing decisions. However, if you have a large enough deployment where you can employ dedicated Hub Transport servers, it's a best practice to not install the Hub Transport server role on Mailbox servers that participate in a DAG.

1.7.1.33 Understanding TLS Certificates

Understanding TLS Certificates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-04*

In cryptographic terms, the certificate and related private keys that are generated by the **New-ExchangeCertificate** cmdlet are TLS keys. The **New-ExchangeCertificate** cmdlet lets you specify metadata about the certificate so that different services can use the same certificate and private key. Before you create certificates or certificate requests for Exchange services that use TLS, you should understand the metadata that are used by the certificates for SSL and TLS services. This metadata is referred to as "fields" in the resulting certificate.

To view the fields of computer certificates on a specific computer, you can use the **Get-ExchangeCertificate** cmdlet in the Exchange Management Shell. Alternatively, you can use the Certificate Manager snap-in in the Microsoft Management Console (MMC).

Looking for management tasks related to TLS certificates? See Certificates.

Contents

Fields Used by Certificates for TLS Services

If you're using the **New-ExchangeCertificate** cmdlet to generate a certificate request from a third-party or other public key infrastructure (PKI) certification authority (CA), make sure that you validate which certificate fields and certificate format are required by the CA.

This section explains the most important certificate fields and provides some best practices for generating certificates and certificate requests.

Subject Name

The Subject Name of a TLS certificate is the field that is used by DNS-aware services. The Subject Name field binds a certificate to a particular server or domain name.

A subject name is an X.500 distinguished name that consists of one or more relative distinguished names, also known as RDN. The following table lists the frequently used relative distinguished names for identifying organizations or server entities.

Name	Abbreviation	Type	Max Size	Frequency Max.\Recommended in certificate\request	Order in subject
Country/Region	**C**	ASCII	2	1\1	1
Domain Component	**DC**	ASCII	255	Many	1
State or Province	**S**	Unicode	128	1	2
Locality	**L**	Unicode	128	1	3
Organization	**O**	Unicode	64	1\1	4
Organizational Unit	**OU**	Unicode	64	Many\Many	5
Common Name	**CN**	Unicode	64	Many\1	6

The Country/Region codes are the ISO 3166-1 codes. For more information, see English country names and code elements.

Domain Component and Country/Region are by convention mutually exclusive. It's a best practice to reference the name by Country/Region or reference the name by Domain Name System (DNS) name. Also, be aware that the maximum size of the Domain Component (255 characters) is the total of all Domain Component values.

Important:

Although certificates can have more than one common name field, some services are implemented on the assumption that there is only one common name. Therefore, multiple common names can cause interoperability issues. We recommend that the certificate or certificate request that you create contains only one common name.

Specifying Relative Distinguished Names

When creating certificate requests using the **New-ExchangeCertificate** cmdlet, subject names are represented as a single parameter that consists of a series of comma-separated names. Each name is identified by the abbreviation for the relative distinguished name. For example, the following subject name represents Country/Region = US, Organization = Contoso Corp, and Common Name = mail1.contoso.com:

```
-SubjectName "C=US o=contoso corp, CN=mail1.contoso.com"
```

Other examples of subject names that can represent the same server include the following examples:

```
-SubjectName  "O=contoso corp, CN=mail1.contoso.com"
-SubjectName "DC=contoso, DC=com, CN=mail1.contoso.com"
-SubjectName "DC= contoso, DC=com, O=contoso corp, CN=mail1.contoso.com"
```

If you have a registered DNS name that you use to send SMTP mail, it's a best practice to use the domain component convention and the DNS name for the certificate name, such as DC=contoso, DC=com, CN=mail1.contoso.com.

However, when you generate a certificate request for a CA provider, you must understand the Subject Name field requirements of the CA and your unique PKI needs. In some cases, you may have to use the Country/Region code ("C"). If that's the case, you must register your relative distinguished name with an X.500 registration authority.

International Subject Names

For subject names that contain non-ASCII characters, you can enter the *SubjectName* parameter as a distinguished name enclosed in quotation marks, as follows:

-*SubjectName* "C=ES,O=Diversión de Bicicleta,CN=mail1. DiversiondeBicicleta.com"

Subject Names and Domain Names

By convention, a common name can contain a fully qualified domain name (FQDN). Although this practice is widespread, be aware of the following two issues with this approach.

First, the maximum size of the Common Name field is 64 characters. This is fewer characters than the maximum size of a FQDN. Therefore, for FQDNs that are more than 64 characters, you must put the domain name in the Subject Alternative Name. The *DomainName* parameter is the parameter that maps to the Subject Alternative Name on the resulting certificate.

Second, the FQDN is restricted to a subset of the ASCII character set. However, the common name (CN) supports Unicode. Therefore, you can create a valid certificate with a CN that seems like a DNS name but is an invalid DNS name. Software that is looking for a FQDN in a certificate CN will not return the correct result if the CN contains non-ASCII characters. For example, if you create a certificate with a Subject Name where CN=mail.mïcrosoft.com, the name would be ignored as a FQDN because the name contains a Unicode character (the ï character with the diacritic (x00ef)). To the eye, the Unicode CN can be easily be mistaken for a FQDN because of the small difference between the ï character with the diacritic (x00ef) and the ASCII i (x0069). The Exchange certificate task doesn't require or enforce that the subject CN be a valid FQDN. By default, this means that the cmdlet includes the FQDN of the server as the default CN.

Certificate Domain Names

For TLS, certificates must contain DNS names because the TLS relies on DNS resolution. Clients verify the DNS name of the server to which they are connecting with the DNS name that they expect to be connecting to. This is true for Web browsers that connect to a Web site over HTTPS and for SMTP servers that transmit e-mail over the Internet or intranet.

A single server may support multiple DNS names for the following reasons:

- A SMTP server supports multiple accepted domains
- A client can access an e-mail server by the server name, by the domain name, by a FQDN local name, or by a load-balanced name.

When a TLS connection is established, if the client finds the name that it is looking for, the client ignores the other names in the certificate. Multiple domain and server names can be added to the Subject Alternative Name field of a TLS certificate. You can create a certificate that contains multiple Subject Alternative Names by using the *DomainName* parameter of the **New-ExchangeCertificate** cmdlet. The *DomainName* parameter is multivalued so that it can accept multiple names.

X.509 certificates can contain zero, one, or more DNS names in the Subject Alternative Name (SubjectAltName) certificate extension. DNS names in the SubjectAltName extension

exactly match the restrictions of a DNS name. They must not exceed 255 characters and must consist of A-Z, a-z, 0-9 and a dash (-).

Name Matching Logic for the Domain Security Feature

The certificate name matching logic for the Domain Security feature checks whether a domain name in the received certificate matches the domain name when it sends mail to that domain. For example, consider the FQDN of the recipient domain woodgrovebank.com. The certificate name matching logic searches through all DNS names in the certificates, and as long as one DNS name matches, the certificate is verified as a match for the specified domain.

In this example, the certificate name matching logic accepts a certificate with an exact domain match, such as woodgrovebank.com. It also supports using wildcard character domain names in certificates so that a certificate with a DNS name of *.woodgrovebank.com is accepted as a match. For more information about wildcard character domain names, see "Wildcard Character Domain Names" later in this topic.

The certificate name matching logic also searches DNS one node deep. Therefore, mail1.woodgrovebank.com is also accepted as a match for woodgrovebank.com. However, DNS names more than two nodes deep aren't accepted. Therefore, mail1.us.woodgrovebank.com, for example, would not be accepted as a match for woodgrovebank.com.

Best Practices for Domain Names for Internet SMTP

When you create a certificate or a certificate request for an Edge Transport server performing SMTP TLS over the Internet, the set of domain names that you should include in the request are as follows:

- **The fully qualified Internet domain name of the server** This may be different from the internal FQDN that is used between Edge Transport servers and Hub Transport servers and should match the A record that is published on the Internet (public) DNS server. This name should be entered as a CN in the *SubjectName* parameter of the **New-ExchangeCertificate** cmdlet.
- **All the accepted domain names of the organization** Use the *IncludeAcceptedDomains* parameter of the **New-ExchangeCertificate** cmdlet to populate the Subject Alternative Name for the resulting certificate.
- **The FQDN for the connector if it isn't covered by either of the previous items** Use the *DomainName* parameter of the **New-ExchangeCertificate** cmdlet to populate the Subject Alternative Name for the resulting certificate.

Wildcard Character Domain Names

Wildcard character domain names are a special type of domain name that represents multiple sub-domains. Wildcard character domain names can simplify certificates because a single wildcard domain name represents all the sub-domains for that domain. They are represented by an asterisk character (*) at the DNS node. For example, ***.contoso.com** represents **contoso.com** and all the sub-domains for **contoso.com**. When you use a wildcard character to create a certificate or a certificate request for all accepted domains, you can simplify the request significantly.

Certificate Selection

Exchange follows different certificate selection processes depending on the type of SMTP connection.

When Hub Transport servers are communicating with each other or with the Edge Transport servers in your organization, anonymous TLS certificates are used. For more information, see Selection of Inbound Anonymous TLS Certificates and Selection of Outbound Anonymous TLS Certificates.

When an SMTP host or client connects to the Edge or Hub Transport servers, then the STARTTLS certificate selection process is used. For more information, see Selection of Inbound STARTTLS Certificates.

Creating TLS Certificates

Exchange 2010 creates a self-signed certificate during installation that uses all the server and domain names that are known to Exchange at the time of installation. You can clone this certificate to use it on additional servers. You can also replace this certificate with certificates that are issued by a third-party CA. The following topics provide step-by-step instructions for each task.

- Generate Request for Third-Party Certificate Services
- Install Certificates Issued for Certificate Requests
- Clone an Existing Certificate

1.7.1.33.1 TLS Functionality and Related Terminology in Exchange 2010

TLS Functionality and Related Terminology in Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-25*

Microsoft Exchange Server 2010 provides administrative functionality and other enhancements that improve the overall management of Transport Layer Security (TLS). As you work with this functionality, you need to learn about some TLS-related features and functionality. Some terms and concepts apply to more than one TLS-related feature. In this topic, a brief explanation of each feature is provided, which is intended to help you understand some differences and general terminology related to TLS and the Domain Security feature set:

- **Transport Layer Security** TLS is a standard protocol that's used to provide secure Web communications on the Internet or intranets. It enables clients to authenticate servers or, optionally, servers to authenticate clients. It also provides a secure channel by encrypting communications. TLS is the latest version of the Secure Sockets Layer (SSL) protocol.
- **Mutual TLS** Mutual TLS authentication differs from TLS as TLS is usually deployed. Typically, when TLS is deployed, it's used only to provide confidentiality in the form of encryption. No authentication occurs between the sender and receiver. In addition to this kind of deployment, sometimes when TLS is deployed, only the receiving server is authenticated. This deployment of TLS is typical of the HTTP implementation of TLS. This implementation, where

only the receiving server is authenticated, is SSL.
With mutual TLS authentication, each server verifies the identity of the other server by validating a certificate that's provided by that other server. In this scenario, where messages are received from external domains over verified connections in an Exchange 2010 environment, Microsoft Outlook displays a Domain Secured icon.

- **Domain Security** Domain Security is the set of features, such as certificate management, connector functionality, and Outlook client behavior that enables mutual TLS as a manageable and useful technology.
- **Opportunistic TLS** In earlier versions of Exchange, you had to configure TLS manually. In addition, you had to install a valid certificate, suitable for TLS usage, on the server running Exchange. In Exchange 2010, Setup creates a self-signed certificate. By default, TLS is enabled. This enables any sending system to encrypt the inbound SMTP session to Exchange. By default, Exchange 2010 also attempts TLS for all remote connections.
- **Direct trust** By default, all traffic between Edge Transport servers and Hub Transport servers is authenticated and encrypted. Again, the underlying mechanism for authentication and encryption is mutual TLS. Instead of using X.509 validation, Exchange 2010 uses direct trust to authenticate the certificates. Direct trust means that the presence of the certificate in Active Directory or Active Directory Lightweight Directory Services (AD LDS) validates the certificate. Active Directory is considered a trusted storage mechanism. When direct trust is used, it doesn't matter if the certificate is self-signed or signed by a certification authority. When you subscribe an Edge Transport server to the Exchange organization, the Edge Subscription publishes the Edge Transport server certificate in Active Directory for the Hub Transport servers to validate. The Microsoft Exchange EdgeSync service updates AD LDS with the set of Hub Transport server certificates for the Edge Transport server to validate.

1.7.1.33.2 Selection of Inbound Anonymous TLS Certificates

Selection of Inbound Anonymous TLS Certificates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-23*

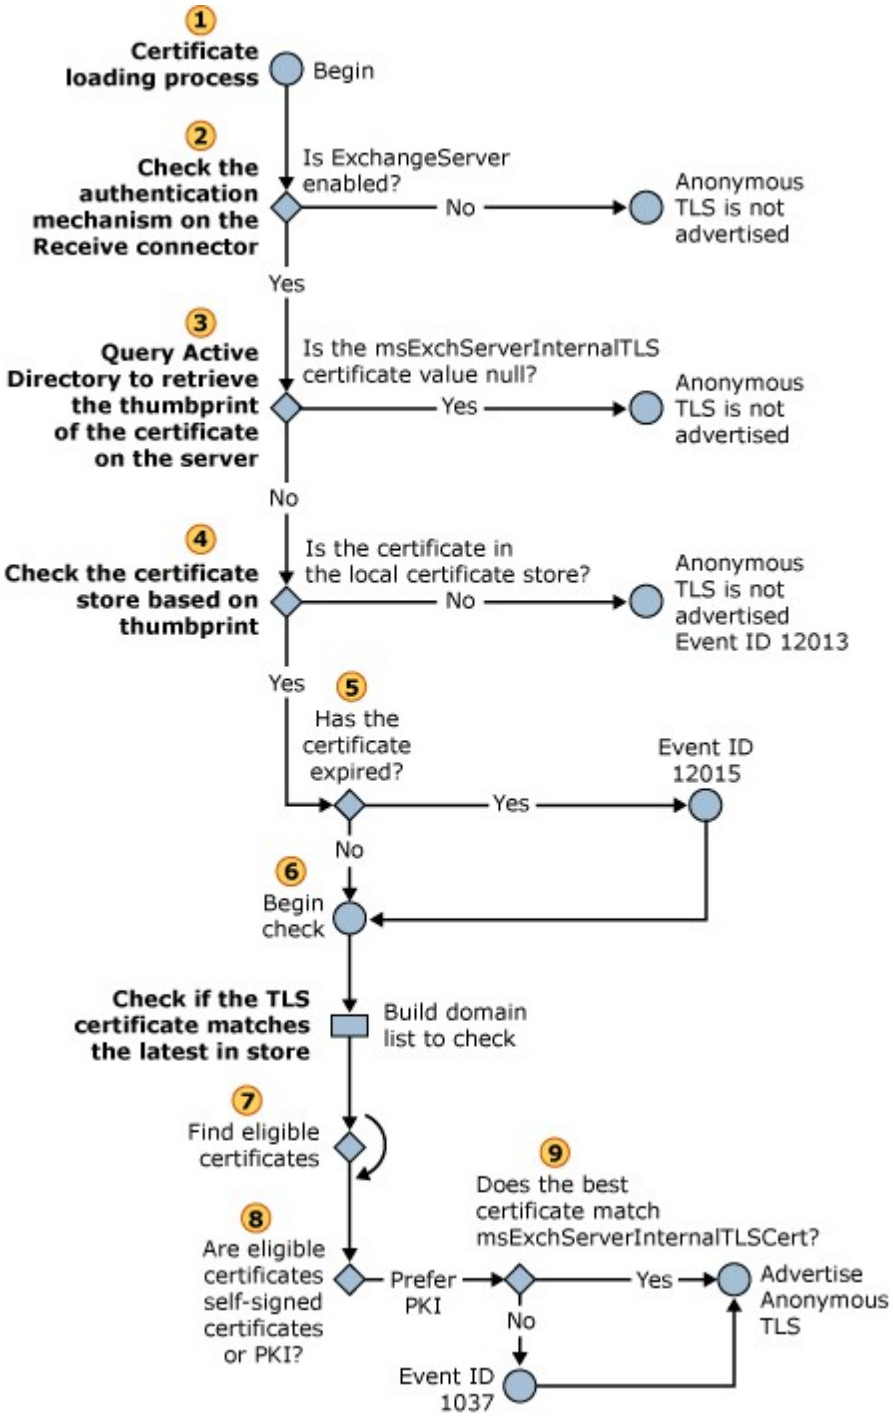
The selection of an inbound anonymous Transport Layer Security (TLS) certificate occurs in the following scenarios:

- SMTP sessions between Edge Transport servers and Hub Transport servers for authentication
- SMTP sessions between Hub Transport servers for encryption only by using public keys

For communication between Hub Transport servers, anonymous TLS and the public keys from certificates are used to encrypt the session. Kerberos is used for authentication. When an SMTP session is established, the receiving server initiates a certificate selection process to determine which certificate to use in the TLS negotiation. The sending server also performs a certificate selection process. For more information about that process, see Selection of Outbound Anonymous TLS Certificates.

This topic describes the selection process for inbound anonymous TLS certificates. All the

steps are performed on the receiving server. The following figure shows the steps of this process.



1. When the SMTP session is established, Microsoft Exchange calls a process to load the certificates.
2. In the load certificate function, the Receive connector to which the session is connected is checked to see whether the **AuthMechanism** property is set to a value of ExchangeServer. You can set the **AuthMechanism** property on the Receive connector by using the Set-ReceiveConnector cmdlet. You can

also set the **AuthMechanism** property to ExchangeServer by selecting **Exchange Server authentication** on the **Authentication** tab of a specific Receive connector.
If ExchangeServer isn't enabled as an authentication mechanism, the server doesn't advertise X-ANONYMOUSTLS to the sending server in the SMTP session and no certificate is loaded. If ExchangeServer is enabled as an authentication mechanism, the certificate selection process continues to the next step.

3. Microsoft Exchange queries Active Directory to retrieve the thumbprint of the certificate on the server. The **msExchServerInternalTLSCert** attribute on the server object stores the certificate thumbprint.
   If the **msExchServerInternalTLSCert** attribute can't be read or if the value is null, Microsoft Exchange doesn't advertise X-ANONYMOUSTLS and no certificate is loaded.

   Note:
   If the **msExchServerInternalTLSCert** attribute can't be read or if the value is null during startup of the Microsoft Exchange Transport service, instead of during the SMTP session, Event ID 12012 is logged in the Application log.

4. If a thumbprint is found, the certificate selection process searches the local computer certificate store for a certificate that matches the thumbprint. If the certificate isn't found, the server doesn't advertise X-ANONYMOUSTLS, no certificate is loaded, and Event ID 12013 is logged in the Application log.
5. After a certificate is loaded from the certificate store, it's checked to see whether it has expired. The *Valid to* field on the certificate is compared to the current date and time. If the certificate has expired, Event ID 12015 is logged in the Application log. In this case, the certificate selection process doesn't fail and continues with the remaining checks.
6. The certificate is checked to see whether it's the latest in the local computer's certificate store. As part of this check, a domain list is built for potential certificate domains. The domain list is based on the following computer configuration:
   - Fully qualified domain name (FQDN), such as mail.contoso.com
   - Host name, such as EdgeServer01
   - Physical FQDN, such as EdgeServer01.contoso.com
   - Physical host name, such as EdgeServer01

   Note:
   If the server is configured as a cluster or for a computer that's running Microsoft Windows Load Balancing, the following registry key is checked instead of the DnsFullyQualifiedDomainName setting: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\WLBS\Parameters\Interface\{GUID}\ClusterName**

7. After the domain list is built, the certificate selection process checks to find all certificates in the certificate store that have a matching FQDN. From this list, the certificate selection process identifies a list of eligible certificates. Eligible certificates must meet the following criteria:
   - The certificate is an X.509 version 3 or a later version certificate.
   - The certificate has an associated private key.
   - The Subject or Subject Alternate Name fields contain the FQDN that was retrieved in step 6.
   - The certificate is enabled for Secure Sockets Layer (SSL)/TLS use. Specifically, the SMTP service has been enabled for this certificate by using the Enable-ExchangeCertificate cmdlet.
8. From the eligible certificates, the best certificate is selected based on the following sequence:
   - Sort eligible certificates by most recent *Valid from* date. *Valid from* is a Version 1 field on the certificate.

- The first valid public key infrastructure (PKI) certificate that's found in this list is used.
- If no valid PKI certificates are found, the first self-signed certificate is used.

9. After the best certificate has been determined, another check is made to determine whether its thumbprint matches the certificate that's stored in the **msExchServerInternalTLSCert** attribute. If the certificate matches, the certificate is used for X-ANONYMOUSTLS. If it doesn't match, Event ID 1037 is logged in the Application log. However, this doesn't cause X-ANONYMOUSTLS to fail.

1.7.1.33.3 Selection of Inbound STARTTLS Certificates

Selection of Inbound STARTTLS Certificates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

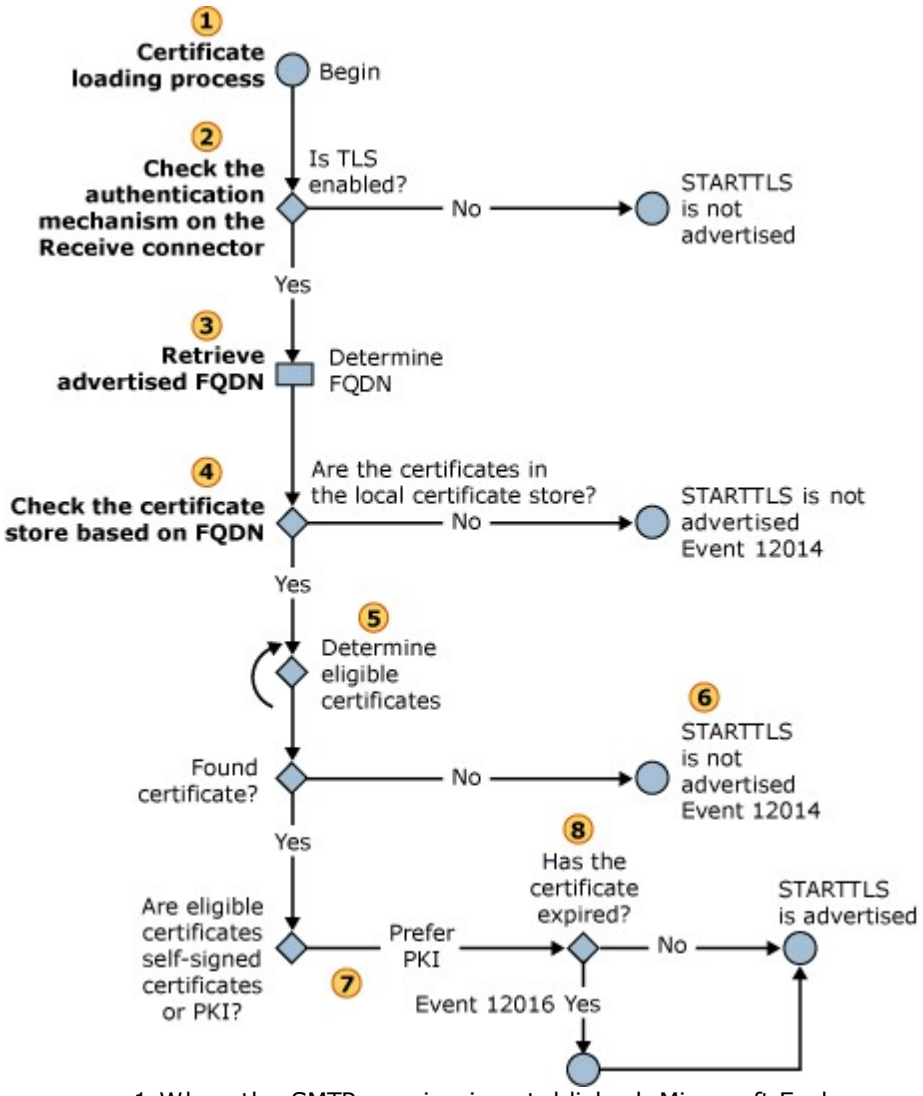
Topic Last Modified: *2011-04-27*

The selection of an inbound STARTTLS certificate occurs in the following scenarios:

- SMTP hosts request Transport Layer Security (TLS) with Edge Transport servers. The host that requests TLS with the Edge Transport server may be any other SMTP host. This also describes the Domain Security scenario. For more information about Domain Security, see Understanding Domain Security.
- SMTP clients, such as Microsoft Outlook Express, request TLS with Hub Transport servers.
- Internet-facing Hub Transport servers request TLS with an Edge Transport server.

When an SMTP session is established, the receiving server initiates a certificate selection process to determine which certificate to use in the TLS negotiation. The sending server also performs a certificate selection process. For more information about that process, see Selection of Outbound Anonymous TLS Certificates.

This topic describes the certificate selection process for inbound STARTTLS. All the steps described in this topic are performed on the receiving server. The following figure shows the steps of this process.



1. When the SMTP session is established, Microsoft Exchange calls a process to load the certificates.
2. In the load certificate function, the Receive connector to which the session is connected is checked to see whether the **AuthMechanism** property is set to a value of TLS. You can set the **AuthMechanism** property on the Receive connector by using the Set-ReceiveConnector cmdlet. You can also set the **AuthMechanism** property to TLS by selecting **Transport Security Layer (TLS)** on the **Authentication** tab of a specific Receive connector.
   If TLS isn't enabled as an authentication mechanism, the server doesn't advertise X-STARTTLS as an option to the sending server and no certificate is loaded. If TLS is enabled as an authentication mechanism, the certificate selection process continues to the next step.
3. The certificate selection process retrieves the fully qualified domain name (FQDN) value from the Receive connector configuration. If the FQDN value on the Receive connector is `null`, the server's physical FQDN is retrieved.
4. The certificate selection process searches the local computer certificate store for certificates that match the FQDN. If a certificate isn't found, the server doesn't advertise X-STARTTLS, no certificate is loaded, and Event ID 12014 is logged in the Application log.
5. The certificate selection process searches for all certificates in the certificate store that have a matching FQDN. From this list, the certificate selection process identifies a list of eligible certificates. Eligible certificates must meet

the following criteria:
- The certificate is an X.509 version 3 or a later version certificate.
- The certificate has an associated private key.
- The Subject or Subject Alternate Name fields contain the FQDN that was retrieved in step 3.
- The certificate is enabled for SSL/TLS use. Specifically, the SMTP service has been enabled for this certificate by using the Enable-ExchangeCertificate cmdlet.

6. If no eligible certificates are found after these checks, the server doesn't advertise X-STARTTLS, no certificate is loaded, and Event ID 12014 is logged in the Application log.
7. From the eligible certificates, the best certificate is selected based on the following sequence:
   - Sort eligible certificates by most recent *Valid from* date. *Valid from* is a Version 1 field on the certificate.
   - The first valid public key infrastructure (PKI) certificate that's found in this list is used.
   - If no valid PKI certificates are found, the first self-signed certificate is used.
8. The certificate is checked to see whether it has expired. The *Valid to* field in the certificate properties is compared to the current date and time. If the certificate hasn't expired, STARTTLS is advertised. If the certificate has expired, Event ID 12016 is logged in the Application log, but STARTTLS is still advertised.

1.7.1.33.4 Selection of Outbound Anonymous TLS Certificates

Selection of Outbound Anonymous TLS Certificates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

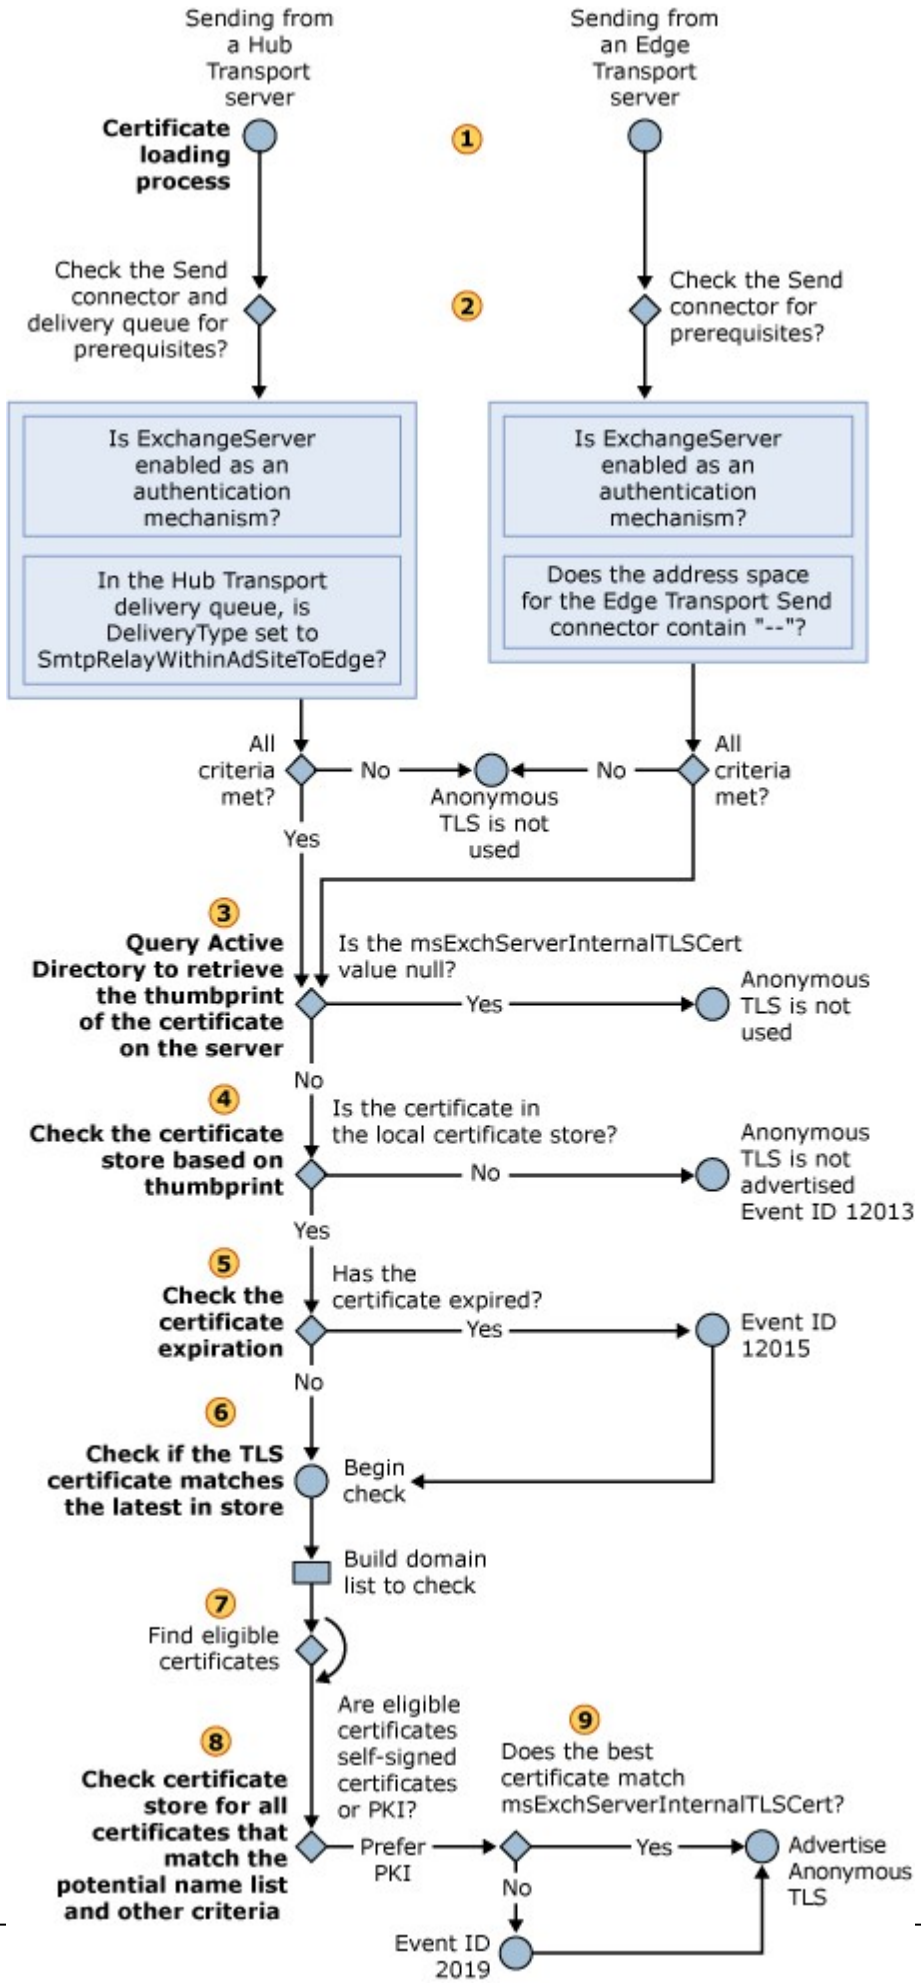
This topic describes the selection process for outbound anonymous Transport Layer Security (TLS) certificates in Microsoft Exchange Server 2010. The selection of an outbound anonymous TLS certificate occurs in the following scenarios:
- SMTP sessions between Edge Transport servers and Hub Transport servers for authentication
- SMTP sessions between Hub Transport servers for encryption only by using public keys

For communication between Hub Transport servers, anonymous TLS and the public keys from certificates are used to encrypt the session. When an SMTP session is established, the receiving server initiates a certificate selection process to determine which certificate to use in the TLS negotiation. The receiving server also performs a certificate selection process. For more information about that process, see Selection of Inbound Anonymous TLS Certificates.

Sending from a Hub Transport Server or an Edge Transport Server

All the steps for the selection of an outbound anonymous TLS certificate are performed on

the sending server. The following figure shows the steps of this process.



Sending from a Hub Transport server
Sending from an Edge Transport server
Certificate loading process
1
Check the Send connector and delivery queue for prerequisites?
2
Check the Send connector for prerequisites?
Is ExchangeServer enabled as an authentication mechanism?
In the Hub Transport delivery queue, is DeliveryType set to SmtpRelayWithinAdSiteToEdge?
Is ExchangeServer enabled as an authentication mechanism?
Does the address space for the Edge Transport Send connector contain "--"?
All criteria met?
No
Anonymous TLS is not used
No
All criteria met?
Yes
3
Query Active Directory to retrieve the thumbprint of the certificate on the server
Is the msExchServerInternalTLSCert value null?
Yes
Anonymous TLS is not used
No
4
Check the certificate store based on thumbprint
Is the certificate in the local certificate store?
No
Anonymous TLS is not advertised Event ID 12013
Yes
5
Check the certificate expiration
Has the certificate expired?
Yes
Event ID 12015
No
6
Check if the TLS certificate matches the latest in store
Begin check
Build domain list to check
7
Find eligible certificates
Are eligible certificates self-signed certificates or PKI?
9
Does the best certificate match msExchServerInternalTLSCert?
8
Check certificate store for all certificates that match the potential name list and other criteria
Prefer PKI
Yes
Advertise Anonymous TLS
No
Event ID 2019

1. When the SMTP session is established from a Hub Transport server or Edge Transport server, Microsoft Exchange calls a process to load the certificates.

   Note:
   During the initial loading of the certificate, the outbound certificate selection process is different for the Edge Transport server role and the Hub Transport server role. The figure shows the starting point for each server role.

2. The certificate loading process depends on whether the SMTP session is initiated from a Hub Transport server or an Edge Transport server.
   On a Hub Transport server The following checks are made:
   2.a. The Send connector to which the session is connected is checked to see whether the **SmartHostAuthMechanism** property is configured for `ExchangeServer`. You can set the **SmartHostAuthMechanism** property on the Send connector by using the **Set-SendConnector** cmdlet. You can also set the **SmartHostAuthMechanism** property to `ExchangeServer` by selecting **Exchange Server Authentication** on the **Configure Smart Host Authentication Settings** page of a specific Send connector. To open the **Configure Smart Host Authentication Settings** page, click **Change** on the **Network** tab of the Send connector properties page.
   2.b. The **DeliveryType** property of the message is checked to determine whether it's set to a value of `SmtpRelayWithinAdSitetoEdge`. You can view the **DeliveryType** property by running the **Get-Queue** cmdlet with the format list argument (| `Format-List`).
   Both of the following conditions must be met. If `ExchangeServer` isn't enabled as an authentication mechanism or if the **DeliveryType** property isn't set to `SmtpRelayWithinAdSitetoEdge`, the sending Hub Transport server doesn't use anonymous TLS and no certificate is loaded. If both conditions are met, the certificate selection process continues to step 3.
   On an Edge Transport server The following checks are made:
   2.c. The Send connector to which the session is connected is checked to see whether the **SmartHostAuthMechanism** property is configured for `ExchangeServer`. As noted earlier in this topic, you can set the **SmartHostAuthMechanism** property on the Send connector by using the **Set-SendConnector** cmdlet. You can also set the **SmartHostAuthMechanism** property to `ExchangeServer` by selecting **Exchange Server Authentication** on the **Configure Smart Host Authentication Settings** page of a specific Send connector. To open the **Configure Smart Host Authentication Settings** page, click **Change** on the **Network** tab of the Send connector properties page.
   2.d. The Send connector to which the session is connected is checked to determine whether the **SmartHost** address space property contains "- -".
   Both of the following conditions must be met. If `ExchangeServer` isn't enabled as an authentication mechanism or the address space doesn't contain "- -", the sending Edge Transport server doesn't use anonymous TLS and no certificate is loaded. If both conditions are met, the certificate selection process continues to step 3.
3. Microsoft Exchange queries Active Directory to retrieve the thumbprint of the certificate on the server. The **msExchServerInternalTLSCert** attribute on the server object stores the certificate thumbprint.
   If the **msExchServerInternalTLSCert** attribute can't be read or if the value is `null`, Microsoft Exchange doesn't advertise X-ANONYMOUSTLS in the SMTP session and no certificate is loaded.

   Note:
   If the **msExchServerInternalTLSCert** attribute can't be read or if the value is `null` during startup of the Microsoft Exchange Transport service, instead of during the SMTP session, Event ID 12012 is logged in the Application log.

4. If a thumbprint is found, the certificate selection process searches the local computer certificate store for a certificate that matches the thumbprint. If the certificate isn't found, the server doesn't advertise X-ANONYMOUSTLS, no certificate is loaded, and Event ID 12013 is logged in the Application log.
5. After a certificate is loaded from the certificate store, it's checked to see whether it has expired. The *Valid to* field on the certificate is compared to the current date and time. If the certificate has expired, Event ID 12015 is logged in the Application log. In this case, the certificate selection process doesn't fail and continues with the remaining checks.
6. The certificate is checked to see whether it's the latest in the local computer's certificate store. As part of this check, a domain list is built for potential certificate domains. The domain list is based on the following computer configuration:
   6.a. Fully qualified domain name (FQDN), such as mail.contoso.com
   6.b. Host name, such as EdgeServer01
   6.c. Physical FQDN, such as EdgeServer01.contoso.com
   6.d. Physical host name, such as EdgeServer01

   Note:
   If the server is running Microsoft Windows Load Balancing, the following registry key is checked instead of the DnsFullyQualifiedDomainName setting: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\WLBS\Parameters\Interface\{GUID}\ClusterName**
7. After the domain list is built, the certificate selection process performs a search to find all certificates in the certificate store that have a matching FQDN. From this list, the certificate selection process identifies a list of eligible certificates. Eligible certificates must meet the following criteria:
   7.a. The certificate is an X.509 version 3 or a later version certificate.
   7.b. The certificate has an associated private key.
   7.c. The Subject or Subject Alternate Name fields contain the FQDN that was retrieved in step 6.
   7.d. The certificate is enabled for Secure Sockets Layer (SSL)/TLS use. Specifically, the SMTP service has been enabled for this certificate by using the Enable-ExchangeCertificate cmdlet.
8. From the eligible certificates, the best certificate is selected based on the following sequence:
   8.a. Sort eligible certificates by most recent *Valid from* date. *Valid from* is a Version 1 field on the certificate.
   8.b. The first valid public key infrastructure (PKI) certificate that's found in this list is used.
   8.c. If no valid PKI certificates are found, the first self-signed certificate is used.
9. After the best certificate has been determined, another check is made to determine whether its thumbprint matches the certificate that's stored in the **msExchServerInternalTLSCert** attribute. If the certificate matches, the certificate is used for X-ANONYMOUSTLS. If it doesn't match, Event ID 1037 is logged in the Application log. However, this doesn't cause X-ANONYMOUSTLS to fail.

1.7.1.33.5 Disabling TLS Between Active Directory Sites to Support WAN Optimization

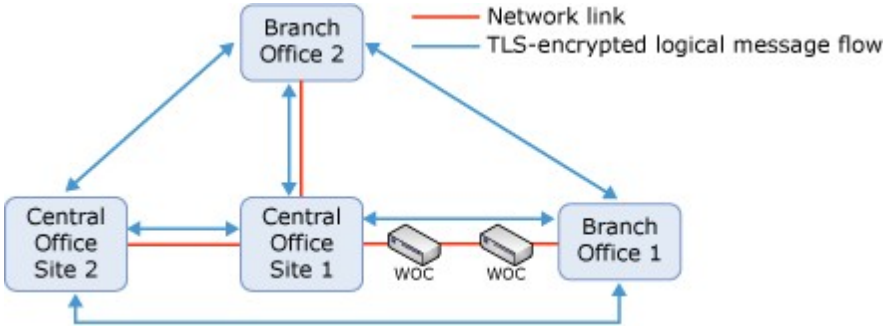
Disabling TLS Between Active Directory Sites to Support WAN Optimization

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

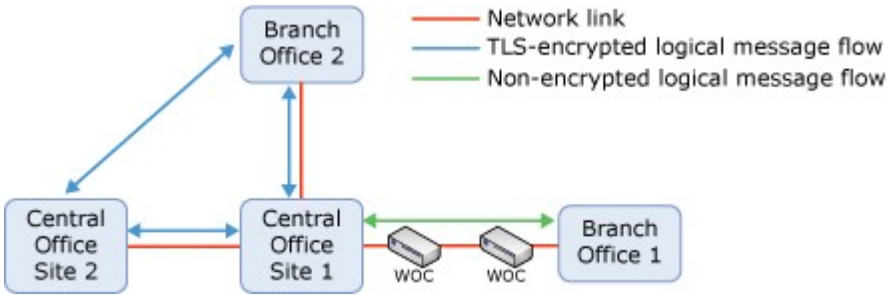
Topic Last Modified: *2009-12-01*

In Microsoft Exchange Server 2007, Transport Layer Security (TLS) encryption is mandatory for all SMTP communication between Hub Transport servers. This increases overall security of hub-to-hub communications. However, in certain topologies where WAN Optimization Controller (WOC) devices are used, the TLS encryption of SMTP traffic may be undesirable. Exchange Server 2010 supports disabling TLS for hub-to-hub communications for these specific scenarios.

Consider the topology shown in the following figure. The assumption for this four-site topology is that the two central office sites and Branch Office 2 are well-connected, whereas the connection between Central Office Site 1 and Branch Office 1 is over a WAN link. The company has installed WOC devices on this link to compress and optimize traffic over the WAN.



In this topology, because Exchange 2010 uses TLS encryption for communication between Hub Transport servers, the SMTP traffic that goes over the WAN link can't be compressed. Ideally, all SMTP traffic that goes over the WAN link should be unencrypted SMTP, while retaining TLS security within well-connected sites. Exchange 2010 gives you the option to disable TLS encryption for traffic between sites by configuring Receive connectors. Using this ability in Exchange 2010, you can configure an exception to the SMTP traffic between Central Office Site 1 and Branch Office 1, as shown in the following figure.



The recommended configuration is to limit the non-encrypted SMTP traffic to only those messages that pass over the WAN link. Therefore, the intrasite hub-to-hub traffic in all sites, and the cross-site hub-to-hub communications that don't involve Branch Office 1 should all be TLS encrypted.

To achieve this end result, you need to do the following, in the specified order, on every Hub Transport server in the sites that contain the WOC devices (Central Office Site 1 and Branch Office 1 in the sample topology):

1. Enable downgraded Exchange Server authentication.
2. Create a Receive connector to handle the traffic over the connection that has WOC devices.

3. Configure the remote IP address range property of the new Receive connector to the IP address ranges of the Hub Transport servers in the remote site.
4. Disable TLS on the new Receive connector.

In addition, you need to do the following to ensure all SMTP traffic over the WAN is handled by the new Receive connectors you created:

- Configure the sites that will participate in the non-TLS communication as hub sites to force all message flow through the new Receive connectors (Central Office Site 1 and Branch Office Site 1 in the sample topology).
- Verify that the IP site link costs are configured in a way that ensures the least cost routing path to your remote site (Branch Office 1 in the sample topology) goes through the network link that has the WOC devices.

The following sections provide an overview of each of these steps. For step-by-step instructions on how to configure your Hub Transport servers to disable TLS, see Suppress Anonymous TLS Connections.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Downgrading Authentication over TLS-Disabled Connections

Kerberos authentication is used with TLS encryption in Exchange. When you disable TLS on hub-to-hub communications, you need to perform another form of authentication. When Exchange 2010 communicates with other servers running Exchange that don't support X-ANONYMOUSTLS, such as the Exchange Server 2003 servers, it falls back to using GSSAPI (Generic Security Services Application Programming Interface) authentication. All communications between Exchange 2010 Hub Transport servers use X-ANONYMOUSTLS. By configuring your Hub Transport server to use downgraded Exchange Server authentication, you are in effect enabling it to use GSSAPI when communicating with other Exchange 2010 Hub Transport servers.

Return to top

Creating and Configuring Receive Connectors

You need to create Receive connectors that will solely be responsible for handling the non-TLS encrypted traffic. Using separate Receive connectors for this purpose ensures that all traffic that doesn't pass through the WAN link remains protected by TLS encryption.

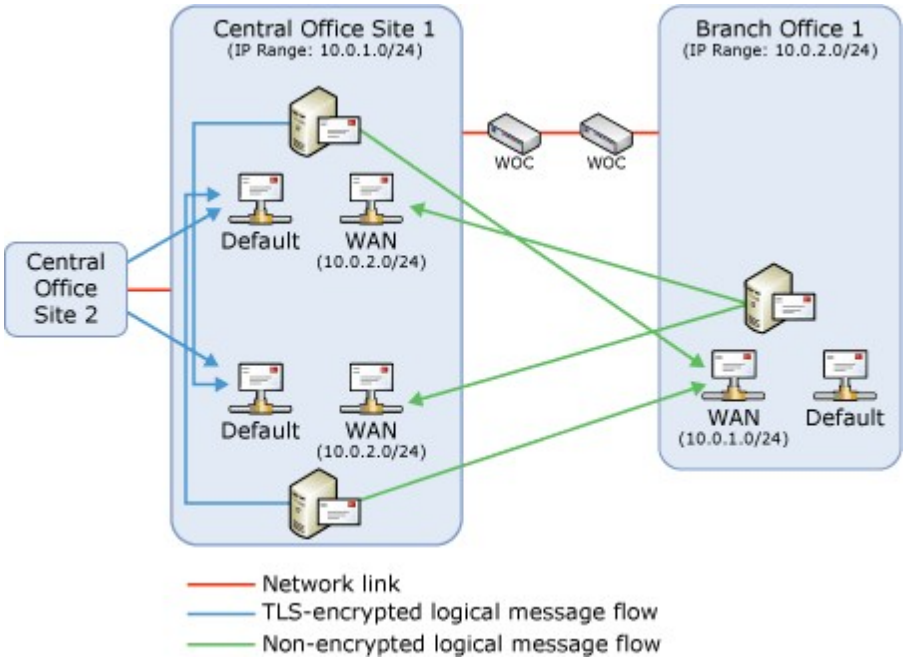
To restrict the new Receive connectors to only the traffic over the WAN, you need to

configure the remote IP address range property. Exchange always uses the connector with the most specific remote IP address range. Therefore, these new connectors will be preferred over the default Receive connector configured to receive messages from anywhere.

Going back to the sample topology, assume that the class C subnet 10.0.1.0/24 is used for the Central Office Site 1 and 10.0.2.0/24 is used for the Branch Office 1. To prepare for disabling TLS between these two sites, you need to:

1. Create a Receive connector (called WAN) on each Hub Transport server in Central Office Site 1 and Branch Office 1.
2. Configure the remote IP address range of 10.0.2.0/24 on each new Receive connector in Central Office Site 1.
3. Configure the remote IP address range of 10.0.1.0/24 on each new Receive connector in Branch Office 1.
4. Disable TLS on all of the new Receive connectors.

The end result is shown in the following figure (with the remote IP address range property of the WAN Receive connectors shown in parentheses). Only a single Hub Transport server is shown in Branch Office 1, and Branch Office 2 is omitted for clarity purposes.



Return to top

Creating Hub Sites

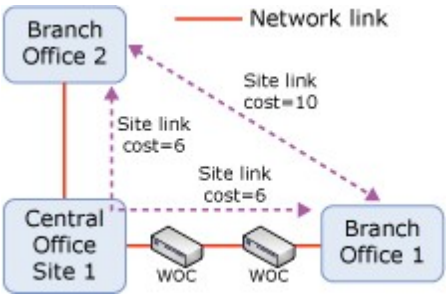
By default, an Exchange 2010 Hub Transport server will attempt a direct connection to the Hub Transport server closest to the final destination of a specific message. In the sample topology, if a user in Branch Office 2 sends a message to a user in Branch Office 1, the Hub Transport server in Branch Office 2 will connect to the Hub Transport server in Branch Office 1 directly to deliver that message. That connection will be encrypted and therefore not desirable in the specific topology. To have such messages pass through the Hub Transport servers on Central Office Site 1, thereby ensuring they aren't encrypted while in transit over the WAN link, Central Office Site 1 and Branch Office 1 need to be configured as hub sites. In short, any site where you have a Hub Transport server with a Receive

connector with TLS disabled needs to be configured as a hub site, so you can force servers in other sites to route traffic through that site. For more information about hub sites, see "Implementing Hub Sites" in Understanding Message Routing.

Return to top

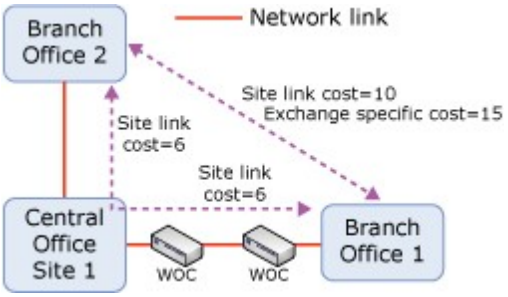
Configuring Site Link Costs

Configuring hub sites alone isn't sufficient to ensure that all traffic is unencrypted over the WAN link. This is because Exchange will route messages through hub sites only if the hub site lies within the least cost routing path. For example, assume that the IP site link costs for our sample topology are configured in Active Directory as shown in the following figure (Central Office Site 2 is omitted for clarity).



In this case, the path from Branch Office 2 to Branch Office 1 that goes through the hub site has a total cost of 12 (6+6), whereas the cost of the direct path is 10. Therefore, none of the messages from Branch Office 2 to Branch Office 1 will go through Central Office Site 1 and therefore all of that traffic will still be TLS encrypted.

To avoid this issue, you need to designate an Exchange-specific cost that is higher than 12 for the IP site link between Branch Office 2 and Branch Office 1, as shown in the following figure. This will ensure that all messages go through the unencrypted channel between Central Office Site 1 and Branch Office 1.



For more information about configuring Exchange-specific IP site link costs, see "Controlling IP Site Link Costs" in Understanding Message Routing.

Return to top

1.7.1.34 Understanding Transport Agents

Understanding Transport Agents

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-15*

Transport agents let you install custom software, created by Microsoft, by third-party vendors, or by your organization, on a computer that is running Microsoft Exchange Server 2010. This software can then process e-mail messages that pass through the transport pipeline on a Hub Transport server or Edge Transport server. Custom transport agents provide additional functionality to Exchange 2010, such as anti-spam or antivirus programs or any transport function that your organization may require.

Transport agents are typically installed automatically as part of applications that are designed to function together with Exchange 2010. However, there may be instances where organizations want to develop their own transport agents to manage mail that flows through their Exchange 2010 organization.

Caution:
Transport agents have full access to all e-mail messages that they encounter. Exchange puts no restrictions on a transport agent's behavior. Transport agents that are unstable or contain security flaws may affect the stability and security of Exchange. Therefore, you must only install transport agents that you fully trust and that have been fully tested in a test environment.

Looking for management tasks related to managing transport agents? See Managing Transport Agents.

Contents

Transport Agents and SMTP Events

Transport agents that are written for Exchange 2010 use SMTP events. These events are triggered as messages move through the transport pipeline. SMTP events give transport agents access to messages at specific points during the SMTP conversation and during routing of messages through the organization. The following tables list the SMTP events that provide access to messages in the transport pipeline.

SMTP Receive events

Sequence	SMTP event	Description
1	**OnConnect**	This event is triggered upon initial connection from a remote SMTP host.

2	**OnEhloCommand**	This event is triggered when the EHLO SMTP verb is issued by the remote SMTP host.
3	**OnHeloCommand**	This event is triggered when the HELO SMTP verb is issued by the remote SMTP host.
4	**OnAuthCommand**	This event is triggered when the AUTH SMTP verb is issued by the remote SMTP host.
5	**OnEndOfAuthentication**	This event is triggered when the remote SMTP host has completed authentication.
6	**OnMailCommand**	This event is triggered when the MAIL FROM SMTP verb is issued by the remote SMTP host.
7	**OnRcptToCommand**	This event is triggered when the RCPT TO SMTP verb is issued by the remote SMTP host.
8	**OnDataCommand**	This event is triggered when the DATA SMTP verb is issued by the remote SMTP host.
9	**OnEndOfHeaders**	This event is triggered when the remote SMTP host as completed submitting the e-mail message headers.
10	**OnEndOfData**	This event is triggered when the remote SMTP host issues <CRLF>, which indicates the end of data.
**	**OnHelpCommand**	This event is triggered when the HELP SMTP verb is issued by the remote SMTP host. This event can occur at any time after the **OnConnect** SMTP event and before the **OnDisconnect** SMTP event.
**	**OnNoopCommand**	This event is triggered when the NOOP SMTP verb is issued by the remote SMTP host. This event can occur at any time after the **OnConnect** SMTP event and before the **OnDisconnect** SMTP event.
**	**OnReject**	This event is triggered when the receiving SMTP host issues a temporary or permanent delivery status notification (DSN) code to the

		sending SMTP host. This event can occur at any time after the **OnConnect** SMTP event and before the **OnDisconnect** SMTP event.
**	**OnRsetCommand**	This event is triggered when the RSET SMTP verb is issued by the sending SMTP host. This event can occur at any time after the **OnConnect** SMTP event and before the **OnDisconnect** SMTP event.
11	**OnDisconnect**	This event is triggered upon disconnection of the SMTP conversation by either a receiving or sending SMTP host.

Categorizer events

Sequence	Categorizer event	Description
1	**OnSubmittedMessage**	This event is triggered upon submission of a message into the Submission queues on the receiving SMTP host. All messages encounter this event whether they arrived via SMTP submission, MAPI submission, or the Pickup or Replay directories.
2	**OnResolvedMessage**	This event is triggered after all the recipients have been resolved, but before the next hop has been determined for each recipient. The **OnResolvedMessage** routing event enables subsequent events to override the default routing behavior by using the per-recipient **SetRoutingOverride** method.
3	**OnRoutedMessage**	This event is triggered after messages have been categorized, distribution lists have been expanded, and recipients have been resolved.
4	**OnCategorizedMessage**	This event is triggered when the Categorizer completes processing the message.

Transport agents can be registered on any of the SMTP events that are listed in the preceding tables. However, the intended action of the transport agent usually dictates which SMTP events it will run on.

Consider anti-spam agents as an example. For these agents, the most important consideration, other than the validity of the message contents, is the point at which a valid spam message is identified and rejected. The sooner a message that has been confirmed to be spam is rejected, the lower the cost to your organization. All the SMTP events that are triggered before the **OnEndOfData** SMTP event do not require that a non-delivery receipt (NDR) be generated by the receiving SMTP host. An NDR isn't generated because the full message contents aren't delivered before the **OnEndOfData** SMTP event is reached. Therefore, the sending SMTP host is still responsible for the final delivery of the message. If delivery to the receiving SMTP host fails before the **OnEndOfData** SMTP event, the sending SMTP host must generate the NDR to the message sender. After the **OnEndOfData** SMTP event is reached, the receiving SMTP host has accepted the full contents of the message. This means that the SMTP host now has the responsibility to successfully deliver the message and generate and send an NDR to the message sender. Therefore, it's critical that an anti-spam agent register itself on the SMTP events before the **OnEndOfData** SMTP event is reached to reduce the chance that the receiving SMTP host will store the message contents and have to generate an NDR to the message sender.

However, for antivirus agents, the most important consideration is to make sure that every message is scanned. Agents that must see every message must be configured on the **OnSubmittedMessage** SMTP event. Every message that flows through the transport pipeline encounters the **OnSubmittedMessage** SMTP event because it occurs after all the possible submission entry points, such as SMTP submission from remote hosts, MAPI submission from computers that are running the Mailbox server role, the Pickup directory that is used by custom applications, or the Replay directory used by third-party e-mail applications.

Return to top

Prioritization of Transport Agents

Exchange 2010 lets you specify the priority of transport agents that are included with Exchange and that are added by custom applications. If you specify the priority of a transport agent, you can control which agents act on a message first. Transport agents can be assigned a priority of 1 or higher. Transport agents with a priority closer to 1 are applied to messages first. However, the priority that you assign to a transport agent is only one factor that is used to determine the order in which transport agents are applied to messages. The second factor that is used to determine the priority of transport agents is where the SMTP event that has a registered transport agent fits within the sequence of SMTP events.

As shown in the tables earlier in this topic, SMTP events have a specific sequence in which they are applied to messages that flow through the transport pipeline. Because transport agents are registered to specific SMTP events, the priority only comes into play for agents that are registered to the same SMTP event.

For example, you may have transport agents configured as follows:

- Transport agent **AgentA** with a priority of 1 registered to the **OnEndofHeaders** SMTP event
- Transport agent **AgentB** with a priority of 4 registered to the **OnMailCommand** SMTP event

When you view the list of registered agents by using the **Get-TransportAgent** cmdlet, transport agent **AgentA** is listed with a higher priority than transport agent **AgentB**. However, when a message flows through the transport pipeline, transport agent **AgentB** will be applied to the message before transport agent **AgentA** because the **OnMailCommand** SMTP event encounters the message before the **OnEndOfHeaders** SMTP event.

Return to top

Built-In Transport Agents

Exchange 2010 includes several default transport agents that enable it to provide features such as transport rules and journaling. By default, the transport agents listed in the following tables are installed on Hub Transport servers and Edge Transport servers. The following tables also provide links to topics that contain more information about each agent.

Hub Transport server transport agents

Agent Name	Priority	SMTP events	Related topic
Transport Rule agent	1	**OnRoutedMessage**	Understanding Transport Rules
RMS Decryption agent	The priority of this agent isn't user-configurable.	**OnSubmittedMessage**	Understanding Information Rights Management
Journal Report Decryption agent	The priority of this agent isn't user-configurable.	**OncCategorizedMessage**	Understanding Journaling
RMS Encryption agent	The priority of this agent isn't user-configurable.	**OnRoutedMessage**	Understanding Information Rights Management
Prelicensing agent	The priority of this agent isn't user-configurable.	**OnRoutedMessage**	Understanding Information Rights Management
Journaling agent	The priority of this agent isn't user-configurable.	**OnSubmittedMessage, OnRoutedMessage**	Understanding Journaling

Edge Transport server transport agents

Agent name	Priority	SMTP events	Related topic
Connection Filtering agent	1	**OnConnectEvent**, **OnMailCommand**, **OnRcptComand**, **OnEndOfHeaders**	Understanding Connection Filtering
Address Rewriting Inbound agent	2	**OnRcptCommand**, **OnEndOfHeaders**	Understanding Address Rewriting
Edge Rule agent	3	**OnEndOfData**	Understanding Transport Rules
Content Filter agent	4	**OnEndOfData**	Understanding Content Filtering
Sender ID agent	5	**OnEndOfHeaders**	Understanding Sender ID
Sender Filter agent	6	**OnMailCommand**, **OnEndOfHeaders**	Understanding Sender Filtering
Recipient Filter agent	7	**OnRcptCommand**	Understanding

			Recipient Filtering
Protocol Analysis agent	8	**OnEndOfHeaders**, **OnEndOfData**, **OnReject**, **OnRsetCommand**, **OnDisconnectEvent**	Understanding Protocol Logging
Attachment Filtering agent	9	**OnEndOfData**	Understanding Attachment Filtering
Address Rewriting Outbound agent	10	**OnRcptCommand**, **OnEndOfHeaders**	Understanding Address Rewriting

Troubleshooting Transport Agents

With transport agents, Exchange helps you control the flow of e-mail messages through your organization. This capability enables you to match your Exchange infrastructure to your organization's requirements instead of forcing your organization to match your e-mail infrastructure. As you customize your environment, the complexity of that environment increases. To help you troubleshoot issues that may occur and to help you verify that the changes that you make are applied to messages in the manner you expect, Exchange provides the following features:

- **Get-TransportPipeline cmdlet** The **Get-TransportPipeline** cmdlet shows all the enabled transport agents, and the SMTP events on which they are registered, that have encountered messages in the transport pipeline between the time when the Microsoft Transport service was started and the time when the cmdlet was run. For more information, see View Transport Agents in the Transport Pipeline.

  Note:
  The information that is displayed by the **Get-TransportPipeline** cmdlet is generated only after a message has been sent through the transport pipeline. Also, only the transport agents that encountered the message are displayed.

- **Pipeline Tracing** Pipeline tracing enables you to create an exact snapshot of a whole message before and after it encounters each transport agent. Pipeline tracing enables you to determine which transport agent may have generated unexpected results or to verify that the transport agent behaves as expected.

1.7.1.35 Understanding Transport Database Configuration Options

Understanding Transport Database Configuration Options

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-26*

Servers that have the Microsoft Exchange Server 2010 Hub Transport server role or the

Edge Transport server role installed use Extensible Storage Engine (ESE) database technology for certain transport server components. Formerly known as JET, ESE is a method that defines a low-level API to the underlying database structures in Exchange 2010. ESE is used for the following transport components:

- **Message queue database** A *queue* is a temporary holding location for messages waiting to enter the next stage of processing. Each queue represents a logical set of messages that a transport server processes in a specific order. For more information, see Understanding Transport Queues.
- **IP filter database** The IP filter database stores the IP Allow lists and IP Block lists that are part of connection filtering. For more information, see Understanding Connection Filtering.

The message queue database and the IP filter database are separate ESE databases. These databases don't share any resources. However, you can configure ESE database configuration options on the Hub Transport server or Edge Transport server that apply to all the ESE databases that exist on the server.

Overview of ESE Databases

ESE databases use log files to accept, track, and maintain data. To enhance performance, all transactions are written first to log files and memory, and then to the database file. The checkpoint file tracks the transaction log entries that have been committed to the database. During an ordinary shutdown of the Microsoft Exchange Transport service, uncommitted database changes found in the transaction logs are always committed to the database.

Circular logging is used for the message queue database and the IP filter database. This means that the history of committed transactions found in the transaction logs isn't maintained. Any transaction logs older than the current checkpoint are immediately and automatically deleted. Therefore, the transaction logs can't be replayed for message queue database recovery or IP filter database recovery from backup.

Understanding Storage Configuration

For best practice guidance about the storage configuration of ESE databases, see Understanding Storage Configuration.

Configuring Shared ESE Database Options on Transport Servers

The shared ESE database configuration options are available in the EdgeTransport.exe.config application configuration file located in the C:\Program Files\Microsoft\Exchange Server\V14\Bin directory. The EdgeTransport.exe.config file is an XML application configuration file associated with the EdgeTransport.exe file. EdgeTransport.exe and MSExchangeTransport.exe are the executable files used by the Microsoft Exchange Transport service. This service runs on every Hub Transport server or Edge Transport server. Changes saved to the EdgeTransport.exe.config file are applied after the Microsoft Exchange Transport service is restarted. If a configuration option is missing or is present and contains the default value, the default value is enforced.

This example shows the typical structure of the EdgeTransport.exe.config file.

```
<configuration>
   <runtime>
      <gcServer enabled="true" />
   </runtime>
```

```
   <appSettings>
      <add key="Configuration Option" value="Value" />
      ...
   </appSettings>
</configuration>
```

You can add new configuration options or modify existing configuration options in the <appSettings> section. Many configuration options are unrelated to the shared ESE database options. Any configuration options that don't involve the shared ESE database options are outside the scope of this topic.

Note:

The parameter names in the <add key=../> section are case sensitive.

For information about the message queue database parameters available in the EdgeTransport.exe.config file, see Understanding Transport Queues.

The following table shows the shared ESE database configuration options available in the EdgeTransport.exe.config file.

Shared ESE database configuration options

Parameter name	Description
DatabaseCacheFlushStart	This parameter enables the removal of cached database transactions from memory when the cache is overused. The value of this parameter represents the percentage of the cache that's unused. When the free database cache resources drop under the specified percentage, a background process writes the cached database transactions to the transaction log. The default value is 3.
DatabaseCacheFlushStop	This parameter suspends the removal of cached database transactions from memory when the cache utilization level returns to normal. The value of this parameter represents the percentage of the cache that's unused. When the free database cache resources increase to more than the specified percentage, the background process that writes the cached database transactions to the transaction log is suspended. The default value is 5.
DatabaseCheckPointDepthMax	This parameter controls the total allowed size of all uncommitted transaction logs that exist on the hard disk drive. The default value is **512MB**. Setting the value of the *DatabaseCheckPointDepthMax* parameter too low can cause significant performance issues because uncommitted transactions are forcibly committed to the database instead of being written to transaction logs. We recommend that you don't modify the default value of the *DatabaseCheckPointDepthMax* parameter.
DatabaseMaxCacheSize	This parameter specifies the maximum size of the database cache in memory. The

	default value is **1GB**.

Remember that the message queue database and the IP filter database are isolated from one another. The ESE database files don't share database files, transaction logs, or caches. The shared configuration options apply to each database and its supporting infrastructure. For example, when you set the *DatabaseMaxCacheSize* parameter, you are also setting the maximum cache size for the message queue database and the IP filter database.

1.7.1.36 Understanding Transport Logs

Understanding Transport Logs

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-09*

Transport logs are generated by Hub Transport and Edge Transport servers and they provide information about the functioning of your transport pipeline. Transport servers can generate agent, connectivity, message tracking, protocol, and routing table logs. The following topics provide detailed information about each of these logs.

Understanding Agent Logging

Understanding Connectivity Logging

Understanding Message Tracking

Understanding Protocol Logging

Understanding Routing Table Logging

1.7.1.36.1 Understanding Agent Logging

Understanding Agent Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-17*

Agent logs record the actions performed on a message by specific anti-spam agents installed and configured on a computer running Microsoft Exchange Server 2010 that has the Edge Transport server role or the Hub Transport server role installed. Only the following agents can write information to the agent log:

- Connection Filter agent
- Content Filter agent
- Edge Rules agent
- Recipient Filter agent
- Sender Filter agent
- Sender ID agent

The information written to the agent log depends on the agent, the SMTP event, and the action performed on the message.

The only configurable option for agent logging is the *AgentLogEnabled* parameter in the EdgeTransport.exe.config application configuration file. By default, agent logging is enabled on Hub Transport servers or Edge Transport servers. The other agent log values that aren't configurable are described in the following list:

- Path where the agent logs are stored is C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\AgentLog.
- Maximum size for the individual agent log files is 10 megabytes (MB).
- Maximum size for the directory that contains the agent log files is 250 MB.
- Maximum age for the agent log files is 30 days.

The Exchange 2010 server uses circular logging to limit the agent logs based on file size and file age to help control the hard disk space used by the log files.

Note:
If you want to keep the agent log files longer than allowed by file age or directory size values that you can't configure, you can create a scheduled task that periodically moves the unused agent log files to a different location.

Note:
By default, the transport logging process has a logging level value of 0 (Lowest). If you want Exchange to write an event log entry when circular logging removes a log file, you must change the logging level value of the transport logging process to 5 (Maximum) or 7 (Expert).

Contents

Looking for management tasks related to agent logging? See Managing Transport Servers.

Overview of Transport Agents

Agents can only act upon messages at specific points in the SMTP command sequence used to transport the messages through a Hub Transport server or Edge Transport server. These access points in the SMTP command sequence are called *SMTP events*. Each agent has a priority value that can be assigned. However, the SMTP events must always occur in a specific order. Therefore, the agent priority depends on the SMTP event. If two agents can act on a message during the same SMTP event, the agent that has the highest priority will act on the message first.

The following table lists the SMTP events in order of occurrence and the agents that write information to the agent log in order of priority from highest to lowest for each SMTP event.

SMTP events in order of occurrence and the agents that write

information to the agent log in order of priority for each SMTP event

SMTP event	Agent
OnConnect	Connection Filter agent
OnMailCommand	Connection Filter agent Sender Filter agent
OnRcptCommand	Connection Filter agent Recipient Filter agent
OnEndOfHeaders	Connection Filter agent Sender ID agent Sender Filter agent
OnEndOfData	Edge Rules agent Content Filter agent

For more information about agents, SMTP events, and agent priority, see Understanding Transport Agents.

Return to top

Structure of the Agent Log Files

The agent logs exist in C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\AgentLog.

The naming convention for the agent log files is AGENTLOG*yyyymmdd-nnnn*.log. The placeholders represent the following information:

- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date that the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches 10 MB. Then, a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the agent log directory reaches 250 MB, or when a log file is 30 days old.

The agent log files are text files that contain data in the comma-separated value file (CSV) format. Each agent log file has a header that contains the following information:

- **#Software** Name of the software that created the agent log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the agent log file. Currently, the value is 8.0.0.0.
- **#Log-Type** Log type value, which is Agent Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.

- **#Fields** Comma delimited field names used in the agent log files.

Return to top

Information Written to the Agent Log

The agent log stores each agent transaction on a single line in the log. The information stored on each line is organized by fields. These fields are separated by commas. The field name is generally descriptive enough to determine the type of information it contains. However, some of the fields may be blank. Or the type of information stored in the field may change based on the agent or the action performed on the message by the agent. The following table describes the fields used to classify each agent transaction.

Fields used to classify each agent transaction

Field name	Description
Timestamp	UTC date-time of the agent event. This is represented in the ISO 8601 format. The value is formatted as *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
SessionId	Unique SMTP session identifier. This identifier is represented as a 16-digit hexadecimal number.
LocalEndpoint	Local IP address and port number that accepted the message. SMTP sessions typically use port 25.
RemoteEndpoint	IP address and port number of the previous SMTP server that connected to this server to deliver the message. In an Edge Transport server and Hub Transport server topology, the value of **RemoteEndpoint** in the agent log on the Hub Transport server will be the IP address of the Edge Transport server. Even though the message is transmitted by SMTP, the port number used by the sending server will be a random number larger than 1,024.
EnteredOrgFromIP	IP address of the remote SMTP server that first connected to the Exchange organization to deliver the message. On an Edge Transport server, the value of **RemoteEndpoint** and **EnteredOrgFromIP** are the same. Anti-spam agents use the IP address in **EnteredOrgFromIP** to examine a message.
MessageId	Value of the `MessageID` header field. If this value is blank, the Exchange 2010 transport server assigns an arbitrary value, but only if the message is accepted. After assigned, the value of `MessageID` is constant for the lifetime of the message.
P1FromAddress	Sender e-mail address specified in `MAIL FROM` in the message envelope. This value is used to transport the message between SMTP messaging servers. This value serves as a comparison to the

	value of **P2FromAddresses** to determine whether the sender address in the message header is forged.
P2FromAddresses	Sender e-mail address specified in the `From` header field or in the `Sender` header field in the message header.
Recipient	E-mail address of the recipients. Although the original message may contain multiple recipients, only one recipient is displayed per line in the agent log.
NumRecipients	Total number of recipients in the original message.
Agent	Name of the agent that took the action. The possible values are as follows: • Connection Filter agent • Content Filter agent • Edge Rules agent • Recipient Filter agent • Sender Filter agent • Sender ID agent
Event	SMTP event where the action was taken by the agent. The value of **Event** depends on the agent. The SMTP events available to each agent are described in the first table earlier in this topic. The possible values for **Event** are as follows: • OnConnect • OnEndOfHeaders • OnEndOfData • OnMailCommand • OnRcptCommand
Action	Action performed on the message by the agent. The possible values for **Action** are as follows: • AcceptMessage • DeleteMessage • DeleteRecipients • Disconnect • QuarantineMessage • QuarantineRecipients • RejectAuthentication • RejectCommand • RejectConnection • RejectMessage • RejectRecipients
SmtpResponse	Enhanced SMTP response as defined in RFC 2034.
Reason	Reason for the action supplied by the agent.
ReasonData	Descriptive details for the action supplied by the agent.

