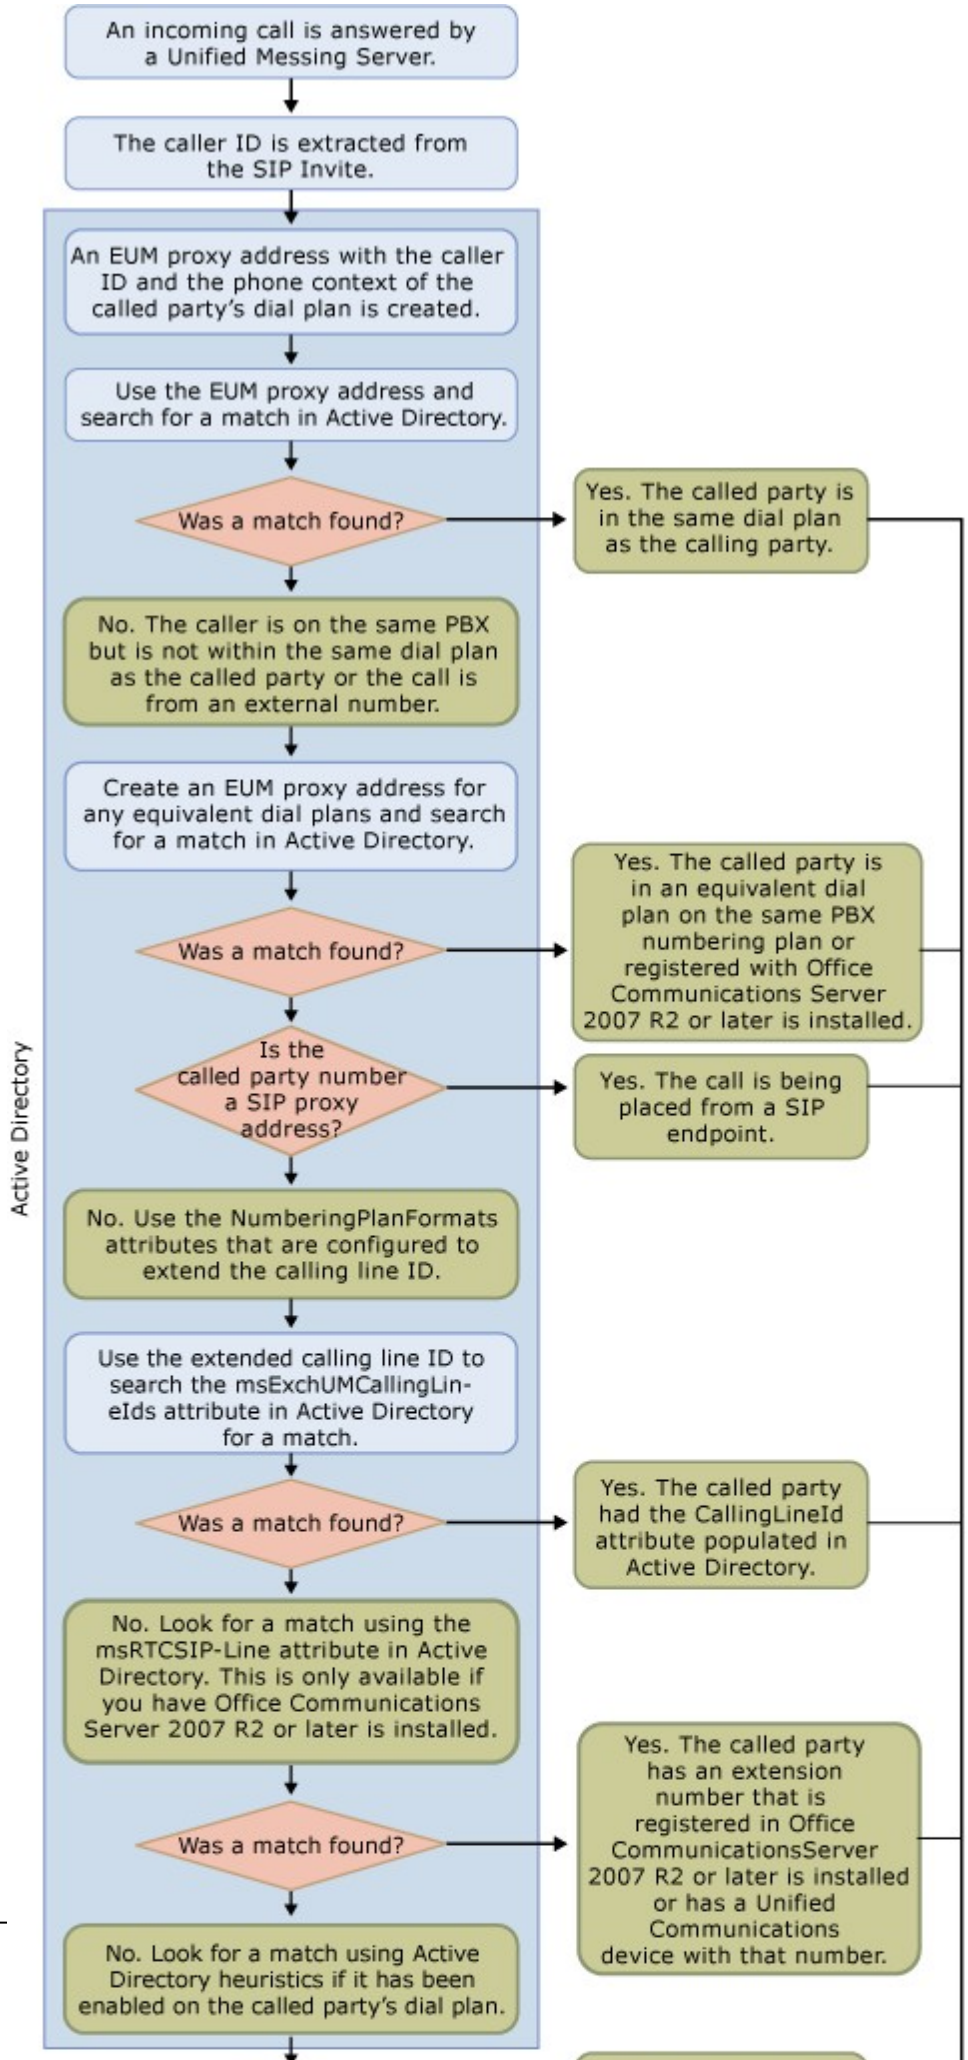
- Using the **msRTCSIP-Line** attribute in Active Directory if Service Pack 1 (SP1) for Exchange 2007 was installed and Exchange 2007 was integrated with Microsoft Office Communications Server 2007 or Office Communications Server 2007 R2.

In Microsoft Exchange Server 2010, the name lookup methods differ from those used in Exchange 2007. The following steps are used in Exchange 2010 to look up a name from the calling party's information:

1. The caller's name is used if the caller signed in to their mailbox from Outlook Voice Access or if they use a Microsoft Unified Communications client such as Microsoft Office Communicator 2007 or Communicator Phone Edition to place the call. The caller's identity is known because they've been authenticated when they use Outlook Voice Access, Office Communicator 2007, or Communicator Phone Edition.
2. The EUM proxy address or addresses in Active Directory are used. If the proxy address contains an '@' sign, it's considered a SIP URI. If the proxy address begins with a '+' character, it's considered to be an E.164 number. If neither of these characters is present, the proxy address is considered an

extension within the same dial plan as the called party or an equivalent dial plan.
3. If the caller ID is a valid SIP URI, Active Directory is used to resolve the SIP URI using the EUM proxy address or addresses.
4. If the caller ID is a valid E.164 number, Active Directory is used to resolve the number to the calling party's name. For this to work correctly, you must have manually configured the *UMCallingLineIds* parameter on the UM-enabled mailbox for the called party. This configuration is useful when you don't want to publish a telephone number, such as a personal mobile phone number, in Active Directory, but still want to resolve the calling party's name by using this phone number.
5. Active Directory heuristic matching is used, if it's enabled, to resolve the number to the calling party's name. Active Directory heuristic matching must be enabled on the dial plan, and the user's account in Active Directory must be populated with one or more of the fields, such as telephone number, home, or mobile, for this to work correctly.
6. The personal Contacts of the called party are used to resolve the number to the calling party's name.

The following figure shows the steps that are performed by a Unified Messaging server when it tries to perform a name lookup from the calling party information that's provided.



An incoming call is answered by a Unified Messing Server.
The caller ID is extracted from the SIP Invite.
Active Directory
An EUM proxy address with the caller ID and the phone context of the called party's dial plan is created.
Use the EUM proxy address and search for a match in Active Directory.
Was a match found?
Yes. The called party is in the same dial plan as the calling party.
No. The caller is on the same PBX but is not within the same dial plan as the called party or the call is from an external number.
Create an EUM proxy address for any equivalent dial plans and search for a match in Active Directory.
Was a match found?
Yes. The called party is in an equivalent dial plan on the same PBX numbering plan or registered with Office Communications Server 2007 R2 or later is installed.
Is the called party number a SIP proxy address?
Yes. The call is being placed from a SIP endpoint.
No. Use the NumberingPlanFormats attributes that are configured to extend the calling line ID.
Use the extended calling line ID to search the msExchUMCallingLin-eIds attribute in Active Directory for a match.
Was a match found?
Yes. The called party had the CallingLineId attribute populated in Active Directory.
No. Look for a match using the msRTCSIP-Line attribute in Active Directory. This is only available if you have Office Communications Server 2007 R2 or later is installed.
Was a match found?
Yes. The called party has an extension number that is registered in Office CommunicationsServer 2007 R2 or later is installed or has a Unified Communications device with that number.
No. Look for a match using Active Directory heuristics if it has been enabled on the called party's dial plan.

Return to top

Improved E.164 Number Resolution

In Exchange 2010 Unified Messaging, four new methods are used to improve resolution of the caller ID to the calling party's name. The four methods are:

- Calling line IDs
- Numbering plan formats
- Active Directory heuristics
- Dial plan equivalency groups

Calling Line IDs

In Exchange 2007, E.164 number resolution was limited and, in some cases, couldn't return the name of the caller in a missed call notification or in the voice message that the called party received in their mailbox. What was needed was the ability to apply an E.164 number or set of numbers for an UM-enabled user and to use these numbers to help resolve an incoming number from another user or a caller from outside the organization.

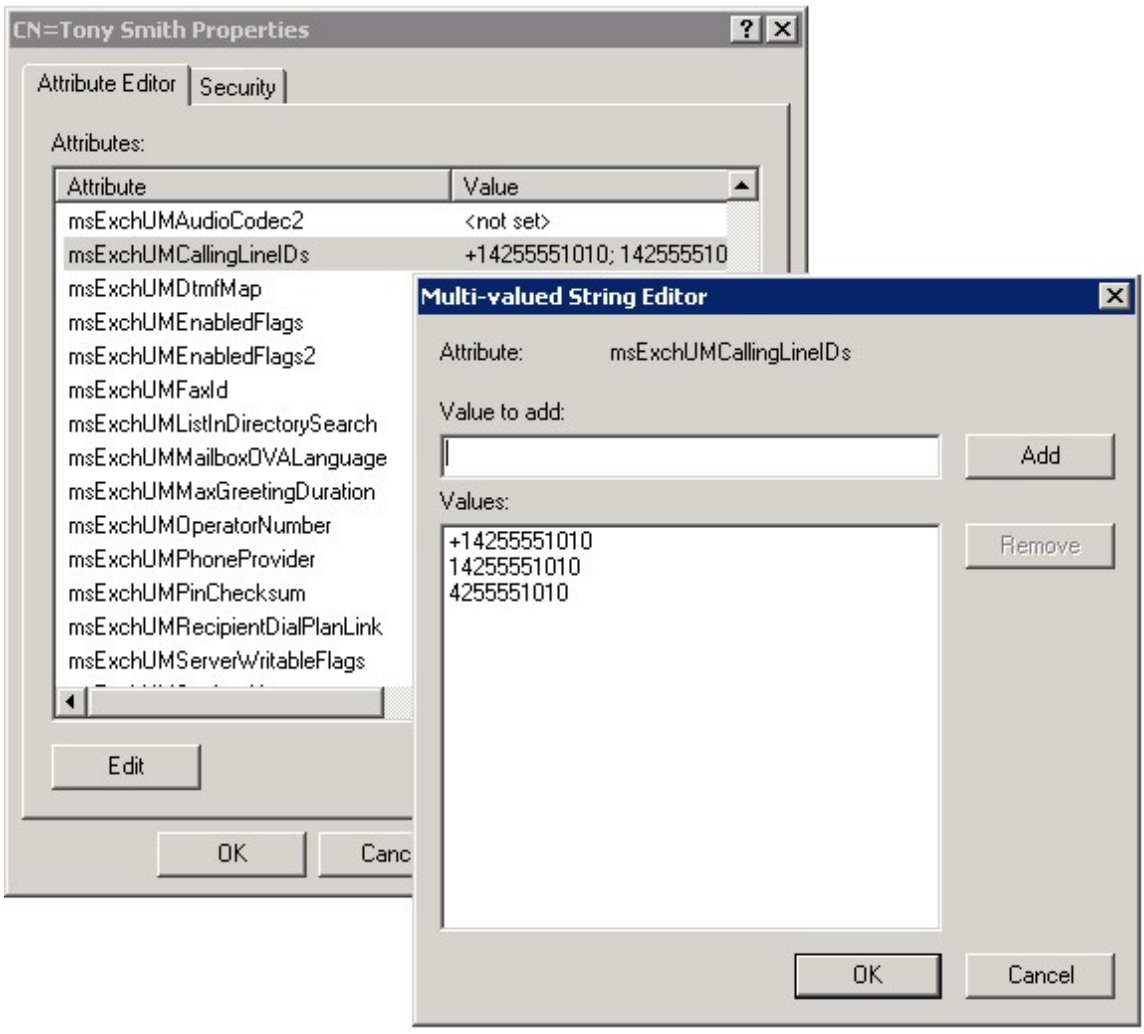
The UM server would take the E.164 number from the caller ID, convert it into an E.164 number, and then just do a lookup for the name of the caller in Active Directory or in the UM-enabled user's personal Contacts. However, without Exchange Unified Messaging being integrated with Communications Server 2007 R2 or Microsoft Lync Server 2010, an E.164 couldn't be used.

In Exchange 2010, a multivalued attribute named **msExchUMCallingLineIDs** was added to the Active Directory schema. This attribute enables a UM server to take an E.164 number or set of numbers, convert the number or numbers, and then perform a name lookup. This attribute can contain a list of numbers that are mapped to a specific user and can be configured on the user's Active Directory object. For example, you could add the numbers, 4255551010, 14255551010, and +14255551010 to the **msExchUMCallingLineIDs** attribute for a specific user. Although the last number in this list is an E.164 number, a correctly formatted E.164 number isn't required. You can add any phone number that looks like a valid phone number that contains digits, and those digits can, optionally, begin with a plus (+) sign.

Note:

The **msExchUMCallingLineIDs** attribute isn't limited to UM-enabled users and can be configured for all users in Active Directory.

The following figure shows where multiple phone numbers are located for a user on the **msExchUMCallingLineIDs** attribute.



msRTCSIP-Line is a Communications Server 2007 R2 or Microsoft Lync Server 2010 schema attribute that exists on an Active Directory recipient object when Communications Server 2007 R2 or Lync Server 2010 is installed. The **msExchUMCallingLineIDs** attribute for Unified Messaging is used for caller ID to name resolution in very much the same way the **msRTCSIP-Line** attribute is used in Communications Server 2007 R2 or Lync Server 2010. A Unified Messaging server will use the **msRTCSIP-Line** attribute to resolve a caller ID to a name, but Exchange Unified Messaging doesn't grant administrators the ability to change or edit this attribute using any method, including Unified Messaging cmdlets.

Communications Server 2007 R2 or Lync Server 2010 specifies the format and validation of the **msRTCSIP-Line** attribute. There are two reasons Unified Messaging administrators aren't allowed to make changes to the attribute.

- Communications Server 2007 or R2 Lync Server 2010 depends on the correct administration of this attribute to correctly route calls to the intended Unified Communications device. If Unified Messaging were allowed to configure this attribute, both Unified Messaging and Communications Server 2007 R2 or Lync Server 2010 would have to share in the validation and administration.
- The **msRTCSIP-Line** isn't very flexible because it's single valued. As an Exchange Unified Messaging administrator, you'd most likely want to provision more than one phone number for a user by including an E.164 formatted number for them.

For these reasons, the Exchange 2010 recipient schema includes the

msExchUMCallingLineIDs attribute as a multivalued and indexed property. When you want to add, remove, or change the phone numbers for a specific user, you'll add or remove numbers by using the *UMCallingLineIds* parameter for the **Set-User** cmdlet. After you add, remove, or change the numbers on the **msExchUMCallingLineIDs** attribute, no further action is needed.

The following table shows the cmdlets, type, description, and the default setting for the *UMCallingLineIds* parameter.

UMCallingLineIds parameter description

Cmdlets	Type	Description	Default
Set-User **Get-User**	Microsoft.Exchange.Data.MultiValuedProperty	The *UMCallingLineIds* parameter specifies telephone numbers or extensions that can be mapped to a UM-enabled user. You can specify more than one telephone number for each user, separated by a comma. This parameter accepts digits less than 128 characters and may include an optional plus sign (+) preceding the numbers. Each UM-enabled user must have a unique *UMCallingLineIds* parameter value.	empty

The **Get-User** and **Set-User** cmdlets will read and write to the **msExchUMCallingLineIDs** attribute. If a caller ID isn't correctly resolved using the **msExchUMCallingLineIDs** attribute, UM will then look at the phone number that's configured on **msRTCSIP-Line** attribute for a user.

Return to top

Number Plan Formats for Dial Plans

In addition to the *UMCallingLineIds* parameter that was added to help resolve a caller ID to the name of the caller, the UM server must also have the ability to take numbers from the *UMCallingLineId*, such as 51010, 555-1010, and 4255551010 and extend them into a correctly formatted E.164 phone number. The *NumberingPlanFormats* parameter on the **Set-UMDialPlan** cmdlet is used to do this.

The syntax for adding numbering plan formats to a UM dial plan is:

```
Set-UMDialplan -identity MyUMDialPlan -NumberingPlanFormats "425567xxxx","425678x
```

There are two requirements if you want to resolve caller ID to calling party name this way:

- Each user must be correctly provisioned with E.164 numbers. However, configuring each recipient in Active Directory make take some time.
- Rules that a UM server can use to map incoming caller IDs and convert them into correctly formatted E.164 phone numbers must be configured. An example of such a rule is extension length IDs.

An Exchange 2010 Unified Messaging server can change non-canonical numbers, such as an extension number of 5 digits, into more canonical forms like the E.164 format by using number masking.

A number mask is used to define the telephone number format that a Unified Messaging server uses to determine what outgoing telephone number it will dial for a user or the phone number that's used in the diversion header of an incoming call. Number masking is done for both incoming calls and outgoing dialing rules. An example of a valid number mask is 91xxxxxxxxx. For example, when an outgoing call is made to a number like 4255551010, the 91xxxxxxxxxx number mask on the dialing rule entry the Unified Messaging server replaces the right-most digits that are matched to the dialed number. In this example, there are 10 digits in the phone number that is dialed and 10 digits (represented by 'x'). Since these digits match, the UM server will dial 914255551010. This field can contain only numbers and the character x. The same process is used for incoming calls.

The *NumberingPlanFormats* parameter is a multivalued property and is used when a caller ID number is received by a UM server that's associated with a UM dial plan that can then be expanded into a correctly formatted E.164 number.

The following table shows the cmdlets, type, description, and default setting for the *NumberingPlanFormats* parameter.

NumberPlanFormats parameter description

Cmdlets	Type	Description	Default
Set- DialPlan **Get-DialPlan**	Microsoft.Exchange.Data.MultiValuedProperty	The *NumberingPlanFormats* parameter specifies one or more phone number masks that can be used for resolving caller ID to names of users in Active Directory.	empty

In Exchange 2007 Unified Messaging, the International number format on a dial plan was used to enhance caller ID resolution by creating an E.164 phone number. The E.164 phone number would then be used when the UM server searched for the phone number for the caller using the **msRTCSIPLine** attribute.

In Exchange 2010 Unified Messaging, equivalent dial plan groups have been added to enhance caller ID resolution to widen the scope of the search. This is done by configuring the numbering plan format on each dial plan, which will help to convert the caller ID into the E.164 format. For details about equivalent dial plans, see Equivalent Dial Plan Groups later in this topic.

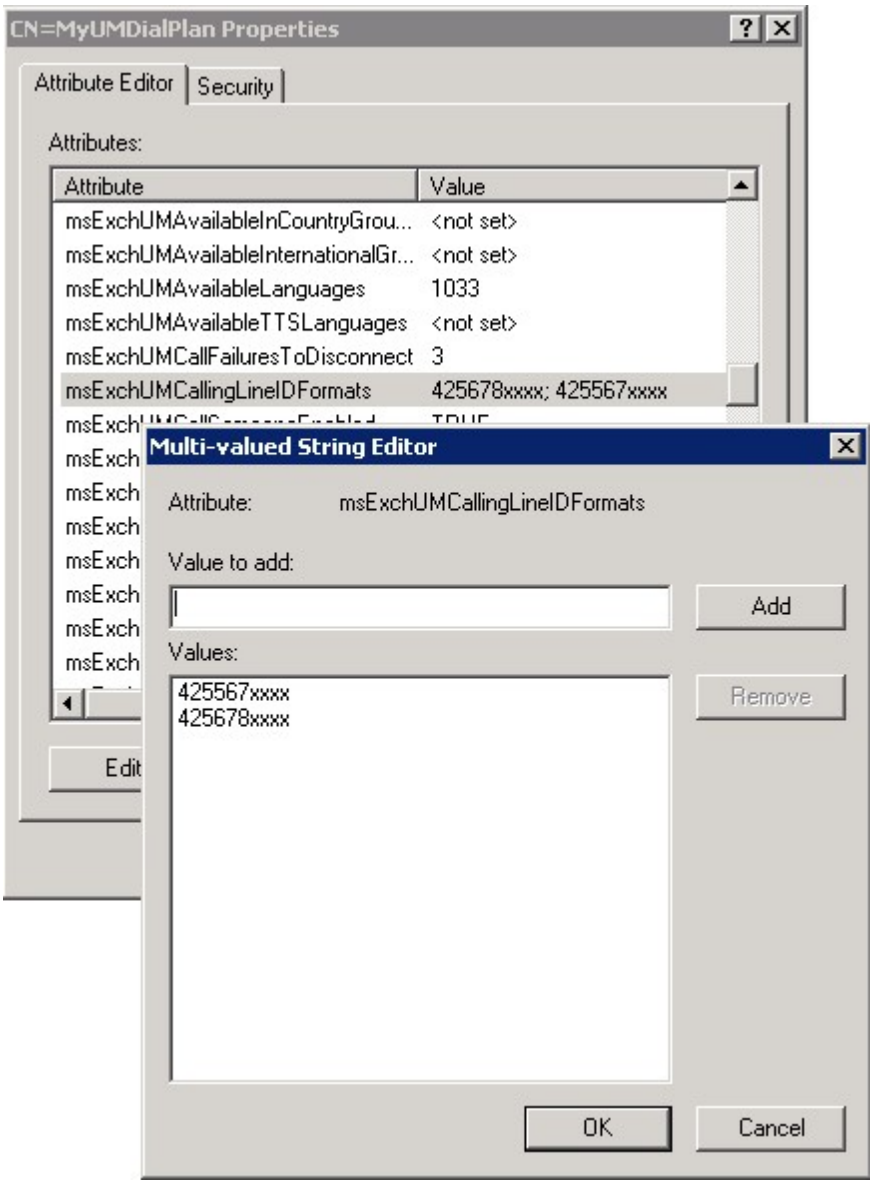
For example, consider a company that has 20,000 employees. This company would need 20,000 unique Direct Inward Dial (DID) telephone numbers for its employees. However, the company couldn't get numbers within consecutive DID ranges, for example, 425-555-xxxx to 425-556-xxxx. Instead, the first group of 10,000 employees had the number prefix 425-567-xxxx, and the second group of 10,000 employees had the number prefix 425-678-xxxx.

Say the administrator creates a single UM dial plan for these 20,000 employees and uses a 5-digit extension for each user. When a call is received by the PBX, the PBX will send the 5-digit caller ID. However, when the company migrates from a legacy PBX to an IP PBX, the users will be on two separate PBXs, each with its own 5-digit UM dial plan. After the users are migrated to the IP PBX, the caller ID name resolution will start to fail, and only

the 5-digit extension will appear in the voice message, instead of the caller's name.

This happens because only a single International number format is configured on the UM dial plan that's shared by these two prefixes. Therefore, only half the UM-enabled users will have correctly formatted E.164 numbers created. Also, the users are on different PBX dial plans. So even if an equivalent dial plan is enabled on the UM dial plan, the caller isn't UM enabled, and the caller's extension number won't resolve to a name.

The *NumberingPlanFormats* parameter can be used to resolve this issue. For each UM dial plan, there's an **msExchangeUMCallingLineIDFormats** attribute that can be configured using the *NumberPlanFormats* parameter to specify one or more phone number masks that can resolve caller IDs to names in Active Directory. The following figure shows this attribute and the numbering plan formats.



When a UM server answers an incoming call, it reads the caller ID. The UM server will parse the list of configured number plan formats from the top down until a match is not found or there's a conflict in the digits where x in the number mask is treated as a wild-

card. When this happens, the UM server will try to back fill the caller ID for the incoming call into each number mask. In the case of the employees whose number prefixes are 425-567-xxxx, and 425-678-xxxx, the digits "7" and "8" are the keys by which a correct mask will be selected for the calling ID number. After the UM server successfully back fills a numbering plan format pattern, it takes the E.164 number that's generated and performs a lookup against the **msExchUMCallingLineIDs** attribute. If that lookup fails, the UM server performs a lookup against the **msRTCSip-Line** attribute.

Unified Messaging administrators must check for ambiguous and nonsensical numbering plan format rules and reconfigure them. Ambiguous numbering plan format rules are two or more rules in which the right-most characters are identical and equal the number of digits configured on the dial plan. A nonsensical numbering plan format rule is one that has a wildcard character in any position other than one of the right-most digits that equals the number of digits in the extension numbers that are configured on the dial plan.

Return to top

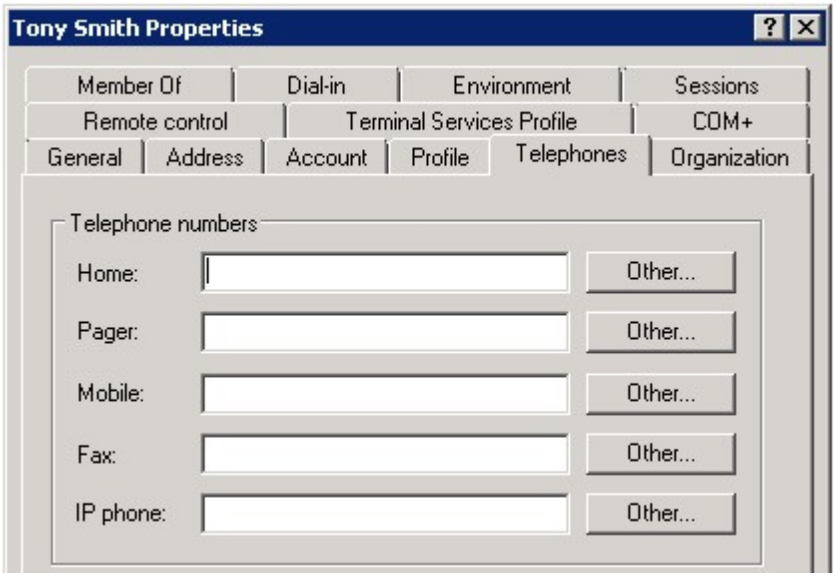
Active Directory Heuristics

In addition to UM calling line IDs and numbering plan formats, Exchange 2010 Unified Messaging enables Active Directory heuristics.