Return to top

Searching the Agent Logs

You can use the **Get-AgentLog** cmdlet in the Exchange Management Shell and the Get-AntiSpamFilteringReport script to search the agent logs. For more information, see Get-AgentLog.

Return to top

Enable or Disable Agent Logging

By default, agent logging is enabled on a Hub Transport server or an Edge Transport server. Agent logging is enabled or disabled by modifying the EdgeTransport.exe.config file located in C:\Program Files\Microsoft\Exchange Server\V14\Bin. For more information, see Understanding the EdgeTransport.exe.Config File. EdgeTransport.exe and MSExchangeTransport.exe are the executable files used by the Microsoft Exchange Transport service.

Many available configuration options are unrelated to agent logging. Any configuration options that don't involve agent logging are outside the scope of this topic.

1. Open the following file by using Notepad: C:\Program Files\Microsoft\Exchange Server\V14\Bin\EdgeTransport.exe.config
2. Modify the following line in the <appSettings> section.

```
<add key="AgentLogEnabled" value="<TRUE | FALSE>" />
```

This example disables agent logging by modifying the *AgentLogEnabled* parameter.

```
<add key="AgentLogEnabled" value="FALSE" />
```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

Return to top

1.7.1.36.2 Understanding Connectivity Logging

Understanding Connectivity Logging

Transport > Understanding Transport > Understanding Transport Logs >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-18*

Connectivity logging records the connection activity of the outbound message delivery queues that exist on computers running Microsoft Exchange Server 2010 that have the Hub Transport server role or the Edge Transport server role installed. The connectivity log tracks the connection activity from the sending queue to the destination Mailbox server, smart host, or domain. It isn't intended to track the transmission of individual e-mail messages. The following list describes the type of information recorded in the connectivity log:

- Source queue, which can be the remote delivery queue or mailbox delivery queue
- Destination Mailbox server, smart host, or domain
- Domain Name System (DNS) resolution information
- Detailed information about connection failures
- Number of messages and bytes transmitted

You use the **Set-TransportServer** cmdlet in the Exchange Management Shell to perform all connectivity log configuration tasks. The following options are available for the

connectivity logs on an Edge Transport server or Hub Transport server:

- Enable or disable connectivity logging. The default is disabled.
- Specify the location of the connectivity log files.
- Specify a maximum size for the individual connectivity log files. The default size is 10 megabytes (MB).
- Specify a maximum size for the directory that contains connectivity log files. The default size is 250 MB.
- Specify a maximum age for the connectivity log files. The default age is 30 days.

By default, the Exchange 2010 server uses circular logging to limit the connectivity logs based on file size and file age to help control the hard disk space used by the connectivity log files.

Looking for management tasks related to connectivity logging? See Managing Transport Servers.

Structure of the Connectivity Log Files

By default, the connectivity log files exist in C:\Program Files\Microsoft\Exchange Server \V14\TransportRoles\Logs\Connectivity.

The naming convention for the connectivity log files is CONNECTLOG*yyyymmdd-nnnn*.log. The placeholders represent the following information:

- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date that the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches its maximum specified value, and a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the connectivity log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The connectivity log files are text files that contain data in the comma-separated value file (CSV) format. Each connectivity log file has a header that contains the following information:

- **#Software** Name of the software that created the connectivity log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the connectivity log file. Currently, the value is 8.0.0.0.
- **#Log-Type** Log type value, which is Transport Connectivity Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
- **#Fields** Comma delimited field names used in the connectivity log files.

Information Written to the Connectivity Log

The connectivity log stores each outbound queue connection event on a single line in the connectivity log. The information stored on each line is organized by fields. These fields are separated by commas. The following table describes the fields used to classify each

outgoing queue event.

Fields used to classify each connection event

Field name	Description
date-time	UTC date-time of the connection event, which is represented in the ISO 8601 format. The value is formatted as *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
session	GUID that's unique for each SMTP session but is the same for each event associated with that SMTP session. For MAPI sessions, the session field is blank.
source	Value of SMTP for connections from the remote delivery queue, or the value of MAPI for connections from the mailbox delivery queue.
Destination	Name of the destination Mailbox server, smart host, or domain.
direction	Single character that represents the start, middle, or end of the connection. The possible values for the direction field are as follows: • **+** Connect • **-** Disconnect • **>** Send
description	Text information associated with the connection event. The following values are examples of values for the description field: • Number and size of messages that were transmitted • DNS MX resource record resolution information for destination domains • DNS resolution information for destination Mailbox servers • Connection establishment messages • Connection failure messages

When an outbound delivery queue establishes a connection to a destination Mailbox server, smart host, or domain, the queue may be prepared to send one message or several messages. The connection and message transmission processes generate multiple events written on multiple lines in the connectivity log. Simultaneous connections to different destinations create connectivity log entries related to different destinations that are interlaced. However, you can use the date-time, session, source, and direction fields to arrange the connectivity log entries for each separate connection from start to finish.

1.7.1.36.3 Understanding Message Tracking

Understanding Message Tracking

Transport > Understanding Transport > Understanding Transport Logs >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-01*

A message tracking log is a detailed log of all message activity as messages are transferred to and from a computer that is running Microsoft Exchange Server 2010 and that has the Hub Transport server role, the Mailbox server role, or the Edge Transport server role installed. Exchange servers that have the Client Access server role or Unified Messaging server role installed don't have message tracking logs. You use message tracking logs for message forensics, mail flow analysis, reporting, and troubleshooting.

You can use the **Set-TransportServer** cmdlet for all message tracking configuration tasks on a Hub Transport server or Edge Transport server. You can use the **Set-MailboxServer** cmdlet for all message tracking configuration tasks on a Mailbox server. For servers that have the Hub Transport server role and the Mailbox server role installed, you can use the **Set-TransportServer** cmdlet or the **Set-MailboxServer** cmdlet. You can use these cmdlets to make the following message tracking configuration changes:

- **Enable or disable message tracking**: The default is enabled.
- **Specify the location of the message tracking log files**
- **Specify a maximum size for the individual message tracking log files**: The default is 10 MB.
- **Specify a maximum size for the directory that contains the message tracking log files**: The default is 1000 MB.
- **Specify maximum age for the message tracking log files**: The default is 30 days.
- **Enable or disable message subject logging in the message tracking logs** The default is enabled.

Note:

You can also use the Exchange Management Console on a Hub Transport server or Edge Transport server to enable or disable message tracking, and to specify the location of the message tracking log files.

Exchange 2010 uses log rotation to limit the message tracking logs based on both file size and age. This helps limit the hard disk space that is used by the log files.

Structure of the Message Tracking Log Files

By default, the message tracking log files exist in C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\MessageTracking.

The naming convention for log files in the message tracking log directory depends on the server role that is installed. On a Hub Transport server or an Edge Transport server, the log files are named MSGTRK*yyyymmdd-nnnn*.log. On a Mailbox server, the log files are named MSGTRKM*yyyymmdd-nnnn*.log. When the Hub Transport server role and Mailbox server role are installed on the same server, separate log files that use these different name prefixes are created in the message tracking log directory.

The placeholders in the log file names represent the following information:

- The placeholder *yyyymmdd* is the coordinated universal time (UTC) date on which the log file was created. *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 daily for each message tracking log file name prefix.

Information is written to each log file until the file size reaches its maximum specified value for each log file. Then, a new log file that has an incremented instance number is

opened. This process is repeated throughout the day. The log file rotation functionality deletes the oldest log files when either of the following conditions is true:

- A log file reaches its maximum specified age.
- The message tracking log directory reaches its maximum specified size.

Important:

The maximum size of the message tracking log directory is calculated as the total size of all log files that have the same name prefix. Other files that do not follow the name prefix convention are not counted in the total directory size calculation. Renaming old log files or copying other files into the message tracking log directory could cause the directory to exceed its specified maximum size. When the Hub Transport server role and the Mailbox server role are installed on the same server, the maximum size of the message tracking log directory is not the specified maximum size, because the message tracking log files that are generated by the different server roles have different name prefixes. When the Hub Transport server role and the Mailbox server role are installed on the same server, the maximum size of the message tracking log directory is two times the specified value.

The message tracking log files are text files that contain data in the comma-separated value (CSV) format. Each message tracking log file has a header that contains the following information:

- **#Software:** The name of the software that created the message tracking log file. Typically, the value is Microsoft Exchange Server.
- **#Version:** The version number of the software that created the message tracking log file. Currently, the value is 14.0.0.0.
- **#Log-Type:** The value of this field is Message Tracking Log.
- **#Date:** The UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
- **#Fields:** The comma-delimited field names that are used in the message tracking log files. The following fields are listed:

Information that is Written to the Message Tracking Log

The message tracking log stores each message event on a single line in the log. The events types that are used to classify each message event are explained in Table 1.

Table 1 Event Types that are Used to Classify Each Message Event

Event name	Description
BADMAIL	A message was submitted by the Pickup directory or the Replay directory that cannot be delivered or returned.
DELIVER	A message was delivered to a mailbox.
DEFER	Message delivery was delayed.
DSN	A delivery status notification (DSN) was generated.
DUPLICATEDELIVER	A duplicate message was delivered to the recipient. Duplication may occur if a recipient is a member of two distribution groups.

	Duplicate messages are detected and removed by the information store.
EXPAND	A distribution group was expanded.
FAIL	Message delivery failed.
POISONMESSAGE	A message is put in the poison message queue or removed from the poison message queue.
RECEIVE	A message was received and committed to the database. The RECEIVE event can be SMTP receive (Source: SMTP) or mail submitted by STOREDRIVER (Source: STOREDRIVER). SMTP RECEIVE can be from any source that submits a message by using SMTP. For example, it can be a Hub Transport server role, an Edge Transport server role, a third-party message transfer agent (MTA), or a POP/IMAP client. STOREDRIVER RECEIVE is logged by the EdgeTransport.exe process, and is the event that corresponds to a STOREDRIVER SUBMIT event. STOREDRIVER SUBMIT is logged by the Mail Submission process. These events can be on the same server if both server roles are installed locally, or they can be on different servers. **Note:** EdgeTransport.exe and MSExchangeTransport.exe are the executable files that are used by the Microsoft Exchange Transport service. This service runs on every Hub Transport server or Edge Transport server.
REDIRECT	A message was redirected to an alternative recipient after an Active Directory directory service lookup.
RESOLVE	A message's recipients were resolved to a different e-mail address after an Active Directory lookup.
SEND	A message was sent by Simple Mail Transfer Protocol (SMTP) to a different server.
SUBMIT	A SUBMIT event is logged by the Mail Submission service on an Exchange 2007 computer that is running the Mailbox server role. The SUBMIT event is logged when the service has successfully notified a Hub Transport server that a message is awaiting submission in the mailbox store. The SourceContext property provides the Messaging Database (MDB) GUID, Mailbox

	GUID, Event sequence number, Message class, Creation time stamp of the client submission to store, and Client type. The Client type can be User (Outlook direct MAPI), RPCHTTP (Outlook Anywhere), Outlook Web Access, Exchange Web Services (EWS), Exchange ActiveSync, Assistants, or Transport. The message tracking logs that are generated by the Mailbox server role contain only SUBMIT events.
TRANSFER	Recipients were moved to a forked message because of content conversion, message recipient limits, or agents.

The message event information that is stored on each line is organized by fields. These fields are separated by commas. The field name is generally descriptive enough to determine the type of information that it contains. However, some fields may be blank, or the type of information that is stored in the field may change based on the message event type as described in Table 1. General descriptions of the fields that are used to classify each message tracking event are explained in Table 2.

Table 2 Fields that are Used to Classify Each Message Tracking Event

Field name	Description
date-time	The UTC date-time of the message tracking event, which is represented in the ISO 8601 format. The value is formatted as *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
client-ip	The TCP/IP address of the messaging server or messaging client that submitted the message.
client-hostname	The name of the messaging server or messaging client that submitted the message.
server-ip	The TCP/IP address of the source or destination Exchange server.
server-hostname	The name of the destination server.
source-context	Extra information associated with the source field.
connector-id	The name of source or destination Send connector or Receive connector.
source	The Exchange transport component responsible for the message tracking event. The possible values for this field are as follows: • ADMIN for Replay directory submission • AGENT • DSN • GATEWAY for Foreign connector submission • PICKUP

	• ROUTING • SMTP • STOREDRIVER for MAPI submission
event-id	The message event type. These events are described fully in Table 1 earlier in this topic. The possible values are BADMAIL, DEFER, DELIVER, DSN, EXPAND, FAIL, POISONMESSAGE, RECEIVE, REDIRECT, RESOLVE, SEND, SUBMIT, and TRANSFER.
internal-message-id	A message identifier that is assigned by Exchange 2010 server that is currently processing the message. A specific message's value of internal-message-id is different in the message tracking log of every Exchange 2010 server that is involved in the delivery of the message.
message-id	The value of the `Message-Id:` field found in the message's header fields. If the `Message-Id:` header field does not exist or is blank, an arbitrary value is assigned. This value is constant for the lifetime of the message.
recipient-address	The e-mail addresses of the message's recipients. Multiple e-mail addresses are separated by the semicolon character (;).
recipient-status	This field is populated for a SEND event or a FAIL event.
total-bytes	The size of the message that includes attachments, in bytes.
recipient-count	The number of recipients in the message.
related-recipient-address	This field is used with EXPAND, REDIRECT, and RESOLVE events to display other recipient e-mail addresses associated with the message.
reference	This field contains additional information for specific types of events: **DSN** The Reference field contains the Internet-Message-Id of the message that caused the DSN. **SEND** The Reference field contains the Internet-Message-Id of any delivery status notification (DSN) messages. **TRANSFER** The Reference field contains the Internal-Message-Id of the message that is being forked. For all other types of events, the Reference field is blank.
message-subject	The message's subject found in the `Subject:` header field. The tracking of message subjects is controlled by the

	MessageTrackingLogSubjectLoggingEnabled parameter in the **Set-TransportServer** cmdlet for Hub Transport servers and Edge Transport servers, or in the **Set-MailboxServer** cmdlet for Mailbox servers. By default, message subject tracking is enabled. Message subject logging can be disabled by setting the value of the *MessageTrackingLogSubjectLoggingEnabled* parameter to `$false`.
sender-address	The e-mail address specified in the `Sender:` header field, or the `From:` header field if `Sender:` is not present.
return-path	The return e-mail address specified by `MAIL FROM:` in the message envelope. Although this field is never empty, it can have the null sender address value represented as <>.
message-info	This field contains the message origination date-time for DELIVER and SEND events. The origination date-time is the time that the message first enters the Exchange organization. The value is formatted as *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.

You can use the **Get-MessageTrackingLog** cmdlet in the Exchange Management Shell or the Message Tracking tool in the Exchange Management Console to search for messages by using specific message criteria.

Security Concerns for the Message Tracking Log

No message content is stored in the message tracking log. By default, the subject line of an e-mail message is stored in the message tracking log. You may want to disable message subject logging to comply with increased security or privacy requirements. Before you enable or disable message subject logging, make sure that you verify your organization's policy about revealing subject line information.

Understanding Protocol Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-23*

Protocol logging records the SMTP conversations that occur between e-mail servers as part of message delivery. These SMTP conversations occur on Send connectors and Receive connectors configured on servers running Microsoft Exchange Server 2010 that have the Hub Transport server role or the Edge Transport server role installed. You can use protocol logging to diagnose mail flow problems.

By default, protocol logging is disabled on all Send connectors and Receive connectors. Protocol logging is enabled or disabled on a per-connector basis. Other protocol logging options are set on a per-connector type basis for the whole server. All the Receive connectors on a Hub Transport server or an Edge Transport server share the same protocol log files and protocol log options. These protocol log files and protocol log options are separate from the Send connector protocol log files and protocol log options on the same server.

The following options are available for the protocol logs of all Send connectors or all Receive connectors on an Edge Transport server or a Hub Transport server:

- Specify the location of the Send connector or the Receive connector protocol log files.
- Specify a maximum size for the Send connector or the Receive connector protocol log files. The default size is 10 megabytes (MB).
- Specify a maximum size for the directory that contains the Send connector or Receive connector protocol log files. The default size is 250 MB.
- Specify a maximum age for the Send connector or Receive connector protocol log files. The default age is 30 days.

By default, the Exchange 2010 server uses circular logging to limit the protocol logs based on file size and file age to help control the hard disk space used by the log files.

A special Send connector named the intra-organization Send connector exists on every Hub Transport server. This connector is implicitly created, invisible, and requires no management. The intra-organization Send connector is used to relay messages to the following destinations:

- To other Hub Transport servers in the Exchange organization, including Exchange 2007 Hub Transport servers
- To Exchange Server 2003 servers in the Exchange organization
- To Edge Transport servers in the Exchange organization

By default, protocol logging for the intra-organization Send connector is disabled. You can enable or disable protocol logging for the intra-organization Send connector by using the *IntraOrgConnectorProtocolLoggingLevel* parameter on the **Set-TransportServer** cmdlet. If you enable protocol logging for the intra-organization Send connector, logging occurs in the Send connector protocol logs configured on the Hub Transport server.

Looking for management tasks related to protocol logging? See Managing Transport Servers.

Structure of the Protocol Log Files

By default, the protocol log files exist in the following locations:

- **Receive connector protocol log files** C:\Program Files\Microsoft\Exchange

Server\V14\TransportRoles\Logs\ProtocolLog\SmtpReceive
- **Send connector protocol log files** C:\Program Files\Microsoft\Exchange Server\V14TransportRoles\Logs\ProtocolLog\SmtpSend

The naming convention for log files in each protocol log directory is *prefixyyyymmdd-nnnn*.log. The placeholders represent the following information:
- The placeholder *prefix* is SEND for Send connectors or RECV for Receive connectors.
- The placeholder *yyyymmdd* is the Coordinated Universal Time (UTC) date on which the log file was created. The placeholder *yyyy* = year, *mm* = month, and *dd* = day.
- The placeholder *nnnn* is an instance number that starts at the value of 1 for each day.

Information is written to the log file until the file size reaches its maximum specified value, and a new log file that has an incremented instance number is opened. This process is repeated throughout the day. Circular logging deletes the oldest log files when the protocol log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The protocol log files are text files that contain data in the comma-separated value file (CSV) format. Each protocol log file has a header that contains the following information:
- **#Software** Name of the software that created the protocol log file. Typically, the value is Microsoft Exchange Server.
- **#Version** Version number of the software that created the protocol log file. Currently, the value is 14.0.0.0.
- **#Log-Type** Log type value of this field, which is either SMTP Receive Protocol Log or SMTP Send Protocol Log.
- **#Date** UTC date-time when the log file was created. The UTC date-time is represented in the ISO 8601 date-time format: *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
- **#Fields** Comma-delimited field names used in the protocol log files.

Information Written to the Protocol Log

The protocol log stores each SMTP protocol event on a single line in the protocol log. The information stored on each line is organized by fields. These fields are separated by commas. The following table describes the fields used to classify each protocol.

Fields used to classify each protocol event

Field name	Description
date-time	UTC date-time of the protocol event, which is represented in the ISO 8601 format. The value is formatted as *yyyy-mm-ddThh:mm:ss.fffZ*, where *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute, *ss* = second, *fff* = fractions of a second, and *Z* signifies Zulu, which is another way to denote UTC.
connector-id	Distinguished name (DN) of the connector associated with the SMTP event.
session-id	GUID that's unique for each SMTP session but is the same for each event associated with that SMTP session.
sequence-number	Counter that starts at 0 and is incremented for

	each event in the same SMTP session.
local-endpoint	Local endpoint of an SMTP session. This consists of an IP address and TCP port number formatted as *<IP address>:<port>*.
remote-endpoint	Remote endpoint of an SMTP session. This consists of an IP address and TCP port number formatted as *<IP address>:<port>*.
event	Single character that represents the protocol event. The possible values for the event are as follows: • + Connect • - Disconnect • > Send • < Receive • * Information
data	Text information associated with the SMTP event.
context	Additional contextual information that may be associated with the SMTP event.

A single SMTP conversation that represents the sending or receiving of a single e-mail message generates multiple SMTP events. These SMTP events cause multiple lines to be written to the protocol log. Multiple SMTP conversations that represent the sending or receiving of multiple e-mail messages can occur at the same time. This creates protocol log entries from different SMTP conversations that are interspersed. You can use the session-id and sequence-number fields to sort the protocol log entries by SMTP conversation.

1.7.1.36.5 Understanding Routing Table Logging

Understanding Routing Table Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-17*

Routing table logging periodically records a snapshot of the routing table that's used by the computer that's running Microsoft Exchange Server 2010 that has the Hub Transport server role or Edge Transport server role installed. The routing table is used to route messages to their destinations. The routing table log is recorded in these cases:

- After a fixed time interval.
- After the Microsoft Exchange Transport service is started.
- After a routing configuration change is detected.

The routing table log can be used to help troubleshoot mail flow and routing issues.

You can control the automatic routing table recalculation interval in the EdgeTransport.exe.config application configuration file. This value controls how frequently the routing table is automatically recalculated and how frequently the routing table is logged. However, regular routing table updates may cause the routing table to be recalculated and logged earlier than the specified automatic recalculation interval as explained later in this topic.

You use the **Set-TransportServer** cmdlet to perform all other routing table log configuration tasks. The following options are available for the routing table logs on an Edge Transport server or Hub Transport server:

- Specify the location of the routing table log files.
- Specify a maximum size for the directory that contains routing table log files. The default size is 50 megabytes (MB).
- Specify a maximum age for the routing table log files. The default age is seven days.

By default, the Exchange 2010 server uses circular logging to limit the connectivity logs based on file size and file age to help control the hard disk space that's used by the log files.

In Exchange 2010, you can use the Routing Log Viewer in the Exchange Management Console to view and search the routing table logs. For more information, see Using the Routing Log Viewer.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Structure of the Routing Table Log Files

By default, the routing table log files exist in C:\Program Files\Microsoft\Exchange Server \V14\TransportRoles\Logs\Routing.

The naming convention for the routing table log files is RoutingConfig#1@*UTCcreationdate-time*.xml. For example, depending on your regional date-time format settings, the routing table log files may be named RoutingConfig#1@*mm_dd_yyyy hh_mm_ss*.xml. The placeholders represent the following information: *yyyy* = year, *mm* = month, *dd* = day, *hh* = hour, *mm* = minute and *ss* = second. The date-time is always represented in Coordinated Universal Time (UTC).

The routing table log is a complete snapshot of the routing table that's stored in memory. The routing table is written to the routing table log when the following events occur:

- A routing configuration change is detected. An example of a configuration change is adding or removing a Send connector in the Exchange organization or a Receive connector on the local server. A regular routing configuration change occurs when the Hub Transport server or Edge Transport server renews its Kerberos token with an Active Directory domain controller. The renewal of the Kerberos token causes a recalculation of the routing table and the creation of a new routing table log. The Kerberos token is renewed every six hours.
- The time interval specified by the *RoutingConfigReloadInterval* parameter in the EdgeTransport.exe.config has passed. This value specifies how frequently the routing table is automatically recalculated and logged if no routing configuration changes are detected. The default value is 12 hours.
- The Microsoft Exchange Transport service is started.

Circular logging deletes the oldest log files when the routing table log directory reaches its maximum specified size, or when a log file reaches its maximum specified age.

The routing table log files are text files that contain data in XML format. The routing table log files contain a large amount of information. However, the actual file size depends on the size and complexity of the Exchange organization.

Information Written to the Routing Table

Log

The routing table log is composed of several sections. Each section identifies a particular element of the Exchange organization, such as connectors, address spaces, or Active Directory sites. The information that's defined in one section is connected to the information that's defined in another section to build a complete routing table for the whole Exchange organization. For large Exchange organizations, the amount of information in the routing table log can be very large. The following table provides a description for each section of the routing table log.

Sections of the routing table log

Section	Description
RoutingTables ID	This section contains basic information about the routing table, such as the following information: • The routing table creation date-time in UTC. • On Hub Transport servers, the ExchangeTopology ID, ADSiteRelayMap ID, and RoutingGroupRelayMap ID that are being used by the routing table. • On Hub Transport servers, the identity of every Mailbox server, Hub Transport server, Edge Transport server, and legacy Exchange server in the Exchange organization. Each identity maps to a ServerRoute ID. • The ConnectorRouting ID for all Send connectors, Receive connectors that are linked to Send connectors on the local server, foreign connectors, and legacy gateway connectors in the Exchange organization. Legacy gateway connectors exist on the server that's running Exchange Server 2003. Legacy gateway connectors send messages to other messaging servers, such as Lotus Notes or GroupWise.
ExchangeTopology ID	This section contains all the Exchange servers, Active Directory sites, and Active Directory site links that exist in the Exchange organization.
TopologyServer ID	This section contains details about every Exchange server in the Exchange organization.
TopologySite ID	This section contains details about every Active Directory site in the Exchange organization.
TopologySiteLink ID	This section contains details about the IP site links that exist in the Exchange organization.
ADSiteRelayMap ID	This section links an ADTopologyPath ID to each remote Active Directory site that contains an Exchange 2010 Hub Transport server.
ADTopologyPath ID	This section contains details about the least cost routing path from the current Active Directory site to any remote Active Directory site.

TargetSite ID	This section contains the names of all remote Active Directory sites that exist in the Active Directory forest, and a list of Hub Transport servers that exist in each remote Active Directory site.
RoutingGroupRelayMap ID	This section maintains the interrelationship between a routing group, the RgTopologySite ID, the RgTopologyPath ID, and the RgConnectorRoute ID.
RgTopologySite ID	This section contains details about each routing group that exists in the Exchange organization.
RgTopologyLink ID	This section contains details about routing group connectors and SMTP connectors with connected routing groups.
RgTopologyPath ID	This section contains details about remote routing groups and is used to link remote routing groups to a routing group connector or an SMTP connector that contains connected routing groups.
RgConnectorRoute ID	This section contains the route to the first hop routing group that can be used to route mail to a remote routing group.
ServerRoute ID	This section lists every Hub Transport server, Edge Transport server, Mailbox server, and legacy Exchange server object in the Exchange organization, and associates a route to that server.
ConnectorRouting ID	This section contains routes to all Send connectors, foreign connectors, and legacy gateway connectors. It also contains a mapping of Receive connectors on the local server that are linked to Send connectors on the local server. When a Receive connector is linked to a Send connector, all messages that arrive on the linked Receive connector are immediately forwarded out through the corresponding Send connector.
ConnectorRoute ID	This section lists all the Send connectors, foreign connectors, and legacy gateway connectors in the Exchange organization, and associates a route to the connector.
SmtpSendConnectorConfig ID	This section contains details about every Send connector that exists in the Exchange organization.
AddressSpace ID	This section lists all the address spaces that are configured on every Send connector, foreign connector, or legacy gateway connector in the Exchange organization.
LegacyGatewayConnector ID	This section lists details about every legacy gateway connector that exists in the Exchange organization. Legacy gateway connectors exist on servers that are running Exchange 2003.

ForeignConnector ID	This section contains details about every foreign connector that exists in the Exchange organization. Foreign connectors are homed on Exchange 2010 Hub Transport servers and use a Drop directory to send messages to non-SMTP messaging servers.
AddressTypeRouting ID	This section maps an address type to an SmtpConnectorIndex ID.
SmtpConnectorIndex ID	This section contains the SMTPIndexNode ID of the root index that's supported by this SMTPConnectorIndex ID.
X400ConnectorIndex ID	This section contains the X400IndexNode ID of the root index that's supported by this X400ConnectorIndex ID.
GenericConnectorIndex ID	This section contains the IndexEntry ID of the root index that's supported by this GenericConnectorIndex ID.
SMTPIndexNode ID	This section contains the SMTPIndexNode ID, which represents a part of an SMTP address space. The values of the index nodes are combined to form the complete SMTP address space. For example, the domain exchange.contoso.com has the following four index nodes: • The root SMTP index node • The com SMTP index node • The contoso SMTP index node • The exchange SMTP index node
X400IndexNode ID	This section contains the X400IndexNode ID, which represents a part of an X.400 address space. The values of the index nodes are combined to form the complete X.400 address space.
IndexEntry ID	This section contains the IndexEntry ID, which represents a part of a non-SMTP address space, such as Lotus Notes or fax. The values of the index entries are combined to form the complete non-SMTP address space.
ConnectorRouteWithCost ID	This section links an address space cost to a connector route.

1.7.1.37 Understanding Transport Pipeline

Understanding Transport Pipeline

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

In Microsoft Exchange Server 2010, the transport pipeline is a collection of Exchange 2010 server roles, connections, components, and queues that work together to route all messages to the categorizer on a Hub Transport server inside the organization.

Messages from outside the organization enter the transport pipeline through a Receive connector on an Edge Transport server and are then routed to a Hub Transport server inside the organization. Messages inside the organization enter the transport pipeline on a Hub Transport server in one of the following ways:

- Through a Receive connector
- From the Pickup directory or the Replay directory
- By direct placement in the Submission queue by the store driver
- Through agent submission

Every message that's sent or received by an Exchange 2010 client must be categorized on a Hub Transport server before it can be routed and delivered. After a message has been categorized, it's put in a delivery queue for delivery to a mailbox in the same Active Directory site as the Hub Transport server on which the message was categorized or for routing to a recipient in a different Active Directory site or forest, or to a recipient outside the organization.

The Exchange 2010 transport pipeline consists of the following components and processes:

- **SMTP Receive** When messages are received at the Edge Transport server, anti-spam and antivirus agents filter connections and message contents, and help identify the sender and the recipient of a message while the message is being accepted into the organization. When messages are received at a Hub Transport server, transport rules are applied and, if anti-spam and antivirus agents are configured, these agents provide an additional layer of anti-spam and antivirus protection.
  The SMTP session has a series of events that work together in a specific order to validate the contents of a message before it's accepted into the organization. After a message has passed completely through SMTP Receive and isn't rejected by receive events or by an anti-spam and antivirus agent, it's put in the Submission queue.
- **Submission** Submission is the process of putting messages into the Submission queue. The categorizer picks up one message at a time for categorization. There are four types of submission:
  - SMTP submission through a Receive connector.
  - Submission through the Pickup directory or the Replay directory. These directories exist on the Hub Transport server or Edge Transport server. Correctly formatted message files that are copied into the Pickup directory or the Replay directory are put directly into the Submission queue.
  - Submission by the store driver, which picks up messages from a sender’s Outbox as they're sent.
  - Submission by an agent.

  On the Edge Transport server, submission is generally only through the Receive connector. On the Hub Transport server, submission can occur through a Receive connector, Pickup directory, Replay directory, or store driver.
- **Categorizer** The categorizer picks up one message at a time from the Submission queue. On the Edge Transport server, categorization is a short process in which the message is put directly in the delivery queue. From the delivery queue, the message is routed to a computer that's running a Hub Transport server role in the organization.
  On the Hub Transport server, the categorizer completes the following steps:
  - Recipient resolution, which includes top-level addressing, expansion, and bifurcation
  - Routing resolution
  - Content conversion

  Additionally, mail flow rules that are defined by the organization are applied. After messages have been categorized, they're put into a delivery queue. A mailbox delivery queue delivers the message to a local mailbox by using the store driver. A remote delivery queue delivers the message to a remote

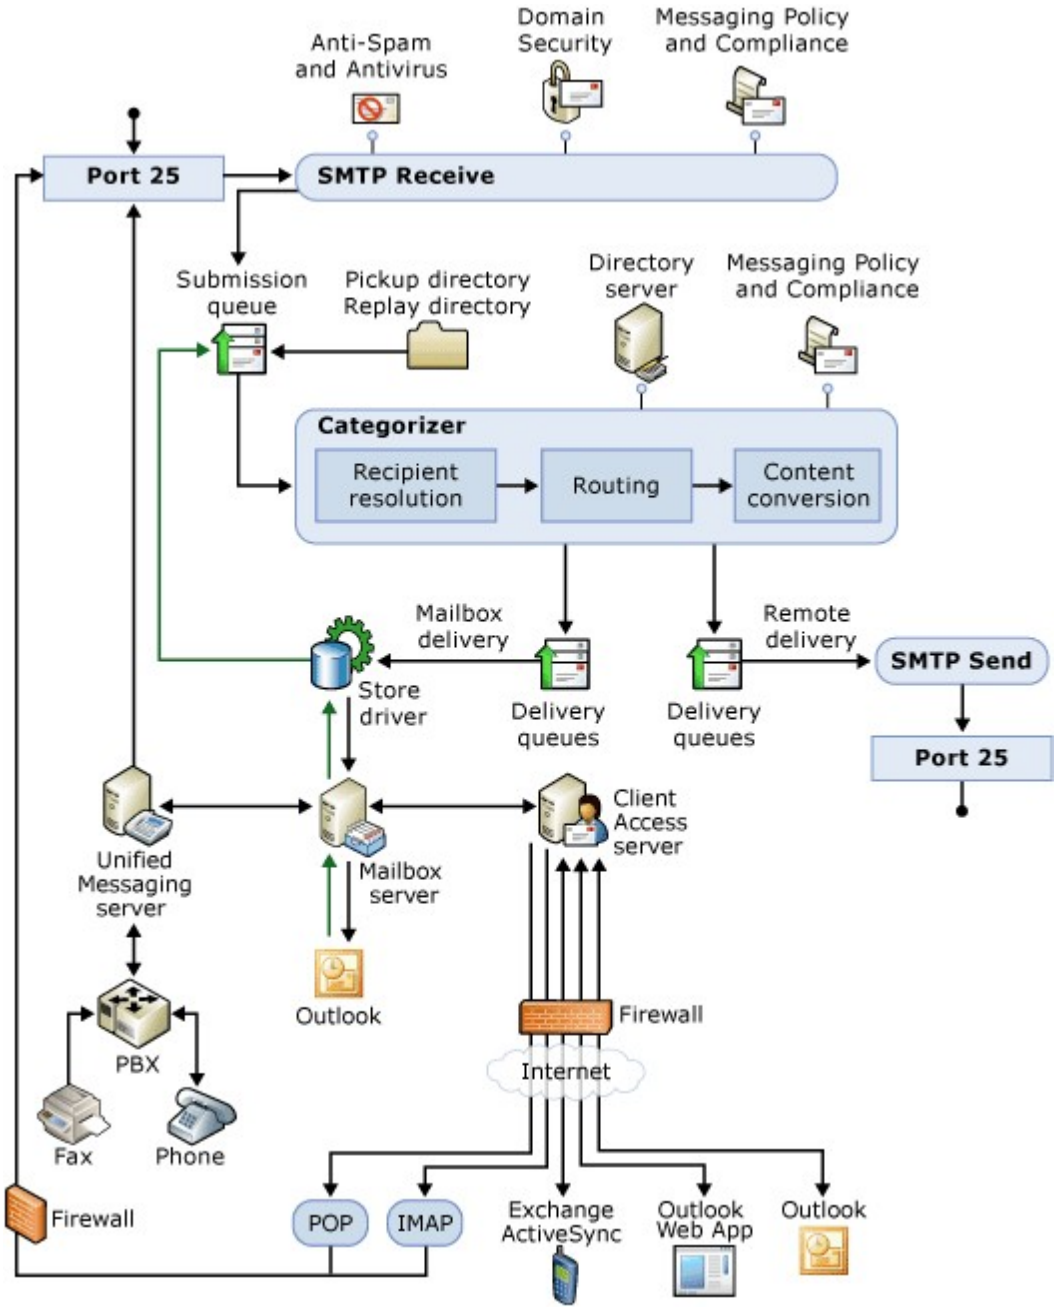
recipient through a Send connector.

- **Local Delivery** Only messages that are sent to a recipient with a mailbox in the same Active Directory site as the Hub Transport server on which categorization occurred are delivered locally. In this case, local delivery means delivery in the same Active Directory site. All messages delivered locally are picked up from a delivery queue by the store driver and put in the recipient's inbox on a Mailbox server.
- **SMTP Send** Messages that are sent to recipients in Active Directory sites that differ from the computer that's running a Hub Transport server role on which categorization occurred are delivered remotely or outside the organization. All messages that are sent to a different Active Directory site, to a mailbox that resides on a computer that's running an earlier version of Exchange, or to a mailbox that resides in a different Active Directory forest must be routed through a Send connector to a Hub Transport server that can deliver the message to the intended recipient. All messages that require delivery through the Internet must be routed through a Send connector to an Edge Transport server that can send messages to the Internet for delivery outside the organization.
- **Client Access and Unified Messaging Scenarios** Several client access scenarios and Unified Messaging scenarios don't interact directly with the transport pipeline. Users of Microsoft Outlook 2007, Outlook 2003, Outlook Web App, Outlook Voice Access, and Exchange ActiveSync interact directly with the Client Access server role, Unified Messaging server role, and Mailbox server role to access their mailbox. In each case, when mail is sent, the message is put in the sender's Outbox directly on the Mailbox server by Outlook or the Client Access server on behalf of the sender.

  Note:
  Outlook Voice Access requires interaction with the Client Access server and with the Mailbox server through the Unified Messaging server.

  After the message is put in the sender's Outbox, the store driver is alerted by the Microsoft Exchange Mail Submission service, which retrieves the message from the sender's Outbox, and then puts it into the Submission queue on a Hub Transport server in the same Active Directory site as the mailbox from which the message was retrieved.

The following figure shows the relationships among the components in the Exchange 2010 transport pipeline.



Looking for management tasks related to managing transport servers? See Managing Transport Servers.

1.7.1.38 Understanding Transport Policy and Compliance Agents

Understanding Transport Policy and Compliance Agents

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Many organizations are obligated by legal, regulatory, or business process requirements to process, filter, modify, and store e-mail messages transferred to and from the organization and the Internet, in addition to internal communications between individuals in the organization. The transport policy and compliance infrastructure of Microsoft Exchange Server 2010 provides a set of rules that govern how e-mail messages are stored and processed based on a set of requirements. The following important features help you comply with these legal, regulatory, and business process requirements more easily:

- **Transport rules agents** There are two transport rules agents in Exchange 2010. The Transport Rule agent runs on Hub Transport servers and helps you meet regulatory and corporate policy requirements. The Edge Rule agent runs on the Edge Transport server and helps you protect your organization from unsolicited commercial e-mail (spam) and viruses. For more information about transport rules agents and specific scenarios where they might be used, see the following topics:
  - Understanding Transport Rules
  - Understanding How Transport Rules Are Applied
  - Understanding Ethical Walls
- **Journaling agent** The Journaling agent helps you configure how Exchange enforces e-mail retention policies on messages sent or received by departments or individuals in your organization, to and from recipients outside your organization, or both.

  Important:
  In Exchange 2010, the Journaling agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TranpsortAgent** cmdlet. For more details, see Understanding Transport Agents.

  For more information about the Journaling agent, journal reports, and journaling in a mixed Exchange Server 2003 and Exchange Server 2007 organization or in a mixed Exchange 2010 and Exchange Server 2007 organization, see the following topics:
  - Understanding Journaling
  - Understanding Journal Reports
  - Protecting Journal Reports
  - Understanding How to Manage Journal Reports
  - Understanding Journaling in a Mixed Exchange 2003 and Exchange 2010 Environment
  - Export and Import Exchange 2007 Journal Rules
- **Information Rights Management (IRM) agents** There are three IRM agents in Exchange 2010. The Encryption agent IRM-protects messages flagged by the Transport Rule agent on Hub Transport servers. The Pre-licensing agent inserts a use license in messages that are IRM-protected by using the organization's Active Directory Rights Management Services (AD RMS) cluster. The Decryption agent decrypts IRM-protected messages to allow other transport agents access to message content, and for including a plaintext copy of the message in journal reports for archival and discovery.
  For more information about IRM agents, see the following topics:
  - Understanding Information Rights Management
  - Understanding Transport Protection Rules
  - Understanding Transport Decryption
  - Understanding Journal Report Decryption

Using Exchange Hosted Services

Policy and compliance features are enhanced by or are also available as services from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

1.7.1.39 Understanding Transport Queues

Understanding Transport Queues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic provides an overview of queues in Microsoft Exchange Server 2010 and the queue management tasks that administrators can perform.

Looking for management tasks related to managing transport servers? See Managing Transport Servers.

Contents

Overview

A *queue* is a temporary holding location for messages that are waiting to enter the next stage of processing. Each queue represents a logical set of messages that a transport server processes in a specific order.

The Exchange Management Shell and Queue Viewer support two types of interaction with queues. You can use these interfaces to view the status and contents of queues and detailed message properties. You can also use these interfaces to perform actions that modify queues or the messages in the queues.

Exchange 2010 uses an Extensible Storage Engine (ESE) database for queue storage. Formerly known as JET, ESE is a method that defines a low-level API to the underlying database structures in Exchange.

Messages that come from and go to the Internet are queued at the computers that have the Edge Transport server role installed. Messages in transit within the Exchange 2010 organization are queued at the computers that have the Hub Transport server role installed.

Types of Queues

The routing of a message determines the type of queue in which a message is stored. The following types of queues are used in Exchange 2010:

- **Submission queue** A persistent queue that's used by the categorizer to gather all messages that have to be resolved, routed, and processed by transport agents. The *categorizer* is a component of Exchange transport that processes all inbound messages and determines what to do with the messages based on information about the intended recipients. In Exchange 2010, the Edge Transport server uses the categorizer to route the message to the appropriate destination. The Hub Transport server uses the categorizer to expand distribution lists and to identify alternative recipients and forwarding addresses. After the categorizer retrieves full information about recipients, it uses that information to apply policies, route the message, and perform content conversion.
  All messages that are received by a transport server enter processing in the Submission queue. Messages are submitted through a Receive connector, the Pickup directory, or the store driver. The categorizer retrieves messages from this queue and, among other things, determines the location of the recipient and the route to that location. After categorization, the message is moved to a delivery queue or to the unreachable queue. Each Exchange 2010 transport server has only one Submission queue. Messages that are in the Submission queue can't be in other queues at the same time.
- **Mailbox delivery queue** The mailbox delivery queues hold messages that are being delivered to a Mailbox server by using encrypted Exchange RPC. Mailbox delivery queues exist on Hub Transport servers only. Mailbox delivery queues hold messages that are being delivered to mailbox recipients whose mailbox data is stored on a Mailbox server that's located in the same site as the Hub Transport server. More than one mailbox delivery queue can exist on a Hub Transport server. The next hop for a mailbox delivery queue is the distinguished name of the mailbox store.
- **Remote delivery queue** Remote delivery queues hold messages that are being delivered to a remote server by using SMTP. Remote delivery queues can exist on both Hub Transport servers and Edge Transport servers, and more than one remote delivery queue can exist on each server. Each remote delivery queue contains messages that are being routed to recipients that have the same delivery destination. On an Edge Transport server, these destinations are external SMTP domains or SMTP connectors. On a Hub Transport server, these destinations are outside the Active Directory site in which the Hub Transport server is located. Remote delivery queues are dynamically created when they're required and are automatically deleted from the server when they no longer hold messages and the configurable expiration time has passed. By default, a remote delivery queue is deleted three minutes after the last message has left the queue. The next hop for a remote delivery queue is an SMTP domain name, a smart host name or IP address, or an Active Directory site name.
- **Poison message queue** The poison message queue is a special queue that's used to isolate messages that are detected to be potentially harmful to the Exchange 2010 system after a server failure. Messages that contain errors that are potentially fatal to the Exchange system are delivered to the poison message queue. This queue is typically empty, and if no poison messages exist, the queue doesn't appear in the queue viewing interfaces. The poison message queue is always in a ready state. By default, all messages in this queue are suspended. The messages can be deleted if they're considered to be harmful to the system. If the event that caused the message to enter the

poison message queue is determined to be unrelated to the message, delivery of the message can be resumed. When delivery is resumed, the message enters the Submission queue.

- **Unreachable queue** Each transport server can have only one Unreachable queue. The Unreachable queue contains messages that can't be routed to their destinations. Typically, an unreachable destination is caused by configuration changes that have modified the routing path for delivery. Regardless of destination, all messages that have unreachable recipients reside in this queue.

The following table lists the queues that exist on a Hub Transport server or Edge Transport server and their characteristics.

Queues that exist on a Hub Transport server or Edge Transport server

Queue name	Server role	Number of queues on the server
Mailbox delivery queue	Hub Transport	One queue for every unique destination Mailbox server
Poison message queue	Edge Transport Hub Transport	1
Remote delivery queue	Edge Transport Hub Transport	Edge Transport: One queue for every unique destination SMTP domain or smart host Hub Transport: One queue for every unique remote Active Directory site
Submission queue	Edge Transport Hub Transport	1
Unreachable queue	Edge Transport Hub Transport	1

When a message is received by transport, a transport mail item is created and saved to the database. A unique identifier is assigned to the transport mail item when it enters the database. If a message, or transport mail item, is being routed to more than one recipient, the item can have more than one destination. Each destination represents a separate routing solution for the transport mail item, and each routing solution causes a routed mail item to be created.

The routed mail item is a reference to the transport mail item and is the unit of operation for queuing actions. If a transport mail item has more than one routing solution, more than one routed mail item references the same transport mail item. A message that's being sent to recipients in two different domains appears as two distinct messages in the delivery queues, even if only one transport mail item is in the database.

About the Poison Message Queue and the Unreachable Queue

The categorizer sends messages to the Unreachable queue when there's no known route to their destinations. Typically, an unreachable destination is caused by a configuration error that affects the delivery path. For example, the messages will be sent to the Unreachable queue if the following conditions are true:

- There are messages in the remote delivery queue named Contoso.com.

- You delete the Send connector that's used to reach the Contoso.com domain.

By default, the messages in the Unreachable queue have the status of Ready. Messages in the Unreachable queue are never automatically resubmitted. Messages remain in the Unreachable queue until they're manually resubmitted by an administrator, removed by an administrator, or the value specified in the *MessageExpirationTimeOut* parameter passes.

The poison message queue contains messages that are determined to be potentially harmful to the Exchange 2010 server after a server failure. The messages may be genuinely harmful in their content and format. Alternatively, they may be the results of a poorly written agent that has caused the Exchange server to fail when it processed the supposedly bad messages. All messages in the poison message queue are in a permanently suspended state. The poison message queue can't be resubmitted with the **Retry-Queue** cmdlet with the *Resubmit* parameter. To resubmit the messages in the poison message queue, you can use Queue Viewer or the **Resume-Message** cmdlet to resume the messages. The messages in the poison message queue are never automatically resumed or expired. Messages remain in the poison message queue until they're manually resumed or removed by an administrator.

Return to top

Queue Database Files

All the different queues are stored in a single ESE database. By default, this queue database is located at C:\Program Files\Microsoft\Exchange Server\TransportRoles\data\Queue.

Like any ESE database, the queue database uses log files to accept, track, and maintain data. To enhance performance, all message transactions are written first to log files and memory, and then to the database file. The checkpoint file tracks the transaction log entries that have been committed to the database. During an ordinary shutdown of the Microsoft Exchange Transport service, uncommitted database changes that are found in the transaction logs are always committed to the database.

Circular logging is used for the queue database. This means that the history of committed transactions that are found in the transaction logs isn't maintained. Any transaction logs that are older than the current checkpoint are immediately and automatically deleted. Therefore, the transaction logs can't be replayed for queue database recovery from backup.

The following table lists the files that constitute the queue database.

Files that constitute the queue database

File	Description
Mail.que	This queue database file stores all the queued messages.
Tmp.edb	This temporary database file is used to verify the queue database schema on startup.
Trn*.log	This transaction log records all changes to the queue database. Changes to the database are first written to the transaction log and then committed to the database. Trn.log is the current active transaction log file. Trntmp.log is the next provisioned

	transaction log file that's created in advance. If the existing Trn.log transaction log file reaches its maximum size, Trn.log is renamed to Trn*nnnn*.log, where *nnnn* is a sequence number. Trntmp.log is then renamed Trn.log and becomes the current active transaction log file.
Trn.chk	This checkpoint file tracks the transaction log entries that have been committed to the database. This file is always in the same location as the mail.que file.
Trnres00001.jrs Trnres00002.jrs	These reserve transaction log files act as placeholders. They're only used when the hard disk that contains the transaction log runs out of space to stop the queue database cleanly.

Options for Configuring the Queue Database

You can't use the Exchange Management Console (EMC) or the Shell to configure the queue database. You configure the queue database by modifying the EdgeTransport.exe.config file. The EdgeTransport.exe.config file is an XML application configuration file that's associated with the EdgeTransport.exe file.

For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File.

The <appSettings> section of the EdgeTransport.exe.config file is where you can add new configuration options or modify existing configuration options. Many configuration options that are completely unrelated to the queue database are also available. However they're outside the scope of this topic and won't be discussed.

The configuration options for the queue database that are available in the EdgeTransport.exe.config file are described in the following table.

Message queue database configuration options that are available in the EdgeTransport.exe.config file

Parameter name	Description
QueueDatabaseBatchSize	This parameter specifies the number of database I/O operations that can be grouped together before they're executed. The default value is 40.
QueueDatabaseBatchTimeout	This parameter specifies the maximum time in milliseconds that the database will wait for multiple database I/O operations to group before it executes them. The database I/O operations are executed without waiting for any more if the following conditions are true: • The number of database I/O operations that's specified by the *QueueDatabaseBatchSize* parameter hasn't been reached. • The time specified by the *QueueDatabaseBatchTimeout* parameter has passed. The default value is 100.

QueueDatabaseMaxConnections	This parameter specifies the number of ESE database connections that can be open. The default value is 4.
QueueDatabaseLoggingBufferSize	This parameter specifies the memory that's used to cache the transaction records before they're written to the transaction log file. The default value is 5242880 bytes.
QueueDatabaseLoggingFileSize	This parameter specifies the maximum size of a transaction log file. When the maximum log file size is reached, a new log file is opened. The default value is 5242880 bytes.
QueueDatabaseLoggingPath	This parameter specifies the default directory for the queue database log files. The default value is C:\Program Files\Microsoft\Exchange Server \TransportRoles\data\Queue. Before you change the queue database logging directory, make sure that the new directory exists. Also make sure that the following file permissions are applied to it: Network Service: Full Control; System: Full Control; Administrators: Full Control.
QueueDatabaseMaxBackgroundCleanup Tasks	This parameter specifies the maximum number of background cleanup work items that can be queued to the database engine thread pool at any time. The default value is 32.
QueueDatabaseOnlineDefragEnabled	The parameter enables or disables scheduled online defragmentation of the mail queue database. The default value is `$true`.
QueueDatabaseOnlineDefragSchedule	This parameter specifies the time of day in 24 hour format to start the online defragmentation of the mail queue database. To specify a value, enter the value as a time: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds. The default value is `1:00:00`, which is 01:00 or 1:00 A.M.
QueueDatabaseOnlineDefragTimeToRun	This parameter specifies the time that span the online defragmentation task is allowed to run. Even if the defragmentation task doesn't finish in the time specified, the queue database is left in a consistent state. To specify a value, enter the value as a time span: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds. The default value is `3:00:00`.
QueueDatabasePath	This parameter specifies the default directory for the queue database files. The default value is C:\Program Files\Microsoft\Exchange Server \TransportRoles\data\Queue. Before you change the queue database directory, make sure that the new directory exists. Also make sure that the following file permissions are applied to it: Network Service: Full Control; System: Full Control; Administrators: Full Control.

Return to top

Queue Management

When you experience a mail flow problem or an influx of spam, you can perform operations that modify the status of queues and messages that are located in queues. You can perform an action on a single object, or you can perform a bulk action on more than one selected object. Use the Queue Viewer graphical user interface and commands in the Shell in Exchange 2010 to retrieve information about messages and delivery queues. After you retrieve this information, you can select the queues and messages that you want to manage.

You use Queue Viewer or commands in the Shell to create filter criteria to identify the queues and messages that you want to manage. The filter criteria are based on the following attributes:

- Queue state
- Queue properties
- Message state
- Message properties

For more information about how to filter queues, see Filter Queues. For more information about how to filter messages, see Filter Messages in Queues.

Queue Management Tasks

You use Queue Viewer or commands in the Shell to view information about queues and messages. You can also use these tools to perform the following actions:

- **Suspend queue** This action temporarily prevents delivery of messages that are currently in the queue. The queue continues to accept new messages, but no messages leave the queue. For more information, see Suspend Queues.
- **Resume queue** This action reverses the effect of the suspend queue action and enables delivery of queued messages to resume. For more information, see Resume Queues.
- **Retry queue** When a connection to the next hop for a queue fails, a retry timer is set. The retry timer schedules subsequent connection tries. The retry queue action overrides the next scheduled connection attempt and tries to connect to the next hop immediately. If no connection is made, the next retry time is reset. For more information, see Retry Queues.
  You can also use the **Retry-Queue** cmdlet together with the *Resubmit* parameter to cause the messages in the queue to be resubmitted to the Submission queue and to go back through the categorization process. You can manually resubmit messages that have the following status:
  - Mailbox delivery queues or remote delivery queues that have the status of Retry. The messages in the queues must not be in the Suspended state.
  - Messages in the Unreachable queue that aren't in the Suspended state.
  - Messages in the poison message queue.

  For more information, see Resubmit Messages in Queues.
- **Suspend message** This action temporarily prevents delivery of a message. You can use the suspend message action to prevent delivery of a message to all the recipients in a specific queue or to all recipients in all queues. For more information, see Suspend Messages.
- **Resume message** This action reverses the effect of the suspend message action and enables delivery of queued messages to resume. You can use the resume message action to resume delivery of a message to all the recipients in a specific queue or to all recipients in all queues. You can also use this action to resubmit messages in the poison message queue. For more information, see Resume Messages.
- **Remove message** This action permanently prevents delivery of a message. You can use the remove message action to prevent delivery of a message to any recipients in a specified queue or to all recipients in all queues. You can also configure the remove message action to send a non-delivery report (NDR)

to the sender when the message is removed. For more information, see Remove Messages from Queues.

- **Export message** This action copies a message to the file path that you specify. The messages aren't deleted from the queue, but a copy of the message is saved to a file location. This enables administrators or officials in an organization to later examine the messages. Before you export a message, you must suspend the message in the queue so that typical delivery doesn't continue during the export process. The export format is compatible with e-mail applications such as Microsoft Office Outlook. Save the message in .eml format to make sure that the operating system associates the file with an e-mail application. For more information, see Export Messages from Queues.

Queue Filtering Scenarios

Filtering generates different views of the queues. You use the queue properties as filter options. By specifying filter criteria, you can quickly locate queues and take action on them. The following scenarios are examples of how you can use queue filtering to manage message flow:

- You receive a message from the Microsoft System Center Operations Manager that indicates that a queue length has exceeded the established threshold. You want to investigate whether a server-wide mail flow problem exists.
  You can create a filter to view all the queues that have a message count that exceeds what you consider typical. If a mail flow problem is indicated, you can select all the queues in the filter results and suspend the queues while you continue to investigate.
- You suspend several queues to investigate the cause of mail flow problems. You determine that the problem was caused by an incorrect connector configuration and is now fixed.
  You can create a filter to view all the queues that have a status of Suspended, and then select all the queues in the filter results and resume the queues.

Queue Properties to Use When Filtering Queues

You can use the queue properties to create a filter and locate queues that meet specified criteria. The following table lists the queue properties by which you can filter and the valid values for those properties.

Queue properties

Queue Viewer queue property	Shell queue property	Property type	Value
Delivery Type	DeliveryType	Enumeration	This value is determined by the next hop selection. The next hop selection identifies where messages are queued for delivery. To use the delivery type property in a filter, you must use the constant values that are assigned to each type. The delivery type can be one of the following values: • **DNSConnectorDelivery** The messages are queued for delivery to an external recipient by using an SMTP connector that's located on the local server and that's configured to use Domain Name

			System (DNS) for routing resolution. • **NonSmtpGatewayDelivery** The messages are queued for delivery to an external recipient by using a non-SMTP connector on the local server. • **SmartHostConnectorDelivery** The messages are queued for delivery to an external recipient by using an SMTP connector that's located on the local server and that's configured to use a smart host for routing resolution. • **SmtpRelayWithinAdSitetoEdge** The messages are queued for delivery to an external recipient by using an SMTP connector that's located on an Edge Transport server that's subscribed to the local Active Directory site. • **MapiDelivery** The messages are queued for delivery to recipients that have mailboxes that are located on a Mailbox server that's located in the local Active Directory site. • **SmtpRelayWithinAdSite** The messages are queued for delivery to a Hub Transport server that's located in the same Active Directory site as the local server. The destination server can be the source server for an SMTP connector, the source server of a routing group

			connector, or an expansion server. • **SmtpRelaytoRemoteAdSite** The messages are queued for delivery to a server that's located in a remote Active Directory site. The destination server can be the source server for a connector that's configured to transport messages for external recipients, an expansion server, or a Hub Transport server that delivers messages addressed to mailbox recipients that are located in the remote Active Directory site. • **SmtpRelaytoTiRg** The messages are queued for delivery to an Exchange Server 2003 routing group. The destination server can be the source server for a connector that's configured to transport messages for external recipients, an expansion server, or an Exchange 2003 bridgehead server that delivers messages addressed to mailbox recipients that are located in the routing group. • **Undefined** The messages are located in the Submission queue, and the next hop destination hasn't yet been resolved. • **Unreachable** The messages are located in the

			Unreachable queue, and a route to the recipient couldn't be established.
Identity	Identity	QueueIdentity	This value specifies the identity of the queue. Enter the queue identity in the form of *Server\destination*, where *destination* is a remote domain, Mailbox server, persistent queue name, or the integer that identifies this queue in the queuing database.
Last Error	LastError	String	This value specifies a text string of the last error that was recorded for a queue.
Last Retry Time	LastRetryTime	DateTime	This value specifies the time of the last connection attempt for a queue that has a status of Retry.
Message Count	MessageCount	Ulong	This value is expressed as an integer that represents the number of items in the queue.
Next Hop Connector	NextHopConnector	GUID	This value is expressed as a system GUID and is the GUID of the connector that was used to create the queue.
Next Hop Domain	NextHopDomain	String	This value specifies the next destination of a delivery queue. The next hop domain can be expressed as follows: • Remote SMTP domain name • Exchange server name • Connector name • Routing group • Active Directory site name • Mailbox server fully qualified domain name (FQDN)
Next Retry Time	NextRetryTime	DateTime	This value specifies the time of the next connection attempt for a queue that has a status of Retry.
Status	Status	Enumeration	This value specifies the current queue status. A queue can have one of the following status values: • Active • Suspended • Ready • Retry

Operators to Use When Filtering Queues

When you create a queue filter, you must include an operator for the property value to match. The following table shows the comparison operators that you can use in a filter expression and how each operator functions.

Filter expression operators

Operator	Shell value	Function	Shell code example
Equals	-eq	This operator is used to specify that the results must exactly match the property value that's supplied in the expression.	To display a list of all queues that have a status of Retry: `Get-Queue -Filter {status -eq "retry"}`
Does Not Equal	-ne	This operator is used to specify that the results shouldn't match the property value that's supplied in the expression.	To display a list of all queues that don't have a status of Active: `Get-Queue -Filter {status -ne "active"}`
Greater Than	-gt	This operator is used with properties where the value is expressed as an integer. The filter results only include queues where the value of the specified property is greater than the value that's supplied in the expression.	To display a list of queues that currently contain more than 1,000 messages: `Get-Queue -Filter {messagecount -gt 1000}`
Greater Than or Equals	-ge	This operator is used with properties where the value is expressed as an integer. The filter results only include queues where the value of the specified property is greater than or equal to the value that's supplied in the expression.	To display a list of queues that currently contain 1,000 or more messages: `Get-Queue -Filter {messagecount -ge 1000}`
Less Than	-lt	This operator is used with properties where the value is expressed as an integer. The filter results only include queues where the value of the specified property is less than the value that's	To display a list of queues that currently contain less than 1,000 messages: `Get-Queue -Filter {messagecount -lt 1000}`

		supplied in the expression.	
Less Than or Equals	-le	This operator is used with properties where the value is expressed as an integer. The filter results only include queues where the value of the specified property is less than or equal to the value supplied in the expression.	To display a list of queues that currently contain 1,000 or fewer messages: `Get-Queue -Filter {messagecount -le 1000}`
Contains	-like	This operator is used with properties where the value is expressed as a text string. The filter results only include queues where the value of the specified property contains the text string that's supplied in the expression. You can include the wildcard character (*) in a **-like** expression that's applied to a text string field, but not with a field that has the enumeration type.	To display a list of delivery queues that have a destination to any SMTP domain that ends in Contoso.com: `Get-Queue -Filter {identity -like "*Contoso.com"}`

You can specify multiple expressions in your queue filter by using the **-and** operator in the Shell or by adding multiple expressions in Queue Viewer. Queues must meet all criteria to be included in the result set. For example, the results of the following command will display a list of queues that have a destination to any SMTP domain name that ends in Contoso.com and that currently contain more than 500 messages.

```
Get-Queue -Filter {Identity -like "*Contoso.com*" -and MessageCount -gt 500}
```

Message Filtering Scenarios

Filtering generates different views of the messages in queues. By specifying filter criteria, you can quickly locate messages and take action on them. When an e-mail message is sent to multiple recipients, the message may be located in multiple queues. When you filter by message properties, you can locate messages across all queues. The following scenarios are examples of how you might use message filtering to manage mail flow:

- The Submission queue on the computer that has the Edge Transport server role installed has a high volume of messages that are queued for delivery. Many of the messages have the same subject. Therefore, you suspect that spam is being sent to your organization. You can create a filter to view all the messages that meet the subject criteria. If you determine that the messages are spam, you can select them all and delete them from the delivery queue without sending an NDR.
- A user reports that mail flow is slow. You examine the queues and see that many messages that have random subjects appear to be coming from a single

domain. You can create a filter to view all the queued messages from that domain. If you determine that the messages are spam, you can select them all and delete them from the queues without sending an NDR.

Message Properties to Use When Filtering Messages

You can use message properties to create a filter and locate messages that meet specified criteria. The following table lists the message properties by which you can filter and the values that are associated with those properties.

Message properties

Queue Viewer message property	Shell message property	Property type	Value
Date Received	DateReceived	DateTime	This value specifies the time stamp when the message was received by the server that holds the queue in which the message is located.
Expiration Time	ExpirationTime	DateTime	This value specifies the time stamp when the message will expire and be deleted from the queue if the message can't be delivered.
From Address	FromAddress	SMTP Address	This value specifies the SMTP address of the sender of the message.
Identity	Identity	Integer	This value is an integer that represents a particular message. The message identity is assigned by the queuing database when the message is received for processing. You can include an optional server and queue identity to identify a unique instance of the message. This value can be expressed as follows: • *Server**QueueId**MessageId* • *Server*\Poison*MessageId* • *MessageId* • *Server**MessageId*
Internet Message ID	InternetMessageId	String	This value specifies the value of the `Message-ID:` message header field that's located in the message header. The value of this property is expressed as a GUID followed by the SMTP address of the sending server, as in this example: 67D754D6103DC4FB3BA6BC7205DACABA61231@exchange.contoso.com

Last Error	LastError	String	This value specifies a text string of the last error that was recorded for a message.
Message Source Name	MessageSourceName	String	This value specifies a text string of the name of the component that submitted this message to the queue.
Queue ID	Queue	QueueIdentity	The value of this property specifies the identity of the queue that holds the message. Enter the queue identity in the form of *Server\destination*, where *destination* is a remote domain, Mailbox server, persistent queue name, or the queuing database identifier. The database identifier is represented as an integer and can be determined by viewing the message properties.
Retry Count	RetryCount	Integer	This value specifies the number of times that delivery of a message to a destination was tried.
SCL	SCL	Integer	The value of the spam confidence level (SCL) property specifies the SCL of the message. Valid SCL entries are integers from 0 through 9. An empty SCL property value indicates that the message hasn't been processed by the Content Filter agent.
Size (KB)	Size	ByteQuantifiedSize	This value specifies the size of the message.
Source IP	SourceIP	IP Address	This value specifies the IP address of the external server that submitted the message to the Exchange organization.
Status	Status	Enumeration	This value specifies the current message status. A message can have one of the following status values: • **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.

			• **Suspended** The message was suspended by the administrator. • **PendingRemove** The message was deleted by the administrator, but was already in delivery. The message will be deleted if the delivery ends in an error that causes the message to reenter the queue. Otherwise, delivery will continue. • **PendingSuspend** The message was suspended by the administrator, but was already in delivery. The message will be suspended if the delivery ends in an error that causes the message to reenter the queue. Otherwise, delivery will continue. • **Ready** The message is waiting in the queue and is ready to be processed. • **Retry** The last connection attempt for the queue in which this message is located failed. The message is waiting for the next queue retry.
Subject	Subject	String	This value specifies the subject of a message that's expressed as a text string.

Operators to Use When Filtering Messages

When you create a message filter, you must include an operator for the property value to match. The following table shows the comparison operators that you can use in a filter expression and how each operator functions.

Filter expression operators

Operator	Shell value	Function	Shell code example
Equals	-eq	This operator is used to specify that the	To display a list of all messages that have

		results must exactly match the property value that's supplied in the expression.	a status of Retry: `Get-Message -Filter {status -eq "retry"}`
Does Not Equal	-ne	This operator is used to specify that the results shouldn't match the property value that's supplied in the expression.	To display a list of all messages that don't have a status of Active: `Get-Message -Filter {status -ne "active"}`
Greater Than	-gt	This operator is used with properties where the value is expressed as an integer. The filter results only include messages where the value of the specified property is greater than the value that's supplied in the expression.	To display a list of messages that currently have a retry count that's more than 3: `Get-Message -Filter {retrycount -gt 3}`
Greater Than or Equals	-ge	This operator is used with properties where the value is expressed as an integer. The filter results only include messages where the value of the specified property is greater than or equal to the value that's supplied in the expression.	To display a list of messages that currently have a retry count that's 3 or more: `Get-Message -Filter {retrycount -ge 3}`
Less Than	-lt	This operator is used with properties where the value is expressed as an integer. The filter results only include messages where the value of the specified property is less than the value that's supplied in the expression.	To display a list of messages that have an SCL that's less than 6: `Get-Message -Filter {SCL -lt 6}`
Less Than or Equals	-le	This operator is used with properties where the value is expressed as an integer. The filter results only include messages where the	To display a list of messages that have an SCL that's 6 or less: `Get-Message -Filter {SCL -le`

		value of the specified property is less than or equal to the value that's supplied in the expression.	6}
Contains	-like	This operator is used with properties where the value is expressed as a text string. The filter results only include messages where the value of the specified property contains the text string that's supplied in the expression. You can include the wildcard character (*) in a **-like** statement that's applied to a text string field, but not a field that has the enumeration type.	To display a list of messages that have a subject that contains the text "payday loan": `Get-Messages -Filter {subject -like "*payday loan*"}`

You can specify a filter that evaluates multiple expressions by using the **-and** comparison operator in the Shell or by adding multiple expressions in Queue Viewer. To be included in the result set, messages must meet all conditions of the filter. For example, the results of the following command will display a list of messages that are sent from any e-mail address that has a domain name that ends in Contoso.com and that have an SCL that's greater than 5.

```
Get-Message -Filter {FromAddress -like "*Contoso.com*" -and SCL -gt 5}
```

Return to top

Message Retry, Resubmit, and Expiration Intervals

Messages that can't be successfully delivered are subject to various retry, resubmit, and expiration deadlines based on the message's source and destination. *Retry* is a renewed connection attempt with the destination domain, smart host, or Mailbox server. *Resubmit* is the act of sending messages back to the Submission queue for the categorizer to reprocess. The message is said to time-out or *expire* after all delivery efforts have failed over a specified period of time. After a message expires, the sender is notified of the delivery failure. Then the message is deleted from the queue.

In all three cases of retry, resubmit, or expire, you can manually intervene before the automatic actions are performed on the messages.

Configuration Options for Message Retry

When a transport server can't connect to the next hop, the queue is put in a status of Retry. Connection attempts continue until the queue expires or a connection is made.

Configuration Options for Automatic Message Retry

The configuration options that are available for message retry intervals are described in the following table.

Configuration options that are available for message retry intervals

Parameter name	Default value	Where to configure	Description
QueueGlitchRetryCount	4	EdgeTransport.exe.config	This parameter specifies the number of connection attempts that are immediately tried when a transport server has trouble connecting with the destination server. Such connection problems are typically caused by very brief network outages. Typically, you don't have to modify this parameter unless the network is unreliable and continues to experience many accidentally dropped connections.
QueueGlitchRetryInterval	1 minute	EdgeTransport.exe.config	This parameter controls the connection interval between each connection attempt that's specified by the *QueueGlitchRetryCount* parameter. Typically, you don't have to modify this parameter unless the network is unreliable and continues to experience many accidentally dropped connections.
TransientFailureRetryCount	6	**Set-TransportServer** cmdlet or transport server properties in the EMC	This parameter specifies the number of connection attempts that are tried after the connection

			attempts that are controlled by the *QueueGlitchRetryCount* and *QueueGlitchRetryInterval* parameters have failed. Connection problems that exhaust the *QueueGlitchRetryCount* and *QueueGlitchRetryInterval* parameters can be caused by such things as server restarts or cached DNS lookup failures.
TransientFailureRetryInterval	• Hub Transport server: 5 minutes • Edge Transport server: 10 minutes	**Set-TransportServer** cmdlet or transport server properties in the EMC	This parameter controls the connection interval between each connection attempt that's specified by the *TransientFailureRetryCount* parameter.
OutboundConnectionFailureRetryInterval	• Hub Transport server: 10 minutes • Edge Transport Server: 30 minutes	**Set-TransportServer** cmdlet or transport server properties in the EMC	This parameter specifies the retry interval for outbound connection attempts that have previously failed. The previously failed connection attempts are controlled by the *TransientFailureRetryCount* and *TransientFailureRetryInterval* parameters.
MessageRetryInterval	1 minute	**Set-TransportServer** cmdlet	This parameter specifies the retry interval for individual messages that have a status of Retry. We recommend that you don't modify the default value unless Microsoft

			Customer Service and Support advises you to do this.
MailboxDeliveryQueueRetryInterval	5 minutes	EdgeTransport.exe.config	This parameter controls the retry interval for mailbox delivery queues between Hub transport servers.

The <appSettings> section of the EdgeTransport.exe.config file is where you can add new configuration options or modify existing configuration options. There are many configuration options available that are completely unrelated to the message retry, resubmit, and expiration intervals. Any configuration options that don't involve these intervals are outside the scope of this topic.

For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File.

For more information, see Configure Message Retry, Resubmit, and Expiration Intervals.

Configuration Options for Manual Message Retry

When a mailbox delivery queue or a remote delivery queue is in the status of Retry, you can manually force an immediate connection attempt by using Queue Viewer in the EMC or the **Retry-Queue** cmdlet in the Shell. The manual retry attempt overrides the next scheduled retry time. If the connection isn't successful, the retry interval timer is reset. The delivery queue must be in a status of Retry for this action to have any effect.

For more information, see Retry Queues.

Configuration Options for Delay DSN Messages

After each message delivery failure, the Edge Transport server or the Hub Transport server generates a delay delivery status notification (DSN) message and queues it for delivery to the sender of the undeliverable message. This delay DSN message is sent only after a specified delay notification time-out interval, and only if the failed message wasn't successfully delivered during that time. By default, the delay notification time-out interval is 4 hours. This delay prevents the sending of unnecessary delay DSN messages that may be caused by temporary message transmission failures. The sending of delay DSN notification messages can be selectively enabled or disabled for messages that originate inside or outside the Exchange organization.

The configuration options that are available for delay DSN notification messages are described in the following table.

Configuration options that are available for delay DSN notification messages

Parameter name	Default value	Location	Description
DelayNotificationTimeOut	4 hours	**Set-TransportServer**	This parameter specifies how long the server waits before it sends a delay DSN message to the message's sender. The value of this parameter should

			always be greater than the value of the *TransientFailureRetryCount* parameter multiplied by the value of the *TransientFailureRetryInterval* parameter.
ExternalDelayDSNEnabled	`$true`	**Set-TransportConfig**	This parameter specifies whether delay DSN messages can be sent to message senders who are outside the Exchange organization.
InternalDelayDSNEnabled	`$true`	**Set-TransportConfig**	This parameter specifies whether delay DSN messages can be sent to message senders who are inside the Exchange organization.

For more information, see Configure Message Retry, Resubmit, and Expiration Intervals.

Configuration Options for Message Resubmission

Message resubmission sends undelivered messages back to the Submission queue to be reprocessed by the categorizer.

Automatic Message Resubmission

Undelivered messages are automatically resubmitted if the delivery queue is in the status of Retry and has been unable to successfully deliver any messages for a specified period of time. That period of time is controlled by the *MaxIdTimeBeforeResubmit* parameter in the EdgeTransport.exe.config application configuration file. By default, the value of the *MaxIdTimeBeforeResubmit* parameter is 12 hours. Only messages in mailbox delivery queues or remote delivery queues are candidates for automatic resubmission.

For more information, see Configure Message Retry, Resubmit, and Expiration Intervals.

Manual Message Resubmission

You can manually resubmit messages that have the following status on a Hub Transport server or an Edge Transport server:

- Mailbox delivery queues or remote delivery queues that have the status of Retry. The messages in the queues must not be in the Suspended state.
- Messages that are in the Unreachable queue and aren't in the Suspended state.
- Messages that are in the poison message queue.

For more information about the poison message queue and the Unreachable queue, see "About the Poison Message Queue and the Unreachable Queue" earlier in this topic.

If you want to manually resubmit messages that are located in the mailbox delivery queues, the remote delivery queues, or the Unreachable queue without waiting for the time that's specified by the *MaxIdleTimeBeforeResubmit* parameter to pass, you must use the **Retry-Queue** cmdlet with the *Resubmit* parameter. To manually resubmit messages that are located in the poison message queue, you can use Queue Viewer or the

Resume-Message cmdlet to resume the message.

For more information, see the following topics:

- Resubmit Messages in Queues
- Resume Messages

Another way that you can manually resubmit messages is to suspend the messages, export the messages to text files that have the .eml file name extension, and then copy the .eml files to the Replay directory on any Hub Transport server or Edge Transport server. This resubmission method works for messages that are located in the mailbox delivery queues, remote delivery queues, or the Unreachable queue. Messages that are located in the poison message queue are already in the Suspended state. Messages that are located in the Submission queue can't be suspended or exported.

Note:

When you export messages from a queue, you don't remove the messages from the queue. After you export the messages and successfully resubmit them by using the Replay directory, you should remove the suspended messages to avoid duplicate message delivery.

For more information, see Export Messages from Queues and Resubmit Messages in Queues.

Configuration Options for Message Expiration

The *message expiration time-out interval* specifies the maximum length of time that an Edge Transport server or a Hub Transport server tries to deliver a failed message. If the message can't be successfully delivered before the expiration time-out interval has passed, an NDR that contains the original message or the message headers is delivered to the sender.

Automatic Message Expiration

The message expiration time-out interval is controlled by the *MessageExpirationTimeOut* parameter in the **Set-TransportServer** cmdlet or in the transport server properties in the EMC. By default, the value of the *MessageExpirationTimeOut* parameter is 2 days.

For more information, see the following topics:

- Configure Message Retry, Resubmit, and Expiration Intervals
- Set-TransportServer

Manual Message Expiration

Although you can't manually force messages to expire, you can manually remove messages from any queue, except the Submission queue, with or without an NDR.

For more information, see Remove Messages from Queues.

1.7.1.40 Understanding Transport in a Hybrid Deployment

Understanding Transport in a Hybrid Deployment

Exchange Server 2010 > Transport > Understanding Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-16*

Service Pack 2 (SP2) for Microsoft Exchange Server 2010 gives you the ability to host some of your Exchange users in an Exchange Online organization hosted in Microsoft Office 365 for enterprises while maintaining a seamless messaging experience for all your users. This topic provides an overview of how Transport servers are used in this scenario.

A hybrid deployment requires at least one server running Exchange Server 2010 SP2 in your organization. If you're currently running a previous version of Exchange, you must add one or more Exchange 2010 SP2 servers to act as gateways to the Exchange Online organization. By doing so, you can enable a hybrid deployment without having to upgrade your entire existing deployment. These Exchange 2010 servers are known as the *hybrid servers*.

Your organization must contain one or more hybrid servers with the Hub Transport and Client Access server roles installed. The Mailbox server role is also required for Exchange Server 2003 organizations that need to support the exchange of free/busy information between your on-premises Exchange 2003 mailboxes and Exchange Online mailboxes. Adding this hybrid server to your organization is equivalent to introducing your first Exchange 2010 server to your deployment. To learn more about hybrid deployments, see Understanding Hybrid Deployments with Exchange 2010 SP3.

Contents

Mail Flow

Mail flow between your on-premises deployment and your Exchange Online organization is secured and protected by Transport Layer Security (TLS). The TLS endpoint in your on-premises organization must be an Exchange 2010 SP2 Hub Transport or Edge Transport server running Exchange 2010 SP1 or SP2.

Your on-premises organization and Exchange Online organization send messages directly to each other through a secure channel. To enable this mail flow, a dedicated hybrid Send connector is automatically created by the Manage Hybrid Configuration wizard. Only a Hub Transport server running on Exchange 2010 SP2 or Edge Transport source server(s) running on Exchange 2010 SP1 or Exchange 2010 SP2 can be selected for this Send connector. If you're running Exchange 2010 SP2 in your organization, any Hub Transport or Edge Transport server can act as the gateway to your Exchange Online organization. If you're running older versions of Exchange, you must deploy hybrid Hub Transport or Edge Transport servers to route messages between your two organizations.

In a hybrid deployment, each organization treats the other one as an internal organization. There is practically no difference between a user hosted on your on-premises servers and an Exchange Online user when Exchange is processing messages. Anti-spam filters are also bypassed for messages between the two organizations.

Secured and Authenticated Mail Flow

Even though messages between the on-premises and Exchange Online organizations go through a logical tunnel, they're still transferred over the Internet and therefore must be protected against malicious users. Exchange 2010 provides the following protection measures:

- **Channel privacy** Unauthorized parties can't access any captured packets.
- **Receiver authentication** Senders are protected from unauthorized parties impersonating valid receivers.

- **Sender authentication** Receivers are protected from unauthorized parties impersonating valid senders.

Channel Privacy

To protect both the on-premises and cloud-based organizations, Exchange 2010 forces TLS using Secure Sockets Layer (SSL) certificates provided by a trusted third-party Certificate Authority (CA). Self-signed certificates are not supported for channel privacy in a hybrid deployment. All messages sent through the TLS-protected channel are encrypted.

The sending and receiving servers examine the certificate configured on the other server. The subject name, or one of the subject alternative names (SANs), configured on the certificates must match the fully qualified domain name (FQDN) that an administrator has explicitly specified on the other server. For example, if the Exchange Online organization is configured to accept and secure messages sent from the mail.contoso.com FQDN, the sending on-premises hybrid servers must have an SSL certificate with mail.contoso.com in either the subject name or SAN. If this requirement isn't met, the connection is refused.

Receiver Authentication

In addition to the regular certificate checks performed during TLS, the Send connectors that participate in hybrid deployment mail flow also perform domain validation. Domain validation is an additional security feature that reduces the risk of malicious users impersonating a receiving server. When domain validation is enabled on a Send connector, the Transport server performs the following security checks on the outbound connection:

- The communication channel is encrypted using TLS.
- The certificate of the receiving server is validated, and revocation list checks are performed.
- The Transport server verifies that the FQDN on the certificate of the receiving server matches the domain configured in the Send connector properties.

Sender Authentication

To prevent a malicious user from impersonating a valid sender, each message is authenticated to verify that it was submitted by the specified sender. Inside an Exchange organization, sender authentication is verified by using custom message headers added by Exchange servers. For messages that are sent between the on-premises and Exchange Online organizations, these header values are encrypted at the source and then decrypted and verified at the destination. While in transit, these headers can’t be decrypted by any third party that might capture the message.

Mail To and From the Internet

Recipients in the on-premises and Exchange Online organizations typically have the same reply address, such as @contoso.com. Because they have the same reply address, all messages to recipients in both organizations must follow the same inbound route. All inbound messages can be delivered either to the on-premises organization or to the Exchange Online organization. Where you decide to route inbound messages depends on where the majority of your mailboxes are located, whether you have a Microsoft Forefront Online for Protection (FOPE), and other factors.

Messages sent from recipients in the on-premises and Exchange Online organizations can either follow the same or different routes to the Internet. Messages sent from on-premises recipients are always sent directly to the Internet. Messages sent from Exchange Online recipients can either be sent directly to the Internet or routed through your on-premises organization first. You may want to route Exchange Online messages through your on-premises organization if you want to apply compliance policies to them first.

There are many considerations that you need to think about when planning transport for your hybrid deployment, such as whether you use FOPE to protect your on-premises

organization, whether you have an Edge Transport server configured, and how you want to route inbound and outbound Internet mail. For detailed information about these considerations and help on deciding which options are best for your organization, see Understanding Transport Options in Exchange 2003 Hybrid Deployments.

Transport Features

This section discusses how various Transport features are used in a hybrid deployment. The information here assumes that you're running Exchange 2010 for your on-premises deployment because some of the features described here don't apply to earlier versions of Exchange. To learn more, see the following topics:

- Upgrade from Exchange 2007 Transport
- Upgrade from Exchange 2003 Transport

Note:
The features discussed in this section are only available in a hybrid deployment.

Transport Rules and Journaling

Transport Rules and Journaling rules aren't synchronized between your on-premises deployment and your Exchange Online organization. Therefore, you must ensure that you keep any rules that you have implemented consistent in both organizations.

Delivery Reports

Users can track messages they've sent and received in a hybrid deployment as long as delivery reports are enabled for the corresponding organizational relationships for both the on-premises and Exchange Online organizations. By default, this feature is enabled in a hybrid deployment. However, keep in mind that if you have older versions of Exchange in your on-premises deployment, the delivery reports will not show the final delivery to recipients hosted on the legacy servers, but rather that the message was transferred to the legacy Exchange system. This isn't a limitation of the hybrid deployment; it's because of changes in the message tracking implementation in Exchange 2010. For more information, see the "Message Tracking Across Versions" section in Upgrade from Exchange 2007 Transport.

MailTips

MailTips are designed to work seamlessly in a hybrid deployment. If an on-premises user addresses a message to a recipient in your Exchange Online organization, your local Client Access servers contact the Client Access servers in the Exchange Online organization and requests MailTips data for the message. Upon this request, the Client Access servers in the Exchange Online organization processes the MailTips request, evaluates the message for any MailTips, and returns all applicable MailTips to your on-premises Client Access servers. The process is the same when a user in your Exchange Online organization addresses a message to an on-premises recipient.

In a hybrid deployment, keep in mind the following differences regarding MailTips:

- The External Recipients MailTip is evaluated only in the local organization. This is because the Exchange Online organization can't determine which recipients would be considered external for an on-premises user.
- Number of external recipients in a group MailTip is only evaluated for the local groups using the local Group Metrics data for the same reason.
- The Oversize Message MailTip is evaluated both locally and in the remote organization. Therefore, it's important to make sure that the message size restrictions for your on-premises organization match those configured for your Exchange Online organization to avoid an inconsistent experience for your users.
- All objects in the remote organization are represented as mail-enabled objects in the local organization. For example, a mailbox in your Exchange Online organization is represented as a mail user in your on-premises organization.

Because all objects can have Custom MailTips, you potentially can configure two different Custom MailTips for the same recipient. In this case, only the local Custom MailTip will be shown. On-premises users will see the Custom MailTip configured for the on-premises object, and cloud-based users will see the Custom MailTip configured for the Exchange Online object.

- It's also possible to have a mismatching configuration for moderated recipients or restricted recipients. For example, an on-premises mailbox may be restricted, but the corresponding mail user in your Exchange Online organization may not be restricted. In this scenario, the Restricted Recipient MailTip will be shown even for an Exchange Online user. The Moderated Recipient MailTip functions in a similar fashion.

MailTips are configured to work in a hybrid deployment by default. However, it's possible to customize the way MailTips are handled if you want different experiences for your on-premises and Exchange Online users. For more information, see the "MailTips Architecture" section in Understanding MailTips and "Use the Shell to configure MailTips for organizational relationships" section in Configure Organizational Settings for MailTips.

Message Moderation

Hybrid deployment message moderation functionality relies on the following requirements:

- Synchronization of moderation attributes of mail-enabled objects.
- At least one arbitration mailbox created in your on-premises organization.
- At least one arbitration mailbox created in your Exchange Online organization.
- Preservation of the headers and TNEF format between the two organizations.

When you configure a hybrid deployment with Office 365, all the requirements above are met. You don't need to do anything additional for message moderation to work.

Edge Transport in a Hybrid Deployment

Mail flow in a hybrid deployment requires an Exchange 2010 SP2 server as the TLS endpoint for your on-premises deployment. This is typically an Exchange 2010 SP2 Hub Transport server in your on-premises organization. However, if you don't want to expose your internal Hub Transport server directly to the Internet, you can use an Exchange 2010 SP2 Edge Transport server as the TLS endpoint. If you use an Edge Transport server, that server will handle mail between your on-premises organization and the Exchange Online organization on behalf of the Hub Transport server. You can also elect to use an Edge Transport server for handling mail sent to and from Internet recipients for your on-premises organization.

To learn more about Edge Transport servers in your hybrid deployment, see:

- Understanding Edge Transport Servers in Exchange 2003 Hybrid Deployments

If you're using Exchange 2007 Edge Transport servers in your organization, they must be upgraded to Exchange 2010 SP2 if you plan to use them in a hybrid deployment.

1.7.2 Managing Transport Servers

Managing Transport Servers

Exchange Server 2010 > Transport >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-09*

1.7.2.1 Change the Method for 7-bit Transfer Encoding

Change the Method for 7-bit Transfer Encoding

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Exchange Server 2010, the 7-bit transfer encoding method for MIME format is fixed to quoted-printable (QP) encoding. You can change the transfer encoding method by editing the EdgeTransport.exe.config file. Use Microsoft Windows Explorer to change the method for transfer encoding on the Microsoft Exchange Server 2010-based computer running the Hub Transport server role.

Looking for other management tasks related to managing transport servers? Check out Managing Transport Servers.

Use Windows Explorer and Notepad to change the method for transfer encoding

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

1. On the Exchange 2010-based server running the Hub Transport server role, start Windows Explorer.
2. Locate the following folder, in which *<drive>* represents the actual installation drive: **<drive>:\Program Files\Microsoft\Exchange Server\V14\Bin**.
3. Make a backup copy of the EdgeTransport.exe.config file, and name the backup file copy **EdgeTransport.exe.config.old**.
4. Start Notepad, and then open the **EdgeTransport.exe.config** file.
5. Locate the following line between the <appsettings> tag and the </appsettings> tag.

   ```
   <add key="ByteEncoderTypeFor7BitCharsets" value="1" />
   ```

   If this line doesn't exist in this location, insert the line between the <appsettings> tag and the </appsettings> tag.
6. Change the value described in the line to an appropriate value from the table in "Values to Change the Method for Transfer Encoding" later in this topic. This value controls the MIME encoding behavior.
7. Save the changes, and then exit Notepad.
8. Start the Microsoft Exchange Transport service.

Values to Change the Method for Transfer Encoding

The following table lists the values that you can use to change the method for transfer encoding. This table also describes the behavior of the value.

Value	Behavior
0	Always use default 7-bit transfer encoding for HTML and for plain text.
1	Always use QP encoding for HTML and for plain text.
2	Always use Base64 encoding for HTML and for plain text.
5	Use QP encoding for HTML and for plain text unless line wrapping is enabled in plain text. If line wrapping is enabled, use 7-bit encoding for plain text.
6	Use Base64 encoding for HTML and for plain text, unless line wrapping is enabled in plain text. If line wrapping is enabled in plain text, use Base64 encoding for HTML, and use 7-bit encoding for plain text.
13	Always use QP encoding for HTML. Always use 7-bit encoding for plain text.
14	Always use Base64 encoding for HTML. Always use 7-bit encoding for plain text.

1.7.2.2 Configure Edge Transport Server Properties

Configure Edge Transport Server Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The property configuration of a transport server running Microsoft Exchange Server 2010 determines how that server processes messages. The transport server settings that you configure on an Edge Transport server apply only to that specific server.

Looking for other management tasks related to configuring Edge Transport server properties? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the EMC to configure the properties of an Edge Transport server
- Use the Shell to configure the properties of an Edge Transport server

Use the EMC to configure the properties of an Edge Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, right-click the Edge Transport server you want to configure, and then select **Properties**.
3. On the **General** tab, you can view general information about the server:
   - **Version** This field displays the version of Exchange installed on the server.
   - **Edition** This field displays the Exchange Server edition. The edition is either Standard Edition or Enterprise Edition.
   - **Role(s)** This field displays the Exchange server roles installed on the server.
   - **Product ID** This field displays the product ID for the Exchange server. If you haven't yet entered the product key for the server, the product ID displayed is **Unlicensed**. To license an unlicensed version of Exchange, see Enter Product Key.
   - **Modified** This field displays the last date and time that a configuration change was made on this server.
4. On the **System Settings** tab, view the domain controller servers and global catalog servers. You can also enable an error reporting feature:
   - **Domain controller servers being used by Exchange** This read-only box displays a list of domain controller servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Global catalog servers being used by Exchange** This read-only box displays a list of global catalog servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Automatically send fatal service error report to Microsoft** Select this

check box if you want to enable the error reporting feature and automatically send an error report to Microsoft in the event of a fatal error.
If you enable the error reporting feature, information about fatal service errors is sent to Microsoft over encrypted channels. The information is used to improve Microsoft products. When this feature is enabled and the issue reported has a known solution, the server receives feedback from Microsoft. This feedback contains a link to information that may help resolve the problem.

5. On the **Customer Feedback Options** tab, you can enroll the selected server into the Customer Experience Improvement Program. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.

6. Use the **External DNS Lookups** tab to specify whether to use the DNS servers that are configured on a network adapter installed on this server or to use specific DNS servers when resolving the addresses of mail servers for external mail delivery. External DNS servers are used by Send connectors that are configured to use the external DNS lookup configuration on the transport server. When messages are routed to these Send connectors, the external DNS lookup settings that are configured for the source servers are used to resolve IP addresses for the delivery destination.
   You can choose one of the following options:
   - **Use network card DNS settings** To select an installed network adapter from the list, select **Use network card DNS settings**, and then select a network adapter from the drop-down list. The server then uses the DNS servers configured on that network adapter. The default setting is **All Available IPv4**. If you select this setting, the server uses the DNS servers configured on all the adapters on that server.
   - **Use these DNS servers** To have the server select from a list of manually entered DNS servers to query when resolving a remote server, select **Use these DNS servers**. To add a server to the list, type the IP address of the external DNS server, and then click **Add**. To change the IP address of a previously added DNS server, select that server, and then click **Edit**. To remove a previously added DNS server, select that server, and then click  .

7. Use the **Internal DNS Lookups** tab to specify whether to use the DNS servers that are configured on a network adapter installed on this server or to use specific DNS servers when resolving the addresses of mail servers for internal mail delivery. Internal DNS servers are used to resolve IP addresses for servers inside your organization.
   You can choose one of the following options:
   - **Use network card DNS settings** To select an installed network adapter from the list, select **Use network card DNS settings**, and then select a network adapter from the drop-down list. The server then uses the DNS servers configured on that network adapter. The default setting is **All Available IPv4**. If you select this setting, the server uses the DNS servers configured on all the adapters on that server.
   - **Use these DNS servers** To have the server select from a list of manually entered DNS servers to query when it's resolving an internal server, select **Use these DNS servers**. To add a server to the list, type the IP address of the internal DNS server, and then click **Add**. To change the IP address of a previously added DNS server, select that server, and then click **Edit**. To remove a previously added DNS server, select that server, and then click  .

8. Use the **Limits** tab to specify the number of times that the server retries message delivery, to set notification for undelivered messages, and to specify connection restrictions.

- **Outbound connection failure retry interval (minutes)** Select this option to specify the retry interval for subsequent connection attempts to a remote server where earlier connection attempts as specified by the transient failure retry attempts and the transient failure retry interval have failed. The valid input range is 1 minute to 28800 minutes (20 days). We recommend that you don't modify the default value unless Microsoft Customer Service and Support has advised you to do this. The default value is 30 minutes.
- **Transient failure retry interval (seconds)** Select this option to specify the interval between each connection attempt specified by the **Transient failure retry attempts** option. The valid input range is 1 second to 43200 seconds (12 hours). The default value is 600 seconds (10 minutes).
- **Transient failure retry attempts** Select this option to specify the maximum number of times that a server immediately retries when it encounters a connection failure with a remote server. The default value is 6. The valid input range is 0 to 15. When this parameter is set to 0, the server doesn't immediately try to reconnect.
- **Maximum time since submission (days)** Select this option to specify the expiration time-out for a particular message. If a message remains in the queue for longer than this period of time, the message is returned to the sender as a hard failure. The default value is 2 days. The valid input range is 1 day to 90 days.
- **Notify sender when message is delayed more than (hours)** Select this option to specify how long the server waits before it generates a delivery status notification (DSN) that notifies the sender of a delivery delay. The default value is 4 hours. The valid input range is 1 hour to 720 hours (30 days).
- **Maximum concurrent outbound connections** Select this option to specify the maximum number of outgoing connections that can be open at a time. If the connection limit is reached, the server doesn't initiate new connections until the number of current connections decreases. The default value is 1000. The valid input range is 1 to 2147483647. To disable this restriction, clear the check box next to **Maximum concurrent outbound connections**.
- **Maximum concurrent outbound connections per domain** Select this option to specify the maximum number of concurrent connections to any single domain. The default value is 20. The valid input range is 1 to 2147483647. To disable this restriction, clear the check box next to **Maximum concurrent outbound connections per domain**.

9. Use the **Log Settings** tab to enable or disable message tracking, enable or disable connectivity logging, and to view or change the path for the message tracking logs, connectivity logs, Send connector protocol logs, and Receive connector protocol logs. On the **Log Settings** tab, you can view or set the following options:
   - **Enable message tracking log** By default, message tracking is enabled on Hub Transport and Edge Transport servers. To disable message tracking, clear the check box next to **Enable message tracking log**. To enable message tracking, select the check box next to **Enable message tracking log**.
   - **Message tracking log path** This field displays the current location of the message tracking logs. By default, the message tracking logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\MessageTracking. To change the location of the message tracking logs, type the path to the new log location. Before you can change the path, message tracking must be enabled.
   - **Enable connectivity log** By default, connectivity logging is disabled on Hub Transport and Edge Transport servers. To enable connectivity logging, select the check box next to **Enable connectivity log**. To disable connectivity logging, clear the check box next to **Enable connectivity log**.

- **Connectivity log path** This field displays the current location of the connectivity logs. By default, the connectivity logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\Connectivity. To change the location of the connectivity logs, type the path to the new log location. Before you can change the path, connectivity logging must be enabled.
- **Send protocol log path** This field displays the current location of the Send connector protocol logs. By default, the Send connector protocol logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpSend. All the Send connectors that are configured on the Edge Transport server share the same protocol logs. By default, protocol logging is disabled on all Send connectors.

  To change the location of the Send connector protocol logs, type the path to the new log location.
- **Receive protocol log path** This field displays the current location of the Receive connector protocol logs. By default, the Receive connector protocol logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpReceive. All the Receive connectors that are configured on the Edge Transport server share the same protocol logs. By default, protocol logging is disabled on all Receive connectors.

  To change the location of the Receive connector protocol logs, type the path to the new log location.

Use the Shell to configure the properties of an Edge Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

You use the **Set-TransportServer** cmdlet to configure the properties of an Edge Transport server. Although the EMC allows you to configure the most commonly used properties of an Edge Transport server, the **Set-TransportServer** cmdlet allows you to configure all the properties of an Edge Transport server. The following examples demonstrate how you can use the Shell to configure the most common properties of an Edge Transport server. For more information about the possible configuration options, see Managing Transport Servers.

This example configures an Edge Transport server to use a specific list of DNS servers for external DNS lookups instead of the DNS servers configured on the adapters installed on that server.

```
Set-TransportServer Edge01 -ExternalDNSAdapterEnabled $false -ExternalDNSServers
```

This example enables connectivity logging on the Edge Transport server and configures it to store the connectivity log files in the C:\SMTP Logs folder.

```
Set-TransportServer Edge01 -ConnectivityLogEnabled $true -ConnectivityLogPath "C:
```

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.3 Configure Edge Transport Server Using Cloned Configuration

Configure Edge Transport Server Using Cloned Configuration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the provided Shell scripts to duplicate the configuration of a computer that has the Microsoft Exchange Server 2010 Edge Transport server role installed. This process is referred to as *cloned configuration*. *Cloned configuration* is the practice of deploying new Edge Transport servers based on the configuration information from a previously configured source server. The configuration information from the previously configured source server is copied and exported to an XML file, which is then imported to the target server.

Edge Transport server configuration information is stored in Active Directory Lightweight Directory Services (AD LDS) and isn't replicated among multiple Edge Transport servers. By using cloned configuration, you can make sure that every Edge Transport server that's deployed in the perimeter network is operating by using the same configuration.

Important:

Cloned configuration doesn't duplicate the Edge Subscription settings of a server. The certificates used by the Microsoft Exchange EdgeSync service aren't cloned. You must run the EdgeSync process separately for each Edge Transport server. The Microsoft Exchange EdgeSync service overwrites any settings included in both cloned configuration information and in EdgeSync replication information.

Included with the Edge Transport server installation are two Shell scripts that you use to perform the following cloned configuration tasks:

- **ExportEdgeConfig.ps1** This script exports all user-configured settings and data from an Edge Transport server and stores that data in an XML file.
- **ImportEdgeConfig.ps1** During the validate configuration step, the ImportEdgeConfig.ps1 script checks the XML file to see whether the server-specific export settings are valid for the target server. If settings have to be modified, the script writes the invalid settings to an answer file that you modify to specify the target server information that's used during the import configuration step. During the import configuration step, the script imports all user-configured settings and data that's stored in the intermediate XML file that was created by the ExportEdgeConfig.ps1 script.

These scripts are located in the \scripts folder in your Exchange installation folder. The default location for this folder is C:\Program Files\Microsoft\Exchange Server\Scripts.

Looking for other management tasks related to managing transport servers? Check out Managing Transport Servers.

Prerequisites

- Understand what configuration data is cloned and the parameters that can be used with the cloned configuration scripts. For more information, see Understanding Edge Transport Server Cloned Configuration.
- The Edge Transport server role is installed and configured on the source server.
- The Edge Transport server role is installed on the target server.

Note:

If any Send connectors are configured to use credentials, the password is

written to the intermediate XML file as an encrypted string. You can use the *-key* parameter with the ImportEdgeConfig.ps1 and ExportEdgeConfig.ps1 scripts to specify the 32-byte string to use for password encryption and decryption. If you don't use the *-key* parameter, a default encryption key is used.

Use the Shell to clone a source server by using the Shell scripts

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

1. Copy the ExportEdgeConfig.ps1 script to the root folder of your user profile on the source server.
2. On the source server, export the server configuration data by using the ExportEdgeConfig.ps1 script. Run the following command in the Shell. In the command, replace *C:\CloneConfigData.xml* with the full path of the XML file to be created by the ExportEdgeConfig.ps1 script.

   ```
   ./ExportEdgeConfig -CloneConfigData:"C:\CloneConfigData.xml"
   ```

   The confirmation message, "Edge configuration data is exported successfully to: *C:\CloneConfigData.xml*," appears.
3. Copy the output file to the target server.

Use the Shell scripts to validate a configuration file and create an answer file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

1. Copy the ImportEdgeConfig.ps1 script to the root folder of your user profile on the target server.
2. On the target server, validate the configuration file by using the ImportEdgeConfig.ps1 script. Run the following command in the Shell. In the command, replace C*:\CloneConfigData.xml* with the full path of the XML file that was created by the ExportEdgeConfig.ps1 script. Replace *C:\CloneConfigAnswer.xml* with the full path of the answer file that will be used by the ImportEdgeConfig.ps1 script to configure server-specific settings.

   ```
   ./ImportEdgeConfig -CloneConfigData:"C:\CloneConfigData.xml" -IsImport
   ```

   The confirmation message, "Answer file is successfully created," appears.
3. Open the answer file and modify any settings that are invalid for the target server. If no modifications are required, the answer file will have no entries. Save your changes.

Use the Shell scripts to import a configuration file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

Import the server configuration data by using the ImportEdgeConfig.ps1 script. Run the following command in the Shell. In the command, replace *C:\CloneConfigData.xml* with the full path of the XML file that was created by the ExportEdgeConfig.ps1 script. Replace *C:\CloneConfigAnswer.xml* with the full path of the answer file that was created by the ImportEdgeConfig.ps1 script.

```
./ImportEdgeConfig -CloneConfigData:"C:\CloneConfigData.xml" -IsImport $true -Clo
```

The confirmation message, "Importing Edge configuration information succeeded," appears.

1.7.2.4 Configure Hub Transport Server Properties

Configure Hub Transport Server Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The property configuration of a transport server running Microsoft Exchange Server 2010 determines how that server processes messages. The transport server settings that you configure on a Hub Transport server apply only to that specific server.

Looking for other management tasks related to configuring Hub Transport server properties? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the EMC to configure the properties of a Hub Transport server
- Use the Shell to configure the properties of a Hub Transport server

Use the EMC to configure the properties of a Hub Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**.
2. In the result pane, right-click the Hub Transport server you want to configure, and then select **Properties**.
3. On the **General** tab, you can view general information about the server:
   - **Version** This field displays the version of Exchange installed on the server.
   - **Edition** This field displays the Exchange Server edition. The edition is either Standard Edition or Enterprise Edition.
   - **Role(s)** This field displays the Exchange server roles installed on the server.

- **Product ID** This field displays the product ID for the Exchange server. If you haven't yet entered the product key for the server, the product ID displayed is **Unlicensed**. To license an unlicensed version of Exchange, see Enter Product Key.
- **Modified** This field displays the last date and time that a configuration change was made on this server.

4. On the **System Settings** tab, view the domain controller servers and global catalog servers. You can also enable an error reporting feature:
   - **Domain controller servers being used by Exchange** This read-only box displays a list of domain controller servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Global catalog servers being used by Exchange** This read-only box displays a list of global catalog servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Automatically send fatal service error report to Microsoft** Select this check box if you want to enable the error reporting feature and automatically send an error report to Microsoft in the event of a fatal error.
     If you enable the error reporting feature, information about fatal service errors is sent to Microsoft over encrypted channels. The information is used to improve Microsoft products. When this feature is enabled and the issue reported has a known solution, the server receives feedback from Microsoft. This feedback contains a link to information that may help resolve the problem.

5. On the **Customer Feedback Options** tab, you can enroll the selected server into the Customer Experience Improvement Program. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.

6. Use the **External DNS Lookups** tab to specify whether to use the DNS servers that are configured on a network adapter installed on this server or to use specific DNS servers when resolving the addresses of mail servers for external mail delivery. External DNS servers are used by Send connectors that are configured to use the external DNS lookup configuration on the transport server. When messages are routed to these Send connectors, the external DNS lookup settings that are configured for the source servers are used to resolve IP addresses for the delivery destination.
   You can choose one of the following options:
   - **Use network card DNS settings** To select an installed network adapter from the list, select **Use network card DNS settings**, and then select a network adapter from the drop-down list. The server then uses the DNS servers configured on that network adapter. The default setting is **All Available IPv4**. If you select this setting, the server uses the DNS servers configured on all the adapters on that server.
   - **Use these DNS servers** To have the server select from a list of manually entered DNS servers to query when resolving a remote server, select **Use these DNS servers**. To add a server to the list, type the IP address of the external DNS server, and then click **Add**. To change the IP address of a previously added DNS server, select that server, and then click **Edit**. To remove a previously added DNS server, select that server, and then click  .

7. Use the **Internal DNS Lookups** tab to specify whether to use the DNS servers that are configured on a network adapter installed on this server or to use specific DNS servers when resolving the addresses of mail servers for

internal mail delivery. Internal DNS servers are used to resolve IP addresses for servers inside your organization.
You can choose one of the following options:

- **Use network card DNS settings** To select an installed network adapter from the list, select **Use network card DNS settings**, and then select a network adapter from the drop-down list. The server then uses the DNS servers configured on that network adapter. The default setting is **All Available IPv4**. If you select this setting, the server uses the DNS servers configured on all the adapters on that server.
- **Use these DNS servers** To have the server select from a list of manually entered DNS servers to query when it's resolving an internal server, select **Use these DNS servers**. To add a server to the list, type the IP address of the internal DNS server, and then click **Add**. To change the IP address of a previously added DNS server, select that server, and then click **Edit**. To remove a previously added DNS server, select that server, and then click  .

8. Use the **Limits** tab to specify the number of times that the server retries message delivery, to set notification for undelivered messages, and to specify connection restrictions.
   - **Outbound connection failure retry interval (minutes)** Select this option to specify the retry interval for subsequent connection attempts to a remote server where earlier connection attempts as specified by the transient failure retry attempts and the transient failure retry interval have failed. The valid input range is 1 minute to 28800 minutes (20 days). We recommend that you don't modify the default value unless Microsoft Customer Service and Support has advised you to do this. The default value is 10 minutes.
   - **Transient failure retry interval (seconds)** Select this option to specify the interval between each connection attempt specified by the **Transient failure retry attempts** option. The valid input range is 1 second to 43200 seconds (12 hours). The default value is 300 seconds (5 minutes).
   - **Transient failure retry attempts** Select this option to specify the maximum number of times that a server immediately retries when it encounters a connection failure with a remote server. The default value is 6. The valid input range is 0 to 15. When this parameter is set to 0, the server doesn't immediately try to reconnect.
   - **Maximum time since submission (days)** Select this option to specify the expiration time-out for a particular message. If a message remains in the queue for longer than this period of time, the message is returned to the sender as a hard failure. The default value is 2 days. The valid input range is 1 day to 90 days.
   - **Notify sender when message is delayed more than (hours)** Select this option to specify how long the server waits before it generates a delivery status notification (DSN) that notifies the sender of a delivery delay. The default value is 4 hours. The valid input range is 1 hour to 720 hours (30 days).
   - **Maximum concurrent outbound connections** Select this option to specify the maximum number of outgoing connections that can be open at a time. If the connection limit is reached, the server doesn't initiate new connections until the number of current connections decreases. The default value is 1000. The valid input range is 1 to 2147483647. To disable this restriction, clear the check box next to **Maximum concurrent outbound connections**.
   - **Maximum concurrent outbound connections per domain** Select this option to specify the maximum number of concurrent connections to any single domain. The default value is 20. The valid input range is 1 to 2147483647. To disable this restriction, clear the check box next to **Maximum concurrent outbound connections per domain**.

9. Use the **Log Settings** tab to enable or disable message tracking, enable or disable connectivity logging, and to view or change the path for the message tracking logs, connectivity logs, Send connector protocol logs, and Receive connector protocol logs. On the **Log Settings** tab, you can view or set the following options:
   - **Enable message tracking log** By default, message tracking is enabled on Hub Transport and Edge Transport servers. To disable message tracking, clear the check box next to **Enable message tracking log**. To enable message tracking, select the check box next to **Enable message tracking log**.
   - **Message tracking log path** This field displays the current location of the message tracking logs. By default, the message tracking logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\MessageTracking. To change the location of the message tracking logs, type the path to the new log location. Before you can change the path, message tracking must be enabled.
   - **Enable connectivity log** By default, connectivity logging is disabled on Hub Transport and Edge Transport servers. To enable connectivity logging, select the check box next to **Enable connectivity log**. To disable connectivity logging, clear the check box next to **Enable connectivity log**.
   - **Connectivity log path** This field displays the current location of the connectivity logs. By default, the connectivity logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\Connectivity. To change the location of the connectivity logs, type the path to the new log location. Before you can change the path, connectivity logging must be enabled.
   - **Send protocol log path** This field displays the current location of the Send connector protocol logs. By default, the Send connector protocol logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpSend. All the Send connectors that are configured on the Edge Transport server share the same protocol logs. By default, protocol logging is disabled on all Send connectors.

     To change the location of the Send connector protocol logs, type the path to the new log location.
   - **Receive protocol log path** This field displays the current location of the Receive connector protocol logs. By default, the Receive connector protocol logs are stored at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpReceive. All the Receive connectors that are configured on the Edge Transport server share the same protocol logs. By default, protocol logging is disabled on all Receive connectors.

     To change the location of the Receive connector protocol logs, type the path to the new log location.

Use the Shell to configure the properties of a Hub Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

You use the **Set-TransportServer** cmdlet to configure the properties of a Hub Transport server. Although the EMC allows you to configure the most commonly used properties of a Hub Transport server, the **Set-TransportServer** cmdlet allows you to configure all the properties of a Hub Transport server. The following examples demonstrate how you can use the Shell to configure the most common properties of a Hub Transport server. For more information about the possible configuration options, see Managing Transport Servers.

This example configures a Hub Transport server to use a specific list of DNS servers for

external DNS lookups instead of the DNS servers configured on the adapters installed on that server.

```
Set-TransportServer Hub01 -ExternalDNSAdapterEnabled $false -ExternalDNSServers {
```

This example enables connectivity logging on the Hub Transport server and configures it to store the connectivity log files in the C:\SMTP Logs folder.

```
Set-TransportServer Hub01 -ConnectivityLogEnabled $true -ConnectivityLogPath "C:\
```

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.5 Configure Transport Settings Properties

Configure Transport Settings Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-12*

Transport settings define how all Hub Transport servers running Microsoft Exchange Server 2010 function in your organization. The options configured are used by all Hub Transport servers.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the EMC to configure global transport settings
- Use the Shell to configure global transport settings

Use the EMC to configure global transport settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport configuration" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, select the **Global Settings** tab, and then double-click **Transport Settings**.
3. Use the **General** tab to configure the transport limits and transport dumpster settings for all Hub Transport servers in your Exchange organization:
   - **Maximum receive size (KB)** This field specifies the maximum message size that can be received by recipients in the organization. The default value is 10240 KB. The valid input range is from 0 through 2097151 KB. If you clear the check box next to **Maximum receive size (KB)**, no limit is imposed on the message size that can be received by recipients in the organization.
   - **Maximum send size (KB)** This field specifies the maximum message size that can be sent by senders in the organization. The default value is 10240 KB. The valid input range is from 0 through 2097151 KB. If you clear the

check box next to **Maximum send size (KB)**, no limit is imposed on the message size that can be sent by senders in the organization.

- **Maximum number of recipients** This field specifies the maximum number of recipients in a message. The default is 5000. The valid input range is from 0 through 2147483647. If you clear the check box next to **Maximum number of recipients**, no limit is imposed on the number of recipients in a message. Exchange 2010 treats an unexpanded distribution group as one recipient.
- **Maximum size per mailbox database (MB)** This field specifies the maximum size of the transport dumpster for each mailbox database. The default value is 18 MB. The valid input range for this parameter is from 0 through 2097151 MB.

  To enable the transport dumpster, the value of **Maximum size per mailbox database (MB)** must be greater than 0, and the value of **Maximum retention time (days)** must be greater than 0.
- **Maximum retention time (days)** This field specifies how long an e-mail message should remain in the transport dumpster. The default value is 7 days. The valid input range is from 0 through 24855 days.

  To enable the transport dumpster, the value of **Maximum size per mailbox database (MB)** must be greater than 0, and the value of **Maximum retention time (days)** must be greater than 0.
- **Specify the external postmaster address** This field specifies the e-mail address used as the sender for system generated messages and notifications sent to senders external to your organization.

4. Use the **Message Delivery** tab to configure the IP addresses of internal SMTP servers installed in your perimeter network that are exempt from Sender ID and connection filtering. You can also configure the delivery status notification (DSN) codes that are monitored for internal senders. The non-delivery reports (NDRs) that correspond to these DSNs are copied to the postmaster mailbox.

   Note:
   NDRs are copied to the postmaster mailbox only when a mailbox is assigned to the Microsoft Exchange recipient. By default, no mailbox is assigned to the Microsoft Exchange recipient.

   On the **Message Delivery** tab, configure the following:
   Enter the IP addresses for servers deployed in the perimeter and the range of IP addresses for your organization. These IP addresses will be ignored by Sender ID and connection filtering Use this list to specify the IP addresses of the SMTP servers deployed in the perimeter of your organization:
   - **Add - IP Address** To enter an IP address without a subnet mask, or to specify the subnet mask by using Classless Interdomain Routing (CIDR) notation, click **Add** or the drop-down arrow located next to **Add** and select **IP Address**. In the **Add Internal SMTP Server IP Address** dialog box, enter the IP address directly or specify a subnet using the CIDR notation. For example, if you enter 192.168.1.1, only that host is added to the list of perimeter servers, but if you specify 192.168.1.0/24, the entire class C subnet of 192.168.1.0 is designated as your perimeter network, and messages from any server on that network aren't subject to Sender ID or connection filtering.

     Add - IP and Mask To enter an IP address or subnet together with a subnet mask in dotted decimal notation, click the drop-down arrow located next to **Add** and select **IP and Mask**. In the **Add Internal SMTP Server - IP and Mask** dialog box, specify the IP address and the subnet mask.
     Add - IP Range To specify an IP address range by using the first IP address and the last IP address in the range, click the

drop-down arrow located next to **Add** and select **IP Range**. In the **Add Internal SMTP Server IP Address - IP Range** dialog box, specify the start and end addresses of the IP address range.

- **Edit** To modify a previously added IP address, select the IP address and click **Edit**.
- **Remove** To remove an existing entry from the IP Block list, select the entry, and then click  .

Enter the delivery status notification (DSN) codes that are monitored for internal senders. NDRs with these DSN codes will be forwarded to the postmaster e-mail account Specify the DSN codes monitored for internal senders. Any NDRs with these DSN codes are copied to the mailbox of the Microsoft Exchange recipient. You can do the following:

- **Add** To add a DSN code, enter the 3-digit DSN code as **x.y.z**, and then click **Add**.
- **Edit** To edit an existing DSN code, select the DSN code, and then click **Edit**.

Remove To remove an existing DSN code, select the DSN code, and then click  .

Use the Shell to configure global transport settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport configuration" entry in the Transport Permissions topic.

You use the **Set-TransportConfig** cmdlet to configure the global transport settings in your organization. Unlike the EMC, which allows you to configure only the most commonly used properties of global settings, the **Set-TransportConfig** cmdlet allows you to configure all the global settings that define how your transport servers function.

The following are a few examples of how you can use this cmdlet.

You can use the **Set-TransportConfig** cmdlet to change the *MaxDumpsterSizePerDatabase* parameter settings for the transport dumpster. We recommend that you configure the maximum size per database (the MaxDumpsterSizePerdatabase parameter) to be 1.5 times the size of the largest message that can be sent. For example, if the maximum messages size is 10 megabytes (MB), you should set the value for the MaxDumpsterSizePerDatabase parameter to 15 MB. For organizations that don't have maximum message sizes, we recommend that you set the value for the maximum size per database to 1.5 times the size of the average-sized message that's sent in the organization.

This example configures postmaster@contoso.com to be the e-mail address that is used as the sender for NDRs and other system generated messages to senders outside your organization.

```
Set-TransportConfig -ExternalPostmasterAddress postmaster@contoso.com
```

This example enables shadow redundancy for your organization.

```
Set-TransportConfig -ShadowRedundancyEnabled $true
```

For detailed syntax and parameter information, see Set-TransportConfig.

1.7.2.6 Configure a Moderated Recipient

Configure a Moderated Recipient

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When you configure a recipient for moderation, all messages sent to that recipient are subject to approval by the designated moderators. For more information about how Exchange 2010 handles recipient moderation, see Understanding Moderated Transport.

Caution:

If you want to moderate a distribution group or a dynamic distribution group and your organization contains older versions of Exchange, you must specify an Exchange 2010 Hub Transport server as the expansion server. This specification is required because previous versions of Exchange don't support moderated recipients. If a message that is sent to a moderated distribution group or dynamic distribution group is expanded on a Hub Transport server running Exchange Server 2007, it will be delivered to all members of that distribution group, bypassing the moderation process. By specifying an Exchange 2010 Hub Transport server as the expansion server, you will ensure that all messages are moderated.

What Do You Want to Do?

- Use the EMC to configure a recipient for moderation
- Use the Shell to configure a recipient for moderation

Use the EMC to configure a recipient for moderation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Moderated Transport" entry in the Transport Permissions topic.

Assume you want to accomplish the following scenario:

- Enable moderation for the All Employees distribution group.
- Designate Rich Haddock and Kim Ralls as the moderators.
- Allow the members of the distribution group HR to bypass moderation.
- Notify internal senders if their message to the distribution group is rejected, but do not send any notifications to senders external to your organization.

To accomplish the tasks in this example scenario, perform the following procedure:

1. In the EMC console tree, click **Recipient Configuration**.
2. In the result pane, click the **All Employees** distribution group and click **Properties**.
3. Select the **Mail Flow Settings** tab.
4. Select **Message Moderation** and then click **Properties**.
5. On the **Message Moderation** dialog, complete the following:
   - 5.a. Select the **Messages sent to this group have to be approved by a moderator** check box.
   - 5.b. For the **Specify group moderators** list, click **Add**.
   - 5.c. In the **Select Recipient** dialog, select Rich Haddock and Kim Ralls from the list and click **OK**.
   - 5.d. For the **Specify senders who don't require message approval** list, click **Add**.

5.e.In the **Select Recipient** dialog, select HR from the list and click **OK**.
5.f.Click the **Notify senders in your organization only when their message is not approved** option.
6. Click **OK**.
7. Click **OK**.

This example shows how to configure a distribution group for moderation, but the same steps can be followed to configure any recipient for moderation.

Use the Shell to configure a recipient for moderation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Moderated Transport" entry in the Transport Permissions topic.

Assume you want to accomplish the following:

- Enable moderation for the All Employees distribution group.
- Designate Rich Haddock and Kim Ralls as the moderators.
- Allow the members of the distribution group HR to bypass moderation.
- Notify internal senders if their message to the distribution group is rejected, but do not send any notifications to senders external to your organization.

To accomplish the tasks in this example scenario, run the following command:

```
Set-DistributionGroup "All Employees" -ModerationEnabled $true -ModeratedBy "rhad
```

For more information about syntax and parameters, see Set-DistributionGroup.

This example shows how to configure a distribution group for moderation, but the same steps can be followed to configure any recipient for moderation. Simply use the corresponding cmdlet.

1.7.2.7 Configure Shadow Redundancy

Configure Shadow Redundancy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-13*

Shadow redundancy in Microsoft Exchange Server 2010 provides a high availability mechanism for messages for the entire time that the messages are in transit. To learn more about shadow redundancy, see Understanding Shadow Redundancy. You can use the Exchange Management Shell to configure shadow redundancy in your organization.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the Shell to enable or disable shadow redundancy
- Use the Shell to configure the shadow redundancy heartbeat
- Use the Shell to configure the maximum age for shadow messages

- Use the Shell to configure the maximum acknowledgement delay on a Receive connector
- Enable Shadow Redundancy Promotion

Use the Shell to enable or disable shadow redundancy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shadow redundancy" entry in the Transport Permissions topic.

Note:
You can't use the Exchange Management Console to enable or disable shadow redundancy.

Use the *ShadowRedundancyEnabled* parameter of the **Set-TransportConfig** cmdlet to enable or disable shadow redundancy in your organization. By default, shadow redundancy is enabled.

This example enables shadow redundancy for your organization.

```
Set-TransportConfig -ShadowRedundancyEnabled $true
```

For detailed syntax and parameter information, see Set-TransportConfig.

Use the Shell to configure the shadow redundancy heartbeat

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shadow redundancy" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the shadow redundancy heartbeat.

Use the *ShadowHearbeatTimeoutInterval* and *ShadowHearbeatRetryCount* parameters of the **Set-TransportConfig** cmdlet to configure the shadow redundancy heartbeat in your organization. The default value for the shadow redundancy time-out interval is 5 minutes in the release to manufacturing (RTM) version of Exchange 2010, and 15 minutes in Exchange 2010 Service Pack 1 (SP1) or later. The default value for the shadow redundancy heartbeat retry count is 3 in Exchange 2010 RTM, and 12 in Exchange 2010 SP1 or later. On each transport server running Exchange 2010, the shadow redundancy heartbeat is used to determine the availability of the other Exchange 2010 transport servers. For more information, see "Heartbeat" in Understanding Shadow Redundancy.

Assume that, because there are unreliable network connections between your Active Directory sites, you want to increase the total time transport servers wait before you determine that a remote server is unavailable. To do this, you want to have the Hub Transport servers wait 30 minutes between connection attempts before determining that a server is unavailable. As a result, you increase the maximum time for detecting a failure from the default value of 3 hours (15-minute time-out interval × 12 retries) to 6 hours (30-minute time-out interval × 12 retries). In the following example, the shadow redundancy heartbeat configuration is revised to increase the heartbeat time-out interval to 30 minutes.

```
Set-TransportConfig -ShadowHeartbeatTimeoutInterval 00:30:00
```

For detailed syntax and parameter information, see Set-TransportConfig.

Use the Shell to configure the maximum age for shadow messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shadow redundancy" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum age for shadow messages.

Use the *ShadowMessageAutoDiscardInterval* parameter of the **Set-TransportConfig** cmdlet to configure the maximum age for shadow messages in your organization. By default, shadow messages are discarded automatically after two days.

Assume that due to the hardware constraints on your servers, you don't want to retain shadow copies for messages that are delayed. This example reduces the retention period of shadow messages to four hours for your organization.

```
Set-TransportConfig -ShadowMessageAutoDiscardInterval 04:00:00
```

Note:
When a message expires, the primary server queues a discard event for that message, and the shadow server discards the shadow message when it receives the discard notification. The value you configure for the *ShadowMessageAutoDiscardInterval* parameter should be equal to or lower than the message expiration time-out interval configured on your transport servers.

For detailed syntax and parameter information, see Set-TransportConfig.

Use the Shell to configure the maximum acknowledgement delay on a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum acknowledgement delay on a Receive connector.

Use the *MaxAcknowledgementDelay* parameter of the **Set-ReceiveConnector** cmdlet to configure how long the Receive connector delays SMTP acknowledgement when receiving messages from systems that don't support shadow redundancy. By default, Receive connectors delay acknowledgement up to 30 seconds. For more information, see "Delayed Acknowledgement" in Understanding Shadow Redundancy.

Example 1

Assume that you have a proprietary application that sends SMTP messages by using your Exchange infrastructure. If the rate of message delivery for messages that are generated by this application is more important than the reliability of message delivery, you may want to disable delayed acknowledgement on the Receive connector that receives

messages from this application. This example sets the maximum acknowledgement delay to zero (0) on the Receive connector Custom App Receive Connector.

```
Set-ReceiveConnector "Custom App Receive Connector" -MaxAcknowledgementDelay 0
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

Example 2

Assume that all messages are typically delivered within 20 seconds in your environment. However, because of performance requirements, you don't want to delay acknowledgement more than 15 seconds for messages received from the Internet. After you analyze the message flow, you conclude that 95 percent of messages are delivered within the 15-second interval. This example configures the Receive connector from the Internet to delay acknowledgement for only 15 seconds. In this scenario, your environment provides shadow redundancy for 95 percent of messages received from the Internet.

```
Set-ReceiveConnector "From the Internet" -MaxAcknowledgementDelay 00:00:15.
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

Enable Shadow Redundancy Promotion

To complete this procedure, you must have local administrator permissions on the Hub Transport server.

1. Edit the Edgetransport.exe.config file. By default, this file is located in the C:\Program Files\Microsoft\Exchange Server\V14\Bin directory.
2. In the Edgetransport.exe.config file, change the **shadowredundancypromotionenabled** key to **true**, and then save the changes.
3. Restart the Microsoft Exchange Transport service (MSExchangeTransport.exe).

For more information, see the "Delayed Acknowledgement" section in Understanding Shadow Redundancy.

1.7.2.8 Configure the External Postmaster Address

Configure the External Postmaster Address

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can configure and manage the external postmaster address. The external postmaster address is used as the sender for system-generated messages and notifications sent to message senders that exist outside the Microsoft Exchange Server 2010 organization. An external sender is any sender that has an e-mail address that contains a domain not defined in the list of accepted domains for the Exchange 2010 organization.

In Exchange 2010, configuration of the external postmaster address is controlled by the *ExternalPostmasterAddress* parameter in the **Set-TransportConfig** cmdlet. In Exchange Server 2007, you configure this parameter using the **Set-TransportServer** cmdlet on every computer running Exchange 2007 that has the Hub Transport server role or Edge Transport server role installed.

Important:
Because management of the external postmaster address changed in Exchange 2010, you must configure the external postmaster address in two places if you have both Exchange 2010 and Exchange 2007 servers in your organization. You need to configure the external postmaster address once for the Exchange 2010 environment and once per server for the Exchange 2007 environment.

By default, the value of the *ExternalPostmasterAddress* parameter on every Hub Transport server and Edge Transport server is set to the value `$null`. The value `$null` causes the following behavior on Hub Transport servers and Edge Transport servers in the Exchange organization:

- For all Hub Transport servers in the Exchange organization or an Edge Transport server that has been subscribed to the Exchange organization, the external postmaster address is postmaster@<*Default accepted domain*>.
- For any Edge Transport server that hasn't been subscribed to the Exchange organization, the external postmaster address is postmaster@<*Edge Transport server FQDN*>.
  After the Edge Transport server is subscribed to the Exchange organization, the external postmaster address becomes postmaster@<*Default accepted domain*>.

Note:
If you specify a custom value for the external postmaster address, that value isn't replicated to any Edge Transport servers subscribed to the Exchange organization. If you specify a custom value for the external postmaster address, you must manually configure the external postmaster address on any Edge Transport servers.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

Use the EMC to modify the external postmaster address for your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport configuration" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, select the **Global Settings** tab.
3. Right-click **Transport Settings**, and then select **Properties**.
4. On the **General** tab, type the e-mail address you want to use as the external postmaster address in the **Specify the external postmaster address** field.
5. Click **OK**.

Use the Shell to modify the external postmaster address for your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport configuration" entry in the Transport Permissions topic.

This example designates postmaster@contoso.com as the external postmaster address.

```
Set-TransportConfig -ExternalPostmasterAddress postmaster@contoso.com
```

For detailed syntax and parameter information, see Set-TransportConfig.

Other Tasks

After you configure the external postmaster address, you may also want to:

- Create a Mailbox
- Add an E-Mail Address for a User Mailbox

1.7.2.9 Managing Accepted and Remote Domains

Managing Accepted and Remote Domains

Exchange Server 2010 > Transport > Managing Transport Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Create an Accepted Domain

Configure Accepted Domain Properties

Remove an Accepted Domain

Configure Exchange 2010 to Accept E-Mail for More Than One Authoritative Domain

Create a Remote Domain

Configure Remote Domain Properties

Remove a Remote Domain

Supported Character Sets for Remote Domain Configuration

1.7.2.9.1 Create an Accepted Domain

Create an Accepted Domain

Transport > Managing Transport Servers > Managing Accepted and Remote Domains >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

An accepted domain is any SMTP domain for which Microsoft Exchange accepts incoming messages. Accepted domains can be authoritative or relay domains. Accepted domains are configured as global settings for the Exchange organization and on computers that have the Edge Transport server role installed.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

Prerequisites

- You can't create an accepted domain that has the same name as an already configured remote domain. For example, if you have fabrikam.com configured as a remote domain, you can't create an accepted domain for fabrikam.com.
- Before you configure an accepted domain, you must verify that a public Domain Name System (DNS) MX resource record for that SMTP namespace exists and that the MX resource record references a server name and an IP address associated with your Exchange organization.

What Do You Want to Do?

- Use the EMC to create an accepted domain
- Use the Shell to create an accepted domain

Use the EMC to create an accepted domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

1. Open the Exchange Management Console. Perform one of the following steps:
   - To create an accepted domain on a computer that has the Edge Transport server role installed, on that computer, in the console tree, select **Edge Transport**, and then in the work pane, click the **Accepted Domains** tab.
   - To create an accepted domain on a computer that has the Hub Transport server role installed, on that computer, in the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Accepted Domains** tab.
2. In the action pane, click **New Accepted Domain**. The New Accepted Domain wizard appears.
3. On the **New Accepted Domain** page, complete the following fields:
   - **Name** To identify the accepted domain, type a unique name in the **Name** field. We recommend that you select a meaningful name to help you easily identify the purpose of this accepted domain. For example, you may want to use a name that easily identifies this as a subsidiary domain or as a hosted domain. You must use a unique name for each accepted domain.
   - **Accepted Domain** Use this field to identify the SMTP namespace for which the Exchange organization accepts e-mail messages. You can use a wildcard character to accept messages for a domain and all its subdomains. For example, you can type ***.contoso.com** to set Contoso.com and all its subdomains as accepted domains.
4. After you complete these fields on the **New Accepted Domain** page, select one of the following options to set the accepted domain type:
   - **Authoritative Domain** To specify that e-mail messages are delivered to a recipient that has a domain account in your Exchange organization, select this option.
   - **Internal Relay Domain** To specify that e-mail messages are either delivered to recipients in your organization or relayed to a server outside your Exchange organization but still under the authority of your company or IT department, select this option.
   - **External Relay Domain** To relay e-mail messages to an e-mail server outside the Exchange organization, select this option.
5. Click **New** to create the new accepted domain.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create an accepted domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

You use the **New-AcceptedDomain** cmdlet to create new accepted domains in your organization. The following examples show how this cmdlet can be used.

The following example creates an authoritative domain.

```
New-AcceptedDomain -Name "Contoso" -DomainName contoso.com -DomainType Authoritat
```

The following example creates an internal relay domain.

```
New-AcceptedDomain -Name "Fourth Coffee" -DomainName fourthcoffee.com -DomainType
```

The following example creates an external relay domain.

```
New-AcceptedDomain -Name "Woodgrove Bank" -DomainName woodgrovebank.com -DomainTy
```

For detailed syntax and parameter information, see New-AcceptedDomain.

1.7.2.9.2 Configure Accepted Domain Properties

Configure Accepted Domain Properties

Transport > Managing Transport Servers > Managing Accepted and Remote Domains >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

An accepted domain is any SMTP domain for which Microsoft Exchange accepts incoming messages. Accepted domains can be authoritative or relay domains. Accepted domains are configured as global settings for the Exchange organization and on computers that have the Edge Transport server role installed.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the EMC to configure the properties of an accepted domain
- Use the Shell to configure the properties of an accepted domain

Use the EMC to configure the properties of an accepted domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

1. If you're configuring an accepted domain on a Hub Transport server, in the console tree, navigate to **Organization Configuration** > **Hub Transport**. On an Edge Transport server, select **Edge Transport** in the console tree.
2. In the work pane, select the **Accepted Domains** tab on the right, and then double-click the accepted domain you want to configure.
3. Use the **General** tab to specify how Exchange handles the e-mail messages that it accepts for this domain:
   - **Name** The name of the accepted domain is displayed in the first field on the **General** tab. This is a display name for the accepted domain and doesn't have to match the actual SMTP domain.
   - **Authoritative Domain** Select this option if this domain is used for e-mail addresses of the recipients in your organization.
   - **Internal Relay Domain** To specify that e-mail messages are either delivered to recipients in your organization or relayed to a server outside your Exchange organization but still under the authority of your company or IT department, select this option.
   - **External Relay Domain** To specify that e-mail messages sent to recipients in this domain are relayed to an e-mail server outside your organization, select this option.

Use the Shell to configure the properties of an accepted domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

You use the **Set-AcceptedDomain** cmdlet to configure the properties of an accepted domain. This example configures the accepted domain for Woodgrove Bank as an authoritative domain.

```
Set-AcceptedDomain "Woodgrove Bank" -DomainType Authoritative
```

For detailed syntax and parameter information, see Set-AcceptedDomain.

1.7.2.9.3 Remove an Accepted Domain

Remove an Accepted Domain

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Accepted domains are any Simple Mail Transfer Protocol (SMTP) namespace for which a Microsoft Exchange organization receives e-mail. This topic explains how to use the EMC

or the Shell to remove an accepted domain.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to accepted domains? Check out Managing Accepted and Remote Domains.

Prerequisites

- Before you remove an accepted domain, verify that the domain name isn't referenced in any e-mail address policy.
- After you remove an accepted domain, the Exchange organization no longer accepts e-mail messages that are addressed to recipients in that domain. Make sure the change doesn't adversely affect the mail flow in your organization.
- You can't delete an accepted domain that is set as the default accepted domain. To delete the default accepted domain, you must first create a new accepted domain, and then set the new accepted domain as the default accepted domain.

What Do You Want to Do?

Use the EMC to remove an Accepted domain

Use the Shell to remove an Accepted domain

Use the EMC to remove an Accepted domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

1. Open the Exchange Management Console. Perform one of the following steps:
   1.a. To remove an accepted domain on a computer that has the Edge Transport server role installed, on that computer, in the console tree, select **Edge Transport**, and then in the work pane, click the **Accepted Domains** tab.
   1.b. To remove an accepted domain on a computer that has the Hub Transport server role installed, on that computer, in the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Accepted Domains** tab.
2. In the result pane, select the accepted domain that you want to remove, and then in the action pane, click **Remove**.
3. A dialog box appears with the text, "**Are you sure you want to remove '***Accepted Domain***'?**", where *Accepted Domain* is the name of the accepted domain that you want to remove. Click **Yes.**

Use the Shell to remove an Accepted

domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

Use the **Remove-AcceptedDomain** cmdlet to remove an existing accepted domain from your organization. The following example removes the accepted domain named "Woodgrove Bank":

```
Remove-AcceptedDomain -Identity "Woodgrove Bank"
```

For detailed syntax and parameter information, see Remove-AcceptedDomain.

1.7.2.9.4 Configure Exchange 2010 to Accept E-Mail for More Than One Authoritative Domain

Configure Exchange 2010 to Accept E-Mail for More Than One Authoritative Domain

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure Microsoft Exchange Server 2010 to accept e-mail for more than one authoritative SMTP domain.

The following examples are scenarios in which your Exchange organization may have to receive and process e-mail for more than one authoritative SMTP domain:

- You are changing your SMTP domain name, but have to continue to accept e-mail for the old domain name for a time, in case customers send e-mail messages to the previous e-mail addresses. You can set the new e-mail address as the primary (reply to) address. This means that the new address will be the default e-mail address displayed on all e-mail messages sent by the recipient. You can set the old e-mail address as a secondary address. This will enable the recipient to continue to receive e-mail sent to the old e-mail address.
- You want to provision different e-mail addresses for business units within your organization. For example, if the Contoso.com forest contains subdomains for the subsidiaries Tailspin Toys and Fourth Coffee, you may want to assign the SMTP domain names Contoso.com, TailspinToys.com, and FourthCoffee.com to the recipients in those respective business units.
- You provide e-mail hosting services and have to accept e-mail for more than one SMTP domain name.

Looking for other management tasks related to accepted and remote domains? Check out Managing Accepted and Remote Domains.

Note:

If you have deployed an Edge Transport server in your organization and have created an Edge Subscription for that server, you perform these procedures only on the Hub Transport server. If the Edge Transport server isn't subscribed, you must create accepted domains on both the Edge Transport server and the Hub Transport server.

Caution:

When you create an accepted domain, you can use a wildcard character (*) in the address space to indicate that all subdomains of the SMTP address space are also accepted by the Exchange organization. For example, to configure Contoso.com and all its subdomains as accepted domains, enter ***.Contoso.com** as the SMTP address space. However, if the subdomain names will be used in an e-mail address policy, each subdomain must have an explicit accepted domain entry.

Prerequisites

- A public Domain Name System (DNS) MX resource record is required for each SMTP domain for which you accept e-mail from the Internet. Each MX record should resolve to the Internet-facing server that receives e-mail for your organization.
- You must configure Send connectors and Receive connectors so that the Exchange organization can send e-mail to and receive e-mail from the Internet. The configuration of the Internet Send connectors and Receive connectors is determined by your Exchange topology. For more information about configuring Internet mail flow, see Managing Message Routing.

Use the EMC to configure Exchange 2010 to accept e-mail for more than one domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic and the "E-mail address policies" entry in the Mailbox Permissions topic.

1. Configure the accepted domain entry by following these steps:
   1.a. Expand the **Organization Configuration** node, and then click **Hub Transport**. In the results pane, click the **Accepted Domains** tab.
   1.b. In the action pane, click **New Accepted Domain**. The **New Accepted Domain** wizard appears.
   1.c. On the **New Accepted Domain** page, type a name to identify the accepted domain entry. In the **Accepted Domain** field, type the SMTP domain name. Select **Authoritative Domain. E-mail is delivered to a recipient in this Exchange organization**.
   1.d. Click **New**.
   1.e. On the **Completion** page, click **Finish**.
2. Configure an e-mail address policy for the authoritative domain by performing the steps in this section that meet the objectives of your scenario.
   To change the primary (reply to) e-mail address assigned to recipients and keep the existing e-mail address as a secondary e-mail address, follow these steps:
   2.a. Expand the **Organization Configuration** node, and then click **Hub Transport**. In the results pane, click the **E-mail Address Policies** tab. Select the e-mail address policy that you want to modify, and then in the action pane, click **Edit**.
   2.b. On the **Introduction** page, click **Next**.
   2.c. On the **Conditions** page, click **Next**.
   2.d. On the **E-mail Addresses** page, click **Add**. In the **SMTP E-mail Address** dialog box, select the option under **E-mail address local part** that determines how the recipient's e-mail address alias will be generated.
   2.e. Click the **Select the accepted domain for the e-mail address** option, and then click **Browse**. In the **Select Accepted Domain** dialog box, select an accepted domain, and then click **OK**. Click **OK** again to close the **SMTP E-mail Address** dialog box.
   2.f. On the **E-mail Addresses** page, select the new address entry, and then click **Set as Reply**. The e-mail address entry is displayed in bold type to

indicate that it's now the primary, or reply to, address for the recipients to which this e-mail address policy applies. Click **Next**.

2.g.On the **Schedule** page, select an option to specify when the e-mail address policy will be applied and the maximum length of time that the task is permitted to run. Click **Next**.

2.h.On the **Edit E-mail Address Policy** page, click **Edit** to save the changes to the policy and apply it to affected recipients.

2.i.On the **Completion** page, click **Finish**.

3. To create additional e-mail addresses that will be used as the primary e-mail address for a filtered set of recipients, follow these steps:

3.a.In the action pane, click **New E-mail Address Policy**. The **New E-mail Address Policy** wizard appears.

3.b.On the **Introduction** page, type a name for the e-mail address policy. If the users that will be assigned this new e-mail address policy are all in a specific organizational unit (OU), click **Browse** to restrict this e-mail address policy to that specific OU. Select an option under **Include these recipient types** to determine to which recipient types this e-mail address policy will be applied. Click **Next**.

3.c.On the **Conditions** page, in the **Step 1** box, select the condition that will be used to filter the recipients to which the policy is applied. For example, you can select **Recipient is in a Company** to apply the policy to only recipients whose properties identify a specific company affiliation. In the **Step 2** box, click the underlined value to specify the value that the filter must match. For example, if you selected **Recipient is in a Company**, click the word **specified**. The **Specify Company** dialog box opens. Type a company name, and then click **Add** to add the company name to the list of names that the recipient's Company attribute must match to have this policy applied to them. If you add multiple entries, the recipient attribute must match only one entry to meet the filter conditions. Click **OK** to close the dialog box, and then click **Next**.

3.d.On the **E-mail Addresses** page, click **Add**. In the **SMTP E-mail Address** dialog box, select the option under **E-mail address local part** that determines how the recipient's e-mail address alias will be generated.

3.e.Click the **Select the accepted domain for the e-mail address** option, and then click **Browse**. In the **Select Accepted Domain** dialog box, select an accepted domain, and then click **OK**. Click **OK** again to close the **SMTP E-mail Address** dialog box. The e-mail address entry is displayed in bold type to indicate that it's now the primary, or reply to, address for the recipients to which this e-mail address policy applies.

3.f.Click **Next**.

3.g.On the **Schedule** page, select an option to specify when the e-mail address policy will be applied and the maximum length of time that the task is permitted to run.

3.h.Click **Next**.

3.i.On the **New E-mail Address Policy** page, click **New** to save the policy and apply it to affected recipients.

3.j.On the **Completion** page, click **Finish**.

Note:

If a recipient meets the filter conditions of more than one e-mail address policy, the e-mail address policy that has the lowest number is set as the primary address. The e-mail address policy that has the lowest number is highest in the priority list. Any other e-mail address policies that also apply are set as secondary addresses.

Use the Shell to configure Exchange 2010 to accept e-mail for more than one

domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic and the "E-mail address policies" entry in the Mailbox Permissions topic.

1. To create an authoritative accepted domain entry for each SMTP domain for which your Exchange organization will host recipient mailboxes, use the **New-AcceptedDomain** cmdlet. This example creates the authoritative domain FourthCoffee.com.

```
New-AcceptedDomain -Name "Fourth Coffee subsidiary" -DomainName Fourth
```

2. To change the primary e-mail address assigned to recipients and keep the existing e-mail address as a secondary address, use the **Set-EmailAddressPolicy** cmdlet to modify an existing e-mail address policy. If your default e-mail address policy sets recipient e-mail addresses to useralias@contoso.com, this example changes the primary (reply to) address to useralias@fourthcoffee.com and continues to use useralias@contoso.com as a secondary address.

```
Set-EmailAddressPolicy -Identity "Default Policy" -EnabledEmailAddress
```

Note:

If you type `SMTP` in all uppercase letters, this indicates the primary (reply to) address. If you type `smtp` in lowercase letters, this indicates the secondary address.

3. To apply the new e-mail address policy to recipients, use the **Update-EmailAddressPolicy** cmdlet. This example applies the new e-mail address policy to recipients.

```
Update-EmailAddressPolicy -Identity "Default Policy"
```

4. To create additional e-mail addresses that will be used as the primary e-mail address for a filtered set of recipients, use the **New-EmailAddressPolicy** cmdlet to create an e-mail address policy for each accepted domain that will be used as part of a recipient's e-mail address. This example creates an e-mail address policy for FourthCoffee.com, assigns that policy to the recipients in the Fourth Coffee department, and sets the highest priority for that e-mail address policy.

```
New-EmailAddressPolicy -Name "Fourth Coffee Recipients" -IncludedRecip
```

5. To apply the new e-mail address policy to recipients, use the **Update-EmailAddressPolicy** cmdlet. This example applies the new e-mail address policy to the Fourth Coffee recipients.

```
Update-EmailAddressPolicy -Identity "Fourth Coffee Recipients"
```

For detailed syntax and parameter information, see the following topics:

- New-AcceptedDomain
- Set-EmailAddressPolicy
- New-EmailAddressPolicy
- Update-EmailAddressPolicy

1.7.2.9.5 Create a Remote Domain

Create a Remote Domain

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Remote domains are SMTP domains that are external to your Microsoft Exchange organization. You can create remote domain entries to define the settings for message transfer between your Exchange organization and domains outside your Active Directory forest. The settings for remote domains are global configuration settings for the Exchange organization.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

Prerequisites

You can't create a remote domain that has the same name as an already configured accepted domain. For example, if your organization accepts mail for fabrikam.com, you can't create a remote domain for fabrikam.com.

What Do You Want to Do?

- Use the EMC to create a remote domain
- Use the Shell to create a remote domain

Use the EMC to create a remote domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration**> **Hub Transport**.
2. In the result pane, click the **Remote Domains** tab.
3. In the action pane, click **New Remote Domain**. The New Remote Domain wizard appears.
4. On the **New Remote Domain** page, complete the following fields:
   - **Name** Use this field to identify the remote domain in the user interface. You can type any name that you want. We recommend that you select a meaningful name that helps you easily identify the purpose of this remote domain. You must use a unique name for each remote domain. The name can't exceed 64 characters. This field is required.
   - **Domain Name** Use this field to identify the SMTP namespace of the remote domain. For example, type **contoso.com**. The remote domain name can't exceed 256 characters. This field is required.
   - **Include all subdomains** To apply the remote domain configuration to all subdomains of the remote domain, such as mail.contoso.com, select this check box.
   - **Use this domain for my Office 365 tenant** If the new remote domain you're creating represents the part of your organization that is hosted on Microsoft Office 365, select this check box.
5. To create the remote domain entry with these settings, click **New**.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a remote domain entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

You use the **New-RemoteDomain** cmdlet to create new remote domains in your organization. This example shows how this cmdlet can be used to create a new remote domain for contoso.com.

```
New-RemoteDomain -Name Contoso -DomainName Contoso.com
```

For detailed syntax and parameter information, see New-RemoteDomain.

1.7.2.9.6 Configure Remote Domain Properties

Configure Remote Domain Properties

Transport > Managing Transport Servers > Managing Accepted and Remote Domains >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Remote domains are SMTP domains that are external to your Microsoft Exchange organization. You can create remote domain entries to define the settings for message transfer between your Exchange organization and domains outside your Active Directory forest. The settings for remote domains are global configuration settings for the Exchange organization.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

What Do You Want to Do?

- Use the EMC to configure the properties of a remote domain
- Use the Shell to configure the properties of a remote domain

Use the EMC to configure the properties of a remote domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.

2. In the work pane, select the **Remote Domains** tab on the right, and then double-click the remote domain you want to configure.