In Exchange 2007, caller ID resolution doesn't include telephone fields on the user's object in Active Directory when trying to resolve the caller ID on an incoming call to a name. This is because:

- The fields located on the **Telephones** tab and **Telephone number** field aren't indexed and searchable.
- The fields located on the **Telephones** tab and in the **Telephone number** field may not be in a standardized format.

The following figure shows these fields in Exchange 2010.



There's a major problem with the **Telephone number** field on the **Telephones** tab on a user's object in Active Directory. The field contains no validation or limits for formatting the numbers that are inserted. This means that there's no standardized format for these numbers. Here are the potential issues that prevent resolution of a caller ID to a name:

- The administrator didn't enter a number in the **Telephone number** field.
- The administrator doesn't use the **Telephones** tab at all for phone numbers.
- E.164 numbers are entered without any parentheses, hyphens, or the correct

spaces.

- The numbers aren't in the correct E.164 format. Examples of the correct format include the following:
  - (425) 555-1010
  - (425) 555-1234 x51010
  - (425) 555-1234 ext. 51010
  - 425-555-1010
  - 425.555.1010
  - 425/555-1010
  - 1425-555-1010
- Both extensions and international numbers are used. Examples that show both extensions and international numbers used together include the following:
  - +7890
  - +441234567890
  - +44(1)234567890
  - +44 (0)1 2345 6789

An Exchange 2010 Unified Messaging server will query Active Directory to examine up to 8 Active Directory attributes, together with the EUM proxy addresses and the **msExchUMCallingLineIDs** and **msRTCSIP-Line** attributes, when it tries to resolve a caller ID. There is an **msExchAllowHeuristicADCallingLineIDResolution** attribute on each dial plan. By default, the **msExchAllowHeuristicADCallingLineIDResolution** attribute is set to true when you create a UM dial plan.

You can use the **Set-UMDialPlan** cmdlet to enable or disable Active Directory heuristics. The following table shows the UM dial plan cmdlets, type, description, and default setting for the *AllowHeuristicADCallingLineIdResolution* parameter.

AllowHeuristicADCallingLineIdResolution parameter description

Cmdlets	Type	Description	Default
Set-UMDialPlan **Get-UMDialPlan**	System.Boolean	The AllowHeuristicADCallingLineIdResolution parameter specifies whether to allow calling line ID resolution using telephone number fields that may be configured in Active Directory. When this parameter is set to $true, the telephone numbers, such as those defined on the **Telephones** tab and the telephone number for a user in Active Directory, are used. Setting this parameter to $true allows resolution of calling IDs for both UM-enabled and non-UM-enabled users. You may want to set this parameter to	Enabled

		$false if the telephone numbers for users aren't in a standard format. If the telephone numbers aren't in a standard format, the Unified Messaging server may be unable to correctly resolve the caller ID to the name of a user consistently.	

After you enable Active Directory heuristics, UM will use the phone number fields, such as telephone number, home, or mobile, that are configured for a user who's in Active Directory. However, there's no way to select which of the phone fields to include. The following telephone attributes for a user in Active Directory will be used to resolve a caller ID to a name:

- **telephoneNumber**
- **homePhone**
- **mobile**
- **facsimileTelephoneNumber**
- **otherTelephone**
- **otherHomePhone**
- **otherMobile**
- **otherFacsimileTelephoneNumber**

If you use the **Set-User** cmdlet to populate one or more of the telephone attributes for a user, you must run **GalGrammarGenerator.exe –u** to update the DTMF map for each user. If you populate the phone fields or update phone numbers before you install the Unified Messaging server role or use a program other than the Exchange Management Shell, you'll also have to run **Galgrammargenerator.exe –u** before the telephone number fields will be indexed. For more information about how to run GalGrammarGenerator.exe, see one of the following topics:

- Update the Speech Grammar Files on a UM Server
- Understanding Automatic Speech Recognition Directory Lookups

Return to top

Equivalent Dial Plan Groups

Sometimes the number of UM dial plans can become unwieldy, either because the number of forests has increased or because the number of UM dial plans in a single forest has been increased. To provide a more scalable solution, a new Active Directory object has been added in Exchange 2010 Unified Messaging: equivalent dial plan group. An equivalent dial plan group is a container object in Active Directory that will contain equivalent dial plans that are from separate Active Directory forests.

Two Active Directory attributes are used with equivalent dial plan groups:

- **msExchangeUMEquivalenceDialPlan**
- **msExchangeUMEquivalentDialPlanPhoneContexts**

The concept of an equivalent dial plan has been added in Exchange 2010 Unified Messaging to allow UM administrators to connect two dial plans that are in the same PBX numbering plan but are broken into two dial plans. Two dial plans might be contained in a single PBX numbering plan, for example, when users in the two separate dial plans sit next to each other and can dial each other using an extension number but exist in different dial plans for reasons unrelated to the telephony infrastructure.

Note:
Extension numbers must be unique within a dial plan, but they must also be unique within an equivalent dial plan group.

For every dial plan, there can be an equivalent dial plan phone context for two or more dial plans that should be one dial plan but have been separate. You can add names for other dial plans and link to other dial plans. The dial plans you enter names for or link to can be in the same Active Directory forest or in different forests. When you add an equivalent dial plan, the dial plan's phone context will be automatically added to the equivalent dial plan group.

After you have added multiple dial plans with different phone contexts, when a call comes in the Unified Messaging server, instead of only looking for EUM proxy addresses that have the same phone context, it will look at EUM proxy addresses that have the phone context listed on an equivalent dial plan. As long as the dial plan is listed as an equivalent dial plan, and only the caller ID is being sent, then all Unified Messaging users' numbers from both dial plans will be resolved correctly to a name.

The following table shows the cmdlets, type, description, and default setting for the *EquivalentDialPlanPhoneContexts* parameter.

EquivalentDialPlanPhoneContexts parameter description

Cmdlets	Type	Description	Default
Set- DialPlan **Get-DialPlan**	Microsoft.Exchange.Data.MultiValuedProperty	The *EquivalentDialPlanPhoneContexts* parameter specifies the name of an equivalency dial plan. This parameter can be used when two UM dial plans exist but are in different forests or when a Private Branch eXchange (PBX) numbering plan spans two UM dial plans. Adding the name of the equivalency dial plan enables name lookups using a caller ID to search in the user's dial plan but then also search for a name for the calling line ID in any equivalent dial plans that are configured.	empty

For example, by having equivalent dial plan phone contexts on a dial plan, you could run the following command to add two UM dial plans to a single equivalent dial plan group.

```
Set-UMDialPlan  -identity MyUMDialPlan1 -EquivalentDialPlanPhoneContexts "dialpla
```

If the extension of a caller matches any UM-enabled user on any of the three dial plans specified in the command, the extension number will be resolved to a name of the caller.

1.9.1.3.11 Understanding the DTMF Interface

Understanding the DTMF Interface

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

In Microsoft Exchange Server 2010 Unified Messaging (UM), callers can use dual tone multi-frequency (DTMF), also referred to as touchtone, and voice inputs to interact with the system. The method callers can use depends on how the UM dial plans and auto attendants are configured.

The DTMF interface enables callers to use the telephone keypad to locate users and navigate the Unified Messaging menu system when they call a subscriber access number configured on a dial plan or when they call a telephone number configured on an auto attendant. This topic discusses the DTMF interface and how it's used by callers to locate users and to navigate the Exchange 2010 Unified Messaging menu system.

Contents

DTMF Overview

DTMF requires a caller to press a key on the telephone keypad that corresponds to a Unified Messaging menu option or to input a user's name by using the letters on the keys to spell the user's name or e-mail alias. Callers might use DTMF because Automatic Speech Recognition (ASR) hasn't been enabled or because they tried to use voice commands and failed. In either case, DTMF inputs are used to navigate menus and search for users.

By default, in Exchange 2010 Unified Messaging, DTMF inputs are used on dial plans and are the default caller interface for UM auto attendants.

Note:
Only auto attendants configured to use English can be speech-enabled.

DTMF inputs can be used by callers for:

- Dial plan subscriber access by using Outlook Voice Access.

- Dial plan directory lookups and searches to locate users.
- Auto attendants that aren't speech-enabled.
- Auto attendants that are speech-enabled that do or don't have a DTMF fallback auto attendant configured.
- DTMF fallback auto attendants (not speech-enabled).

UM Dial Plans and Dial by Name

When you create a UM dial plan, you can configure the primary and secondary input method that callers will use to look up names when they search for a user or want to contact a user. These settings are located on the dial plan's **Settings** tab and are called **Dial by name primary method** and **Dial by name secondary method**. The following options are available for the **Dial by name primary method** and the **Dial by name secondary method**:

- Last First
- First Last
- SMTP Address

Additionally, **None** is an available option on the **Dial by name secondary method**.

By default, **Last First** is selected for the **Dial by name primary method** and **SMTP Address** is selected as the **Dial by name secondary method.** Therefore, when a caller dials in to the subscriber access number configured on the UM dial plan, the dial plan's welcome message is played and the operator says something like, "Welcome to Contoso Outlook Voice Access. To access your mailbox, enter your extension. To contact someone, press the # key." After the caller presses the # key, the system responds with "Spell the name of the person you are calling, last name first, or to spell their e-mail alias, press the # key twice." In this scenario, depending on how your dial plan is configured, the system then prompts the caller to enter the user's last name first and then the user's first name (Last First) or to spell the e-mail alias, excluding the domain name.

For example, if the user's e-mail alias is tsmith@contoso.com, the caller would enter tsmith. If you want to change this configuration because the default setting doesn't meet your needs, you can change it to enable callers to enter the user's e-mail alias first or the user's first name followed by the last name. In this case, you would configure the **Dial by name primary method** with the **SMTP Address** setting and configure the **Dial by name secondary method** with the **First Last** setting. The settings for the dial by name methods will also apply to any UM auto attendants that are associated with the dial plan. For callers to be able to enter the name of the user by using DTMF inputs or the keys on the telephone keypad, a DTMF map and values for the user must exist within the Active Directory directory service.

For more information about how to change the dial by name primary and secondary methods on a UM dial plan, see Configure the Dial by Name Primary Method on a Unified Messaging Dial Plan and Configure the Dial by Name Secondary Method on a UM Dial Plan.

Return to top

DTMF Maps

In an Exchange 2010 organization, an attribute named **msExchUMDtmfMap** is associated with each user created in Active Directory. This attribute is used by Unified Messaging to map the user's first name, last name, and e-mail alias to a set of numbers. This mapping is referred to as a DTMF map. A DTMF map enables a caller to enter the digits on the telephone keypad that correspond to the letters of the user's name or e-mail alias. This attribute contains the values needed to create a DTMF map for the user's first name followed by the last name, for the user's last name followed by the first name, and for the user's e-mail alias.

The following table shows the DTMF map values that would be stored in Active Directory on the **msExchUMDtmfMap** attribute for a UM-enabled user named Tony Smith with an alias of tsmith@contoso.com.

DTMF values stored in Active Directory for a UM-enabled user named Tony Smith

Active Directory entry	User's name
• firstNameLastName:866976484	tonysmith
• lastNameFirstName:764848669	smithtony
• emailAddress:876484	tsmith

- Names and e-mail aliases may contain other characters that aren't alphanumeric, such as commas, hyphens, underscores, or periods. Characters such as these won't be used in a DTMF map for a user. For example, if the e-mail alias for Tony Smith is tony-smith@contoso.com, the DTMF map value would be 866976484, and the hyphen wouldn't be included. However, if a user's e-mail alias contains a number or numbers, for example, tonysmith123@contoso.com, the numbers would be used in the DTMF map that's created. The DTMF map for tonysmith123 would be 866976484123.

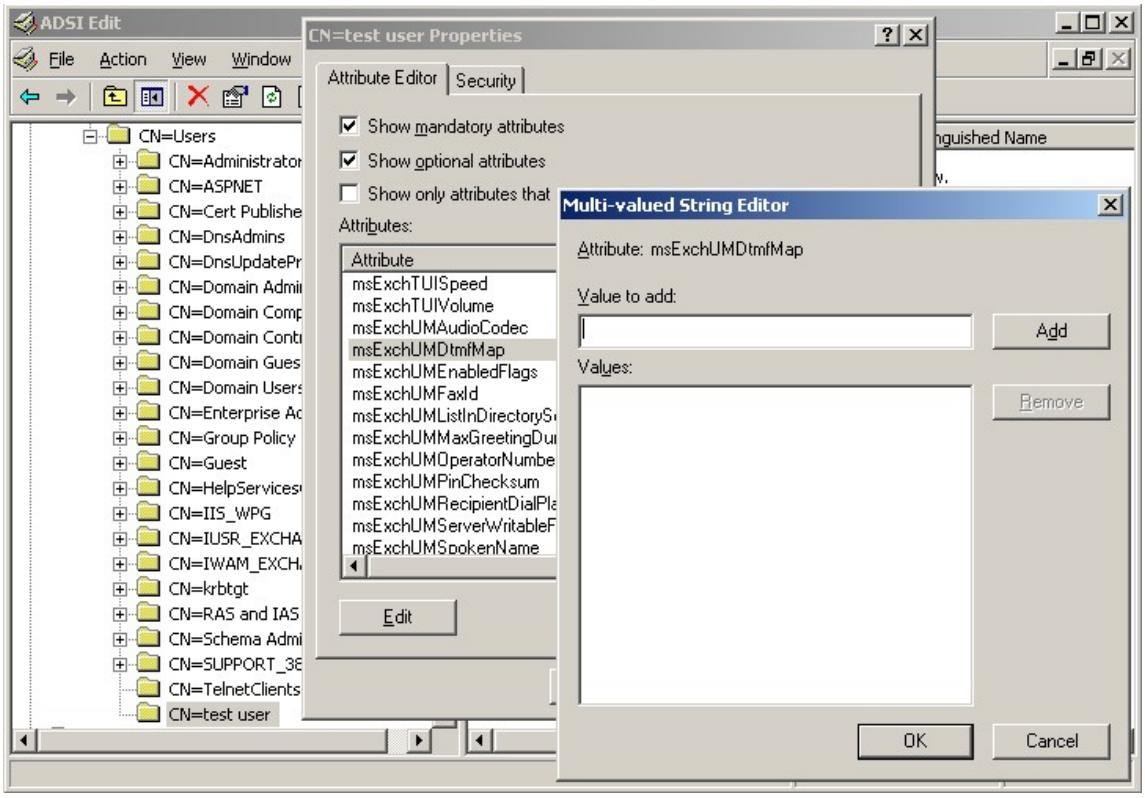
A DTMF map must exist for a user for callers to be able to enter the user's name or e-mail alias. However, in some cases, not all users will have a DTMF map associated with their user account.

Return to top

DTMF Maps for Users Who Aren't Enabled for Unified Messaging

Users, including mailbox-enabled users, aren't enabled for Unified Messaging by default. Therefore, the **msExchUMDtmfMap** attribute isn't populated with the values needed for a DTMF map for those users. The following figure illustrates the properties of a user for which the **msExchUMDtmfMap** attribute hasn't been populated.

msExchUMDtmfMap attribute without values



Because the user shown in the previous figure doesn't have DTMF map values defined for the user account, callers will be unable to contact the user when they press a telephone key from a UM auto attendant menu or perform a directory search. Also, UM-enabled users will be unable to send messages or transfer calls to users who don't have a DTMF map unless they can use ASR. To enable callers to transfer calls or contact users who aren't UM-enabled by using the telephone keypad, you must create the necessary values for the DTMF map for users. To create the values for a DTMF map for users who aren't enabled for Unified Messaging, you can run the **galgrammargenerator.exe -u** command. This command updates the DTMF maps for all users within your Exchange organization. The **galgrammargenerator.exe** command updates or creates DTMF maps for all users who aren't UM-enabled. You can use the **Set-User** cmdlet with the *-CreateDtmfMap* parameter to create and update a single user's DTMF map or update a DTMF map for a user if the name of the user was changed after a DTMF map was created. Optionally, you can create an Exchange Management Shell script by using this cmdlet to update the DTMF map values for multiple users.

For more information about the **Set-User** Exchange Management Shell cmdlet, see Set-User.

For more information about galgrammargenerator.exe, see Understanding Automatic Speech Recognition Directory Lookups.

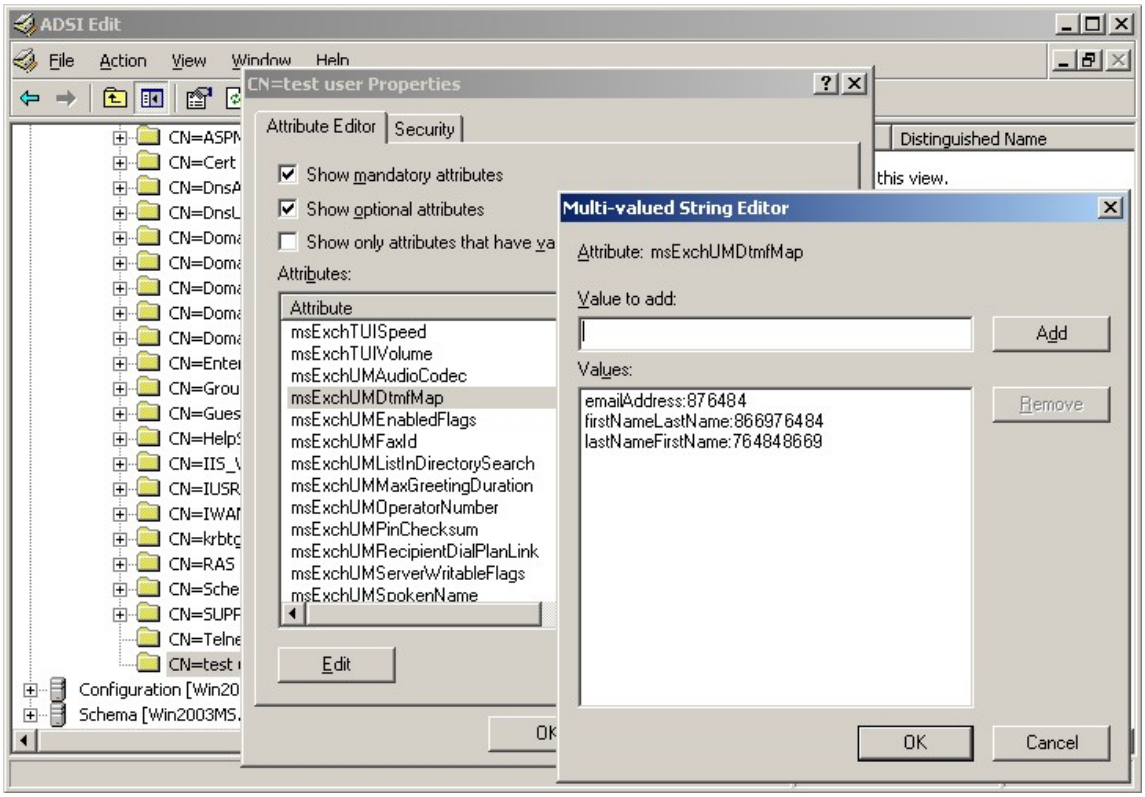
Return to top

DTMF Maps for Users Who Are Enabled for Unified Messaging

A DTMF map is created for UM-enabled users so that callers can contact them. By default, a DTMF map is created for users when they are enabled for Unified Messaging. This makes

it possible for calls to be transferred to a UM-enabled user from external callers, from users who aren't enabled for Unified Messaging, and from other UM-enabled users who use the telephone keypad to spell the user's name or e-mail alias. The following figure illustrates the properties on a user account where the **msExchUMDtmfMap** attribute has been populated with DTMF map values.

msExchUMDtmfMap attribute with values



After the DTMF map values have been created for a UM-enabled user, callers can use the directory search feature. Callers use directory search when they use the telephone keypad in the following situations:

- To identify or search for a user when they call in to the subscriber access number.
- To locate or transfer calls to a UM-enabled user when they call in to a UM auto attendant.

For more information about how to enable a user for Unified Messaging, see Enable a User for Unified Messaging.

Sometimes a user's first name, last name, or e-mail alias changes after the user is enabled for Unified Messaging. The user's DTMF map values aren't updated automatically in Active Directory. If a caller enters the user's new last name or e-mail alias and the user's DTMF map hasn't been updated to reflect the change to the name or e-mail alias, the caller will be unable to locate the user in the directory, send a message to the user, or transfer calls to the user. If you have to update a user's DTMF map after the user has been enabled for Unified Messaging, you can use the **Set-User** cmdlet with the -*CreateDtmfMap* parameter. You can also create an Exchange Management Shell script using this cmdlet if you want to update the DTMF maps for multiple UM-enabled users.

Note:

You can also use the **galgrammargenerator.exe -u** command to update the DTMF map

for UM-enabled users. However, if you use the **galgrammargenerator.exe -u** command, it will update or create DTMF maps for all users.

Caution:
We recommend that you don't manually change the DTMF values for users using a tool such as ADSI Edit because it might result in inconsistent configurations or other errors. We recommend that you only use **galgrammargenerator.exe** or the **Set-User** cmdlet to create or update DTMF maps for users.

Adsiedit Overview

1.9.1.3.12 Understanding Automatic Speech Recognition Directory Lookups

Understanding Automatic Speech Recognition Directory Lookups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

Microsoft Exchange Server 2010 Unified Messaging (UM) offers a voice user interface (VUI) that uses Automatic Speech Recognition (ASR). This is the telephone interface callers use to navigate the menu systems and access their mailbox using speech inputs. ASR enables callers to use speech inputs instead of dual tone multi-frequency (DTMF), also known as touchtone, inputs to navigate the UM auto attendant menus or when UM-enabled users accesses their mailbox. This topic discusses how ASR is used in Exchange 2010 Unified Messaging and how grammar files are used with ASR.

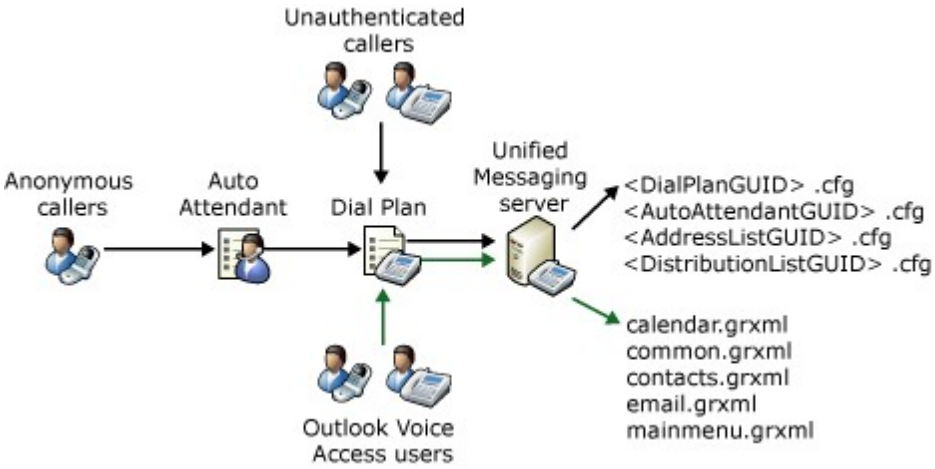
Note:
ASR for directory lookups and searches is currently available only in English for Outlook Voice Access users and for calls to UM auto attendants. However, support for ASR in other languages is planned for a future release.

Contents

Overview of Grammar Files

A speech grammar file contains words and phrases that the speech engine will try to recognize when the grammar file is being used. Grammar files define things such as the

commands available to users while they're reviewing their mail or their calendar or the names of people recognized by the speech engine when a caller searches the directory. Speech grammar files are first generated as files that have a .grxml extension. They're then processed into a compiled form with a .cfg extension before they're loaded into the speech engine. Because the .cfg file is loaded into the memory of the Microsoft Exchange Speech Engine service, there is no .cfg file created and saved to a disk. The following figure shows how the grammar files are used by callers.



Note:

If you want to locate the .grxml file that corresponds to a .cfg file, look in the event log for events that have the IDs 1040 or 1041. The event will show which .grxml file was used to produce a particular .cfg file.

Default Grammar Files

When the Unified Messaging server role is installed, many files are copied to the server. These files include the default grammar files that are used by ASR to enable the VUI. By default, these grammar files are installed in the <Program Files>\Microsoft\ Exchange Server\V14\UnifiedMessaging\grammars\<*language*> folder. However, when these grammar files are used by the Unified Messaging server, they're loaded and compiled into a .cfg file by the Microsoft Exchange Speech Engine service.

The default grammar files include the following files:

- Calendar.grxml
- Common.grxml
- Contacts.grxml
- Email.grxml
- Mainmenu.grxml

Custom Grammar Files

Several custom grammar files are created when the Unified Messaging server role is installed and then again when you create UM objects in the Active Directory directory service and the Microsoft Exchange Unified Messaging service runs grammar generation at its scheduled time, once each day. These grammar files contain the names of users and other objects, for example distribution lists, that are in Active Directory. For each name, there is additional data, for example an e-mail alias. This data lets the name be associated with a unique object.

The following grammar files are created when the Microsoft Exchange Unified Messaging service runs grammar generation at the scheduled time:

- Gal.grxml

- *<DialPlanGUID>*.grxml
- *<AddressListGUID>*.grxml
- DistributionList.grxml

Note:
UM-enabled users may not be immediately available for callers. You must either wait until the next scheduled grammar generation to occur or manually run **galgrammargenerator.exe** to include the UM-enabled user's name in a grammar file.

When the Unified Messaging server creates a speech grammar file, it examines many directory objects to determine which names should be added to the speech grammar file. The types of objects it processes are based on the scope of the grammar being created. However, for all these objects, Unified Messaging won't add the object to the grammar if the object is hidden from the Exchange 2010 address lists or the **msExchHideFromAddressLists** attribute is set to true for the object.

- For the global address list grammar file, Unified Messaging will consider the following:
  - Mail-enabled users
  - Mail-enabled contacts
- For dial plan grammar files, Unified Messaging will consider the following:
  - UM-enabled users in the specified dial plan
- For the distribution list grammar file, Unified Messaging will consider the following:
  - Distribution lists that are visible in address lists

A default global address list is created when the Mailbox server role is installed on a computer running Exchange 2010. When the Unified Messaging server role is installed, it creates a grammar file for the global address list based on the speech grammar filters that are configured. If you create custom address lists or distribution lists in your Exchange 2010 organization, additional grammar files will be created for each custom address list or distribution list you create.

If you create an address list that contains, for example, all recipients in a particular department, and then later add a new user in this department, the recipient won't be included as a member of the address list until you run the **Update-AddressList** cmdlet.

If you create an address list that contains, for example, all recipients in a particular department, and then the membership of the address list changes, you must run the **Update-AddressList** cmdlet before Unified Messaging name speech grammar generation occurs. This ensures that, when the grammar is generated or updated, it will contain all the recipients currently in the address list. When you run the **Update-AddressList** cmdlet, it will include each recipient in every address list that the recipient is a member of.

If a UM-enabled user isn't stamped as a member of an address list before grammar generation occurs, the user won't be added as a member. The next time grammar generation occurs, either on the defined schedule or manually when you run **galgrammargenerator.exe**, the UM-enabled user won't be added to the grammar for the address list. Therefore, their name won't be available when the directory is searched.

Note:
For a grammar file to be generated for a distribution list, the distribution list must not be hidden.