3. Use the **General** tab to configure the settings that determine the types of out-of-office messages sent to recipients in the remote domain. The type of out-of-office messages available in your organization depends on both the Exchange client version and the Exchange server version. The out-of-office message is set on the client and is sent by the server. Exchange Server 2010 and Exchange Server 2007 can send different out-of-office messages to internal and external users. Users that use Microsoft Office Outlook 2007 can set different internal and external out-of-office replies. Earlier versions of Outlook or Exchange only support a single type of out-of-office message used for both internal and external recipients.
   The **General** tab shows the following:
   - **Domain name** Shows the display name for the domain.
   - **Modified** Shows the date and time when the remote domain properties were last modified.
   - **Allow none** If you select this option, no out-of-office messages are delivered to the remote domain.
   - **Allow external out-of-office messages only** If you select this option, only out-of-office messages configured as external by an Outlook 2007 client, or by using Microsoft Office Outlook Web App for a mailbox located on an Exchange 2010 or Exchange 2007 Mailbox server are delivered to the remote domain.
   - **Allow external out-of-office messages and legacy out-of-office messages (configured by using Outlook 2003 or earlier clients, or configured on Exchange 2003 mailboxes)** If you select this option, out-of-office messages configured as external by an Outlook 2007 client or by using Outlook Web App for a mailbox located on an Exchange 2010 Mailbox server are delivered to the remote domain. Out-of-office messages set by Outlook 2003 or earlier clients, regardless of the server version of their mailbox store, are delivered to the remote domain. Out-of-office messages sent by Exchange 2003 or earlier servers, regardless of the client version used to set the out-of-office message, are delivered to the remote domain.
   - **Allow internal out-of-office messages and legacy out-of-office messages (configured by using Outlook 2003 or earlier clients, or configured on Exchange Server 2003 mailboxes)** If you select this option, out-of-office messages configured as internal by an Outlook 2007 client or by using Outlook Web App for a mailbox located on an Exchange 2010 Mailbox server are delivered to the remote domain. Out-of-office messages set by Outlook 2003 or earlier clients, regardless of the server version of their mailbox store, are delivered to the remote domain. Out-of-office messages sent by Exchange 2003 or earlier servers, regardless of the client version used to set the out-of-office message, are delivered to the remote domain.

4. Use the **Message Format** tab to specify message policy, format, and character sets for the messages sent to this remote domain.
   Use the **Message Format Options** section to specify message delivery and formatting:
   - **Allow automatic replies** To allow messages that are automatic replies from client e-mail programs in your organization, select this option.
   - **Allow automatic forward** To allow messages that are auto-forwarded by client e-mail programs in your organization, select this option.
   - **Allow delivery reports** To allow read receipts from client software in your organization to the remote domain, select this option.
   - **Allow non-delivery reports** To allow non-delivery reports (NDRs) from your organization, select this option.
   - **Display sender's name on messages** To have the sender's display name appear on messages, select this option. We recommend that you leave this

option selected.

- **Use message text line wrap at column** To allow line wrap in message text for outgoing messages, select this option, and then in the text box, type the line-wrap size, from 0 through 132. To set the value to unlimited, leave the field blank. The default value is unlimited (blank).
- **Always use** To always send messages that use Exchange rich-text format, select this text box.
- **Never use** To never send messages that use Exchange rich-text format, select this check box.
- **Determined by individual user settings** To send e-mail messages that use the Exchange rich-text settings specified by the Outlook user, select this check box.

Use the following character set options to specify acceptable character sets:

- **MIME character set** To identify a MIME character set, type the character encoding set in the text box.
- **Non-MIME character set** To identify a non-MIME character set, type the character encoding set in the text box.

5. Use the **Office 365 Tenant Domain** tab to specify whether this remote domain is used for your cloud-based organization.
   - **Use this domain for my Office 365 tenant** If the new remote domain you're creating represents the part of your organization that is hosted on Microsoft Office 365, select this check box.

Use the Shell to configure the properties of a remote domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

You use the **Set-RemoteDomain** cmdlet to configure the properties of a remote domain. This section provides examples on how to configure various properties of a remote domain.

This example makes sure that no out-of-office messages are sent to the domain.

```
Set-RemoteDomain "RemoteDomain" -AllowedOOFType None
```

This example allows only external out-of-office messages.

```
Set-RemoteDomain "RemoteDomain" -AllowedOOFType External
```

This example allows external out-of-office messages and out-of-office messages set by Outlook 2003 or earlier clients or sent by Exchange 2003 or earlier servers.

```
Set-RemoteDomain "RemoteDomain" -AllowedOOFType ExternalLegacy
```

This example allows internal out-of-office messages and out-of-office messages set by Outlook 2003 or earlier clients or sent by Exchange 2003 or earlier servers.

```
Set-RemoteDomain "RemoteDomain" -AllowedOOFType InternalLegacy
```

This example allows automatic replies to the remote domain. By default, this setting is disabled.

```
Set-RemoteDomain -Identity Contoso -AutoReplyEnabled $true
```

This example allows automatic forwards to the remote domain. By default, this setting is disabled.

```
Set-RemoteDomain -Identity Contoso -AutoForwardEnabled $true
```

This example disables delivery reports to the remote domain. By default, this setting is enabled.

```
Set-RemoteDomain -Identity Contoso -DeliveryReportEnabled $false
```

This example disables non-delivery reports to the remote domain. By default, this setting is enabled.

```
Set-RemoteDomain -Identity Contoso -NDREnabled $false
```

This example disables the display of the sender's name on messages. By default, this setting is enabled. We recommend that you leave this option enabled.

```
Set-RemoteDomain -Identity Contoso -DisplaySenderName $false
```

This example enables the line wrapping of message text and sets the column width to 76 characters.

```
Set-RemoteDomain -Identity Contoso -LineWrapSize 76
```

This example allows notification to be sent to a remote domain when a meeting request from a sender in the remote domain is forwarded to another recipient. By default, this setting is disabled.

```
Set-RemoteDomain -Identity Contoso -MeetingForwardNotificationEnabled $true
```

This example configures both the MIME and non-MIME characters sets to the Western European character set (ISO-8859-1).

```
Set-RemoteDomain -Identity Contoso -CharacterSet "ISO-8859-1" -NonMimeCharacterSe
```

This example specifies that Transport Neutral Encapsulation Format (TNEF) encoding is used for all messages sent to the remote domain. By default, the value for this setting is `$null`, and TNEF encoding is controlled by individual user settings. The TNEF settings are shown as the Exchange rich-text format options in the EMC.

```
Set-RemoteDomain -Identity Contoso -TNEFEnabled $true
```

For detailed syntax and parameter information, see Set-RemoteDomain.

1.7.2.9.7 Remove a Remote Domain

Remove a Remote Domain

Transport > Managing Transport Servers > Managing Accepted and Remote Domains >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Remote domains define override settings for the message transfer between the Microsoft Exchange Server 2010 organization and domains outside your Active Directory forest. When you create a remote domain entry, you control the types of messages sent to that domain. You can also apply message format policies and acceptable character sets for messages sent from mailbox users in your organization to the remote domain. The settings for remote domains are global configuration settings for the Exchange organization.

If you remove a remote domain entry, the settings for message transfer no longer apply to messages sent to the remote domain. Removing a remote domain entry doesn't disable mail flow to the remote domain. After a remote domain entry is removed, the configuration settings of the default remote domain apply to new messages sent to that domain. You can't remove the default remote domain.

Looking for other management tasks related to remote domains? Check out Managing Accepted and Remote Domains.

Use the EMC to remove a remote domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **Remote Domains** tab.
3. In the result pane, select the remote domain entry that you want to remove.
4. In the action pane, click **Remove**.
5. A message appears asking "**Are you sure you want to remove '***Remote Domain***'?"** Click **Yes**.

Use the Shell to remove a remote domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote domains" entry in the Transport Permissions topic.

Use the **Remove-RemoteDomain** cmdlet to remove a remote domain. This example removes the remote domain Contoso.

```
Remove-RemoteDomain -Identity Contoso
```

For detailed syntax and parameter information, see Remove-RemoteDomain.

1.7.2.9.8 Supported Character Sets for Remote Domain Configuration

Supported Character Sets for Remote Domain Configuration

Transport > Managing Transport Servers > Managing Accepted and Remote Domains >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-06*

The following character sets are supported for the *CharacterSet* parameter and *NonMimeCharacterSet* parameter in the Set-RemoteDomain cmdlet. When you enter a value for the *CharacterSet* parameter and *NonMimeCharacterSet* parameter, use the value in the Name column in the following table.

Supported character sets for remote domain configuration

Name	Description
big5	Chinese Traditional (Big5)
DIN_66003	German (IA5)

euc-jp	Japanese (EUC)
euc-kr	Korean (EUC)
GB18030	Chinese Simplified (GB18030)

1.7.2.10.1 Configure Attachment Filtering

Configure Attachment Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Attachment filtering can block attachments from entering the Microsoft Exchange Server 2010 organization by attachment content type or by attachment file name. How the attachments are processed depends on how attachment filtering is configured.

Important:
Configuration changes that you make to attachment filtering by using the Shell are made only to the local computer that has the Edge Transport server role installed. If you have multiple instances of the Edge Transport server role running in your organization, you must apply attachment filter configuration changes to each computer.

You can configure an attachment filter entry to filter attachments by attachment content type or by attachment file name. Before you add an attachment filter entry, you must determine whether you want to filter by MIME content type or by file name. Your choice of

attachment filter type depends on your business needs and policies. For more information, see Understanding Attachment Filtering.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Use the Shell to enable the Attachment Filter agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable the Attachment Filter agent.

By default, the Attachment Filter agent is enabled on the computer that has the Edge Transport server role installed.

This example enables the Attachment Filter agent if it isn't enabled.

```
Enable-TransportAgent -Identity "Attachment Filter agent"
```

For detailed syntax and parameter information, see Enable-TransportAgent.

Use the Shell to add an attachment filter entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:
You can't use the EMC to add an attachment filter entry.

With Exchange 2010, you can configure multiple attachment filters on each Edge Transport server.

To add an attachment filter that filters e-mail attachments that have a specific MIME content type, use the following syntax.

```
Add-AttachmentFilterEntry -Name <MIMEContentType> -Type ContentType
```

This example filters all JPEG images by using an attachment filter. Note that you must run the following command on each Edge Transport server.

```
Add-AttachmentFilterEntry -Name image/jpeg -Type ContentType
```

To add an attachment filter that filters e-mail attachments based on a file name or file name extension, use the following syntax.

```
Add-AttachmentFilterEntry -Name <FileName> -Type FileName
```

This example filters all e-mail attachments that have the file name extension EXE.

```
Add-AttachmentFilterEntry -Name *.EXE -Type FileName
```

For detailed syntax and parameter information, see Add-AttachmentFilterEntry.

Use the Shell to configure attachment filtering behavior

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure attachment filtering behavior.

To configure attachment filtering on an Edge Transport server role, use the **Set-AttachmentFilterListConfig** cmdlet. This example makes the following configuration changes to the Attachment Filter agent.

- Sets the Attachment Filter agent to reject messages that have prohibited attachments.
- Configures a custom response for rejected messages.

```
Set-AttachmentFilterListConfig -Action -Reject -RejectResponse "The attachment yo
```

For detailed syntax and parameter information, see Set-AttachmentFilterListConfig.

1.7.2.10.2 Enable or Disable Content Filtering

Enable or Disable Content Filtering

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, in Microsoft Exchange Server 2010, content filtering is enabled on the Edge Transport server only for inbound, unauthenticated messages from the Internet. These messages are handled as external messages.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Content Filtering.

Use the EMC to enable or disable content filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. Open the EMC on the Edge Transport server.
2. In the console tree, click **Edge Transport**.
3. In the work pane, click the **Anti-spam** tab, and then select **Content Filtering**.
4. In the action pane, click **Enable** or **Disable** as appropriate.

Use the Shell to enable or disable content filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

This example enables content filtering.

```
Set-ContentFilterConfig -Enabled $true
```

This example disables content filtering.

```
Set-ContentFilterConfig -Enabled $false
```

Use the Shell to enable or disable content filtering for internal and external messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable content filtering for internal and external messages.

This example enables content filtering for external messages.

```
Set-ContentFilterConfig -ExternalMailEnabled $true
```

This example disables content filtering for external messages.

```
Set-ContentFilterConfig -ExternalMailEnabled $false
```

Note:
By default, content filtering functionality is enabled for external messages.

This example enables content filtering for internal messages.

```
Set-ContentFilterConfig -InternalMailEnabled $true
```

This example disables content filtering for internal messages.

```
Set-ContentFilterConfig -InternalMailEnabled $false
```

Note:
As a best practice, you should not filter messages from trusted partners or from inside your organization. When you run anti-spam filters, there's always a chance that the filters will detect false positives. To reduce the chance that filters will mishandle legitimate e-mail messages, you should enable anti-spam agents to run only on messages from potentially untrusted and unknown sources.

For detailed syntax and parameter information, see Set-ContentFilterConfig.

1.7.2.10.3 Configure Content Filtering Properties

Configure Content Filtering Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When the Content Filter agent is enabled on a computer, it filters all messages that come through all receive connectors on that computer. Only messages that come from non-authenticated sources are filtered.

This topic explains how to use the EMC or the Shell to configure content filtering on Exchange Edge Transport servers.

Note:

Content filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to configure content filtering
- Use the Shell to configure content filtering
- Use the Shell to configure allowed and blocked phrases
- Use the Shell to configure recipient and sender exceptions
- Use the Shell to configure SCL thresholds
- Use the Shell to configure rejection response
- Use the Shell to configure Outlook e-mail postmark validation

Use the EMC to configure content filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge Transport server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **Content Filtering** and then select **Properties**.
4. The **General** tab displays the following information about the content filtering feature.
   - **Status** Shows whether content filtering is enabled or disabled.
   - **Modified** Shows the date and time when content filtering properties were last modified.
   - **Description** Provides a brief description of content filtering.
5. Use the **Custom Words** tab on to configure the Content Filter agent to

recognize and filter certain words or phrases. When the Content Filter agent encounters the specified words or phrases, it adjusts the Sender Confidence Level rating. The SCL rating is a number between 0 and 9. A higher SCL rating indicates that a message is more likely to be spam.

- **Allow messages containing these words or phrases** In this field, type a word or phrase that isn't likely to be contained in spam messages, and then click **Add** to add the word or phrase to the allowed phrases list.
  To remove a word or phrase from the allowed phrases list, select the word or phrase, and then click .
  When the Content Filter agent encounters an allowed word or phrase, the SCL rating on that message is set to 0.
- **Block messages containing these words or phrases (messages containing words or phrases listed above will not be blocked)** In this field, type a word or phrase that is likely to be contained in spam messages, and then click **Add** to add the word or phrase to the blocked phrases list. To remove a word or phrase from the list, select the word or phrase, and then click .
  When the Content Filter agent encounters a blocked phrase in a message, the SCL rating on that message is set to 9.

Note:
The allowed phrases list overrides the blocked phrases list. Therefore, if the message contains a phrase that is listed in the allowed phrases list, it is assigned an SCL rating of 0 even if it also contains blocked phrases.

6. Use the **Exceptions** tab to specify up to 100 recipients in your organization for whom messages should not be checked by the Content Filter agent. For example, if you have a customer support e-mail alias, you may want to accept all inbound e-mail messages for that address.
   - **Don't filter messages sent to the following recipients** In this field, type the full SMTP address of a recipient in your organization and then click **Add**.
     To change a recipient address that you have previously added, select the address and click **Edit**.
     To remove a recipient address that you have previously added, select the address and click .

7. Use the **Action** tab to define the action the Content Filter agent will take on messages according to their SCL rating. The Delete action takes precedence over the Reject action, and the Reject action takes precedence over the Quarantine action. Therefore, the SCL threshold for the Delete action must be greater than the SCL threshold for the Reject action, which in turn should be greater than the SCL threshold for the Quarantine action.
   - **Delete messages that have an SCL rating greater than or equal to** Select this option to configure an SCL threshold for the Delete action, and in the corresponding SCL rating box, type or select a number from 0 to 9.
   - **Reject messages that have an SCL rating greater than or equal to** Select this option to configure an SCL threshold for the Reject action, and in the corresponding SCL rating box, type or select a number from 0 to 9.
   - **Quarantine messages that have an SCL rating greater than or equal to** Select this option to configure an SCL threshold for the Quarantine action, and in the corresponding SCL rating box, type or select a number from 0 to 9.
     ? **Quarantine mailbox e-mail address** Use this field to type the SMTP address of the mailbox where you want to store any quarantined messages.

Use the Shell to configure content filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You can use the **Set-ContentFilterConfig**, **Add-ContentFilterPhrase**, **Remove-ContentFilterPhrase** cmdlets to modify all available content filtering settings. The following examples show how you can use these cmdlets to accomplish various tasks.

Use the Shell to configure allowed and blocked phrases

You use the **Add-ContentFilterPhrase** cmdlet to add both allowed and blocked words and phrases. The value of the *Influence* parameter determines if the word or phrase is allowed or blocked. For example, if you want to allow all messages that contain the phrase "customer feedback", but block all messages that contain the phrase "stock tip", you need to run the following commands:

```
Add-ContentFilterPhrase -Phrase "customer feedback" -Influence GoodWord
Add-ContentFilterPhrase -Phrase "stock tip" -Influence BadWord
```

For detailed syntax and parameter information, see Add-ContentFilterPhrase.

Use the Shell to configure recipient and sender exceptions

You use the **Set-ContentFilterConfig** cmdlet to configure both recipient and send exceptions.

- The following example creates an exception for the recipient tiffany@contoso.com. Messages sent to this recipient aren't checked by the Content Filter agent:

  ```
  Set-ContentFilterConfig -BypassedRecipients tiffany@contoso.com
  ```

- The following example creates an exception for the sender joe@fabrikam.com. Messages received from this sender aren't checked by the Content Filter agent:

  ```
  Set-ContentFilterConfig -BypassedSenders joe@fabrikam.com
  ```

  To enter multiple SMTP addresses when specifying either recipient or sender exceptions, separate the addresses by using a comma. For example: joe@contoso.com, jeffrey@contoso.com. The maximum number of recipients you can specify is 100.

- You can also bypass content filtering for all messages received from specific domains. The following example creates an exception for the domain fabrikam.com. Messages received from this domain aren't checked by the Content Filter agent:

  ```
  Set-ContentFilterConfig -BypassedSenderDomains fabrikam.com
  ```

  To bypass content filtering of messages from specific domains and their subdomains, a wildcard character (*) can be used as shown in the following example:

  ```
  Set-ContentFilterConfig -BypassedSenderDomains *.fabrikam.com
  ```

  To enter multiple SMTP domains, separate the domains by using a comma. For example: fabrikam.com,*nwtraders.com. The maximum number of domains you can specify is 400.

For detailed syntax and parameter information, see Set-ContentFilterConfig.

Use the Shell to configure SCL thresholds

You use the **Set-ContentFilterConfig** cmdlet to configure SCL thresholds and actions. The

Delete action takes precedence over the Reject action, and the Reject action takes precedence over the Quarantine action. Therefore, the SCL threshold for the Delete action must be greater than the SCL threshold for the Reject action, which in turn should be greater than the SCL threshold for the Quarantine action.

- The following example enables the Delete action and sets the corresponding SCL threshold to 9:

```
Set-ContentFilterConfig -SCLDeleteEnabled $true -SCLDeleteThreshold 9
```

- The following example enables the Reject action and sets the corresponding SCL threshold to 8:

```
Set-ContentFilterConfig -SCLRejectEnabled $true -SCLRejectThreshold 8
```

- The following example enables the Quarantine action and sets the corresponding SCL threshold to 7:

```
Set-ContentFilterConfig -SCLQuarantineEnabled $true -SCLQuarantineThres
```

For detailed syntax and parameter information, see Set-ContentFilterConfig.

Use the Shell to configure the rejection response

If you enable the Reject action, you can also customize the response that is sent to the message originator when a message is rejected. The following example configures the Content Filter agent to send a customized rejection response.

```
Set-ContentFilterConfig -RejectionResponse "Your message was rejected because it
```

Note:

Don't write a rejection response that exceeds 240 characters.

For detailed syntax and parameter information, see Set-ContentFilterConfig.

Use the Shell to configure Outlook E-mail Postmarking

Outlook E-mail Postmarking validation is a computational proof that Microsoft Office Outlook applies to outgoing messages to help recipient messaging systems distinguish legitimate e-mail from junk e-mail. Postmarking first became available in Outlook 2007 or newer. Postmarking helps reduce false positives. To enable Outlook E-mail Postmarking, run the following command:

```
Set-ContentFilterConfig -OutlookEmailPostmarkValidationEnabled $true
```

To disable Outlook E-mail Postmarking, run the following command:

```
Set-ContentFilterConfig -OutlookEmailPostmarkValidationEnabled $false
```

For detailed syntax and parameter information, see Set-ContentFilterConfig.

1.7.2.10.4 Release Quarantined Messages from the Spam Quarantine Mailbox

Release Quarantined Messages from the Spam Quarantine Mailbox

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use Microsoft Outlook to recover a quarantined message from the spam quarantine mailbox. This topic provides step-by-step instructions using Outlook 2007, but you can also use Outlook 2010.

Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. Spam quarantine provides a temporary storage location for messages that are identified as spam and that shouldn't be delivered to a user mailbox inside the organization. When a message meets the spam quarantine threshold, it's wrapped in a non-delivery report (NDR) and delivered to the spam quarantine mailbox. For more information about the spam quarantine feature, see Understanding Spam Quarantine.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- A spam quarantine mailbox is configured. For more information, see Specify a Spam Quarantine Mailbox.
- You have been granted owner rights to the spam quarantine mailbox.

Use Outlook 2007 to release a message from the spam quarantine mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox access" entry in the Transport Permissions topic.

Any quarantined messages will be stored as NDRs in the Inbox folder of your quarantine mailbox. To access the quarantine mailbox, you need to configure an Outlook profile for that mailbox and then open the mailbox using Outlook. For more information about configuring and using multiple Outlook profiles, see Overview of Outlook e-mail profiles.

1. Log on to the quarantine mailbox using Outlook 2007 on a client computer.
2. In the **Mail Folders** list, select the **Inbox** folder.
3. Find the NDR of the message that you want to recover, and then double-click the NDR to open it.
4. On the **Report** tab, in the **Respond** group, click **Send Again**.
5. When the e-mail message opens, click **Send** to resend the e-mail message to the intended recipient.

Other Tasks

Because the quarantined messages are stored as NDRs in the quarantine mailbox, the postmaster address of your organization will be listed as the From: address for all messages. To make it easier to locate the message you want to recover, you can create a custom Outlook form and modify the default view to expose the original sender address in the list of messages. For detailed steps, see Configure Outlook to Expose Original Sender Field in the Quarantine Mailbox.

1.7.2.10.5 Configure Outlook to Expose Original Sender Field in the Quarantine Mailbox

Configure Outlook to Expose Original Sender Field in the Quarantine Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Spam quarantine is a feature of the Content Filter agent that reduces the risk of losing legitimate messages. Spam quarantine provides a temporary storage location for messages that are identified as spam and that shouldn't be delivered to a user mailbox inside the organization.

When a message meets the spam quarantine threshold, it's wrapped in a non-delivery report (NDR) and delivered to the spam quarantine mailbox. Because the quarantined messages are stored as NDRs in the quarantine mailbox, the postmaster address of your organization will be listed as the From: address for all messages.

However, having the original sender address in the field list would make it easier to locate the message you want to recover. This topic explains how you can create a custom Outlook form and modify the default view to expose the original sender address in the list of messages.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- A spam quarantine mailbox is configured. For more information, see Specify a Spam Quarantine Mailbox.
- You have been granted owner rights to the spam quarantine mailbox.
- You have an Outlook profile configured to access the spam quarantine mailbox on the management workstation you'll be using to perform this procedure.

Configure Outlook to expose original sender field in the quarantine mailbox

You need to be assigned owner permissions to the quarantine mailbox in Microsoft Office Outlook before you can perform this procedure.

The original sender field isn't a default field that you can choose. Therefore, before you can add the original sender field in the message view, you must first create an Outlook form that will add the original sender field as an option. After you create this custom form, you can then configure Microsoft Office Outlook 2007 to expose the original sender field in the message view.

1. Open an ASCII text editor, such as Notepad, and copy the following code into the document.

```
[Description]
MessageClass=IPM.Note
CLSID={00020D31-0000-0000-C000-000000000046}
DisplayName=Quarantine Extension Form
Category=Standard
Subcategory=Form
Comment=This forms allows the Original Sender Address to be viewed as
LargeIcon=IPML.ico
SmallIcon=IPMS.ico
Version=1.0
Locale=enu
Hidden=1
Owner=Microsoft Corporation
Contact=Your Name
[Platforms]
Platform1=Win16
```

```
Platform2=NTx86
Platform9=Win95
[Platform.Win16]
CPU=ix86
OSVersion=Win3.1
[Platform.NTx86]
CPU=ix86
OSVersion=WinNT3.5
[Platform.Win95]
CPU=ix86
OSVersion=Win95
[Properties]
Property01=OriginalSenderAddress
[Property.OriginalSenderAddress]
Type=30
NmidInteger=0x0067
DisplayName=Original Sender Address
[Verbs]
Verb1=1
[Verb.1]
DisplayName=&Open
Code=0
Flags=0
Attribs=2
[Extensions]
Extensions1=1
[Extension.1]
Type=30
NmidPropset={00020D0C-0000-0000-C000-000000000046}
NmidInteger=1
Value=1000000000000000
```

2. Save the file with a .cfg file name extension to a location on the local hard disk. For the rest of this procedure, we assume that the file is named QTNE.cfg.
3. If Outlook isn't open, start Outlook with the profile configured for the quarantine mailbox.
4. In Outlook 2007 on a client computer, click **Tools**, and then click **Options**.
5. In the **Options** dialog box, click the **Other** tab, and then under **General**, click **Advanced Options**.
6. In the **Advanced Options** dialog box, click **Custom Forms**, and then in the **Custom Forms** dialog box, click **Manage Forms**.
7. In the **Forms Manager** dialog box, click **Install**. Locate the directory where you saved QTNE.cfg in step 2. Select **QTNE.cfg**, and then click **Open** to install QTNE.cfg as the Quarantine Extension Form in your Personal Forms library.
8. Close the **Forms Manager** dialog box, and then click **OK** to close the remaining dialog boxes and return to the main Outlook interface. In the default message view of Outlook, in the Inbox, right-click the column heading row, and then select **Field Chooser**.

Note:

If you don't see Field Chooser as an option, you may need to expand the width of your message list.

9. In the **Field Chooser** drop-down menu, click **Forms**. You may have to scroll to find **Forms**.
10. In the **Select Enterprise forms for this Column** dialog box, from the drop-down menu, select **Personal Forms**, expand the **Standard** form, and then select **Quarantine Extension Form**. Click **Add**, and then click **Close**.

Note:

In some cases, you may have to remove the default **Message** form to add the **Quarantine Extension Form**.

11. In the **Field Chooser** dialog box, drag the **OriginalSenderAddress** property into the column heading row.

1.7.2.10.6 Specify a Spam Quarantine Mailbox

Specify a Spam Quarantine Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to specify a spam quarantine mailbox for content filtering. If the spam confidence level (SCL) quarantine threshold is enabled, all messages that are quarantined are wrapped as non-delivery reports (NDR) and are sent to the SMTP address that you specify as the spam quarantine mailbox. You can then review quarantined messages and, as appropriate, release them to their intended recipients by using the Send Again feature in Microsoft Office Outlook. For more information, see Release Quarantined Messages from the Spam Quarantine Mailbox.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Caution:

By the nature of the feature, the person responsible for the spam quarantine mailbox can view potentially private and sensitive messages, and then send mail on behalf of anybody in the Exchange organization.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Content Filtering.
- Read Understanding Spam Quarantine.

Use the Shell to specify a spam quarantine mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:

You can't use the EMC to specify a spam quarantine mailbox.

Specify a spam quarantine mailbox by using the following command syntax.

```
Set-ContentFilterConfig -QuarantineMailbox <SmtpAddress>
```

This example sends all messages that exceed the spam quarantine to spamQ@contoso.com.

```
Set-ContentFilterConfig -QuarantineMailbox spamQ@contoso.com
```

For detailed syntax and parameter information, see Set-ContentFilterConfig.

1.7.2.10.7 Enable or Disable Connection Filtering

Enable or Disable Connection Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Connection Filter agent is an anti-spam agent that's enabled on computers that have the Microsoft Exchange Server 2010 Edge Transport server role installed.

When the Connection Filter agent and the associated connection filtering features are enabled on a computer, the Connection Filter agent filters all messages that come through all Receive connectors on that computer. Only messages that come from external sources are filtered. *External sources* are defined as non-authenticated sources. These are considered anonymous Internet sources.

The Connection Filter agent is an underlying transport agent that enables the following features:

- IP Block list
- IP Allow list
- IP Block List providers
- IP Allow List providers

Each of these features can be enabled or disabled separately.

For more information about how to configure the connection filtering features, see the following topics:

- Configure IP Allow List Properties
- Configure IP Block List Properties
- Configure IP Allow List Providers Properties
- Configure IP Block List Providers Properties

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Note:

By default, the connection filtering features are enabled on the Edge Transport server for inbound messages that come from the Internet but aren't authenticated. The Connection Filtering agent must be enabled for the connection filtering features to operate. By default, the Connection Filter agent is enabled on Edge Transport servers. To enable the Connection Filter agent, use the Enable-TransportAgent cmdlet. To disable the Connection Filter agent, use the Disable-TransportAgent cmdlet.

Prerequisites

Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.

Use the EMC to enable or disable connection filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the work pane, click the **Anti-spam** tab, and then select one of the following:
   - **IP Allow List**
   - **IP Allow List Providers**
   - **IP Block List**
   - **IP Block List Providers**
3. In the action pane, click **Enable** or **Disable** as appropriate.
4. Repeat the steps for each connection filtering data store that you want to enable or disable.

Use the Shell to enable or disable connection filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

This example enables or disables the IP Allow list.

```
Set-IPAllowListConfig -Enabled <$true | $false>
```

This example enables or disables IP Allow List providers.

```
Set-IPAllowListProvider -Enabled <$true | $false>
```

This example enables or disables the IP Block list.

```
Set-IPBlockListConfig -Enabled <$true | $false>
```

This example enables or disables the IP Block List providers.

```
Set-IPBlockListProvider -Enabled <$true | $false>
```

For detailed syntax and parameter information, see the following topics:

- Set-IPAllowListConfig
- Set-IPAllowListProvider
- Set-IPBlockListConfig
- Set-IPBlockListProvider

1.7.2.10.8 Configure IP Allow List Properties

Configure IP Allow List Properties

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When the IP Allow List feature is enabled on a computer, the Connection Filter agent analyzes all messages that come through all Receive connectors on that computer and it routes all messages from the addresses in the IP Allow list without additional processing by other anti-spam agents.

This topic explains how to use the EMC or the Shell to manage the IP Allow List.

Note:

Connection filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to manage the IP Allow List
- Use the Shell to manage the IP Allow List

Use the EMC to manage the IP Allow list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right click **IP Allow** List and then select **Properties**.

4. The **General** tab displays the following information about the IP Allow List feature.
   - **Status** Shows whether the IP Allow List feature is enabled or disabled.
   - **Modified** Shows the date and time when IP Allow list properties were last modified.
   - **Description** Provides a brief description of the IP Allow List feature.

5. Use the **Allowed Addresses** tab to create and manage a list of IP addresses that are explicitly allowed. The Connection Filter agent will route all inbound messages from these IP addresses without additional processing by other anti-spam agents.
   - **Add - IP Address** To enter an IP address without a subnet mask, or to specify the subnet mask by using Classless Interdomain Routing (CIDR) notation, click **Add** or the drop-down arrow located next to **Add** and select **IP Address**. In the **Add Allowed IP Address - CIDR** dialog, enter the IP address directly or specify a subnet using the CIDR notation. For example, if you enter 192.168.1.1, only that host will be added to the IP Allow list, but if you specify 192.168.1.0/24, the entire class C subnet of 192.168.1.0 will be added to the IP Allow list.

     Add - IP and Mask To enter an IP address or subnet together with a subnet mask in dotted decimal notation, click the drop-down arrow located next to **Add** and select **IP and Mask**. In the **Add Allowed IP Address - IP and Mask** dialog, specify the IP address and the subnet mask.

     Add - IP Range To specify an IP address range by using the

first IP address and the last IP address in the range, click the drop-down arrow located next to **Add** and select **IP Range**. In the **Add Allowed IP Address - IP Range** dialog, specify the start and end addresses of the IP range.

- **Remove** To remove an existing entry from the IP Allow list, select the entry, and then click  .

Use the Shell to manage the IP Allow list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Add-IPAllowListEntry** and **Remove-IPAllowListEntry** cmdlets to manage the addresses in the IP Allow list. You can specify individual IP addresses, IP subnets using the CIDR notation, or IP ranges.

The following example adds the IP address 192.168.0.100 to the IP Allow list.

```
Add-IPAllowListEntry -IPAddress 192.168.0.100
```

The following example adds the IP subnet 192.168.1.1/24 to the IP Allow list.

```
Add-IPAllowListEntry -IPRange 192.168.1.1/24
```

The following example adds the IP range 10.0.0.100-10.0.0.255 to the IP Allow list.

```
Add-IPAllowListEntry -IPRange 10.0.0.100-10.0.0.255
```

As you add entries to the IP Allow list, Exchange automatically assigns IDs to the entries. To remove an address from the IP Allow list using the Shell, you must specify this ID. However, an easier way to remove an address is to pipeline the output of the **Get-IPAllowListEntry** cmdlet to the **Remove-IPAllowListEntry** cmdlet. For example, if you want to remove the IP address 192.168.0.100 from your IP Allow list, run the following command:

```
Get-IPAllowListEntry -IPAddress 192.168.0.100 | Remove-IPAllowListEntry
```

If you want to remove a range, specify an IP address that is within that range for the *IPAddress* parameter of the **Get-IPAllowListEntry** cmdlet. The following example shows how you can remove the subnet 192.168.1.1/24:

```
Get-IPAllowListEntry -IPAddress 192.168.1.1 | Remove-IPAllowListEntry
```

When using the Shell to add an address to the IP Allow list, you can also specify an expiration date and time. After the specified date and time, messages received from the specified address receive no preferential treatment. The following example adds the IP address 10.0.10.25 to the IP Allow list and configures it to expire on January 1, 2010 at 10:00 AM.

```
Add-IPAllowListEntry -IPAddress 10.0.10.25 -ExpirationTime "1/1/2010 10:00"
```

For detailed syntax and configuration information, see the following topics:

- Add-IPAllowListEntry
- Get-IPAllowListEntry
- Remove-IPAllowListEntry

Configure IP Allow List Providers Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-24*

IP Allow List Providers is part of the connection filtering feature in Exchange. When the IP Allow List Providers feature is enabled on a computer, the Connection Filter agent queries the specified IP Allow List provider services to determine if the messaging server that has initiated the connection is a host that can be relied on to not send spam.

This topic explains how to use the EMC or the Shell to manage the IP Allow List Providers feature.

Note:

Connection filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

Note:

Make sure that the IP Allow list that you want to add does not contain more than 1,000 entries. The IP allow list cannot contain more than 1,000 entries because of a limitation in byte size that applies to this field. Instead, use IP address ranges if more than 1,000 entries are required.

What Do You Want to Do?

- Use the EMC to manage the IP Allow List Providers
- Use the Shell to manage the IP Allow List Providers

Use the EMC to manage IP Allow List provider services

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **IP Allow List Providers** and then select **Properties**.
4. The **General** tab displays the following information about the IP Allow List Providers feature.
   - **Status** Shows whether the IP Allow List Providers feature is enabled or disabled.
   - **Modified** Shows the date and time when IP Allow List Providers properties were last modified.
   - **Description** Provides a brief description of the IP Allow List Providers feature.

5. Use the **Providers** tab to manage the IP Allow List provider services for the local computer. We recommend that you put the most reliable IP Allow List provider service first to optimize performance. If the Connection Filter agent receives an IP Allow list match from one of the providers, it stops querying other IP Allow List provider services.
   - **Add** Click **Add** to add a new IP Allow List provider service. In the dialog that appears, configure the following options:
     ? **Provider name** Type the name of the IP Allow List provider service. This name is for your own use to identify the provider.
     ? **Lookup domain** Type the domain name that the Connection Filter agent queries for updated IP Allow list information.
     ? **Return status codes** This field shows the IP address status code that is returned by the IP Allow List provider service. If the IP address of a remote server that is sending a message matches an IP address on an IP Allow List provider service's IP Allow list, the provider service may return different types of codes. Most IP Allow List provider services return either a bitmask or absolute value code type.
     Match any return code When you select this option, the Connection Filter agent treats any IP Address status code that is returned by the IP Allow List provider service as a match.
     Match specific mask and responses When you select this option, the Connection Filter agent acts only on messages that match the IP Address status code that is returned by the IP Allow List provider service.
     Providers that return bitmask status codes may return a status code of **127.0.0.***x*, where the integer *x* is any one of the following values:
     1: The IP address is on an IP Allow list.
     2: The Simple Mail Transfer Protocol (SMTP) server is configured to act as an open relay.
     4: The IP address supports a dial-up IP address.
     Providers that return absolute values and the explicit responses may return one of the following responses:
     127.0.0.2: The IP address is a direct spam source
     127.0.0.4: The IP address is a bulk mailer
     127.0.0.5: The remote server that is sending the message is known to support multistage open relays.
     Match to the following mask Type the bitmask status code you want to use.
     Match any of the following responses Type the responses you want to use and then click **Add**. To modify a previously added response, select the response and click **Edit**. To remove a previously added response, select the response and click  .
   - **Edit** To view or update settings for an IP Allow List provider, select a provider, and then click **Edit**.
   - **Remove** To delete an IP Allow List provider, select the provider, and then click  .
   - **Enable** To enable a disabled IP Allow List provider, select the provider, and then click **Enable**.
   - **Disable** To stop using the selected IP Allow List provider, but retain the provider information, click **Disable**.
   - **Up arrow** To move a provider higher in the **Provider name** list, select the provider, and then click  . The up arrow is enabled only when there is more than one provider in the **Provider name** list.
   - **Down arrow** To move a provider lower in the **Provider name** list, select the provider, and then click  . The down arrow is enabled only when there is more than one provider in the **Provider name** list.

Use the Shell to manage IP Allow List provider services

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Add-IPAllowListProvider**, **Set-IPAllowListProvider,** and **Remove-IPAllowListProvider** cmdlets to manage the IP Allow List provider services you use in your organization.

The following example adds a new IP Allow List provider called "Contoso IP Allow List Provider", and configures it to match any return code:

```
Add-IPAllowListProvider -Name "Contoso IP Allow List Provider" -LookupDomain "con
```

The following example configures the same IP Allow List provider to be the top preferred provider:

```
Set-IPAllowListProvider "Contoso IP Allow List Provider" -Priority 1
```

For detailed syntax and parameter information, see the following topics:

- Add-IPAllowListProvider
- Set-IPAllowListProvider
- Remove-IPAllowListProvider

1.7.2.10.10 Configure IP Block List Properties

Configure IP Block List Properties

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

IP Block List is part of the connection filtering feature in Exchange. When the IP Block List feature is enabled on a computer, the Connection Filter agent analyzes all messages that come through all Receive connectors on that computer and it block all incoming messages from addresses specified in the IP Block list.

This topic explains how to use the EMC or the Shell to manage the IP Block list.

Note:

Connection filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to manage the IP Block List
- Use the Shell to manage the IP Block List

Use the EMC to manage the IP Block list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **IP Block List** and then select **Properties**.
4. The **General** tab displays the following information about the IP Block List feature.
   - **Status** Shows whether the IP Block List feature is enabled or disabled.
   - **Modified** Shows the date and time when IP Block List properties were last modified.
   - **Description** Provides a brief description of the IP Block List feature.
5. Use the **Blocked Addresses** tab to manage a list of specific IP addresses for which e-mail messages are always blocked by the Connection Filter agent. If an originating IP address matches an IP address or IP address range on the IP Block list, the Connection Filter agent disconnects the SMTP session after all RCPT TO: headers in the message are processed.
   - **Add - IP Address** To enter an IP address without a subnet mask, or to specify the subnet mask by using Classless Interdomain Routing (CIDR) notation, click **Add** or the drop-down arrow located next to **Add** and select **IP Address**. In the **Add Blocked IP Address - CIDR** dialog, enter the IP address directly or specify a subnet using the CIDR notation. For example, if you enter 192.168.1.1, only that host will be added to the IP Block list, but if you specify 192.168.1.0/24, the entire class C subnet of 192.168.1.0 will be added to the IP Block list.

     Add - IP and Mask To enter an IP address or subnet together with a subnet mask in dotted decimal notation, click the drop-down arrow located next to **Add** and select **IP and Mask**. In the **Add Blocked IP Address - IP and Mask** dialog, specify the IP address and the subnet mask.

     Add - IP Range To specify an IP address range by using the first IP address and the last IP address in the range, click the drop-down arrow located next to **Add** and select **IP Range**. In the **Add Blocked IP Address - IP Range** dialog, specify the start and end addresses of the IP range.

     Regardless of the method you choose to add an IP address, the dialog also gives you the option to specify an expiration date. By default, the **Never let this address expire** option is selected and messages from this address are blocked permanently. However, if you want to specify an expiration date, select **Block until date and time** and specify a date. Messages from this IP address will no longer be blocked after the date you specified.
   - **Remove** To remove an existing entry from the IP Block list, select the entry, and then click  .

Use the Shell to manage the IP Block list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Add-IPBlockListEntry** and **Remove-IPBlockListEntry** cmdlets to manage the addresses in the IP Block list. You can specify individual IP addresses, IP subnets using the CIDR notation, or IP ranges.

The following example adds the IP address 192.168.0.100 to the IP Block list.

```
Add-IPBlockListEntry -IPAddress 192.168.0.100
```

The following example adds the IP subnet 192.168.1.1/24 to the IP Block list.

```
Add-IPBlockListEntry -IPRange 192.168.1.1/24
```

The following example adds the IP range 10.0.0.100-10.0.0.255 to the IP Block list.

```
Add-IPBlockListEntry -IPRange 10.0.0.100-10.0.0.255
```

As you add entries to the IP Block list, Exchange automatically assigns IDs to the entries. To remove an address from the IP Block list using the Shell, you must specify this ID. However, an easier way to remove an address is to pipeline the output of the **Get-IPBlockListEntry** cmdlet to the **Remove-IPBlockListEntry** cmdlet. For example, if you want to remove the IP address 192.168.0.100 from your IP Block list, run the following command:

```
Get-IPBlockListEntry -IPAddress 192.168.0.100 | Remove-IPBlockListEntry
```

If you want to remove a range, specify an IP address that is within that range for the *IPAddress* parameter of the **Get-IPBlockListEntry** cmdlet. The following example shows how you can remove the subnet 192.168.1.1/24:

```
Get-IPBlockListEntry -IPAddress 192.168.1.1 | Remove-IPBlockListEntry
```

When using the Shell to add an address to the IP Block list, you can also specify an expiration date and time. After the specified date and time, messages received from the specified address will no longer be blocked. The following example adds the IP address 10.0.10.25 to the IP Block list and configures it to expire on January 1, 2010 at 10:00 AM.

```
Add-IPBlockListEntry -IPAddress 10.0.10.25 -ExpirationTime "1/1/2010 10:00"
```

For detailed syntax and configuration information, see the following topics:

- Add-IPBlockListEntry
- Get-IPBlockListEntry
- Remove-IPBlockListEntry

1.7.2.10.11 Configure IP Block List Providers Properties

Configure IP Block List Providers Properties

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

IP Block List Providers are part of the connection filtering feature in Exchange. When the

IP Block List Providers feature is enabled on a computer, the Connection Filter agent queries the specified IP Block List provider services to determine if the messaging server that has initiated the connection is a host that is known to send spam.

This topic explains how to use the EMC or the Shell to manage the IP Block List Providers.

Note:

Connection filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to manage the IP Block List Providers
- Use the Shell to manage the IP Block List Providers

Use the EMC to manage IP Block List provider services

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **IP Block List Providers** and then select **Properties**.

4. The **General** tab displays the following information about the IP Block List Providers feature.
   - **Status** Shows whether the IP Block List Providers feature is enabled or disabled.
   - **Modified** Shows the date and time when IP Block List Providers properties were last modified.
   - **Description** Provides a brief description of the IP Block List Providers feature.

5. Use the **Providers** tab to manage the IP Block List provider services for the local computer. We recommend that you put the most reliable IP Block List provider service first to optimize performance. If the Connection Filter agent receives an IP Block List match from one of the providers, it stops querying other IP Block List provider services.
   - **Add** Click **Add** to add a new IP Block List provider service. In the dialog that appears, configure the following options:
     ? **Provider name** Type the name of the IP Block List provider service. This name is for your own use to identify the provider.
     ? **Lookup domain** Type the domain name that the Connection Filter agent queries for updated IP Block list information.
     ? **Return Status codes** This field shows the IP address status code that is returned by the IP Block List provider service. If the IP address of a remote server that is sending a message matches an IP address on an IP Block List provider service's IP Block list, the provider service may return different types of codes. Most IP Block List provider services return either a

bitmask or absolute value code type.
Match any return code When you select this option, the Connection Filter agent treats any IP Address status code that is returned by the IP Block List provider service as a match.
Match specific mask and responses When you select this option, the Connection Filter agent acts only on messages that match the IP Address status code that is returned by the IP Block List provider service.
Providers that return bitmask status codes may return a status code of **127.0.0.***x*, where the integer *x* is any one of the following values:
1: The IP address is on an IP Block list.
2: The Simple Mail Transfer Protocol (SMTP) server is configured to act as an open relay.
4: The IP address supports a dial-up IP address.
Providers that return absolute values and the explicit responses may return one of the following responses:
127.0.0.2: The IP address is a direct spam source
127.0.0.4: The IP address is a bulk mailer
127.0.0.5: The remote server that is sending the message is known to support multistage open relays.
Match to the following mask Type the bitmask status code you want to use.
Match any of the following responses Type the responses you want to use and then click **Add**. To modify a previously added response, select the response and click **Edit**. To remove a previously added response, select the response and click  .
Error Messages To configure the message text that will be delivered in the SMTP session to senders whose messages are blocked by the Connection Filter agent when an IP Block List provider service matches the sender's IP address, click **Error Messages** and configure the following:

Default error message	To send a standard SMTP 550 error message to blocked senders, select **Default error message**.
Custom error message	To compose and send a customized error message, select **Custom error message**, and then type the message text in the text box. We recommend that you specify the IP Block List provider service in the response so that legitimate senders can contact the IP Block List provider service, as in the following example: **Originating IP addresses matched contoso.com's IP Block List provider service**.

- **Edit** To view or update settings for an IP Block List provider service, select a provider, and then click **Edit**.
- **Remove** To delete an IP Block List provider service, select the provider, and then click  .
- **Enable** To enable a disabled provider service, select the provider, and then click **Enable**.
- **Disable** To stop using the selected provider service, but retain the

provider information, click **Disable**.

- **Up arrow** To move a provider higher in the **Provider name** list, select the provider, and then click  . The up arrow is enabled only when there is more than one provider in the **Provider name** list.
- **Down arrow** To move a provider lower in the **Provider name** list, select the provider, and then click  . The down arrow is enabled only when there is more than one provider in the **Provider name** list.

6. Use the **Exceptions** tab to specify recipients in your organization for which you don't want to use IP Block List provider services. For example, if you have a customer support e-mail alias, you may want to accept all inbound e-mail messages for that address.
   - **Do not block messages sent to the following e-mail addresses, regardless of provider feedback** In this field, type the SMTP address for an existing recipient for which you want to create an exception. For example, kim@contoso.com.
   - **Add** To add that recipient to the Exceptions list, after you type the recipient's SMTP address, click **Add**.
   - **Edit** To change a previously added SMTP address, select the recipient's SMTP address from the list, and then click **Edit.**
   - **Remove** To delete a recipient from the exceptions list, select the recipient's SMTP address, and then click  .

Use the Shell to manage IP Block List provider services

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Add-IPBlockListProvider**, **Set-IPBlockListProvider,** and **Remove-IPBlockListProvider** cmdlets to manage the IP Block List Provider services you use in your organization.

The following example adds a new IP Block List provider service called "Contoso IP Block List Provider", and configures it to use bitmask matching for 127.0.0.1 (block messages from IP addresses that are on the block list):

```
Add-IPBlockListProvider -Name "Contoso IP Block List Provider" -LookupDomain "con
```

The following example configures the same IP Block List provider service to use a custom rejection response:

```
Set-IPBlockListProvider "Contoso IP Block List Provider" -RejectionMessage "Your
```

The following example adds another IP Block List provider service called "Fabrikam IP Block List Provider", and configures it to use explicit response matching for 127.0.0.2 and 127.0.0.5 (the host is a known spam source or is an open relay). The command also adds this new provider as the top preferred provider.

```
Add-IPBlockListProvider -Name "Fabrikam IP Block List Provider" -LookupDomain "fa
```

For detailed syntax and configuration information, see the following topics:

- Add-IPBlockListProvider
- Set-IPBlockListProvider
- Remove-IPBlockListProvider

1.7.2.10.12 Enable or Disable Recipient Filtering

Enable or Disable Recipient Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When recipient filtering functionality is enabled, it filters all messages that come through all Receive connectors on that computer. By default, recipient filtering is enabled on the computer that has the Edge Transport server role installed for inbound messages that come from the Internet but aren't authenticated. These messages are handled as external messages.

Note:

The Recipient Filter agent is the underlying agent for recipient filtering functionality. It's important to understand that when you perform the following procedures, recipient filtering functionality is enabled or disabled, but the underlying Recipient Filter agent is still enabled. To disable the underlying Recipient Filter agent, run the Disable-TransportAgent cmdlet.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Recipient Filtering.
- Verify that the *AddressBookEnabled* parameter is set to `$true` on any Receive connectors that receive e-mail for the accepted domains in your organization. For more information, see Set-AcceptedDomain.

Use the EMC to enable or disable recipient filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. Open the EMC on the Edge Transport server.
2. In the console tree, click **Edge Transport**.
3. In the work pane, click the **Anti-spam** tab, and then select **Recipient Filtering**.
4. In the action pane, click **Enable** or **Disable** as appropriate.

Use the Shell to enable or disable recipient filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions

topic.

This example enables recipient filtering.

```
Set-RecipientFilterConfig -Enabled $true
```

This example disables recipient filtering.

```
Set-RecipientFilterConfig -Enabled $false
```

For detailed syntax and parameter information, see Set-RecipientFilterConfig.

1.7.2.10.13 Configure Recipient Filtering Properties

Configure Recipient Filtering Properties

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Recipient Filter agent is an anti-spam agent that is enabled on Edge Transport servers. You can use the Recipient Filter to block incoming messages for specific recipients in your organization. You can also block incoming messages to recipients that do not exist in Active Directory.

This topic explains how to use the EMC or the Shell to add recipients to the list of blocked recipients.

Note:
Recipient filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to configure recipient filtering
- Use the Shell to configure recipient filtering

Use the EMC to configure recipient filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **Recipient Filtering** and then select **Properties**.
4. The **General** tab displays the following information about the recipient filtering feature.

- **Status** Shows whether recipient filtering is enabled or disabled.
- **Modified** Shows the date and time when recipient filtering properties were last modified.
- **Description** Provides a brief description of recipient filtering.

5. Use the **Blocked Recipients** tab to maintain the Recipient Block list, an administrator-defined list of up to 800 recipients for which incoming messages from the Internet should never be accepted.
   - **Block messages sent to recipients that do not exist in the directory** To prevent delivery to recipients that aren't in the organization's global address book, select this option. This feature is maintained through the EdgeSync process.
   - **Block messages sent to the following recipients** To create an administrator-maintained list of recipients that should be blocked from receiving messages from the Internet, this option, type the SMTP address for the recipient, and then click **Add**. You can enter up to 800 recipients.
     To change an existing recipient address, select the address and then click **Edit**.
     To remove an existing recipient address, select the address and click  .

Use the Shell to configure recipient filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Set-RecipientFilterConfig** cmdlet to manage recipient filtering. The following example configures the Recipient Filter agent to block specific recipients:

```
Set-RecipientFilterConfig -BlockListEnabled $true
```

To add SMTP addresses to the Recipient Block list, you use the *BlockedRecipients* parameter of the **Set-RecipientFilterConfig** cmdlet. You can separate multiple SMTP addresses with commas. The following example adds the e-mail addresses mark@contoso.com and kim@contoso.com to the Recipient Block list:

```
Set-RecipientFilterConfig -BlockedRecipients mark@contoso.com,kim@contoso.com
```

The values that you specify by using the *BlockedRecipients* parameter replace the existing list of SMTP addresses. To preserve the existing list, you could specify the existing addresses along with new addresses you want to add. However, this can be a cumbersome task especially if you have many SMTP addresses for which you block incoming messages. Instead, you can use a temporary Shell variable to add an address to the Recipient Block list. The following example uses the temporary variable `$Configuration` to add the SMTP address john@contoso.com to the Recipient Block list:

```
$Configuration = Get-RecipientFilterConfig
$Configuration.BlockedRecipients += "john@contoso.com"
Set-RecipientFilterConfig -BlockedRecipients $Configuration.BlockedRecipients
```

To block messages to recipients that don't exist in your organization, run the following command:

```
Set-RecipientFilterConfig -RecipientValidationEnabled $true
```

For detailed syntax and parameter information, see Set-RecipientFilterConfig.

1.7.2.10.14 Enable or Disable Sender Filtering

Enable or Disable Sender Filtering

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Sender Filter agent is an anti-spam filter that is enabled on computers that have the Microsoft Exchange Server 2010 Edge Transport server role installed. The Sender Filter agent relies on the MAIL FROM: SMTP header to determine what action, if any, to take on an inbound e-mail message.

When sender filtering functionality is enabled on a computer, sender filtering functionality filters all messages that come through all Receive connectors on that computer.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Sender Filtering.

Use the EMC to enable or disable sender filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. Open the EMC on the Edge Transport server.
2. In the console tree, click **Edge Transport**.
3. In the work pane, click the **Anti-Spam** tab, and then select **Sender Filtering**.
4. In the action pane, click **Enable** or **Disable** as appropriate.

Use the Shell to enable or disable sender filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

This example enables sender filtering.

```
Set-SenderFilterConfig -Enabled $true
```

This example disables sender filtering.

```
Set-SenderFilterConfig -Enabled $false
```

For detailed syntax and parameter information, see Set-SenderFilterConfig.

Configure Sender Filtering Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Sender Filter agent is an anti-spam agent that is enabled on Edge Transport servers. You can use the Sender Filter to block incoming messages from specific individual senders or domains.

This topic explains how to use the EMC or the Shell to configure sender filtering.

Note:

Sender filtering is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to configure sender filtering
- Use the Shell to configure sender filtering

Use the EMC to configure sender filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **Sender Filtering** and then select **Properties**.
4. The **General** tab displays the following information about the sender filtering feature.
   - **Status** Shows whether sender filtering is enabled or disabled.
   - **Modified** Shows the date and time when sender filtering properties were last modified.
   - **Description** Provides a brief description of sender filtering.
5. Use the **Blocked Senders** tab to specify e-mail addresses or domains from which you want to block messages.
   - **Add** To add new addresses and domains to the blocked senders list, click **Add**. In the dialog that appears, use the following fields to specify a sender:
     ? **Individual e-mail address** To block an individual sender, select **Individual e-mail address** and then type the Simple Mail Transfer Protocol (SMTP) address of the sender that you want to block. For example, type **kim@contoso.com**.
     ? **Domain** To add all senders from a domain to the blocked senders list, select **Domain**, and then type the domain name in the domain field, such as **contoso.com**.

? **Include all subdomains** To include all subdomains to the blocked domain, select **Include all subdomains**. This check box is active only when you select **Domain**.

- **Edit** To change a blocked sender's address or domain, click the sender's address, and then click **Edit**.
- **Remove** To delete a blocked sender's address or domain, click the sender's address, and then click  .
- **Block messages that don't have sender information** To block messages that don't have sender information, select this check box.

6. Use the **Action** tab on the sender filtering properties to configure the Sender Filter agent to take one of the following actions when a blocked sender or domain is identified.
   - **Reject message** To reject the message and send a "554 5.1.0 Sender Denied" SMTP session error to the sending server, select **Reject message**. **Reject message** is the recommended setting.
   - **Stamp message with blocked sender and continue processing** To update the metadata of the message to indicate that this message was sent by a blocked sender, select this setting. This stamp is used by the Content Filter agent when it calculates the spam confidence level (SCL) for the message. Additionally, sender reputation uses the SCL for a particular message when it calculates a sender reputation level (SRL) for the sender of the message.

Use the Shell to configure sender filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Set-SenderFilterConfig** cmdlet to manage sender filtering. The following example configures the Sender Filter agent to block messages from the specific e-mail addresses kim@contoso.com and john@contoso.com:

```
Set-SenderFilterConfig -BlockedSenders kim@contoso.com,john@contoso.com
```

The following example configures the Sender Filter agent to block messages from the specific domain fabrikam.com:

```
Set-SenderFilterConfig -BlockedDomains fabrikam.com
```

The following example configures the Sender Filter agent to block messages from the specific domain northwindtraders.com and all its subdomains:

```
Set-SenderFilterConfig -BlockedDomainsAndSubdomains northwindtraders.com
```

The values that you specify by using the parameters shown in the examples above replace the existing list of blocked senders. To preserve the existing list, you could specify the existing senders along with any new senders you want to add. However, this can be a cumbersome task especially if you have many SMTP addresses or domains from which you block incoming messages. Instead, you can use a temporary Shell variable to add an address or domain to the blocked senders list. The following example uses the temporary variable `$Configuration` to add the sender john@contoso.com and the domain tailspintoys.com to the blocked senders list:

```
$Configuration = Get-SenderFilterConfig
$Configuration.BlockedSenders += "john@contoso.com"
$Configuration.BlockedDomains += "tailspintoys.com"
Set-SenderFilterConfig -BlockedSenders $Configuration.BlockedSenders -BlockedDoma
```

The following example shows how to configure the Sender Filter agent to block messages

that don't specify a sender in the MAIL FROM: SMTP command:

```
Set-SenderFilterConfig -BlankSenderBlockingEnabled $true
```

For detailed syntax and parameter information, see Set-SenderFilterConfig.

1.7.2.10.16 Enable or Disable Sender ID

Enable or Disable Sender ID

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, Sender ID is enabled on the Edge Transport server role for inbound messages that come from the Internet but aren't authenticated. These messages are handled as external messages.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Note:

The Sender ID agent is the underlying agent for Sender ID functionality. It's important to understand that when you perform the following procedures, the Sender ID functionality is enabled or disabled, but the underlying Sender ID agent is still enabled. To disable the underlying Sender ID agent, run the Disable-TransportAgent cmdlet.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Sender ID.

Use the EMC to enable or disable Sender ID

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. Open the EMC on the Edge Transport server.
2. In the console, click **Edge Transport**.
3. In the work pane, click the **Anti-spam** tab, and then select **Sender ID**.
4. In the action pane, click **Enable** or **Disable** as appropriate.

Use the Shell to enable or disable Sender ID

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

This example enables Sender ID.

```
Set-SenderIDConfig -Enabled $true
```

This example disables Sender ID.

```
Set-SenderIDConfig -Enabled $false
```

1.7.2.10.17 Configure Sender ID Properties

Configure Sender ID Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Sender ID agent is an e-mail authentication technology protocol that helps address the problem of spoofing and phishing by verifying the domain name from which e-mail is sent. Sender ID validates the origin of e-mail by verifying the IP address of the sender against the purported owner of the sender domain.

This topic explains how to use the EMC or the Shell to configure Sender ID.

Note:

Sender ID is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to configure Sender ID action for spoofed messages
- Use the Shell to configure Sender ID
- Use the Shell to configure Sender ID action for spoofed messages
- Use the Shell to configure Sender ID action for transient errors
- Use the Shell to configure recipient and sender domain exceptions

Use the EMC to configure Sender ID action for spoofed messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **Sender ID** and then select **Properties**.
4. The **General** tab displays the following information about the Sender ID feature.
   - **Status** Shows whether the Sender ID feature is enabled or disabled.

- **Modified** Shows the date and time when Sender ID properties were last modified.
- **Description** Provides a brief description of the Sender ID feature.

5. Use the **Action** tab on the Sender ID properties to configure Sender ID to take one of the following actions when Sender ID determines that a message is spoofed or when a transient error is returned.
   - **Reject message** To reject the message and send a SMTP error response to the sending server, select **Reject message**. The SMTP error response is a 5xx level protocol response with text that corresponds to the Sender ID status.
   - **Delete message** To delete the message without informing the sending server of the deletion, select **Delete message**. The Edge Transport server sends a fake "OK" SMTP command to the sending server and then deletes the message.
   - **Stamp message with Sender ID result and continue processing** To stamp the message with the Sender ID status, select this option. This metadata is evaluated by the Content Filter agent when a spam confidence level (SCL) is calculated. This setting is the default option for Sender ID properties.

Use the Shell to configure Sender ID

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Set-SenderIDConfig** cmdlet to configure Sender ID options and actions. Although the EMC only allows you to configure actions for messages that are spoofed, you can also configure actions for transient failures using the Shell. For example, it's considered a transient error if a DNS server is unavailable when Exchange attempts to verify the Sender ID for a sending domain. Another thing you can only do in the Shell is to configure exceptions for specific sending domains or recipients. The following sections provide examples of how you can use the **Set-SenderIDConfig** cmdlet to accomplish these various tasks.

Use the Shell to configure Sender ID action for spoofed messages

The following example configures the Sender ID agent to reject any messages that were spoofed. These are messages where the IP address of the sending server isn't listed as an authoritative SMTP sending server in the DNS Sender Policy Framework record for the sending domain.

```
Set-SenderIDConfig -SpoofedDomainAction Reject
```

For detailed syntax and parameter information, see Set-SenderIdConfig.

Use the Shell to configure Sender ID action for transient errors

The following example configures the Sender ID agent to stamp the messages for which the Sender ID status can't be determined due to a temporary error. The message will be processed by other anti-spam agents and the Content Filter agent will use the mark when determining the SCL value for the message.

```
Set-SenderIDConfig -TempErrorAction StampStatus
```

For detailed syntax and parameter information, see Set-SenderIdConfig.

Use the Shell to configure recipient and sender domain exceptions

The following example configures the Sender ID agent to bypass the Sender ID check for the specific recipients kim@contoso.com and john@contoso.com:

```
Set-SenderIDConfig -BypassedRecipients kim@contoso.com,john@contoso.com
```

The following example configures the Sender ID agent to bypass the Sender ID check for messages that are received from the specific domain fabrikam.com.

```
Set-SenderIDConfig -BypassedSenderDomains fabrikam.com
```

The values that you specify by using the parameters shown in the examples in this section replace the existing list of exceptions. To preserve the existing list of recipients or sender domains, you could specify the existing values along with any new exceptions you want to add. However, this can be a cumbersome task especially if you have many recipients or domains for which you want to bypass Sender ID checking. Instead, you can use a temporary Shell variable to add a recipient or domain to the exceptions list. The following example uses the temporary variable `$Configuration` to add the domain tailspintoys.com to the list of domains for which you want to bypass Sender ID check:

```
$Configuration = Get-SenderIDConfig
$Configuration.BypassedSenderDomains += "tailspintoys.com"
Set-SenderIDConfig -BypassedSenderDomains $Configuration.BypassedSenderDomains
```

For detailed syntax and parameter information, see Set-SenderIdConfig.

1.7.2.10.18 Enable or Disable Sender Reputation

Enable or Disable Sender Reputation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Sender reputation is anti-spam functionality that's enabled on computers that have the Microsoft Exchange Server 2010 Edge Transport server role installed to block messages according to various characteristics of the sender. Sender reputation relies on persisted data about the sender to determine what action, if any, to take on an inbound message.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Note:

By default, sender reputation processing is enabled on the Edge Transport server for inbound messages that come from the Internet but aren't authenticated and are therefore handled as external messages.
The Protocol Analysis agent is the underlying agent for sender reputation functionality. It's important to understand that when you perform the following procedures, sender reputation functionality is enabled or disabled, but the underlying Protocol Analysis agent is still enabled. To disable the underlying Protocol Analysis agent, run the Disable-TransportAgent cmdlet.

Prerequisites

- Review Understanding Anti-Spam and Antivirus Functionality to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- Read Understanding Sender Reputation.

Use the EMC to enable or disable sender reputation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. Open the EMC on the Edge Transport server.
2. In the console tree, click **Edge Transport**.
3. In the work pane, click the **Anti-spam** tab, and then select **Sender Reputation**.
4. In the action pane, click **Enable** or **Disable** as appropriate.

Use the Shell to enable or disable sender reputation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

This example enables sender reputation.

```
Set-SenderReputationConfig -Enabled $true
```

This example disables sender reputation.

```
Set-SenderReputationConfig -Enabled $false
```

For detailed syntax and parameter information, see Set-SenderReputationConfig.

Use the Shell to enable or disable sender reputation for internal and external messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable sender reputation for internal and external messages.

This example enables sender reputation for external messages.

```
Set-SenderReputationConfig -ExternalMailEnabled $true
```

This example disables sender reputation for external messages.

```
Set-SenderReputationConfig -ExternalMailEnabled $false
```

Note:
By default, sender reputation is enabled for external messages.

This example enables sender reputation for internal messages.

```
Set-SenderReputationConfig -InternalMailEnabled $true
```

This example disables sender reputation for internal messages.

```
Set-SenderReputationConfig -InternalMailEnabled $false
```

For detailed syntax and parameter information, see Set-SenderReputationConfig.

1.7.2.10.19 Configure Sender Reputation Properties

Configure Sender Reputation Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Sender reputation is anti-spam functionality that can be used to block messages according to many characteristics of the sender. Sender reputation continuously monitors senders and their past SMTP interactions, such as the amount of spam and messages that aren't spam that a sender has sent. Sender reputation relies on such data about the sender to determine what action, if any, to take on an inbound message.

This topic explains how to use the EMC or the Shell to configure sender reputation.

Note:
Sender reputation is part of the suite of anti-spam features in Exchange. The anti-spam features are only available on Edge Transport servers by default. You can enable anti-spam features on a Hub Transport server even though it isn't recommended. To learn more about enabling anti-spam features on a Hub Transport server, see Enable Anti-Spam Functionality on a Hub Transport Server. The procedures listed in this topic are for configuring anti-spam functionality on an Edge Transport server, but the process is identical on Hub Transport servers.

What Do You Want to Do?

- Use the EMC to configure sender reputation
- Use the Shell to configure sender reputation

Use the EMC to configure sender reputation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the Edge server you want to configure and then select the **Anti-spam** tab in the work pane.
3. Right-click **Sender Reputation** and then select **Properties**.
4. The **General** tab displays the following information about the Sender Reputation feature.
   - **Status** Shows whether the Sender Reputation feature is enabled or disabled.
   - **Modified** Shows the date and time when sender reputation properties were last modified.
   - **Description** Provides a brief description of the Sender Reputation feature.
5. Use the **Sender Reputation** tab to enable or disable detection of open proxy servers. A test for open proxy servers is one of the characteristics that

sender reputation evaluates to calculate the sender reputation level (SRL). The SRL is a number between 0 and 9 that predicts the probability that a sender is a spammer or an otherwise malicious user. When it's enabled, sender reputation filters all external messages that come through all Receive connectors on that computer. If sender reputation verifies that the proxy server is an open proxy server, it adjusts the SRL rating appropriately. By default, detection of open proxy servers is enabled.

- **Perform an open proxy test when determining sender reputation level** To disable detection of open proxy servers, clear this check box. To enable the detection of open proxy servers, select the check box.

6. Use the **Action** tab to set the threshold for sender blocking based on SRL. The SRL block threshold defines the SRL value that must be exceeded for sender reputation to block a sender. By default, the SRL value is set at 7. Before you adjust the SRL value, you should monitor its effectiveness at the default level.
   - **Sender Reputation Level Block Threshold** Drag the slider to set the SRL block threshold.
   - **Threshold Action** Type or select the number of hours that the sender is put on the IP Block list if the SRL block threshold is exceeded. The value must be between 0 to 48 hours.

Use the Shell to configure sender reputation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

You use the **Set-SenderReputationConfig** cmdlet to configure sender reputation options for your organization.

The following example configures sender reputation to perform an open proxy test for determining sender confidence:

```
Set-SenderReputationConfig -OpenProxyDetectionEnabled $true
```

The following example configures sender reputation to add the IP addresses of hosts that fail the open proxy test to the IP Block List. When you use this parameter, you must also set the *OpenProxyDetectionEnabled* parameter to `$true`:

```
Set-SenderReputationConfig -SenderBlockingEnabled $true -OpenProxyDetectionEnable
```

The following example sets the SRL block threshold to 6 and configures sender reputation to add offending senders to the IP Block List for 36 hours:

```
Set-SenderReputationConfig -SrlBlockThreshold 6 -SenderBlockingPeriod 36
```

For detailed syntax and parameter information, see Set-SenderReputationConfig.

1.7.2.10.20 Configure Outbound Access for Detection of Open Proxy Servers for Sender Reputation

Configure Outbound Access for Detection of Open Proxy Servers for Sender Reputation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to configure outbound access for the detection of open proxy servers for sender reputation.

Looking for other management tasks related to managing anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Prerequisites

- **Configuring firewall ports** If you've enabled the detection of open proxy servers on sender reputation, you may have to perform additional configuration to enable sender reputation to traverse any firewalls that are between the Edge Transport server and the Internet. The open proxy detection test uses many protocols to test for open proxy servers. The following table lists the ports that must be opened outbound for sender reputation.

Protocols	Ports
SOCKS4, SOCKS5	1081, 1080
Wingate, Telnet, Cisco	23
HTTP CONNECT, HTTP POST	6588, 3128, 80

- **Configuring sender reputation to use a specific proxy server** If your organization uses a proxy server to manage outbound traffic through a firewall, you must configure sender reputation to use the proxy server. Sender reputation must have outbound connectivity to the Internet to detect open proxy servers. You must specify the proxy server name, type, and port number that sender reputation will use to access the Internet.
- **Review** Understanding Anti-Spam and Antivirus Functionality You need to understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.
- **Read** Configure Sender Reputation Properties You need to understand how to configure sender reputation properties.

Use the Shell to configure outbound access for detection of open proxy servers for sender reputation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure outbound access for detection of open proxy servers for sender reputation.

To successfully configure sender reputation to detect open proxy servers, you must provide the following information:

- The name of your organization's proxy server.
- The port number for your organization's proxy server.
- The type of proxy server that your organization runs.

To configure outbound access for the detection of open proxy servers, use the following

syntax.

```
Set-SenderReputationConfig -ProxyServerName <String> -ProxyServerPort <Int32> -Pr
```

This example configures sender reputation to use the open proxy server SERVER01 that uses an HTTP CONNECT protocol type with 80 as its server port.

```
Set-SenderReputationConfig - ProxyServerName SERVER01 -ProxyServerPort 80 -ProxyS
```

For detailed syntax and parameter information, see Set-SenderReputationConfig.

1.7.2.10.21 Configure Safelist Aggregation

Configure Safelist Aggregation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-28*

In Microsoft Exchange Server 2010, *safelist aggregation* refers to anti-spam functionality shared across Microsoft Outlook and Exchange. This functionality collects data from the anti-spam Safe Recipients Lists, Safe Senders Lists, Blocked Senders Lists, and contact data that Outlook users configure, and makes this data available to the anti-spam agents on the computer that has the Edge Transport server role installed. Safelist aggregation can help reduce the instances of false-positives in anti-spam filtering performed by the Edge Transport server.

This topic provides an overview about how to configure safelist aggregation. To learn more about safelist aggregation, see Understanding Safelist Aggregation.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Use the Shell to configure mailbox safelist collection limits

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure mailbox safelist collection limits.

You can configure the maximum number of safe senders and blocked senders a user can configure for each user. You use the **Set-Mailbox** cmdlet to configure these limits. By default, users can configure up to 5,000 safe senders and 500 blocked senders. Typically, it isn't necessary to modify these limits.