When you first create a UM dial plan, no grammar files are created. However, when a Unified Messaging server joins a dial plan for the first time, a single grammar file for the UM dial plan is created in the appropriate language folder. The UM dial plan speech grammar file is then filtered to include only UM-enabled users associated with the dial plan. The grammar files for these objects are named using the GUIDs of the objects they represent after they're compiled, for example, 2da514a1-06f4-44a1-9ce5-

610854f7d2ee.grxml or the corresponding .cfg file.

When the grammar files for UM dial plans, the global address list, address lists, and distribution lists are created, they're created in a language-specific folder on the local Unified Messaging server. The language folder used is selected based on the default language that is configured on the UM dial plan. For example, if the default language on the dial plan is set to US-English (en-US), a grammar file will be created in the <Program Files>\Microsoft\ Exchange Server\V14\UnifiedMessaging\grammars\en folder. After the grammar file is created, it will be updated according to the schedule that is configured on the Unified Messaging server.

For more information, see the following topics:

- Add a UM Server to a Dial Plan
- Create a UM Dial Plan
- Create a UM Auto Attendant

Grammar Generation

Frequently, the default grammar generation schedule will meet your needs. However, there are times when you must manually generate grammar files or update existing grammar files before the scheduled grammar generation task runs. There may also be times when you want to change the default grammar generation schedule.

Grammar generation occurs in the following situations:

- When the Unified Messaging server is added to a UM dial plan, and daily after that at a scheduled interval.
- When you run the **galgrammargenerator.exe** command to manually update or create grammar files.

The grammar file that is created is then updated when the scheduled grammar generation task runs. To display the default grammar generation schedule for a UM server, use the following cmdlet in the Exchange Management Shell:

```
(Get-UMServer $env:COMPUTERNAME).GrammarGenerationSchedule
```

For more information about the **Get-UMServer** cmdlet, see Get-UMServer.

By default, grammar generation occurs daily at the time specified by the *GrammarGenerationSchedule* parameter of the UM server. By default, the schedule is defined so that grammar generation starts at 2:00 A.M. each day. However, the grammar generation schedule can be changed and is controlled using the **Set-UMserver** cmdlet in the Shell. There is no graphical user interface that you can use to control the grammar generator schedule. This schedule can be controlled only by using the **Set-UMserver** cmdlet in the Shell. For more information about how to change the phonetic display name using the **Set-UMServer** cmdlet, see Set-UMServer.

By default, the grammar generation schedule is set to start once a day at 2:00 A.M. local time on the UM server. After it starts, grammar generation will run until it is completed, whether this is before the scheduled end time for the active period or not. Grammar generation won't run if there is another grammar generation that is running. Although you can configure additional scheduled times, grammar generation won't run within one hour of a previously scheduled grammar generation period. Because grammar generation uses lots of system resources, we recommend that you configure all grammar generation schedules so that grammar generation will occur during off-peak hours. However, you can stagger the grammar generation schedules on multiple UM servers, for example, Umserver1 starts at 2:00 A.M., Umserver2 starts at 2:30 A.M., and Umserver3 starts at 3:00 A.M. This helps minimize the effect of grammar generation on the Active Directory domain controllers.

Note:
A log file named UMSpeechGrammar.log will be created in the %ExchangeRoot%\UnifiedMessaging\temp folder. This log file contains information about all grammar files created or updated on a UM server. This file will be overwritten every time that scheduled grammar generation runs.

In the following circumstances, you can wait for the next scheduled grammar generation for the changes to be reflected, or you can force an update using the **galgrammargenerator.exe** command:

- When you complete a new installation of the UM server role and enable users for Unified Messaging
- When a UM dial plan, UM auto attendant, custom address list, or custom distribution list is created
- When you create UM-enabled users
- If you change a UM dial plan or UM auto attendant

Note:
When an Outlook Voice Access user tries to locate a UM-enabled user using the directory search feature with ASR immediately after you complete a new installation of the Unified Messaging server role and enabled users for UM, the caller will hear a system prompt that says, "I'm sorry I couldn't help." Then they are disconnected. This occurs because a grammar file for the global address list hasn't been generated. Use the **galgrammargenerator.exe** command to create the required grammar file for the global address list.

Each grammar file is overwritten every time that the Microsoft Exchange Unified Messaging service automatically runs or when you manually run the galgrammargenerator.exe program to force an update of the grammar files. This ensures that users who have just been enabled for UM can be accessed from the directory search in a time-efficient manner when a caller uses ASR. You can use **galgrammargenerator.exe** to force an update, or to generate or overwrite the grammar files used by Unified Messaging if they become corrupted. For example, when you first enable users for Unified Messaging, those users won't be available to callers who use ASR to perform a directory search until the scheduled grammar generation task runs. To make sure that those new users who were recently UM-enabled are visible to callers, run the galgrammargenerator.exe program to force the .grxml files to be created or updated and to compile the appropriate .cfg files so that callers can use ASR to move through the menu systems or locate users using ASR. For detailed steps, see Update the Speech Grammar Files on a UM Server.

Galgrammargenerator.exe is also useful when a UM server has joined a dial plan and one or more speech-enabled auto attendants are associated with the dial plan. By default, callers who call into a speech-enabled auto attendant can only reach UM-enabled users who are associated with the dial plan. Before callers can be transferred to UM-enabled users using voice inputs, a grammar file must be generated. The grammar file isn't generated automatically when the server joins a dial plan. Instead, it is generated the next time grammar generation is scheduled. Grammar generation occurs according to the default schedule, at 2:00 AM local time each day, unless the schedule has been changed.

If you want UM-enabled users to be available from a directory search from the speech-enabled auto attendant immediately after you create the auto attendant, you must generate the required grammar file for the auto attendant using galgrammargenerator.exe with the *–d* option.

A grammar file isn't required with auto attendants that aren't speech-enabled. This is because a DTMF map is added to Active Directory for each user when they're enabled for Unified Messaging. DTMF maps enable callers to enter the digits that correspond to the letters of the user's name or e-mail alias on a telephone keypad.

However, a DTMF map won't automatically be created for users who aren't UM-enabled. By using galgrammargenerator.exe with the *-u* option, you can generate a DTMF map for all users who are mail-enabled but not UM-enabled. This lets users who are mail-enabled but not UM-enabled be reached from the auto attendant when their name or e-mail alias is entered by a caller using DTMF inputs. For more information about the DTMF interface, see Understanding the DTMF Interface.

The following table lists the switches and descriptions for the switches for galgrammargenerator.exe.

Galgrammargenerator.exe and the switches

Switch	Description
-d <dialplan>	Creates a grammar file that contains the names of UM-enabled users only in the specified UM dial plan.
-g	Generates the grammar file.
-l	Generates a grammar file for a distribution list.
-o	Generates a log file. The path can be an absolute path, for example, C:\Logfiles. By default, the UM server will also automatically create a log file in the \UnifiedMessaging \Temp folder.
-p	Preloads all generated grammars into the Microsoft Speech Server platform.
-s <UMserver>	Creates a grammar file for each UM dial plan to which the specified UM server belongs.
-u	Creates or updates DTMF maps for users who are enabled for UM and who aren't enabled for UM. **Note:** If mailbox-enabled users or mail-enabled contacts have a character in their e-mail alias that isn't valid and you run the **galgrammargenerator.exe /u command** to create a DTMF map for users, the command won't complete successfully and Unified Messaging will report an error. To ensure that all mailbox users and mail-enabled contacts have no characters in their e-mail addresses that aren't valid, use the **Get-User** cmdlet to view all users. The **Get-User** cmdlet will perform a validation check for the user attributes. If any field has a character that isn't valid, an error will be generated that identifies the recipient and the field that contains the character.
-x	Defines the speech filter list that is used in XML format.

Note:
The default speech grammar filter list (SpeechGrammarFilterList.xml) is installed in the

<Program Files>\Microsoft\ Exchange Server\V14\Bin folder on each server that has the Unified Messaging server role installed. The contents of the speech filter list file must be the same on each UM server. The speech grammar filter list contains several rules that specify input patterns against which display names are matched and output patterns that define transformations of the matched name. If the name matches a pattern, it will be replaced in the speech grammar by the name or names generated from the associated output pattern or patterns. If the name doesn't match a pattern, it is passed through unchanged to the speech grammar. Names will be rejected from insertion in the speech grammar if they to have two or more distinct ways of being said. We recommend that you don't manually modify the SpeechGrammarFilterList.xml file.

Customizing Grammar Files

Currently, ASR is available only in English and includes the prerecorded prompts and Text-to-Speech (TTS) support for English. Although ASR support is included in the English language pack, there are times when it is difficult for speech recognition to locate the correct UM-enabled user because the user has a name that is difficult to pronounce, the caller's speech is matched against the wrong name, or the caller speaks a form of the user's name that differs from the name that exists in the speech grammar. However, adding an additional UM language pack won't resolve this problem.

Note:

Because ASR is enabled by default for U.S. English, a folder named \grammars\en is created on each Unified Messaging server. A folder is created for each language pack you install on the Unified Messaging server.

Unified Messaging uses two Active Directory attributes to generate names to use with ASR grammar files: Display name (**displayName**) and Phonetic display name (**msDS-PhoneticName**). By default, Unified Messaging uses the **displayName** attribute to recognize the name of a user when a caller speaks their name. This works well if the user's name is easy to pronounce. However, in some cases, users have names that are difficult to pronounce. To help Unified Messaging find users whose names are difficult to pronounce, we recommend that you configure the Unified Messaging system by supplying a phonetic display name for users who have names that ASR has trouble recognizing. However, to supply a phonetic display name, you must predict how the speech engine would perceive a certain spelling of a name to provide an accurate pronunciation for the phonetic name.

Note:

By default, the UM server will try to insert both the phonetic display name, if one exists, and the display name into the speech grammar file.

For example, the display name "Kweku Ako-Adjei" could be given a phonetic display name of "Quaykoo Akoo Oddjay", and UM would insert that into the speech grammar file. The drawback to creating phonetic names for users is that it is difficult to do on a large scale. It would be very time-consuming to create and test phonetic display names for every user whose name isn't correctly recognized by ASR, especially in large enterprise environments.

To add or change the phonetic display name for a UM-enabled user, you must use ADSI Edit (AdsiEdit.msc) or the **Set-User** cmdlet in the Shell. You can't use Active Directory Users and Computers or the Exchange Management Console to change a user's phonetic display name. For more information about how to change a phonetic display name using the **Set-User** cmdlet, see Set-User.

The *PhoneticDisplayName* parameter specifies a phonetic pronunciation for the display name. The display name is specified using the *DisplayName* parameter. If the display name isn't easy for the UM server to pronounce or recognize, you can use the *PhoneticDisplayName* parameter to specify a phonetic version. If you specify a value, it is

used by ASR to recognize the user's name and by the TTS engine to pronounce the user's name. If you don't specify a value, the UM server uses the *DisplayName* parameter. The maximum length of this parameter value is 255 characters.

For more information about ADSI Edit, see Adsiedit Overview.

Understanding Unified Messaging Dial Plans

Understanding Unified Messaging Auto Attendants

1.9.1.3.13 Understanding Telephony Concepts and Components

Understanding Telephony Concepts and Components

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-22*

If you're planning and deploying Microsoft Exchange Server 2010 Unified Messaging (UM) on your network, you must understand Unified Messaging and telephony networks. This topic provides an overview of telephony infrastructure concepts and components that will help you plan and deploy a server running Exchange 2010 Unified Messaging.

Contents

Overview

In versions of Microsoft Exchange before Exchange Server 2007, the Exchange administrator's main responsibility was managing e-mail messages and, sometimes,

managing a network infrastructure. Earlier versions of Exchange didn't have Unified Messaging capabilities. Exchange Server version 5.5, Exchange 2000 Server, and Exchange Server 2003 administrators focused on the Exchange environment and the network infrastructure, and relied heavily on telephony consultants to manage their telephony environment and infrastructure.

Concepts and Components

To successfully deploy a Unified Messaging server in Exchange 2010, you must have a good understanding of basic telephony concepts and telephony components. After you gain a good understanding of telephony basics, you can successfully integrate Exchange 2010 Unified Messaging into an Exchange 2010 organization. Basic concepts and components include the following:

- Circuit-switched and packet-switched networks
- Private Branch eXchange (PBX)
- IP PBX
- Voice over Internet Protocol (VoIP)
- IP gateways

Circuit-Switched Networks

In circuit-switched networks, such as the Public Switched Telephone Network (PSTN), multiple calls are transmitted across the same transmission medium. Frequently, the medium used in the PSTN is copper. However, fiber optic cable might also be used.

A circuit-switched network is a network in which there exists a dedicated connection. A dedicated connection is a circuit or channel set up between two nodes so that they can communicate. After a call is established between two nodes, the connection may be used only by these two nodes. When the call is ended by one of the nodes, the connection is canceled.

Note:

PSTN is a grouping of the world's public circuit-switched telephone networks. This grouping resembles the way that the Internet is a grouping of the world's public IP-based packet-switched networks.

There are two basic types of circuit-switched networks: analog and digital. Analog was designed for voice transmission. For many years, the PSTN was only analog, but today, circuit-based networks such as the PSTN have transitioned from analog to digital. To support an analog voice transmission signal over a digital network, the analog transmission signal must be encoded or converted into a digital format before it enters the telephony WAN. On the receiving end of the connection, the digital signal must be decoded or converted back into an analog signal format.

There are advantages and disadvantages to circuit-switched networks. Circuit-switched networks have several disadvantages. Circuit-switched networks can be relatively inefficient, because bandwidth can be wasted. This isn't the case when VoIP is used on a packet-switched network. VoIP shares the available bandwidth with all other network applications and makes more efficient use of the available bandwidth. Another disadvantage to circuit-switched networks is that you have to provision for the maximum number of telephone calls that will be required for peak usage times and then pay for the use of the circuit or circuits to support the maximum number of calls.

Circuit switching has one big advantage over packet-switched networks. In a circuit-switched network when you use a circuit, you have the full circuit for the time that you're using the circuit without competition from other users. This isn't the case with packet switched networks.

Note:

Synchronous Digital Hierarchy (SDH) has become the primary transmission protocol for most PSTN networks. SDH is carried over fiber optic networks.

Return to top

Packet-Switched Networks

Packet switching is a technique that divides a data message into smaller units called packets. Packets are sent to their destination by the best route available, and then they are reassembled at the receiving end.

In packet-switched networks such as the Internet, packets are routed to their destination through the most expedient route, but not all packets traveling between two hosts travel the same route, even those from a single message. This almost guarantees that the packets will arrive at different times and out of order. In a packet-switched network, packets (messages or fragments of messages) are individually routed between nodes over data links that may be shared by other nodes. With packet switching, unlike circuit switching, multiple connections to nodes on the network share the available bandwidth.

Note:

With circuit switching, all packets go to the receiver in order and along a single path.

Packet-switched networks exist to enable data communication on the Internet throughout the world. A public data network or packet-switched network is the data counterpart to the PSTN.

Packet-switched networks are also found in such network environments as LAN and WAN networks. A WAN packet-switched environment relies on telephone circuits, but the circuits are arranged so that they retain a permanent connection with their endpoint. In a LAN packet-switched environment, such as with an Ethernet network, the transmission of the data packets relies on packet switches, routers, and LAN cables. In a LAN, the switch establishes a connection between two segments only long enough to send the current packet. Incoming packets are saved to a temporary memory area or buffer in memory. In an Ethernet-based LAN, an Ethernet frame contains the payload or data portion of the packet and a special header that includes the media access control (MAC) address information for the source and destination of the packet. When the packets arrive at their destination, they are put back in order by a packet assembler. A packet assembler is needed because of the different routes that the packets may take.

Packet-switched networking has made it possible for the Internet to exist and, at the same time, has made data networks—especially LAN-based IP networks—more available and widespread.

Return to top

PBX

A legacy PBX is a telephony device that acts as a switch for switching calls in a telephony or circuit-switched network.

Note:

A legacy PBX is a PBX that cannot pass IP packets. In many businesses, legacy PBXs have been replaced by IP PBXs.

A PBX is a telephony device used by most medium-size and larger-size companies. A PBX enables users or subscribers of the PBX to share a certain number of outside lines for making telephone calls considered external to the PBX. A PBX is a much less expensive

solution than giving each user in a business a dedicated external telephone line. Telephone sets, in addition to fax machines, modems, and many other communication devices, can be connected to a PBX.

The PBX equipment is typically installed at a business's premises and connects calls between the telephones located and installed in the business site. A limited number of outside lines, also known as trunk lines, are typically available for making and receiving calls external to the business from an external source such as the PSTN.

Internal business calls made to external telephone numbers using a PBX are made by dialing 9 or 0 in some systems followed by the external number. An outgoing trunk line is automatically selected to complete the call. Conversely, the calls placed between users within the business don't ordinarily require special dialing digits or use of an external trunk line. This is because the internal calls are routed or switched by the PBX between telephones physically connected to the PBX.

In medium-size and larger-size businesses, the following PBX configurations are possible:

- A single PBX that supports the whole business.
- A grouping of two or more PBXs not networked or connected to each other.
- A grouping of two or more PBXs connected together or networked.

Note:
An Exchange 2010 UM dial plan can span more than one PBX and one IP gateway.

Return to top

IP PBX

An IP PBX is a PBX that supports the IP protocol to connect phones using an Ethernet or packet-switched LAN and sends its voice conversations in IP packets. A hybrid IP PBX supports the IP protocol for sending voice conversations in packets, but also connects traditional analog and digital circuit-switched Time Division Multiplex (TDM) telephones. An IP PBX is telephone switching equipment that resides in a private business instead of the telephone company.

IP PBXs are frequently easier to administer than legacy PBXs, because administrators can easily configure their IP PBX services using an Internet browser or another IP-based utility. Plus, no additional wiring, cabling, or patch panels must be installed. With an IP PBX, moving an IP-based telephone is as simple as unplugging a telephone and plugging it in at a new location, instead of the costly service calls to move a telephone from legacy PBX vendors. Additionally, businesses that own an IP PBX don't have the additional infrastructure costs required to maintain and manage two separate circuit-switched and packet-switched networks.

VoIP

Voice over Internet Protocol (VoIP) is a technology that contains hardware and software that enables people to use an IP-based network as the transmission medium for telephone calls. In VoIP, voice data is sent in packets using IP instead of traditional circuit transmissions or the circuit-switched telephone lines of the PSTN. An IP gateway that you connect to your IP network uses VoIP to send voice data packets between an Exchange 2010 Unified Messaging server and a PBX system.

IP Gateways

An IP gateway is a third-party hardware device or product that connects a legacy PBX to

your LAN. The IP gateway lets the PBX system communicate with your Exchange 2010 Unified Messaging server running IP.

Note:

The IP gateway can also connect to PBX systems that use VoIP instead of PSTN circuit-switched protocols.

Exchange 2010 Unified Messaging relies on the gateway's abilities to translate or convert TDM or telephony circuit-switched based protocols like ISDN and QSIG from a PBX to IP-based or VoIP-based protocols like Session Initiated Protocol (SIP), Realtime Transport Protocol (RTP), or T.38 for Realtime Facsimile Transport. The IP gateway is integral to the functionality and operation of Unified Messaging.

Important:

After you install the IP gateway, you must create an IP Gateway object in Active Directory to represent the IP gateway. After you create a UM IP Gateway object, the Unified Messaging server associated with the UM IP gateway will send a SIP OPTIONS request to the IP gateway to ensure that the IP gateway is responsive. If the IP gateway doesn't respond to the SIP OPTIONS request from the Unified Messaging server, the Unified Messaging server will log an event with ID 1088 stating that the request failed. To resolve this issue, ensure that the IP gateway is available and online and that the Unified Messaging configuration is correct.

For more information about IP PBX and PBX configurations, see Understanding PBX and IP PBX Configurations.

1.9.1.3.14 Understanding Protocols, Ports, and Services in Unified Messaging

Understanding Protocols, Ports, and Services in Unified Messaging

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-05-09*

Microsoft Exchange Server 2010 Unified Messaging (UM) requires that several TCP and User Datagram Protocol (UDP) ports be used to establish communication between servers running Exchange 2010 and other devices. By allowing access through these IP ports, you enable Unified Messaging to function correctly. This topic discusses the TCP and UDP ports used in Exchange 2010 Unified Messaging.

Unified Messaging Protocols and Services

Exchange 2010 Unified Messaging features and services rely on static and dynamic TCP and UDP ports to ensure correct operation of the computer running the Unified Messaging server role.When Exchange 2010 is installed, static Windows Firewall rules are added for Exchange. If you change the TCP ports that are used by the Unified Messaging server role, you may also need to reconfigure the Windows Firewall rules to allow Unified

Messaging to work correctly.

Important:

On Exchange 2010 Unified Messaging servers, Exchange setup creates the **SESWorker (TCP-In)** and **SESWorker (GFW) (TCP-In)** rules which allow inbound communication without any TCP port restrictions. We recommend you disable these two rules after you've setup the Unified Messaging server, and create a new rule to allow only the ports required for the SESWorker process which include 5065 and 5067 for TCP (unsecured). 5066 and 5068 for mutual TLS (secured). For details, see Exchange Network Port Reference.

Session Initiation Protocol

Session Initiation Protocol (SIP) is a protocol used for initiating, modifying, and ending an interactive user session that involves multimedia elements such as video, voice, instant messaging, online games, and virtual reality. It's one of the leading signaling protocols for Voice over IP (VoIP), together with H.323. Most VoIP standards-based solutions use either H.323 or SIP. However, several proprietary designs and protocols also exist. The VoIP protocols typically support features such as call waiting, conference calling, and call transfer.

SIP clients such as IP gateways and IP Private Branch eXchanges (PBXs) can use TCP and UDP port 5060 to connect to SIP servers. SIP is used only for setting up and tearing down voice or video calls. All voice and video communications occur over Realtime Transport Protocol (RTP).

Realtime Transport Protocol

RTP defines a standard packet format for delivering audio and video over a specific network, such as the Internet. RTP carries only voice/video data over the network. Call setup and teardown are generally performed by the SIP protocol.

RTP doesn't require a standard or static TCP or UDP port to communicate with. RTP communications occur on an even number UDP port, and the next higher odd number port is used for TCP communications. Although there are no standard port range assignments, RTP is generally configured to use ports 1024 and 65535. It's difficult for RTP to traverse firewalls because it uses a dynamic port range.

Unified Messaging Web Services

The Unified Messaging Web services installed on a Client Access server use IP for network communication between a client, the Unified Messaging server, the Client Access server, and computers running other Exchange 2010 server roles. There are several Exchange 2010 Outlook Web App and Microsoft Office Outlook 2007 client features that rely on Unified Messaging Web services to operate correctly.

The following Unified Messaging client features rely on Unified Messaging Web services:

- Voice mail options available with Exchange 2010 Outlook Web App, including the Play on Phone feature and the ability to reset a PIN.
- Play on Phone feature found in the Outlook 2007 client.

Note:

When an organization uses the Play on Phone and other client features in Exchange 2010 Unified Messaging, a computer running the Client Access, Hub Transport, and Mailbox server roles within the same Active Directory site is required in addition to the computer or computers that have the Unified Messaging server role installed.

Port Assignments

The following table shows the IP ports that Unified Messaging uses for each protocol and whether the IP ports used for each protocol can be changed.

IP ports used for Unified Messaging protocols

Protocol	TCP port	UDP port	Can ports be changed?
SIP (Microsoft Exchange Unified Messaging service)	5060 (unsecured) 5061 (secured) The service listens on both ports.		Ports can be changed in the msexchangeum.config configuration file. The msexchangeum.config file is located in the \Program Files \Microsoft\Exchange \V14\bin folder on an Exchange 2010 Unified Messaging server.
SIP (UM worker process)	5065 and 5067 for TCP (unsecured). 5066 and 5068 for mutual TLS (secured)		Ports can be changed in the msexchangeum.config configuration file. The msexchangeum.config file is located in the \Program Files \Microsoft\Exchange \V14\bin folder on an Exchange 2010 Unified Messaging server.
RTP		Ports between 1024 and 65535	Ports can be changed in the msexchangeum.config configuration file. The msexchangeum.config file is located in the \Program Files \Microsoft\Exchange \V14\bin folder on an Exchange 2010 Unified Messaging server.
Unified Messaging Web service	443		The port is configured on the Web site that hosts the Unified Messaging virtual directory. The port can be changed using IIS Manager.

Exchange 2010 Unified Messaging supports Network Address Translation (NAT) traversal and allows for the RTP media to be tunneled through a NAT firewall. However, for this to work, you must also have Microsoft Office Communications Server 2007 deployed in your environment. If you deploy both Exchange 2010 and Communications Server 2007 on your network, this deployment will enable Unified Messaging servers to communicate with endpoints outside a NAT firewall. The Unified Messaging server is associated with a Communications Server 2007 pool and obtains the appropriate authentication tokens from the Communications Server 2007 A/V Authentication Service on a computer serving that particular Communications Server 2007 pool.

The A/V Authentication Service is used to allow voice media to traverse NAT devices and

firewalls. This is necessary because media gateways handle signaling only and cannot transport voice securely across a NAT device or firewall. When you configure a mediation server in Communications Server 2007, you specify the A/V Edge server on which the A/V Authentication Service is running so that the mediation server will know where to forward the incoming media packets.

For more information about how to deploy Communications Server 2007 and Exchange 2010 Unified Messaging, see the following:

- Office Communications Server and Client Documentation Rollup
- Deploy Unified Messaging and Communications Server 2007 R2
- Understanding Unified Messaging and Communications Server 2007 R2

1.9.1.3.15 Understanding PBX and IP PBX Configurations

Understanding PBX and IP PBX Configurations

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Increasingly, organizations are purchasing, installing, and maintaining the hardware components, for example, Private Branch eXchanges (PBXs) or IP PBXs, which are required to support their own telephony system. Many organizations are buying their own telephony equipment and training their staff to reduce expenses associated with maintaining their telephony systems and because they want more control over the telephony features they offer.

For an organization to own and maintain their telephony network, they must buy the required telephony hardware components. They must also consider the day-to-day maintenance of the telephony equipment and the training required for their staff to support their telephony system. This topic discusses the different types of telephony business or organizational systems and the telephony hardware components they require. The topic also gives examples of the different types of telephony configurations.

Important:

We recommend that all customers who plan to deploy Microsoft Exchange Server 2010 Unified Messaging obtain the help of a UM specialist. This will help ensure a smooth upgrade from a legacy voice mail system. Rolling out a new UM deployment or performing an upgrade of an existing voice mail system requires significant knowledge about PBXs, IP PBXs, and Unified Messaging. For more information about who to contact, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Contents

Overview of Telephony Systems

In circuit-switched networks, such as the Public Switched Telephone Network, multiple calls are transmitted across the same transmission medium. Frequently, the medium that's used in the PSTN is copper. However, fiber optic cable might also be used.

A circuit-switched network is a network in which there exists a dedicated connection. A dedicated connection is a circuit or channel that's set up between two nodes so they can communicate. After a call is established between two nodes, the connection may be used only by these two nodes. When the call is ended by one of the nodes, the connection is canceled.

Different types or categories of telephone systems found in businesses and organizations include a circuit-based network, an IP-based network, or both. Each type of telephone system has distinct advantages and disadvantages you need to consider when planning and implementing a telephony system.