This example configures the mailbox john@contoso.com to have a maximum of 2,000 safe senders and 200 blocked senders.

```
Set-Mailbox john@contoso.com -MaxSafeSenders 2000 -MaxBlockedSenders 200
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to run the Update-Safelist command

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam" entry in the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to run the **Update-Safelist** command.

In Exchange 2010, safelist aggregation is done automatically; therefore, you no longer need to schedule or manually run the **Update-Safelist** cmdlet. However, you may still want to run this cmdlet when you're testing safelist aggregation.

The **Update-SafeList** cmdlet reads the safelist collection from the Microsoft Outlook user mailbox, hashes each entry, sorts the entries for easy search, and then converts the hash to a binary attribute. Finally, the command compares the binary attribute created to any value stored on the attribute. If the two values are identical, the command doesn't update the user attribute value with the safelist aggregation data.

Be mindful of the network and replication traffic that may be generated when you run this command. If you run the command on multiple mailboxes where safelists are heavily used, this may generate a significant amount of traffic. We recommend that if you run the command on multiple mailboxes, you should run the command during off-peak, non-business hours.

Important:

Safelist aggregation data contains both the user's Safe Senders List and the user's Safe Recipients List. When you use the **Update-Safelist** cmdlet, you can specify whether you update the Safe Senders List or the Safe Recipients List, or both. However, only Safe Senders List data is used by the safelist aggregation feature; the safelist aggregation feature doesn't act on Safe Recipients List data. Therefore, to reduce storage and replication in Active Directory, we don't recommend running the **Update-Safelist** cmdlet with the *Type* parameter set to the `SafeRecipients` or `Both` values. The default value for the *Type* parameter is `SafeSenders`. Safe sender data is used by the safelist aggregation feature.

Important:

Microsoft Exchange Server 2010 provides functionality that allows you to specify whether to include the safe domain data for the anti-spam agents on the Edge Transport server by using the **Update-Safelist** cmdlet. In most cases, we don't recommend that you include domains because users may include the domains of large Internet service providers (ISP), which could unintentionally provide addresses that may be used or spoofed by spammers.

This example writes the safe senders list for the mailbox john@contoso.com to Active Directory.

```
Update-Safelist -Identity john@contoso.com -Type SafeSenders
```

For detailed syntax and parameter information, see Update-SafeList.

Options available in the msexchangemailboxassistants.exe.config

file

To activate the options to include safe domains, or to change the maximum values for the default settings, you must change the msexchangemailboxassistants.exe.config file. Specifically, the following settings and values can be changed in the **appsettings** section of the msexchangemailboxassistants.exe.config file:

Setting	Value
IncludeSafeDomains	The value for this setting can be True or False.
UpdateInterval	By default, the value for this setting is 15 minutes. This setting can have a value from 15 minutes through 1 day.
TestUpdateInterval	TestUpdateInterval is used in test environments. This setting can have a value from 10 seconds through 1 hour.
MaxSafeSenders	3*1024
MaxSafeRecipients	2*1024
MaxBlockedSenders	By default, the value for this setting is 500. The maximum value is 1000.

For example, the settings in the **appsettings** section of the msexchangemailboxassistants.exe.config file may be as follows:

```
<configuration>
  <runtime>
    <gcConcurrent enabled="false" />
    <generatePublisherEvidence enabled="false" />
  </runtime>
  <appSettings>
        <add key="IncludeSafeDomains" value="true" />
</appSettings>
</configuration>
```

Verify safelist aggegation

You may need to verify that safelist aggregation when you first deploy your Edge Transport servers and configure EdgeSync replication, or when you're troubleshooting. Typically, you need to verify the following:

- Make sure that the safelist aggregation data is being replicated by the EdgeSync service.
- Make sure that content filtering is enabled.
- Verify the safelist aggregation functionality using a test message

The following sections provide step by step instructions for each scenario:

Use AD LDS to verify EdgeSync replication of safelist aggregation data

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

You can view the user objects in the Active Directory Lightweight Directory Services (AD LDS) instance on the Edge Transport server to verify that the safelist collection data is updated for the user objects and that the Microsoft Exchange EdgeSync service has

replicated the data to the AD LDS instance.

There are three safelist collection attributes for each user object:

- **msExchSafeRecipientsHash** This attribute stores the hash of the Safe Recipients List collection for the user.
- **msExchSafeSendersHash** This attribute stores the hash of the Safe Senders List collection for the user.
- **msExchBlockedSendersHash** This attribute stores the hash of the Blocked Senders List collection for the user.

If a hexadecimal string, such as `0xac 0xbd 0x03 0xca`, is present on the attribute, the user object was updated. If the attribute has a value of `<Not Set>`, the attribute wasn't updated.

You can search for and view the attributes by using the AD LDS Active Directory Service Interfaces (ADSI) Edit snap-in.

Verify that content filtering is enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

The safelist aggregation feature relies on content filtering to recognize the senders on an Outlook user's Safe Senders List or Blocked Senders List. Verify that content filtering is enabled on each Edge Transport server on which the anti-spam and antivirus features are running. By default, content filtering is enabled.

Use the EMC to verify that content filtering is enabled

1. In the console tree, click **Edge Transport**.
2. In the result pane, click the **Anti-spam** tab, click **Content Filtering**, and then in the action pane, click **Enable**.

Use the Shell to verify that content filtering is enabled

This example verifies whether content filtering is enabled.

```
Get-ContentFilterConfig | Format-List Enabled
```

If the output shows the *Enabled* parameter to be `True`, content filtering is enabled. If it isn't, use the following command to enable content filtering.

```
Set-ContentFilterConfig -Enabled:$true
```

For detailed syntax and parameter information, see the Get-ContentFilterConfig or Set-ContentFilterConfig topics.

Use a message to verify that safelist aggregation is functioning

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" and "EdgeSync" entries in the Transport Permissions topic.

To test whether safelist aggregation is functioning, you need to send a message, which would be blocked by content filtering, from a sender marked as a safe sender. If safelist aggregation is functioning, the message should arrive in your Outlook Inbox.

1. Create an e-mail account by using a free Web-based e-mail provider like Hotmail.
2. Add that account to your Safe Senders List in Outlook.
3. Use the **Update-SafeList** cmdlet to have the safelist collection from that mailbox copied to Active Directory.
4. Run the **Start-EdgeSynchronization** cmdlet to force EdgeSync replication.

This will replicate the updated data to the Edge Transport servers. For detailed steps, see Force EdgeSync Synchronization.
5. Add a specific word as a blocked phrase to your content filtering configuration. For detailed steps, see Configure Content Filtering Properties.
6. From the Hotmail account you created in step 1, send a message to your Exchange mailbox that includes the blocked phrase you configured in step 5.

1.7.2.10.22 View Anti-Spam Stamps in Outlook 2010 and Outlook 2007

View Anti-Spam Stamps in Outlook 2010 and Outlook 2007

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Microsoft Outlook 2010 and Office Outlook 2007 to view the anti-spam stamps applied to an e-mail message. Anti-spam stamps are functionality in Microsoft Exchange Server 2010 that helps the messaging administrator diagnose spam-related problems by applying diagnostic metadata, or stamps, such as sender-specific information, puzzle validation results, and content filtering results, to messages as the messages pass through the anti-spam features that filter inbound messages from the Internet.

Looking for other management tasks related to managing anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

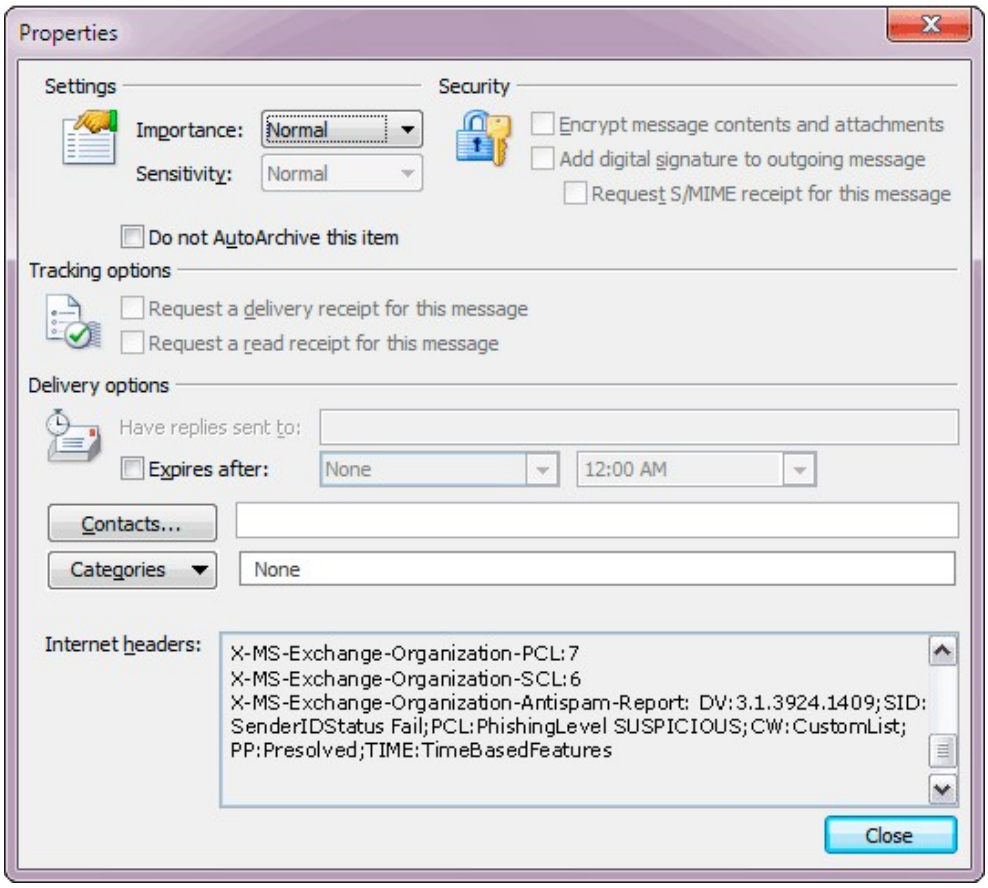
Prerequisites

- You have a mailbox to which you have owner rights.
- You have received messages to this mailbox from the Internet.
- You have reviewed Managing Anti-Spam and Antivirus Features.
- You have read Understanding Anti-Spam Stamps.

Use Outlook 2010 to view anti-spam stamps

The user account you use needs to be assigned Owner permissions on the mailbox before you can perform this procedure.

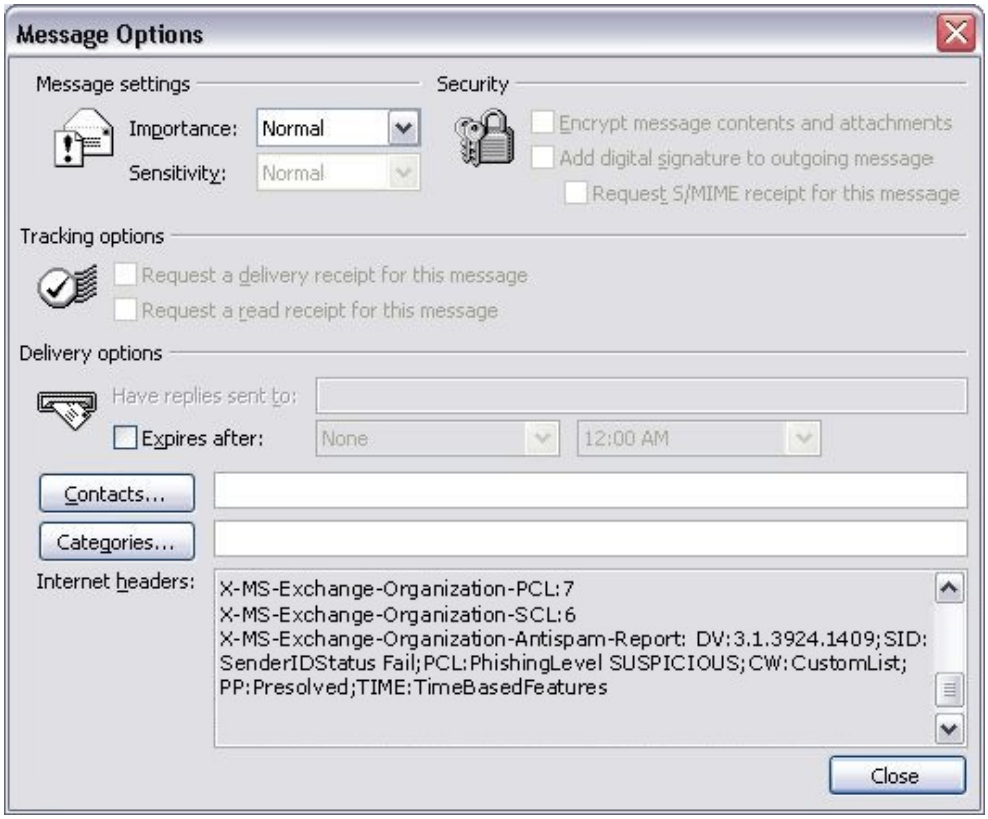
1. In Outlook 2010, on a client computer, in the **Mail** view, double-click a message to open it.
2. In the **Tags** section of the ribbon toolbar, click the **Options** icon to display the message **Properties** dialog box.
3. In the **Properties** dialog box, in the **Internet headers** section, use the scroll bar to view the anti-spam stamps as shown in the following figure.



Use Outlook 2007 to view anti-spam stamps

The user account you use needs to be assigned Owner permissions on the mailbox before you can perform this procedure.

1. In Outlook 2007, on a client computer, in the **Mail** view, double-click a message to open it.
2. On the **Message** tab, in the **Options** group, click **Message Options**.
3. In the **Message Options** dialog box, in the **Internet headers** section, use the scroll bar to view the anti-spam stamps as shown in the following figure.



1.7.2.10.23 Enable Anti-Spam Functionality on a Hub Transport Server

Enable Anti-Spam Functionality on a Hub Transport Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In some small organizations, it may make sense to run Microsoft Exchange Server 2010 anti-spam features on Hub Transport servers. For example, some organizations may not have enough e-mail volume to justify the cost of installing and maintaining a full perimeter network together with an Edge Transport server. You can enable Exchange anti-spam functionality on Hub Transport servers.

Important:

It isn't a best practice to run anti-spam functionality on the Hub Transport server. We recommend that you run anti-spam features on the Edge Transport server at the perimeter of your organization. Only run anti-spam features on the Hub Transport server if you haven't deployed an Edge Transport server.

To install and enable the anti-spam features on a Hub Transport server, you must run the Install-AntispamAgents.ps1 script. This script is installed when you run Exchange Setup. After you run the script, you must restart the Microsoft Exchange Transport service to finish the installation of the following anti-spam features:

- Connection filtering
- Content filtering
- Sender ID
- Sender filtering
- Recipient filtering
- Sender reputation

Notice that attachment filtering is an antivirus feature that isn't enabled or installed. Attachment filtering only runs on the Edge Transport server. However, the file filtering functionality that's provided by Microsoft Forefront Protection for Exchange Server includes advanced features that are unavailable in the default Attachment Filter agent that's included with Microsoft Exchange Server 2010 Standard Edition. Forefront Protection for Exchange Server is fully supported on the Hub Transport server role.

Important:

Most Exchange 2010 documentation doesn't refer to the anti-spam features in the context of the Hub Transport server. Therefore, as you read documentation about how to configure, manage, and maintain anti-spam features, remember that all functionality that's documented in the context of the Edge Transport server is also available on the Hub Transport server, unless specifically noted otherwise.

Looking for other management tasks related to managing anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Enable anti-spam functionality on a Hub Transport server

After you run the Install-AntispamAgents.ps1 script, restart the Microsoft Exchange Transport service, and set the *InternalSMTPServers* parameter.

Run the Install-AntispamAgents.ps1 script

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

1. Run the following command from the %system drive%/Program Files\Microsoft \Exchange Server\V14\Scripts folder.

```
.\install-AntispamAgents.ps1
```

2. After the script has run, restart the Microsoft Exchange Transport service by running the following command.

```
Restart-Service MSExchangeTransport
```

Use the Shell to set the InternalSMTPServers parameter

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport configuration" entry in the Transport Permissions topic.

You must specify all internal SMTP servers on the transport configuration object in Active Directory forest before you run connection filtering. Specify the internal SMTP servers by using the *InternalSMTPServers* parameter on the **Set-TransportConfig** cmdlet.

Important:

For all anti-spam features to work correctly, you must have at least one IP address of an internal SMTP server set on the *InternalSMTPServers* parameter on the **Set-TransportConfig** cmdlet. If the Hub Transport server on which you're running the anti-spam features is the only SMTP server in your organization, enter the IP address of that computer.

This example adds the internal SMTP server addresses 10.0.1.10 and 10.0.1.11 to the transport configuration of your organization.

```
Set-TransportConfig -InternalSMTPServers 10.0.1.10,10.0.1.11
```

For detailed syntax and parameter information, see Set-TransportConfig.

1.7.2.10.24 File-Level Antivirus Scanning on Exchange 2010

File-Level Antivirus Scanning on Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-03*

This topic describes the effects of file-level antivirus programs on computers that are running Microsoft Exchange Server 2010. If you implement the recommendations described in this topic, you can help enhance the security and health of your Exchange organization.

File-level scanners are frequently used. However, if they are configured incorrectly, they can cause problems in Exchange 2010. There are two types of file-level scanners:

- *Memory-resident file-level scanning* refers to a part of file-level antivirus software that is loaded in memory at all times. It checks all the files that are used on the hard disk and in computer memory.
- *On-demand file-level scanning* refers to a part of file-level antivirus software that you can configure to scan files on the hard disk manually or on a schedule. Some versions of antivirus software start the on-demand scan automatically after virus signatures are updated to make sure that all files are scanned with the latest signatures.

The following problems may occur when you use file-level scanners with Exchange 2010:

- File-level scanners may scan a file when the file is being used or at a scheduled interval. This can cause the scanners to lock or quarantine an Exchange log or a database file while Microsoft Exchange tries to use the file. This behavior may cause a severe failure in Microsoft Exchange and may also cause -1018 errors.
- File-level scanners don't provide protection against e-mail viruses, such as the Storm Worm. Storm Worm was a backdoor Trojan horse virus that propagated itself through e-mail messages. The worm joined the infected computer to a botnet, where the computer was used to send spam e-mail messages in periodic bursts. Such viruses can affect the performance of the computer and the network that it is attached to.

Recommendations for Using File-Level Scanning with Exchange 2010

If you're deploying file-level scanners on Exchange 2010 servers, make sure that the appropriate exclusions, such as directory exclusions, process exclusions, and file name extension exclusions, are in place for both memory-resident and file-level scanning. This section describes directory exclusions, process exclusions, and file name extension exclusions for each server or server role.

Directory Exclusions

You must exclude specific directories for each Exchange server or server role on which you run a file-level antivirus scanner. This section describes the directories that you should exclude from file-level scanning for each server or server role.

Mailbox server role

- Exchange databases, checkpoint files, and log files. By default, these are located in sub-folders under the %ExchangeInstallPath%\Mailbox folder. You can obtain the directory location by running the following commands in the Exchange Management Shell:
  - To determine the location of a mailbox database, transaction log, and checkpoint file, run the following command: `Get-MailboxDatabase -server <servername>| format-list *path*`
- Database content indexes. By default, these are located in the same folder as the database file.
- Group Metrics files. By default, these files are located in the %ExchangeInstallPath%\GroupMetrics folder.
- General log files, such as message tracking and calendar repair log files. By default, these files are located in subfolders under the %ExchangeInstallPath%\TransportRoles\Logs folder and %ExchangeInstallPath%\Logging folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-MailboxServer <servername> | format-list *path*`
- The Offline Address Book files. By default, these are located in subfolders under the %ExchangeInstallPath%\ExchangeOAB folder
- IIS system files in the %SystemRoot%\System32\Inetsrv folder
- The temporary folder that is used with offline maintenance utilities, such as Eseutil.exe. By default, this folder is the location where the .exe file is run from. However, you can configure where you perform the operation when you run the utility.
- The Mailbox database temporary folder: %ExchangeInstallPath%\Mailbox\MDBTEMP
- Any Exchange-aware antivirus program folders

Mailbox server that is a member of a Database Availability Group

All the items listed in the Mailbox server role list and in the %Winnt%\Cluster folder.

Witness server

- The witness directory files. These are located on another server in the environment, typically a Hub Transport server. By default, these files are located in \\%SystemDrive%:\DAGFileShareWitnesses\<DAGFQDN> and default share (<DAGFQDN>) on that server. For more information about a database availability group (DAG) and witness servers, see Managing Database Availability Groups.

Hub Transport server role

- General log files, for example, message tracking and connectivity logs. By default, these files are located in subfolders under the %ExchangeInstallPath%\TransportRoles\Logs folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-TransportServer <servername>| format-list *logpath*,*tracingpath*`
- Pickup and Replay message directory folders. By default, these folders are located under the %ExchangeInstallPath%\TransportRoles folder. To determine the paths being used, run the following command in the Exchange Management Shell: `Get-TransportServer <servername>| fl *dir*path*`
- The transport server role queue database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\Queue folder. For more information, see Managing Transport Queues.
- The transport server role Sender Reputation database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\SenderReputation folder.

- The transport server role IP filter database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\IpFilter folder.
- The temporary folders that are used to perform conversions:
  - By default, content conversions are performed in the Exchange server's TMP folder.
  - By default, OLE conversions are performed in %ExchangeInstallPath%\Working\OleConvertor folder.
- Any Exchange-aware antivirus program folders

Edge Transport server role

- The Active Directory Lightweight Directory Service database (AD LDS) and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\Adam folder. For more information about AD LDS database files, see Modify AD LDS Configuration.
- General log files, for example message tracking. By default, these files are located in subfolders under the %ExchangeInstallPath%\TransportRoles\Logs folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-TransportServer <servername> | format-list *logpath*,*tracingpath*`
- The Pickup and Replay message folders. By default, these are located under the %ExchangeInstallPath%\TransportRoles folder. To determine the log paths being used, run the following command in the Exchange Management Shell: `Get-TransportServer <servername>| format-list *dir*path*`
- The transport server role queue database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\Queue folder. For more information about transport server queues, see Managing Transport Queues.
- The transport server role Sender Reputation database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\SenderReputation folder
- The transport server role IP filter database, checkpoint, and log files. By default, these are located in the %ExchangeInstallPath%\TransportRoles\Data\IpFilter folder
- The temporary folders that are used to perform conversions:
  - By default, content conversions are performed in the server's TMP folder.
  - By default, OLE conversions are performed in %ExchangeInstallPath%\Working\OleConvertor folder.
- Any Exchange-aware antivirus program folders

Client Access server role

- For servers using Internet Information Services (IIS) 7.0, the compression folder that is used with Microsoft Outlook Web App. By default, the compression folder for IIS 7.0 is located at %SystemDrive%\inetpub\temp\IIS Temporary Compressed Files.
- For servers using IIS 6.0, the compression folder that is used with Microsoft Outlook Web App. By default, the compression folder for IIS 6.0 is located at %systemroot%\IIS Temporary Compressed Files. For more information about possible errors resulting from scanning the IIS compression folder, see Microsoft Knowledge Base article 817442, A 0-byte file may be returned when compression is enabled on a server that is running IIS.
- IIS system files in the %SystemRoot%\System32\Inetsrv folder
- Inetpub\logs\logfiles\w3svc
- The Internet-related files that are stored in the sub-folders of the %ExchangeInstallPath%\ClientAccess folder
- For servers that have protocol logging enabled for POP3 or IMAP4, the following folders:
  - POP3 folder: %ExchangeInstallPath%\Logging\POP3
  - IMAP4 folder: %ExchangeInstallPath%\Logging\IMAP4

- The temporary folders that are used to perform conversions:
  - By default, content conversions are performed in the server's TMP folder.
  - By default, OLE conversions are performed in %ExchangeInstallPath% \Working\OleConvertor folder.

Unified Messaging server role

- The grammar files for different locales, for example en-EN or es-ES. By default, these are stored in the subfolders in the %ExchangeInstallPath% \UnifiedMessaging\grammars folder.
- The voice prompts, greetings and informational message files. By default, these are stored in the subfolders in the %ExchangeInstallPath% \UnifiedMessaging\Prompts folder
- The voicemail files that are temporarily stored in the %ExchangeInstallPath %\UnifiedMessaging\voicemail folder.
- The temporary files generated by Unified Messaging. By default, these are stored in the %ExchangeInstallPath%\UnifiedMessaging\temp folder.

Microsoft Forefront Protection for Exchange

- The Forefront installation folder. By default, this is %Program Files (x86)% \Microsoft Forefront Protection for Exchange Server\.
- Any archived messages. By default, these are stored in the %Program Files (x86)%\Microsoft Forefront Protection for Exchange Server\Data\Archive folder.
- Any quarantined files. By default, these are stored in the %Program Files (x86)%\Microsoft Forefront Protection for Exchange Server\Data \Quarantine folder.
- The antivirus engine files. By default, these are stored in the subfolders of %Program Files (x86)%\Microsoft Forefront Protection for Exchange Server \Data\Engines\x86 folder or the %Program Files (x86)%\Microsoft Forefront Protection for Exchange Server\Data\Engines\amd64 folder.
- The configuration files. By default, these are stored in the %Program Files (x86)%\Microsoft Forefront Protection for Exchange Server\Data folder.

Process Exclusions

Many file-level scanners now support the scanning of processes, which can adversely affect Microsoft Exchange if the incorrect processes are scanned. Therefore, you should exclude the following processes from file-level scanners.

Cdb.exe	Microsoft.Exchange.Search.Exsearch.exe
Cidaemon.exe	Microsoft.Exchange.Servicehost.exe
Clussvc.exe	MSExchangeADTopologyService.exe
Dsamain.exe	MSExchangeFDS.exe
Microsoft.Exchange.EdgeCredentialSvc.exe	MSExchangeMailboxAssistants.exe
EdgeTransport.exe	MSExchangeMailboxReplication.exe
ExFBA.exe	MSExchangeMailSubmission.exe
GalGrammarGenerator.exe	MSExchangeRepl.exe
Inetinfo.exe	MSExchangeTransport.exe
Mad.exe	MSExchangeTransportLogSearch.exe
Microsoft.Exchange.AddressBook.Service.exe	MSExchangeThrottling.exe
Microsoft.Exchange.AntispamUpdateSvc.exe	Msftefd.exe

Microsoft.Exchange.ContentFilter.Wrapper.exe	Msftesql.exe
Microsoft.Exchange.EdgeSyncSvc.exe	OleConverter.exe
Microsoft.Exchange.Imap4.exe	Powershell.exe
Microsoft.Exchange.Imap4service.exe	SESWorker.exe
MSExchangeMailboxAssistants.exe	SpeechService.exe
Microsoft.Exchange.Monitoring.exe	Store.exe
Microsoft.Exchange.Pop3.exe	TranscodingService.exe
Microsoft.Exchange.Pop3service.exe	UmService.exe
Microsoft.Exchange.ProtectedServiceHost.exe	UmWorkerProcess.exe
Microsoft.Exchange.RPCClientAccess.Service.exe	W3wp.exe

If you're also deploying Forefront Protection for Exchange Server, exclude the following processes.

Adonavsvc.exe	FscStatsServ.exe
FscController.exe	FscTransportScanner.exe
FscDiag.exe	FscUtility.exe
FscExec.exe	FsEmailPickup.exe
FscImc.exe	FssaClient.exe
FscManualScanner.exe	GetEngineFiles.exe
FscMonitor.exe	PerfmonitorSetup.exe
FscRealtimeScanner.exe	ScanEngineTest.exe
FscStarter.exe	SemSetup.exe

File Name Extension Exclusions

In addition to excluding specific directories and processes, you should exclude the following Exchange-specific file name extensions in case directory exclusions fail or files are moved from their default locations.

Application-related extensions

- .config
- .dia
- .wsb

Database-related extensions

.chk	.jrs	.log
.edb	.jsl	.que

Offline address book-related extensions

- .lzx

Content Index-related extensions

.ci	.wid	.001

.dir	.000	.002

Unified Messaging-related extensions

- .cfg
- .grxml

GroupMetrics

- .dsc
- .bin
- .xml

Forefront Protection for Exchange Server–related extensions

.avc	.dt	.lst
.cab	.fdb	.mdb
.cfg	.fdm	.ppl
.config	.ide	.set
.da1	.key	.v3d
.dat	.klb	.vdb
.def	.kli	.vdm

The file name extensions listed for Forefront Protection for Exchange Server are the signature files from various antivirus directory engines. In most cases, these file name extensions don't change. However, file name extensions may be added in the future as third-party antivirus vendors update their antivirus signature files.

1.7.2.10.25 Configure Proxy Settings for WinHTTP

Configure Proxy Settings for WinHTTP

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Exchange Server 2010, several server roles rely on the underlying Microsoft Windows HTTP Services (WinHTTP) to manage all HTTP and HTTPS traffic. Both Hub Transport servers and Edge Transport servers may use HTTP to access filter updates for the Microsoft Exchange Anti-spam Update service and the Microsoft Forefront Protection for Exchange Server anti-spam update service, and for certificate revocation list (CRL) validation. If your organization supports smart card authentication for clients to connect to Exchange, and the CRL for the presented client certificates is hosted outside your firewall, Client Access servers need to be configured for proxy servers to make outbound requests to perform CRL validation. Additionally, Exchange organizations that have their archives hosted by Windows Live require that their Client Access and Mailbox servers are able to make outbound HTTP requests to Microsoft datacenters.

In most organizations, a proxy server is used for HTTP and HTTPS communications with destinations on the Internet. If your organization uses a proxy server and your Exchange transport servers aren't configured to use the proxy server for HTTP and HTTPS, you must configure them so that HTTP-enabled CRL validation works.

The simplest way to configure WinHTTP is to use the Netsh.exe tool. Netsh.exe is a command-line tool included in the %System32% directory on all computers running Windows Server 2008. You can use Netsh.exe to set and view WinHTTP configurations. All the WinHTTP-related commands are included under the WinHTTP context within the Netsh.exe tool.

For more information about how to use the Netsh.exe tool, see How to Use the Netsh.exe Tool and Command-Line Switches.

Looking for other management tasks related to anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Use Netsh.exe to configure proxy settings for WinHTTP

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

To navigate to the WinHTTP context, open an administrator Command Prompt window, type **netsh**, and then type **winhttp**.

```
C:\Windows\system32>netsh
netsh>winhttp
netsh winhttp>
```

You use the **set proxy** command to configure the proxy settings. You can type the command followed by a question mark to see the syntax for this command.

```
netsh winhttp>set proxy /?
```

This example specifies that HTTP servers and HTTPS servers are accessed through the proxy server proxy_server, except for host names that don't contain a period specified by the "*<local>*" argument.

```
netsh winhttp>set proxy proxy_server "<local>"
```

This example imports proxy information used by Internet Explorer by using the **import proxy** command.

```
netsh winhttp>import proxy source=ie
```

This examples uses the **reset proxy** command to reset the WinHTTP proxy to DIRECT.

```
netsh winhttp>reset proxy
```

Even if you aren't running a proxy server, we recommend that you use Netsh.exe to check whether a previous proxy has been set. By running the tool without arguments, this example shows the current configuration.

```
netsh winhttp>show proxy
```

Important:

You must restart the Microsoft Exchange Transport service and the Microsoft Exchange Anti-spam Update service after you have made configuration changes to WinHTTP.

1.7.2.10.26 Make the SCL Value Available to Edge Transport Rules

Make the SCL Value Available to Edge Transport Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to make the spam confidence level (SCL) value on messages available for processing in transport rules that run on computers that have the Edge Transport server role installed.

Looking for other management tasks related to managing anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Caution:
The following procedure stops and starts the Microsoft Exchange Transport service on the local Edge Transport server. Mail that flows through this Edge Transport server isn't delivered while the Microsoft Exchange Transport service is stopped.

Use the Shell to modify the priority of the Content Filter agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to modify the priority of the Content Filter agent.

This example sets the priority value of the Content Filter agent to 3. Because the Edge Rule agent by default uses priority value 3, its priority value is increased to 4.

1. Use the Shell to set the priority value of the Content Filter agent to 3.

```
Set-TransportAgent "Content Filter Agent" -Priority 3
```

2. Stop the Microsoft Exchange Transport service.

```
Net Stop MSExchangeTransport
```

3. Start the Microsoft Exchange Transport service.

```
Net Start MSExchangeTransport
```

For detailed syntax and parameter information, see Set-TransportAgent.

Use the Shell to verify transport agent priority order

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to verify transport agent priority order.

You can verify the transport agent priority order by sending a test message through the Edge Transport server that you just configured. Then you can use the **Get-TransportPipeline** cmdlet to view the transport agent priority order. You must send a message through the Edge Transport server because the **Get-TransportPipeline** cmdlet retrieves information about the transport pipeline that's built dynamically every time a message is sent.

This example verifies the transport agent priority order.

1. Send a message through the Edge Transport server that you just configured.
2. Run the following command.

```
Get-TransportPipeline
```

The output produced by this procedure will resemble the following example. In the following example, the Content Filter agent is listed before the Edge Rule agent on the OnEndOfData SMTP event. This indicates that the Content Filter agent is now being applied to messages before the Edge Rule agent on the OnEndOfData SMTP event.

```
Event           : OnConnectEvent
TransportAgents : {Connection Filtering Agent, Protocol Analysis Agent}
Event           : OnHeloCommand
TransportAgents : {}
Event           : OnEhloCommand
TransportAgents : {}
Event           : OnAuthCommand
TransportAgents : {}
Event           : OnEndOfAuthentication
TransportAgents : {}
Event           : OnMailCommand
TransportAgents : {Connection Filtering Agent, Sender Filter Agent}
Event           : OnRcptCommand
TransportAgents : {Connection Filtering Agent, Address Rewriting Inbound Agent,
                  Recipient Filter Agent}
Event           : OnDataCommand
TransportAgents : {}
Event           : OnEndOfHeaders
TransportAgents : {Connection Filtering Agent, Address Rewriting Inbound Agent,
                   Sender Id Agent, Sender Filter Agent, Protocol Analysis Agen
                  t}
Event           : OnEndOfData
TransportAgents : {Content Filter Agent, Edge Rule Agent, Protocol Analysis Age
                  nt, Attachment Filtering Agent}
Event           : OnHelpCommand
TransportAgents : {}
Event           : OnNoopCommand
TransportAgents : {}
Event           : OnReject
TransportAgents : {Protocol Analysis Agent}
Event           : OnRsetCommand
TransportAgents : {Protocol Analysis Agent}
Event           : OnDisconnectEvent
TransportAgents : {Protocol Analysis Agent}
Event           : OnSubmittedMessage
TransportAgents : {Address Rewriting Outbound Agent}
Event           : OnRoutedMessage
TransportAgents : {Address Rewriting Outbound Agent}
```

For detailed syntax and parameter information, see Get-TransportPipeline.

1.7.2.10.27 Manage Anti-Spam Agent Log Output

Manage Anti-Spam Agent Log Output

Transport > Managing Transport Servers > Managing Anti-Spam and Antivirus Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the EdgeTransport.exe.config file to manage the anti-spam agent log files. By default, Microsoft Exchange Server 2010 logs all anti-spam agent activity in the %programfiles%\Microsoft\Exchange Server\V14\TransportRoles\Logs\AgentLog directory. To filter the anti-spam agent logs, use the **Get-AgentLog** cmdlet. For more information, see Get-AgentLog.

The default configuration of the agent log files are as follows:

- Maximum size of the agent log directory: 250 megabytes (MB)
- Maximum size of a single agent log file: 10 MB
- Maximum age of log files: 30 days

Looking for other management tasks related to managing anti-spam and antivirus features? Check out Managing Anti-Spam and Antivirus Features.

Modifying the EdgeTransport.exe.config File

All modifications of configuration options for managing agent log output must be made in the EdgeTransport.exe.config file that's located in the %programfiles%\Microsoft \Exchange Server\V14\Bin directory. The EdgeTransport.exe.config file is an XML application configuration file that's associated with the Microsoft Exchange Transport service. Changes that are saved to the EdgeTransport.exe.config file are applied after the Microsoft Exchange Transport service is restarted.

You can add new configuration options or modify existing configuration options in the `<appSettings>` section.

Agent Log Output Keys

Agent log output is managed by various keys in the EdgeTransport.exe.config file. By default, only the `AgentLogEnabled` key is present in the EdgeTransport.exe.config file. You must add all other keys. The following table explains each key in more detail.

Key	Value type	Description
`AgentLogEnabled`	System.Boolean	Valid values for this key are `true` or `false`. The default value is `true`.
`AgentLogMaxDirectorySize`	System.Int32	The value of this key specifies the maximum size, in bytes, of the AgentLog directory. When this value is exceeded, the oldest log file in the directory is deleted and a new log file is created. If this key isn't specified, the default value is 250 MB, or 262144000 bytes, which is determined as follows: 250×1,024×1,024.
`AgentLogMaxFileSize`	System.Int32	The value of this key specifies the maximum size, in bytes, of each log file in the directory. When a log file reaches the size specified, a new log file is created. If this key isn't specified, the default is 10 MB, or 10485760 bytes, which is

		determined as follows: 10×1024×1024.
AgentLogMaxAge	System.TimeSpan	The value of this key specifies the maximum age limit of a specified log file. When a log file exceeds the age limit, it's deleted. This key is of system type TimeSpan. The value of this key can be represented as a string in the format *d.hh:mm:ss.ff* where *d* is days, *hh* is hours, *mm* is minutes, *ss* is seconds, and *ff* is fractions of a second. If this key isn't specified, the default value is 30 days, or 30.00:00:00.00.

Add and configure the agent log output keys in the EdgeTransport.exe.config file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

This example adds and configures agent log output keys for the AgentLogEnabled key in the EdgeTransport.exe.config file.

1. On the Hub Transport server or Edge Transport server on which you want to manage the agent log output, open the EdgeTransport.exe.config in an ASCII text editor such as Notepad. The EdgeTransport.exe.config file is located in the %programfiles%\Microsoft\Exchange Server\V14\Bin directory.
2. Locate the AgentLogEnabled key. By default, the keys are listed in alphabetical order under <appsettings>.
3. Paste the following keys under the AgentLogEnabled key.

```
<add key="AgentLogMaxDirectorySize" value="system.int32" />
<add key="AgentLogMaxFileSize" value="system.int32" />
<add key="AgentLogMaxAge" value="system.timespan" />
```

4. Verify that the AgentLogEnabled key is set to true, and add values for the other keys.
5. When you have finished updating the EdgeTransport.exe.config file, save the file and close it.
6. You must restart the Microsoft Exchange Transport service before the configuration changes will take effect.

1.7.2.11 Managing Connectors

Create an SMTP Send Connector

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Send connectors create a logical connection to remote e-mail systems and are responsible for outbound transmission of e-mail messages. If you use the EdgeSync process, it will configure the Send connectors required for mail flow to the Internet and to the Edge Transport servers in your Microsoft Exchange Server 2010 organization. If your organization requires a Send connector with specific configuration options, or if you don't use the EdgeSync process, you must manually configure Send connectors.

You can use the EMC or the Shell to create a Send connector for Exchange 2010.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Prerequisites

You should determine the specific usage for the Send connector before you create it so you can correctly configure its properties. To learn more about Send connectors, see Understanding Send Connectors.

What Do You Want to Do?

- Use the EMC to create a Send connector
- Use the Shell to create a Send connector

Use the EMC to create a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

1. Open the Exchange Management Console. Perform one of the following:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the work pane, click the **Send Connectors** tab.
   - To create a Send connector on a Hub Transport server role, in the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Send Connectors** tab.
2. In the action pane, click **New Send Connector**. The New SMTP Send Connector wizard starts.

3. On the **Introduction** page, follow these steps:
   - In the **Name** field, type a meaningful name for this connector. Specify a name for the Send connector that helps you distinguish this Send connector from other Send connectors in your configuration.
   - In the **Select the intended use for this connector** field, select the usage

type for the connector. The usage type determines the default permission sets assigned on the connector and grants those permissions to trusted security principals. The following usage types are available:

Custom Select this option to create a customized connector to connect with systems that aren't servers running Exchange 2010.

Internal Internal Send connectors send e-mail to servers in your Exchange organization. This connector is configured to route e-mail to your internal Exchange servers as smart hosts.

Internet Internet Send connectors send e-mail to the Internet. This connector is configured to use Domain Name System (DNS) MX records to route e-mail.

Partner Partner Send connectors send e-mail to partner domains. This connector is configured to only allow connections to servers that authenticate with Transport Layer Security (TLS) certificates for SMTP domains included in the list of domain-secured domains. You can add domains to this list by using the *TLSSendDomainSecureList* parameter in the **Set-TransportConfig** command.

For more information about Send connector usage types, see Understanding Send Connectors.

- Click **Next**.

4. On the **Address space** page, specify an address space to which the Send connector sends mail.
   You can configure either an SMTP address space or a custom address space. Custom address spaces may only be configured on Send connectors that exist on Hub Transport servers. If you use a custom address space type, you must use a smart host to route e-mail.

Note:

Although you can configure custom address spaces on a Send connector, the Hub Transport server still uses SMTP as the transport mechanism to send messages to other messaging servers using this Send connector. To send messages to messaging servers that don't use SMTP as their primary transport mechanism, such as a third-party fax gateway server, you must use a Foreign connector. For more information about Foreign connectors, see Understanding Foreign Connectors.

To configure an address space, do the following:

- **Add** To specify an address space for which this Send connector is responsible, click **Add** or the drop-down arrow located next to **Add**. If you click **Add**, the address space type is SMTP. If you click the drop-down arrow located next to **Add**, you can select **SMTP Address Space** or **Custom Address Space**. For each new address space, you need to configure the following:
  - **Type** This field describes the address space that you enter in the **Address** field. If you clicked **Add**, this field is set to SMTP and is unavailable.
  - **Address** Specify the address space for the Send connector. If you entered **SMTP** or **X400** in the **Type** field, Exchange verifies the syntax of the address space that you enter. Exchange can't verify any other types of addresses; therefore, you need to make sure that you specify any custom addresses using the correct syntax. If you're entering an SMTP address, you can include the wildcard character (*) in the address space as defined in RFC 1035. For example, `*`, `*.com`, and `*.contoso.com` are permitted, but `*contoso.com` isn't permitted.
  - **Include all subdomains** This option is only available when you're specifying an SMTP address space. Select this option if

you also want to use this connector to route mail to all subdomains of the specified address space. If you entered an address space that contains the wildcard character, this option is automatically selected.

• **Cost** Use the address space cost to set the selection priority when more than one Send connector is configured for the same address space. During routing resolution, when the connector selection is made, the least cost routing path to the destination address space is selected. The valid input range is from 1 through 100.

- **Edit** To modify an existing address space in the address space list, select the address space, and then click **Edit**. You can configure the same options described for the **Add** button previously, with the exception of **Type**. You can't change the type of an existing address space.
- **Remove** To delete the domain name from the list of domains, select a domain name, and then click  .
- **Scoped send connector** By default, all Send connectors that you create can be used by all the Hub Transport servers in your Exchange organization. However, you can limit the scope of any Send connector so that it can be used only by other Hub Transport servers that exist in the same Active Directory site. To limit the scope of this Send connector, select **Scoped send connector**.

After you finish, click **Next**.

5. On the **Network settings** page, select how to send e-mail with the Send connector. The following options are available:
   - **Use domain name system (DNS) "MX" records to route mail automatically** This option is available only if you selected a usage type of **Custom**, **Partner**, or **Internet** in step 3. When you select this option, the Send connector uses DNS to resolve the IP address of the remote SMTP servers and route mail.
   - **Route mail through the following smart hosts** This option is available only if you selected a usage type of **Custom**, **Internal**, or **Internet** in step 3. Select this option to route all outbound mail to specific smart hosts instead of using DNS to resolve the IP addresses of remote SMTP servers. After you select this option, you can select the following:

     Add To add a smart host, click **Add**. You can specify either of the following options in the window that appears:

     ? **IP Address** Select this option to identify the smart host by IP address (for example: 192.168.100.1).

     ? **Fully qualified domain name (FQDN)** Select this option to identify the smart host by FQDN (for example, smarthost.contoso.com).

     Edit To edit an existing smart host, select the smart host, and then click **Edit**.

     Remove To remove an existing smart host, select the smart host, and then click  .
   - **Use the External DNS Lookup settings on the transport server** Select this check box if you want to use a specific list of external DNS servers instead of the DNS servers configured on the network adapters of the source servers configured for this Send connector.

     Important:

     Verify that you have configured the external DNS servers list by using the **Set-TransportServer** cmdlet, or by using the **External DNS Lookups** tab in the properties of the Hub Transport server object or the Edge Transport server object.

   After you finish, click **Next**.

6. On the Configure **smart host authentication settings** page, select the method used to authenticate to the smart host.
   By default, no authentication is used. To configure the smart host authentication settings, click **Change**. You can specify one of the following options in the window that appears:
   • **None** Select this option if the smart host is configured to accept anonymous connections.
   • **Basic Authentication** Select this option if the smart host requires Basic authentication. Basic authentication requires that you provide a user name and password. We strongly recommend that you use an encrypted connection if you're using Basic authentication, because the user name and password are sent in clear text. Select the **Basic Authentication over TLS** check box to enable encryption on the connection. Also, if you specify more than one smart host for this Send connector, all of the specified smart hosts must accept the same user name and password.
   • **Exchange Server Authentication** Select this option to authenticate to a smart host by using an Exchange authentication mechanism, such as TLS direct trust or TLS\Kerberos.
   • **Externally Secured (for example, with IPsec)** Select this option if the connection to the smart host is secured by external means, such as being physically secured over a private network or secured using Internet Protocol security (IPsec). When you select this option, you make an assertion of external security that can't be programmatically verified by Exchange.
   Click **Next**.

7. The **Source Server** page only appears on Hub Transport servers. By default, the Hub Transport server that you are currently working on is listed as a source server. To add a source server, click **Add**. In the **Select Hub Transport or Subscribed Edge Transport Server** dialog box, select the Hub Transport servers or the subscribed Edge Transport servers that will be used as the source server for sending messages to the address space that you provided in step 4. The list of source servers can contain all Hub Transport servers or all subscribed Edge Transport servers, but not a combination of both. After you finish adding additional source servers, click **OK**.
   To add more source servers, click **Add** and repeat this step.
   To remove an existing source server, select the source server, and then click  .

   Note:
   Removing a subscribed Edge Transport server from the list doesn't remove the Send connector from the Edge Transport server. It just stops the Microsoft Exchange EdgeSync service from propagating this Send connector configuration to that Edge Transport server.

   After you finish, click **Next**.

8. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Send connector by using the settings in the configuration summary, click **New**.

9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

This command creates a Send connector.

```
New-SendConnector -Name <Connector Name> -AddressSpaces <Address Space> <Optional
```

This example creates a Send connector called `Subsidiary Send Connector` that has the following settings:

- Connector usage type is **Custom**.
- Connector sends messages to the SMTP address space Contoso.com and all subdomains. The address space cost is 5.
- Connector sends messages to the SMTP address space named Fabrikam.com and all subdomains. The address space cost is 8.
- E-mail is routed through a smart host at IP address 192.168.1.20.
- Maximum message size of 20 MB is allowed on this connector.

```
New-SendConnector -Name "Subsidiary Send Connector" -Usage Custom -AddressSpace "
```

For detailed syntax and parameter information, see New-SendConnector.

1.7.2.11.2 Create Linked Connectors

Create Linked Connectors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to create linked connectors on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or Edge Transport server role installed. A *linked connector* is a Receive connector linked to a Send connector. For linked connectors, the regular routing logic based on the destination domain is overridden. All messages received by the Receive connector are forwarded to the Send connector to which the Receive connector is linked. This scenario is useful when you want to send messages to a third-party anti-spam and antivirus service for processing, and then return the messages to the Exchange 2010 organization for delivery.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Prerequisites

- Only one Receive connector can be linked to one Send connector.
- The Receive connector must exist before it can be linked to a Send connector.
- A linked Send connector must route messages to a smart host. You can use an IP address or the fully qualified domain name (FQDN) of the smart host to specify the smart host identity.

Linked Connector Scenario

This section describes a typical linked connector scenario on an Edge Transport server. The following table describes the Send connectors and Receive connectors in that scenario.

Send connectors and Receive connectors in a typical linked connector scenario on an Edge Transport server

Connector name	Linked status	Connector description
ReceiveConnectorA	Linked to SendConnectorC	This connector receives all messages from the Internet.
ReceiveConnectorB	Not linked	This connector receives messages only from the third-party anti-spam and antivirus service.
SendConnectorC	Contains linked ReceiveConnectorA	This connector sends all messages to the third-party anti-spam and antivirus service smart host.
SendConnectorD	Not linked	This connector sends all messages into the Exchange organization.

In this scenario, all messages destined for the Exchange 2010 organization arrive at the Edge Transport server through ReceiveConnectorA. Because ReceiveConnectorA is linked to SendConnectorC, the messages are immediately redirected to the third-party anti-spam and antivirus service through SendConnectorC. After the third-party anti-spam and antivirus service has finished processing the messages, the messages are delivered back to the Edge Transport server through ReceiveConnectorB.

ReceiveConnectorB is an unlinked Receive connector, which is important in this scenario. Without ReceiveConnectorB, the messages would return to the Edge Transport server through ReceiveConnectorA, and would then be forwarded back to the third-party anti-spam and antivirus service. This process would continue indefinitely. However, because ReceiveConnectorB isn't linked to a Send connector, the Edge Transport server is free to select the route into the Exchange organization. This will occur through SendConnectorD. The messages are then delivered to the original recipients in the Exchange organization through SendConnectorD.

Use the Shell to link a Receive connector to a new Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Note:

You can't use the EMC to link a Receive connector to a new Send connector.

Use the **New-SendConnector** cmdlet to create a Send connector that's linked to a specific Receive connector. This example links the Receive connector From Internet on server Edge01 to a new Send connector with the following configuration options:

- Send connector name: "To Hygiene Service"
- Linked Receive connector identity: "Edge01\From Internet"
- Smart host identity: hygiene.contoso.com
- Smart host authentication mechanism: `ExternalAuthoritative`
- No message size limits imposed on the Send connector

```
New-SendConnector -Name "To Hygiene Service" -LinkedReceiveConnector "Edge01\From
```

For detailed syntax and parameter information, see New-SendConnector.

Use the Shell to link a Receive connector to an existing Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Note:
You can't use the EMC to link a Receive connector to an existing Send connector.

Use the **Set-SendConnector** cmdlet to link an existing Send connector to a specific Receive connector. This example links the Receive connector From Internet on server Edge01 to the Send connector To Hygiene Service with the following configuration options:

- Send connector identity: "To Hygiene Service"
- Linked Receive connector identity: "Edge01\From Internet"
- Smart host identity: hygiene.contoso.com
- Smart host authentication mechanism: `ExternalAuthoritative`
- No message size limits imposed on the Send connector

```
Set-SendConnector "To Hygiene Service" -LinkedReceiveConnector "Edge01\From Inter
```

For detailed syntax and parameter information, see Set-SendConnector.

Use the Shell or the EMC to remove a linked connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

After you link a Receive connector to a Send connector, you may want to break the link at some time. Here are options for breaking the link:

- **Remove the Send connector to which the Receive connector is linked** You can remove the Send connector by using the EMC or by using the **Remove-SendConnector** cmdlet in the Shell. After you remove the Send connector, you don't have to modify the configuration of the Receive connector.
- **Remove the Receive connector linked to the Send connector** You can remove the Receive connector by using the EMC or by using the **Remove-ReceiveConnector** cmdlet in the Shell. After you remove the Receive connector, you must modify the configuration of the Send connector. After the linked Receive connector is removed, the Send connector will have no address spaces configured. If you try to view or modify the Send connector, you receive an error message that states that the Send connector is corrupted. To configure an address space for the Send connector, you can use the EMC or the **Set-SendConnector** cmdlet in the Shell.

For step-by-step instructions for removing connectors, see the following topics:

- Remove a Send Connector
- Remove a Receive Connector

1.7.2.11.3 Configure a Dedicated Send Connector for a Specific Domain

Configure a Dedicated Send Connector for a Specific Domain

See Also

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-11-19*

In some Microsoft Exchange Server 2010 environments, you may want to configure conditional SMTP forwarding so that all messages that are sent to a specific domain are routed through a separate Send connector. To do this in Exchange 2010, create a dedicated Send connector, and specify a different recipient domain for each Send connector.

Use the Exchange Management Console to create a dedicated Send connector

1. Open the Exchange Management Console on a computer that has the Hub Transport server role.
2. In the console tree, expand **Organization Configuration**, select **Hub Transport**, and then click the **Send Connectors** tab in the work pane.
3. In the action pane, click **New Send Connector**.

   Note:
   The New SMTP Send Connector wizard starts.
4. On the **Introduction** page, type a name for the connector in the **Name** field.
5. In the **Select the intended use for this connector** field, click **Custom**.
6. On the **Address space** page, click **Add**.
7. In the **SMTP Address Space** dialog box, specify the address to which you want to route the mail. To do this, enter the recipient's domain name under **Address space**. to For example, enter **contoso.com**.

   Note:
   If it's applicable, click to select the **Include all subdomains** check box, click **OK**, and then click **Next**.
8. On the **Network Settings** page, select **Route mail through the following smart hosts**, and then click **Add**.
9. In the **Add smart host** dialog box, enter the FQDN of the smart host that you want to use to route mail to the recipient's domain. For example, to send connector to route mail to the contoso.com domain, use the smart host for contoso.com.
10. Click **OK**.
11. On the "Configure smart host authentication settings" page, select the method that's used to authenticate to the smart host. By default, no authentication is used. To configure the smart host authentication settings, click **Change**, and then specify one of the following options in the window

that opens:

- **None** Select this option if the smart host is configured to accept anonymous connections.
- **Basic Authentication** Select this option if the smart host requires Basic authentication. Basic authentication requires that you provide a user name and password. We strongly recommend that you use an encrypted connection if you're using Basic authentication. This is because the user name and password are sent in clear text. Select the **Basic Authentication over TLS** check box to enable encryption on the connection. Also, if you specify more than one smart host for this Send connector, all the specified smart hosts must accept the same user name and password.
- **Exchange Server Authentication** Select this option to authenticate to a smart host by using an Exchange authentication mechanism, such as TLS direct trust or TLS\Kerberos.
- **Externally Secured (for example, with IPsec)** Select this option if the connection to the smart host is secured by external means, such as being physically secured over a private network or secured by using Internet Protocol security (IPsec).

12. Click **Next**.
13. On the Source Server page, select the Hub transport server that you are working on. To use a different Hub Transport server, click **Add**, and then select the Hub Transport servers that you want in the **Select Hub Transport or Subscribed Edge Transport Server** dialog box.
14. To create the Send connector, click **New**.

Repeat these steps for each new Send connector. Make sure that you specify a different recipient domain name on the "Address space" page for each dedicated Send connector for which you want to configure conditional forwarding.

Concepts

Understanding Send Connectors

1.7.2.11.4 Configure Send Connector Properties

Configure Send Connector Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Send connectors create a logical connection to remote e-mail systems and are responsible for outbound transmission of e-mail messages. If you use the EdgeSync process, it configures the Send connectors required for mail flow to the Internet, and to the Edge Transport servers in your Microsoft Exchange organization. If your organization requires a Send connector with specific configuration options, or if you don't use the EdgeSync process, you must manually configure Send connectors.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

Prerequisites

- Send connector. For detailed steps about creating a new Send connector, see Create an SMTP Send Connector.
- You should determine the specific usage for this Send connector so you can correctly configure its properties. To learn more about Send connectors, see Understanding Send Connectors.

What Do You Want to Do?

- Use the EMC to configure the properties of a Send connector
- Use the Shell to configure the properties of a Send connector

Use the EMC to configure the properties of a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

1. If you're configuring a Send connector on a Hub Transport server, in the console tree, navigate to **Organization Configuration** > **Hub Transport**. On an Edge Transport server, select **Edge Transport** in the console tree.
2. In the work pane, select the **Send Connectors** tab on the right, and then double-click the Send connector you want to configure.
3. Use the **General** tab to modify the general properties of the Send connector:
   - **Connector name** To rename the connector, type a new name in the connector name field, and then click **Apply**.
   - **Connector status** This field shows whether the connector is enabled or disabled. You can't change a connector's status from the properties page. You need to use the **Enable** or **Disable** actions in the EMC or the corresponding Shell commands. For detailed steps about enabling or disabling Send connectors, see Enable or Disable a Send Connector.
   - **Modified** This field shows the last date that the connector settings were modified.
   - **Protocol logging level** Use this pull-down list to select the protocol logging level. Select **None** to turn off protocol logging. Select **Verbose** to turn on protocol logging.
   - **Specify the FQDN this connector will provide in response to HELO or EHLO** When a transport server uses this Send connector to transmit outbound messages, it needs to establish an SMTP connection to the destination messaging server. This field specifies the fully qualified domain name (FQDN) used in that SMTP connection to identify the source server. The value of this field is displayed to the destination messaging servers whenever a source server name is required. To learn more about how the value of this field is used, see Understanding Send Connectors.
   - **Maximum message size (KB)** To set a maximum message size for messages that can pass through this connector, select the check box, and then enter a value in KB in the adjacent field. The valid input range is from 0 through 2147483647 KB. To remove any restriction on the maximum message size, clear the check box next to **Maximum message size (KB)**.
4. Use the **Address Space** tab to maintain the list of address spaces for which

this Send connector is responsible.
You can configure either an SMTP address space or a custom address space. Custom address spaces may only be configured on Send connectors that exist on Hub Transport servers. If you use a custom address space type, you must use a smart host to route e-mail.

Note:
Although you can configure custom address spaces on a Send connector, the Hub Transport server still uses SMTP as the transport mechanism to send messages to other messaging servers using this Send connector. To send messages to messaging servers that don't use SMTP as their primary transport mechanism, such as a third-party fax gateway server, you must use a Foreign connector. For more information about Foreign connectors, see Understanding Foreign Connectors.

To configure an address space, do the following:

- **Add** To specify an address space for which this Send connector is responsible, click **Add** or the drop-down arrow located next to **Add**. If you click **Add**, the address space type is SMTP. If you click the drop-down arrow located next to **Add**, you can select **SMTP Address Space** or **Custom Address Space**. For each new address space, you need to configure the following:
  - **Type** This field describes the address space that you enter in the **Address** field. If you clicked **Add**, this field is set to SMTP and is unavailable.
  - **Address** Specify the address space for the Send connector. If you entered **SMTP** or **X400** in the **Type** field, Exchange verifies the syntax of the address space that you enter. Exchange can't verify any other types of addresses; therefore, you need to make sure that you specify any custom addresses using the correct syntax. If you're entering an SMTP address, you can include the wildcard character (*) in the address space as defined in RFC 1035. For example, `*`, `*.com`, and `*.contoso.com` are permitted, but `*contoso.com` isn't permitted.
  - **Include all subdomains** This option is only available when you're specifying an SMTP address space. Select this option if you also want to use this connector to route mail to all subdomains of the specified address space. If you entered an address space that contains the wildcard character, this option is automatically selected.
  - **Cost** Use the address space cost to set the selection priority when more than one Send connector is configured for the same address space. During routing resolution, when the connector selection is made, the least cost routing path to the destination address space is selected. The valid input range is from 1 through 100.
- **Edit** To modify an existing address space in the address space list, select the address space, and then click **Edit**. You can configure the same options described for the **Add** button previously, with the exception of **Type**. You can't change the type of an existing address space.
- **Remove** To delete the domain name from the list of domains, select a domain name, and then click  .
- **Scoped send connector** By default, all Send connectors that you create can be used by all the Hub Transport servers in your Exchange organization. However, you can limit the scope of any Send connector so that it can be used only by other Hub Transport servers that exist in the same Active Directory site. To limit the scope of this Send connector, select **Scoped send connector**.

5. Use the **Network** tab to configure how outbound mail is routed through the

Send connector:

- **Use domain name system (DNS) "MX" records to route mail automatically** Select this option to use DNS to route outbound mail. The connector uses DNS to resolve the IP address of the remote SMTP server.
- **Enable Domain Security (Mutual Auth TLS)** Select this check box to configure this Send connector to attempt to establish a mutual Transport Layer Security (TLS) connection with remote servers when sending mail. There are additional configuration steps required before you can start using TLS. For more information about how to configure mutual TLS, see Using Domain Security: Configuring Mutual TLS.
- **Route mail through the following smart hosts** Select this option to route all outbound mail to specific smart hosts instead of using DNS to resolve the IP addresses of remote SMTP servers.
- **Add** To add a new smart host, click **Add**. You can specify either of the following options in the window that appears:
  IP Address Select this option to identify the smart host by IP address (for example: 192.168.100.1).
  Fully qualified domain name (FQDN) Select this option to identify the smart host by FQDN (for example, smarthost.contoso.com).
- **Edit** To edit an existing smart host, select the smart host, and then click **Edit**.
- **Remove** To remove an existing smart host, select the smart host, and then click  .
- **Smart host authentication** This field shows the authentication type that the connector uses to authenticate with the smart hosts.
  By default, no authentication is used. To configure the smart host authentication settings, click **Change**. You can specify one of the following options in the window that appears:
  • **None** Select this option if the smart host is configured to accept anonymous connections.
  • **Basic Authentication** Select this option if the smart host requires Basic authentication. Basic authentication requires that you provide a user name and password. We strongly recommend that you use an encrypted connection if you're using Basic authentication, because the user name and password are sent in clear text. Select the **Basic Authentication over TLS** check box to enable encryption on the connection. Also, if you specify more than one smart host for this Send connector, all of the specified smart hosts must accept the same user name and password.
  • **Exchange Server Authentication** Select this option to authenticate to a smart host by using an Exchange authentication mechanism, such as TLS direct trust or TLS \Kerberos.
  • **Externally Secured (for example, with IPsec)** Select this option if the connection to the smart host is secured by external means, such as being physically secured over a private network or secured using Internet Protocol security (IPsec). When you select this option, you make an assertion of external security that can't be programmatically verified by Exchange.
- **Use the External DNS Lookup settings on the transport server** Select this option to use the external DNS servers list to resolve the names of the remote SMTP servers.

Important:
Verify that you have configured the external DNS servers list by using the **Set-TransportServer** cmdlet or by using the **External DNS Lookups** tab in the properties of the Hub Transport server object, or the Edge Transport server object.

6. Use the **Source Server** tab to specify the transport servers that can use this Send connector. The list of source servers can contain only Hub Transport servers or only subscribed Edge Transport servers, but not a mix of both. Only those Hub Transport servers in the list use this Send connector for outbound messages. In the case of subscribed Edge Transport servers, the EdgeSync service propagates this Send connector configuration to only the Edge Transport servers in the list.

   Note:
   The **Source Server** tab is only available on Hub Transport servers.

   Select one of the following:
   - **Add** Click to add a Hub Transport server or a subscribed Edge Transport server.
   - **Remove** To remove a server from the list, select the server, and then click  .

     Note:
     Removing a subscribed Edge Transport server from the list doesn't remove the Send connector from the Edge Transport server. It just stops the EdgeSync service from propagating this Send connector configuration to that Edge Transport server.

Use the Shell to configure the properties of a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

You can use the **Set-SendConnector** cmdlet to modify all available settings for an existing Send connector. The following command is an example of how you can use this cmdlet to update the properties of a Send connector. In this example, the following changes are made to the configuration of a Send connector named "Connection to Contoso.com":

- Changes the maximum message size allowed on the connector to 50 MB.
- Enables protocol logging on the Send connector.

```
Set-SendConnector "Connection to Contoso.com" -MaxMessageSize 50MB -ProtocolLoggi
```

The values that you specify by using the **Set-SendConnector** cmdlet parameters replace the existing values configured on the Send connector. This isn't an issue for single value attributes such as maximum message size, but it can be a problem for multivalued attributes such as smart hosts or address spaces. To preserve any existing values in a multivalued attribute, you must specify the existing value and any new values that you want to add when you run the **Set-SendConnector** cmdlet.

For example, assume that you want to add an address space to the "Connection to Contoso.com" Send connector. Currently, this Send connector has a single address space defined, contoso.com, with a cost of 1. You want to add an address space for fabrikam.com with a cost of 10. The following command accomplishes this by specifying the existing value along with the new value being added.

```
Set-SendConnector "Connection to Contoso.com" -AddressSpaces "SMTP:contoso.com;1"
```

If you have numerous values for a multivalued property, you may not want to retype all of the values just to add another value. To avoid that, you can make use of temporary Shell variables. The following example also adds the fabrikam.com address space with a cost of 10 to the "Connection to Contoso.com" Send connector using a temporary variable called *$ConnectorConfiguration*.

```
$ConnectorConfiguration = Get-SendConnector "Connection to Contoso.com"
$ConnectorConfiguration.AddressSpaces += "SMTP:fabrikam.com;10"
Set-SendConnector "Connection to Contoso.com" -AddressSpaces $ConnectorConfigurat
```

For detailed syntax and configuration information, see Set-SendConnector.

1.7.2.11.5 Enable or Disable a Send Connector

Enable or Disable a Send Connector

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the EMC or the Shell to modify the status of an existing Send connector for a computer that has the Microsoft Exchange Server 2010 Edge Transport server role or the Hub Transport server role installed.

In Exchange 2010, Send connectors are responsible for outbound transmission of e-mail messages. A Send connector must be enabled for it to send messages. Disable a Send connector to stop sending messages by using the configuration represented by that connector. By default, when you create a Send connector, it's enabled.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

What Do You Want to Do?

- Use the EMC to modify the status of a Send connector
- Use the Shell to modify the status of a Send connector

Use the EMC to modify the status of a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

1. Perform one of the following:
   - To modify the status of an existing Send connector on an Edge Transport server, in the console tree, select **Edge Transport**, and then click the **Send Connectors** tab.
   - To modify the status of an existing Send connector on a Hub Transport server, in the console tree, expand **Organization Configuration**, select **Hub Transport**, and then click the **Send Connectors** tab.
2. Select a Send connector. If the connector is enabled and you want to disable it, in the action pane, click **Disable**. If the connector is disabled and you want to enable it, in the action pane, click **Enable**.

Use the Shell to modify the status of a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Use the **Set-SendConnector** cmdlet to modify the status of a Send connector.

This example disables the Send connector Contoso.com Send Connector.

```
Set-SendConnector -Identity "Contoso.com Send Connector" -Enabled $false
```

This example enables the same Send connector.

```
Set-SendConnector -Identity "Contoso.com Send Connector" -Enabled $true
```

You may want to temporarily stop all Hub Transport servers from sending messages. To do this, you can disable all Send connectors in your organization. This example first gets a list of all Send connectors using the **Get-SendConnector** cmdlet, and then disables all Send connectors that are returned:

```
Get-SendConnector | Set-SendConnector -Enabled $false
```

For detailed syntax and parameter information, see Set-SendConnector.

1.7.2.11.6 Remove a Send Connector

Remove a Send Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You use Send connectors to create a connection to the Internet and to remote e-mail systems that require a specific configuration. For example, some remote e-mail systems may use a smart host or may require that you send e-mail messages that are larger than your standard Exchange organization limit. This topic shows you how to remove an existing Send connector in Microsoft Exchange Server 2010.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Prerequisites

Removing a Send connector may affect mail flow in your organization. Make sure you understand how the Send connector is being used prior to removing it.

What Do You Want to Do?

Use the EMC to remove a Send connector

Use the Shell to remove a Send connector

Use the EMC to remove a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

1. Open the Exchange Management Console. Perform one of the following steps:
   - To remove an existing Send connector on an Edge Transport server, in the console tree, select **Edge Transport**.
   - To remove an existing Send connector on a Hub Transport server, expand **Organization Configuration** in the console tree, and select **Hub Transport**.
2. In the work pane, click the **Send Connectors** tab, and select the Send connector to remove.
3. Under the name of the Send connector in the action pane, click **Remove**.
4. A warning appears that asks you, "Are you sure you want to remove *<selected Send connector>*?" Click **Yes**.

Use the Shell to remove a Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Use the **Remove-SendConnector** cmdlet to remove a Send connector. This example removes the existing Send connector connection to Contoso.com.

```
Remove-SendConnector "Connection to Contoso.com"
```

For detailed syntax and parameter information, see Remove-SendConnector.

1.7.2.11.7 Create an SMTP Receive Connector

Create an SMTP Receive Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Receive connectors represent a logical gateway through which all inbound messages are received. Receive connectors are configured on a per-server basis, and they control how that server receives messages from the Internet, e-mail clients, and other messaging servers.

By default, the Receive connectors required for internal mail flow are automatically created when the Hub Transport server role is installed. Similarly, when you install the Edge Transport server role, the Receive connector capable of receiving mail from the Internet and from Hub Transport servers is automatically created. However, end-to-end mail flow is possible only after the Edge Transport server has been subscribed to the Active Directory

site by using the Edge Subscription process. Other scenarios, such as an Internet-facing Hub Transport server or an Edge Transport server that doesn't use EdgeSync, require manual connector configuration to establish end-to-end mail flow.

You can use the EMC or the Shell to create a new Receive connector for Microsoft Exchange Server 2010.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Prerequisites

You should determine the specific usage for the Receive connector before you create it so you can correctly configure its properties. To learn more about Receive connectors, see Understanding Receive Connectors.

What Do You Want to Do?

- Use the EMC to create a Receive connector
- Use the Shell to create a Receive connector

Use the EMC to create a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

1. Open the Exchange Management Console. Perform one of the following:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
   - To create a Receive connector on a Hub Transport server role, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the result pane, select the server on which you want to create the connector, and then click the **Receive Connectors** tab.
2. In the action pane, click **New Receive Connector**. The New SMTP Receive Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   - In the **Name** field, type a meaningful name for this connector. Specify a name for the Receive connector that helps you distinguish this Receive connector from other Receive connectors in your configuration.
   - In the **Select the intended use for this Receive connector** field, select the usage type for this connector. The usage type determines the permissions granted to sessions that connect to the Receive connector and the supported authentication mechanisms. The following usage types are available:

     Client Client Receive connectors receive e-mail from users of Microsoft Exchange. This connector is configured to only accept client submissions from authenticated Microsoft Exchange users.

The **Client** usage type is only available for Receive connectors configured on Hub Transport servers.
Custom Select this option to create a customized connector that connects with systems that don't include servers running Exchange.
Internet Internet Receive connectors receive e-mail from servers on the Internet. This connector is configured to accept connections from anonymous users.

Note:
We strongly recommend against configuring Receive connectors to accept anonymous connections from unknown IPv6 addresses. If you configure a Receive connector to accept anonymous connections from unknown IPv6 addresses, the amount of spam that enters your organization is likely to increase. Currently, there is no broadly accepted industry standard protocol for looking up IPv6 addresses. Most IP Block list providers don't support IPv6 addresses. Therefore, if you allow anonymous connections from unknown IPv6 addresses on a Receive connector, you increase the chance that spam messages bypass IP Block list providers and are successfully delivered into your organization.

Internal Internal Receive connectors are used to receive e-mail from servers within your Exchange organization. This connector is configured to only accept connections from Exchange servers.
Partner Partner Receive connectors are used to receive e-mail from partner domains. This connector is configured to receive mail from domains included in the list of secure receive domains. You can add domains to this list by using the *TLSReceiveDomainSecureList* parameter in the **Set-TransportConfig** command. Mutually authenticated TLS connections are required for domains that are on this list.

- Click **Next**.

4. On the **Local network settings** page, do the following:
   - Specify the IP addresses and port numbers on which this Receive connector listens for incoming mail. The **Local network settings** page appears only if you selected a usage type of **Custom**, **Partner**, or **Internet** in step 3. By default, all available local IP addresses are listed. The following options are available:

Add To add a new IP address or port number, click **Add** and specify the following:
• **Use all IP addresses available on this server** Select this option to use all IP addresses associated with this computer. This is the recommended option.
• **Specify an IP address** Select this option to use a specific IP address associated with this computer.

Important:
You must specify a local IP address that's valid for the Hub Transport server or Edge Transport server on which the Receive connector is located. If you specify an invalid local IP address, the Microsoft Exchange Transport service may fail to start when the service is restarted.

• **Port** This field identifies the TCP port number on which this Receive connector listens for incoming mail. TCP port 25 is the default port used for message transmission between SMTP servers.
Edit Click **Edit** to change an existing IP address or port.

Remove Click  to remove an existing IP address.

- In the **Specify the FQDN this connector will provide in response to HELO or EHLO** field, type the name advertised in response to the SMTP HELO or EHLO verb. If you leave this field blank, the fully qualified domain name (FQDN) of the Hub Transport server or Edge Transport server is automatically added when the connector is created.
- Click **Next**.

5. On the **Remote network settings** page, enter the IP address or IP address range of the remote servers from which the connector accepts incoming connections. The **Remote network settings** page appears only if you selected a usage type of **Custom**, **Partner**, **Internal**, or **Client** in step 3. To add the remote IP address or remote IP address range, use one of the following methods:
   Add - IP Address To enter an IP address without a subnet mask, or to specify the subnet mask by using Classless Interdomain Routing (CIDR) notation, click **Add** or the drop-down arrow next to **Add** and select **IP Address**. In the **Add IP address(es) of Remote Servers** dialog box, enter the IP address directly or specify a subnet using the CIDR notation. For example, if you enter 192.168.1.1, the Receive connector accepts messages from that host only, but if you specify 192.168.1.0/24, the Receive connector accepts messages from the entire class C subnet of 192.168.1.0.
   Add - IP and Mask To enter an IP address or subnet together with a subnet mask in dotted decimal notation, click the drop-down arrow next to **Add** and select **IP and Mask**. In the **Add Remote Servers - IP and Mask** dialog box, specify the IP address and the subnet mask.
   Add - IP Range To specify an IP address range by using the first IP address and the last IP address in the range, click the drop-down arrow next to **Add** and select **IP Range**. In the **Add Remote Servers - IP Range** dialog box, specify the start and end addresses of the IP range.
   Edit To edit an existing IP address range, select the IP address range, and then click **Edit**.
   Remove To remove an existing IP address range, select the IP address range, and then click  .
   After you finish, click **Next**.

6. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Receive connector by using the settings in the configuration summary, click **New**.

7. On the **Completion** page, click **Finish**.

Use the Shell to create a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

This example creates a Receive connector on the local server that has the default settings for the **Internal** usage type, and accepts connections from the specified remote IP address range.