- **Centrex** Centrex is a type of telephone service that telephone companies lease to businesses and organizations. A traditional Centrex telephone system eliminates the need for a business or organization to purchase the telephony hardware used onsite to support the organization's telephone system. Typically, Centrex systems are used by small offices that rent Centrex services from a telephone company on a line-by-line and month-by-month basis. Centrex telephony systems are sometimes used by larger organizations, but are most frequently found in government, public, and private organizations. Centrex frequently uses analog telephone lines for the connections to a business or organization. But it can also use T1-circuits with a demultiplexer onsite to support analog and digital telephones or ISDN lines. In a Centrex-based telephony system, the telephone company's central office acts as the telephone exchange. It's designed specifically to support the needs of a given organization. The central telephone office routes the calls that originate from inside the company to the appropriate internal or external telephone number. Centrex uses the telephone company’s central office exchange to route internal calls back to an extension. For example, with Centrex, the telephone exchange or telephone company's central office knows which extensions are internal. So an employee who's located within the organization's telephony network can dial another employee in the same telephony network or dial plan by using a 4-digit extension number. When a call is dialed to the internal telephone extension number, it's forwarded to the telephone company’s central office and then routed back to the extension number that initiated the call.

A variation of a traditional Centrex telephony system is called *IP Centrex*. In an IP Centrex telephone system, the call is sent through an IP gateway located at a telephone company’s central office or located onsite at a service provider. In this kind of telephone system, the IP gateway translates the call into IP-based data packets that can be sent over the Internet or over a Voice over IP–based network. However, if the call is sent over the Internet, there's typically another IP gateway that receives the call and then translates the call back to a traditional circuit-switched call.

Organizations that currently have a traditional Centrex telephone system in place have to install, deploy, and maintain one or more IP gateways for Unified Messaging to work correctly. Unified Messaging may require that you install, deploy, and maintain IP gateways to work with IP Centrex. Several variables will determine whether you need an IP gateway. These variables include the type of telephones used in your organization (analog, digital, or IP) and the protocols supported by the IP Centrex system.

- **Key telephone** In a Key telephone system, the telephone company’s central office is connected to the organization using standard analog or digital telephone lines. A single telephone extension number is connected to multiple telephones so when a call is placed into the organization using this telephone

number, all the telephones associated with that line or extension number will ring at the same time.

With Key telephone systems, individual users share lines across telephones. Therefore, callers won't experience frequent busy signals when they try to call into an organization. Key telephone systems are typically used by small offices where internal call volume is high but external call volume is low.

Key telephone systems have become more sophisticated over time and can work with Unified Messaging if an IP gateway is added. However, some less sophisticated systems may not work even if a supported IP gateway is used.

- **PBX** A legacy PBX is a telephony device that switches calls in a telephony or circuit-switched network. A legacy PBX is a PBX that doesn't have a network adapter and can't pass IP packets. Because they can't pass IP packets, some businesses and organizations have replaced legacy PBXs with IP PBXs. For a list of PBXs supported by Unified Messaging, see Telephony Advisor for Exchange 2010.
  PBXs are used by most medium- and larger-sized companies. A PBX enables users or subscribers of the PBX to share a certain number of outside lines for making telephone calls considered external to the PBX. A PBX is a much less expensive solution than giving each user in a business a dedicated external telephone line. Telephones, in addition to fax machines, modems, and many other communication devices, can be connected to a PBX.
  The PBX equipment is typically installed on an organization's premises and connects calls between the telephones located onsite and the telephone company. A limited number of outside lines, also known as trunk lines, are typically available for making and receiving calls external to the business from an external source such as the PSTN.
  To enable a legacy PBX to be used with Unified Messaging, you need to deploy a supported IP gateway. For a list of supported IP gateways, see Telephony Advisor for Exchange 2010.
- **IP PBX** An IP PBX is a PBX that has a network adapter that supports the IP protocol. It's a piece of telephone switching equipment that generally resides in an organization or business instead of being located at a telephone company office. There are two types of IP PBXs: traditional IP PBXs and hybrid IP PBXs. Both traditional IP PBXs and hybrid IP PBXs support the IP protocol for sending voice conversations in packets to VoIP-based telephones. However, hybrid IP PBXs also connects traditional analog and digital telephones.
  IP PBXs are frequently easier to administer than legacy PBXs, because administrators can more easily configure IP PBX services using an Internet browser or another IP-based tool. Also, no additional wiring, cabling, or patch panels has to be installed. With an IP PBX, you can move an IP-based telephone by merely unplugging a telephone and plugging it in at a new location. This lets you avoid the costly service calls required to move a telephone from legacy PBX vendors. Additionally, organizations that own an IP PBX don't have to incur the additional infrastructure costs required to maintain and manage separate circuit-switched and packet-switched networks. For a list of IP PBXs supported for Unified Messaging, see Telephony Advisor for Exchange 2010.

Return to top

Legacy and Traditional PBX Configurations

On telephony networks that have legacy or traditional PBXs, a PBX does the following:

- Creates connections or circuits between the telephone sets of two users
- Maintains the connection as long as the users need the connection
- Provides information for accounting purposes (for example, meters calls)

In addition to the three functions included in the previous list, PBXs may offer other calling features such as:

- Auto attendants
- Call accounting
- Call pick-up
- Call transfer
- Call waiting
- Conference calling
- Direct Inward Dialing (DID)
- Do Not Disturb (DND)

Although there are several manufacturers of PBXs, they all fit into two basic categories: analog and digital. These types of PBXs are frequently known as *legacy* or *traditional* PBXs.

Typically, PBX systems are connected to the telephone company's central office by using special telephone lines, known as T1- and E1-lines. T1- and E1-lines have multiple channels. These telephone lines are also known as *trunk lines.* They let the central office or the PBX send multiple calls over the same line for better efficiency using a simplified wiring layout. A PBX can also work with analog or ISDN lines.

By correctly configuring your PBX, you can control how many channels or lines you want to configure to receive calls that come from external callers and how many channels or lines to devote to calls that come from callers inside your organization. Configuring the number of channels or lines helps prevent busy signals and lets you configure the number of channels or lines devoted to applications such as call centers. Correctly configuring your PBX is a cost effective method for managing the channels or lines in your organization because it reduces the number of leased lines required.

A PBX can route a specific dialed telephone number to a specific telephone so users can have their own individual telephone number or extension number. This is known as a Direct Inward Dialing number. When the telephone number is dialed for a user, the telephone company sends the DID number to the PBX by using Dialed Number Identification Service. Because the telephone company uses DNIS to send the number, there's no need for operator intervention to route the call. The PBX has the information about the call to correctly route it to the number that was dialed by the caller. For a list of PBXs supported by Unified Messaging, see Telephony Advisor for Exchange 2010.

Return to top

Analog and Digital PBXs

Analog PBXs send voice and call signaling information, such as the touch tones of a dialed telephone number, as an analog sound. Therefore, the sound is never digitized. To correctly direct the call, the PBX and the telephone company's central office have to listen for the signaling information.

Note:

Touchtone is more technically known as dual tone multi-frequency. When a caller presses a key on a telephone keypad, the telephone produces two separate tones: a high frequency tone and a low frequency tone. When a person speaks into the telephone, only a single tone or frequency is emitted. Sending two tones with different frequencies at the same time reduces the possibility that the signaling tones will be interpreted as a human voice or that a human voice will be interpreted as the signaling tones.

Digital PBXs encode or digitize the analog sound into a digital format. Digital PBXs typically encode the voice sounds using a standard industry audio codec like G.711 or G.729. After the digitized voice is encoded, it's sent over a channel by using circuit switching. Circuit switching sets up an end-to-end open connection. It leaves the channel open for the length of the call and for the caller's exclusive use. However, the signaling method that's used by the PBX depends on the manufacturer. PBX manufacturers may have their own

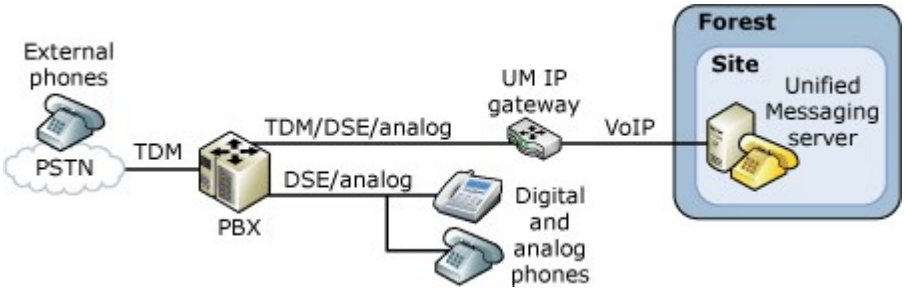
proprietary signaling method for call setup. For more information about the audio codecs used, see Understanding Unified Messaging Audio Codecs.

Note:
Digital PBXs can support both digital and analog trunk lines.

In larger organizations, PBXs make it possible for employees in separate physical locations to contact one another by dialing an extension number for a user. This can be done by using a single PBX or may involve multiple PBXs networked together. PBXs at different office locations can be connected to a single transparent circuit-switched network by using T1- or E1-lines. When these lines connect PBXs together, they are frequently known as *tie lines*. The PBXs communicate with one another across the tie lines using a PBX-to-PBX protocol, such as QSIG. QSIG lets a set of PBXs act as if they are a single PBX.

This kind of PBX environment can also include advanced features, such as call transferring and telephone conferencing. In addition to allowing for advanced features, having two connected PBXs can also save the organization money because long distance charges between employees in the different locations will be reduced. This is because a call made between two employees remains on a tie line between the PBXs and requires that the user dial only an extension number for the other user instead of placing a long distance call.

The following figure illustrates a typical telephony and data network that includes legacy or traditional PBXs.



In a telephony environment that includes a single or multiple analog or digital PBXs, an IP gateway is required between the PBX and the Exchange 2010 computer that has the Unified Messaging server role installed to convert the circuit-based protocols found on a telephony network into the IP-based protocols found on a data network. For more information about IP gateways, see the following topics:

- Understanding Unified Messaging IP Gateways
- Managing IP Gateways

For a list of IP gateways supported for Unified Messaging, see Telephony Advisor for Exchange 2010.

Return to top

IP PBX Configurations

An IP PBX is a PBX that supports the IP protocol to connect telephones by using an Ethernet or packet-switched LAN. It sends voice conversations in IP or data packets. An IP PBX may have multiple interfaces. These include interfaces for a data network and other interfaces that allow for a connection to a telephony or circuit-switched network.

The development of real-time Internet protocols has made it possible to successfully send

voice and fax messages over a data network. Such real-time Internet protocols include the VoIP protocols used with Unified Messaging: Session Initiation Protocol (SIP) over Transmission Control Protocol (TCP) for voice messaging. These protocols have made it possible to successfully send voice and fax messages over a data network. Real-time VoIP protocols are required to send voice messages over a packet-switched or data network so the delivery order and timing of data packets can be maintained and controlled. If these protocols weren't used to maintain and control the delivery and timing of the data packets, a person's voice would be broken up and sound incoherent or the images might appear garbled. For more information about VoIP protocols used in Unified Messaging, see Understanding Protocols, Ports, and Services in Unified Messaging. For a list of IP PBXs supported for Unified Messaging, see Telephony Advisor for Exchange 2010.

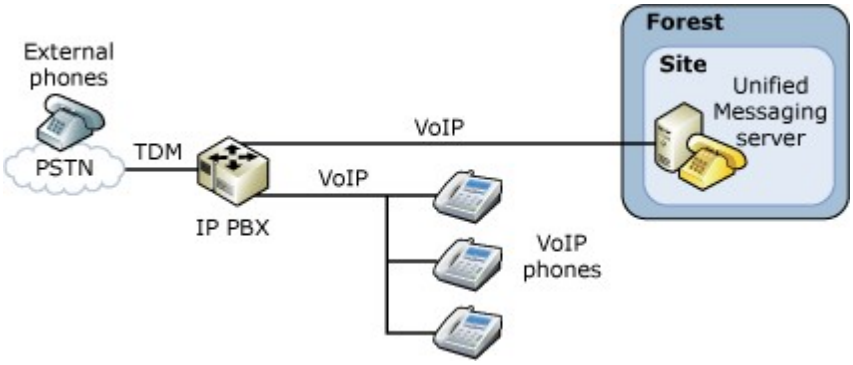
Note:

Unified Messaging supports only SIP over TCP.

Traditional IP PBX Configurations

A standard or traditional IP PBX contains at least a single network interface that connects to a data network using VoIP protocols. It may also contain additional network interfaces or other telephony interfaces that enable it to connect to an existing telephony network such as the PSTN. The connection to the data network allows for communication with other VoIP hosts located on the data network by using IP data packets. These VoIP hosts include other IP PBXs, VoIP-based telephones, IP gateways, and Unified Messaging servers. A traditional IP PBX is doesn't support analog or digital telephones. It supports only VoIP telephones.

The following figure illustrates a typical telephony and data network that includes a traditional IP PBX.



Because the IP PBX can already connect to a data network and can convert the circuit-based protocols from the PSTN to packet-switched VoIP protocols, an IP gateway may not be required to enable communication with UM servers on the data network.

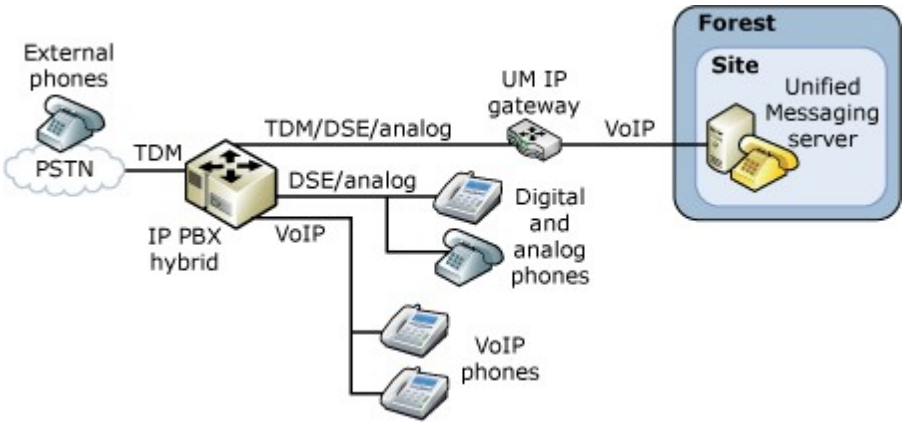
IP PBX Hybrid Configurations

Hybrid IP PBXs can provide analog, digital, and VoIP-based capabilities. If the correct interfaces are installed on an IP PBX and the software that supports multiple types of interfaces is installed correctly, the IP PBX is considered a hybrid IP PBX. An IP PBX hybrid makes it possible to use a mixture of analog, digital, and IP-based telephones.

Most modern IP PBXs can support and provide all three types of voice communication or a traditional IP PBX can be upgraded to a hybrid IP PBX by installing the necessary interfaces and software or firmware updates.

The mixture of analog, digital, and IP-based telephones makes it possible for users in your organization to use many new features and also provides great flexibility in your telephony environment. Using an IP PBX hybrid also allows for a more gradual migration to a completely VoIP-based telephony environment and voice messaging system for your organization.

The following figure illustrates a typical telephony and data network that includes an IP PBX hybrid configuration.



Several factors determine whether an IP gateway will be required when you connect with an UM server. One of these factors is the compatibility of the VoIP protocols used by the IP PBX or hybrid IP PBX and Unified Messaging. If an IP gateway isn't required, it will reduce the complexity of the telephony infrastructure, and the support that you must have for Unified Messaging will be simpler.

Return to top

Calling or Called Party Identification

Calling or called party identification is a telephone company service that can tell the person who is receiving the call the telephone number and sometimes the name of the person who is calling and other information about the call. This information is sent over a serial cable by using call signaling. When a call is received by a PBX or IP PBX from a telephone company, the call includes calling identification information such as the following:

- The calling party's number
- The called party's number
- Status codes such as a ring-no-answer, the state or condition of the line, line busy, and call forward always
- The line or port number that's being used for the call
- In telephony, the signaling information is used to exchange information between endpoints on a network to set up, control, and end calls. Several signaling methods used by IP gateways and IP PBXs are supported by Unified Messaging. The signaling method that's used depends on the type of device that's being used and the type of signaling method that's used by the telephone company. The most important factor is that the device that's connecting to the telephone company and to the IP gateway or IP PBX must support at least one of the signaling methods that enable calling or called party information to be sent and received by callers. For more information about signaling configuration information for a supported IP gateway, see Telephony Advisor for Exchange 2010.

Although other signaling methods can be used, the two most popular signaling methods are as follows:

- **Simplified Message Desk Interface (SMDI)** SMDI is a protocol that's used to provide signaling, call control, and calling identification information from an interface between a telephone system and a voice mail system. It's used to provide the voice mail system with the information it needs to process an

incoming call. Every time an incoming call is sent by using SMDI over a serial interface or RS-232 interface, the information that's sent will identify the line or port, the type of call, and the calling or called party numbers. The SMDI cable connects from a device such as a PBX to a serial connection on the IP gateway. However, SMDI is also used with IP PBXs. The SMDI protocol allows for a maximum of only 10 digits for each calling and called number. This is a limitation of the protocol and can't be changed.

- **In-band** In-band signaling allows for the exchange of signaling, call control, and calling identification information from a telephone company. This information is sent over the same channel and in the same band (300 Hz to 3.4 kHz) as the voice and other sounds that are being made during the call. For example, when a user places a call by using DTMF or touchtone dialing and talks to the called party, both the touchtone and the voice conversation use the same channel and band. In-band signaling is less secure because the control signals are exposed to the user and is a less popular signaling method than SMDI. In-band signaling applies only to Channel Associated Signaling (CAS).

Important:

We recommend that all customers who plan to deploy Unified Messaging obtain the assistance of a UM specialist. A UM specialist will help make sure there's a smooth upgrade to Unified Messaging from a legacy voice mail system. Performing a new deployment or upgrading a legacy voice mail system requires significant PBX and UM knowledge. For more information about how to contact a Unified Messaging specialist, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Return to top

1.9.1.3.16 Understanding Faxing in Unified Messaging

Understanding Faxing in Unified Messaging

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-22*

Microsoft Exchange Server 2010 Unified Messaging (UM) enables voice mail messages to be delivered to a user's Exchange 2010 mailbox and also lets users receive fax messages in their Exchange 2010 mailbox. In Exchange 2010 Unified Messaging, a fax message is sent to the user's mailbox as an e-mail message that has an image file with a .tif extension attached. The user can open the attached file using a software application that can open and view image files that have a .tif extension. This topic discusses faxing and how it works in Exchange 2010 Unified Messaging.

Note:

Although Unified Messaging doesn't let users send outgoing faxes, many third-party solutions, such as an Internet fax service, e-mail faxing service, or a third-party fax server application, can be used to send outgoing faxes.

Contents

Overview of Faxing

Fax is an abbreviation for the word facsimile. It's a technology that's used to electronically transfer documents. Generally, faxes are sent and received by fax machines or computer fax/modems by using the Public Switched Telephone Network (PSTN), which is a telephony or circuit-based network. However, there are other faxing options that can be used to send and receive faxes.

Most organizations today want their users to be able to send and receive faxes. Organizations use one or more of the methods described in the following list to send or receive faxes over the PSTN or over the Internet. There are advantages and disadvantages to each of these methods.

- Traditional fax machines and computer-based faxing
- Faxing by using fax servers or gateways
- Faxing by using a Voice over IP (VoIP) network
- Faxing by using an e-mail client application

To send a fax message, users in an organization may have to do the following:

- Print a hard copy of the document to be faxed and use a physical fax machine to send it.
- Save the document on their computer and use a fax modem to send the fax.
- Use an Internet fax service that lets them fax a document from a software application.
- Send an outgoing fax to a fax server by using a software application that's configured to use the fax server.

To receive a fax, users in an organization may have to do the following:

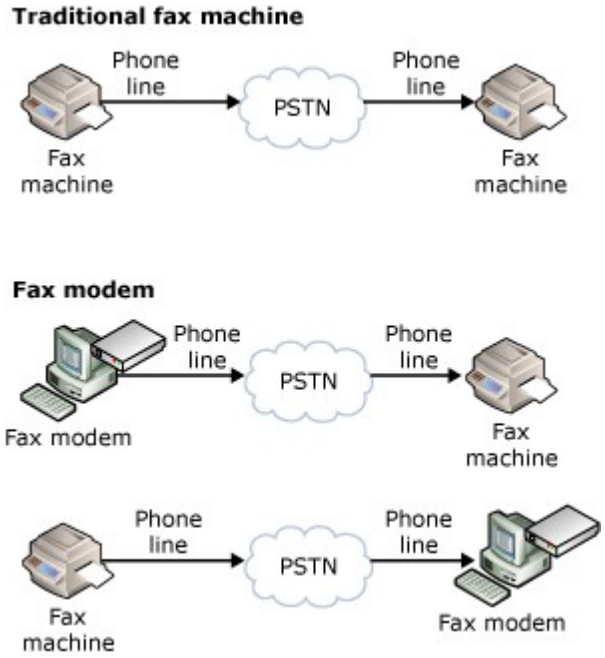
- Receive a fax on a physical fax machine within the organization.
- Receive a fax by using a fax modem that's installed on their computer.
- Receive a fax from an Internet faxing service.
- Receive a fax from a fax server that's configured on a network.
- Receive a fax from a Unified Messaging server on a VoIP network.

Faxing Methods

There are several options for sending and receiving faxes, including the following:

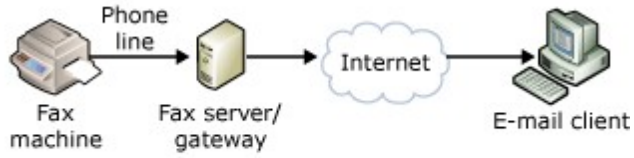
Traditional fax machines and computer-based faxing Scanners, a fax modem in a computer, a printer with built-in faxing capabilities, or a dedicated fax machine can be used to send and receive faxes. All of these can be used to transmit data in the form of pulses by using a telephone line to another fax device, usually another fax machine or computer that has a fax modem. The pulses are then transformed into images or used to print the image on paper.

The traditional fax method requires at least a single telephone line on the sending and receiving device, and only one fax can be sent or received at a time. A disadvantage of sending and receiving faxes by using a fax modem is that the computer must be turned on and running fax software or a fax service. This kind of computer-based faxing doesn't use the Internet to send or receive faxes. The following figure shows how traditional and computer-based faxing are used to send and receive faxes.

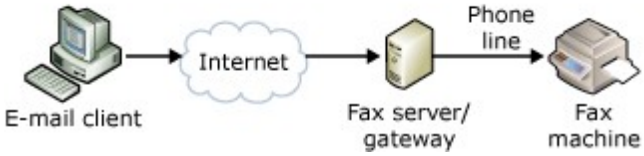


Fax servers or gateways and Internet fax services There are several ways to send and receive faxes over the Internet. These include using a software application on a computer or using an e-mail client to receive faxes. In most cases, this kind of faxing involves using a fax server or fax gateway to convert between faxes and e-mail. This has become increasingly popular because it enables organizations to remove or avoid purchasing additional fax machines. It also eliminates the need to install additional telephone lines. This kind of faxing involves creating a document, including a fax cover page with the correct identifying information, and then sending the document to a traditional fax machine. For example, the user uses a software application such as Microsoft Office Word or Outlook to create and send the fax to the fax server or gateway. The fax server or gateway receives the fax and then sends it by using a traditional telephone line to a fax machine or fax modem that's installed on a computer. The following figure shows how fax servers, gateways, and Internet fax services can be used to send and receive faxes.

Fax Receiving



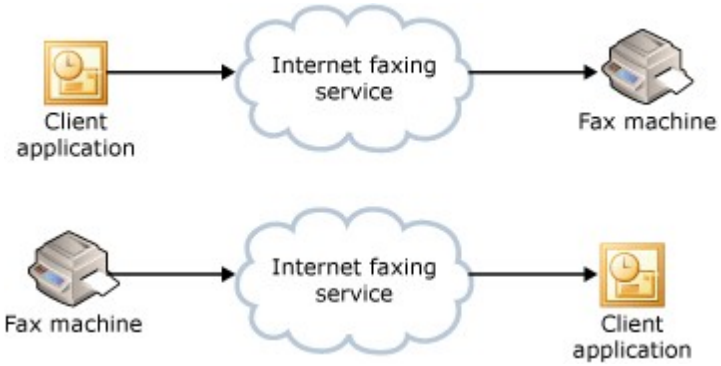
Sending a fax



Internet fax services let a user send faxes from a computer by using the Internet. A software application such as Word or Outlook can be used to create and send the fax to an Internet fax service. There are many companies that offer Internet faxing services on a subscription basis or by charging for each fax message that's sent. Internet fax services offer the following advantages:

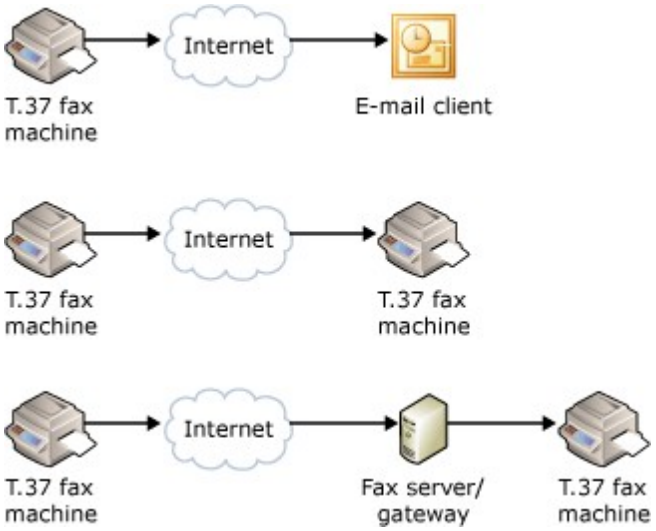
- No fax machine is required.
- No software or hardware must be installed.
- No dedicated telephone lines are required.
- Confidentiality.
- Multiple faxes can be sent at the same time.
- Faxes can be received when the computer is shut off.

The following figure shows how Internet fax services can be used to send and receive faxes.



Faxing by using an e-mail client application Faxes can be sent and received by a fax machine over the Internet and then received by an e-mail client such as Outlook.

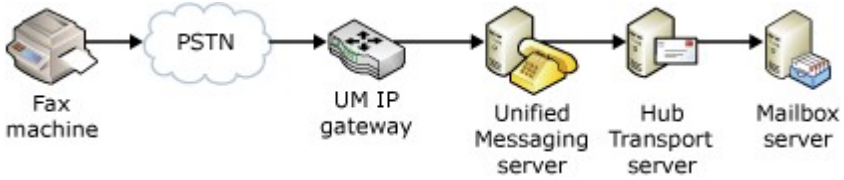
The T.37 protocol was designed to enable a fax machine to send fax messages over the Internet to an e-mail client. The faxes are sent over the Internet as an e-mail attachment, typically as .tif or .pdf files. In this kind of faxing, a fax machine that supports iFax or T.37 is required, in addition to an e-mail address for the sending and receiving fax machines. To work with existing traditional fax machines and fax modems, all T.37 fax machines support standard faxing by using a telephone line. However, in some cases, T.37 fax machines can be used when a fax gateway is also being used. The following figure shows how T.37-based fax machines and e-mail clients can be used to send and receive faxes.



Faxing by using a VoIP network VoIP is a technology that contains hardware and software that enables people to use an IP-based network as the transmission medium for telephone calls. On a VoIP network, voice and fax data is sent in packets by using IP instead of traditional circuit transmissions or the circuit-switched telephone lines of the PSTN. An IP gateway that you connect to your IP network uses VoIP to send voice data packets between an Exchange 2010 Unified Messaging server and a Private Branch eXchange (PBX) system. Or, you can use an IP PBX to perform the functions of both an IP gateway and a PBX.

There are two basic types of networks: circuit-switched and packet-switched. A circuit-switched network is a network in which there exists a dedicated connection. A dedicated connection is a circuit or channel that's set up between two nodes so that they can communicate. After a call is established between two nodes, the connection may be used only by these two nodes. When the call is ended by one of the nodes, the connection is canceled. In circuit-switched networks, such as the PSTN, multiple calls are transmitted across the same transmission medium. Frequently, the medium that's used in the PSTN is copper. However, fiber optic cable might also be used.