```
New-ReceiveConnector -Name "Contoso.com Receive Connector" -Usage Internal -Remot
```

For detailed syntax and parameter information, see New-ReceiveConnector.

1.7.2.11.8 Configure Receive Connector Properties

Configure Receive Connector Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-26*

Receive connectors represent a logical gateway through which all inbound messages are received. Receive connectors are configured on a per-server basis, and they control how that server receives messages from the Internet, e-mail clients, and other messaging servers.

By default, the Receive connectors required for internal mail flow are automatically created when the Hub Transport server role is installed. Similarly, when you install the Edge Transport server role, the Receive connector capable of receiving mail from the Internet and from Hub Transport servers is automatically created. However, end-to-end mail flow is possible only after the Edge Transport server is subscribed to the Active Directory site by using the Edge Subscription process. Other scenarios, such as an Internet-facing Hub Transport server or an Edge Transport server that doesn't use EdgeSync, require manual connector configuration to establish end-to-end mail flow.

You can use the EMC or the Shell to configure the properties of a Receive connector.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Prerequisites

- You must have an existing Receive connector. For detailed steps about creating a Receive connector, see Create an SMTP Receive Connector.
- You should determine the specific usage for this Receive connector so you can correctly configure its properties. To learn more about Receive connectors, see Understanding Receive Connectors.

What Do You Want to Do?

- Use the EMC to configure the properties of a Receive connector
- Use the Shell to configure the properties of a Receive connector

Use the EMC to configure the properties of a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

1. If you are configuring a Receive connector on a Hub Transport server, expand **Server Configuration** in the console tree, and select **Hub Transport**. On an Edge Transport server, select **Edge Transport** in the console tree.
2. In the work pane, select the **Receive Connectors** tab, and then double-click

the Receive connector you want to configure.

3. Use the **General** tab to modify the general properties of the Receive connector:
   - **Connector name** To rename the connector, type a new name in the **Connector name** field, and then click **Apply**.
   - **Connector status** This field shows whether the connector is enabled. You can't change a connector's status from the properties page. You need to use the **Enable** or **Disable** actions in the EMC or the corresponding Shell commands. For detailed steps about enabling or disabling Receive connectors, see Enable or Disable a Receive Connector.
   - **Modified** This field shows the last date that the connector settings were modified.
   - **Protocol logging level** Use this drop-down list to select the protocol logging level. Select **None** to turn off protocol logging. Select **Verbose** to turn on protocol logging.
   - **Specify the FQDN this connector will provide in response to HELO or EHLO** This field specifies the fully qualified domain name (FQDN) that the transport server uses to identify itself whenever a destination server name is required during an inbound SMTP connection. To learn more about how the value of this field is used, see Understanding Receive Connectors.
   - **Maximum message size (KB)** To set a maximum message size for messages that can pass through this connector, select the check box next to **Maximum message size (KB)** and enter a value in kilobytes (KB). The valid input range is from 64 through 2097151 KB. To remove any restriction on the maximum message size, clear the check box next to **Maximum message size (KB)**.

4. Use the **Network** tab to specify the IP addresses and TCP ports on which this Receive connector receives connections. You can also configure the IP address ranges from which this Receive connector accepts connections. The following options are available:
   - **Use these local IP Addresses to receive mail** Use this list to specify the IP addresses and port numbers on which this Receive connector listens for incoming mail. For each entry, you must specify a different set of IP addresses or specify all available IP addresses. The following options are available:

     Add To add a new IP address or port number, click **Add.** The following options are available in the window that appears:
     • **Use all IP addresses available on this server** Select this option to use all IP addresses associated with this computer. This is the recommended option.
     • **Specify an IP address** Select this option to use a specific IP address associated with this computer.

     Important:
     You must specify a local IP address that's valid for the Hub Transport server or Edge Transport server on which the Receive connector is located. If you specify an invalid local IP address, the Microsoft Exchange Transport service may fail to start when the service is restarted.

     • **Port** This field identifies the TCP port number on which this Receive connector listens for incoming mail. TCP port 25 is the default port used for message transmission between SMTP servers.
     Edit Click **Edit** to change an existing IP address or port.
     Remove Click  to remove an existing IP address.
   - **Receive mail from remote servers that have these IP addresses** Use this list to specify the IP address or IP address range from which this Receive connector accepts connections. To add the remote IP address or

remote IP address range, use one of the following methods:

Add - IP Address To enter an IP address without a subnet mask, or to specify the subnet mask by using Classless Interdomain Routing (CIDR) notation, click **Add** or the drop-down arrow next to **Add** and select **IP Address**. In the **Add IP address(es) of Remote Servers** dialog box, enter the IP address directly or specify a subnet using the CIDR notation. For example, if you enter 192.168.1.1, the Receive connector accepts messages from that host only, but if you specify 192.168.1.0/24, the Receive connector accepts messages from the entire class C subnet of 192.168.1.0.

Add - IP and Mask To enter an IP address or subnet together with a subnet mask in dotted decimal notation, click the drop-down arrow next to **Add** and select **IP and Mask**. In the **Add Remote Servers - IP and Mask** dialog box, specify the IP address and the subnet mask.

Add - IP Range To specify an IP address range by using the first IP address and the last IP address in the range, click the drop-down arrow next to **Add** and select **IP Range**. In the **Add Remote Servers - IP Range** dialog box, specify the start and end addresses of the IP range.

Edit To edit an existing IP address range, select the IP address range, and then click **Edit**.

Remove To remove an existing IP address range, select the IP address range, and then click  .

5. Use the **Authentication** tab to configure security options for incoming SMTP connections:
   - **Transport Layer Security (TLS)** Select this option to offer Transport Layer Security (TLS) transmission for all messages received by this connector. When you select this option, the **STARTTLS** keyword is advertised in the EHLO response to connecting SMTP servers, and TLS authentication is accepted.
     - **Enable Domain Security (Mutual Auth TLS)** To instruct this Receive connector to accept a mutual TLS connection from a remote server, select this check box. There are additional configuration steps required before you can enable mutual TLS. For more information about configuring mutual TLS, see Using Domain Security: Configuring Mutual TLS.
   - **Basic Authentication** Select this option to offer Basic authentication for all mail received by this connector. When you select **Basic Authentication**, the **AUTH** keyword is advertised in the EHLO response to connecting SMTP servers, and Basic authentication is accepted. Because the user name and password are sent in plaintext when Basic authentication is used, Basic authentication without encryption isn't recommended.
     - **Offer Basic Authentication only after starting TLS** When you select this option, the connector starts TLS first, and then after TLS encryption is complete, the connector offers Basic authentication.
   - **Exchange Server authentication** Select this option to authenticate by using an Exchange authentication mechanism, such as TLS direct trust or Kerberos through TLS.
   - **Integrated Windows authentication** Select this option to use Integrated Windows authentication, which represents NTLM, Kerberos, and Negotiate authentication mechanisms.
   - **Externally Secured (for example, with IPsec)** Use this option if the incoming connections to this Receive connector are secured by external means. For example, use this option if the connection is physically secured over a private network or by using Internet Protocol security (IPsec). When you select this option, you make an assertion of external security that can't

be programmatically verified by Exchange. Before you select this authentication method, you must first select the **Exchange servers** permissions group on the **Permission Groups** tab.

6. Use the **Permission Groups** tab to select the permission groups assigned to this Receive connector. A permission group is a predefined set of permissions granted to well-known groups of users, computers, or security groups. Members of the selected permission groups on this tab are allowed to submit messages to this Receive connector.

   Important:
   When selected on this tab, each permission group is granted a different set of permissions. For example, members of the Exchange users permission group are granted the ms-Exch-Bypass-Anti-Spam extended right whereas anonymous users aren't. To see a complete list of extended rights granted to each permission group, see "Permission Groups" in Understanding Receive Connectors.

   The following options are available:
   - **Anonymous users** Non-authenticated users
   - **Exchange users** Authenticated user accounts
   - **Exchange servers** Members of the Exchange Servers universal security group
   - **Legacy Exchange servers** Members of the ExchangeLegacyInterop universal security group
   - **Partners** Partner service accounts

Use the Shell to configure the properties of a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

You can use the **Set-ReceiveConnector** cmdlet to modify all available settings for an existing Receive connector. In this example, the following changes are made to the configuration of the Receive connector Connection from Contoso.com:

- Change the maximum message size allowed on the connector to 50 megabytes (MB).
- Enable protocol logging on the Receive connector.
- Set the tarpitting interval.

```
Set-ReceiveConnector "Connection from Contoso.com" -MaxMessageSize 50MB -Protocol
```

The values that you specify by using the **Set-ReceiveConnector** cmdlet parameters replace the existing values configured on the Receive connector. This isn't an issue for single value attributes such as maximum message size, but it can be a problem for multivalued attributes such as remote IP address ranges. To preserve any existing values in a multivalued attribute, you must specify the existing value and any new values that you want to add when you run the **Set-ReceiveConnector** cmdlet.

For example, assume that you want to add the subnet 10.0.10.0/24 to the IP addresses from which the Connection from Contoso.com Receive connector accepts messages. Currently, this Receive connector is configured to accept messages only from the IP range of 192.168.180.0 to 192.168.180.255. This example does this by specifying the existing value along with the new value being added.

```
Set-ReceiveConnector "Connection from Contoso.com" -RemoteIPRanges "10.0.10.0/24"
```

If you have numerous values for a multivalued property, you may not want to retype all of

the values just to add another value. Instead, you can use temporary Shell variables. This example also adds the 10.0.10.0/24 subnet to the remote IP ranges of the Connection from Contoso.com connector using the temporary variable *$ConnectorConfiguration*.

```
$ConnectorConfiguration = Get-ReceiveConnector "Connection from Contoso.com"
$ConnectorConfiguration.RemoteIPRanges += "10.0.10.0/24"
Set-ReceiveConnector "Connection from Contoso.com" -RemoteIPRanges $ConnectorConf
```

When you specify a tarpitting interval time on a Receive connector, tarpitting is enabled. The default value is 5 seconds, and we recommend that you start at this value. Use caution if you decide to change this value. An overly long interval could disrupt ordinary mail flow, whereas an overly brief interval may not be as effective in thwarting a directory harvest attack. If you change the tarpitting interval value, do it in small increments.

The following example changes the tarpitting interval of the "Connection from Contoso.com" connector by increasing it to 6 seconds.

```
Set-ReceiveConnector "Connection from Contoso.com" -TarpitInterval 00:00:06
```

For detailed syntax and configuration information, see Set-ReceiveConnector.

1.7.2.11.9 Modify the Default SMTP Banner

Modify the Default SMTP Banner

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The *SMTP banner* is the SMTP connection response that a remote SMTP messaging server receives after it connects to a Receive connector configured on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed. You may want to modify the default SMTP banner for Internet-facing SMTP Receive connectors on an Edge Transport server so that the server name and messaging server software aren't disclosed by the SMTP banner.

Looking for other management tasks related to connectors? Check out Managing Connectors.

Use the Shell to modify the default SMTP banner

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Note:

You can't use the EMC to modify the default SMTP banner. Don't use the **Specify the FQDN this connector will provide in response to EHLO or HELO** field in the Receive connector properties page in the EMC.

You control the SMTP banner by using the *Banner* parameter in the **Set-ReceiveConnector** cmdlet or the **New-ReceiveConnector** cmdlet. The default value of the *Banner* parameter is `$null`. When the *Banner* parameter isn't specified on a Receive connector, or the *Banner* parameter is specified with the value of `$null`, a remote SMTP

messaging server that connects to that Receive connector receives the following response.

```
220 <Servername> Microsoft ESMTP MAIL service ready at <RegionalDay-Date-24HourTi
```

When you specify a value for the *Banner* parameter on a Receive connector, a remote SMTP messaging server that connects to that SMTP Receive connector receives the following response.

```
<220 BannerText>
```

Note:
The replacement SMTP banner text string must always start with 220. As defined in RFC 2821, the default service ready SMTP response code is 220.

This example modifies the SMTP banner on the existing Receive connector From the Internet so the SMTP banner displays 220 Contoso Corporation.

```
Set-ReceiveConnector "From the Internet" -Banner "220 Contoso Corporation"
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

1.7.2.11.10 Allow Anonymous Relay on a Receive Connector

Allow Anonymous Relay on a Receive Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to create and configure a Receive connector that allows anonymous relay.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Prerequisites

Allowing anonymous relay on a Receive connector is a security risk, especially on Internet-facing servers. Make sure you fully understand the implications by reading the "Using a Receive Connector for Anonymous Relay" section in Understanding Receive Connectors.

Grant the relay permission to anonymous connections

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

You can create the Receive connector using either EMC or the Shell; however, you must use the Shell to grant the relay permission to anonymous connections.

Use the EMC to create the Receive connector

1. Perform one of the following steps:

1.a.To create a Receive connector on a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
1.b.To create a Receive connector on a Hub Transport server role, in the console tree, expand **Server Configuration** and select **Hub Transport**. In the result pane, select the server on which you want to create the connector, and then click the **Receive Connectors** tab.
2. In the action pane, click **New Receive Connector**. The New Receive Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a.In the **Name** field, type a meaningful name for this connector. This name is used to identify the connector.
   3.b.In the **Select the intended use for this Receive connector** field, select **Custom**.
   3.c.Click **Next**.
4. On the **Local Network settings** page, follow these steps:
   4.a.Select the existing **All Available IPv4** entry, and then click  .
   4.b.Click **Add**. In the **Add Receive Connector Binding** dialog box, select **Specify an IP address**. Type an IP address assigned to a network adapter on the local server that's best able to communicate with the remote messaging server. In the **Port** field, type **25**, and then click **OK**. Leave the **Specify the FQDN this connector will provide in response to HELO or EHLO** field blank.
   4.c.Click **Next**.
5. On the **Remote Network settings** page, follow these steps:
   5.a.Select the existing **0.0.0.0 - 255.255.255.255** entry, and then click  .
   5.b.Click **Add** or the drop-down arrow located next to **Add** and type the IP address or IP address range for the remote messaging server or servers that are allowed to relay mail on this server. When you're finished entering the IP addresses, click **OK**.
   5.c.Click **Next**.
6. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Receive connector by using the settings in the configuration summary, click **New**.
7. On the **Completion** page, click **Finish**.
8. In the work pane, select the Receive connector that you created.
9. Under the name of the Receive connector in the action pane, click **Properties** to open the **Properties** page.
10. Click the **Permission Groups** tab. Select **Anonymous users**.
11. Click **OK** to save your changes and exit the **Properties** page.

Use the Shell to create the Receive connector

This example uses the **New-ReceiveConnector** cmdlet to create the Receive connector Anonymous Relay that listens on local IP address 10.2.3.4 on port 25 from a source server at IP address 192.168.5.77.

```
New-ReceiveConnector -Name "Anonymous Relay" -Usage Custom -PermissionGroups Anon
```

For detailed syntax and configuration information, see New-ReceiveConnector.

Use the Shell to grant relay permission to anonymous connections on the new Receive connector

Note:
You can't use the EMC to perform this task.

This example retrieves the specified Receive connector information and pipes the result to the **Add-ADPermission** cmdlet to grant relay permission to anonymous connections on the new Receive connector.

```
Get-ReceiveConnector "Anonymous Relay" | Add-ADPermission -User "NT AUTHORITY\ANO
```

For detailed syntax and configuration information, see Get-ReceiveConnector or Add-ADPermission.

Configure the Receive connector as externally secured

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Use the EMC to create the Receive connector as externally secured

1. Perform one of the following steps:
   1.a. To create a Receive connector on a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
   1.b. To create a Receive connector on a Hub Transport server role, in the console tree, expand **Server Configuration** and select **Hub Transport**. In the result pane, select the server on which you want to create the connector, and then click the **Receive Connectors** tab.
2. In the action pane, click **New Receive Connector**. The New Receive Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a. In the **Name** field, type a meaningful name for this connector. This name is used to identify the connector.
   3.b. In the **Select the intended use for this Receive connector** field, select **Custom**.
   3.c. Click **Next**.
4. On the **Local Network settings** page, follow these steps:
   4.a. Select the existing **All Available** entry, and then click  .
   4.b. Click **Add**. In the **Add Receive Connector Binding** dialog box, select **Specify an IP address**. Type an IP address assigned to a network adapter on the local server that's best able to communicate with the remote messaging server. In the **Port** field, type **25**, and then click **OK**. Leave the **Specify the FQDN this connector will provide in response to HELO or EHLO** field blank.
   4.c. Click **Next**.
5. On the **Remote Network settings** page, follow these steps:
   5.a. Select the existing **0.0.0.0 - 255.255.255.255** entry, and then click  .
   5.b. Click **Add** or the drop-down arrow located next to **Add** and type the IP address or IP address range for the remote messaging server or servers that are allowed to relay mail on this server. When you're finished entering the IP addresses, click **OK**.
   5.c. Click **Next**.
6. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Receive connector by using the settings in the configuration summary, click **New**.
7. On the **Completion** page, click **Finish**.
8. In the work pane, select the Receive connector that you created.
9. Under the name of the Receive connector in the action pane, click **Properties** to open the **Properties** page.
10. Click the **Permission Groups** tab. Select **Exchange servers**.
11. Click the **Authentication** tab. Select **Externally Secured (for example, with IPsec)**.

12.Click **OK** to save your changes and exit the **Properties** page.

Use the Shell to create the Receive connector as externally secured

This example creates the Receive connector Anonymous Relay that listens on local IP address 10.2.3.4 on port 25 from a source server at IP address 192.168.5.77.

```
New-ReceiveConnector -Name "Anonymous Relay" -Usage Custom -AuthMechanism Externa
```

For detailed syntax and configuration information, see New-ReceiveConnector.

1.7.2.11.11 Enable or Disable a Receive Connector

Enable or Disable a Receive Connector

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the EMC or the Shell to modify the status of an existing Receive connector for a computer that has the Microsoft Exchange Server 2010 Edge Transport server role or the Hub Transport server role installed.

In Exchange 2010, you use Receive connectors to accept e-mail messages from remote e-mail systems. A Receive connector must be enabled for it to accept messages. Disable a Receive connector to stop accepting messages by using the configuration represented by that connector. By default, when you create a Receive connector, it's enabled.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Looking for other management tasks related to connectors? Check out Managing Connectors.

What Do You Want to Do?

- Use the EMC to modify the status of a Receive connector
- Use the Shell to modify the status of a Receive connector

Use the EMC to modify the status of a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

1. Perform one of the following:
   - To modify the status of an existing Receive connector on an Edge Transport server, in the console tree, select **Edge Transport**, and then click the **Receive Connectors** tab.
   - To modify the status of an existing Receive connector on a Hub Transport

server, in the console tree, expand **Organization Configuration**, select **Hub Transport**, and then click the **Receive Connectors** tab.

2. Select a Receive connector. If the connector is enabled and you want to disable it, in the action pane, click **Disable**. If the connector is disabled and you want to enable it, in the action pane, click **Enable**.

Use the Shell to modify the status of a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Use the **Set-ReceiveConnector** cmdlet to modify the status of a Receive connector.

This example disables the Receive connector Contoso.com Receive Connector.

```
Set-ReceiveConnector -Identity "Contoso.com Receive Connector" -Enabled $false
```

This example enables the same Receive connector.

```
Set-ReceiveConnector -Identity "Contoso.com Receive Connector" -Enabled $true
```

You may want to temporarily stop all of your Hub Transport servers from accepting messages. To do this, you can disable all Receive connectors in your organization. This example first gets a list of all Receive connectors using the **Get-ReceiveConnector** cmdlet, and then disables all Receive connectors that are returned:

```
Get-ReceiveConnector | Set-ReceiveConnector -Enabled $false
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

1.7.2.11.12 Remove a Receive Connector

Remove a Receive Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the EMC or the Shell to remove a Receive connector in Microsoft Exchange Server 2010. Receive connectors accept e-mail messages from the Internet and from remote e-mail systems that require specific configuration options.

Caution:

Deleting a Receive connector may affect mail flow throughout the organization. Make sure you understand how the Receive connector is being used before you remove it.

Looking for other management tasks related to connectors? Check out Managing Connectors.

What Do You Want to Do?

- Use the EMC to remove a Receive connector
- Use the Shell to remove a Receive connector

Use the EMC to remove a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

1. Perform one of the following:
   - To remove an existing Receive connector on an Edge Transport server, in the console tree, select **Edge Transport**, and then click the **Receive Connectors** tab.
   - To remove an existing Receive connector on a Hub Transport server, expand **Server Configuration** in the console tree, and select **Hub Transport**. In the result pane, select the server that has the Receive connector that you want to remove, and then click the **Receive Connectors** tab.
2. In the work pane, select the Receive connector to remove.
3. Under the name of the Receive connector in the action pane, click **Remove**.
4. A message appears asking "**Are you sure you want to remove** *selected Receive connector***?"** Click **Yes**.

Use the Shell to remove a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Use the **Remove-ReceiveConnector** cmdlet to remove a Receive connector. This example removes the Receive connector `Connection from Contoso.com`.

```
Remove-ReceiveConnector "Connection from Contoso.com"
```

For detailed syntax and parameter information, see Remove-ReceiveConnector.

1.7.2.11.13 Create a Foreign Connector

Create a Foreign Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the Shell to create a Foreign connector for Microsoft Exchange Server 2010. A Foreign connector can only be installed on a computer running Exchange 2010 that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism. These messaging servers are known as foreign gateway servers. Examples of foreign gateway servers include Lotus Notes and third-party fax gateway servers. The address spaces assigned to a Foreign connector may be SMTP or non-SMTP.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Prerequisites

- You should determine the specific usage for this Foreign connector so you can correctly configure its properties. To learn more about Foreign connectors, see Understanding Foreign Connectors.
- Exchange 2010 introduces a new feature called Delivery Agent connector, which is also used to route messages to foreign systems that don't use SMTP. Delivery Agent connectors provide better administrative control for messages addressed to foreign systems. Whenever possible, you should consider using Delivery Agent connectors instead of Foreign connectors. To learn more about Delivery Agent connectors, see Understanding Delivery Agents.

Use the Shell to create a Foreign connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

Use the **New-ForeignConnector** cmdlet to create a Foreign connector.

Note:

You can't create a Foreign connector by using the EMC. To create a Foreign connector, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example creates a Foreign connector that has the following settings:

- The connector sends messages to the X.400 address space o=MySite;p=MyOrg;a=contoso;c=us. The address space cost is 1.
- The connector is assigned to Hub Transport servers Hub01 and Hub02.

```
New-ForeignConnector -Name "Contoso.com Foreign Connector" -AddressSpaces "X400:o
```

For detailed syntax and parameter information, see New-ForeignConnector.

1.7.2.11.14 View the Configuration of a Foreign Connector

View the Configuration of a Foreign Connector

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the Exchange Management Shell to view the configuration of an existing Foreign connector for a computer that has the Microsoft Exchange Server 2010 Hub Transport server role installed.

A Foreign connector can only be installed on a computer running Exchange 2010 that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism.

Looking for other management tasks related to connectors? Check out Managing

Connectors.

Use the Shell to view the configuration of a Foreign connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view the configuration of a Foreign connector.

You can use the **Get-ForeignConnector** cmdlet to view the configuration of a Foreign connector. The *Identity* parameter specifies the Foreign connector that you want to view. The *Identity* parameter can be the GUID or the name of the Foreign connector. If you don't specify an identity, the command returns the configuration information for all Foreign connectors.

This example returns a list of all Foreign connectors in your organization.

```
Get-ForeignConnector
```

This example displays the detailed configuration of the Foreign connector Contoso.com Foreign Connector.

```
Get-ForeignConnector "Contoso.com Foreign Connector" | Format-List
```

For detailed syntax and parameter information, see Get-ForeignConnector.

1.7.2.11.15 Modify the Configuration of a Foreign Connector

Modify the Configuration of a Foreign Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to modify a Foreign connector for Microsoft Exchange Server 2010. A Foreign connector can only be installed on a computer running Exchange 2010 that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Prerequisites

You must have an existing Foreign connector. For detailed steps about creating a Foreign connector, see Create a Foreign Connector.

Use the Shell to modify a Foreign

connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

You can use the **Set-ForeignConnector** cmdlet to modify all available settings for a Foreign connector.

Note:

You can't modify the configuration of a Foreign connector by using the Exchange Management Console. To modify the configuration of a Foreign connector, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example makes the following changes to the settings on the Foreign connector Contoso.com Foreign Connector:

- Change the maximum message size allowed on the connector to 50 MB.
- Add a new address space for the SMTP domain named Contoso.com that has an address space cost of 5. You want to preserve the existing X.400 address space **o=MySite;p=MyOrg;a=contoso;c=us** that has an address space cost of 1, which is already configured on the connector.

```
Set-ForeignConnector "Contoso.com Foreign Connector" -AddressSpaces "X400:o=MySit
```

For detailed syntax and configuration information, see Set-ForeignConnector.

1.7.2.11.16 Configure the Drop Directory

Configure the Drop Directory

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-21*

You can use the Shell to configure the Drop directory used by a Foreign connector in Microsoft Exchange Server 2010. Every Foreign connector installed on or assigned to a computer running Exchange 2010 that has the Hub Transport server role installed uses a different Drop directory. The Drop directory is used by the Foreign connector to send messages to the foreign gateway server that doesn't use SMTP to transmit messages. Messages sent to recipients that exist in the address space defined on the Foreign connector are copied into the Drop directory of the Foreign connector.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Prerequisites

- You must have an existing Foreign connector. For detailed steps about creating a foreign connector, see Create a Foreign Connector.
- You must have created the Drop directory for your Foreign connector. By default, the Drop directory isn't created automatically when you create a Foreign connector. You must manually create each Drop directory folder in Windows Explorer.

What Do You Want to Do?

- Use the Shell to configure the Drop directory location
- Use the Shell to configure the maximum size of the Drop directory

Use the Shell to configure the Drop directory location

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub server" entry in the Transport Permissions topic.

Two items control the location of the Drop directory for each Foreign connector:

- The RootDropDirectoryPath parameter in the **Set-TransportServer** cmdlet
  This option is used for all Foreign connectors that exist on the Hub Transport server. The value of the *RootDropDirectoryPath* parameter may be a local path or a Universal Naming Convention (UNC) path to a remote server. By default, the value of this parameter is blank. This indicates the value of the *RootDropDirectoryPath* parameter is the Exchange 2010 installation folder. The default Exchange 2010 installation folder is C:\Program Files\Microsoft \Exchange Server\.
- The DropDirectory parameter in the **Set-ForeignConnector** cmdlet
  This value is set for each Foreign connector that exists on the Hub Transport server. The value of the *DropDirectory* parameter may be a simple directory name or an absolute file path. If the value of the *RootDropDirectoryPath* is specified, the value of the *DropDirectory* parameter must be a simple directory name. If the value of the *RootDropDirectoryPath* isn't specified, the *DropDirectory* parameter may contain absolute path information or may be a simple directory name. By default, the value of the *DropDirectory* parameter is the name of the Foreign connector.
  If the value of the *DropDirectory* parameter doesn't contain absolute path information, the location of the Drop directory is defined by the combination of the *DropDirectory* and the *RootDropDirectoryPath* parameters. If the value of the *DropDirectory* parameter contains absolute path information, the value of the *RootDropDirectoryPath* parameter must be unspecified.

Note:

You can't configure the Drop directory by using the EMC. To configure the Drop directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example sets the root Drop directory for all Foreign connectors on the Exchange 2010 computer Hub01 to C:\Drop Directory. Then it configures the Foreign connector Fax Connector to use the Drop directory Fax. As a result of running these two commands, the Fax Connector Foreign connector uses C:\Drop Directory\Fax folder as its Drop directory.

```
Set-TransportServer Hub01 -RootDropDirectoryPath "C:\Drop Directory"
Set-ForeignConnector "Fax Connector" -DropDirectory "Fax"
```

When you change the location of the Drop directory, you have to be aware of the following:

- Changing the location of the Drop directory doesn't copy any existing message files from the old Drop directory to the new Drop directory. The new Drop directory location is active almost immediately after the configuration change, but any existing message files are left in the old Drop directory.
- The Drop directory must have the following permissions assigned to it:
  - Network Service: Full Control
  - System: Full Control

- Administrators: Full Control

For detailed syntax and parameter information, see Set-TransportServer and Set-ForeignConnector.

Use the Shell to configure the maximum size of the Drop directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

The maximum size of the Drop directory used by a Foreign connector is controlled by the **Set-ForeignConnector** cmdlet. When the specified maximum value is reached, no new message files can be copied into the Drop directory until the existing messages are delivered and deleted. By default, the maximum size of the Drop directory is `unlimited`.

Note:
You can't configure the Drop directory by using the EMC. To configure the Drop directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example sets the maximum size of the Drop directory to 400 MB for the Foreign connector named "Fax Connector."

```
Set-ForeignConnector "Fax Connector" -DropDirectoryQuota 400MB
```

The valid input range for this parameter is from 1 byte through about 2GB (2147483647 bytes).

For detailed syntax and parameter information, see Set-ForeignConnector.

1.7.2.11.17 Enable or Disable a Foreign Connector

Enable or Disable a Foreign Connector

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the Shell to enable or disable an existing Foreign connector for Microsoft Exchange Server 2010. A Foreign connector can only be installed on a computer running Exchange 2010 that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Prerequisites

You must have an existing Foreign connector. For detailed steps about creating a Foreign connector, see Create a Foreign Connector.

Use the Shell to enable or disable a Foreign connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

You can use the **Set-ForeignConnector** cmdlet to enable or disable a Foreign connector. The *Identity* parameter specifies the Foreign connector that you want to enable or disable. The *Identity* parameter can be the GUID or the name of the Foreign connector.

Note:

You can't enable or disable a Foreign connector by using the Exchange Management Console. To enable or disable a Foreign connector, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example disables the Foreign connector Contoso.com Foreign Connector.

```
Set-ForeignConnector "Contoso.com Foreign Connector" -Enabled $False
```

This example enables the same Foreign connector.

```
Set-ForeignConnector "Contoso.com Foreign Connector" -Enabled $True
```

This example disables all Foreign connectors in your organization.

```
Get-ForeignConnector | Set-ForeignConnector -Enabled $False
```

For detailed syntax and parameter information, see Set-ForeignConnector.

1.7.2.11.18 Remove a Foreign Connector

Remove a Foreign Connector

Transport > Managing Transport Servers > Managing Connectors >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to remove an existing Foreign connector in Microsoft Exchange Server 2010. A Foreign connector can only be installed on a computer running Exchange 2010 that has the Hub Transport server role installed. A Foreign connector uses a Drop directory to send messages to a local messaging server that doesn't use SMTP as its primary transport mechanism.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Use the Shell to remove a Foreign connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Foreign connectors" entry in the Transport Permissions topic.

You can use the **Remove-ForeignConnector** cmdlet to remove a Foreign connector. The *Identity* parameter specifies the Foreign connector that you want to remove. The *Identity* parameter can be the GUID or the name of the Foreign connector.

Note:

You can't remove a Foreign connector by using the Exchange Management Console. To remove a Foreign connector, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example removes the Foreign connector Contoso.com Foreign Connector.

```
Remove-ForeignConnector "Contoso.com Foreign Connector"
```

For detailed syntax and parameter information, see Remove-ForeignConnector.

1.7.2.11.19 Configure the Pickup Directory

Configure the Pickup Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to configure the properties of the Pickup directory in Microsoft Exchange Server 2010. By default, the Pickup directory exists on every computer running Exchange 2010 that has the Hub Transport server role or the Edge Transport server role installed. Correctly formatted e-mail message files that you copy to the Pickup directory are submitted for delivery. The Pickup directory is used by administrators for mail flow testing, or by applications that must create and submit their own messages.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

What Do You Want to Do?

- Use the Shell to configure the Pickup directory location
- Use the Shell to configure the maximum size for message headers
- Use the Shell to configure the maximum number of recipients per message
- Use the Shell to configure the maximum rate of message processing for the Pickup directory

Use the Shell to configure the Pickup directory location

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub server" entry in the Transport Permissions topic.

Use the *PickupDirectoryPath* parameter of the **Set-TransportServer** cmdlet to configure the location of the Pickup directory. By default, the Pickup directory is located at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\PickUp. The directory must be local to the Exchange 2010 computer.

Note:

You can't configure the Pickup directory by using the Exchange Management Console (EMC). To configure the Pickup directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example changes the Pickup directory location to C:\Pickup Directory on server Exchange 01.

```
Set-TransportServer Exchange01 -PickupDirectoryPath "C:\Pickup Directory"
```

When changing the location of the Replay directory, you need to be aware of the following:

- Setting the value of the *PickupDirectoryPath* parameter to `$null` disables the Pickup directory.
- The directory specified by the *PickupDirectoryPath* parameter and the *ReplayDirectoryPath* parameter can't be the same.
- Changing the location of the Pickup directory doesn't copy any existing message files from the old Pickup directory to the new Pickup directory. The new Pickup directory location is active almost immediately after the configuration change, but any existing message files are left in the old Pickup directory.

You also need to make sure that the permissions are configured correctly on the new location of the Pickup directory. To learn more about the permission requirements, see "Permissions for the Pickup and Replay Directories" in Understanding the Pickup and Replay Directories.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to configure the maximum size for message headers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub server" entry in the Transport Permissions topic.

Use the *PickupDirectoryMaxHeaderSize* parameter of the **Set-TransportServer** cmdlet to set the maximum message header size for a Pickup directory. By default, the maximum size for the header part of a message that can be processed by the Pickup directory is 64 KB. Messages that contain headers larger than the specified maximum value are rejected by the Exchange 2010 server.

Note:

You can't configure the Pickup directory by using the EMC. To configure the Pickup directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example configures the maximum size for message headers accepted by the Pickup directory to 96 KB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -PickupDirectoryMaxHeaderSize 96KB
```

The valid input range for the *PickupDirectoryMaxHeaderSize* parameter is from 32 KB through about 2 GB (2147483647 bytes).

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to configure the maximum

number of recipients per message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub server" entry in the Transport Permissions topic.

Use the *PickupDirectoryMaxRecipientsPerMessage* parameter of the **Set-TransportServer** cmdlet to set the maximum number of recipients per message that the Pickup directory accepts. By default, the maximum number of recipients in a message that can be processed by the Pickup directory is 100. Messages that contain more recipients than the specified maximum value are rejected by the Exchange 2010 server.

Note:
You can't configure the Pickup directory by using the EMC. To configure the Pickup directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example sets the maximum number of recipients in a message accepted by the Pickup directory to 200 on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -PickupDirectoryMaxRecipientsPerMessage 200
```

The valid input range for the *PickupDirectoryMaxRecipientsPerMessage* parameter is from 1 through 10000.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to configure the maximum rate of message processing for the Pickup directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub server" entry in the Transport Permissions topic.

The rate of message processing for both the Pickup directory and the Replay directory is specified by the *PickupDirectoryMaxMessagesPerMinute* parameter of the **Set-TransportServer** cmdlet. By default, the Pickup directory can process messages at a rate of 100 messages per minute. Limiting the rate of message processing helps prevent performance issues caused by processing numerous messages in the Pickup directory.

Note:
You can't configure the Pickup directory by using the EMC. To configure the Pickup directory, you must use the Shell. For more information about how to use the Shell, see Exchange Management Shell.

This example increases the maximum rate of message processing for the Pickup and Replay directories to 200 messages per minute on server Exchange01.

```
Set-TransportServer Exchange01 -PickupDirectoryMaxMessagesPerMinute 200
```

The valid input range for the *PickupDirectoryMaxMessagesPerMinute* parameter is from 1 through 20000.

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.11.20 Configure the Replay Directory

Configure the Replay Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure the properties of the Replay directory in Microsoft Exchange Server 2010. By default, the Replay directory exists on every computer running Exchange 2010 that has the Hub Transport server role or the Edge Transport server role installed. Correctly formatted e-mail message files that you copy to the Replay directory are submitted for delivery. The Replay directory receives messages from non-SMTP foreign gateway servers and resubmits messages that administrators export from the queues of Exchange 2010 servers.

Looking for other management tasks related to managing connectors? Check out Managing Connectors.

Use the Shell to configure the Replay directory location

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the Replay directory.

Use the *ReplayDirectoryPath* parameter of the **Set-TransportServer** cmdlet to configure the location of the Replay directory. By default, the Replay directory is located at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Replay. The directory must be local to the computer running Exchange 2010.

This example changes the Replay directory location to C:\Replay Directory on server Exchange01.

```
Set-TransportServer Exchange01 -ReplayDirectoryPath "C:\Replay Directory"
```

When changing the location of the Replay directory, you need to be aware of the following:

- Setting the value of the *ReplayDirectoryPath* parameter to `$null` disables the Replay directory.
- The directory specified by the *ReplayDirectoryPath* parameter and the *PickupDirectoryPath* parameter can't be the same.
- Changing the location of the Replay directory doesn't copy any existing message files from the old Replay directory to the new Replay directory. The new Replay directory location is active almost immediately after the configuration change, but any existing message files are left in the old Replay directory.

You also need to make sure that the permissions are configured correctly on the new location of the Replay directory. To learn more about the permission requirements, see "Permissions for the Pickup and Replay Directories" in Understanding the Pickup and Replay Directories.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to configure the maximum rate of message processing for the Replay directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the Replay directory.

The rate of message processing for both the Pickup directory and the Replay directory is specified by the *PickupDirectoryMaxMessagesPerMinute* parameter of the **Set-TransportServer** cmdlet. By default, the Replay directory can process messages at a rate of 100 messages per minute. Limiting the rate of message processing helps prevent performance issues caused by processing numerous messages in the Replay directory.

This example increases the maximum rate of message processing for the Pickup and Replay directories to 200 messages per minute on server Exchange01.

```
Set-TransportServer Exchange01 -PickupDirectoryMaxMessagesPerMinute 200
```

The valid input range for the *PickupDirectoryMaxMessagesPerMinute* parameter is from 1 through 20000.

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.12 Managing Delivery Status Notifications

Managing Delivery Status Notifications

Exchange Server 2010 > Transport > Managing Transport Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Create a Custom DSN Message

View or Modify an Existing Custom DSN Message

Remove a Custom DSN Message

1.7.2.12.1 Create a Custom DSN Message

Create a Custom DSN Message

Transport > Managing Transport Servers > Managing Delivery Status Notifications >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to create a customized delivery status notification (DSN) message on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed.

Looking for other management tasks related to DSNs? Check out Managing Delivery Status Notifications.

Prerequisites

Before you perform these procedures, you must specify the identity of the message and prepare the text that you want to include in the message. For more information about how to specify the identity of a DSN message and how to work with the text of a customized DSN message, including how to format HTML DSN messages, see DSN Message Identity and DSN Message Text.

Use the Shell to create a customized DSN message targeted to internal senders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to create a customized DSN message targeted to internal senders.

Use the **New-SystemMessage** cmdlet to create a customized DSN. This example creates a customized DSN with the following settings:

- Customized DSN is created for DSN code 5.1.2.
- DSN is sent to internal senders only.
- DSN is customized for the English language.

```
New-SystemMessage -DSNCode 5.1.2 -Text "The mailbox you tried to send an e-mail m
```

For detailed syntax and parameter information, see New-SystemMessage.

Use the Shell to create a customized DSN message targeted to external senders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to create a customized DSN message targeted to external senders.

Use the **New-SystemMessage** cmdlet to create a customized DSN. This example creates a customized DSN with the following settings:

- Customized DSN is created for DSN code 5.1.2.
- DSN is sent to external senders only.
- DSN is customized for the English language.

```
New-SystemMessage -DSNCode 5.1.2 -Text "The mailbox you tried to send an e-mail m
```

For detailed syntax and parameter information, see New-SystemMessage.

Use the Shell to create a customized HTML DSN message targeted to internal senders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to create a customized HTML DSN message targeted to internal senders.

Use the **New-SystemMessage** cmdlet to create an HTML formatted customized DSN. This example creates a customized DSN with the following settings:

- Customized DSN is created for code 5.1.2.
- DSN text is HTML formatted, including a hyperlink.
- DSN is sent to internal senders only.
- DSN is customized for the English language.

```
New-SystemMessage -DSNCode 5.1.2 -Text 'The mailbox you tried to send an e-mail m
```

For detailed syntax and parameter information, see New-SystemMessage.

1.7.2.12.2 View or Modify an Existing Custom DSN Message

View or Modify an Existing Custom DSN Message

Transport > Managing Transport Servers > Managing Delivery Status Notifications >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to view or modify a custom delivery status notification (DSN) message on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed.

You can only use the **Set-SystemMessage** cmdlet to modify DSN messages that have already been customized by using the **New-SystemMessage** cmdlet. If you want to customize the original text of a default DSN message provided by Exchange 2010, you must use the **New-SystemMessage** cmdlet to create a custom DSN. For more information about how to create a custom DSN message, see Create a Custom DSN Message.

Looking for other management tasks related to DSNs? Check out Managing Delivery Status Notifications.

Prerequisites

Before you perform these procedures, you must specify the identity of the message and prepare the text that you want to include in the message. For more information about how to specify the identity of a DSN message and how to work with the text of a customized DSN message, including how to format HTML DSN messages, see DSN Message Identity and DSN Message Text.

Use the Shell to change the text of a custom DSN message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to change the text of a custom DSN message.

Use the **Set-SystemMessage** cmdlet to modify the settings of a custom DSN message. This example changes the text assigned to the DSN customized for DSN code 5.1.2 for the English language.

```
Set-SystemMessage En\Internal\5.1.2 -Text "The mailbox you tried to send an e-mai
```

For detailed syntax and parameter information, see Set-SystemMessage.

Use the Shell to view a list of custom DSN messages in your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view a list of custom DSN messages in your organization.

By default, the **Get-SystemMessage** cmdlet, which you use to view the configuration of custom DSN messages, returns a summary list of all custom DSN messages in your organization. This example returns a tabular list of all custom DSNs in your organization.

```
Get-SystemMessage
```

For detailed syntax and parameter information, see Get-SystemMessage.

Use the Shell to view a list of built-in DSN messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view a list of built-in DSN messages.

This example, which requires the **Get-SystemMessage** command with the *Original* parameter, returns a list of the original DSN messages included with Exchange 2010.

```
Get-SystemMessage -Original
```

For detailed syntax and parameter information, see Get-SystemMessage.

Use the Shell to view detailed information

about a custom DSN message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view detailed information about a custom DSN message.

Use the **Get-SystemMessage** command to view detailed configuration about a custom DSN message. This example shows detailed configuration for the internal 5.1.2 DSN customized for English.

```
Get-SystemMessage En\Internal\5.1.2 | Format-List
```

For detailed syntax and parameter information, see Get-SystemMessage.

1.7.2.12.3 Remove a Custom DSN Message

Remove a Custom DSN Message

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to remove a custom delivery status notification (DSN) message on a computer running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed.

Looking for other management tasks related to DSNs? Check out Managing Delivery Status Notifications.

Prerequisites

Before you perform this procedure, you must specify the identity of the DSN message or messages that you want to view. For more information about how to specify the identity of a DSN message, see DSN Message Identity.

Use the Shell to remove an existing DSN message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "DSNs" entry in the Transport Permissions topic.

Note:
You can't use the EMC to remove an existing DSN message.

When you remove a customiz DSN message, the DSN code associated with that message reverts to the original DSN message included with Exchange 2010.

Note:
You can't remove an original DSN message included with Exchange 2010. To change an original DSN message, you must create a customiz DSN message for the DSN code that you want to customize.

This example removes the customiz 5.1.2 DSN for the English locale configured to be sent to Internal senders.

```
Remove-SystemMessage En\Internal\5.1.2
```

For detailed syntax and parameter information, see Remove-SystemMessage.

1.7.2.13 Managing Edge Subscriptions

Managing Edge Subscriptions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Import an Edge Subscription File to an Active Directory Site

Create an Edge Subscription File on an Edge Transport Server

Force EdgeSync Synchronization

Remove an Edge Subscription

Verify EdgeSync Results for a Recipient

Modify AD LDS Configuration

1.7.2.13.1 Import an Edge Subscription File to an Active Directory Site

Import an Edge Subscription File to an Active Directory Site

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you create a new Edge Subscription, the Edge Transport server referenced in the Edge Subscription file is associated with the Hub Transport servers in an Active Directory site. For more information about Edge Subscriptions, see Understanding Edge Subscriptions.

Looking for other management tasks related to transport servers? Check out Managing Transport Servers.

Prerequisites

- The Active Directory site to which the Edge Transport server is subscribed must contain at least one Hub Transport server.
- Verify that you have configured the settings on the Hub Transport server that are replicated to the Edge Transport server. For more information, see Understanding Edge Subscriptions.
- Read the following topics:

- Create an Edge Subscription File on an Edge Transport Server
- Understanding Edge Subscriptions

- Create the Edge Subscription file by running the **New-EdgeSubscription** cmdlet on the Edge Transport server. By running the **New-EdgeSubscription** cmdlet, you create an Edge Subscription file that you must copy to your Hub Transport server's hard disk.
- Copy the Edge Subscription file from the Edge Transport server to the Hub Transport server where you will perform this procedure.

Note:
It's a best practice to delete the Edge Subscription file from the Edge Transport server after you copy the file to the Hub Transport server where you will import the Edge Subscription file, and from the Hub Transport server after the subscription is imported.

What Do You Want to Do?

- Use the EMC to import the Edge Subscription file
- Use the Shell to import the Edge Subscription file

Use the EMC to import the Edge Subscription file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **Edge Subscriptions** tab.
3. In the action pane, click **New Edge Subscription**. On the **New Edge Subscription** page, complete the following fields:
   - **Active Directory site** Click **Browse**, and then select an Active Directory site in the drop-down list. This field identifies the Active Directory site where the Hub Transport server is connecting to the Edge Transport server for which the Edge Subscription exists.
   - **Subscription file** Click **Browse**, and then select an Edge Subscription file.
   - **Automatically create a Send connector for this Edge Subscription** Select this check box to automatically create a Send connector that routes messages from the Exchange organization to the Internet. The Edge Subscription is configured as the source server for the Send connector. The Send connector is configured to route messages to all domains by using Domain Name System (DNS) MX resource records.
4. Click **New** to create the new Edge Subscription.
5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to import the Edge Subscription file

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

This example subscribes an Edge Transport server to the specified site and creates the Internet Send connector and the Send connector from the Edge Transport server to the Hub Transport servers automatically.

```
New-EdgeSubscription -FileData ([byte[]]$(Get-Content -Path "C:\EdgeSubscriptionI
```

Note:
The default value of the *CreateInternetSendConnector* parameter and the *CreateInboundSendConnector* parameter is `$true`. It's shown here for demonstration only.

For detailed syntax and parameter information, see New-EdgeSubscription.

1.7.2.13.2 Create an Edge Subscription File on an Edge Transport Server

Create an Edge Subscription File on an Edge Transport Server

Transport > Managing Transport Servers > Managing Edge Subscriptions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can export an Edge Subscription file from a computer that has the Edge Transport server role installed. The Edge Subscription file is used in the EdgeSync process, and it contains information about the credentials that are used during the LDAP communication process. These credentials are used to authenticate and authorize the connection between Active Directory Lightweight Directory Service (AD LDS) and Active Directory during replication. To learn more about Edge Subscriptions, see Understanding Edge Subscriptions.

After you perform this procedure on the Edge Transport server, you must copy the Edge Subscription file to a location in your internal network and then import the file to your Exchange organization to complete the subscription process.

Note:
After you complete the subscription, it's a best practice to delete the Edge Subscription file from all locations: the Edge Transport server and the internal network location to which you copied the file for importing to your Exchange organization.

Looking for other management tasks related to managing Edge Subscriptions? Check out Managing Edge Subscriptions.

Use the Shell to create an Edge Subscription file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

Note:
You can't use the EMC to export an Edge Subscription file.

This example exports an Edge Subscription file.

```
New-EdgeSubscription -FileName "C:\EdgeSubscriptionInfo.xml"
```

Note:
When the **New-EdgeSubscription** cmdlet is run on the Edge Transport server, you receive a prompt to acknowledge the commands that will be disabled and the configuration that will be overwritten on the Edge Transport server. To bypass this confirmation, you must use the *Force* parameter. This parameter is useful when you script the **New-EdgeSubscription** cmdlet. The *Force* parameter is also used to overwrite an existing file with the same name as the file that you're creating when you resubscribe an Edge Transport server.

For detailed syntax and parameter information, see New-EdgeSubscription.

1.7.2.13.3 Force EdgeSync Synchronization

Force EdgeSync Synchronization

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can manually start synchronization of data from Active Directory to the subscribed Edge Transport servers.

The configuration and recipient data is kept up to date by periodically synchronizing changes from Active Directory to Active Directory Lightweight Directory Services (AD LDS). By default, configuration data is synchronized to AD LDS once every hour, and recipient data is synchronized to AD LDS once every four hours. You can change these intervals using the **Set-EdgeSyncService** cmdlet.

You may want to force EdgeSync synchronization to start initial replication immediately after you create the Edge Subscription, or if you've made significant changes to the configuration or recipients in Active Directory. The **Start-EdgeSynchronization** cmdlet resets the EdgeSync synchronization schedule. The time of the subsequent synchronization intervals is based on the time that this command is initiated. You can force a full replication or only the changes since last replication.

Looking for other management tasks related to managing Edge Subscriptions? Check out Managing Edge Subscriptions.

Use the Shell to force EdgeSync synchronization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

Note:
You can't use the EMC to force EdgeSync synchronization.

This example starts EdgeSync synchronization with the following options:

- The synchronization is initiated from the Hub Transport server Hub01.
- All Edge Transport servers are synchronized.
- Only the changes since the last replication are synchronized.

```
Start-EdgeSynchronization -Server Hub01
```

This example starts EdgeSync synchronization with the following options:

- The synchronization is initiated from the Hub Transport server Hub01.
- Only the Edge Transport server Edge03 is synchronized.
- All recipient and configuration data are fully synchronized.

```
Start-EdgeSynchronization -Server Hub01 -TargetServer Edge03 -ForceFullSync
```

For detailed syntax and parameter information, see Start-EdgeSynchronization.

1.7.2.13.4 Remove an Edge Subscription

Remove an Edge Subscription

Transport > Managing Transport Servers > Managing Edge Subscriptions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove an Edge Subscription. After you remove the Edge Subscription, synchronization of information from Active Directory to Active Directory Lightweight Directory Services (AD LDS) stops. All the accounts that are stored in AD LDS are removed, and the computer that has the Edge Transport server role installed is removed from the source server list of any Send connector. You will no longer be able to use the Edge Transport server features that rely on Active Directory data.

Note:

To completely remove the Edge Subscription, you must run this procedure on the Edge Transport server and on the Hub Transport server. To run this procedure on the Edge Transport server, you can only use the Shell. To run this procedure on the Hub Transport server, you can use the EMC or the Shell.

Looking for other management tasks related to managing Edge Subscriptions? Check out Managing Edge Subscriptions.

Use the EMC to remove an Edge Subscription

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Sync" entry in the Transport Permissions topic.

1. Expand **Organization Configuration**, select **Hub Transport**, and then in the result pane, click the **Edge Subscriptions** tab.
2. Select the Edge Subscription that you want to remove. In the action pane, click **Remove**.

Use the Shell to remove an Edge Subscription

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

To remove an Edge Subscription, use the following syntax.

```
Remove-EdgeSubscription -Identity <EdgeorHubServerName> -DomainController <dc.dom
```

Note:
The *DomainController* parameter is optional. Use this parameter when you want to specify the domain controller that will write this change to Active Directory.

For detailed syntax and parameter information, see Remove-EdgeSubscription.

1.7.2.13.5 Verify EdgeSync Results for a Recipient

Verify EdgeSync Results for a Recipient

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Shell to verify the EdgeSync synchronization results for a specific recipient.

Looking for other management tasks related to Edge Subscriptions? Check out Managing Edge Subscriptions.

Prerequisites

You must have an Edge server subscribed to your Internet-facing Active Directory site.

Use the Shell to verify EdgeSync results for a single recipient

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

Note:
You can't use the EMC to verify EdgeSync results for a single recipient.

Use the **Test-EdgeSynchronization** cmdlet to verify EdgeSync results for a single recipient. This cmdlet is also used to verify configuration replication. To verify a single recipient, you need to use the *VerifyRecipient* parameter.

The following command verifies EdgeSync results for the user kate@contoso.com:

```
Test-EdgeSynchronization -VerifyRecipient kate@contoso.com
```

1.7.2.13.6 Modify AD LDS Configuration

Modify AD LDS Configuration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the ConfigureAdam.ps1 script in the Shell to modify the default configuration

of the Active Directory Lightweight Directory Services (AD LDS) on the Edge Transport server.

Important:
Don't modify the AD LDS configuration of an Edge Transport server after the Edge Transport server is subscribed to the Microsoft Exchange Server 2010 organization. If you modify the AD LDS configuration of a subscribed Edge Transport server, you must resubscribe the Edge Transport server to the Exchange organization. For more information, see Import an Edge Subscription File to an Active Directory Site.

After you install the Edge Transport server role, you can use the ConfigureAdam.ps1 script provided with Exchange 2010 to modify the ports and directories that AD LDS uses.

The ConfigureAdam.ps1 script invokes the **dsdbutil** command to change the registry settings for AD LDS. The **dsdbutil** command is a management tool for AD LDS that's intended for use by experienced administrators only.

Caution:
Don't modify the registry settings without using the script. Manual registry changes to the AD LDS configuration make the AD LDS instance unavailable.

The following table lists the parameters that can be used by the ConfigureAdam.ps1 script and how each parameter is used. You can use one, all, or a combination of any of these parameters to modify AD LDS. You must run the script by using the Shell.

ConfigureAdam.ps1 parameters and their use

Parameter	Use
Ldapport	Use this parameter to modify the port used for LDAP communication. By default, the Edge Transport server uses the nonstandard port 50389.
Sslport	Use this parameter to modify the communication port used for secure LDAP communication. By default, the Edge Transport server uses the nonstandard port 50636.
LogPath	Use this parameter to modify the location of the log files. By default, the Edge Transport server creates log files in the path C:\Program Files\Microsoft\Exchange server\V14\Transport Roles\Data\adam.
DataPath	Use this parameter to modify the location of the directory database file. By default, the Edge Transport server stores the directory database in the path C:\Program Files\Microsoft\Exchange server\V14\Transport Roles\Data\adam.

Looking for other management tasks related to Edge Subscription? See Managing Edge Subscriptions.

Prerequisites

- Determine the settings that you will use with this command.

- If you modify the LDAP port or the SSL port used by AD LDS, first verify that the selected port isn't being used by another application. You can use the **netstat** command to view ports being used on the Edge Transport server.

Use the ConfigureAdam.ps1 script in the Shell to modify AD LDS configuration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

The ConfigureAdam.ps1 script is located by default in the C:\Program Files\Microsoft \Exchange Server\V14\Scripts folder.

This example uses the ConfigureAdam.ps1 script to change the LDAP port to 5000.

```
ConfigureAdam.ps1 -LdapPort:5000
```

This example uses the ConfigureAdam.ps1 script to make the following changes to the AD LDS configuration:

- Changes the LDAP port to 5000
- Changes the SSL port to 5001
- Changes the log path to D:\Exchange Server\Data\ADLDS
- Changes the data path to D:\Exchange Server\Data\ADLDS

```
ConfigureAdam.ps1 -LdapPort:5000 -SslPort:5001 -LogPath:"D:\Exchange Server\Data\
```

1.7.2.14 Managing MailTips

Managing MailTips

Exchange Server 2010 > Transport > Managing Transport Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-04-03*

Configure Organizational Settings for MailTips

Configure Group Metrics

Configure Custom MailTips for Recipients

1.7.2.14.1 Configure Organizational Settings for MailTips

Configure Organizational Settings for MailTips

Transport > Managing Transport Servers > Managing MailTips >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

MailTips are informative messages displayed to users while they compose a message. Microsoft Exchange Server 2010 analyzes the message, including the list of recipients to which it's addressed. If a potential problem is detected, MailTips notify users prior to

sending the message. With the help of the information provided by MailTips, senders can adjust the message they are composing to avoid undesirable situations or non-delivery reports (NDRs). To learn more about MailTips, see Understanding MailTips.

You can configure various settings that define how you use MailTips in your organization.

Looking for other management tasks related to MailTips? Check out Managing MailTips.

Use the Shell to enable or disable MailTips

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable MailTips.

You use the **Set-OrganizationConfig** cmdlet to enable or disable MailTips in your organization. MailTips are enabled by default, when you install a new Exchange 2010 organization. This example shows how to enable MailTips in your organization.

```
Set-OrganizationConfig -MailTipsAllTipsEnabled $true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Use the Shell to configure the large audience size for your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the large audience size for your organization.

You use the **Set-OrganizationConfig** cmdlet to configure the large audience size for your organization. When senders address messages to more recipients than the size you configure, they are shown the Large Audience MailTip. The large audience size is set to 25 by default. This example configures the large audience size to 50 in your organization.

```
Set-OrganizationConfig -MailTipsLargeAudienceThreshold 50
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Use the Shell to enable or disable the External Recipients MailTip

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable the External Recipients MailTip.

When enabled, senders are notified that the message will leave your organization if they add an external recipient or a distribution group that contains external recipients. By default, the External Recipients MailTip is disabled.

Note:
The External Recipients MailTip relies on group metrics data. Therefore, if you enable the External Recipients MailTip, make sure that the group metrics MailTip is also enabled.

Depending on the communications profile of your organization, you may want to enable or disable the External Recipients MailTip. For example, travel agencies may choose to disable the External Recipients MailTip because most of their communication is with people outside their organization. In contrast, law firms may want to enable this to ensure that the senders are aware when information is being shared outside the firm.

You use the **Set-OrganizationConfig** cmdlet to enable or disable the External Recipients MailTip in your organization. This example enables the External Recipients MailTip.

```
Set-OrganizationConfig -MailTipsExternalRecipientsTipsEnabled $true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Use the Shell to enable or disable MailTips that rely on mailbox data

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable MailTips that rely on mailbox data.

You use the **Set-OrganizationConfig** cmdlet to enable or disable MailTips that rely on mailbox data. The Recipient Out of Office and Mailbox Full MailTips rely on the mailbox data. The Client Access server evaluates these MailTips by querying the Mailbox server using RPC. By default, these MailTips are enabled. This example enables MailTips that rely on mailbox data.

```
Set-OrganizationConfig -MailTipsMailboxSourcedTipsEnabled $true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Use the Shell to enable or disable MailTips that rely on group metrics data

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable MailTips that rely on group metrics data.

You use the **Set-OrganizationConfig** cmdlet to enable or disable MailTips that rely on group metrics data. By default, these MailTips are enabled. group metrics data consists of the membership count and external members count for all distribution groups and dynamic distribution groups in your organization. MailTips like Large Audience and External Recipients rely on this data. This example enables MailTips that rely on group metrics data in your organization.

```
Set-OrganizationConfig -MailTipsGroupMetricsEnabled $true
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Use the Shell to configure MailTips for organizational relationships

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), you can configure organizational relationships with Exchange Online or other organizations. By establishing an organizational relationship, you can enhance the user experience for both organizations by sharing free/busy data, configuring secure message flow, and enabling message tracking. For more information about organizational relationships, see Understanding Federation.

You can use various settings to control how MailTips are used between two organizations that have established an organizational relationship. The procedures in this section illustrate these various controls. In all examples, the on-premises organization is contoso.com, the remote organization is online.contoso.com, and the organizational relationship is named Contoso Online.

You use the **Set-OrganizationRelationship** cmdlet to configure these settings.

Use the Shell to enable or disable MailTips between two organizations

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable or disable MailTips between two organizations.

This example configures the organizational relationship so that MailTips are returned to senders in the remote organization when composing messages to recipients in your organization.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessEnabled $t
```

This example configures the organizational relationship to prevent MailTips from being returned to senders in the remote organization when composing messages to recipients in your organization.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessEnabled $f
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

Use the Shell to configure which MailTips are returned to the remote organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure which MailTips are returned to the remote organization.

For each organizational relationship, you can determine which set of MailTips are returned to senders in the other organization. This example configures the organizational relationship so that all MailTips are returned.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessLevel All
```

This example configures the organizational relationship so that only the Automatic Replies, Oversize Message, Restricted Recipient, and Mailbox Full MailTips are returned.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessLevel Limi
```

This example configures the organizational relationship so that no MailTips are returned.

Note:
Don't use this method to disable MailTips for this relationship. To disable MailTips, set the *MailTipsAccessEnabled* parameter to `$false`.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessLevel None
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

Use the Shell to configure a specific group of users for whom recipient-specific MailTips are returned

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "MailTips" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure a specific group of users for whom recipient-specific MailTips are returned.

You can restrict the return of recipient-specific MailTips to a specific group of users. By default, when you enable MailTips for an organizational relationship, the following recipient-specific MailTips are returned for all users:

- Automatic Replies
- Mailbox Full
- Custom MailTip

You can specify a MailTips access group on the organizational relationship. After you specify a group, the recipient-specific MailTips are returned only for mailboxes, mail contacts, and mail users that are members of that group. This example configures the organizational relationship to return recipient-specific MailTips only for members of the ShareMailTips@contoso.com group.

```
Set-OrganizationRelationship -Identity "Contoso Online" -MailTipsAccessScope Shar
```

For detailed syntax and parameter information, see Set-OrganizationRelationship.

1.7.2.14.2 Configure Group Metrics

Configure Group Metrics

Transport > Managing Transport Servers > Managing MailTips >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

MailTips that provide information about the size of distribution groups and dynamic distribution groups rely on group metrics data. Group metrics data is generated on designated Mailbox servers and is copied to Client Access servers using the Microsoft Exchange File Distribution Service. For more information about group metrics, see Understanding Group Metrics.

You can enable or disable group metrics generation on a Mailbox server and configure the time when group metrics data is generated.

Looking for other management tasks related to MailTips and group metrics? Check out

Managing MailTips.

Prerequisites

Group metrics data is only used for MailTips. Make sure that group metrics MailTips are enabled in your organization. For detailed steps, see Configure Organizational Settings for MailTips. To learn more about MailTips, see Understanding MailTips.

Use the Shell to enable or disable group metrics generation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Group metrics" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable or disable group metrics generation.

Note:
By default, group metrics data is generated on any server responsible for generating the offline address book (OAB). The configuration shown in this example is only necessary for organizations that don't use OABs. For more information, see Understanding Group Metrics.

You use the **Set-MailboxServer** cmdlet to enable or disable group metrics generation on a Mailbox server. This example forces group metrics generation on server MBX1.

```
Set-MailboxServer MBX1 -ForceGroupMetricsGeneration $true
```

This example disables group metrics generation on server MBX1.

Note:
If this server is generating OABs, it will continue to generate group metrics data. This example is only applicable for servers that don't generate OABs.

```
Set-MailboxServer MBX1 -ForceGroupMetricsGeneration $false
```

Note:
In the release to manufacturing (RTM) version of Microsoft Exchange Server 2010, this parameter was named *GroupMetricsGenerationEnabled*.

For detailed syntax and parameter information, see Set-MailboxServer.

Use the Shell to configure the group metrics generation time

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Group metrics" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure the group metrics generation time.

You use the **Set-MailboxServer** cmdlet to configure the time of day when group metrics data is generated on a Mailbox server. You must use the 24-hour clock notation (*HH:MM*) when specifying the generation time. These examples configure group metrics generation on servers MBX1 and MBX3 to occur at 11:30 P.M. and 3:00 A.M. respectively.

```
Set-MailboxServer MBX1 -GroupMetricsGenerationTime 23:30
Set-MailboxServer MBX3 -GroupMetricsGenerationTime 03:00
```

For detailed syntax and parameter information, see Set-MailboxServer.

1.7.2.14.3 Configure Custom MailTips for Recipients

Configure Custom MailTips for Recipients

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

MailTips are informative messages displayed to users while they are composing a message. In Microsoft Exchange Server 2010, you can assign custom MailTips to recipients. You must specify a default custom MailTip.

You can assign MailTips in multiple languages. When a sender addresses a message to a recipient that has a custom MailTip configured, the MailTip translation that matches the language of the client the sender is using is displayed. If there's no MailTip translation that matches the client language, the default MailTip is displayed.

If some of your user mailboxes are hosted on Exchange Online and there's coexistence with an Exchange Online scenario, consider the following:

- You must set the *MailTipsAccessLevel* parameter on the organization relationship to `All`. Otherwise, the custom MailTips aren't returned when the sender and the recipient are on either side of the organizational relationship.
- Each mailbox is represented as a mail user on the other side of the organization relationship. For example, a mailbox hosted on Exchange Online is represented as a mail user in your on-premises deployment. If both of these recipients are configured with a custom MailTip, the local one is returned. In this example, the on-premises users that compose messages to that recipient will see the custom MailTip configured on the mail user, whereas Exchange Online users will see the custom MailTip configured on the mailbox.

Looking for other management tasks related to MailTips? Check out Managing MailTips.

Prerequisites

Make sure that MailTips are enabled in your organization. For detailed steps, see Configure Organizational Settings for MailTips. To learn more about MailTips, see Understanding MailTips.

Use the Shell to configure custom MailTips

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient data properties" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure custom MailTips.

You use the following cmdlets to configure custom MailTips for recipients:

- **Set-Mailbox**

- **Set-MailContact**
- **Set-MailUser**
- **Set-DistributionGroup**
- **Set-DynamicDistributionGroup**
- **Set-MailPublicFolder**

Custom MailTips can include HTML links, but no scripts are allowed. The length of a custom MailTip can't exceed 250 characters.

For example, assume that the response time service level agreement (SLA) for your Help Desk is two hours, and you have a Help Desk mailbox to which your users can submit problems. This example configures a custom MailTip for that mailbox to inform senders that they will receive a response within two hours.

```
Set-Mailbox -Identity "Help Desk" -MailTip "A Help Desk representative will conta
```

Custom MailTips are also useful for recipients whose display name may be misunderstood. For example, assume that you have a distribution group called HR that's used for departmental communications. This example informs senders what the distribution group is used for and directs them to the correct address if they have a question or complaint to submit to Human Resources.

```
Set-DistributionGroup -Identity "HR" -MailTip "This distribution group is used fo
```

Custom MailTip translations are stored in the multivalued property **MailTipTranslations** on a recipient object. When you're adding a MailTip translation, be sure that you don't overwrite any existing MailTip translations. This example creates a custom MailTip for the mailbox Notifications@contoso.com informing the user that it isn't a monitored mailbox, and then adds the Spanish translation. This is done by using the temporary variable *$Temp*.

```
Set-Mailbox -Identity Notifications@contoso.com -MailTip "This mailbox is not mon
$Temp = Get-Mailbox Notifications@contoso.com
$Temp.MailTipTranslations += "ES:Esta caja no se supervisa."
Set-Mailbox -Identity Notifications@contoso.com -MailTipTranslations $Temp.MailTi
```

Important:

You must use the preceding method when adding MailTip translations even if you're adding a single language. This is because the custom MailTip configured using the *MailTip* parameter is also stored in the *MailTipTranslations* parameter as the default translation.

For detailed syntax and parameter information, see the following topics:

- Set-Mailbox
- Set-MailContact
- Set-MailUser
- Set-DistributionGroup
- Set-DynamicDistributionGroup
- Set-MailPublicFolder

1.7.2.15 Managing Message Routing

Managing Message Routing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Configure a Hub Site

Set an Exchange Cost on an Active Directory IP Site Link

Configure Exchange 2010 to Route Messages for a Shared Address Space

Suppress Anonymous TLS Connections

Configure Internet Mail Flow Through a Subscribed Edge Transport Server

Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync

Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway

Configure Internet Mail Flow Directly Through a Hub Transport Server

1.7.2.15.1 Configure a Hub Site

Configure a Hub Site

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can configure an Active Directory site as a hub site for message routing in Microsoft Exchange Server 2010. For more information about hub sites, see Understanding Message Routing.

Looking for other management tasks related to managing message routing? Check out Managing Message Routing.

Prerequisites

Examine the contents of the routing table logs and view the data in the ADTopologyPath ID section to verify that the selected site exists along the least cost routing path between two Active Directory sites. If this isn't the case, you need to assign Exchange-specific costs to the IP site links to make the least cost routing path go through the selected sites. For detailed steps, see Set an Exchange Cost on an Active Directory IP Site Link.

Use the Shell to configure an Active Directory site as a hub site

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory site and site link management" entry in the Transport Permissions topic.

Note:

You can't use the EMC to configure an Active Directory site as a hub site.

This example configures the Active Directory site Site A as a hub site.

```
Set-AdSite "Site A" -HubSiteEnabled $true
```

For detailed syntax and parameter information, see Set-AdSite.

1.7.2.15.2 Set an Exchange Cost on an Active Directory IP Site Link

Set an Exchange Cost on an Active Directory IP Site Link

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set an Exchange cost on an Active Directory IP site link in Microsoft Exchange Server 2010. By default, Exchange uses the cost assigned to an IP site link for Active Directory replication purposes to compute a routing topology.

Looking for other management tasks related to managing message routing? Check out Managing Message Routing.

Prerequisites

- Understand how Exchange uses Active Directory sites to route messages. For more information, see Understanding Message Routing.
- Determine the name of the Active Directory IP site link for which you want to set an Exchange cost. You can examine the contents of the routing table logs and view the data in the ADTopologyPath ID section to view details about the calculated least cost routing path between two Active Directory sites.

Use the Shell to set an Exchange cost on an Active Directory IP site link

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory site and site link management" entry in the Transport Permissions topic.

Note:

You can't use the EMC to export an Edge Subscription file.

This example sets an Exchange specific cost of 10 to the IP site link IPSiteLinkAB.

```
Set-AdSiteLink -Identity IPSiteLinkAB -ExchangeCost 10
```

This example clears the Exchange specific cost on the IP site link IPSiteLinkAB.

```
Set-AdSiteLink -Identity IPSiteLinkAB -ExchangeCost $null
```

For detailed syntax and parameter information, see Set-AdSiteLink.

Configure Exchange 2010 to Route Messages for a Shared Address Space

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

An organization may have to share the same SMTP address space between two or more different e-mail systems. For example, you may have to share the SMTP address space between Exchange and a third-party e-mail system, or between Exchange environments that are configured in different Active Directory forests. In these scenarios, users in each e-mail system have the same domain suffix as part of their e-mail addresses.

You can use the EMC or the Shell to configure a Microsoft Exchange Server 2010 Hub Transport server to route messages for a shared address space.

Looking for other management tasks related to managing message routing? Check out Managing Message Routing.

Step 1: Create an internal relay domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Accepted domains" entry in the Transport Permissions topic.

To support routing messages for a shared address space, you must create an accepted domain that's configured as an internal relay domain. When you configure an accepted domain as an internal relay domain, Exchange first tries to deliver to a recipient in the Exchange organization. If the recipient isn't found, the message is routed to the Send connector that has the closest address space match.

Use the EMC to create an internal relay domain

1. In the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Accepted Domains** tab.
2. In the action pane, click **New Accepted Domain**. The New Accepted Domain wizard appears.
3. On the **New Accepted Domain** page, complete the following fields:
   - **Name** Use this field to identify the accepted domain in the user interface. You can type any name that you want. We recommend that you select a meaningful name that helps you easily identify the purpose of this accepted domain. For example, you may want to use a name that identifies this as a subsidiary domain or as a hosted domain. You must use a unique name for each accepted domain.
   - **Accepted Domain** Use this field to identify the SMTP namespace for which the Exchange organization will accept e-mail messages. You can use a wildcard character to accept messages for a domain and all its subdomains. For example, you can type *.contoso.com to set Contoso.com and all its subdomains as accepted domains.
4. After you complete these fields on the **New Accepted Domain** page, select the following option: **Internal Relay Domain**.
5. Click **New**.
6. On the **Completion** page, click **Finish**.

Use the Shell to create an internal relay domain

This example creates the internal relay domain Contoso for the SMTP domain

contoso.com.