In packet-switched networks such as the Internet or a local area network (LAN), packets are routed to their destination through the most expedient route, but not all packets traveling between two hosts travel the same route, even those from a single message. This almost guarantees that the packets will arrive at different times and out of order. In a packet-switched network, packets (messages or fragments of messages) are individually routed between nodes over data links that may be shared by other nodes. With packet switching, unlike circuit switching, multiple connections to nodes on the network share the available bandwidth. Packet-switched networking has made it possible for the Internet to exist and, at the same time, has made data networks—especially LAN-based IP and VoIP networks—more available and widespread. The following figure shows how a VoIP network and Exchange Unified Messaging can be used to deliver faxes.



T.38

T.38 is a faxing standard and protocol that enables faxing over an IP-based network. An

IP-based network that uses the T.38 protocol uses Simple Mail Transfer Protocol (SMTP) and MIME to send the message to a recipient's mailbox. T.38 allows for IP fax transmissions for IP-enabled fax devices and fax gateways. The devices can include IP network-based hosts such as client computers and printers. In Exchange 2010 Unified Messaging, the fax images are separate documents encoded as .tif files and attached to an e-mail message. Both the e-mail message and the .tif file attachment are sent to the recipient's Exchange 2010 UM-enabled mailbox.

Exchange 2010 Unified Messaging relies on the gateway's abilities to translate or convert Time Division Multiplex (TDM) or telephony circuit-switched based protocols like Integrated Services Digital Network (ISDN) and QSIG from a PBX to IP-based or VoIP-based protocols like Session Initiation Protocol (SIP), Real-Time Transport Protocol (RTP), or T.38 for receiving fax messages. The IP gateway is integral to the functionality and operation of Unified Messaging. The IP gateway is responsible for sensing fax tones. Unified Messaging servers rely on the IP gateway to send a notification that a fax has been detected. Then the Unified Messaging server will renegotiate the media session and use the T.38 protocol.

Return to top

Overview of Faxing with Exchange 2010 Unified Messaging

In Exchange 2010 Unified Messaging, the user receives the fax images as separate documents encoded as .tif image files that are attached to an e-mail message. Both the e-mail message and the .tif attachment are sent to the recipient's Exchange 2010 UM-enabled mailbox.

There are several advantages to sending a fax message to the user's mailbox. These advantages include the following:

- You can reduce the number of physical or traditional fax machines.
- The number of telephone lines used for faxing in an organization can be reduced, because the Unified Messaging server can queue many faxes and send each fax when one of the telephone lines becomes available.
- Faxes that are received as a .tif image file are better quality than a traditional fax. Incoming faxes can be printed by a local or shared printer.
- Faxes sent to the user's mailbox are more secure because they're less likely than hard copy faxes to be picked up by someone other than the recipient.
- Users can receive faxes without leaving their desk.
- Fax messages that are received can be monitored to make sure that they comply with an organization's security policies.

A single fax message can be sent only to a single UM-enabled user. Exchange 2010 Unified Messaging can't forward fax messages to a distribution list. If you need to have this functionality, you must follow these steps:

1. Create a mailbox to answer the fax call. This will be the mailbox for the distribution list.
2. UM-enable the distribution list mailbox.
3. Create a rule for this UM-enabled mailbox. The rule will be configured to forward all messages to the selected distribution list.

Note:

If you’re using the RTM version of Exchange 2010 Unified Messaging, you may have to enable inband fax tone detection for fax receiving to work correctly with some IP PBXs. You do this by changing the *EnableInbandFaxDetection* setting to True in the msexchangeum.config file. The msexchangeum.config file is located in the \Program Files\Microsoft \Exchange\V14\bin folder on an Exchange 2010 Unified Messaging server. If

you don't configure this setting, Unified Messaging servers must rely on IP gateways to perform inband fax tone detection.
Changing the *EnableInbandFaxDetection* setting to True in the msexchangeum.config file isn't required in Exchange 2010 Service Pack 1 (SP1). Enabling fax tone detection isn't necessary on a Unified Messaging server with Exchange 2010 SP1 installed because the Unified Communications Managed API v. 2.0 (UCMA) enables the Unified Messaging server to listen to both inband and out-of-band fax events.

Return to top

Receiving Incoming Faxes

Receiving a fax on a VoIP network differs from receiving a fax on a standard fax machine or by using a fax server that's located on an IP-based network. To enable faxes to be sent and received over a VoIP network, you must have an IP gateway or an IP PBX that supports the T.38 protocol and a server that also supports T.38. T.38 allows for IP-based fax transmissions for IP network-based hosts, for example, client computers, printers with built-in faxing capabilities, and servers such as a Unified Messaging server.

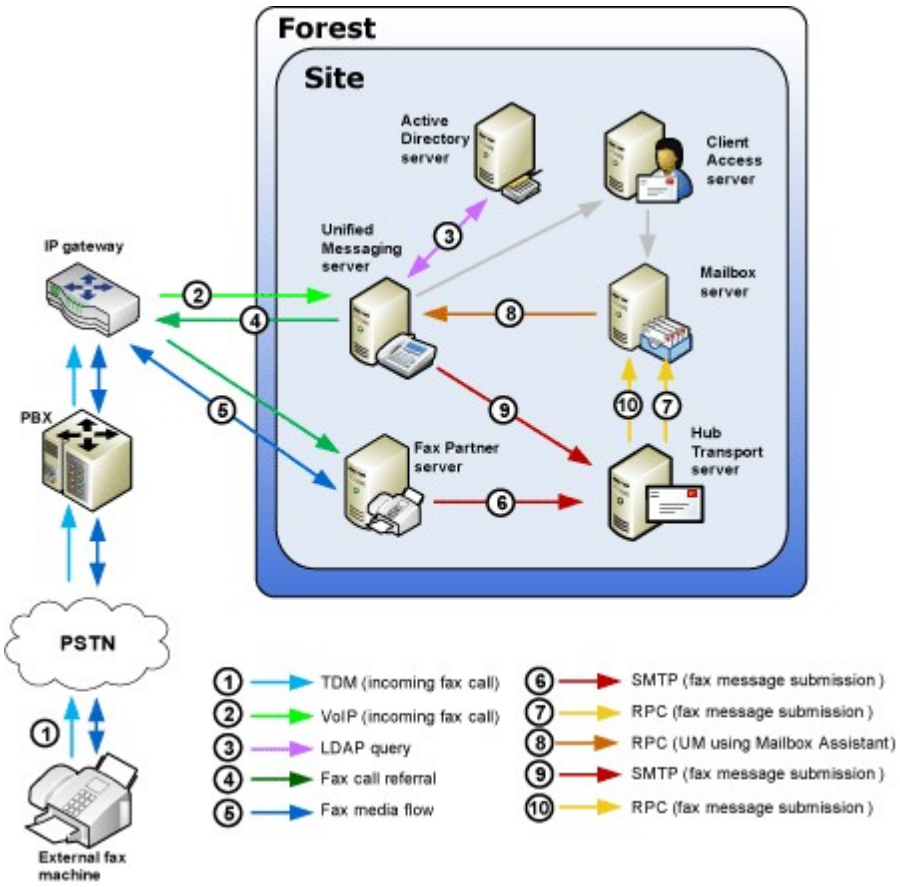
Important:

Sending and receiving faxes using T.38 or G.711 isn't supported in an environment where Unified Messaging and Microsoft Office Communications Server 2007 are integrated.

When a call is received into a PBX, the PBX forwards the call to the appropriate extension. If a ring-no-answer occurs at the user's extension number, the PBX forwards the call to an IP gateway, and the IP gateway forwards the fax call to the appropriate Unified Messaging server. When the call is received by the Unified Messaging server, the Unified Messaging server must decide whether it's a voice call or a fax call. When the SIP protocol is used, the Unified Messaging server processes the call as a voice message. However, if the T.38 protocol is used from the IP gateway, the Unified Messaging server recognizes that the call is for a fax and processes the call. Exchange 2010 Unified Messaging forwards incoming fax calls to a dedicated fax partner server, which then establishes the fax call with the fax sender and receives the fax on behalf of the UM-enabled user. The fax partner's server then sends the fax included as a .tif attachment in the SMTP message to the recipient's mailbox.

When an incoming T.38 fax signal is sent from the IP gateway to the Exchange 2010 UM server, the UM server queries Active Directory using LDAP to determine if the intended recipient of the incoming fax call is allowed to receive incoming fax messages and to determine the SIP address of the fax partner server. After these have been checked, the UM server sends a fax call referral request to the IP gateway or SIP peer, which then forwards the fax request on to the fax partner server. After the fax call has been successfully established, the fax sender sends the fax media and data to a fax partner server. After the fax media and data has been received by the fax partner server, the fax partner server sends an e-mail message to a Hub Transport server using SMTP that contains a .tif image of the fax message and special X-headers to the intended fax recipient.

After the fax message is authenticated and is sent from a valid fax partner server, the UM mailbox assistant on the Mailbox server issues an RPC call to the UM server. By doing this, the UM server ensures that the fax message properties match those of fax messages that are created by an Exchange 2010 Unified Messaging server. Finally, the UM server again submits the final fax message, which includes the e-mail message and .tif attachment for the incoming fax, to a Hub Transport server. Then, using MAPI RPC, the completed and formatted version of the fax message is delivered to the intended recipient. The following figure shows the steps that are involved when an incoming fax is received.



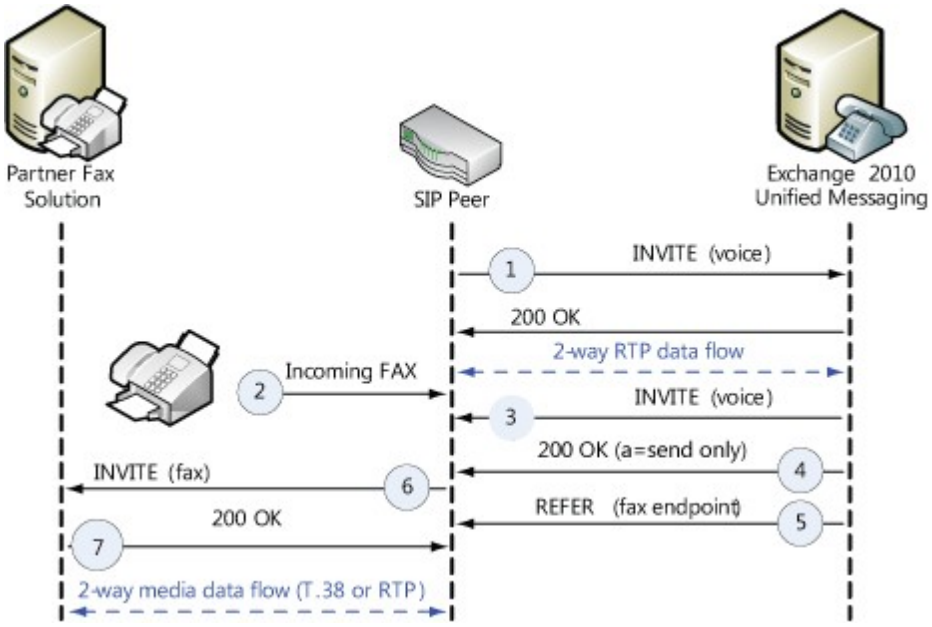
Return to top

Fax Call Referral Methods

An incoming fax call can be signaled to Exchange 2010 UM through either SIP re-INVITE from the IP gateway or SIP peer (media gateway), CNG notification by the SIP peer, or CNG detection by the UM server. The following subsections detail the fax call referral in each case.

Re-INVITE from a SIP Peer

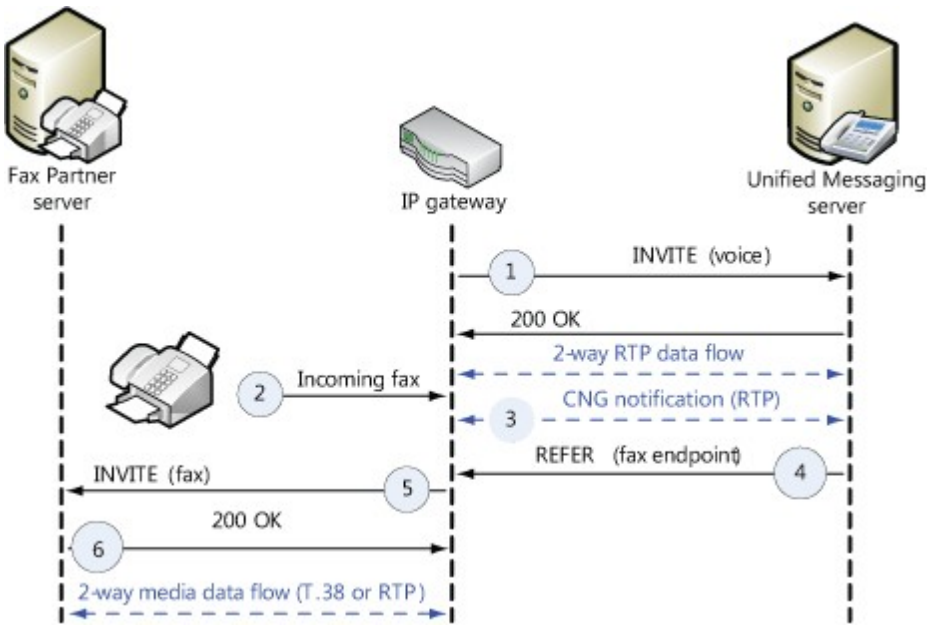
The call flow in this scenario proceeds as shown in the following figure.



An incoming call to a UM pilot number is directed to UM as an INVITE with a voice (RTP/ audio) SDP profile (1). UM accepts the invitation and media streams are established. After the call has been established, fax transmission is initiated by the caller (2). The SIP peer detects the calling fax tone (CNG). The SIP peer issues a re-INVITE to the UM server, this time specifying a fax (T.38 or G.711) profile in the SDP (3). UM responds to the invitation with a 200 OK that places the SIP peer "on hold" (4). UM issues a REFER, referring the SIP (CNG) peer to a fax partner solution end point, obtained from its configuration data (5). The SIP peer sends the fax session INVITE to the fax partner solution (6). The fax partner solution accepts the invitation, and a media session is established with the SIP peer.

CNG Notification by a SIP Peer

The call flow in this scenario proceeds as shown in the following figure.

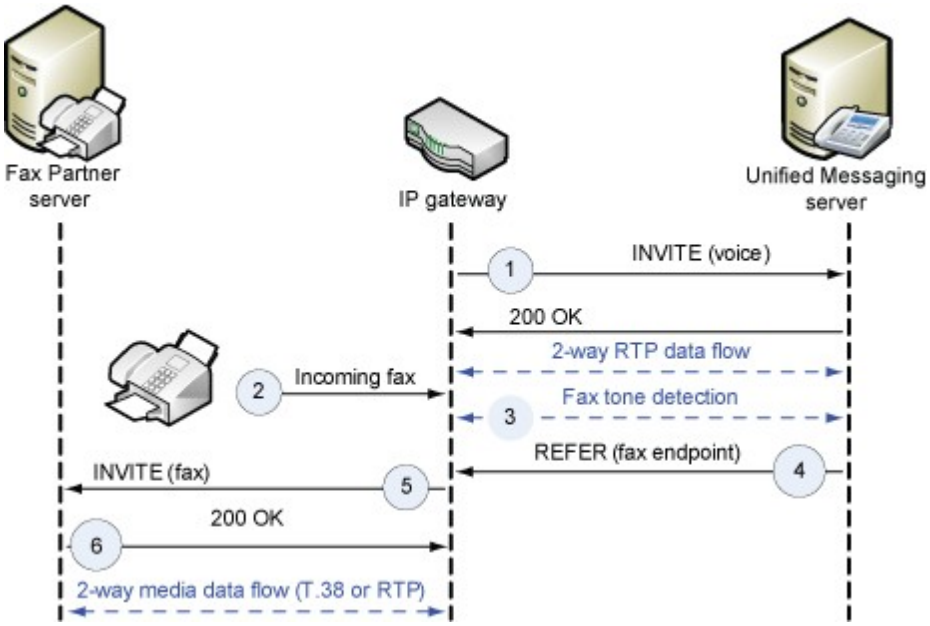


An incoming call to a UM pilot number is directed to UM as an INVITE with a voice (RTP/

audio) SDP profile (1). UM accepts the invitation and media streams are established. After the call has been established, fax transmission is initiated by the caller (2). The SIP peer detects the calling fax tone (CNG).The SIP peer notifies the UM server of the fax by sending a CNG notification in the RTP stream, compliant with RFC 4733 (3). UM responds to the notification by immediately issuing a REFER, therefore referring the SIP peer to a fax partner solution end point, obtained from its configuration data (4). The SIP Peer sends the fax session INVITE to the Fax Partner Solution (5). The fax partner solution accepts the invitation (6), and a media session is established with the SIP peer.

CNG Detection by a UM Server

The call flow in this scenario proceeds as shown in the following figure.



An incoming call to a UM pilot number is directed to UM as an INVITE with a voice (RTP/ audio) SDP profile. UM accepts the invitation and media streams are established (1). After the call has been established, fax transmission is initiated by the caller (2). The UM server detects the fax tone (CNG) in the RTP audio stream (3). UM responds to the notification by immediately issuing a REFER and therefore referring the SIP peer to a fax partner solution end point, obtained from its configuration data (4). The SIP peer sends the fax session INVITE to the fax partner solution (5). The fax partner solution accepts the invitation (6), and a media session is established with the SIP peer.

Return to top

Configuring Faxing

By default, when you install the Unified Messaging server role, the server isn't configured to allow incoming fax calls to be processed or delivered to a UM-enabled user. To configure Exchange 2010 UM with a fax partner server, you must configure the UM mailbox policy and configure authentication between the UM server and the fax partner server. For more information, see Deploy and Configure Incoming Faxing.

Telephone Numbers and Faxing

Exchange 2010 Unified Messaging offers the following options when you're configuring

UM-enabled users to receive fax messages:

- A Direct Inward Dial (DID) telephone number that's used with voice mail.
- A separate DID telephone number that's used for receiving faxes.
- A central fax telephone number that will receive all faxes.

A Single DID Telephone Number

When you enable a user for Unified Messaging by using the Enable Unified Messaging wizard or the **Enable-UMMailbox** cmdlet, you must specify at least a single extension number for the user. This extension number is enabled on a per-user basis and must be unique within a given dial plan. The extension is used by Unified Messaging to locate the correct user in Active Directory and to deliver voice and fax messages to the user's Exchange 2010 mailbox. For more information, see Enable-UMMailbox.

In this scenario, the user will use a single DID number for voice and fax. This configuration is easy to administer and doesn't waste additional DID numbers. If the user is away or on the phone when a fax call arrives, UM answers the call, detects the fax tone, creates the fax message, and sends it to the user.

However, in this scenario, the user may receive calls from fax machines. The user can:

- Not answer the telephone when it rings so that the fax call will be forwarded and answered by a Unified Messaging server and the fax message will be created and forwarded to the user's mailbox.
- Answer the fax call, and then transfer it to himself or herself so that the call will be forwarded and answered by a Unified Messaging server and the fax message will be created and forwarded to the user's mailbox.
- Wait for the caller to retry sending the fax and let the fax call be transferred to a Unified Messaging server.

In summary, using a single DID number requires the user to perform additional actions to be able to receive fax messages.

Return to top

Multiple DID Telephone Numbers

When you enable a user for Unified Messaging, you must enter at least a single extension number for that user. However, you can also add multiple extension numbers for a UM-enabled user by using the *SecondaryAddress* parameter with the **Set-Mailbox** cmdlet. For more information, see Set-UMMailbox.

Important:

In Exchange 2007 SP1, you can use the **Set-Mailbox** cmdlet or the Exchange Management Console to add multiple extension numbers. For more information, see Modify an Extension Number for a UM-Enabled User.

Adding multiple extension numbers is useful when a UM-enabled user:

- Receives many faxes
- Doesn't want to be bothered with answering the phone to receive a fax
- Doesn't want to hear a fax tone when they answer their phone

Adding multiple extensions is more complex than using a single extension and may require additional configuration settings on a PBX. To configure multiple extension numbers for a UM-enabled user, you must have DID extension numbers that are available but aren't being used in your organization. Therefore, it isn't a good idea to use multiple numbers for a UM-enabled user if your organization has a limited number of available DID extension numbers.

The benefit of using multiple DID telephone numbers is that the UM-enabled user receives voice calls on one DID extension number and fax calls on the other DID extension number. Although, this may be more complex and requires additional configuration steps, using

separate DID numbers for voice mail and fax calls is easier for the user.

If you configure two DID extension numbers for a specific user, the DID extension numbers can come from separate UM dial plans. In this scenario, you can create a dial plan, add Unified Messaging servers to the dial plan, and use a Unified Messaging server as a dedicated server that will receive fax calls and forward fax messages to the users. For more information, see Create a UM Dial Plan.

You have the following options for configuring multiple DID extension numbers for UM-enabled users:

- **Multiple DID numbers (one for fax without Unified Messaging and one for voice)** This type of configuration is enabled on a per-user basis and is used when you have extra or unused DID extension numbers available. One DID extension number is published as the user's voice mail number and the other DID extension number is published as the user's fax number. In this scenario, voice calls that are answered by a ring-no-answer or busy signal are forwarded to a Unified Messaging server, and a voice message is created and sent to the UM-enabled user's mailbox. The other extension number can be connected to a fax machine or to another computer that has a fax modem. Although this configuration is possible, it doesn't require that Unified Messaging servers process the fax calls, and fax messages won't be sent to the UM-enabled user's mailbox.
- **Multiple DID numbers (one for fax and one for voice)** This type of configuration is enabled on a per-user basis and can be used when your organization has many DID extension numbers available. In this scenario, both DID extension numbers that are answered by a ring-no-answer or a busy signal are forwarded to a Unified Messaging server that will create a voice or fax message depending on the DID extension number that's called. Although the user will publish one number for voice and one for fax, the Unified Messaging server detects the type of call that's being received on the DID extension number and can create a voice or fax message from calls to either of the DID extension numbers. This is very useful when a user doesn't have a separate fax machine or dedicated computer that has a fax modem to answer incoming fax calls.
- **Two DID numbers (one "phantom" extension for fax and one for voice)** This type of configuration is enabled on a per-user basis. It's basically the same as the configuration that uses two DID numbers (one for fax and one for voice). However, in this configuration, the number that's published for fax calls for the UM-enabled user is configured on the PBX as a "phantom" extension. Incoming calls that are received on this "phantom" DID extension number are always forwarded to a Unified Messaging server.
  The advantage of this kind of configuration is that incoming fax calls are answered by a Unified Messaging server. When a ring-no-answer occurs, a fax is created and forwarded by the Unified Messaging server to the UM-enabled user's mailbox without disturbing the user. This happens because no telephone or fax device is positioned close to the user, and the user doesn't hear the ring of an incoming call.
  The disadvantages of this kind of configuration are that you must have additional DID extensions available and you must configure the PBX to forward the call to a Unified Messaging server.

Central Fax Telephone Number

When you enable a user for Unified Messaging by using the Enable Unified Messaging wizard or the **Enable-UMMailbox** cmdlet, you must specify at least a single extension number for the user. This kind of fax configuration is defined on each Unified Messaging dial plan.

In some organizations, especially those that receive many faxes each day, you might have to publish one fax number for the whole organization. This fax number would be

used by all callers when they submit faxes to users in the organization. This kind of configuration is useful in the following situations:

- A user within the organization receives too many faxes in their mailbox to manage them effectively.
- A user receives too many spam faxes in their mailbox.
- Business logic is too complex to warrant creating a transport rule. This might be the case if your organization requires that you route certain faxes to one group and other faxes to another group. For more information, see the following topics:
  - Understanding Transport Rules
  - Understanding How Transport Rules Are Applied
- Filtering fax messages by using Outlook isn't effective.

Publishing one fax number for the whole organization enables your organization to control the types of faxes that are received by users. The advantage of this configuration is that it requires only a single DID extension number or an external telephone number. Also, it doesn't require a separate DID number for faxing for each UM-enabled user. However, it does require a "fax secretary" or other person to distribute the incoming faxes to users within the organization based on information that's included on the fax cover page or in the fax message itself.

Note:

Using a central fax number with optical character recognition (OCR) is not available in Exchange 2010 Unified Messaging. This kind of configuration can use a central fax number. However, instead of having to be routed to the recipient by a person, the faxing software receives the fax, performs OCR, and then tries to locate the recipient based on the information on the cover page or fax message.

Journaling UM Fax Messages

Many organizations that implement journaling may also use Unified Messaging to consolidate their e-mail, voice mail, and fax infrastructure. However, you may not want the journaling process to generate journal reports for messages that are generated by Unified Messaging. In this case, you can decide whether to journal voice mail messages and missed call notification messages that are handled by an Exchange 2010 Unified Messaging server or to skip such messages. If your organization doesn't require journaling of such messages, you can reduce the hard disk space that's required to store journal reports by skipping such messages. When you enable or disable the journaling of voice mail messages and missed call notification messages, your change is applied to all Hub Transport servers in your organization. For more information, see Understanding Journaling.

Note:

Messages that contain faxes that are generated by a Unified Messaging server are always journaled, even if you configure a journal rule that specifies not to journal Unified Messaging voice mail and missed call notification messages.

1.9.1.3.17 Understanding Quality of Service (QoS) in Unified Messaging

Understanding Quality of Service (QoS) in Unified Messaging

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-20*

Microsoft Exchange Server 2010 Unified Messaging (UM) supports DiffServ through Differentiated Services Code Point (DSCP) marking.

In Windows Server 2008, TCP/IP performs DiffServ marking when you've installed the Quality of Service (QoS) Packet Scheduler. When you install the Unified Messaging server role on a computer that's running Windows Server 2008 with the QoS Packet Scheduler installed, all outgoing Unified Messaging packets will be marked with a DSCP value that's configured. However, you can change this value for the packets by using Registry Editor or by modifying the Group Policy. For more information about DSCP marking, see Differentiated Services Code Point (DSCP) overview. By default, the QoS Packet Scheduler is installed on Windows Server 2008.

The Microsoft Exchange Unified Messaging service doesn't perform any classification of network packets. However, the media platform that's included with Unified Messaging instructs the Microsoft Windows networking stack that all audio packets are to be marked as *Guaranteed Service*. The operating system will then use Group Policy settings to determine how the data packets should be marked and then mark the TOS field of the IP header. For more information about QoS in Windows, see How QoS Works.

Note:

The media stack QoS marking is performed on UDP traffic only because TCP traffic has its own flow control.

You can enter IP addresses and IP address ranges in the Internet Protocol Version 4 (IPv4) format, Internet Protocol Version 6 (IPv6) format, or both formats. However, when you install the Unified Messaging server role on Windows Server 2008, you must have the IPv4 protocol stack enabled with or without having the IPv6 protocol stack enabled. This is because there are limitations with the telephony and speech components that are required and used by Unified Messaging.

Note:

Layer 3 network devices, such as routers, must also support DiffServ.

1.9.1.3.18 Understanding Unified Messaging Subscriber Access

Understanding Unified Messaging Subscriber Access

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When you're deploying Microsoft Exchange Server 2010 Unified Messaging (UM), you must understand subscriber access and the features included with Exchange 2010 that depend on subscriber access. This topic describes subscriber access and how it's used in Exchange 2010 Unified Messaging to let subscribers, also known as UM-enabled users, access their Exchange 2010 mailbox.

Subscriber Access

A subscriber is an internal business user or network user who's enabled for Exchange 2010 Unified Messaging. Subscriber access is used by users to access their individual

mailboxes to retrieve e-mail, voice messages, contacts, and calendaring information. Outlook Voice Access is an Exchange 2010 Unified Messaging feature that lets subscribers access their Exchange 2010 mailbox.

When you enable subscriber access for Exchange 2010 UM-enabled users, you must install the Exchange 2010 Unified Messaging server role on the computer that's running Exchange 2010 and verify that at least one of each of the following have been created:

- A UM dial plan
- A UM mailbox policy
- A UM IP gateway
- A UM hunt group

When you configure subscriber access, you configure the UM dial plan to have a subscriber access number. The telephone number or number that's configured on the UM dial plan is the telephone number that subscribers will use to access their Exchange 2010 mailboxes over the telephone using Outlook Voice Access. The subscriber access feature included with Exchange 2010 Unified Messaging resembles other unified messaging solutions. However, Exchange 2010 offers more advanced features than other unified messaging solutions. For more information about how to create or modify UM dial plans and enable subscriber access, see Create a UM Dial Plan

Note:
A UM dial plan must contain at least one subscriber access number, but can contain multiple subscriber access numbers.

For more information about how to enable a user for Unified Messaging, see Enable a User for Unified Messaging.

Return to top

Outlook Voice Access

There are two Exchange 2010 Unified Messaging user interfaces available to subscribers: the Telephone User Interface (TUI) and the Voice User Interface (VUI). These two interfaces together are called Outlook Voice Access. Outlook Voice Access can be used when subscribers access the Unified Messaging system from an external or internal telephone to access their individual mailbox, including their personal e-mail, voice messages, contacts, and calendaring information in their Exchange 2010 mailbox.

If you want to prevent users from receiving voice mail but want to allow them access to their Exchange 2010 mailbox using Outlook Voice Access, you can enable users for Unified Messaging and configure the users' mailbox with an extension number that isn't currently being used by another user in the organization.

Important:
For the VUI or Automatic Speech Recognition (ASR) to be used for subscriber access, it must be enabled on the UM dial plan to enable the VUI functionality as described in the earlier scenarios.

For a copy of the Microsoft Exchange 2010 Unified Messaging Outlook Voice Access Quick Start Guide, see the Microsoft Download Center.

The following scenarios demonstrate how Outlook Voice Access can be used for subscriber access from a telephone:

- **Access e-mail** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access voice mail. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension number, the voice prompt

says, "Please enter your PIN and press the # key." After the user enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." When the user says "E-mail," Unified Messaging reads the message header and then the name, subject, time, and priority for the messages that are in the subscriber's mailbox.

- **Access calendar** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access voice mail. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension, the voice prompt says, "Please enter your PIN and press the # key." After the user enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." When the user says "Calendar," Unified Messaging says, "Sure, and which day should I open?" The user says, "Today's calendar." Unified Messaging responds by saying, "Opening today's calendar." Unified Messaging reads each of the calendar appointments for that day for the user.

  Note:
  If a Unified Messaging server encounters a corrupted calendar item in a user's mailbox, it will fail to read the item, but will return the caller to the Outlook Voice Access main menu and will skip reading any additional meetings that may be scheduled for the rest of the day.

- **Access voice mail** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access voice mail. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension number, the voice prompt says, "Please enter your PIN and press the # key." After the user enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." The user says "Voice mail" and Unified Messaging reads the message header and then the name, subject, time, and priority for the voice messages that are in the user's mailbox.

  Note:
  If speech recognition is enabled, users can access their UM-enabled mailbox using speech input. However, subscribers can also use touchtone, also known as dual tone multi-frequency (DTMF), by pressing 0. Speech recognition is not enabled for PIN input.

- **Locate an e-mail alias** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to locate a person in the directory by spelling the e-mail alias. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To contact someone, press the # key." The user presses the # key, and then spells the name of the person using DTMF or touchtone inputs.

  Note:
  The directory search feature with subscriber access is not speech-enabled. Users will be able to spell the name of the person who they want to contact only using DTMF inputs.

  Important:
  In some companies (especially in East Asia), office telephones may not have letters on the keys of the telephone. This makes the spell-the-name feature that uses the DTMF interface almost impossible to use, without a working

knowledge of the key mappings. By default, Exchange 2010 Unified Messaging uses the E.161 key mapping. For example, 2=ABC, 3=DEF, 4=GHI, 5=JKL, 6=MNO, 7=PQRS, 8=TUV, 9=WXYZ.
When inputting a combination of letters and numbers, for example, Mike1092, the numeric digits are mapped to themselves. For an e-mail alias of Mike1092 to be entered correctly, the user must press the numbers 64531092. Also, for characters other than A-Z and 0-9, there won't be a telephone key equivalent. Therefore, these characters shouldn't be entered. For example, the e-mail alias mike.wilson would be entered as 6453945766. Even though there are 11 characters to be input, only 10 digits are entered by the user because the period (.) does not have a digit equivalent.

Important:
If you need to access the e-mail message after you delete it using Outlook Voice Access, you can use Outlook Web App or Outlook to move the e-mail message back into the appropriate folder from the Deleted Items folder. You can't use Outlook Voice Access to access the Deleted Items folder.

Return to top

1.9.1.3.19 Understanding Protected Voice Mail

Understanding Protected Voice Mail

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-09-24*

Some legacy PBX telephony systems allow the caller to mark a voice mail message as private, blocking the intended recipient of the message from forwarding it to others when they listen to the message. In integrated voice mail systems, a voice message can be accessed in multiple ways, which makes it more of a challenge to prevent voice messages marked private from being exposed to unintended listeners.

Unified Messaging (UM) in Exchange Server 2010 can be configured to use Active Directory Rights Management Services (AD RMS) to protect voice messages for an organization. This feature is known as Protected Voice Mail.

When a voice message is protected, the recipient is not only blocked from forwarding the message, but UM also assures that only the intended recipient or recipients of the message can access its content. Protected voice messages can be accessed by using Microsoft Office Outlook 2010, Office Outlook Web App, and Exchange Server 2010 Outlook Voice Access.

Contents

UM Mailbox Policies

SMS Notifications and Protected Voice Mail

Overview of Protected Voice Mail

The Protected Voice Mail feature is available with Exchange 2010 Unified Messaging (UM). It can be configured on a UM mailbox policy, and all Protected Voice Mail settings can be configured using the Exchange Management Console (EMC) or cmdlets in the Exchange Management Shell.

Note:
In a deployment where both Exchange 2010 servers and Microsoft Exchange Server 2007 servers exist, Voice Mail Preview isn't available to UM-enabled users who have an Exchange 2007 mailbox.

Protected Voice Mail is implemented by applying Information Rights Management (IRM) to voice messages. When voice messages are protected by UM:

- Users can reply to protected voice messages.
- Recipients of a voice message can't forward it.
- Users can't save a copy of the voice message.
- Users can't save or copy the attached audio of the voice message.
- A voice mail message can be opened only by the intended recipient or recipients.

Both call answering voice mail messages and interpersonal voice messages (voice messages that are sent to a user using Outlook Voice Access) can be protected by UM. However, protection won't be applied to the following types of messages:

- Fax messages.
- Non-voice messages. For example, e-mail messages or meeting requests, even when they're created using Outlook Voice Access (voice replies).

Overview of Active Directory Rights Management Services

AD RMS, a component of Windows Server 2008, is available to help protect files so that only the users who the sender intends to view a file can do so. AD RMS protects a file by specifying the rights that a user must have to access the file. Rights can be configured to allow a user to open, modify, print, forward, or take other actions with the rights-managed information. With AD RMS, you can safeguard data when it's distributed outside your network.

An AD RMS system has both a server and a client component, including the following:

- A Windows Server 2008 R2–based server running the Active Directory Rights Management Services server role, which handles certificates and licensing.
- A database server.
- The AD RMS client. The latest version of the AD RMS client is included as part of the Windows 7 and Windows Vista operating systems.

The server component is made up of several Web services that run on a Microsoft server such as Windows Server 2008. The client component can be run on either a client or server operating system and includes functions that enable an application to encrypt and decrypt content, retrieve templates and revocation lists, and acquire licenses and certificates from a server.

By using AD RMS and the AD RMS client, you can augment an organization's security

strategy by protecting information through persistent usage policies that remain with the information, regardless of where it's moved. You can use AD RMS to help prevent sensitive information—such as financial reports, product specifications, customer data, and confidential e-mail and voice mail messages—from intentionally or accidentally getting into the wrong hands. For detailed information, see AD RMS Overview.

In Exchange 2010, you can use Information Rights Management (IRM) features to apply persistent protection to messages and attachments. IRM uses AD RMS, an information protection technology in Windows Server 2008 and Windows Server 2008 R2. To use IRM to implement Protected Voice Mail, you need Windows Server 2008 R2 with AD RMS.

Using the IRM features in Exchange 2010, and Protected Voice Mail, your organization and your users can control the rights recipients have to access e-mail and voice mail messages. IRM can be also used to restrict recipient actions such as forwarding a message to other recipients, printing a message or attachment, or extracting message or attachment content by copying and pasting. For details, see Understanding Information Rights Management.

IRM Requirements

Before you can implement IRM in Exchange 2010, you must first deploy and configure your AD RMS infrastructure. For detailed information, see Active Directory Rights Management Services. To implement IRM to support Protected Voice Mail in your Exchange 2010 organization, your deployment must meet the following requirements.

Return to top

Server	Requirement
AD RMS Cluster	• **Windows Server 2008 Service Pack 2 (SP2)** with the following hotfix. For more information, see A hotfix is available for the Active Directory Rights Management Services role in Windows Server 2008. • **Service connection point (SCP)** Exchange 2010 and AD RMS-aware applications use the SCP registered in Active Directory to discover AD RMS clusters and URLs. AD RMS allows you to register the SCP within AD RMS setup. If the account used to set up AD RMS isn't a member of the Enterprise Admins security group, SCP registration can be performed after setup. There is only one SCP for AD RMS in an Active Directory forest. • **Permissions** Servers in the Exchange servers group or individual Exchange servers must be assigned Read and Execute permissions to the AD RMS server certification pipeline (The default path is \inetpub\wwwroot_wmcs \certification\ServerCertification.asmx on AD RMS servers). • **AD RMS super users** To enable transport decryption, journal report decryption, IRM in Outlook Web App, and IRM for Exchange Search, you must add the Federated Delivery Mailbox, a system mailbox created by Exchange

	2010 Setup, to the AD RMS super users group on the AD RMS cluster. For detailed information, see Add the Federation Mailbox to the AD RMS Super Users Group.
Exchange Server	• **Exchange Server 2010** • Recommended: This hotfix for the Microsoft .NET Framework 2.0 Service Pack 2 (SP2). For information, see FIX: ArgumentNullException exception error message when a .NET Framework 2.0 SP2-based application tries to process a response with zero-length content to an asynchronous ASP.NET Web service request: "Value cannot be null".

Configuring and Testing IRM

You must use the Shell to configure IRM features in Exchange 2010. To configure individual IRM features, use the Set-IRMConfiguration cmdlet. For more information about how to configure IRM features, see Managing Information Rights Management.

After you've set up an Exchange 2010 server, you can use the Test-IRMConfiguration cmdlet to perform end-to-end tests of your IRM deployment. This cmdlet verifies the IRM configuration for an organization and should be run before enabling Protected Voice Mail. The **Test-IRMConfiguration** cmdlet performs the following tests:

- Inspects the IRM configuration for your Exchange 2010 organization
- Checks the AD RMS server for version and hotfix information
- Verifies whether an Exchange server can be activated for RMS by retrieving a Rights Account Certificate and Client Licensor Certificate (CLC)
- Acquires AD RMS rights policy templates from the AD RMS server
- Verifies that the specified sender can send IRM-protected messages
- Retrieves a super user use license for the specified recipient
- Acquires a pre-license for the specified recipient

Client Support and End User Features

The e-mail client software that's used to listen to a Protected Voice Mail message must support IRM and know how to read a UM-protected voice message. E-mail clients that are supported include Microsoft Outlook 2010, Outlook Web App, and Exchange 2010 Outlook Voice Access. The following table contains a list of e-mail clients and whether or not they're supported.

E-mail client	Description
Microsoft Outlook	• Protected voice messages are supported in Outlook 2010 only.
Outlook Web App	• Outlook Web App in Exchange 2010 supports Protected Voice Mail messages. Earlier versions of Outlook Web App or Microsoft Outlook Web Access don't support them.
Outlook Voice Access	• Outlook Voice Access in Exchange 2010 supports Protected Voice Mail. Outlook Voice Access included with Exchange 2007 doesn't support Protected Voice Mail. • The user's mailbox must reside on an Exchange 2010 Mailbox server.
Windows Mobile	• Windows Mobile doesn't currently support Protected Voice Mail.

Other e-mail clients	• Protected Voice Mail isn't supported.

Return to top

Protected Voice Message Structure

There are actually two messages involved for each Protected Voice Mail message. The first message is the outer message, which isn't encrypted. It contains an attachment named message.rpmsg. The attachment contains the IRM-protected voice message and internal rights management control data. The Rights Management Control data includes a content key, and rights information that specifies who can access the voice message and how those users can access it.

Protected voice messages are shown in the user's Inbox in the **Voice Mail** search folder. The user can listen to the voice messages by using the embedded audio player just as they would listen to a regular voice message, except that the Forward button will be disabled and a note will be shown at the top of the message stating that it's protected and that it can't be forwarded.

For e-mail clients that don't support Protected Voice Mail, the body of the outer message will be displayed. Default text is provided by UM when the protected voice message is being created. Administrators can overwrite this text by using the UM mailbox policy configuration objects.

If the user is using an e-mail client that doesn't support Protected Voice Mail, the following default text will appear on the user's client application e-mail form: "*Your e-mail program doesn't support opening voice messages that are sent with restricted permission. To listen to this message, use Outlook 2010 or Outlook Web App in Exchange 2010. Or, if you're using Exchange 2010 Unified Messaging, you can use Outlook Voice Access*."

You can customize the default text that's included in the e-mail message by configuring a UM mailbox policy. For example, you could configure the UM mailbox policy with customized text such as, *"You can't open this voice mail message because it's protected. To view or listen to this voice message, sign in to your mailbox at https://mail.contoso.com or call +1 (425) 555-1234 to call in to Outlook Voice Access."*

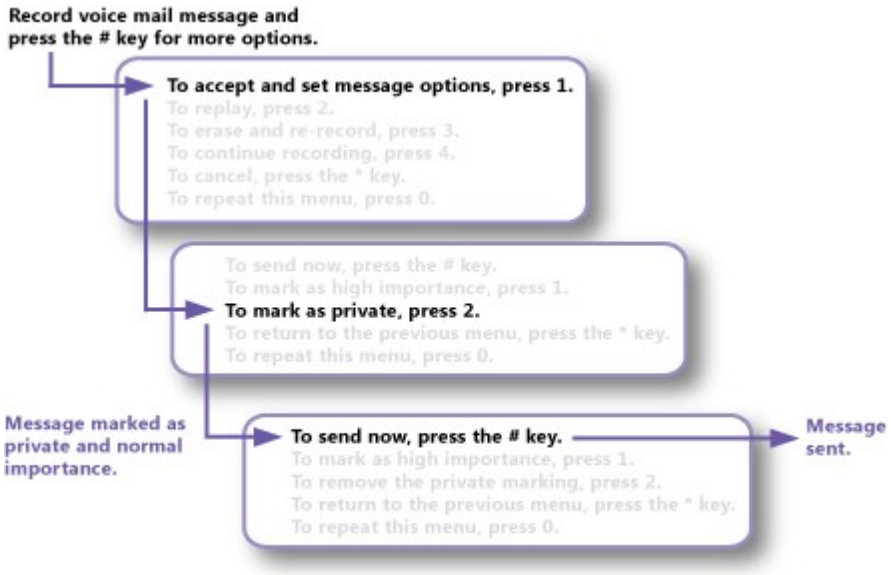
Composing a Protected Voice Mail Message

There are two situations in which protected voice messages can be created:

- **Call Answering** Call answering occurs when a caller calls a UM-enabled user, but the user isn't available to answer the call or forwards it directly to his or her voice mail. In call answering scenarios, the voice mail system will play a series of voice prompts after the caller records their voice mail message. The caller can then choose from additional message options, including the option to mark the voice message as private by pressing the pound (#) key. If the caller pressed the # key, they can follow the instructions provided by UM to mark the message as private, remove the private marking from the private voice message, or mark the voice message with High importance. The following diagram shows the menu options that are available to callers when they leave a private voice message for a user.

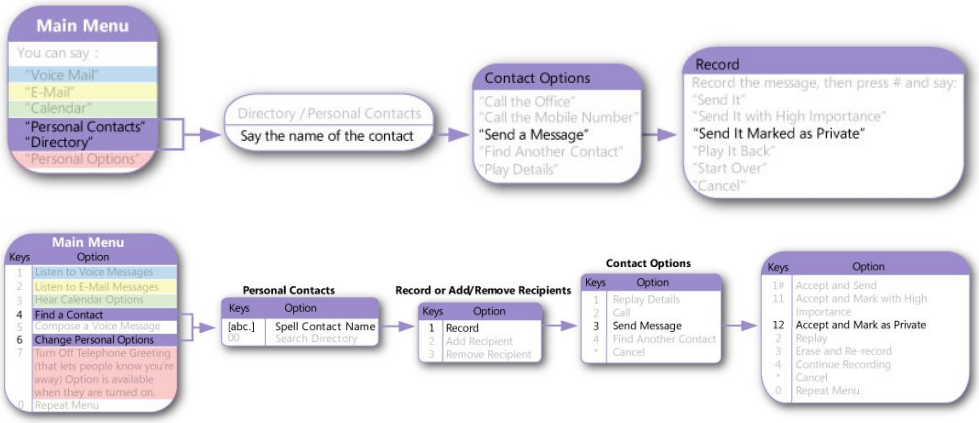
  Note:

  For call answering calls, the Protected Voice Mail settings on the UM mailbox policy of the intended recipient of the message are used by UM, because the caller isn't authenticated.



- **Outlook Voice Access** Outlook Voice Access lets UM-enabled users access their Exchange 2010 mailbox using analog, digital, or cellular telephones by dialing their Outlook Voice Access number. There are two Exchange 2010 Unified Messaging user interfaces available to UM-enabled users: the telephone user interface (TUI) and the voice user interface (VUI). Outlook Voice Access users can search for contacts in the directory and send them voice messages. If Protected Voice Mail has been enabled for the UM-enabled recipients, callers can mark the messages as private after they're recorded. Alternatively, administrators can configure a UM mailbox policy to ensure that all voice messages sent by authenticated users are protected by UM.

Note:
If a caller is authenticated, the Protected Voice Mail settings on the UM mailbox policy that is linked to the caller are applied, regardless the UM mailbox policy settings for the intended recipient of the voice mail message.



Return to top

UM Mailbox Policies

You can create a Unified Messaging mailbox policy to apply a common set of UM policy

settings, such as PIN policy settings, dialing restrictions, and Protected Voice Mail settings to a collection of UM-enabled mailboxes. To learn more about UM mailbox policies, see Managing UM Mailbox Policies.

You can use the EMC or the Exchange **Set-UMMailboxPolicy** cmdlet to configure Protected Voice Mail options. The following table lists the settings that can be configured for Protected Voice Mail.

Protected Voice Mail settings

Shell Parameter	Setting available in EMC?	Description
ProtectAuthenticatedVoiceMail	Yes	The *ProtectAuthenticatedVoiceMail* parameter specifies whether UM-enabled users can send protected voice messages when they're accessing their mailbox using Outlook Voice Access. The default setting is `None`. This means that no protection is applied when voice mail messages are composed and that callers won't have the option to mark voice messages as Private. If the value is set to `Private`, only messages marked as Private by the caller are protected. If the value is set to `All`, every voice message is protected, regardless of the option chosen by the caller.
ProtectUnauthenticatedVoiceMail	Yes	The *ProtectUnauthenticatedVoiceMail* parameter specifies whether the Unified Messaging servers that answer calls for UM-enabled users associated with a UM mailbox policy create protected voice messages. This setting also applies when a message is sent from a UM auto attendant to a UM-enabled user. The default setting is `None`. This means that no protection is applied to voice messages and that the caller won't be offered the option to mark the message as Private. If the value is set to `Private`, only messages marked as Private by the caller are protected. If the value is set to `All`, every voice message is protected, regardless of whether if the message has been marked

		as private by the caller.
ProtectedVoiceMailText	Yes	The *ProtectedVoiceMailText* parameter specifies the text to be included in the body of the outer message of a Protected Voice Mail message. This text will be shown in all e-mail client applications that don't support Protected Voice Mail messages. Note that a default message is always provided by UM when this property is set to `Null` or is empty.
RequireProtectedPlayOnPhone	Yes	The *RequireProtectedPlayOnPhone* parameter specifies whether users associated with the UM mailbox policy will be forced to listen to the protected voice message over the phone (using Play On Phone). The default value is `$false`. When the value is set to `$true`, the audio media player on Protected Voice Mail forms in Outlook or Outlook Web App will be shown as disabled. Note that the preview text for the voice message can always be accessed. The user can't play the audio file using any media player software or use the embedded media player to listen to the voice message.
AllowVoiceResponseToOtherMessageTypes	Yes	The *AllowVoiceResponseToOtherMessageTypes* parameter specifies whether callers who have authenticated to Outlook Voice Access to access their e-mail will be able to compose a voice reply to e-mails and meeting requests.

For more information about how to manage Protected Voice Mail settings, see the following topics:

- Configure Protected Voice Mail from Authenticated Callers on a UM Mailbox Policy
- Configure Protected Voice Mail from Unauthenticated Callers on a UM Mailbox Policy
- Enable or Disable Multimedia Playback of Protected Voice Messages on a UM

Mailbox Policy
- Specify the Text to Display for E-Mail Clients that Don't Support Windows Rights Management on a UM Mailbox Policy
- Set-UMMailboxPolicy

Return to top

SMS Notifications and Protected Voice Mail

Users who configure their UM account to send SMS (also called text message) notifications to their mobile phone when voice messages are received will also receive audio transcription (Voice Mail Preview) text as part of the body of the text message. However, for protected voice messages, this represents a security issue because the content of the voice messages should always be protected.

When UM creates a text message notification for a voice message that's protected, it checks whether the voice message is marked as Private. If so, it won't add the transcribed audio text to the text message that it sends to the mobile phone. The following text will be included in the text message instead: "Use Outlook Voice Access to access this protected voice mail message."

1.9.1.3.20 Understanding Message Waiting Indicator

Understanding Message Waiting Indicator

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-24*

Message Waiting Indicator (MWI) is a feature that's found in most legacy voice mail systems. In its most common form, this feature lights up a lamp on a user's phone to indicate the presence of a new or unheard voice mail message. In general, this is the way that legacy voice mail systems let voice mail subscribers know that they have new or unheard voice mail messages. However, in the context of Microsoft Exchange Unified Messaging (UM), MWI refers to a feature that's available in traditional IP gateway, PBX, and Microsoft Exchange Server 2010 Unified Messaging and Microsoft Lync Server 2010 deployments.

In a traditional telephony environment, MWI allows for a lamp or some other mechanism to notify the UM-enabled user that they have a new voice mail message. In environments where Microsoft Office Communications Server 2007 R2 or Lync Server 2010 and VoIP phones are used, the mechanism for letting a user know that a new voice message was received is different than in a traditional telephony environment. Enterprise Voice UM-enabled users see different lights than users in a traditional telephony environment, or other types of notifications.

Contents

MWI Resilience

MWI Administration

Overview

In general, Message Waiting Indicator (MWI) can refer to any mechanism that indicates the existence of a new or unheard voice message. The message can be new or marked as an unread e-mail message, or it can be new or marked as an unheard voice message. The message-waiting indicator mechanism could be:

- A new voice mail message as seen from Outlook or Microsoft Office Outlook Web App.
- A text or SMS message sent to a registered mobile phone.
- An outbound call made from Exchange UM to a preconfigured number.
- A light or phone lamp on a phone.
- A special dial tone.
- Icons or buttons on the display screen of a phone.
- A highlighted notification within a software application.

In Microsoft Exchange Server 2007 and Exchange 2010, a UM-enabled user's voice mail is stored in an Exchange mailbox. It can be accessed from a telephone using Outlook Voice Access, from a desktop or portable computer using Outlook and Outlook Web App, and mobile phone clients. When a UM-enabled user receives a new voice message, the message appears in their Voice Mail search folder. If the voice message is accessed using Outlook or Outlook Web App, an e-mail message will be included with the voice message. UM-enabled users who access their Inbox via Outlook and Outlook Web App already have a very efficient mechanism to let them know that they have a new voice message. However, not all UM-enabled users access their voice mail and e-mail messages using Outlook and Outlook Web App.

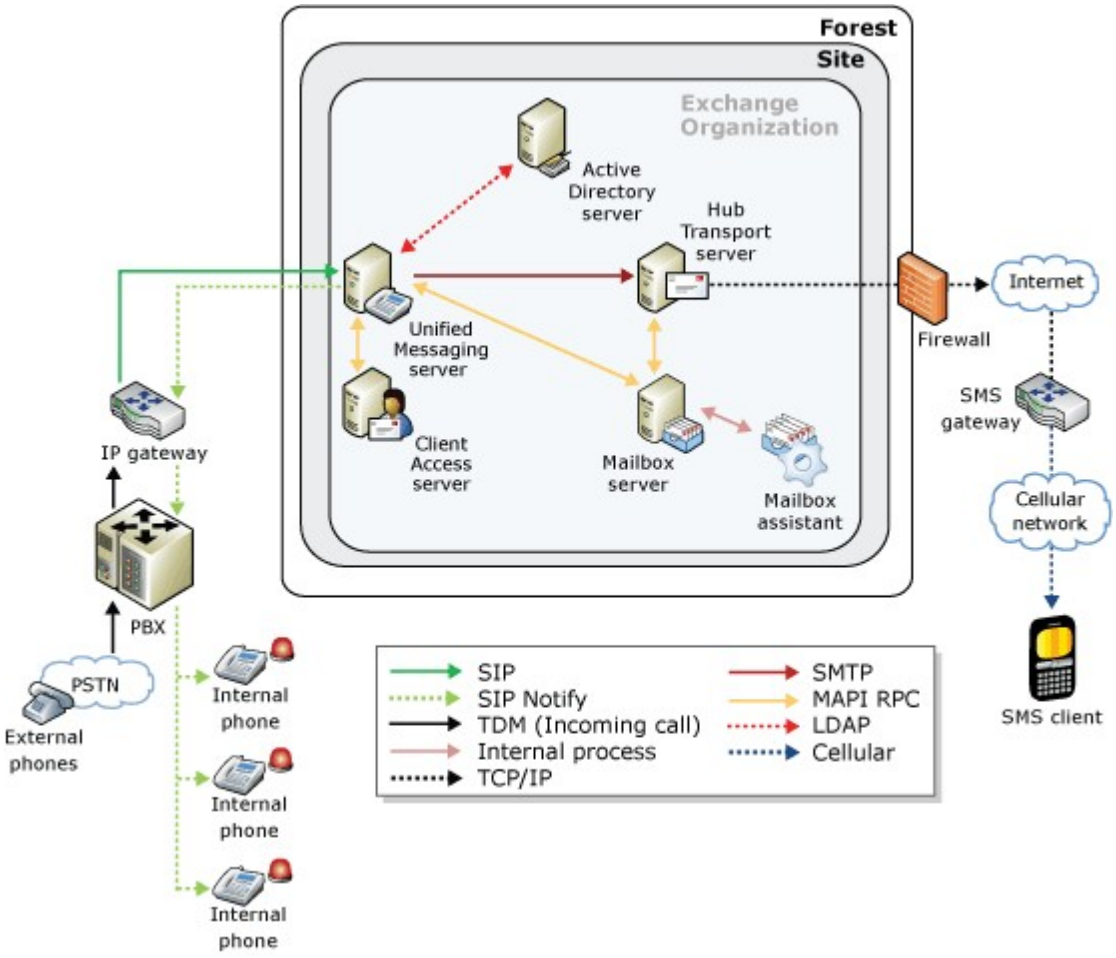
In Exchange 2007, MWI was supported in a traditional or an IP PBX environment by using a third-party solution or application. Exchange 2010 includes built-in support for MWI. Office Communications Server 2007 R2 and Lync Server 2010 also support MWI. However, the actual MWI mechanism depends on the type of IP-based phone that's used by the Enterprise Voice and UM-enabled user. The following examples show message-waiting indicators from IP-based phones used with Communications Server 2007 R2 or Lync Server 2010:

In Exchange 2010, MWI doesn't require that any additional server roles or services be installed. By default, MWI is turned on. It's controlled through settings on a UM mailbox policy or on the UM-enabled user's mailbox. MWI also works with protected voice messages and is a feature found only in Exchange 2010.