```
New-AcceptedDomain -Name "Contoso" -DomainName contoso.com -DomainType InternalRe
```

For detailed syntax and parameter information, see New-AcceptedDomain.

Step 2: Create a Send connector to route e-mail to the shared domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

You must also add a Send connector that's sourced on a Hub Transport server and configured to send e-mail to the shared address space.

Caution:

To achieve the correct routing behavior, you must specify a Hub Transport server as the source server for the Send connector. If the Edge Transport server is specified as the source server for the Send connector, a routing loop will occur.

Use the EMC to create a Send connector to route e-mail to the shared domain

1. In the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Send Connectors** tab.
2. In the action pane, click **New Send Connector**. The New Send Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   - In the **Name** field, type a meaningful name for this connector. This name is used to identify the connector.
   - In the **Select the intended use for this connector** field, select one of the following usage types for the connector. The usage type determines the default permission sets that are assigned on the connector and grants those permissions to trusted security principals:
     - **Internal** Select this usage type if the e-mail system with which Exchange 2010 shares an address space is another Exchange 2010 organization.
     - **Internet** Select this usage type if the e-mail system with which Exchange 2010 shares an address space is a third-party e-mail system.
4. Click **Next**.
5. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, enter the domain name to which this connector will send mail, for example, contoso.com or *.contoso.com. You may select the **Include all subdomains** check box to use this connector to send e-mail to all subdomains of the address space. If necessary, you can also provide a specific cost for this connector. When you're finished, click **OK**. Leave the **Scoped send connector** check box cleared, and then click **Next**.
6. On the **Network settings** page, select **Route mail through the following smart hosts**. Click **Add**.
7. In the **Add Smart Host** dialog box, select **IP Address** or **Fully qualified domain name (FQDN)** to specify how to locate the smart host. If you select **IP Address**, enter the IP address of the smart host. If you select **Fully qualified domain name (FQDN)**, enter the FQDN of the smart host. The sending server must be able to resolve the FQDN. When you're finished, click **OK**. To add more smart hosts, click **Add**, and repeat this step. If you want to use a specific list of external DNS servers instead of the DNS servers specified in the adapter settings, select the **Use the External DNS Lookup settings on**

the transport server check box. When you're finished, click **Next**.

8. On the **Configure smart host authentication settings** page, select the method that's used to authenticate to the smart host. The following smart host authentication methods are available:
   - **None**
   - **Basic Authentication**
   - **Basic Authentication over TLS**
   - **Exchange Server Authentication**
   - **Externally Secured (for example, with IPsec)**
9. Click **Next**.
10. On the **Source Server** page, click **Add** to add a source server. By default, the Hub Transport server that you're currently working on is listed as a source server. In the **Select Hub Transport or Subscribed Edge Transport** dialog box, select the Hub Transport servers that will be used as the source server for sending messages to the shared address space. When you finish adding source servers, click **OK**. Click **Next**.
11. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Send connector by using the settings in the configuration summary, click **New**.
12. On the **Completion** page, click **Finish**.

Use the Shell to create a Send connector to route e-mail to the shared domain

This example creates a Send connector with the following settings:

- Configures the connector as an Internet usage type
- Assigns the address space contoso.com
- Routes messages to the smart host smarthost.contoso.com
- Uses the Externally Secured authentication mechanism
- Sets the maximum message size to 20 megabytes (MB)

```
New-SendConnector -Name "Contoso.com Send Connector" -Internet -AddressSpace cont
```

For detailed syntax and parameter information, see New-SendConnector.

1.7.2.15.4 Suppress Anonymous TLS Connections

Suppress Anonymous TLS Connections

Transport > Managing Transport Servers > Managing Message Routing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In Microsoft Exchange Server 2007, Transport Layer Security (TLS) encryption is mandatory for all SMTP communication between Hub Transport servers. This increases overall security of hub-to-hub communications. However, in certain topologies where WAN Optimization Controller (WOC) devices are used, the TLS encryption of SMTP traffic may be undesirable. Exchange Server 2010 supports disabling TLS for hub-to-hub communications for these specific scenarios.

This topic provides step-by-step instructions on how to configure your Hub Transport servers to disable TLS. To learn more about this feature, see Disabling TLS Between Active Directory Sites to Support WAN Optimization.

Looking for other tasks related to managing message routing? Check out Managing Message Routing.

Caution:
Make sure you disable TLS only on connections that pass through WOC devices.

Prerequisites

- Exchange is deployed in multiple Active Directory sites, with at least one site connected to the other sites over a WAN link.
- WOC devices are deployed to compress SMTP traffic over the WAN link.
- A logical message flow path exists for Exchange going over the WAN link that has the WOC devices deployed.

Step 1: Use the Shell to configure the Hub Transport server to use downgraded Exchange Server authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this procedure.

You use the **Set-TransportServer** cmdlet to configure a Hub Transport server to use downgraded Exchange Server authentication. This example makes this configuration change on the server Hub01.

```
Set-TransportServer Hub01 -UseDowngradedExchangeServerAuth $true
```

For detailed syntax and parameter information, see Set-TransportServer.

Step 2: Use the Shell to create a Receive connector on the Hub Transport server for the specific remote IP address range of the target Active Directory site

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

You use the **New-ReceiveConnector** cmdlet to create a Receive connector on your Hub Transport server to use for non-encrypted traffic. This example creates the Receive connector WAN on server Hub01 with the following configuration options:

- The *RemoteIPRanges* parameter is set to 10.0.2.0/24. This IP address range should correspond to the remote Active Directory site from where this Receive connector will receive unencrypted connections. If there's more than one IP subnet in the remote site, you can enter them all separated by commas.
- The usage type is set to Internal.

```
New-ReceiveConnector -Name WAN -Server Hub01 -RemoteIPRanges 10.0.2.0/24 -Interna
```

For detailed syntax and parameter information, see New-ReceiveConnector.

You can also create the Receive connector using the EMC. If you choose to use the EMC, make sure you create the connector with the following settings:

- Select **Internal** for the intended usage for the connector.
- Specify the remote IP address range (for example, in the preceding example, 10.0.2.0/24).

For more information, see Create an SMTP Receive Connector.

Step 3: Use the Shell to disable X-ANONYMOUSTLS on the new Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this procedure.

You use the **Set-ReceiveConnector** cmdlet to disable TLS on the newly created Receive connector. This example disables TLS on the Receive connector WAN on server Hub01.

```
Set-ReceiveConnector Hub01\WAN -SuppressXAnonymousTLS $true
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

Step 4: Use the Shell to designate the Active Directory sites on either side of the WAN connection as hub sites

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory site and site link management" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this procedure.

You use the **Set-AdSite** cmdlet to configure a specific Active Directory site as a hub site. You need to do this once in each site that has Hub Transport servers that participate in non-encrypted traffic.

This example configures the Active Directory site Central Office Site 1 as a hub site.

```
Set-AdSite "Central Office Site 1" -HubSiteEnabled $true
```

For detailed syntax and parameter information, see Set-AdSite.

Step 5: Use the Shell to verify the lowest-cost routing path goes through the WAN

connection

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory site and site link management" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this procedure.

Depending on how the IP site link costs are configured in Active Directory, this step may not be necessary. You need to make sure that the network link with the WOC devices deployed lies on the least-cost message path. If this isn't the case, you'll need to assign an Exchange-specific cost to the particular IP site link to ensure messages are routed correctly. To learn more about this particular issue, see "Configuring Site Link Costs" in Disabling TLS Between Active Directory Sites to Support WAN Optimization.

This example configures an Exchange-specific cost of 15 on the IP site link Branch Office 2-Branch Office 1.

```
Set-AdSiteLink "Branch Office 2-Branch Office 1" -ExchangeCost 15
```

For detailed syntax and parameter information, see Set-AdSiteLink.

1.7.2.15.5 Configure Internet Mail Flow Through a Subscribed Edge Transport Server

Configure Internet Mail Flow Through a Subscribed Edge Transport Server

Transport > Managing Transport Servers > Managing Message Routing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to configure Internet mail flow when your organization sends and receives Internet e-mail by relaying through a subscribed Edge Transport server.

To establish Internet mail flow for this scenario, you subscribe the Edge Transport server to an Active Directory site. We recommend this method for establishing Internet mail flow for your Exchange 2010 organization. This process automatically creates the following Send connectors, which are required for Internet mail flow:

- A Send connector configured to send e-mail to all Internet domains.
- A Send connector configured to send e-mail from the Edge Transport server to the Hub Transport server.

If you don't want to subscribe the Edge Transport server to an Active Directory site, you can manually create the Send connectors that are required to establish mail flow between the Hub Transport server and the Edge Transport server. For more information, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync. We recommend that you subscribe the Edge Transport server to the Active Directory site whenever possible.

Looking for other management tasks related to message routing? Check out Managing Message Routing.

Prerequisites

- Authoritative domains are configured on the Hub Transport server. For more information, see Transport Server Post-Deployment Tasks.
- E-mail address policies are configured on the Hub Transport server. For more information, see Managing E-Mail Address Policies.
- Network communications over the secure LDAP port 50636/TCP are enabled through the firewall that separates your perimeter network from the Exchange organization.

Use the Shell to subscribe an Edge Transport server to an Active Directory site

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "EdgeSync" entry in the Transport Permissions topic.

Note:
You can't use the EMC to subscribe an Edge Transport server to an Active Directory site.

1. On the Edge Transport server, run the following command.

```
New-EdgeSubscription -FileName "C:\EdgeSubscriptionInfo.xml"
```

2. Copy the resulting XML file to a Hub Transport server in the Active Directory site to which you want to subscribe the Edge Transport server. On the Hub Transport server, run the following command.

```
New-EdgeSubscription -FileData ([byte[]]$(Get-Content -Path "C:\EdgeSu
```

Note:
By default, the value of the *CreateInternetSendConnector* parameter and *CreateInboundSendConnector* parameter is `$true`. You don't have to provide these parameters if you want to use the default configuration. They are shown here for illustration only.

Note:
You can also use the New Edge Subscription wizard in the EMC to import the Edge Subscription file you created in Step 1. For more information, see Import an Edge Subscription File to an Active Directory Site.

3. On the Hub Transport server, run the following command.

```
Start-EdgeSynchronization
```

For detailed syntax and parameter information, see New-EdgeSubscription or Start-EdgeSynchronization.

1.7.2.15.6 Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync

Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

We always recommend that you use the Edge Subscription process to establish mail flow between the Exchange organization and a computer that's running Microsoft Exchange Server 2010 that has the Edge Transport server role installed. However, we realize that there are situations where you can't subscribe the Edge Transport server to the Exchange organization by using the Edge Subscription process. To manually establish mail flow between the Exchange organization and an Edge Transport server, you must create and configure the Send connectors and Receive connectors on the Edge Transport server and on the Hub Transport servers in the Exchange organization.

Looking for other tasks related to managing message routing? Check out Managing Message Routing.

Prerequisites

- This procedure uses Basic authentication over Transport Layer Security (TLS) to provide encryption and authentication. When you use Basic authentication over TLS, the receiving server must have an X.509 Secure Sockets Layer (SSL) server certificate installed. The fully qualified domain name (FQDN) value configured on the Receive connector must match the FQDN in the SSL server certificate. By default, the value of the FQDN on the Receive connector is the FQDN of the server that contains the Receive connector.
- You can also use the Externally Secured authentication method. However, if you do so, the communication between the Edge Transport server and Hub Transport server isn't authenticated or encrypted by Exchange. We recommend that you use the Externally Secured authentication method only when an additional encryption method is used. The encryption method can be an Internet Protocol security (IPsec) association or a virtual private network (VPN).
- An Edge Transport server is typically *multihomed*. This means that the Edge Transport server has network adapters that are connected to multiple network segments. Each of these network adapters has a unique IP configuration. The network adapter that's connected to the external, or public, network segment should be configured to use a public Domain Name System (DNS) server for name resolution. This enables the server to resolve SMTP domain names to MX resource records and route mail to the Internet. The network adapter that's connected to the internal, or private, network segment should be configured to use a DNS server in the perimeter network or should have a Hosts file available.
  For more information, see "Configuring DNS settings for the Edge Transport server role" in Planning Roadmap for New Deployments.
- You must create a user account in Active Directory and add the account to the Exchange Servers universal security group. This account is used by the Send connector on the Edge Transport server to authenticate to the destination Hub Transport server in the Exchange organization.

Important:

This account is granted the permissions that are associated with Exchange servers. Make sure that you safeguard the account credentials to prevent misuse of the account. You can configure the account to allow logon to specific computers only.

Edge Transport Server Procedures

The following connectors are required on the Edge Transport server:

- A Send connector configured to send messages to the Internet
- A Send connector configured to send messages to the Hub Transport servers in the Exchange organization
- A Receive connector configured to receive messages only from Hub Transport

servers in the Exchange organization
- A Receive connector configured to accept messages only from the Internet

By default, a single Receive connector is created during the installation of the Edge Transport server role. This connector can be used for both incoming Internet messages and incoming messages from the Hub Transport servers. Typically, the Edge Subscription process automatically configures the correct permissions and authentication on the default Receive connector. When you don't use the Edge Subscription process, we recommend that you modify the default Receive connector on the Edge Transport server to only accept messages from the Internet. You should then create a Receive connector on the Edge Transport server that's configured to only accept messages from internal Hub Transport servers.

The following sections walk you through all the configuration steps required to prepare your Edge Transport server to communicate with your Exchange organization.

Step 1: Create a Send connector configured to send messages to the Internet

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors - Edge Transport" entry in the Transport Permissions topic.

This Send connector requires the following configuration:

- **Name** To Internet.
- **Usage type** Internet.
- **Address spaces** "*" (all domains).
- **Network settings** Use DNS MX records to route mail automatically. Depending on your network configuration, you can also route mail through a smart host. The smart host then routes mail to the Internet.

Use the EMC to create a Send connector configured to send messages to the Internet

1. Open the EMC. Select **Edge Transport**, and then in the work pane, click the **Send Connectors** tab.
2. In the action pane, click **New Send Connector**. The New Send Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a. In the **Name** field, type a meaningful name for this connector, such as To Internet.
   3.b. In the **Select the intended use for this connector** field, select **Internet**.
4. Click **Next**.
5. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, enter *, and then click **OK**.
6. Click **Next**.
7. On the **Network settings** page, select **Use domain name system (DNS) "MX" records to route mail automatically**, and then click **Next**.
8. On the **New connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Send connector by using the settings in the configuration summary, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   9.a. A status of **Completed** indicates that the wizard completed the task successfully.
   9.b. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector configured to send messages to the Internet

You use the **New-SendConnector** cmdlet to create a Send connector.

```
New-SendConnector -Name "To Internet" -AddressSpaces * -Usage Internet -DNSRoutin
```

For detailed syntax and parameter information, see New-SendConnector.

Step 2: Create a Send connector configured to send messages to the Exchange organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors - Edge Transport" entry in the Transport Permissions topic.

This Send connector requires the following configuration:

- **Name** To Internal Org
- **Usage type** Internal
- DNS Routing disabled (smart host routing enabled)
- **Address spaces** All accepted domains for the Exchange organization
- **Network settings** Fully qualified domain name (FQDN) of one or more Hub Transport servers as smart hosts andsmart host authentication setting configured to Basic authentication over TLS
- **Smart host authentication mechanism** Basic authentication and Basic authentication requiring TLS

Use the EMC to create the Send connector configured to send messages to the Exchange organization

1. Open the EMC. Select **Edge Transport**, and then in the work pane, click the **Send Connectors** tab.
2. In the action pane, click **New Send Connector**. The New Send Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a. In the **Name** field, type a meaningful name for this connector, such as To Internal Org.
   3.b. In the **Select the intended use for this connector** field, select **Internal**.
4. On the **Address space** page, follow these steps:
   4.a. Click **Add**.
   4.b. In the **SMTP Address Space** dialog box, enter the accepted domains for the Exchange organization. You may select the **Include all subdomains** check box to use this connector to send e-mail to all subdomains of the address space. When you're finished, click **OK**.
   To add more address spaces to this connector, click **Add**, repeat this step, and then click **OK**.
   4.c. When you're finished, click **Next**.
5. On the **Network settings** page, following these steps:
   5.a. Select **Route mail through the following smart hosts**, and then click **Add**.
   5.b. In the **Add Smart Host** dialog box, select **Fully qualified domain name (FQDN)**, and enter the FQDN of the destination Hub Transport server. The Edge Transport server must be able to resolve the specified FQDN of the destination Hub Transport server. When you're finished, click **OK**.
   To add more Hub Transport servers as smart hosts, click **Add** and repeat this step.
   5.c. When you're finished, click **Next**.
6. On the **Configure smart host authentication settings** page, select **Basic Authentication and Basic Authentication over TLS**. In the **Username** and **Password** fields, enter the credentials for the user account in the internal domain. Use the *domain**user* format or user principal name (UPN) format to enter the user name and provide the user's password. Click **Next**.
7. On the **New connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Send connector by using the settings in the configuration summary, click **New**.
8. On the **Completion** page, review the following, and then click **Finish** to close

the wizard:

8.a.A status of **Completed** indicates that the wizard completed the task successfully.

8.b.A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create the Send connector configured to send messages to the Exchange organization

You use the **New-SendConnector** cmdlet to create a Send connector.

Note:

Before you create the Send connector, you first need to run the **Get-Credential** command to save the user name and password you will use in a temporary variable. You need to do this because the **New-SendConnector** cmdlet doesn't accept the user credentials in plain text.

```
$HubCredentials = Get-Credential
New-SendConnector -Name "To Internal Org" -Usage Internal -AddressSpaces *.contos
```

For detailed syntax and parameter information, see New-SendConnector.

Step 3: Modify the default Receive connector to only accept messages from the Internet

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors - Edge Transport" entry in the Transport Permissions topic.

You should make the following configuration changes to the default Receive connector:

- Modify the name to reflect that the connector will be used solely to receive e-mail from the Internet
- Change the network bindings to accept messages only from the network adapter that is accessible from the Internet

Use the EMC to modify the default Receive connector to only accept messages from the Internet

1. Open the EMC. Select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
2. In the work pane, select the Receive connector to modify. The default Receive connector is named Default internal Receive connector *Servername*.
3. Under the name of the Receive connector in the action pane, click **Properties** to open the **Properties** page.
4. Click the **General** tab to modify the name of the connector and give it a specific name to signify that it will be used only for receiving messages from the Internet.
5. Click the **Network** tab. Under **Use these local IP addresses to Receive mail**, click **Edit**. In the **Edit Receive Connector Binding** dialog box, select **Specify an IP address**, and then enter the IP address of the Internet-facing network adapter. Click **OK**.
6. Click **OK** to save your changes and exit the **Properties** page.

Use the Shell to modify the default Receive connector to only accept messages from the Internet

You use the **Set-ReceiveConnector** cmdlet to modify the properties of the default Receive connector.

```
Set-ReceiveConnector "Default internal Receive connector Edge01" -Name "From Inte
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

Step 4: Create a Receive connector configured to only accept messages from the Exchange organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors - Edge Transport" entry in the Transport Permissions topic.

This Receive connector requires the following configuration:

- **Name** From Internal Org
- **Usage type** Internal
- **Local network bindings** Internal network-facing network adapter
- **Remote network settings** IP address of one or more Hub Transport servers in the Exchange organization
- **Authentication method** Basic authentication over TLS

Use the EMC to create a Receive connector configured to only accept messages from the Exchange organization

1. Open the EMC. Select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
2. In the action pane, click **New Receive Connector**. The New Receive Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a. In the **Name** field, type a meaningful name for this connector, such as From Internal Org.
   3.b. In the **Select the intended use for this connector** field, select **Internal**.
4. On the **Remote network settings** page, follow these steps:
   4.a. Select the default IP address range entry 0.0.0.0 - 255.255.255.255, and then click  .
   4.b. Click **Add** or the drop-down arrow located next to **Add** and type the IP address or IP address range of the internal Hub Transport server or servers. When you're finished, click **OK**.

        To add multiple destination Hub Transport servers to this connector, click **Add** and repeat this step. Each Hub Transport server that you define in this step must also be listed as a source server in the corresponding Send connectors that are configured on the Hub Transport servers.
   4.c. When you're finished, click **Next**.
5. On the **New Connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Receive connector by using the settings in the configuration summary, click **New**.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   6.a. A status of **Completed** indicates that the wizard completed the task successfully.
   6.b. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. In the work pane, select the Receive connector that you created.
8. Under the name of the Receive connector in the action pane, click **Properties** to open the **Properties** page.
9. Click the **Network** tab. Under **Use these local IP addresses to Receive mail**, click **Edit**. In the **Edit Receive Connector Binding** dialog box, select **Specify an IP address**, and then enter the IP address of the internal organization-facing network adapter. Click **OK**.
10. Click the **Authentication** tab. Select **Basic Authentication** and **Offer Basic authentication only after starting TLS**.
11. Click **OK** to save your changes and exit the **Properties** page.

Use the Shell to create a Receive connector configured to only accept

messages from the Exchange organization
You use the **New-ReceiveConnector** cmdlet to create a Receive connector.

This example creates a Receive connector configured to accept messages from the Exchange organization.

```
New-ReceiveConnector -Name "From Internal Org" -Usage Internal -AuthMechanism TLS
```

For detailed syntax and parameter information, see New-ReceiveConnector.

Hub Transport Server Procedures

The following connector is required for the Hub Transport servers in your organization:

- A Send connector that's configured to send messages to the Edge Transport server in the perimeter network for relay to the Internet

By default, two Receive connectors are created during the installation of the Hub Transport server role. The connector named Client *ServerName* is configured to accept messages from all POP3 and IMAP messaging clients. The connector named Default *ServerName* is configured to accept messages from an Edge Transport server. No modifications to these connectors are required.

Create a Send connector configured to send outgoing messages to the Edge Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

This Send connector requires the following configuration:

- **Usage type** To Edge
- **Usage type** Internal
- **Address spaces** *
- **Network settings** IP address or FQDN of the Edge Transport server as a smart host and smart host authentication setting configured to Basic Authentication over TLS

Use the EMC to create a Send connector configured to send outgoing messages to the Edge Transport server

1. Open the EMC. In the console tree, expand **Organization Configuration**, select **Hub Transport**, and then in the work pane, click the **Send Connectors** tab.
2. In the action pane, click **New Send Connector**. The New Send Connector wizard starts.
3. On the **Introduction** page, follow these steps:
   3.a. In the **Name** field, type a meaningful name for this connector, such as To Edge.
   3.b. In the **Select the intended use for this connector** field, select **Internal**.
4. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, enter * in the **Address** field, and then click **OK**.
   When you're finished, click **Next**.
5. On the **Network settings** page, follow these steps:
   5.a. Select **Route mail through the following smart hosts**, and then click **Add**.
   5.b. In the **Add Smart Host** dialog box, select **Fully qualified domain name (FQDN)**, and enter the FQDN of the destination Edge Transport server. The Hub Transport server must be able to resolve the specified FQDN of the destination Edge Transport server. Click **OK**.
   5.c. When you're finished, click **Next**.
6. On the **Configure smart host authentication settings** page, select **Basic**

Authentication and Basic Authentication over TLS. In the **Username** and **Password** fields, enter the credentials for the user account on the destination Edge Transport server. Click **Next**.

7. By default, the **Source Server** page lists the Hub Transport server on which you're performing this procedure. If you want to add more Hub Transport servers for fault tolerance, those Hub Transport servers must be configured as sources on the corresponding Receive connector on the Edge Transport server. To add more source servers, click **Add**. In the **Select Hub Transport servers and Edge Subscriptions** dialog box, select the Hub Transport servers that will be used as the source servers for sending messages to the Edge Transport server that you provided in step 6. When you're finished adding additional source servers, click **OK**.
   To add more source servers, click **Add** and repeat this step.
   When you're finished, click **Next**.
8. On the **New connector** page, review the configuration summary for the connector. If you want to modify the settings, click **Back**. To create the Send connector by using the settings in the configuration summary, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   9.a. A status of **Completed** indicates that the wizard completed the task successfully.
   9.b. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector configured to send outgoing messages to the Edge Transport server

You use the **New-SendConnector** cmdlet to create a Send connector.

The following example creates a new Send connector with the following settings:

- Usage type: Internal
- Address Space: *
- DNS Routing disabled (smart host routing enabled)
- Smart hosts: edge01.contoso.net
- Source Transport servers: hub01.contoso.com, hub 02.contoso.com
- Smart host authentication mechanism: Basic authentication, basic authentication requiring TLS

Note:

Before you create the Send connector, you first need to run the **Get-Credential** command to save the user name and password you will use in a temporary variable. You need to do this because the **New-SendConnector** cmdlet doesn't accept the user credentials in plain text.

```
$EdgeCredentials = Get-Credential
New-SendConnector -Name "To Edge" -Usage Internal -AddressSpaces * -DNSRoutingEna
```

For detailed syntax and parameter information, see New-SendConnector.

1.7.2.15.7 Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway

Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure Internet mail flow through Microsoft Exchange Hosted Services or an external SMTP gateway.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

In Exchange Server 2010, to establish Internet mail flow through Exchange Hosted Services or an external SMTP gateway, you create a Send connector and a Receive connector between the Hub Transport servers in the Exchange organization and the external SMTP servers that process and route Internet e-mail.

The following authentication methods can be used in this scenario:

- **Basic authentication** The servers running the Exchange 2010 Hub Transport server role and the external SMTP servers authenticate by using Basic authentication. A user name and password is required. This authentication method is unavailable for Exchange Hosted Services.
- **Externally Secured** The network connection between the Hub Transport servers and the external SMTP servers is secured by using a method that's external to Exchange 2010.

  Note:

  Configuring a Receive connector as externally secured without using an Externally Secured authentication method is functionally equivalent to configuring the Receive connector as an open relay for the external SMTP server. The messages that originate from the external SMTP server are treated as authenticated messages. The messages bypass anti-spam checks and message size limit checks. The external SMTP server is allowed to submit messages as if they originated from internal senders within your Exchange organization. For more information, see Allow Anonymous Relay on a Receive Connector.

- **Anonymous relay** This method should be considered the method of last resort. If you allow an external SMTP server to anonymously relay messages by using the designated Receive connector on the Hub Transport server, you must apply the following restrictions on the Receive connector:
  - **Local network settings** If your Hub Transport server has multiple network adapters, restrict the Receive connector to listen only on the appropriate network adapter.
  - **Remote network settings** Restrict the Receive connector to accept connections only from the specified server or servers. This restriction is necessary because the Receive connector is configured to accept relay from anonymous users. Restricting the source servers by IP address is the only measure of protection that's allowed on this Receive connector.

  For more information, see Allow Anonymous Relay on a Receive Connector.

Looking for other management tasks related to managing message routing? Check out Managing Message Routing.

Prerequisites

- If you're using Basic authentication, a domain account must exist in the Active Directory forest. For example, create a domain user account that has the user principal name (UPN) smtpgateway@fabrikam.com as the credentials that must be used for authentication by the SMTP gateway when delivering mail to the Exchange servers in the Fabrikam domain.
- If you're using Basic authentication over Transport Layer Security (TLS), the target server must be configured to use an X.509 certificate that contains a fully qualified domain name (FQDN) that's the same as the FQDN of the Receive connector.
- If you're using external authentication, a trusted network connection must exist between the Hub Transport server and the SMTP gateway server. This connection can be an IPsec association or virtual private network (VPN). Alternatively, the servers may reside in a trusted physically controlled network.

Establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using Basic authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Note:

Because the default Receive connector will accept e-mail submissions from the authenticated SMTP gateway, a new Receive connector isn't needed when using Basic Authentication.

Use the EMC to establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using Basic authentication

1. On the Hub Transport server, open the EMC. Expand **Organization Configuration**, click **Hub Transport**, and then, in the action pane, click **New Send connector**.
2. On the New Send Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
3. From the **Select the intended use for this Send connector** drop-down list, select **Custom**, and then click **Next**.
4. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, type **"*"** in the **Address** field, and then click **OK**. Click **Next**.
5. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Select this setting and click **Add**.
6. In the **Add smart host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of the external SMTP gateway server, and then click **OK**. To specify more than one SMTP gateway as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
7. On the **Configure smart host authentication settings** page, select **Basic Authentication**, click **Basic Authentication over TLS**, type the user name and password that will be used to authenticate the connection, and then click **Next**.
8. On the **Source Server** page, click **Add**. In the **Select Hub Transport and subscribed Edge Transport servers** dialog box, select one or more Hub

Transport servers in your organization, click **OK**, and then click **Next**.

9. On the **New Connector** page, click **New**, and then on the **Completion** page, click **Finish**.

Use the Shell to establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using Basic authentication

1. Run the following command.

```
$mycred = Get-Credential
```

2. In the dialog box that appears, enter the credentials for the user account on the external SMTP gateway server. Enter the user name and provide the user's password. Click **OK**.
3. This example creates the Send connector ToInternetGateway that's used by the Hub Transport server HubA that connects to the external SMTP gateway smtpgateway1.contoso.com by using basic authentication.

```
New-SendConnector -Name "ToInternetGateway" -AddressSpaces "*" -SmartH
```

For detailed syntax and parameter information, see New-SendConnector.

Establish Internet mail flow between a Hub Transport server and Exchange Hosted Services or an external SMTP gateway by using Externally Secured authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Use the EMC to establish Internet mail flow between a Hub Transport server and Exchange Hosted Services or an external SMTP gateway by using Externally Secured authentication

1. Create a Send connector on the Hub Transport server to the external SMTP gateway by following these steps:
   1.a. Expand **Organization Configuration**, click **Hub Transport**, and then in the action pane, click **New Send connector**.
   1.b. On the New Send Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended use for this connector** drop-down list, select **Internal**, and then click **Next**.
   1.c. On the **Address Space** page, click **Add**. In the **Add Address Space** dialog box, type **"*"** in the **Address** field, and then click **OK**. Click **Next**.
   1.d. On the **Network Settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
   1.e. In the **Add smart host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of the SMTP gateway server, and then click **OK**. To specify more than SMTP gateway server as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
   1.f. On the **Configure smart host authentication settings** page, select **Externally Secured (for example with IPsec)**, and then click **Next**.
   1.g. On the **Source Server** page, click **Add**. In the **Select Hub Transport and subscribed Edge Transport servers** dialog box, select one or more Hub

Transport servers in your organization, click **OK**, and then click **Next**.

1.h.On the **New Connector** page, click **New**, and then on the **Completion** page, click **Finish**.

2. Create a Receive connector on the Hub Transport server to receive mail from the external SMTP gateway by following these steps:
   2.a.Expand **Server Configuration**, click **Hub Transport**, and then in the action pane, click **New Receive Connector**.
   2.b.On the New Receive Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
   2.c.From the **Select the intended use for this connector** drop-down list, select **Internal**, and then click **Next**.
   2.d.On the **Remote Network settings** page, remove the all network ranges entry, and then click **Add**.
   2.e.In the **Add IP Address(es) of Remote Servers** dialog box, type the IP address of the external SMTP gateway server, click **OK**, and then click **Next**.
   2.f.On the **New Connector** page, click **New**, and then on the **Completion** page, click **Finish**.
3. For the Receive connector that you just created, set the authentication method to Externally Secured by following these steps:
   3.a.In the task pane, select the Receive connector that you created in step 2, and then in the action pane, click **Properties**.
   3.b.Click the **Authentication** tab. Clear the check boxes for **Basic Authentication** and **Exchange Server**, select **Externally Secured (for example with IPsec)**, and then click **OK**.

Use the Shell to establish Internet mail flow between a Hub Transport server and Exchange Hosted Services or an external SMTP gateway by using Externally Secured authentication

1. This example creates the Send connector ToInternetGateway used by the Hub Transport server HubA that's configured to send outgoing e-mail through the external SMTP gateway smtpgateway1.contoso.com by using Externally Secured authentication.

```
New-SendConnector -Name "ToInternetGateway" -Usage Internal -AddressSp
```

2. This example creates the Receive connector FromInternetGateway on the Hub Transport server HubA that uses Externally Secured authentication to receive mail from the external SMTP gateway that has the IP address 192.168.1.10.

```
New-ReceiveConnector -Name "FromInternetGateway" -Server HubA -Usage I
```

For detailed syntax and parameter information, see New-SendConnector and New-ReceiveConnector.

Establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using anonymous relay

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Use the EMC and Shell to establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using anonymous relay

Note:
This procedure uses the EMC for steps 1 through 4. The last step of this procedure, granting relay permission to anonymous access on the Receive connector, can't be performed by using the EMC. You must use the Shell for that step.

1. Create a Send connector on the Hub Transport server to the external SMTP gateway by following these steps:
   1.a. Expand **Organization Configuration**, click **Hub Transport**, and then in the action pane, click **New Send connector**.
   1.b. On the New Send Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended use for this Send connector** drop-down list, select **Internet**, and then click **Next**.
   1.c. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, type **"*"** in the **Address** field, and then click **OK**. Click **Next**.
   1.d. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
   1.e. In the **Add smart host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of the SMTP gateway server, and then click **OK**. To specify more than SMTP gateway server as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
   1.f. On the **Configure smart host authentication settings** page, select **None**, and then click **Next**.
   1.g. On the **Source Server** page, click **Add**. In the **Select Hub Transport and subscribed Edge Transport servers** dialog box, select one or more Hub Transport servers in your organization, click **OK**, and then click **Next**.
   1.h. On the **New Connector** page, click **New**, and then on the **Completion** page, click **Finish**.
2. Create a Receive connector on the Hub Transport server to receive mail from the external SMTP gateway by following these steps:
   2.a. Expand **Server Configuration**, click **Hub Transport**, and then in the action pane, click **New Receive Connector**.
   2.b. On the New Receive Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
   2.c. From the **Select the intended use for this connector** drop-down list, select **Custom**, and then click **Next**.
   2.d. On the **Local Network settings** page, remove the existing **All Available IPv4** entry, and then click **Add**.
   2.e. In the **Add Receive Connector Binding** dialog box, select **Specify an IP address**. Type an IP address assigned to a network adapter on the local server that's best able to communicate with the external SMTP gateway. Make sure that the **Port** field has the value **25** and click **OK**. Leave the **Specify the FQDN this connector will provide in response to HELO or EHLO** field blank, and then click **Next**.
   2.f. On the **Remote Network settings** page, remove the all network ranges entry, and then click **Add**.
   2.g. In the **Add IP Addresses of Remote Servers** dialog box, type the IP address of the external SMTP gateway server, click **OK**, and then click **Next**.
   2.h. On the **New Connector** page, review the **Configuration Summary**. If you're satisfied, click **New**. If you'd like to make changes, click **Back**.
   2.i. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
      - A status of **Completed** indicates that the wizard completed the task successfully.
      - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
3. For the Receive connector that you just created, add the Anonymous permission group by following these steps:

3.a.In the task pane, select the Receive connector that you created in step 2, and then in the action pane, click **Properties**.
3.b.Click the **Permission Groups** tab. Select **Anonymous users**, and then click **OK**. Click **OK** to save your changes and exit the **Properties** page.
4. For the Receive connector that you just modified, grant the relay permission to the Anonymous logon security principal by following these steps:
4.a.Open the Shell.
4.b.Run the following command using the name of the Receive connector that you created in step 2 and modified in step 3.

```
Get-ReceiveConnector "Receive Connector Name" | Add-ADPermi
```

For detailed syntax and parameter information, see Get-ReceiveConnector and Add-ADPermission topics.

Use the Shell to establish Internet mail flow between a Hub Transport server and an external SMTP gateway by using anonymous relay

1. This example creates the Send connector ToInternetGateway used by the Hub Transport server HubA that's configured to send outgoing e-mail through the external SMTP gateway smtpgateway1.contoso.com by using anonymous relay.

```
New-SendConnector -Name "ToInternetGateway" -Usage Internet -AddressSp
```

2. This example creates the Receive connector FromInternetGateway on the Hub Transport server HubA that listens on local IP address 10.2.3.4 on port 25 for anonymous connections from an SMTP gateway server at the IP address 192.168.5.77.

```
New-ReceiveConnector -Name "FromInternetGateway" -Server HubA -Usage C
```

3. This example grants the relay permission to the Anonymous logon security principal on the Receive connector that you created in step 2.

```
Get-ReceiveConnector "FromInternetGateway" | Add-ADPermission -User "N
```

For detailed syntax and parameter information, see New-SendConnector, New-ReceiveConnector, Get-ReceiveConnector, and Add-ADPermission.

1.7.2.15.8 Configure Internet Mail Flow Directly Through a Hub Transport Server

Configure Internet Mail Flow Directly Through a Hub Transport Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure an Internet-facing Hub Transport server. To establish Internet mail flow directly through a Hub Transport server, you create a Send connector that routes e-mail to the Internet. Also, you modify the configuration of the default Receive connector to accept e-mail from the Internet. In this scenario, the Microsoft Exchange Server 2010 Hub Transport server can be reached directly through the Internet. We don't recommend this topology because it increases security risks by exposing to the Internet the Exchange 2010 server and all roles installed on that server. We recommend that you implement a perimeter network-based SMTP gateway, such as

the Edge Transport server, instead.

If you decide to configure Internet mail flow directly through your Hub Transport server, you may want to install the anti-spam agents on your Hub Transport servers. For more information, see Enable Anti-Spam Functionality on a Hub Transport Server.

Looking for other management tasks related to managing message routing? Check out Managing Message Routing.

Prerequisites

- Register MX resource records for all accepted domains in a public domain name system (DNS) server. Consult the documentation of your DNS provider for information about how to register MX records for your domain. Detailed procedures about how to complete this step are outside the scope of this topic.
- Configure network gateways to allow SMTP traffic to and from the Hub Transport server. Consult the documentation for your network routers and firewalls for information about how to route SMTP traffic to and from the Hub Transport server. Detailed procedures about how to complete this step are outside the scope of this topic.

Step 1: Create a Send connector on the Hub Transport server to send e-mail to the Internet

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" entry in the Transport Permissions topic.

Use the EMC to create the Send connector

1. Expand **Organization Configuration**, click **Hub Transport**, and then in the action pane, click **New Send connector**.
2. On the New Send Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended use for this Send connector** drop-down list, select **Internet**, and then click **Next**.
3. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, type **"*"** in the **Address** field, and then click **OK**. Click **Next**.
4. On the **Network settings** page, select **Use Domain Name System (DNS) to route mail automatically.** Select the **Use External DNS Lookup settings** check box. Click **Next**.

   Note:

   For more information about how to configure external DNS lookup settings, see Configure Hub Transport Server Properties.

5. On the **Source Server** page, click **Add**. In the **Select Hub Transport and subscribed Edge Transport servers** dialog box, select one or more Hub Transport servers in your organization, click **OK**, and then click **Next**.
6. On the **New Connector** page, click **New**, and then on the **Completion** page, click **Finish**.

Use the Shell to create the Send connector

This example creates a Send connector that's used by the Hub Transport server HubA to send e-mail to the Internet.

```
New-SendConnector -Name "Internet" -Usage Internet -AddressSpaces "*" -SourceTran
```

For detailed syntax and parameter information, see New-SendConnector.

Step 2: Modify the default Receive connector to allow anonymous connections

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Use the EMC to configure the Receive connector

1. Expand **Server Configuration**, click **Hub Transport**, and in the work pane under the **Receive Connectors** tab, select the **Default <Server Name>** connector. In the action pane, click **Properties**.
2. In **<Connector> Properties**, select the **Permissions** tab.
3. Select **Anonymous Users** to add anonymous permissions. Click **OK**.

Use the Shell to configure the Receive connector

This example modifies the default Receive connector on the Hub Transport server HubA to allow anonymous connections.

```
Set-ReceiveConnector "HubA\Default HubA" -PermissionGroups AnonymousUsers,Exchang
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

1.7.2.15.9 Configure Windows Network Load Balancing for Hub Transport Servers

Configure Windows Network Load Balancing for Hub Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Windows Network Load Balancing (NLB) to distribute non-Exchange messages among your Hub Transport or Edge Transport servers. To learn more about load balancing SMTP traffic, see Understanding SMTP Failover and Load Balancing in Transport.

Caution:

Using a load balancing solution to handle message traffic between the Exchange servers in your organization isn't supported. You must exclude message traffic between Exchange servers from any load balancing solution you deploy in your environment.

Looking for other management tasks related to handling SMTP traffic? Check out Managing Message Routing.

Prerequisites

- Microsoft Exchange Server 2010 is deployed and functional in your organization.

- You have reviewed Understanding SMTP Failover and Load Balancing in Transport.

Step 1: Use DNS Manager to create the SMTP namespace

You first need to create an SMTP namespace that will be used for Windows NLB. The following steps apply to the Active Directory-integrated Windows Domain Name System (DNS). If you use a third-party DNS server, refer to that documentation to create the necessary DNS records with the attributes shown in this procedure.

To perform this step, the account you use must be delegated membership in the DNS Admins group or the Domain Admins group.

1. Log on to a computer that has the DNS management console installed, click **Start**, point to **Administrative Tools**, and then click **DNS** to open DNS Manager.
2. If you aren't connected to the DNS server of your domain, use the following steps to connect to a DNS server. If you are connected to the correct server, go to step 3.
   2.a. On the **Action** menu, select **Connect to DNS Server**.
   2.b. Click **The following computer**, type the name of the DNS server to which you want to connect, and then click **OK**.
3. On the menu, click **View**, and then select **Advanced mode** unless it's already selected.
4. Expand the server name, and then expand the **Forward Lookup Zones** node.
5. Right-click the zone in which you want to create the SMTP namespace, and then select **New Host (A)**.
6. Specify the host name for the SMTP namespace and the associated IP address, and then set **Time to live (TTL)** to 5 minutes. For example:
   6.a. **Name** mail
   6.b. **IP Address** 10.0.0.10

   Note:
   You will notice that when you type the host name, the **FQDN** box is automatically updated. Make sure that the **FQDN** box shows the exact name you want to use for your SMTP namespace.
7. Click **Add Host**.
8. Click **OK** in the confirmation window, and then click **Done**.
9. Close DNS Manager.

Step 2: Use Windows to install and configure NLB

The Windows NLB cluster must be created and configured before you can create additional Receive connectors on your Hub Transport servers, and all Hub Transport servers must be added to the Windows NLB cluster.

Create your Windows NLB cluster by following the guidance in Implementing a New Network Load Balancing Cluster in the Windows Server 2008 documentation. Use the DNS record for the SMTP namespace you created in step 1 as the name and IP address of your Windows NLB cluster.

After the Windows NLB cluster has been created and configured, an extra IP address is added to each Hub Transport server. This IP address is known as the virtual IP address.

Step 3: Use the EMC to create a Receive connector

This step should be completed for each Hub Transport server participating in Windows NLB.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" or "Receive connectors - Edge Transport" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**.
2. In the result pane, select the server on which you want to create the connector, and then click the **Receive Connectors** tab.
3. In the action pane, click **New Receive Connector**. The New SMTP Receive Connector wizard opens.
4. On the **Introduction** page, enter a name for the connector, and then select **Custom** in the **Select the intended use for this Receive connector** box. Click **Next**.
5. On the **Local network settings** page, select **(All Available IPv4)**, and then click **Edit**.
6. In the **Edit Receive Connector Binding** window, select **Specify an IP address**, and then enter the virtual IP address of the Hub Transport server created when you configured Windows NLB. Click **OK**.
7. On the **Local network settings** page, enter the SMTP namespace you created in step 1 in the **Specify the FQDN this connector will provide in response to HELO or EHLO** box, and then click **Next**.
8. On the **Remote network settings** page, leave the default values, and then click **Next**.
9. On the **New connector** page, click **New**.
10. Click **Finish** to exit the wizard.

Other Tasks

After you configure Windows NLB for Hub Transport servers, you may also want to do the following:

- If the Hub Transport server needs to accept messages from non-authenticated sources, make sure **Anonymous users** is enabled on the new Receive connector. For more information, see step 6 in Configure Receive Connector Properties.
- If the Receive connector also needs to be used for relaying purposes, you need to perform additional configuration. For example, you may have line-of-business (LOB) applications that need to relay messages through the local Exchange organization for delivery to external recipients. For more information, see Allow Anonymous Relay on a Receive Connector. Also, review the Exchange Server Team Blog article Allowing application servers to relay off Exchange Server.

Note:

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

Configure Hardware Load Balancing for Hub Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a hardware load balancing solution to distribute non-Exchange messages among your Hub Transport or Edge Transport servers. To learn more about load balancing SMTP traffic, see Understanding SMTP Failover and Load Balancing in Transport.

Caution:

Using a load balancing solution to handle message traffic between the Exchange servers in your organization isn't supported. You must exclude message traffic between Exchange servers from any load balancing solution you deploy in your environment.

Looking for other management tasks related to handling SMTP traffic? Check out Managing Message Routing.

Prerequisites

- Microsoft Exchange Server 2010 is deployed and functional in your organization.
- You have deployed and verified a hardware load balancing device.
- You have reviewed Understanding SMTP Failover and Load Balancing in Transport.

Step 1: Use DNS to create the SMTP namespace

You first need to create an SMTP namespace that will be used for Windows Network Load Balancing (NLB). The following steps apply to the Active Directory-integrated Windows Domain Name System (DNS). If you use a third-party DNS server, refer to that documentation to create the necessary DNS records with the attributes shown in this procedure.

To perform this step, the account you use must be delegated membership in the DNS Admins group or the Domain Admins group.

1. Log on to a computer that has the DNS management console installed, click **Start**, point to **Administrative Tools**, and then click **DNS** to open DNS Manager.
2. If you aren't connected to the DNS server of your domain, use the following steps to connect to a DNS server. If you are connected to the correct server, go to step 3.
   2.a. On the **Action** menu, select **Connect to DNS Server**.
   2.b. Click **The following computer**, type the name of the DNS server to which you want to connect, and then click **OK**.
3. On the menu, click **View**, and then select **Advanced mode** unless it's already selected.
4. Expand the server name, and then expand the **Forward Lookup Zones** node.
5. Right-click the zone in which you want to create the SMTP namespace, and then select **New Host (A)**.
6. Specify the host name for the SMTP namespace and the associated IP address, and then set **Time to live (TTL)** to 5 minutes. For example:

6.a. **Name** mail
6.b. **IP Address** 10.0.0.10

> **Note:**
> You will notice that when you type the host name, the **FQDN** box is automatically updated. Make sure that the **FQDN** box shows the exact name you want to use for your SMTP namespace.

7. Click **Add Host**.
8. Click **OK** in the confirmation window, and then click **Done**.
9. Close DNS Manager.

Step 2: Use your vendor documentation to configure the virtual SMTP service on your hardware load balancing solution

For the steps required to create and configure the virtual SMTP service on the hardware load balancing solution used within your organization, see the hardware load balancing documentation provided by your vendor. Most hardware load balancing vendors have detailed documentation about how their product works with Exchange 2010 including steps about how to create a virtual SMTP service that can distribute incoming SMTP traffic among the Hub Transport servers in your organization.

For more information about Exchange 2010 server load balancing solutions, see Microsoft Unified Communications Hardware Load Balancer Deployment.

Step 3: Use Network and Sharing Center to add additional IP addresses to your Hub Transport servers

This step should be completed for each Hub Transport server participating in the hardware load balancing solution.

To perform this step, the account you use must be delegated membership in the Server Operators group or the local Administrators group.

1. Click **Start**, click **Control Panel**, and then double-click **Network and Sharing Center**.
2. Click **Manage network connections**.
3. Right-click the connection for the internal network, and then select **Properties**.
4. Double-click **Internet Protocol Version 4 (TCP/IPv4)**.
5. Click the **Advanced** button.
6. Under **IP addresses**, click **Add**.
7. Enter the IP address and subnet mask to which your hardware load balancer will direct SMTP traffic.
8. Click **Add**, and then click **OK** twice to close the property page for **Internet Protocol Version 4 (TCP/IPv4)**.
9. Click **Close** to exit the property page for the connection.

Step 4: Use the EMC to create a Receive connector

This step should be completed for each Hub Transport server participating in the hardware load balancing solution.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" or "Receive connectors - Edge Transport" entry in the Transport Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**.
2. In the result pane, select the server on which you want to create the connector, and then click the **Receive Connectors** tab.
3. In the action pane, click **New Receive Connector**. The New SMTP Receive Connector wizard opens.
4. On the **Introduction** page, enter a name for the connector, and then select **Custom** in the **Select the intended use for this Receive connector** box. Click **Next**.
5. On the **Local network settings** page, select **(All Available IPv4)**, and then click **Edit**.
6. In the **Edit Receive Connector Binding** window, select **Specify an IP address**, and then enter the virtual IP address of the Hub Transport server that you added to this Hub Transport server in step 3. Click **OK**.
7. On the **Local network settings** page, enter the SMTP namespace you created in step 1 in the **Specify the FQDN this connector will provide in response to HELO or EHLO** box, and then click **Next**.
8. On the **Remote network settings** page, leave the default values, and then click **Next**.
9. On the **New connector** page, click **New**.
10. Click **Finish** to exit the wizard.

Other Tasks

After you configure hardware load balancing for Hub Transport servers, you may also want to do the following:

- If the Hub Transport server needs to accept messages from non-authenticated sources, make sure **Anonymous users** is enabled on the new Receive connector. For more information, see step 6 in Configure Receive Connector Properties.
- If the Receive connector also needs to be used for relaying purposes, you need to perform additional configuration. For example, you may have line-of-business (LOB) applications that need to relay messages through the local Exchange organization for delivery to external recipients. For more information, see Allow Anonymous Relay on a Receive Connector. Also, review the Exchange Server Team Blog article Allowing application servers to relay off Exchange Server.

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

1.7.2.16 Managing Transport Agents

Managing Transport Agents

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

1.7.2.16.1 Install a Transport Agent

Install a Transport Agent

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you install a transport agent, Microsoft Exchange Server 2010 only registers the DLLs associated with the transport agent. You must make sure all files, registry keys, and other objects that the transport agent depends on are installed correctly and configured. After Exchange loads the DLLs, it continues to reference the DLLs after the command has completed.

Transport agents are installed in a disabled state to make sure mail flow isn't affected by transport agents that haven't been configured. Therefore, after a transport agent has been configured correctly, you must enable the transport agent.

You can use the Shell to install a transport agent on a computer that has the Hub Transport server role or Edge Transport server role installed. For more information about transport agents, see Understanding Transport Agents.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Caution:

Transport agents have full access to all e-mail messages that they encounter. Exchange puts no restrictions on a transport agent's behavior. Transport agents that are unstable or contain security flaws may affect the stability and security of Exchange. Therefore, you must only install transport agents that you fully trust and that have been fully tested in a test environment.

Use the Shell to install a transport agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions

topic.

Note:
You can't use the EMC to install a transport agent.

Use the following syntax to install a transport agent.

```
Install-TransportAgent -Name <"TransportAgentID"> -TransportAgentFactory <"Transp
```

This example installs a fictitious transport agent that scans messages for viruses.

```
Install-TransportAgent -Name "Antivirus for Exchange" -TransportAgentFactory "ven
```

This example enables the newly installed transport agent.

```
Enable-TransportAgent "Antivirus for Exchange"
```

For detailed syntax and parameter information, see Enable-TransportAgent.

1.7.2.16.2 View or Configure a Transport Agent

View or Configure a Transport Agent

Transport > Managing Transport Servers > Managing Transport Agents >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to view or modify an existing transport agent on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or Edge Transport server role installed. For more information about transport agents, see Understanding Transport Agents.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Use the Shell to view a summary list of transport agents

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view a summary list of transport agents.

This example provides a summary list of transport agents configured on a local computer.

```
Get-TransportAgent
```

For detailed syntax and parameter information, see Get-TransportAgent.

Use the Shell to view detailed configuration of a specific transport agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view detailed configuration of a specific transport agent.

This example provides detailed configuration of the Journaling agent configured on a Hub Transport server.

```
Get-TransportAgent "Journaling agent" | Format-List
```

For detailed syntax and parameter information, see Get-TransportAgent.

Use the Shell to configure a transport agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure a transport agent.

To modify the priority of an existing transport agent, use the following syntax.

```
Set-TransportAgent <TransportAgentID> [-Priority <Priority>]
```

This example modifies the priority of the existing transport agent Antivirus for Exchange.

```
Set-TransportAgent "Antivirus for Exchange" -Priority 3
```

For detailed syntax and parameter information, see Set-TransportAgent.

1.7.2.16.3 Uninstall a Transport Agent

Uninstall a Transport Agent

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to uninstall an existing transport agent on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or Edge Transport server role installed. You can uninstall transport agents configured on the local computer. When the transport agent is uninstalled, Exchange unregisters the DLL files used with the agent. Exchange doesn't remove any files, registry keys, or other objects added by the installation of the transport agent. For more information about transport agents, see Understanding Transport Agents.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Use the Shell to uninstall a transport

agent

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to uninstall a transport agent.

Use the following syntax to uninstall an existing transport agent.

```
Uninstall-TransportAgent <TransportAgentID>
```

This example uninstalls an existing transport agent.

```
Uninstall-TransportAgent "Antivirus for Exchange"
```

For detailed syntax and parameter information, see Uninstall-TransportAgent.

1.7.2.16.4 View Transport Agents in the Transport Pipeline

View Transport Agents in the Transport Pipeline

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to view a list of transport agents in the transport pipeline on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or Edge Transport server role installed. You can view a list of all the enabled transport agents that have encountered messages in the transport pipeline and the SMTP events they are registered on.

For more information about transport agents, see Understanding Transport Agents.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Use the Shell to view a list of transport agents in the transport pipeline

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport agents" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view a list of transport agents in the transport pipeline.

This example lists transport agents in the transport pipeline.

```
Get-TransportPipeline
```

Important:
Only transport agents that have encountered messages in the transport pipeline

between the time when the Exchange Transport service was started and the time when the **Get-TransportPipeline** cmdlet was run are displayed by the cmdlet. A transport agent that hasn't encountered a message in the transport pipeline won't appear in the results displayed by the **Get-TransportPipeline** cmdlet, even if that transport agent is enabled.

The **Get-TransportPipeline** cmdlet lists each SMTP event in the order that the SMTP events encounter messages in the transport pipeline. Listed next to each SMTP event is each transport agent that's registered on the SMTP event and has encountered a message. This example shows output from the **Get-TransportPipeline** cmdlet run on an Edge Transport server.

```
Event                                 TransportAgents
-----                                 ---------------
OnConnectEvent                        {Connection Filtering Agent}
OnHeloCommand                         {}
OnEhloCommand                         {}
OnAuthCommand                         {}
OnEndOfAuthentication                 {}
OnMailCommand                         {Connection Filtering Agent, Sender Fil
                                      ter Agent}
OnRcptCommand                         {Connection Filtering Agent, Address Re
                                      writing Inbound Agent, Recipient Filter
                                       Agent}
OnDataCommand                         {}
OnEndOfHeaders                        {Connection Filtering Agent, Address Re
                                      writing Inbound Agent, Sender Id Agent,
                                       Sender Filter Agent, Protocol Analysis
                                       Agent}
OnEndOfData                           {Edge Rule Agent, Content Filter Agent,
                                       Protocol Analysis Agent, Attachment Fi
                                      ltering Agent}
OnHelpCommand                         {}
OnNoopCommand                         {}
OnReject                              {Protocol Analysis Agent}
OnRsetCommand                         {Protocol Analysis Agent}
OnDisconnectEvent                     {Protocol Analysis Agent}
```

For detailed syntax and parameter information, see Get-TransportPipeline.

1.7.2.16.5 Enable Pipeline Tracing

Enable Pipeline Tracing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to enable pipeline tracing of e-mail messages as they move through the transport pipeline on computers that have the Exchange Server 2010 Hub Transport server role or Edge Transport server role installed. Pipeline tracing generates log files only for e-mail messages sent from the SMTP e-mail address that you specify by using the *PipelineTracingSenderAddress* parameter on the **Set-TransportServer** cmdlet. Pipeline tracing doesn't generate log files for messages sent from any other e-mail address. The SMTP e-mail address that you specify can be internal or external to your Exchange organization.

If you want to generate log files for messages generated by e-mail servers, such as automatic replies, delivery status notification (DSN) messages, journal reports, and other

system-generated messages, you can specify the value "<>" with the *PipelineTracingSenderAddress* parameter.

Caution:

Setting the value for the *PipelineTracingSenderAddress* parameter to "<>" captures all e-mail server-generated messages received by the Hub Transport or Edge Transport server that you are configuring. Depending on the amount of e-mail server-generated messages that your organization receives, this may place a significant load on the server and may quickly consume available disk space. Always monitor available disk space when pipeline tracing is enabled.

After you specify the pipeline tracing sender address, you can enable pipeline tracing.

Caution:

Pipeline tracing copies the complete contents of e-mail messages sent from the e-mail account configured by using the *PipelineTracingSenderAddress* parameter on the **Set-TransportServer** cmdlet. To avoid unwanted exposure of confidential information, you must set appropriate security permissions on the location of the pipeline tracing log file specified by the *PipelineTracingPath* parameter on the **Set-TransportServer** cmdlet. Don't enable pipeline tracing for long periods of time. Pipeline tracing creates verbose log files that can accumulate quickly. Always monitor available disk space when pipeline tracing is enabled.

For more information about the transport pipeline and transport agents, see Understanding Transport Pipeline and Understanding Transport Agents. Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Step 1: Use the Shell to configure the pipeline tracing sender address

Use the Shell to configure the pipeline tracing sender address to capture messages from a specific SMTP address

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:

You can't use the Exchange Management Console (EMC) to configure the pipeline tracing sender address.

Use the following syntax to configure the pipeline tracing sender address to capture messages from a specific SMTP address.

```
Set-TransportServer <Identity> -PipelineTracingSenderAddress <SMTPAddress>
```

This example configures the SMTP address, chris@contoso.com, as the pipeline tracing sender address on the Server1 computer.

```
Set-TransportServer Server1 -PipelineTracingSenderAddress chris@contoso.com
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to configure the pipeline tracing sender address to capture messages generated by e-mail servers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the pipeline tracing sender address.

Use the following syntax to configure the pipeline tracing sender address to capture messages generated by e-mail servers.

```
Set-TransportServer <Identity> -PipelineTracingSenderAddress "<>"
```

This example configures <> as the pipeline tracing sender address on the Server2 computer.

```
Set-TransportServer Server2 -PipelineTracingSenderAddress "<>"
```

For detailed syntax and parameter information, see Set-TransportServer.

Step 2: Use the Shell to configure the location of the pipeline tracing log directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to configure the location of the pipeline tracing log directory.

By default, the pipeline tracing log directory is located at C:\Program Files\Microsoft \Exchange Server\TransportRoles\Logs\PipelineTracing. The directory must be located on the Exchange 2010 computer.

Use the following syntax to configure the pipeline tracing log location.

```
Set-TransportServer <Identity> -PipelineTracingPath <LocalFilePath>
```

This example sets the location of the pipeline tracing log directory to C:\Pipeline Tracing Logs.

```
Set-TransportServer Server1 -PipelineTracingPath "C:\Pipeline Tracing Logs"
```

For detailed syntax and parameter information, see Set-TransportServer.

Step 3: Use the Shell to enable pipeline tracing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable pipeline tracing.

By default, pipeline tracing is disabled on computers that run Exchange 2010. You can enable or disable pipeline tracing on each Exchange server.

Configure the pipeline tracing sender address according to the previous procedures

earlier in this topic. You must configure the pipeline tracing sender address before you enable pipeline tracing.

Use the following syntax to enable pipeline tracing.

```
Set-TransportServer <Identity> -PipelineTracingEnabled <$True | $False>
```

This example enables pipeline tracing on the Server1 computer.

```
Set-TransportServer Server1 -PipelineTracingEnabled $True
```

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.16.6 Create an Address Rewrite Entry

Create an Address Rewrite Entry

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to create an address rewrite entry on a computer that has the Microsoft Exchange Server 2010 Edge Transport server role installed. For more information about address rewriting, see Understanding Address Rewriting.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Note:
The Address Rewriting Inbound agent and the Address Rewriting Outbound agent must be enabled so that address rewrite entries are applied to e-mail messages that enter and leave the Edge Transport server. If address rewrite entries have been created, but the Address Rewriting agents are disabled, Exchange 2010 won't apply the address rewrite entries.

Use the Shell to verify that Address Rewriting agents are enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to verify that Address Rewriting agents are enabled.

This example verifies whether Address Rewriting agents are enabled on the Edge Transport server. Make sure that the Address Rewriting Inbound and Address Rewriting Outbound agents are enabled.

```
Get-TransportAgent
```

For detailed syntax and parameter information, see Get-TransportAgent.

Use the Shell to enable Address Rewriting agents

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to enable Address Rewriting agents.

This example enables the Address Rewriting agents if they aren't enabled.

```
Enable-TransportAgent -Identity "Address Rewriting Inbound agent"
Enable-TransportAgent -Identity "Address Rewriting Outbound agent"
```

For detailed syntax and parameter information, see Enable-TransportAgent.

Use the Shell to rewrite a single e-mail address

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to rewrite a single e-mail address.

You can rewrite the headers of e-mail messages sent to and from specific internal e-mail addresses when messages are sent to and from the Internet.

When you configure Exchange 2010 to rewrite a single e-mail address, the headers of e-mail messages sent to and from that e-mail address are rewritten. For example, the internal address joe@contoso.com can be rewritten so that it appears to be support@contoso.com when e-mail is sent from that account to the Internet. When replies to that e-mail address or new messages to that address arrive, Exchange 2010 rewrites the recipient address in the header of the inbound messages by using the internal address joe@contoso.com.

When you rewrite e-mail addresses, there is a one-to-one correlation between the internal e-mail address and the external e-mail address. This correlation enables Exchange 2010 to automatically rewrite e-mail messages to and from the Internet.

This example creates an address rewrite entry that rewrites a single e-mail address.

```
New-AddressRewriteEntry -name "joe@contoso.com to support@northwindtraders.com" -
```

For detailed syntax and parameter information, see New-AddressRewriteEntry.

Use the Shell to rewrite a single domain

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:

You can't use the EMC to rewrite a single domain.

You can rewrite the headers of e-mail messages sent to and from recipients that send messages from specific internal domain names when messages are sent to and from the Internet.

For example, in the following procedure, the headers of e-mail messages sent from mailboxes in the internal contoso.com domain are rewritten so that the messages appear to originate from the fabrikam.com domain when they are sent to the Internet. When new messages, or replies to messages that originated from the rewritten domain, arrive at the computer that has the Edge Transport server role installed, Exchange 2010 rewrites the recipient address in the header of the inbound messages that have the internal domain contoso.com and delivers the message to the recipient.

This example creates an address rewrite entry that rewrites a single domain.

```
New-AddressRewriteEntry -Name "Contoso to Fabrikam" -InternalAddress contoso.com
```

For detailed syntax and parameter information, see New-AddressRewriteEntry.

Use the Shell to rewrite multiple subdomains

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:

You can't use the EMC to rewrite a multiple subdomains.

You can rewrite the headers of e-mail messages sent from mailboxes located in one of multiple internal subdomains. When you rewrite multiple subdomains, you have the following options:

- **Rewrite e-mail messages from all subdomains** This option enables you to rewrite all subdomains to a single external domain without exception. All e-mail messages from all subdomains will be rewritten.
- **Rewrite e-mail messages from specific subdomains** You may have to rewrite e-mail messages from specific subdomains, but don't want to affect other subdomains. This option is especially convenient when you have many subdomains but only want to rewrite addresses for a few of them. In Exchange 2010, you can configure address rewriting for only those specific subdomains without creating many exceptions.
- **Rewrite e-mail messages from all subdomains with exceptions** You may have to configure address rewriting for many subdomains, but may also have to prevent some subdomains from being rewritten. Instead of creating individual address rewrite entries for each subdomain, you can create an address rewrite entry that encompasses all subdomains, and then specify exceptions for those subdomains that you don't want to rewrite.

Before you configure address rewriting for multiple internal subdomains, you must first prepare your subdomains.

The following examples show how you can use the **New-AddressRewriteEntry** cmdlet to configure address rewriting for multiple subdomains.

This example creates an address rewrite entry that rewrites all e-mail messages sent from multiple subdomains and the parent domain.

```
New-AddressRewriteEntry -Name "Rewrite all contoso.com subdomains" -InternalAddre
```

This example creates an address rewrite entry that rewrites all e-mail messages sent from specific subdomains.

```
New-AddressRewriteEntry -Name "Rewrite sales.contoso.com to contoso.com" -Interna
New-AddressRewriteEntry -Name "Rewrite marketing.contoso.com to contoso.com" -Int
New-AddressRewriteEntry -Name "Rewrite research.contoso.com to contoso.com" -Inte
```

This example creates an address rewrite entry that rewrites all e-mail messages sent from multiple subdomains and the parent domain, except subdomains that you specify.

```
New-AddressRewriteEntry -name "Rewrite all contoso.com subdomains except legal.co
```

For detailed syntax and parameter information, see New-AddressRewriteEntry.

1.7.2.16.7 View or Configure an Address Rewrite Entry

View or Configure an Address Rewrite Entry

Transport > Managing Transport Servers > Managing Transport Agents >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to view or modify an existing address rewrite entry on a computer that has the Microsoft Exchange Server 2010 Edge Transport server role installed.For more information about address rewriting, see Understanding Address Rewriting.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Caution:

Be careful when you modify an address rewrite entry. Any changes that you make are applied immediately when the command is run. We recommend that you first run the command with the *WhatIf* parameter.
For more information about the *WhatIf* parameter, see WhatIf, Confirm, and ValidateOnly Switches.

Prerequisites

Read Create an Address Rewrite Entry.

Use the Shell to view a summary list of all address rewrite entries

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:

You can't use the EMC to view a summary list of all address rewrite entries.

This example provides a summary list of all address rewrite entries.

```
Get-AddressRewriteEntry
```

For detailed syntax and parameter information, see Get-AddressRewriteEntry.

Use the Shell to view detailed configuration of a single address rewrite entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to view detailed configuration of a single address rewrite entry.

To view detailed configuration of an address rewrite entry, you must pipe the output of the **Get-AddressRewriteEntry** command to the **Format-List** command by using the following command syntax.

```
Get-AddressRewriteEntry <GUID or address rewrite entry name> | Format-List
```

For more information about pipelining, see Pipelining. For more information about how to work with the information returned by a command, see Working with Command Output.

This example provides detailed configuration of the Rewrite Contoso.com to Northwindtraders.com address rewrite entry.

```
Get-AddressRewriteEntry "Rewrite Contoso.com to Northwindtraders.com" | Format-Li
```

For detailed syntax and parameter information, see Get-AddressRewriteEntry.

Use the Shell to modify an address rewrite entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to modify an address rewrite entry.

To modify an address rewrite entry, you must provide the *Identity* parameter of the address rewrite entry that you want to modify. You typically use the name of the address rewrite entry as its identity, although you can use its GUID.

You can modify several parameters configured on an address rewrite entry. To modify an address rewrite entry, specify the identity of the entry in double quotation marks. You don't have to specify the *Identity* parameter label because it's implied. Also, you should include each parameter that you want to modify, together with its value.

To modify an address rewrite entry, use the following syntax.

```
Set-AddressRewriteEntry <Identity> -Parameter <value>
```

This example modifies the *ExternalAddress* parameter.

Important:
On a single address rewrite entry, the *ExternalAddress* parameter and the *InternalAddress* parameter both must either be an e-mail address or a domain. You can't mix the two types of values on a single address rewrite entry.

```
Set-AddressRewriteEntry "Contoso to Northwindtraders" -ExternalAddress northwindt
```

This example modifies the *InternalAddress* parameter.

```
Set-AddressRewriteEntry "Northwindtraders to Contoso" -InternalAddress northwindt
```

This example modifies the *OutboundOnly* parameter.

Important:
You must use the *OutboundOnly* parameter when you configure address rewrite entries to rewrite multiple internal subdomains to a single external domain. If the *OutboundOnly* parameter is enabled on an address rewrite entry, Exchange 2010 doesn't rewrite inbound e-mail messages sent to the rewritten external domain that you specified.

```
Set-AddressRewriteEntry "Contoso to Northwindtraders" -OutboundOnly:$true
```

This example modifies the *ExceptionList* parameter.

```
Set-AddressRewriteEntry "Contoso to Northwindtraders" -ExceptionList sales.northw
```

Note:
If the **ExceptionList** property that the *ExceptionList* parameter modifies contains multiple values, be sure that you don't overwrite existing values when you add subdomains. For more information about how to add values to, and remove values from, the **ExceptionList** property, see Modifying Multivalued Properties.

This example modifies the *Name* parameter.

```
Set-AddressRewriteEntry "Contoso to Northwindtraders" -Name "Contoso to Woodgrove
```

For detailed syntax and parameter information, see Set-AddressRewriteEntry.

1.7.2.16.8 Remove an Address Rewrite Entry

Remove an Address Rewrite Entry

Transport > Managing Transport Servers > Managing Transport Agents >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to remove a single address rewrite entry and multiple address rewrite entries on a computer that has the Edge Transport server role installed.

In Microsoft Exchange Server 2010, you can use the Address Rewriting agent to modify the addresses of senders and recipients on messages that enter and leave an Exchange 2010 organization.

For more information about address rewriting, see Understanding Address Rewriting.

Looking for other management tasks related to transport agents? Check out Managing Transport Agents.

Caution:
Be careful when you remove an address rewrite entry or multiple address rewrite entries. The changes that you make are applied immediately. Make sure that you are removing the correct address rewrite entries and make a note of the configuration of any entry before you delete it. After you decide which address rewrite entries to remove, we recommend that you first run the command with the *WhatIf* parameter. For more information about the *WhatIf* parameter, see WhatIf, Confirm, and ValidateOnly Switches.

Use the Shell to remove a single address rewriting entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to remove a single address rewriting entry.

Remove a single address rewrite entry by using the following command syntax.

```
Remove-AddressRewriteEntry <GUID or address rewrite entry name>
```

This example runs the **Remove-AddressRewriteEntry** cmdlet with the *WhatIf* switch. The *WhatIf* switch lets the command run as if it were going to perform the action you specified but doesn't commit any changes. Instead, it displays the results of what would have happened, so you can verify that the actions are correct.

```
Remove-AddressRewriteEntry "Contoso.com to Northwindtraders.com" -WhatIf
```

This example removes a single address rewriting entry.

```
Remove-AddressRewriteEntry "Contoso.com to Northwindtraders.com"
```

For detailed syntax and parameter information, see Remove-AddressRewriteEntry.

Use the Shell to remove multiple address rewriting entries

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Note:
You can't use the EMC to remove multiple address rewriting entries.

To remove multiple address rewrite entries, you must use pipelining to pipe the output of the **Get-AddressRewriteEntry** command to the **Remove-AddressRewriteEntry** command. The **Get-AddressRewriteEntry** command accepts wildcard characters that let you specify matches based on partial names that you supply. The **Remove-AddressRewriteEntry** command accepts the results from the **Get-AddressRewriteEntry** command and removes the address rewrite entries that are returned.

For example, assume that you have configured the following address rewrite entries:

- "Rewrite sales.northwindtraders.com to contoso.com"
- "Rewrite marketing.northwindtraders.com to contoso.com"
- "Rewrite research.northwindtraders.com to contoso.com"

- "Rewrite john@northwindtraders to support@contoso.com"
- "Rewrite joe@northwindtraders to support@contoso.com"

You can use a wildcard character to match a subset of these address rewrite entries. The following examples show how to use a wildcard character to match specific entries in this list:

- Match only the subdomain address rewrite entries.

```
Get-AddressRewriteEntry "*to contoso.com"
```

- Match only the e-mail address rewrite entries.

```
Get-AddressRewriteEntry "*support@contoso.com"
```

Caution:

If you don't specify match criteria when you pipe the results of **Get-AddressRewriteEntry** to **Remove-AddressRewriteEntry**, all address rewrite entries on the local server will be deleted. Therefore, we recommend that you always use the *WhatIf* parameter to make sure that the changes that you are making are correct.

For more information about pipelining, see Pipelining.

Remove multiple address rewrite entries by using the following command syntax.

```
Get-AddressRewriteEntry <match criteria> | Remove-AddressRewriteEntry
```

This example runs the **Get-AddressRewriteEntry** cmdlet with the *WhatIf* switch. The *WhatIf* switch lets the command run as if it were going to perform the action you specified but doesn't commit any changes. Instead, it displays the results of what would have happened, so you can verify that the actions are correct.

```
Get-AddressRewriteEntry "*to contoso.com" | Remove-AddressRewriteEntry -WhatIf
```

This example removes multiple address rewriting entries.