To implement MWI in Exchange 2010 in a traditional telephony environment, a UM server

sends an MWI SIP NOTIFY message to a SIP peer or an IP gateway that's represented by a UM IP gateway in Active Directory. The SIP peer or IP gateway sends the notification to the PBX. The PBX, in turn, lights up the lamp on the desktop phone to notify the user of a new or unheard voice message.

There are two voice-mail scenarios: call answering and Outlook Voice Access. With call answering, the UM server answers an incoming call and allows the caller to leave a voice message for a UM-enabled user. With Outlook Voice Access, when a caller calls a subscriber access number, they can leave a voice message for a UM-enabled user. The following figure shows an overview of how MWI in Exchange 2010 Unified Messaging works in a call-answering scenario.



Note:
The Mailbox Assistant only looks for Voice Mail search folder events.

Return to top

The UM Server's Role in Message Waiting Indicator

After a caller calls a UM-enabled user and the user doesn't answer their phone, the UM server sends a SIP NOTIFY message to an IP gateway or a SIP peer. The UM server receives MWI state change information over RPC from the Mailbox server and sends the request for a change of notification to an IP gateway or IP PBX using a SIP NOTIFY message. The RPC request to the Mailbox server will include the following information:

- Message waiting indicator enabled (Yes or No).
- Number of new/marked unheard voice messages.

- Number of old/marked heard voice messages.
- Number of new/marked unheard urgent voice messages.
- Number of old/marked heard urgent voice messages.
- The primary extension number on the primary UM dial plan.
- The IP address or fully qualified domain name (FQDN) of the SIP peer or IP gateway to be used for SIP NOTIFY messages.
- The security type of the UM dial plan (Unsecured, SIP secured, or Secured). This information will be used by the UM server to determine whether the connection to the IP gateway must be SIP over TCP or SIP over TLS. TLS is supported for MWI SIP Notify.

The UM server uses the diversion information on the header of the incoming call to determine the extension number or phone number of the UM-enabled user. When the extension or phone number is determined, the UM server sends the request to the SIP peer, and the SIP peer sends the message on to the PBX. The PBX then changes the state of the MWI and lights the phone's lamp.

Note:

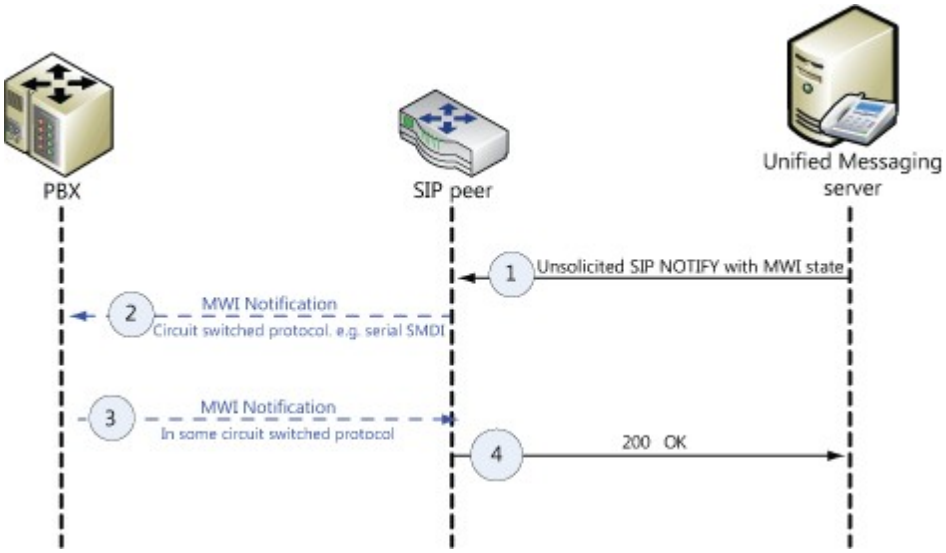
Although PBX outages should be rare, Exchange UM will automatically refresh the MWI status for every mailbox at least once every 12 hours. There is no way to force a refresh, but if the PBX is powered off and all the MWI lamps go off, it should be a maximum of 6 hours until all lamps are restored to the correct state.

Return to top

MWI SIP NOTIFY Messages

MWI notifications use SIP NOTIFY messages to communicate with SIP peers or IP gateways. These messages are sent to the SIP peer with MWI state change information. MWI state change information is included in the SIP NOTIFY message and indicates whether or not MWI notifications will be sent to users. Whenever there's a change in MWI state, the Mailbox Assistant sends this information to a UM server over RPC. After the UM server receives this information, it parses the message to obtain the target SIP peer or IP gateway and the MWI state change information. It will then form a SIP NOTIFY message with the MWI state change information in the message body and send this information on to the SIP peer or IP gateway.

MWI in Exchange 2010 is based on RFC 3842. RFC 3842 states that SIP event notifications must be used for message-waiting notifications. MWI is based on the SIP model, and is driven by the endpoints found in a unified messaging system. SIP endpoints, either IP gateways or IP PBXs, which obtain MWI information must send a SIP SUBSCRIBE message to the Unified Messaging system. The SIP SUBSCRIBE message will be replied to with a NOTIFY message that accepts the subscription. All MWI state change information will be conveyed from the unified message system to a SIP endpoint using NOTIFY messages that are embedded within the subscription that was previously created. The exact syntax of the SIP NOTIFY message to be sent to the SIP peer is based on the format described in RFC 3842. The call flow is shown in the following figure.



The UM server sends an MWI NOTIFY message to the SIP peer. The event header is set to "message-summary", which indicates that this is an MWI-related NOTIFY message. The To header field indicates the SIP endpoint for which the MWI service must be provided. The Subscription-State header must be set to "terminated" instead of "active".

- The SIP peer or IP gateway conveys this information to the PBX using a circuit-switched protocol such as SMDI.
- The PBX sends a success message over a circuit-switched protocol.
- The SIP peer or IP gateway can respond with any of the following messages: 200 OK (Success) or 480 (Temporarily Unavailable). A UM server can handle both these responses and additional failure responses.

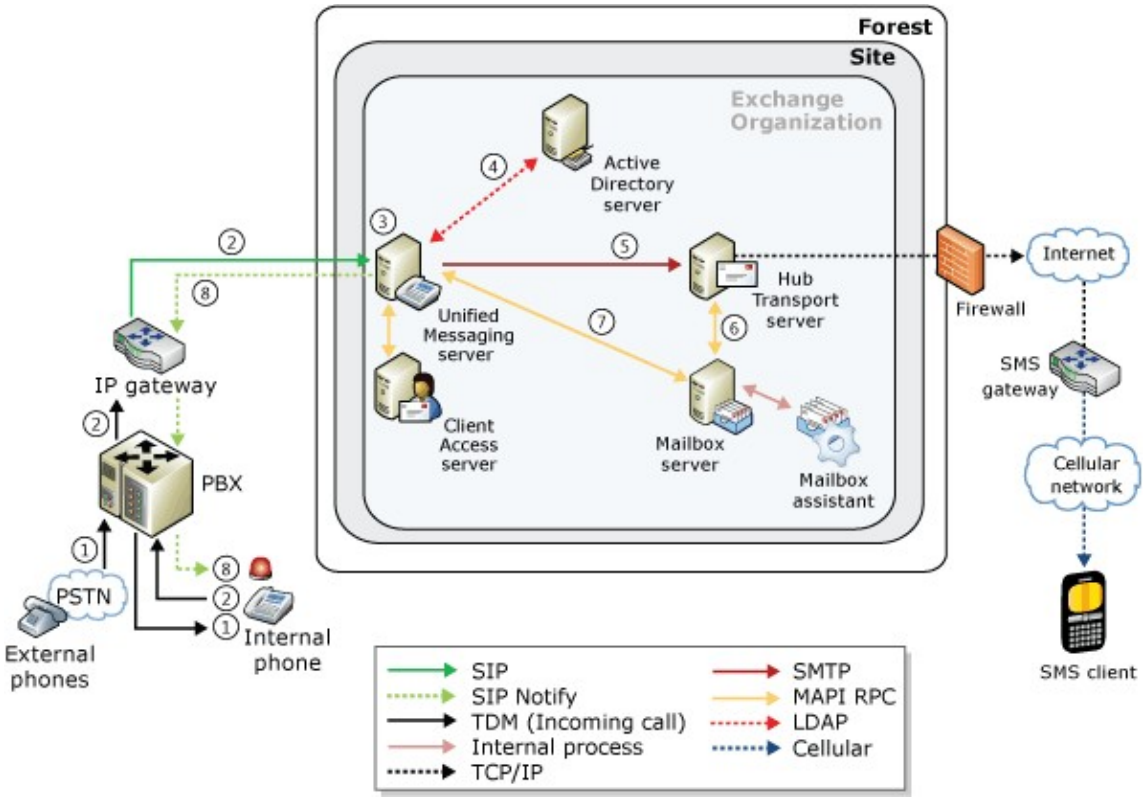
MWI in a Traditional Telephony Environment

In a traditional telephony environment, an incoming call is received by the PBX and then sent on to the IP gateway. The UM server and the Mailbox Assistant are used to determine the MWI state for the UM-enabled user. They're responsible for delivering the SIP notification back to the IP gateway and PBX. In a traditional telephony environment, the call flow and MWI notification are as follows:

1. The incoming call is received by the PBX, and then sent from the PBX to the phone of the UM-enabled user. The user doesn't answer and the caller is prompted to leave a voice message.
2. The call is first sent from the PBX to the IP gateway.
3. The IP gateway then submits the call to a UM server.
4. The UM server performs an LDAP query to locate the UM-enabled user's information, such as the extension number and the greetings for the user. The greeting or greetings for the UM-enabled user are played.
5. The voice message that was created by the UM server is submitted to a Hub Transport server within the same site.
6. The Hub Transport server submits the voice message to a Mailbox server. The Mailbox Assistant receives a MAPI event for a new voice message.
7. The Mailbox Assistant reads the UM dial plan and the UM mailbox policy to determine whether MWI notifications should be sent to the UM-enabled user. The Mailbox Assistant queries for all UM servers that are associated with the UM dial plan of the UM-enabled user. The Mailbox Assistant tries to send the RPC event to the first UM server that's returned. If this fails, it tries the next one. It will keep retrying for 5 minutes, or until all servers have been tried. If all the RPC calls fail, the Mailbox Assistant logs the error in Event Viewer. The UM server queries for all UM IP gateways that are associated with the UM dial plan of the UM-enabled user's mailbox.
8. UM sends a SIP NOTIFY message to the first IP gateway that's returned from

the query. If this fails, the UM server will choose the next IP gateway. The UM server will keep trying for an IP gateway for 5 minutes. If all attempts to find an IP gateway fail, the UM server will log an error. If an IP gateway is located successfully, the IP gateway will send the notification to the PBX, and the PBX in turn will send a notification of the MWI event to the user's phone to light the phone lamp.

The following figure shows the call flow in a traditional telephony environment.



Return to top

MWI in a Lync Server 2010 Environment

In telephony environments that include Lync Server 2010, an incoming call can be sent from an external phone to the mediation server, sent from a Lync 2010 client, or from a Unified Communications (UC)-based phone. After the call is received, it's sent on to the Lync Server 2010 front-end server pool. The UM server and the Mailbox Assistant are used to determine the MWI state for the UM-enabled user and to deliver this notification to the client or UC-based phone.

Note:

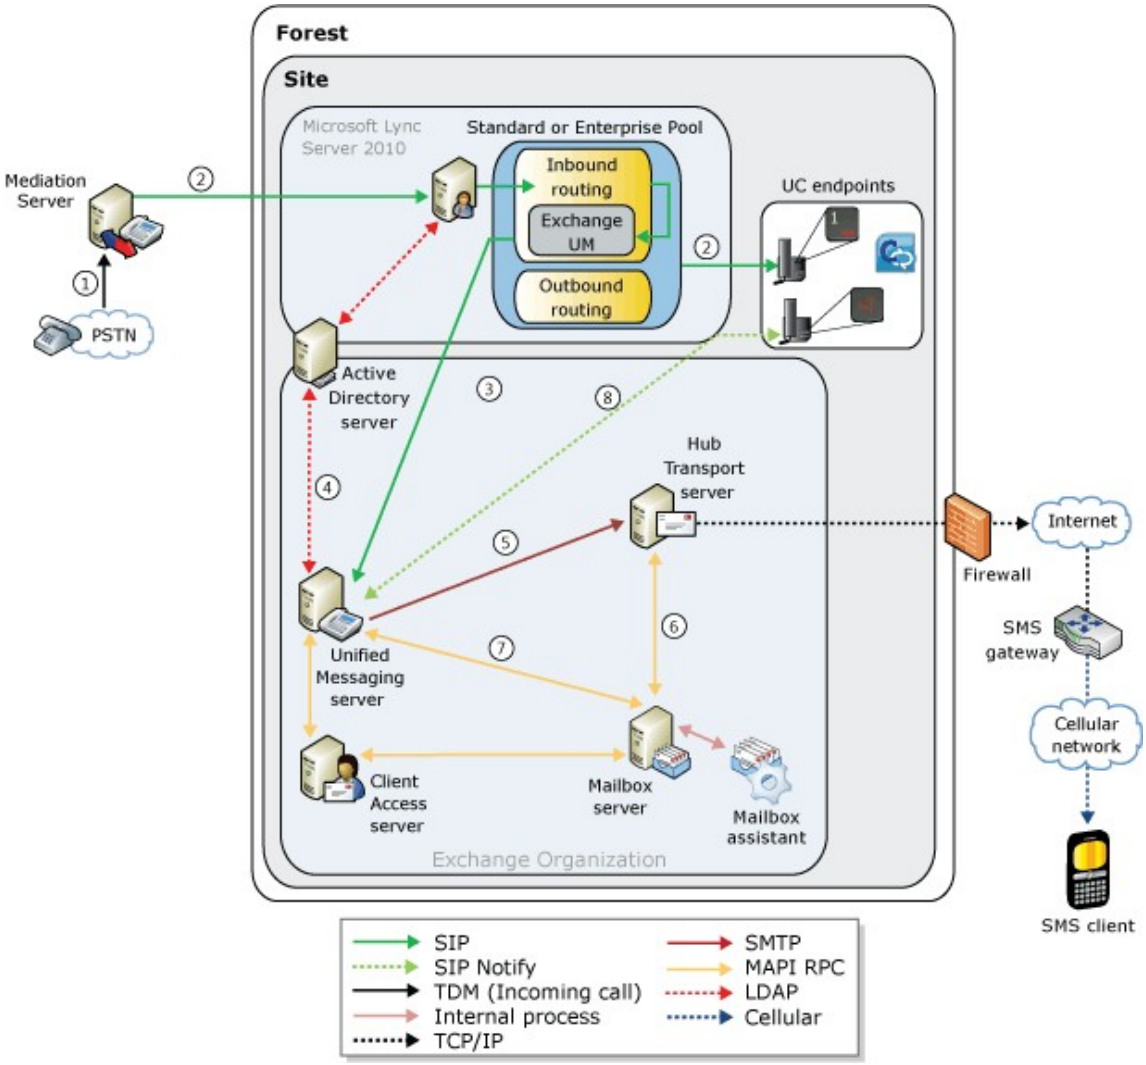
Message waiting notification is only supported in Lync Server 2010 deployments. It is also available in cross-premises deployments that include Lync Server 2010. Office Communications Server 2007 R2 doesn't support MWI and isn't supported in cross-premises deployments.

In a telephony environment with Lync Server 2010, the call flow and MWI notification is as follows:

1. The call is sent from one of the following:
   1.a. An external phone to a mediation server
   1.b. A Lync 2010 client
   1.c. A UC-based phone.

2. The incoming call is received by the Lync Server 2010 front-end server pool and sent on to the phone of the UM-enabled user. The user doesn't answer and the caller is prompted to leave a voice message.
3. The Lync Server 2010 front-end server pool then submits the call to a UM server.
4. The UM server performs an LDAP query to locate information for the UM-enabled user, such as their extension number and greetings. The greetings are played, and the caller is prompted to leave a voice message.
5. The voice message that was created by the UM server is submitted to a Hub Transport server within the same site.
6. The Hub Transport server submits the voice message to a Mailbox server. The Mailbox Assistant receives a MAPI event for a new voice message.
7. The Mailbox Assistant reads the UM dial plan and the UM mailbox policy to decide whether MWI notifications should be sent to the user. The Mailbox Assistant queries for all UM servers that are associated with UM dial plan of the user. The Mailbox Assistant tries to send the RPC event to the first UM server that's returned. If this attempt fails, the Mailbox Assistant tries the next one. It will keep trying to find a UM server for 5 minutes or until all servers have been tried. If all the RPC calls fail, the Mailbox Assistant will log an error in the Event Viewer. The UM server queries for all UM IP gateways associated with the UM dial plan of the UM-enabled user's mailbox.
8. UM sends a SIP NOTIFY message to the first IP gateway that's returned from the query. If this fails, the UM server will choose the next IP gateway. The UM server will keep trying to find an IP gateway for 5 minutes. If all attempts to contact an IP gateways fail, the UM server will log an error. If it's successful, the IP gateway will send the notification to the Lync Server 2010 front-end server pool, which in turn will send a notification of the MWI event to the user's phone or Lync 2010 client.

The following figure shows the call flow in a traditional telephony environment.



Return to top

MWI Resilience

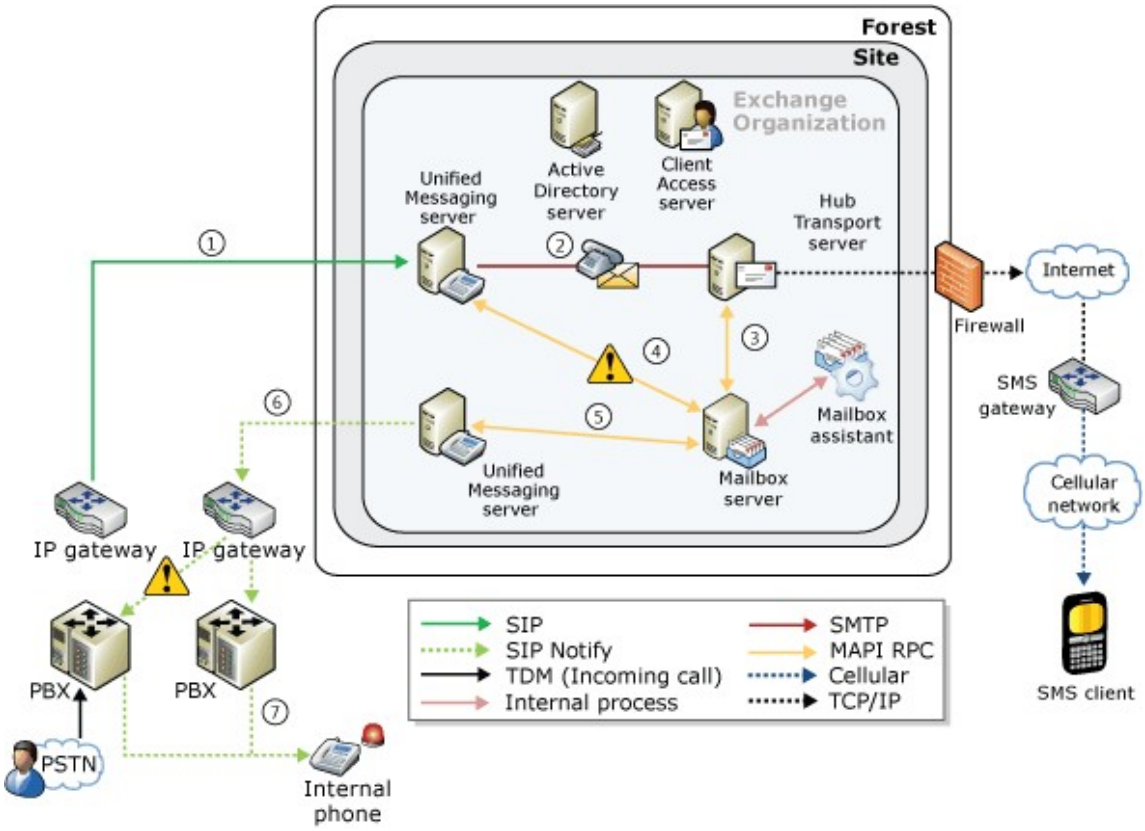
When you're deploying UM servers, UM dial plans, and UM IP gateways, and are using MWI for UM-enabled users, it's best to deploy multiple UM servers and multiple IP gateways to create fault tolerance and resiliency. Doing this also creates MWI resilience. When you deploy multiple UM servers and UM IP gateways, if a UM server or IP gateway isn't available and the Mailbox server can't connect, the next UM server will be used. If the UM server can't connect to the IP gateway, the next IP gateway will be used. In both cases, a round robin mechanism is used.

To enable fault tolerance for MWI in Unified Messaging, you must create and configure one or more of the following:

- A UM dial plan that's associated with the UM-enabled user who will receive MWI notifications.
- A UM mailbox policy that's associated with the UM-enabled user who will receive MWI notifications.
- A UM IP gateway that's associated with the UM dial plan that's associated with the UM-enabled user who will receive MWI notifications.

- A UM server that's added to the UM dial plan that's associated with the UM-enabled user who will receive MWI notifications.

The following figure shows that MWI can use multiple paths to send SIP NOTIFY messages.



MWI Administration

MWI can be administered by configuring settings on two Active Directory objects: UM mailbox policies and UM IP gateways. For both Active Directory objects, you can enable or disable MWI by using the **Set-UMMailboxPolicy** cmdlet or the **Set-UMIPgateway** cmdlet, or by configuring the settings using the Exchange Management Console (EMC). You can view the status of the MWI notification by using the **Get-UMMailboxPolicy** cmdlet and the **Get-UMIPgateway** cmdlet, or by viewing the settings in the EMC.

UM Mailbox Policies and MWI

You can create a Unified Messaging mailbox policy to apply a common set of UM policy settings to a collection of UM-enabled mailboxes. For example, you can use a UM mailbox policy to apply PIN policy settings, dialing restrictions, and MWI settings. If you enable MWI, it will be enabled for all users who are associated with the UM mailbox policy. If you disable MWI on a UM mailbox policy, MWI will be disabled for all UM-enabled users who are associated with the UM mailbox policy. Thus, disabling MWI can disable MWI for all UM-enabled users associated with a single or multiple UM dial plans or a single or multiple UM mailbox policies. If you enable or disable MWI on a UM mailbox, you can affect large groups of UM-enabled users in your Exchange organization. The MWI setting will apply to a subset of the users who are associated with a UM dial plan. To learn more about UM mailbox policies, including how to enable or disable MWI for a group of UM-enabled users, see Managing UM Mailbox Policies.

You can use the EMC and the **Set-UMMailboxPolicy** cmdlet to configure the MWI setting.

The following table lists the setting that can be configured for MWI.

Message Waiting Indicator setting on a UM mailbox policy

Shell parameter	Setting available in the EMC?	Description
AllowMessageWaitingIndicator	Yes	The *AllowMessageWaitingIndicator* parameter specifies whether users who are associated with a UM mailbox policy can receive notifications when they receive a new voice message. The default value is `$true`. Enabling this setting will allow voice mail notifications to be sent to users who are associated with a single UM mailbox policy for calls taken by a UM IP gateway. This setting allows the UM IP gateway to receive and send SIP NOTIFY messages to UM-enabled users' phones. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 server.

For more information about how to manage MWI settings, see the following topics:

- Managing UM Mailbox Policies
- View or Configure the Properties of a UM Mailbox Policy
- Enable or Disable Message Waiting Indicator on a UM Mailbox Policy
- Set-UMMailboxPolicy

UM IP Gateways and MWI

If you disable MWI on a UM IP gateway, you'll disable MWI for all users who connect to the IP gateway that's represented by the UM IP gateway. Therefore, disabling MWI can disable MWI for all UM-enabled users associated with a single or multiple UM dial plans or a single or multiple UM mailbox policies. If you enable or disable MWI on a UM IP gateway, you can affect large groups of users in your Exchange organization. To learn more about UM mailbox policies, including how to enable or disable MWI for a group of UM-enabled users, see Managing UM Mailbox Policies.

You can use the EMC and the **Set-UMMailboxPolicy** cmdlet to configure the MWI setting. The following table lists the setting that can be configured for MWI.

Message Waiting Indicator setting on a UM IP gateway

Shell parameter	Setting available in the EMC?	Description
MessageWaitingIndicatorAllowed	Yes	The *MessageWaitingIndicatorAllowed* parameter specifies whether to enable the UM IP gateway to allow SIP NOTIFY

		messages to be sent to users associated with a UM dial plan. The default value is `$true`. When this setting is enabled, voice mail notifications can be sent to users for calls that are received by the UM IP gateway. This setting allows the UM IP gateway to send message-waiting notifications to UM-enabled users. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 server.