```
Get-AddressRewriteEntry "*to contoso.com" | Remove-AddressRewriteEntry
```

For detailed syntax and parameter information, see Get-AddressRewriteEntry.

1.7.2.16.9 Import Address Rewrite Entries

Import Address Rewrite Entries

Transport > Managing Transport Servers > Managing Transport Agents >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Shell to import address rewrite entries into a computer that has the Microsoft Exchange Server 2010 Edge Transport server role installed.

The following are some of the common scenarios in which you may want to perform a bulk import of address rewrite entries:

- **Migration** You may want to bulk import address rewrite entries from a

previous solution that is being replaced by an Edge Transport server solution.
- **Outsourcing** You may have to bulk import address rewrite entries when you enter into agreements with third-party solution providers where their e-mail addresses must be rewritten.
- **Acquisition** You may have to bulk import address rewrite entries when the acquisition of other organizations requires the interim rewriting of the e-mail addresses of the acquired organizations.

If you have more than one Edge Transport server, we recommend that you use the following procedures to import address rewrite entries into a single Edge Transport server, and then clone the configuration of that Edge Transport server to other Edge Transport servers in your organization. For more information about how to clone an Edge Transport server, see Understanding Edge Transport Server Cloned Configuration.

Looking for other management tasks related to address rewrite entries? Check out Managing Transport Agents.

Prerequisites

You must be familiar with how to create an address rewrite entry before you try to use comma-separated value (CSV) files to perform bulk imports of address rewrite entries. For information, see Create an Address Rewrite Entry.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Rewriting agent" entry in the Transport Permissions topic.

Step 1: Create a CSV file

First, you must create a CSV file that contains columns of values that correlate to the parameters that are required by the **New-AddressRewriteEntry** cmdlet. The following values are required by the **New-AddressRewriteEntry** cmdlet and therefore must have corresponding columns in the CSV file:

- *Name* This parameter must be a string that uniquely identifies the address rewrite entry.
- *InternalAddress* This parameter specifies the internal SMTP address to be rewritten.
- *ExternalAddress* This parameter specifies the external SMTP address to be rewritten.

The following parameters are optional. You can include columns for them in the CSV file if you need them:

- *ExceptionList* This parameter specifies the list of subdomains that should not be rewritten. No SMTP addresses contained within the specified subdomains are rewritten. You must enclose the values that are used with the *ExceptionList* parameter in double quotation marks ("). If you want to specify multiple domains that have the *ExceptionList* parameter, you must separate each value by using commas (,). For example, the string `"domain1.com,domain2.com, domain3.com"` contains three domains enclosed with double quotation marks and separated by commas.
- *OutboundOnly* This parameter specifies whether the address rewrite entry should rewrite SMTP addresses on messages that are inbound and outbound to the Exchange 2010 organization, or rewrite only those messages that are outbound from the Exchange 2010 organization. Unlike Boolean usage elsewhere in the Shell, when you specify a value for the *OutboundOnly* parameter in a CSV file, you must specify a value of `True` or `False`, not `$True` or `$False`. This is because the value in the CSV file is converted to a Boolean value when the CSV file is interpreted on the command line.

Important:
If you specify values for optional columns in the CSV file, every row must include a value in that column. This is because the cmdlet expects a value for each parameter specified in the CSV file. If you want to create multiple address rewrite entries where some entries have optional parameters and some entries do not, you must separate those address rewrite entries and create two separate CSV files, and then import each of those CSV files.

Important:
You can only specify exception lists for address rewrite entries that are outbound-only. If you use both the *ExceptionList* and *OutboundOnly* columns in your CSV file, you can only put outbound-only address rewrite entries in that CSV file.

The following example shows how a CSV file can be populated with the optional *ExceptionList* and *OutboundOnly* parameters included:

```
Name,InternalAddress,ExternalAddress,ExceptionList,OutboundOnly
"Wingtip UK", *.wingtiptoys.co.uk, tailspintoys.com,"legal.wingtiptoys.co.uk,fina
"Wingtip USA", *.wingtiptoys.com, tailspintoys.com,"legal.wingtiptoys.com,finance
"Wingtip Canada", *.wingtiptoys.ca, tailspintoys.com,"legal.wingtiptoys.ca,financ
```

Step 2: Import a CSV file to create multiple address rewrite entries

You use the **New-AddressRewriteEntry** cmdlet in conjunction with the **Import-CSV** cmdlet to bulk import multiple address rewrite entries.

The following example imports the address rewrite entries that are listed in a previously created CSV file named ImportAddressRewriteEntries.csv.

```
Import-Csv C:\ImportAddressRewriteEntries.csv | ForEach { New-AddressRewriteEntry
```

For detailed syntax and parameter information, see New-AddressRewriteEntry.

1.7.2.17 Managing Transport Logs

Managing Transport Logs

Exchange Server 2010 > Transport > Managing Transport Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

Configure Connectivity Logging

Configure Message Tracking

Search Message Tracking Logs

Configure Protocol Logging

Configure Routing Table Logging

Configure Connectivity Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure connectivity logging in Microsoft Exchange Server 2010. You must use the Shell to configure size and age restrictions on the connectivity log files.

Connectivity logging records the connection activity of the outgoing message delivery queues that exist on computers running Exchange 2010 that have the Hub Transport server role or Edge Transport server role installed. The purpose of the connectivity log isn't to track the transmission of individual e-mail messages. Rather, the connectivity log tracks the connection activity from the sending queue to the destination Mailbox server, smart host, or domain.

Looking for other management tasks related to transport logs? Check out Managing Transport Logs.

Enable or disable connectivity logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

By default, connectivity logging is disabled on all Exchange 2010 computers that have the Hub Transport server role or Edge Transport server role installed.

Use the EMC to enable or disable connectivity logging

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Connectivity log** section, perform one of the following steps:
   - Select **Enable connectivity logging** to enable connectivity logging.
   - Clear **Enable connectivity logging** to disable connectivity logging.
4. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to enable or disable connectivity logging

To enable or disable connectivity logging, use the following syntax.

```
Set-TransportServer <Identity> -ConnectivityLogEnabled <$true | $false>
```

This example enables connectivity logging on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ConnectivityLogEnabled $true
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the location of the connectivity log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

By default, the connectivity log files are stored in the C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\Connectivity directory. The directory must be local to the Exchange 2010 computer.

Use the EMC to change the location of the connectivity log files

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Connectivity log** section, click **Browse** next to **Connectivity log path**.
4. In the **Browse for folder** window, browse to the new location where you want to store the connectivity log files. If you want to create a folder, select a parent folder, click **Make New Folder**, and then type the name of the new folder. After you make your folder selection, click **OK** to close the **Browse for folder** window.
5. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to change the location of the connectivity log files

To change the location of the connectivity log files, use the following syntax.

```
Set-TransportServer <Identity> -ConnectivityLogPath <LocalFilePath>
```

This example changes the location of the connectivity log file to C:\Connectivity on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ConnectivityLogPath "C:\Connectivity"
```

Note:

If you set the value of the *ConnectivityLogPath* parameter to `$null`, you effectively disable connectivity logging. However, if you set the value of the *ConnectivityLogPath* parameter to `$null` when the value of the **ConnectivityLogEnabled** attribute is `$true`, event log errors are generated. The preferred method to disable connectivity logging is to use the *ConnectivityLogEnabled* parameter with the **Set-TransportServer** cmdlet.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum size of individual connectivity log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to change the maximum size of individual connectivity log files.

By default, the maximum size for each connectivity log file is 10 megabytes (MB). When a connectivity log file reaches its maximum size, Exchange 2010 opens a new connectivity log file. This process continues until either the connectivity log directory reaches its specified maximum size or a connectivity log file reaches its specified maximum age. After the maximum size or age limit is reached, circular logging deletes the oldest connectivity log files.

To change the maximum size of individual connectivity log files, use the following syntax.

```
Set-TransportServer <Identity> -ConnectivityLogMaxFileSize <FileSize>
```

This example sets the maximum size of a connectivity log file to 20 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ConnectivityLogMaxFileSize 20MB
```

Note:
The value of the *ConnectivityLogMaxFileSize* parameter must be less than or equal to the value of the *ConnectivityLogMaxDirectorySize* parameter. The valid input range for either parameter is 1 through 9223372036854775807 bytes.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum size of the connectivity log directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to change the maximum size of the connectivity log directory.

By default, the maximum size for the whole connectivity log directory is 250 MB. Circular logging deletes the oldest connectivity log files when either the connectivity log directory reaches its specified maximum size or a connectivity log file reaches its specified maximum age.

To change the maximum size of the connectivity log directory, use the following syntax.

```
Set-TransportServer <Identity> -ConnectivityLogMaxDirectorySize <DirectorySize>
```

This example sets the maximum size of the connectivity log directory to 400 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ConnectivityLogMaxDirectorySize 400MB
```

Note:
The value of the *ConnectivityLogMaxDirectorySize* parameter must be greater than or equal to the value of the *ConnectivityLogMaxFileSize* parameter. The valid input range for either parameter is 1 through 9223372036854775807 bytes.

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum age of the connectivity log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to change the maximum age of the connectivity log files.

By default, the maximum age for any connectivity log file is 30 days. Circular logging deletes the oldest connectivity log files when either the connectivity log directory reaches its specified maximum size or a connectivity log file reaches its specified maximum age.

To change the maximum age of the connectivity log files, use the following syntax.

```
Set-TransportServer <Identity> -ConnectivityLogMaxAge <Age>
```

This example changes the maximum age of a connectivity log file to 45 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ConnectivityLogMaxAge 45.00:00:00
```

To specify an age value, enter it as a time span, as follows: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is 00:00:00 through 24855.03:14:07. Setting the value of the *ConnectivityLogMaxAge* parameter to 00:00:00 prevents the automatic removal of connectivity log files because of their age.

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.17.2 Configure Message Tracking

Configure Message Tracking

Transport > Managing Transport Servers > Managing Transport Logs >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Message tracking records the SMTP transport activity of all messages transferred to and from a computer running Exchange 2010 that has the Hub Transport, Edge Transport, or Mailbox server role installed. You can use message tracking logs for message forensics, mail flow analysis, reporting, and troubleshooting.

Looking for other management tasks related to transport logs? Check out Managing Transport Logs.

Enable or disable message tracking

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable or disable message tracking on Mailbox servers.

You can enable or disable message tracking on Hub Transport, Edge Transport, and Mailbox servers. By default, message tracking is enabled on all Exchange 2010 computers that have the Hub Transport, Edge Transport, or Mailbox server roles installed.

Use the EMC to enable or disable message tracking on transport servers

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Message tracking log** section, perform one of the following steps:
   - Select **Enable message tracking log** to enable message tracking.
   - Clear **Enable message tracking log** to disable message tracking.
4. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to enable or disable message tracking on transport servers

This example disables message tracking on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogEnabled:$false
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to enable or disable message tracking on Mailbox servers

This example disables message tracking on the Exchange 2010 computer Mailbox01.

```
Set-MailboxServer Mailbox01 -MessageTrackingLogEnabled:$false
```

For detailed syntax and parameter information, see Set-MailboxServer.

Configure the location of message tracking logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure the location of message tracking logs on Mailbox servers.

By default, the message tracking logs are stored in the C:\Program Files\Microsoft \Exchange Server\V14\TransportRoles\Logs\MessageTracking directory. The directory must be local to the Exchange 2010 computer.

If you set the value of the *MessageTrackingLogPath* parameter to `$null`, you effectively disable message tracking. However, if you set the value of the *MessageTrackingLogPath* parameter to `$null` when the value of the *MessageTrackingLogEnabled* attribute is `$true`, event log errors are generated. The preferred method to disable message tracking is to use the *MessageTrackingLogEnabled* parameter with the **Set-TransportServer** cmdlet or the **Set-MailboxServer** cmdlet.

Use the EMC to change the location of message tracking logs on transport servers

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Message tracking log** section, click **Browse** next to **Message tracking log path**.
4. In the **Browse for folder** window, browse to the new location where you want to store the message tracking log files. If you want to create a folder, select a parent folder, click **Make New Folder**, and then type the name of the new folder. After you make your folder selection, click **OK** to close the **Browse for folder** window.
5. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to change the location of message tracking logs on transport servers

To change the location of the message tracking logs on transport servers, use the following syntax.

```
Set-TransportServer <Identity> -MessageTrackingLogPath <LocalFilePath>
```

This example changes the location of the message tracking log to C:\Message Tracking on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogPath "C:\Message Tracking"
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the location of message tracking logs on Mailbox servers

To change the location of message tracking logs on Mailbox servers, use the following syntax.

```
Set-MailboxServer <Identity> -MessageTrackingLogPath <LocalFilePath>
```

This example changes the location of the message tracking log to C:\Message Tracking on the Exchange 2010 computer Mailbox01.

```
Set-MailboxServer Mailbox01 -MessageTrackingLogPath "C:\Message Tracking"
```

For detailed syntax and parameter information, see Set-MailboxServer.

Configure the size of each message

tracking log file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure the size of each message tracking log file.

By default, the maximum size for each message tracking log file is 10 megabytes (MB). When a message tracking log file reaches its maximum size, Exchange 2010 opens a new message tracking log file. This process continues until either the message tracking log directory reaches its specified maximum size or a message tracking log file reaches its specified maximum age. After the maximum size or age limit is reached, circular logging deletes the oldest message tracking log files.

Use the Shell to change the maximum size of each message tracking log file on transport servers

To change the maximum size of each message tracking log file on transport servers, use the following syntax.

```
Set-TransportServer <Identity> -MessageTrackingLogMaxFileSize <FileSize>
```

This example sets the maximum size of a message tracking log file to 20 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogMaxFileSize 20MB
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum size of each message tracking log file on Mailbox servers

To change the maximum size of each message tracking log file on Mailbox servers, use the following syntax.

```
Set-MailboxServer <Identity> -MessageTrackingLogMaxFileSize <FileSize>
```

This example sets the maximum size of a message tracking log file to 20 MB on the Exchange 2010 computer Mailbox01.

```
Set-MailboxServer Mailbox01 -MessageTrackingLogMaxFileSize 20MB
```

For detailed syntax and parameter information, see Set-MailboxServer.

Configure the size of the message tracking log directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure the size of the message tracking log directory.

By default, the maximum size for the whole message tracking log directory is 250 MB.

Circular logging deletes the oldest message tracking log files when either a message tracking log file reaches its specified maximum age, or the message tracking log directory reaches its specified maximum size.

Important:

The maximum size of the message tracking log directory is calculated as the total size of all log files that have the same name prefix. Other files that don't follow the name prefix convention aren't counted in the total directory size calculation. Renaming old log files or copying other files into the message tracking log directory could cause the directory to exceed its specified maximum size.
When the Hub Transport server role and the Mailbox server role are installed on the same server, the maximum size of the message tracking log directory isn't the specified maximum size because the message tracking log files generated by the different server roles have different name prefixes.
Message tracking log files for the Hub Transport server role or Edge Transport server role begin with the name prefix *MSGTRK*. Message tracking log files for the Mailbox server role begin with the name prefix *MSGTRKM*. When the Hub Transport server role and the Mailbox server role are installed on the same server, the maximum size of the message tracking log directory is two times the specified value.

Use the Shell to change the maximum size of the message tracking log directory on transport servers

To change the maximum size of the message tracking log directory on transport servers, use the following syntax.

```
Set-TransportServer <Identity> -MessageTrackingLogMaxDirectorySize <DirectorySize
```

This example sets the maximum size of the message tracking log directory to 400 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogMaxDirectorySize 400MB
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum size of the message tracking log directory on Mailbox servers

To change the maximum size of the message tracking log directory on Mailbox servers, use the following syntax.

```
Set-MailboxServer <Identity> -MessageTrackingLogMaxDirectorySize <DirectorySize>
```

This example sets the maximum size of the message tracking log directory to 400 MB on the Exchange 2010 computer Mailbox01.

```
Set-TransportServer Mailbox01 -MessageTrackingLogMaxDirectorySize 400MB
```

For detailed syntax and parameter information, see Set-MailboxServer.

Configure the age of message tracking logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure the age of message tracking logs.

By default, the maximum age for any message tracking log file is 30 days. Circular logging deletes the oldest message tracking log files if the message tracking log directory reaches its specified maximum size or a message tracking log file reaches its specified maximum age.

Use the Shell to change the maximum age of message tracking logs on transport servers

To change the maximum age of message tracking logs on transport servers, use the following syntax.

```
Set-TransportServer <Identity> -MessageTrackingLogMaxAge <Age>
```

This example changes the maximum age of a message tracking log file to 45 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogMaxAge 45.00:00:00
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to change the maximum age of message tracking logs on Mailbox servers

To change the maximum age of message tracking logs on Mailbox servers, use the following syntax.

```
Set-MailboxServer <Identity> -MessageTrackingLogMaxAge <Age>
```

This example changes the maximum age of a message tracking log file to 45 days on the Exchange 2010 computer Mailbox01.

```
Set-MailboxServer Mailbox01 -MessageTrackingLogMaxAge 45.00:00:00
```

To specify an age value, enter it as a time span, as follows: *dd.hh:mm:ss* where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is 00:00:00 through 24855.03:14:07. Setting the value of the *MessageTrackingLogMaxAge* parameter to 00:00:00 prevents the automatic removal of message tracking log files because of their age.

For detailed syntax and parameter information, see Set-MailboxServer.

Configure message subject logging in message tracking logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" or "Edge Transport server" entries in the Transport Permissions topic and the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure message subject logging in message tracking logs.

By default, the subject line of an SMTP e-mail message is stored in the message tracking log. However, you may want to disable message subject logging to comply with increased security or privacy requirements. Before you enable or disable message subject logging, verify your organization's policy about revealing subject line information.

Use the Shell to enable or disable message subject logging in message tracking logs on transport servers

To enable or disable message subject logging in message tracking logs on transport servers, use the following syntax.

```
Set-TransportServer <Identity> -MessageTrackingLogSubjectLoggingEnabled <$true|$f
```

This example disables message subject tracking on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageTrackingLogSubjectLoggingEnabled $false
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the Shell to enable or disable message subject logging in message tracking logs on Mailbox servers

To enable or disable message subject logging in message tracking logs on Mailbox servers, use the following syntax.

```
Set-MailboxServer <Identity> -MessageTrackingLogSubjectLoggingEnabled <$true|$fal
```

This example disables message subject tracking on the Exchange 2010 computer Mailbox01.

```
Set-MailboxServer Mailbox01 -MessageTrackingLogSubjectLoggingEnabled $false
```

For detailed syntax and parameter information, see Set-MailboxServer.

1.7.2.17.3 Search Message Tracking Logs

Search Message Tracking Logs

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-21*

This topic describes how to use the Exchange Management Console or the Exchange Management Shell to search the message tracking logs.

A message tracking log is a detailed log of all message activity as messages are transferred to and from a Microsoft Exchange Server 2010-based computer that has the Hub Transport server role, the Mailbox server role, or the Edge Transport server role installed. Exchange servers that have the Client Access server role or Unified Messaging server role don't have message tracking logs. You can use message tracking logs for message forensics, for mail flow analysis, for reporting, and for troubleshooting.

You can use the **Get-MessageTrackingLog** cmdlet in the Exchange Management Shell and the Message Tracking tool in the Toolbox in the Exchange Management Console to search for entries in the message tracking logs by using specific search criteria.

Before You Begin

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message tracking" entry in the Transport Permissions topic.

For more information about permissions, about delegating roles, and about the rights that are required to administer Exchange 2010, see Understanding Permissions.

When you search the message tracking log on a Hub Transport server or a Mailbox server, you cannot access the message tracking logs on an Edge Transport server. If you want to search the message tracking logs on an Edge Transport server, you must run the **Get-MessageTrackingLog** cmdlet or the Message Tracking tool directly from the Edge Transport server.

A search of the message tracking logs depends on the Microsoft Exchange Transport Log Search service. If you disable or stop this service, you cannot search the message tracking log files. However, stopping this service does not affect other features in Exchange.

Important:

You cannot copy the message tracking log files from a server that is running Microsoft Exchange and then search them by using the **Get-MessageTrackingLog** cmdlet or the Message Tracking tool. Also, if you save an existing message tracking log, the change in the date and time stamp on the message tracking log file breaks the query logic that Exchange uses to search the message tracking logs.

Criteria for Message Tracking Log Searches

Although many data fields are available for every message tracking log entry, not every field can be used as a search filter. Additionally, the Exchange Management Shell provides more flexibility for searching because of the many search filters that are available for use with the **Get-MessageTrackingLog** cmdlet.

Common Search Filters Used with the Get-MessageTrackingLog Cmdlet

The search filters described in the following list are available for use with the **Get-MessageTrackingLog** cmdlet in the Exchange Management Shell:

Note:

Use of a search filter that contains a partial value or multiple values is not supported unless otherwise noted.

- **Recipients** This search filter uses the recipient-address field. You must enter the complete e-mail address of the recipient. Multiple recipient values can be specified by using commas as a delimiter. Multiple individual recipients that are included in a single message are logged by using a single message tracking log entry. Unexpanded distribution group recipients are logged by using the distribution group's SMTP e-mail address.
- **Sender** This search filter uses the sender field. You must enter the complete e-mail address of the sender. The sender field contains the sender's e-mail address as specified in the `Sender:` header field, or in the `From:` header field if `Sender:` is not present.
- **Server** This search filter specifies the Exchange server that contains the message tracking logs to be searched. You can describe the server by using any of the following values:
  - Name
  - Fully qualified domain name (FQDN)
  - Distinguished name (DN)
  - Legacy Exchange DN
  - GUID
- **EventID** This search filter uses the event-id field. In the Message Tracking tool, you select the value of EventID from a drop-down list. In the **Get-MessageTrackingLog** cmdlet, you enter the value of EventID as text. However, the value must exactly match one of the possible EventID values. EventID is the event classification that is assigned to each message tracking

log entry. The available values are as follows:

- BADMAIL
- DEFER
- DELIVER
- DSN
- EXPAND
- FAIL
- POISONMESSAGE
- RECEIVE
- REDIRECT
- RESOLVE
- SEND
- SUBMIT
- TRANSFER

- **MessageID** This search filter uses the message-id field. MessageID is the value of the `Message-ID:` header field. If the `Message-ID:` header field does not exist or is blank, an arbitrary value is assigned. This value is constant for the lifetime of the message.
- **InternalMessageID** This search filter uses the internal-message-id field. InternalMessageID is a message identifier integer that is assigned by the Exchange server that is currently processing the message.
- **Subject** The parameter in the **Get-MessageTrackingLog** cmdlet is named *MessageSubject*. This search filter uses the message-subject field. Partial values are supported. This is the message's subject as specified in the `Subject:` header field. The tracking of message subjects is controlled by the *MessageTrackingLogSubjectLoggingEnabled* parameter in the **Set-TransportServer** cmdlet on Hub Transport servers and Edge Transport servers, and by the **Set-MailboxServer** cmdlet on Mailbox servers. By default, message subject logging is enabled. You can disable message subject logging by setting the value of the *MessageTrackingLogSubjectLoggingEnabled* parameter to `$False`.
- **Reference** This search filter uses the reference field. This field contains additional information for specific event types. For a DSN event, the reference field contains the `MessageID:` of the message that caused the DSN. For a SEND event, the reference field contains the `MessageID:` of any DSN messages. For a TRANSFER event, the reference field contains the `MessageID:` of the message that is being forked.
- **Start** This search filter uses the date-time field to look for message tracking entries that begin with the specified End date and time. You can use this filter by itself to retrieve all message tracking log entries after the specified date-time or as a lower limit with the *End* parameter.
- **End** This search filter uses the date-time field to look for message tracking entries up to but not including the specified End date and time. You can use this filter by itself to retrieve all message tracking log entries before the specified date-time or as an upper limit with the *Start* parameter.

Note:

The date-time field in the message tracking log stores information in Coordinated Universal Time (UTC). However, you should enter your date-time search criteria in the regional date-time format of the computer that you are using to perform the search. The message tracking log search tools automatically convert your regional date-time query into UTC. The search results are automatically converted from UTC back into your regional data-time format for display. The date-time field records the date-time of a particular message tracking event. The message origination date-time is the date-time that the message first enters the Exchange organization. The message origination date-time is stored in the message-info field for all SEND and DELIVER events.

Search Filters that are Different in the Exchange Management Console and the Exchange Management Shell

In the Exchange Management Shell, the **Get-MessageTrackingLog** cmdlet offers more control over the number of search results to display by using the *ResultSize* parameter. By default, a search displays up to 1,000 results. However, you can change the maximum value to a specific number. Alternatively, you can display all results by using the value of `Unlimited`. The Message Tracking tool in the Exchange Management Console does not have a way to customize the maximum number of search results that are displayed.

Searching the Message Tracking Logs by Using the Exchange Management Shell

The following table lists the search filters that are available by using the **Get-MessageTrackingLog** cmdlet in the Exchange Management Shell.

Search filters that are available by using the Get-MessageTrackingLog cmdlet

Search filter	Corresponding field in the message tracking log
End	date-time
EventId	event-id
InternalMessageId	internal-message-id
MessageId	message-id
MessageSubject	message-subject
Recipients	recipient-address
Reference	reference
ResultSize	None. This parameter limits the number of results that are displayed by the search.
Sender	sender-address
Start	date-time

All the parameters that are available with the **Get-MessageTrackingLog** cmdlet are optional. If you enter the **Get-MessageTrackingLog** cmdlet without any parameters, you will see a display of the last 1,000 message tracking log entries.

To use the Exchange Management Shell to search the message tracking logs

- Run the following command:

```
Get-MessageTrackingLog <SearchFilters>
```

For example, to search the message tracking log for all entries from 3/28/2011 8:00 AM to 3/28/2011 5:00 PM for all FAIL events sent by pat@contoso.com, run the following command:

```
Get-MessageTrackingLog -ResultSize Unlimited -Start "3/28/2011 8:00AM"
```

Controlling the Output of a Message

Tracking Log Search Performed in the Exchange Management Shell

When you perform a message tracking log search by using the **Get-MessageTrackingLog** cmdlet, not all the fields are displayed for each message tracking event. The following table lists the fields that are displayed by default by the **Get-MessageTrackingLog** cmdlet.

Fields that are displayed by default by the Get-MessageTrackingLog cmdlet

Search field	Corresponding field in the message tracking log
EventId	event-id
Source	message-source
Sender	sender-address
Recipients	recipient-address
MessageSubject	message-subject

You can control the output of the **Get-MessageTrackingLog** cmdlet by using command output options in the Exchange Management Shell according to the following guidelines:

- You can control the output format of the message tracking log search. You can display the results in a list or in a table.

  Important:
  Although the table format seems like a good choice for an output format, it may not be the best choice. If the field displayed in the table has values that are long, the values are truncated to fit in the columns of the table. Truncation also occurs if you try to display too many fields at the same time. The complete field values are always present if you use the list format. To view more columns, you can also increase the width of the Exchange Management Shell window from the default value of 80 characters. You adjust the size of the Exchange Management Shell window in the properties of the Exchange Management Shell window.

- You can display or hide specific fields that are returned from a message tracking log search. Wildcard characters (*) are supported.
- You can send the results of the search to a file.

The field names displayed by the results from the **Get-MessageTrackingLog** cmdlet are the same field names that you can use to filter the search results. These field names differ slightly from the actual field names that are stored in the message tracking log. The following table juxtaposes the field names that are used in the message tracking log and the field names that are used by the **Get-MessageTrackingLog** cmdlet.

Comparing the field names that are used in the message tracking log and the field names that are used by the Get-MessageTrackingLog cmdlet

Field name that is used in the message tracking log	Field name that is used to filter the Get-MessageTrackingLog results
date-time	Timestamp

client-ip	ClientIp
client-hostname	ClientHostname
server-ip	ServerIp
server-hostname	ServerHostname
source-context	SourceContext
connector-id	ConnectorId
source	Source
event-id	EventId
internal-message-id	InternalMessageId
message-id	MessageId
recipient-address	Recipients
recipient-status	RecipientStatus
total-bytes	TotalBytes
recipient-count	RecipientCount
related-recipient-address	RelatedRecipientAddress
reference	Reference
message-subject	MessageSubject
sender-address	Sender
return-path	ReturnPath
message-info	MessageInfo

To use the Exchange Management Shell to Control the Output of a Search of the Message Tracking Logs

- Use the following command:

```
Get-MessageTrackingLog <SearchFilters> | <Format-Table | Format-List> <
```

For example, to search the message tracking logs for the first 1,000 Send events, display the results that are shown in list format, display the values of any field names that begin with "Send" or "Receive," and write the results to a new file that is named "C:\send search.txt", run the following command:

```
Get-MessageTrackingLog -EventId "Send" | Format-List Send*,Receive* > "
```

Searching the Message Tracking Logs for a Message on Multiple Servers by Using the Exchange Management Shell

A message property that remains constant as it travels throughout the Exchange organization is the value of the `MessageID:` header field. This value is named

InternetMessageId in queue viewing utilities, and MessageId in the message tracking log utilities. After you have determined the value of MessageID:, you can search for that message in the message tracking logs on every Hub Transport server or Mailbox server in the Exchange organization.

To use the Exchange Management Shell to Search Message Tracking Log Entries for a Specific Message Across all Hub Transport Servers and Mailbox Servers

- Use the following command:

```
Get-ExchangeServer | where {$_.isHubTransportServer -eq $true -or $_.is
```

For example, to search the message tracking logs on all Hub Transport servers and Mailbox servers for any entries related to a message that has a MessageID: of ba18339e-8151-4ff3-aeea-87ccf5fc9796@contoso.com, to display the fields date-time, server-hostname, client-hostname, source, event-id, and recipient-address for each entry, and to sort the results by the date-time field, run the following command:

```
Get-ExchangeServer | where {$_.isHubTransportServer -eq $true -or $_.is
```

For detailed syntax and parameter information, see Get-MessageTrackingLog.

For more information about command output options in the Exchange Management Shell, see Exchange Management Shell.

Searching the Message Tracking Logs by Using the Exchange Management Console

To use the Exchange Management Console to Search the Message Tracking Log

1. Start the Exchange Management Console.
2. In the console tree, click **Toolbox**. In the result pane, click **Message Tracking**. In the action pane, click **Open tool**.
3. Log on to Outlook Web App when you are prompted.
4. In the **Select what to manage** list, click **My Organization**, and then click **Reporting** in the navigation pane.
5. Set the search criteria for your message tracking log search by configuring the values for the following available options:
   - **Mailbox to search** Click **Browse**, and then select the appropriate mailbox.
   - **Search for messages sent to** Click this option if you want to search for sent messages, and then click **Select users** to select one or more users.
   - **Search for messages received from** Alternatively, click this option to search for received messages, and then click Select a user to select the particular recipient.
   - **Search for these words in the subject line** Enter the search criteria text if you want to search for messages that contain a particular subject.
6. Click **Search**, and then review the results in the **Search Results** pane.

For More Information

For more information, see the following topics:

Understanding Message Tracking

Configure Message Tracking

1.7.2.17.4 Configure Protocol Logging

Configure Protocol Logging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Protocol logging records the SMTP conversations that occur between e-mail servers as part of message delivery. These SMTP conversations occur on Send connectors and Receive connectors configured on servers running Microsoft Exchange Server 2010 that have the Hub Transport server role or the Edge Transport server role installed. You can use protocol logging to diagnose mail flow problems.

By default, protocol logging is disabled on all Send connectors and Receive connectors. Protocol logging is enabled or disabled on a per-connector basis. Other protocol logging options are set on a per-connector type basis for the whole server. All the Receive connectors on a Hub Transport server or an Edge Transport server share the same protocol log files and protocol log options. These protocol log files and protocol log options are separate from the Send connector protocol log files and protocol log options that are on the same server. By default, Exchange 2010 uses circular logging to limit the protocol logs based on file size and file age to help control the hard disk space used by the protocol log files.

Looking for other management tasks related to transport logs? Check out Managing Transport Logs.

Caution:

Don't perform this procedure on an Edge Transport server that has been subscribed to the Exchange organization by using EdgeSync. Instead, make the changes on the Hub Transport server. The changes are then replicated to the Edge Transport server next time EdgeSync synchronization occurs.

Enable or disable protocol logging on connectors

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" and "Send connectors" entries in the Transport Permissions topic.

Use the EMC to enable or disable protocol logging on connectors

1. Perform one of the following steps:
   - To modify an existing Receive connector on an Edge Transport server, in the console tree, select **Edge Transport**, and then in the work pane, click the **Receive Connectors** tab.
   - To modify an existing Receive connector on a Hub Transport server, expand **Server Configuration** in the console tree, and select **Hub Transport**. In the result pane, select the server that has the Receive connector that you want to modify, and then click the **Receive Connectors** tab.
2. In the work pane, select the Receive connector to modify.
3. Under the name of the Receive connector in the action pane, click **Properties** to open the **Properties** page.
4. Click the **General** tab and use the drop-down box next to **Protocol logging**

level to enable or disable protocol logging. **None** disables protocol logging, and **Verbose** enables protocol logging.

5. After you make your protocol logging selection, click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

The procedure is similar for Send connectors. To access Send connectors, you navigate to **Organization Configuration** > **Hub Transport**.

Use the Shell to enable or disable protocol logging on connectors

This example enables protocol logging for the Receive connector Connection from Contoso.com.

```
Set-ReceiveConnector "Connection from Contoso.com" -ProtocolLoggingLevel Verbose
```

The procedure is similar for Send connectors. For Send connectors, you use the **Set-SendConnector** cmdlet.

For detailed syntax and parameter information, see Set-ReceiveConnector or Set-SendConnector.

Enable or disable protocol logging for the intra-organization Send connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:

You can't use the EMC to enable or disable protocol logging for the intra-organization Send connector.

A special Send connector named the intra-organization Send connector exists on every Hub Transport server. This connector is implicitly created, invisible, and requires no management. The intra-organization Send connector is used to relay messages to the following destinations:

- To other Hub Transport servers in the Exchange organization
- To Exchange Server 2003 servers in the Exchange organization
- To Edge Transport servers in the Exchange organization

By default, protocol logging for the intra-organization Send connector is disabled. You can enable or disable protocol logging for the intra-organization Send connector by using the **Set-TransportServer** cmdlet.

This example enables protocol logging on the intra-organization Send connector on a Hub Transport server.

```
Set-TransportServer "Exchange01" -IntraOrgConnectorProtocolLoggingLevel Verbose
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the location of the protocol log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server"

entries in the Transport Permissions topic.

By default, the Receive connector protocol log files are located at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpReceive, and the Send connector protocol log files are located at C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\ProtocolLog\SmtpSend. The directory must be local to the Exchange 2010 computer.

Use the EMC to change the location of the Receive connector protocol log files

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Protocol log** section, click **Browse** next to **Receive connector protocol log file path**.
4. In the **Browse for folder** window, browse to the new location where you want to store the Receive connector protocol log files. If you want to create a folder, select a parent folder, click **Make New Folder**, and then type the name of the new folder. After you make your folder selection, click **OK** to close the **Browse for folder** window.
5. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to change the location of the Receive connector protocol log files

This example sets the Receive connector protocol log directory to C:\Receive SMTP Log on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ReceiveProtocolLogPath "C:\Receive SMTP Log"
```

For detailed syntax and parameter information, see Set-TransportServer.

Use the EMC to change the location of the Send connector protocol log files

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, select **Edge Transport**, and then in the action pane, click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and select **Hub Transport**. In the action pane, click the **Properties** link that's directly under the server name.
2. On the **Properties** page, click the **Log Settings** tab.
3. In the **Protocol log** section, click **Browse** next to **Send connector protocol log file path**.
4. In the **Browse for folder** window, browse to the new location where you want to store the Send connector protocol log files. If you want to create a folder, select a parent folder, click **Make New Folder**, and then type the name of the new folder. After you make your folder selection, click **OK** to close the **Browse for folder** window.
5. Click **Apply** to save changes and remain on the **Properties** page, or click **OK** to save changes and exit the **Properties** page.

Use the Shell to change the location of the Send connector protocol log files

This example sets the Send connector protocol log directory to C:\Send SMTP Log on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -SendProtocolLogPath "C:\Send SMTP Log"
```

Setting the value of the *SendProtocolLogPath* parameter or *ReceiveProtocolLogPath* parameter to `$null` disables protocol logging for all Send connectors or all Receive connectors on the server. However, setting either of these parameters to `$null` when protocol logging is enabled for any Send connector, including the intra-organization Send connector, or Receive connector on the server generates event log errors. The preferred method of disabling protocol logging is to use the **Set-SendConnector** or **Set-ReceiveConnector** cmdlets to set the *ProtocolLoggingLevel* parameter to `None`. Also, you can use the **Set-TransportServer** cmdlet to set the *IntraOrgProtocolLoggingLevel* parameter to `None`.

For detailed syntax and parameter information, see Set-TransportServer.

Configure the maximum size of each protocol log file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum size of each protocol log file.

By default, the maximum size for each protocol log file is 10 MB. All Receive connectors on the server share the same protocol log files, and all Send connectors on the server share the same protocol log files. When a protocol log file reaches its maximum size, Exchange 2010 opens a new protocol log file. This process continues until either of the following conditions is true:

- The protocol log directory reaches its specified maximum size. For more information about how to change the maximum size of the protocol log directory, see "Configure the maximum size of the protocol log directory" later in this topic.
- A protocol log file reaches its specified maximum age. For more information about how to change the maximum age of a protocol log file, see "Configure the maximum age of the protocol log files" later in this topic.

After the maximum size or age limit is reached, circular logging deletes the oldest protocol log files.

This example sets the maximum size of Receive connector protocol log files to 20 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ReceiveProtocolLogMaxFileSize 20MB
```

This example sets the maximum size of Send connector protocol log files to 20 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -SendProtocolLogMaxFileSize 20MB
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the maximum size of the protocol log directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum size of the protocol log directory.

By default, the maximum size for the protocol log directory is 250 MB. All Receive connectors on the server share the same protocol log directory, and all Send connectors on the server share the same protocol log directory. Circular logging deletes the oldest protocol log files when either of the following conditions is true:

- The protocol log directory reaches its specified maximum size.
- A protocol log file reaches its specified maximum age.

This example sets the maximum size of the Receive connector protocol log directory to 400 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ReceiveProtocolLogMaxDirectorySize 400MB
```

This example sets the maximum size of the Send connector protocol log directory to 400 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -SendProtocolLogMaxDirectorySize 400MB
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the maximum age of the protocol log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum age of the protocol log files.

By default, the maximum age for any protocol log file is 30 days. All Receive connectors on the server share the same protocol log files, and all Send connectors on the server share the same protocol log files. Circular logging deletes the oldest protocol log files if either of the following conditions is true:

- The protocol log directory reaches its specified maximum size.
- A protocol log file reaches its specified maximum age.

This example sets the age limit of the Receive connector protocol log files to 45 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ReceiveProtocolLogMaxAge 45.00:00:00
```

This example sets the age limit of the Send connector protocol log files to 45 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -SendProtocolLogMaxAge 45.00:00:00
```

To specify an age value, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h*

= hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:00 through 24855.03:14:07. Setting the value of the *ReceiveProtocolLogMaxAge* parameter or the *SendProtocolLogMaxAge* parameter to 00:00:00 prevents the automatic removal of protocol log files because of their age.

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.17.5 Configure Routing Table Logging

Configure Routing Table Logging

Transport > Managing Transport Servers > Managing Transport Logs >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Routing table logging periodically records a snapshot of the routing table used by the server running Exchange 2010 that has the Hub Transport server role or Edge Transport server role installed. The routing table is used to route messages to their destinations.

Looking for other management tasks related to transport logs? Check out Managing Transport Logs.

Configure the location of the routing table logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the location of the routing table logs.

By default, the routing table logs are stored in the C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\Logs\Routing directory. The directory must be local to the Exchange 2010 computer.

This example changes the location of the routing table log to C:\Routing Table on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -RoutingTableLogPath "C:\Routing Table"
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the interval for automatic recalculation of the routing table

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The routing table is recalculated and logged after a routing configuration change, or after a specified time interval has passed if no changes are detected. By default, the routing

table is automatically recalculated every 12 hours.

The interval for automatic recalculation of the routing table is controlled by the *RoutingConfigReloadInterval* parameter in the EdgeTransport.exe.config file located in C:\Program Files\Microsoft\Exchange Server\V14\Bin. The EdgeTransport.exe.config file is an XML application configuration file associated with the EdgeTransport.exe file. EdgeTransport.exe and MSExchangeTransport.exe are the executable files used by the Microsoft Exchange Transport service. This service runs on every Hub Transport server or Edge Transport server. Changes made to the EdgeTransport.exe.config file are applied after the Microsoft Exchange Transport service is restarted.

The following example shows the typical structure of the EdgeTransport.exe.config file.

```
<configuration>

<runtime>

<gcServer enabled="true" />

</runtime>

<appSettings>

<add key=" Configuration Option " value=" Value " />

...

</appSettings>

</configuration>
```

You can add new configuration options or modify existing configuration options in the <appSettings> section. Many available configuration options are unrelated to the routing table. Any configuration options that don't involve the routing table are outside the scope of this topic.

Note:
The parameter names in the <add key=../> section are case sensitive.

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\ V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section.

   ```
   <add key="RoutingConfigReloadInterval" value="<interval>" />
   ```

   This example changes the interval for automatic recalculation of the routing table to 10 hours, by modifying the *RoutingConfigReloadInterval* parameter.

   ```
   <add key="RoutingConfigReloadInterval" value="10:00:00" />
   ```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

To specify an age value, enter it as a time span, as follows: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds.

The routing table will be recalculated and logged earlier than the value specified by the *RoutingConfigReloadInterval* parameter if any of the following conditions occur:

- A routing configuration change is detected. For example, a Send connector or a Receive connector is added, removed, or modified, or the 6 hour Kerberos token renewal occurs.
- The Microsoft Exchange Transport service is started.

Configure the maximum size of the routing table log directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum size of the routing table log directory.

By default, the maximum size for the whole routing table log directory is 50 megabytes (MB). Circular logging deletes the oldest routing table log files if either of the following conditions is true:

- The routing table log directory reaches its specified maximum size.
- A routing table log file reaches its specified maximum age.

This example sets the maximum size of the routing table log directory to 70 MB on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -RoutingTableLogMaxDirectorySize 70MB
```

For detailed syntax and parameter information, see Set-TransportServer.

Configure the maximum age of the routing table logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to configure the maximum age of the routing table logs.

By default, the maximum age for any routing table log file is 7 days. Circular logging deletes the oldest routing table log files if either of the following conditions is true:

- The routing table log directory reaches its specified maximum size.
- A routing table log file reaches its specified maximum age.

To configure the maximum age of the routing table logs, use the following syntax.

```
Set-TransportServer <Identity> -RoutingTableLogMaxAge <Age>
```

This example changes the maximum age of a routing table log file to 45 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -RoutingTableLogMaxAge 45.00:00:00
```

To specify an age value, enter it as a time span, as follows: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is 00:00:00 through 24855.03:14:07. Setting the value of the *RoutingTableLogMaxAge* parameter to 00:00:00 prevents the automatic removal of routing table log files because of their age.

For detailed syntax and parameter information, see Set-TransportServer.

1.7.2.18 Managing Transport Queues

Managing Transport Queues

Exchange Server 2010 > Transport > Managing Transport Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-01*

1.7.2.18.1 Change the Location of the Queue Database

Change the Location of the Queue Database

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *queue* is a temporary holding location for messages that are waiting to enter the next stage of processing. Each queue represents a logical set of messages that a transport server processes in a specific order.

Microsoft Exchange Server 2010 uses an Extensible Storage Engine (ESE) database for queue message storage. Formerly known as JET, ESE is a method that defines a low-level API to the underlying database structures in Exchange. All the different queues are stored

in a single ESE database. Queues exist only on servers that have the Hub Transport server role or the Edge Transport server role installed.

The location of the queue database and queue database transaction logs are controlled by the *QueueDatabasePath* and *QueueDatabaseLoggingPath* parameters in the EdgeTransport.exe.config application configuration file that's located in the C:\Program Files\Microsoft\Exchange Server\V14\Bin directory. The following list describes some important items to consider when you change the location of the queue database:

- If the target directory doesn't exist, it will be created for you if the parent directory has the following permissions applied to it:
  - Network Service: Full Control
  - System: Full Control
  - Administrators: Full Control
- The existing queue database files Mail.que and Trn.chk aren't moved. New queue database files are created at the new location after you save the EdgeTransport.exe.config application configuration file and restart the Microsoft Exchange Transport service. The existing database files are left at the old location. However, they're no longer used.
- If you want to change the location of the queue database but reuse the existing queue database files, you must move or copy the database files when the Microsoft Exchange Transport service is stopped.
- The existing queue database transaction log files Trn.log, Trntmp.log, Trn*nnn*.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb aren't moved. New queue database transaction logs are created at the new location after you save the EdgeTransport.exe.config application configuration file and restart the Microsoft Exchange Transport service. The existing transaction log files are left at the old location. However, they're no longer used.

Note:

Temp.edb is used to verify the queue database schema when the Microsoft Exchange Transport service starts. Although Temp.edb isn't a transaction log file, it's kept in the same location as the transaction log files.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Change the location of the queue database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Use Notepad to create a queue database at a new location

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section.

```
<add key="QueueDatabasePath" value="<LocalPath>" />
```

This example creates a queue database at the location C:\Queue\QueueDB.

```
<add key="QueueDatabasePath" value="C:\Queue\QueueDB" />
```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.
5. Verify that the new Mail.que and Trn.chk files are created at the new location.
6. Remove the unused Mail.que and Trn.chk files from the original location.

Use Notepad to reuse an existing queue database at a new

location

1. Create the directory where you want to keep the queue database. Make sure that the correct permissions are applied to the directory.
2. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
3. Modify the following line in the <appSettings> section.

   ```
   <add key="QueueDatabasePath" value="<LocalPath>" />
   ```

   This example changes the location to C:\Queue\QueueDB.

   ```
   <add key="QueueDatabasePath" value="C:\Queue\QueueDB" />
   ```

4. Save and close the EdgeTransport.exe.config file.
5. Stop the Microsoft Exchange Transport service.
6. Copy the files Mail.que and Trn.chk from the original location to the new location.
7. Start the Microsoft Exchange Transport service.
8. Remove the unused Mail.que and Trn.chk files from the original location.

Change the location of the queue database transaction logs

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Use Notepad to create queue database transaction logs at a new location

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section.

   ```
   <add key="QueueDatabaseLoggingPath" value="<LocalPath>" />
   ```

   This example creates a queue database at the location C:\Queue \QueueLogs.

   ```
   <add key="QueueDatabaseLoggingPath" value="C:\Queue\QueueLogs" />
   ```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.
5. Verify that the new Trn.log, Trntmp.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files are created at the new location.
6. Remove the unused Trn.log, Trntmp.log, Trn*nnnnn*.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files from the original location.

Use Notepad to reuse existing queue database transaction logs at a new location

Under ordinary circumstances, you shouldn't have to reuse existing transaction logs at a new location. An ordinary shutdown of the Microsoft Exchange Transport service commits all uncommitted transaction log entries to the queue database. Circular logging is used. Therefore transaction logs that contain previously committed database changes aren't preserved. Only disaster recovery scenarios where the Microsoft Exchange Transport service wasn't shut down correctly or a hard disk drive failure would require that you restore and relocate an existing queue database and its existing transaction logs.

1. Create the directory where you want to keep the queue database transaction logs. Make sure that the correct permissions are applied to the directory.
2. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
3. Modify the following line in the <appSettings> section:

```
<add key="QueueDatabaseLoggingPath" value="<LocalPath>" />
```

This example changes the location to C:\Queue\QueueLogs.

```
<add key="QueueDatabaseLoggingPath" value="C:\Queue\QueueLogs" />
```

4. Save and close the EdgeTransport.exe.config file.
5. Stop the Microsoft Exchange Transport service.
6. Copy the existing Trn.log, Trntmp.log, Trn*nnnnn*.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files to the new location.
7. Start the Microsoft Exchange Transport service.
8. Remove the unused Trn.log, Trntmp.log, Trn*nnnnn*.log, Trnres00001.jrs, Trnres00002.jrs, and Temp.edb files from the original location.

1.7.2.18.2 Using Queue Viewer

Using Queue Viewer

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-02*

Queue Viewer is an Exchange Management Console snap-in that's installed when you install the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role. Queue Viewer is located in the Toolbox node of the Exchange Management Console. You can use this tool to view information about queues on a transport server and the messages that are present in those queues and to perform management actions on queues and mail items. Queue Viewer is useful for troubleshooting mail flow and identifying spam.

When you're using Queue Viewer to manage queues, consider the following:

- You must connect to a transport server. By default, Queue Viewer focuses on the queuing database located on the server to which Queue Viewer connects to run the tasks. However, you can connect to a different server than the one on which you're running the Queue Viewer tasks. For more information, see Connect to a Server by Using Queue Viewer.
- The list of queues and messages can be large, depending on current mail flow, and the list of queues and messages changes when messages enter and leave the server. You can configure the options for Queue Viewer to control the interval at which the list of queues and messages is refreshed and the number of items displayed on each page. For more information, see Set Queue Viewer Options.
- You can create a filter to display the specific set of queues or messages that you want to monitor. After you locate the queues and messages that you want to monitor, you can view the property information for these queues and messages. This information is helpful when you troubleshoot the cause of mail flow problems. For more information, see Filter Queues and Filter Messages in Queues.
- You can use the **Export List** link in the action pane to export the list of queues or a list of messages. For more information, see Export Lists from the Exchange Management Console.

1.7.2.18.2.1 Connect to a Server by Using Queue Viewer

Connect to a Server by Using Queue Viewer

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Queue Viewer to connect to a remote computer that has a Microsoft Exchange Server 2010 Hub Transport server installed. By default, Queue Viewer connects to the queuing database on the server on which Queue Viewer is being run. When you use Queue Viewer on an Edge Transport server, you can't change the focus of the tool.

When you use Queue Viewer on an Exchange 2010 server that's located inside the Exchange organization, you can use Queue Viewer to connect to any Hub Transport server in the organization. You can start more than one instance of Queue Viewer so that each instance focuses on a different server. You can tile Queue Viewer windows so that you can easily monitor more than one Hub Transport server at a time.

You can also specify which server to connect to for the remote Shell. This doesn't need to match the remote server whose queues you're managing using the tool.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to choose a server to connect to for the remote Shell session

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the Shell to perform this task.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Properties**.
4. In the **Queue Viewer Properties** dialog box, select one of the following options:
   - **Connect to the automatically selected server** Select this option to automatically connect to the server whose queues you're managing for running remote Shell.
   - **Specify a server to connect to** Select this option to specify a server to run remote Shell. If you select this option, click **Browse** to open the **Select Exchange Server** dialog box. Select the server to which you want to connect for running the remote Shell, and then click **OK**.

For more information about remote Shell, see Overview of Exchange Management Shell.

Use the EMC to choose a server to manage its queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:

You can't use the Shell to perform this task.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Connect to server**.
4. In the **Connect to Server** window, click **Browse** to view a list of the available Hub Transport servers.
5. In the **Select Exchange Server** window, select a Hub Transport server. To search for a Hub Transport server to connect to, use one of the following procedures:
   - Enter the exact server name or the first few letters of the server name in the **Search** field, and then click **Find Now**. Select a server from the result pane.
   - Select the **View** menu, and then click **Show Filter**. In the **Name** column or **Version** column, click the filter icon, and then select the filter operator. Type the filter criteria in the **Enter text here** field. Press ENTER. Select a server from the result pane.
6. Click **OK** to close the **Select Exchange Server** window.
7. After you select a server, in the **Connect to server** window, select the **Set as default server** check box if you want Queue Viewer to focus on this server first whenever Queue Viewer is opened.
8. In the **Connect to server** window, click **Connect**.

1.7.2.18.2.2 Set Queue Viewer Options

Set Queue Viewer Options

Managing Transport Servers > Managing Transport Queues > Using Queue Viewer >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set options in Queue Viewer to adjust the number of items that are displayed on the page and adjust the auto-refresh interval. The auto-refresh interval determines how frequently the results in Queue Viewer are updated.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to set Queue Viewer options

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:

You can't use the Shell to perform this task.

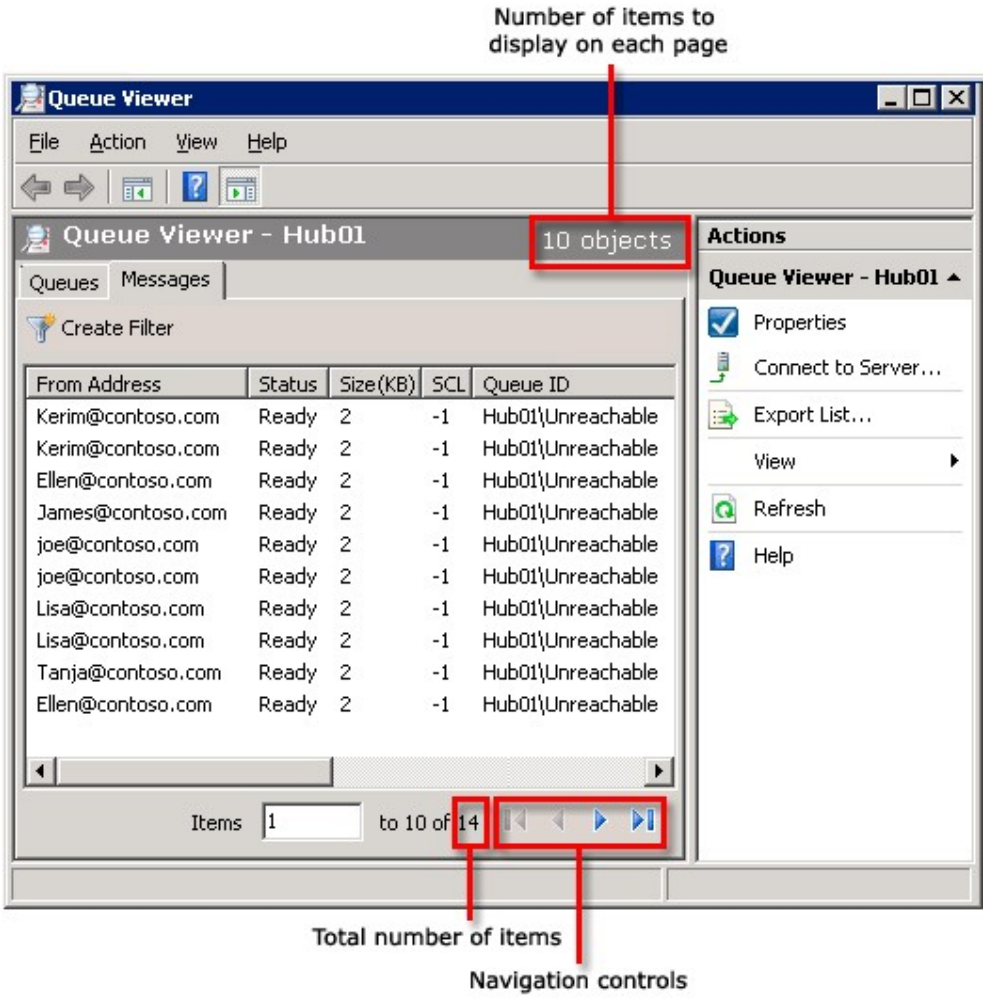
1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. Navigate to **View** > **Options** to open the **Queue Viewer Options** dialog box. Configure the following settings:
   4.a. In the **Refresh interval (seconds)** field, enter the frequency at which Queue Viewer should update the display.

Note:

The default auto-refresh interval is 30 seconds and can't be set for a shorter time. If you disable auto-refresh functionality by clearing the **Auto-refresh screen** check box on the **Queue Viewer Options** page, you must manually update the results that are displayed in Queue Viewer by clicking **Refresh**.

4.b. In the **Number of items to display on each page** field, enter the maximum number of items to display in Queue Viewer. This number must be from 1 through 10,000. If you have more items than the limit, you will see the items in groups of the maximum number of items. For example, the following figure shows a queue with 14 messages with Queue Viewer configured to display 10 items on each page. The number of objects on the page is displayed on the upper right. At the bottom of the page, you can see the total number of items in the queue. You can use the navigation controls to see the additional items in the queue.

5. Click **OK**.



Using the Exchange Management Shell to Manage Queues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

This topic explains how you can use the cmdlets and parameter sets in the Exchange Management Shell to create a query, retrieve the results, and perform modifying actions. For more information about the queue tasks and how they can be used for monitoring and troubleshooting, see Understanding Transport Queues.

In Microsoft Exchange Server 2010, you can use the Shell to perform management and configuration tasks and to create scripts to automate tasks. You can also use the Shell to view information about queues on a server and the messages in those queues, and to perform management actions on queues and mail items. These operations are useful for troubleshooting mail flow and identifying spam. For more information about how to use the Shell, see Exchange Management Shell.

Looking for management tasks related to queues? See Managing Transport Queues.

Contents

Managing Queues and Messages

Queue tasks are grouped into two categories:

- Viewing actions display queues and messages queued on the server and select how that data is grouped and sorted when it's displayed.
- Modifying actions change the status of queues and messages.

Both types of tasks access data by connecting to the transport worker process by using a remote procedure call (RPC).

By default, Queue Viewer focuses on the queuing database located on the server that Queue Viewer connects to, to run the tasks. However, you can connect to a different server than the one that you are running the Queue Viewer tasks on.

For more information about the Exchange 2010 transport process, see Understanding Transport Pipeline. For more information about how to use the Shell to view queues and messages, see View Queues and View Queued Message Properties.

Return to top

Queue Cmdlets

The following table lists the cmdlets available in the Shell for managing queues and the messages in the queues. For more information about how to use each cmdlet, see the Help topics listed in the **For more information** column.

Queue cmdlets

Cmdlet	Usage	For more information
Export-Message	This cmdlet saves a copy of a message in an administrator-specified file path.	Export-Message Export Messages from Queues
Get-Message	This cmdlet displays the details of the messages currently queued for delivery. You can use the **Get-Message** cmdlet to retrieve a set of messages and then pipe the results to one of the other message management cmdlets.	Get-Message View Queued Message Properties
Get-Queue	This cmdlet displays the configuration details of the queues on transport servers. You can use the **Get-Queue** cmdlet to retrieve a set of queues and then pipe the results to one of the other queue management cmdlets.	Get-Queue View Queues
Remove-Message	This cmdlet deletes a message from a queue. You can select whether a non-delivery report (NDR) is sent.	Remove-Message Remove Messages from Queues
Resume-Message	This cmdlet resumes delivery of a previously suspended message. You can also use the **Resume-Message** cmdlet to resubmit messages in the poison message queue to the Submission queue for the categorizer to reprocess.	Resume-Message Resume Messages Resubmit Messages in Queues
Resume-Queue	This cmdlet resumes deliveries of messages from a previously suspended queue.	Resume-Queue Resume Queues
Retry-Queue	This cmdlet forces a connection attempt for a queue that currently has a status of Retry. This connection attempt overrides the next scheduled retry. You can also use the **Retry-Queue** cmdlet together with the *Resubmit* parameter to send messages in delivery queues or in the Unreachable queue to the Submission queue for the categorizer to reprocess.	Retry-Queue Retry Queues Resubmit Messages in Queues

Suspend-Message	This cmdlet suspends delivery of a message located in a queue on an Exchange 2010 transport server.	Suspend-Message Suspend Messages
Suspend-Queue	This cmdlet suspends outgoing activities for a queue on an Exchange 2010 transport server.	Suspend-Queue Suspend Queues

Return to top

Queue Task Parameter Sets

Queue tasks support multiple parameter sets. These parameter sets are as follows: Identity, Filter, and Queue. The Identity, Filter, and Queue parameter sets can't be combined in a command. The Queue parameter set is available only with message commands.

You can also use the advanced paging parameters available in the Shell in combination with the Identity, Filter, and Queue parameter sets. The advanced paging parameters are used with the **Get-Message** and **Get-Queue** cmdlets to control how the result set is sorted and displayed. The advanced paging parameters are described in a table in "Advanced Paging Parameters" later in this topic.

You must use an Identity, Filter, or Queue parameter set when using a command that modifies messages or queues. If you don't provide any parameters, the **Get-Message** and **Get-Queue** cmdlets display every message or queue object that exists on the local server.

If the result set for a queue or message query contains more than 250,000 items, an error occurs, and you will be prompted to apply a filter to reduce the number of results.

Identity Parameter

Use the *Identity* parameter when the specific message or queue that you want to view or that you will take action against is known. The search by identity is faster than formulating the same query as a filter.

The server name can be expressed as a host name or as a fully qualified domain name (FQDN). You can enter the name of a remote server as part of the identity to initiate an RPC connection to that server so that you can query the queues on that server. If you don't use a server name, the local host is implied.

When an identity is provided to a modifying action, the object identified must be fully defined and unique. If the identity isn't explicit, the action won't be performed. If you omit the server part of the identity, the local computer will be assumed.

When you use the *Identity* parameter as part of a **Get-Queue** or **Get-Message** cmdlet, the *Identity* parameter supports the use of wildcard expressions.

Queue Identity

Persistent queues have unique names and can be specified by name. Delivery queues are assigned a unique database identity. You can use this database identity to specify a queue, or you can use the name of the delivery destination to specify a queue. To perform an operation on a queue by specifying its unique database identity, you must first run the **Get-Queue** cmdlet. The database identity will be returned in the results. The accepted identity formats for queues are shown in the following table.

Queue identity formats

Queue identity format	Usage
Server\QueueJetID (Int64)	The complete, unique identity for a delivery queue.
\QueueJetID	The identity of a queue on the local server. The server name is omitted. Therefore, the local server is implied.
Server*	Any queue on the specified server.
Server\NextHopDomain	A queue on the specified server holding messages for delivery to a specific remote domain.
\NextHopDomain	A queue holding messages destined for a specific domain and located on the local server.
Server\Poison	The poison message queue located on the specified server.
Server\Submission	The queue that contains items waiting to be processed by the categorizer.
Server\Unreachable	The queue that contains items that can't be routed and located on the specified server.

The following code is an example of how to use a queue identity with the **Get-Queue** cmdlet. This example returns a list of all queues holding messages for delivery to SMTP domain names that end in Contoso.com. This example also formats the result set as a detailed list.

```
Get-Queue -Identity Server\*Contoso.com | format-list
```

Message Identity

The identity of a message is an aggregation of the unique database mail item and the queue identity. An identity, in the form of an integer, is assigned to a message when the message enters the queuing Extensible Storage Engine (ESE) database (formerly known as Jet), and that integer is appended to the queue identity to create the message identity.

To perform an operation on a message by specifying its database identity, you must first run the **Get-Message** cmdlet. The identity is returned in the results. If you want to connect to a remote server, you can include the server name as part of the message identity. If the server name is omitted, the local server is assumed.

A message being sent to more than one recipient may be located in multiple queues. You can use a wildcard character to specify that you want to locate the message in every queue to which the message was routed. The following table provides examples of a valid message identity.

Message identity formats

Message identity format	Usage
Server\QueueJetId\MessageJetID	Full denomination of a message in a queue.
Server\Poison\MessageJetID	A message in the poison message queue.

MessageJetID	All messages that have this database identity and are routed to any queue on the local server (one message routed to multiple queues).
Server*\MessageJetID	All messages that have this database identity and are routed to any queue on the specified server.

The following code is an example of how to use a message identity with the **Get-Message** cmdlet. This example returns a list of all messages that have the specified identity and are located in any queue on the specified server. This example also formats the result set as a detailed list.

```
Get-message -Identity Server\*\1234 | Format-List
```

Filter Parameter

Queue tasks support the *Filter* parameter so you can specify criteria for which queues and messages should be retrieved. The queue and message properties are used as filter criteria. Create a filter to display a limited set of queues or messages. After you locate the queues and messages that you want to monitor, you can view property information for each object. This information is helpful when you troubleshoot mail flow problems.

Use the *Filter* parameter to supply an expression with logical and relational operators so that only the queue or message objects that meet the filter criteria are displayed. You can use the **-and** logical operator to specify multiple conditions that the results will match. If you use the **-and** operator, only objects that match all specified conditions of the expression are displayed. A subset of the properties of a message or a queue is used to specify the filter criteria. When you specify a property, it must be a valid property for the object for which you are querying, and the value to match must be expressed by using the correct syntax. When a property value is expressed as anything other than a single integer, make sure that you enclose the value in quotation marks.

The *Server* parameter can be included in a command together with the *Filter* parameter. Use the *Server* parameter to specify the host name or FQDN of the server that you want to connect to by using RPC to query the queues and messages on that server and retrieve a result set.

For more information about the properties that can be used for filtering, the correct syntax for these properties, and the supported operators, see the following topics:

- Filter Queues
- Filter Messages in Queues

Queue Parameter

The *Queue* parameter is used only with message commands. Use this parameter to specify the identity of the queue from which messages are retrieved. If a queue is specified, all messages in that queue are retrieved. You can retrieve all messages from a particular queue without having to use a filter expression. You can retrieve messages in multiple queues by using a wildcard character.

When you use the *Queue* parameter with a message command, use the queue identity format from the table in "Queue Identity" earlier in this topic. The following code example shows how to use the *Queue* parameter with a **Get-Message** cmdlet. This example produces a result set that contains only messages located on the specified server and queued for delivery to the SMTP domain Contoso.com.

```
Get-message -Queue Server\Contoso.com
```

Advanced Paging Parameters

Depending on current mail flow, queries against queues and messages can return a large set of objects. You can use the advanced paging parameters to control how query results are retrieved and displayed.

When you use the Shell to view queues and the messages in the queues, your query retrieves one page of information at a time. The advanced paging parameters control the size of the result set and can also be used to sort the results. All advanced paging parameters are optional and can be combined with any one of the parameter sets that can be used with the **Get-Queue** and **Get-Message** cmdlets. If you don't specify any advanced paging parameters, the query returns the results in ascending order of identity.

By default, when a sort order is specified, the message identity property is always included and is sorted in an ascending order. This is the default ordering relationship. The message identity property is included because the other properties that can be included in a sort order aren't unique. By explicitly including the message identity property in the sort order, you can specify that the results display the message identity sorted in descending order.

You can use the *BookmarkIndex* and *BookmarkObject* parameters to mark a position in the sorted result set. If the bookmark object no longer exists when the next page of results is retrieved, the default ordering relationship makes sure that the result set starts with the closest object to the bookmark. The closest object depends on the specified sort order.

The following table describes the advanced paging parameters.

Advanced paging parameters

Parameter	Description
BookmarkIndex	The *BookmarkIndex* parameter specifies the position in the result set where the displayed results start. The value of the *BookmarkIndex* parameter is a 1-based index in the total result set. If the value is less than or equal to zero, the first complete page of results is returned. If the value is set to Int.MaxValue, the last complete page of results is returned.
BookmarkObject	The *BookmarkObject* parameter specifies the object in the result set where the displayed results start. If you specify a bookmark object, that object is used as the point to start the search. The rows before or after that object, depending on the value of the *SearchForward* parameter, are retrieved. You can't combine the *BookmarkObject* parameter and the *BookmarkIndex* parameter in a single query.
IncludeBookmark	The *IncludeBookmark* parameter specifies whether to include the bookmark object in the result set. By default, this value is set to `$true` and the bookmark object is included. You may run a query for a limited result size, and then specify the last item in that result set as the bookmark for the next query. In this case, you may want to set *IncludeBookmark* to `$false` so that the object isn't included in both result sets.

ResultSize	The *ResultSize* parameter specifies the number of results to display per page. If you don't specify a value, the default result size of 1,000 objects is used. Exchange 2010 limits the result set to 250,000.
ReturnPageInfo	The *ReturnPageInfo* parameter is a hidden parameter. It returns information about the total number of results and the index of the first object of the current page. The default value is `$false`.
SearchForward	The *SearchForward* parameter specifies whether to search forward or backward in the result set. This parameter doesn't affect the order in which the result set is returned. It determines the direction of search relative to the bookmark index or object. If no bookmark index or object is specified, the *SearchForward* parameter determines whether the search starts from the first or last object in the result set. The default value for this parameter is `$true`. If the *SearchForward* parameter is set to `$true` and a bookmark is specified, the query searches forward from that bookmark. If you use this configuration and there are no results beyond the bookmark, the query returns the last full page of results. If the *SearchForward* parameter is set to `$false` and a bookmark is specified, the query searches backward from that bookmark. If you use this configuration and there is less than a full page of results beyond the bookmark, the query returns the first full page of results.
SortOrder	The *SortOrder* parameter specifies an array of message properties used to control the sort order of the result set. The sort order properties are specified in descending order of precedence. Each property is separated by a comma and appended with a plus sign (+) to sort in ascending order, or a minus sign (-) to sort in descending order. If an explicit sort order isn't specified by using this parameter, the records that match the query are displayed and sorted by the Identity field for the respective object type. The results are always sorted by identity in ascending order when a sort order isn't explicitly specified.

The following code example shows how to use the advanced paging parameters in a query. In this example, the command connects to the specified server and retrieves a result set that contains 500 objects. The results are displayed in a sorted order, first in

ascending order by sender address, and then in descending order of message size.

```
Get-message -Server Exchange.Contoso.com -ResultSize 500 -SortOrder
+FromAddress,-Size
```

If you want to view successive pages, you can set a bookmark for the last object retrieved in a result set and run an additional query. You must use the scripting capabilities of the Shell to perform this procedure.

The following example uses scripting to retrieve the first page of results, sets the bookmark object, excludes the bookmark object from the result set, and then retrieves the next 500 objects on the specified server.

1. Open the Shell and type the following command to retrieve the first page of results.

   ```
   $Results=Get-message -Server Exchange.Contoso.com -ResultSize 500 -Sor
   ```

2. To set the bookmark object, type the following command to save the last element of the first page to a variable.

   ```
   $temp=$results[$results.length-1]
   ```

3. To retrieve the next 500 objects on the specified server and to exclude the bookmark object, type the following command.

   ```
   Get-message -Server Exchange.Contoso.com -BookmarkObject:$temp -Includ
   ```

1.7.2.18.4 Filter Queues

Filter Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Queue Viewer or the Exchange Management Shell to filter queues on a computer that has the Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed. The list of queues can be lengthy, depending on current mail flow. The list of queues can also frequently change when messages enter and leave the server. By filtering queues, you can adjust your search to specific criteria and locate queues that are experiencing a mail flow problem. You can then perform operations that modify the status of those queues.

To learn more about filtering queues, see "Queue Filtering Scenarios" in Understanding Transport Queues.

Looking for other management tasks related to queues? Check out Managing Transport Queues.

Use Queue Viewer to filter queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. Open the EMC.
2. In the console tree, click **Toolbox**.
3. In the result pane, click **Exchange Queue Viewer**.

4. In the action pane, click **Open Tool**.
5. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you are connected is displayed.
6. Click **Create Filter**, and enter your filter expression as follows:
   6.a. Select a queue property from the queue property drop-down list.
   6.b. Select a comparison operator from the comparison operator drop-down list.
   6.c. Enter a value from the value drop-down list. If the property has fixed values, select a value from the drop-down list. If the property requires a date/time expression, change the current date/time values or click the drop-down list to select a date from the calendar interface.
7. (Optional) Click **Add Expression** to specify additional filter criteria. Only queues that meet all filter criteria will be displayed.
8. Click **Apply Filter**. The results of queues that meet the filter criteria are displayed.

Use the Shell to filter queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

This example uses the **Get-Queue** cmdlet to view all queues that have a message count equal to or greater than 1,000 and that have a status of Retry.

```
Get-Queue -Filter {MessageCount -ge 1000 -and Status -eq "Retry"}
```

For detailed syntax and parameter information, see Get-Queue.

1.7.2.18.5 View Queues

View Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view queues that are present on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to view queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
5. You can use the **Export List** link in the action pane to export the list of queues. For more information, see Export Lists from the Exchange Management Console.

Use the Shell to view queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

This example displays basic information about all queues on the Edge Transport server on which the command is run.

```
Get-Queue
```

This example displays detailed information for all queues on the Edge Transport server on which the command is run.

```
Get-Queue | Format-List
```

Note:
This command supports the use of paging parameters that let you control how results are displayed. For more information about how to use paging parameters, see Using the Exchange Management Shell to Manage Queues.

For detailed syntax and parameter information, see Get-Queue.

1.7.2.18.6 Resume Queues

Resume Queues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can resume queues that are present on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed.

By resuming a queue, you restart outgoing activities on a queue that has a status of Suspended. The queue must have a status of Suspended for this action to have any effect. When you resume a queue, the status of messages in the queue doesn't change. Messages that have a status of Suspended remain suspended and don't leave the queue.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to resume queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
5. Click **Create Filter**, and enter your filter expression as follows:
   5.a. Select **Status** from the queue property drop-down list.
   5.b. Select **Equals** from the comparison operator drop-down list.
   5.c. Select **Suspended** from the value drop-down list.

6. Click **Apply Filter**. All queues on the server that are currently suspended are displayed.
7. Select one or more queues from the list, right-click, and then select **Resume**.

Use the Shell to resume queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

To resume queues, use the following syntax.

```
Resume-Queue -Filter {property -operator "value"}
```

This example resumes all queues that have a status of Suspended.

```
Resume-Queue -Filter {status -eq "Suspended"}
```

For detailed syntax and parameter information, see Resume-Queue.

1.7.2.18.7 Retry Queues

Retry Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can retry a mailbox delivery queue or a remote delivery queue that's present on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed.

When a transport server can't connect to the next hop, the delivery queue is put in a status of Retry. When you retry a delivery queue by using Queue Viewer or the Shell, you force an immediate connection attempt and override the next scheduled retry time. If the connection isn't successful, the retry interval timer is reset. The delivery queue must be in a status of Retry for this action to have any effect.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to retry a queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
5. Click **Create Filter**, and enter your filter expression as follows:
   5.a. Select **Status** from the queue property drop-down list.