For more information about how to manage MWI settings, see the following topics:

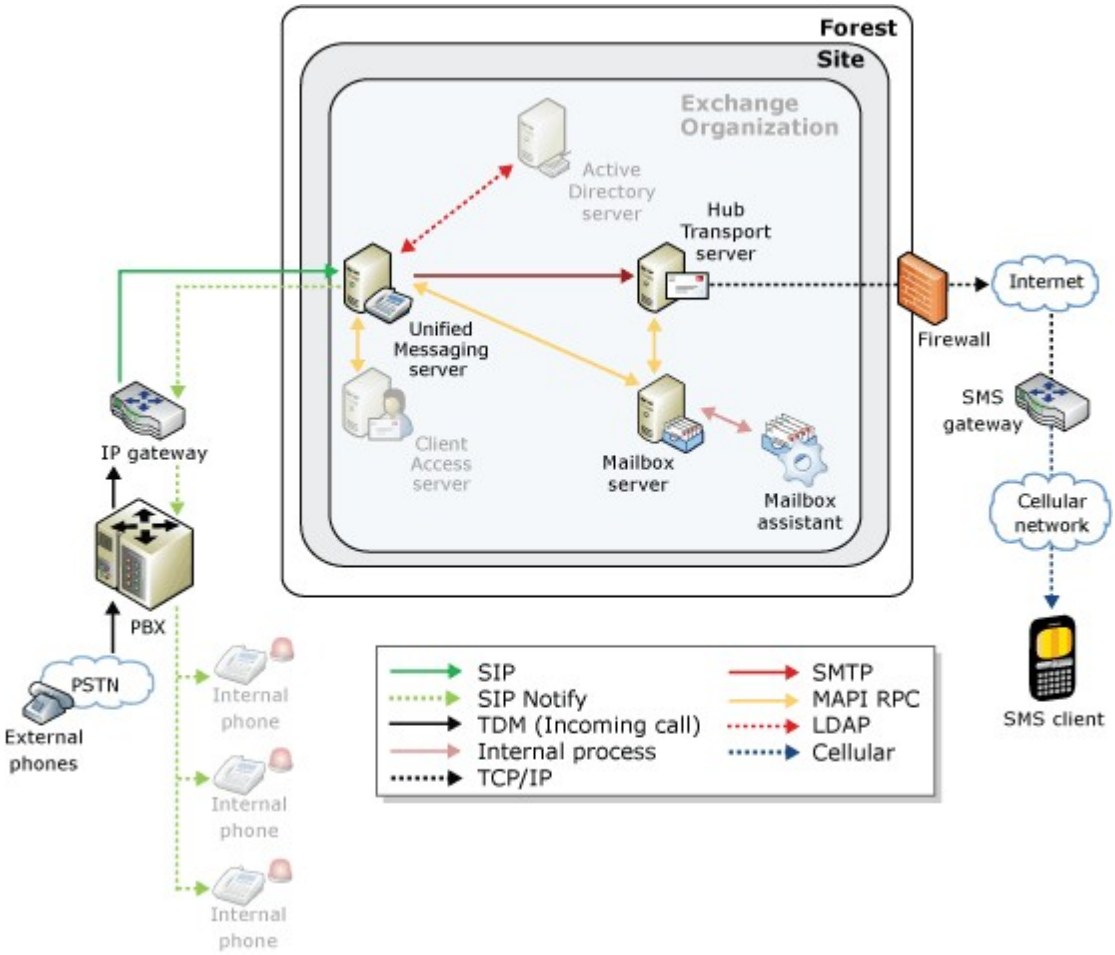
- Managing UM IP Gateways
- View or Configure the Properties of a UM IP Gateway
- Allow or Prevent Message Waiting Indicator on a UM IP Gateway
- Set-UMIPGateway

Return to top

SMS MWI Notifications

Message Waiting Indicator can refer to any mechanism that indicates the existence of a new voice mail message. It can take the form of a Short Messaging Service (SMS) message, also known as a text message. The text message can be sent to the user's registered mobile phone along with other MWI notifications such as a light on their phone, a light on their phone keypad, or a light on a UC-based phone display.

The following figure shows an overview of how SMS MWI notifications work in an in Exchange 2010 Unified Messaging call answering scenario.



Note:

The SMS or text message that's sent to a UM-enabled user includes voice mail preview.

SMS MWI notifications can be administered by configuring settings on two Active Directory objects: UM mailbox policies and UM mailboxes. For both Active Directory objects, you can enable or disable SMS MWI by using the **Set-UMMailboxPolicy** cmdlet and the **Set-UMMailbox** cmdlet. You can view the status of SMS MWI notifications by using the **Get-UMMailboxPolicy** cmdlet and the **Get-UMMailbox** cmdlet.

You can only use the **Set-UMMailbox** cmdlet to configure the SMS MWI setting. This setting can't be configured by using the EMC. The following table lists the setting that can be configured for MWI.

SMS and Message Waiting Indicator setting on a UM mailbox

Shell parameter	Setting available in the EMC?	Description
UMSMSNotificationOption	No	The *UMSMSNotificationOption* parameter specifies whether a UM-enabled user can receive text messaging notifications for voice mail only, for voice mail and missed calls, or isn't allowed to receive notifications. The values for this parameter

		are: `VoiceMail`, `VoiceMailAndMissedCalls`, and `None`. The default value is `None`. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 server.

For more information about how to manage SMS MWI settings, see the following topics:

- Managing Unified Messaging Users
- View or Configure the Properties of a UM-Enabled User
- Set-UMMailbox

You can only use the **Set-UMMailboxPolicy** cmdlet to configure the MWI setting. This setting isn't available using EMC. The following table lists the setting that can be configured for MWI.

SMS and Message Waiting Indicator setting on a UM mailbox policy

Shell parameter	Setting available in the EMC?	Description
AllowSMSNotification	No	The *AllowSMSNotification* parameter specifies whether UM-enabled users whose mailboxes are associated with the UM mailbox policy are allowed to receive SMS or text messages sent to their mobile phones. If this parameter is set to $true, you must also use the **Set-UMMailbox** cmdlet and set the *UMSMSNotificationOption* parameter for the UM-enabled user to either `voicemail` or `VoiceMailAndMissedCalls`. The default value is $true. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 server.

For more information about how to manage MWI settings, see the following topics:

- Managing UM Mailbox Policies
- View or Configure the Properties of a UM Mailbox Policy
- Set-UMMailboxPolicy

Return to top

Understanding Secondary Dial Plans

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-08*

When you enable a user for Unified Messaging (UM) in Microsoft Exchange Server 2007 or the RTM version of Exchange Server 2010, you're required to assign at least a single extension number and associate a single UM dial plan to that UM-enabled user. You can assign additional extension numbers for that user within the same dial plan but you can't add a secondary dial plan with a single or multiple extension numbers. In Exchange 2010 Service Pack 1 (SP1), in addition to being required to assign the user a single primary UM dial plan with a single or multiple extension numbers, you can add a secondary UM dial plan with single or multiple extension numbers. This can be very useful, for example, if the user has two physical phones or travels between locations.

Contents

Overview

When you enable a user for Unified Messaging in the RTM version of Exchange 2010, you must define at least one extension number and one UM dial plan for Unified Messaging to use to locate the user when a voice mail message is submitted to the user's Exchange 2010 mailbox. After you've enabled the user for Unified Messaging, you can add additional extension numbers or EUM proxy addresses to the user's mailbox, but you can't associate the UM-enabled user with a secondary dial plan. In Exchange 2010 SP1, after you enable the user for Unified Messaging, add the required extension number, and associate the user with a single dial plan, you can add a secondary UM dial plan with a single or multiple extension numbers.

Note:

There's no limit to the number of secondary extension numbers that you can add for a UM-enabled user.

There may be times when a user travels between locations, has two or more phones, or wants to receive voice mail on one Direct Inward Dial (DID) extension number and to receive faxes on a different DID extension number. To achieve this, you must add an additional DID extension to the user's mailbox and, in some cases, add a secondary dial plan.

In some configurations, after you add a second extension on a primary dial plan or add a single or multiple extension numbers to a secondary dial plan, the user can receive voice messages or faxes using one or more of the extension numbers. If you want a Unified Messaging server to answer these fax calls and send them to the second DID extension number, you must configure the telephony equipment in your organization to forward the fax call to the second DID extension number.

The mailbox of a UM-enabled user can be assigned the following:

- A single extension number, Session Initiation Protocol (SIP) address, or E.164 address on a single dial plan.
- Multiple extension numbers on a single dial plan.
- Multiple extension numbers on two separate dial plans.

When an Exchange 2010 user's mailbox is enabled for Unified Messaging, the administrator must specify an extension number and a UM mailbox policy. The extension number is required by a UM server to identify the user when they log on to Outlook Voice Access to retrieve messages. The UM mailbox policy contains a collection of configuration properties, with values that UM applies to any user who is UM-enabled under that policy. The UM mailbox policy is similar to the "class of service" found in other systems (for example, voice mail or PBX), in the sense that a change to a UM mailbox policy value can affect the behavior for a large number of associated users.

One property on a UM mailbox policy refers to a UM dial plan. This is a configuration object that represents a set of telephony-capable extensions. This set has a numbering plan in which duplicate extension numbers aren't allowed.

Therefore, a user's extension number is unique within the UM dial plan in which they're UM enabled. In fact, the UM dial plan and extension number pair must be unique within the Exchange organization. This is one way that UM uniquely identifies a UM-enabled user in an Exchange organization. Using a secondary dial plan makes it easier to keep the dial plan and extension number unique within an organization. For example, imagine an organization has two UM dial plans: Dial Plan A and Dial Plan B. A user's extension number in Dial Plan A is 55555 and, in Dial Plan B, it's 66666. When a secondary dial plan is used, the user's extension for Dial Plan A can be 55555 and their extension in Dial Plan B can also be 55555. In both cases, the user's extension within the dial plan that's used is unique.

The following table defines terms that are used when discussing primary and secondary extensions, pilot numbers, and UM dial plans.

Term	Definition
primary extension	The extension number that's specified when the user is UM enabled.
primary dial plan	The UM dial plan that's specified when the user is UM enabled. The UM-enabled user is associated with the dial plan when the user is linked to the UM mailbox policy.
primary pilot number	The pilot number for the user's primary dial plan. The user's calls are forwarded to this number if there's no answer or their line is busy. It's also the number that the user calls when they want to log on to Outlook Voice Access.
secondary extension	One or more extension numbers that may be added to a UM-enabled user's configuration.
secondary dial plan	A UM dial plan other than the primary dial plan in which one or more secondary extensions can be configured.
secondary pilot number	The pilot number of a user's secondary dial plan. A user can call this number from their

	secondary extension number when they want to log on to Outlook Voice Access.

Return to top

Use of Secondary Extensions

In most deployments, only one extension is configured per UM-enabled user. However, there are some more advanced deployments that require you to add secondary extensions for your users.

When Microsoft Lync Server 2010 and Microsoft Office Communications Server R2 are used for Enterprise Voice, Exchange Unified Messaging can provide the voice mail system. However, the UM dial plan used for Enterprise Voice must be a SIP URI dial plan that's specific to UM configurations with Lync Server 2010 and Office Communications Server R2. In these deployments, the user's extension is provided by a Microsoft Unified Communications endpoint, such as Microsoft Office Communicator, running on the user's computer, or Office Communicator Phone Edition, running on a supported IP phone device. Thus, in most cases, the user's primary dial plan must be the same SIP URI dial plan used with Lync Server and Office Communications Server. But if the user requires more extension numbers, you shouldn't add another secondary extension to the primary dial plan. You must add a secondary dial plan and then add the secondary extension or EUM proxy address to the UM-enabled user.

Call Answering

Exchange Unified Messaging provides both of the following:

- **Call answering** Occurs when a user doesn't answer their phone and UM takes the call**.**
- **Outlook Voice Access** Used by users when they dial in to the Unified Messaging system to access to their mailbox.

Two configurations are used frequently:

- A UM-enabled user has two extension numbers (one primary, one secondary) in the primary dial plan. These extensions correspond to different phones on the user's desk and are connected to the same PBX. These different numbers are available to two separate audiences. In this configuration, the primary extension is the "general" work number and the secondary extension is the "task-specific" number, possibly a helpdesk line, or a dedicated fax number.
- A UM-enabled user spends a certain length of time, perhaps 3 weeks out of 4, in their company's main office and the rest of the time in another office at one of the company's remote locations. The two offices have different PBXs, and the extension numbers are unique to each PBX. In this example, the user is configured to have a primary extension in their primary dial plan on the main office PBX and a secondary extension in a secondary dial plan on the PBX of the other office.

In either configuration, voice messages or missed call notification messages that are generated by unanswered calls to either extension will be sent to the user's Inbox.

Outlook Voice Access

You may want UM-enabled users to be able to log on to Outlook Voice Access from any extension, primary or secondary. While this is possible, there may be some architectural restrictions that keep this from working identically from all extensions. To log on to Outlook Voice Access in the RTM version of Exchange 2010 or Exchange 2010 SP1, UM-enabled users must perform the following steps:

1. Call a UM pilot number (subscriber access number).
2. Key in their extension number if they're calling from another phone number.
3. Key in their PIN if they aren't enabled for Enterprise Voice and are calling from

a Unified Communications phone, Office Communicator or Lync Server.

Usage Scenarios

- **Single extension with Outlook Voice Access** If the user has a single primary extension, they must always call the pilot number for their primary UM dial plan. If they call from their extension number, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped.
- **Two extensions in the primary dial plan with Outlook Voice Access** If the user has only two extensions, primary and secondary, and both the primary and secondary extension are in the same UM dial plan, they must always call the pilot number of the dial plan. If they call from either the primary or secondary extension, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped. Outlook Voice Access features will work the same way, whichever extension is used to log on.
- **Extensions in the primary dial plan and in a secondary dial plan with Outlook Voice Access** If the user has only two extensions, primary and secondary, and both primary and secondary extensions are in different UM dial plans (primary and secondary); they should call the pilot number appropriate to their dial plan. From their primary extension, they should call the pilot number of the primary dial plan, and from their secondary extension, they should call the pilot number of the secondary dial plan. If they do this, they won't be prompted to enter the extension number, and step 2 of the preceding steps will be skipped.
  Outlook Voice Access features that don't involve outbound dialing (for example "Call the sender" or "Call the office") will work the same way, whichever extension is used to log on. However, Outlook Voice Access features that do require outbound dialing won't work as expected when the user logs on to the secondary dial plan unless the outbound dialing rules are exactly the same in both dial plans. For the behavior of outbound dialing to be exactly the same, you must ensure that the following properties are configured identically on the primary and secondary dial plans:
  - Dialing codes (trunk access, national, and international)
  - In-country or region dialing codes
  - Dialing rules
  - Dialing rule group names

A UM-enabled user is associated with a UM mailbox policy, and this UM mailbox policy is associated with the user's primary dial plan. The UM mailbox policy settings that are associated with the UM-enabled user's primary dial plan will be applied to the user. If a user is associated with a secondary dial plan with a second extension number in the secondary dial plan, the UM mailbox policy settings associated with the primary dial plan will still be applied. In Outlook Voice Access, the same UM mailbox policy settings associated with the primary dial plan are applied whether the user calls in to the primary dial plan or to a secondary dial plan.

The **AllowedInCountryOrRegionGroups and AllowedInternationalGroups** properties on the UM mailbox policy contain the names of groups of dialing rules that are configured on the **ConfiguredInCountryOrRegionGroups** and **ConfiguredInternationalGroups** properties of a UM dial plan. When a UM-enabled user calls in to Outlook Voice Access, the outbound calling rules from the UM mailbox policy associated with the primary or secondary dial plan will apply to calls the user makes, depending on whether the UM-enabled user has called in to the primary or secondary dial plan's subscriber access or pilot number.

For example, if a primary dial plan named "Contoso Dial Plan 1" has a dialing rule named "US and Canada" in its **ConfiguredInCountryOrRegionGroups** property, the UM mailbox policy "Contoso UM Policy 1" might also have "US and Canada" in its **AllowedInCountryOrRegionGroups** property. If you want to add a secondary extension in "Contoso Dial Plan 2" for a user in "Contoso UM Policy 2", you would have to ensure that the **ConfiguredInCountryOrRegionGroups** property of "Contoso Dial Plan 2" also

contains a rule named "US and Canada". Otherwise, if the user logs on to Outlook Voice Access from their secondary extension, UM won't be able to find a rule on the secondary dial plan named "US and Canada". If this happens, Unified Messaging will only allow the user to call numbers allowed to any caller to the secondary dial plan, which could be more restrictive.

Return to top

UM Features That Operate Differently for Secondary Dial Plans

There's a set of UM features that can use secondary dial plans but may not work correctly in certain situations. It's important that you understand how each of these features is affected when you configure UM-enabled users to use a secondary dial plan.

Play on Phone

In Microsoft Outlook 2010 or Office Outlook Web App in Exchange 2010, Play on Phone uses the IP gateway that's associated with the user's primary dial plan to make the outbound call. It applies dialing rules from the primary dial plan and the UM mailbox policy that's associated with the user's mailbox.

Directory Search (Outlook Voice Access)

A search of the directory for a user who's been authenticated will follow these rules:

- The ability to search for a user and then leave a voice message or call an Exchange 2010 user will be available only if the user conducting the search is UM enabled and has a primary extension on the same dial plan as the user that's being called. If so, a search by name, alias, and primary extension will locate the user. However, searching by using the secondary extension won't locate the user.
- If the user being searched for is UM enabled and has a secondary extension on the called dial plan, then a search by name, alias, and secondary extension will find the user. However, although options to leave a voice message and call the contact will be offered, the call contact option won't succeed. In this case, a search by primary extension won't find the user.
- To find and be able to either call or leave a voice message for the user they're searching for, the UM-enabled user should use Outlook Voice Access through their primary dial plan's pilot number and search by name, alias, or primary extension. If the searched-for user is called using the secondary dial plan's pilot number, the user will only be found if the search is made by name, alias, or secondary extension. If the primary extension is used, the only option that will be available is for the user to leave a voice mail.

Directory Search (Subscriber Access)

A search of the directory for a user who hasn't been authenticated will follow these rules:

- The user being searched for will be found and the option to leave a voice message or call the user will be offered only if the user is UM enabled and has a primary extension on the called dial plan. If so, a search by name, alias, and primary extension will find the user. However, a search by secondary extension won't find the user.
- If the user being searched for is UM enabled, has a secondary extension on the called dial plan, and the option **Features** > **Callers can contact** > **Anyone on the default global address list** is selected on the called dial plan, then a search by name, alias, and secondary extension will find them. However, the option to leave voice mail will be offered to the caller, and there will be no option to call them.
- To find and be able to either call or leave a voice message for a user, the caller

must call the pilot number of the user's primary dial plan and search by name, alias, or the user's secondary extension. If the user's secondary pilot number is called, they will only be found if the **Callers can contact** option is set to **global address list (GAL)**. In this case, only the option to leave a voice message will be provided.

Call the Sender (Outlook Voice Access)

When a user calls in to Outlook Voice Access and chooses the option to Call the Sender, they can send either an e-mail message or a voice mail message to a UM-enabled user. The options available depend on whether the caller is associated with the same dial plan as the sender they're calling. Calls to a UM-enabled user when the caller dials in to a subscriber access number, pilot number, or Outlook Voice Access number and the caller is authenticated will follow these rules:

- **E-mail messages** If the sender of the e-mail message is a UM-enabled user, choosing the option to call the sender will result in a call to the sender's primary extension that's configured on the user's primary dial plan. In the case where the sender's primary extension is on a dial plan that's different from the caller's, the prompt to "Call the Sender" will only be provided if there's a business, home, or mobile phone configured for the sender in Active Directory and the dialing rules are configured to allow the call.
- **Voice mail messages** If the caller is a UM-enabled user, the option to call the sender will always result in a call to the extension that the sender uses to leave their voice message. If this extension has a number of digits different from the called dial plan, the prompt to call the sender won't be provided unless there are dialing rules in place that would permit the call. For example:
  - The "Call the sender" option will be offered if the sender uses an extension on the dial plan that was used to send the voice message.
  - The "Call the sender" option will be played if the sender uses an extension from a different dial plan than the dial plan that's used with Outlook Voice Access to send the voice message and both dial plans have the same number of digits. The success of the call will depend on whether the IP gateway and PBX infrastructure permit the call transfer.
  - The "Call the sender" option won't be played if the sender uses an extension from a different dial plan than the dial plan that's used with Outlook Voice Access to send the voice message, the dial plans have a different number of digits, and there are no outdialing rules that match the sender's extension.

1.9.1.3.22 Understanding Client Features in Unified Messaging

Understanding Client Features in Unified Messaging

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic describes Unified Messaging (UM) client features that give UM-enabled users access to their e-mail and UM messages in their Microsoft Exchange Server 2010 mailbox. The Unified Messaging client capabilities enable you to provide users simplified voice mail and e-mail access options and an improved overall user experience.

Contents

Outlook Voice Access

Outlook Voice Access is an Exchange 2010 feature that enables subscribers to retrieve e-mail messages from their individual mailbox using an analog, digital, or mobile telephone. They can then interact with their mailbox using touchtone or voice commands. When UM-enabled users access their Exchange 2010 mailbox using a telephone, they are presented with a series of voice prompts. These voice prompts help users navigate the Unified Messaging system and enable users to access their Exchange 2010 Inbox. Outlook Voice Access lets users retrieve, listen to, reply to, create, and forward voice or e-mail messages and listen to or change calendar information. For a copy of the Microsoft Exchange Server 2010 Unified Messaging Outlook Voice Access Quick Reference Guide, visit the Microsoft Download Center.

Important:

If you need to access the e-mail message after you delete it using Outlook Voice Access, you can use Outlook Web App or Microsoft Outlook to move the e-mail message back into the appropriate folder from the Deleted Items folder. You can't use Outlook Voice Access to access the Deleted Items folder.

Unified Messaging and ActiveSync Clients

The Microsoft Exchange ActiveSync protocol is used to connect mobile clients, such as those found on Internet capable mobile phones, to an Exchange 2010 server and mailbox. There are many mobile phones that users can use to access their Exchange 2010 mailbox and view e-mail messages, view and change calendar information, and listen to their voice messages. Many wireless and mobile phones used today enable users to continually be connected to their Exchange 2010 mailbox.

Return to top

Unified Messaging Integration with Outlook 2007 and Outlook 2010 Clients

Using Microsoft Office Outlook 2007, users can access their individual Exchange 2010 mailbox and view e-mail messages in their Inbox, view and change calendar information, and listen to voice messages using a Microsoft Windows Media Player, which is embedded inside the e-mail messages on their portable device or computer. Using the Exchange 2010 client, users gain additional features, such as the Play on Phone functionality. For more information about the Outlook features for Exchange Unified Messaging, see Outlook 2007 Features for Exchange Unified Messaging.

Note:

When you install Outlook 2007 on a client computer, the Outlook 2007 Unified Messaging voice mail features are included. The Unified Messaging features for configuring voice mail are available only with Outlook 2007 and aren't available with earlier versions of Outlook.

Unified Messaging Integration with Outlook Web App Clients

Outlook Web App provides users with a set of Unified Messaging interfaces and tools comparable to a full-featured e-mail client like Exchange 2010. As in earlier versions, known as Outlook Web Access, users can access their Exchange 2010 mailbox using a compliant Web browser. However, similar to the Exchange 2010 e-mail client, Outlook Web App offers users a Windows Media Player embedded in the e-mail message, which can be used to listen to voice messages, and enables users to access other features such as Play on Phone.

Note:

When you use Exchange ActiveSync on a mobile phone, you can listen to the attached .wma file that contains the voice mail message. The advanced Unified Messaging features found in the Outlook Web App Premium client, such as the voice mail configuration options, aren't available in Outlook Web App Light.

Caution:

When you use the light version of Outlook Web App and Pocket Internet Explorer on a mobile phone, you may be able to listen to the .wma attachment in a voice message. However, this isn't a supported configuration.

1.9.1.3.22.1 Understanding Outlook Voice Access

Understanding Outlook Voice Access

Understanding Unified Messaging > Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-30*

Outlook Voice Access lets Unified Messaging (UM)–enabled users access their Microsoft Exchange Server 2010 or Exchange Server 2007 mailbox using analog, digital, or cellular telephones.

A subscriber is an internal business user or network user who's enabled for Exchange 2010 Unified Messaging. Subscriber access is used by users to access their individual mailboxes to retrieve e-mail, voice messages, contacts, and calendaring information. Outlook Voice Access is an Exchange 2010 Unified Messaging feature that lets subscribers access their Exchange 2010 mailbox.

Outlook Voice Access Overview

In Exchange Server 2007 and also in Exchange 2010, a UM-enabled user can call in to an internal or external telephone number that's configured on a UM dial plan to access their mailbox and use the menu system found in Outlook Voice Access. Using this menu system, UM-enabled users can read e-mail, listen to voice messages, interact with their Outlook calendar, access their personal contacts, and perform tasks such as configuring their Outlook Voice Access PIN or recording their voice mail greetings.

Outlook Voice Access Interfaces

There are two Exchange 2010 Unified Messaging user interfaces available to subscribers:

the telephone user interface (TUI) and the voice user interface (VUI). These two interfaces together are called Outlook Voice Access. For a list of all the commands that are available in Outlook Voice Access, see Outlook Voice Access Command Reference.

You can prevent users from receiving voice mail, but let them retain the ability to access their Exchange 2010 mailbox using Outlook Voice Access. You can enable users for Unified Messaging and configure the users' mailbox with an extension number that isn't currently being used by another user in the organization.

Important:

For the VUI or Automatic Speech Recognition (ASR) to be used for subscriber access, it must be enabled on the UM dial plan to enable the VUI functionality as described in the scenarios in the following section.

For a copy of the Microsoft Exchange 2010 Unified Messaging Outlook Voice Access Quick Start Guide, see the Microsoft Download Center. You can also see Outlook Voice Access Quick Start Guide for a copy.

Outlook Voice Access Scenarios

The following scenarios demonstrate how Outlook Voice Access can be used for subscriber access from a telephone:

- **Access e-mail** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access their e-mail. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension number, the voice prompt says, "Please enter your PIN and press the # key." After the user enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." When the user says "E-mail," Unified Messaging reads the message header and then the name, subject, time, and priority for the messages that are in the subscriber's mailbox.
- **Access calendar** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access their calendar. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension, the voice prompt says, "Please enter your PIN and press the # key." After the user enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." When the user says "Calendar," Unified Messaging says, "Sure, and which day should I open?" The user says, "Today's calendar." Unified Messaging responds by saying, "Opening today's calendar." Unified Messaging reads each calendar appointment for that day for the user.

  Note:

  If a Unified Messaging server encounters a corrupted calendar item in a user's mailbox, it will fail to read the item, but will return the caller to the Outlook Voice Access main menu and will skip reading any additional meetings that may be scheduled for the rest of the day.

- **Access voice mail** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to access voice mail. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To access your mailbox, please enter your extension. To contact someone, press the # key." After the user enters a mailbox extension number, the voice prompt says, "Please enter your PIN and press the # key." After the user

enters a PIN, the voice prompt says, "You have 2 new voice mails, 10 new e-mail messages, and your next meeting is at 10:00 A.M. Please say voice mail, e-mail, calendar, personal contacts, directory, or personal options." The user says "Voice mail" and Unified Messaging reads the message header and then the name, subject, time, and priority for the voice messages that are in the user's mailbox.

Note:
If speech recognition is enabled, users can access their UM-enabled mailbox using speech input. However, subscribers can also use touchtone, also known as dual tone multi-frequency (DTMF), by pressing 0. Speech recognition isn't enabled for PIN input.

- **Locate an e-mail alias** An Outlook Voice Access user places a call to the subscriber access number from a telephone and wants to locate a person in the directory by spelling their e-mail alias. The voice prompt says, "Welcome. You're connected to Microsoft Exchange. To contact someone, press the # key." The user presses the # key, and then spells the name of the person using touchtone inputs.

Note:
The directory search feature with subscriber access isn't speech-enabled. Users will be able to spell the name of the person who they want to contact only by using touchtone inputs.

Important:
In some companies (especially in East Asia), office telephones may not have letters on the keys of the telephone. This makes the spell-the-name feature that uses the touchtone interface almost impossible to use without a working knowledge of the key mappings. By default, Exchange 2010 Unified Messaging uses the E.161 key mapping. For example, 2=ABC, 3=DEF, 4=GHI, 5=JKL, 6=MNO, 7=PQRS, 8=TUV, 9=WXYZ.

When inputting a combination of letters and numbers, for example, Mike1092, the numeric digits are mapped to themselves. For an e-mail alias of Mike1092 to be entered correctly, the user must press the numbers 64531092. Also, for characters other than A-Z and 0-9, there won't be a telephone key equivalent. Therefore, these characters shouldn't be entered. For example, the e-mail alias mike.wilson would be entered as 6453945766. Even though there are 11 characters to be input, only 10 digits are entered by the user because there's no digit equivalent for the period (.). For details, seeOutlook Voice Access User Scenarios.

Public and Personal Contact Groups

You can use Outlook Voice Access to send or forward a voice message, an e-mail message, or a meeting request. You can send or forward the message or meeting request to any of the following:

- A person in your personal Contacts folder
- A person in your organization’s shared address list
- A group you’ve created in your personal Contacts folder
- A public group included in your organization’s shared address list

You can send messages and meeting requests using the voice user interface (VUI) (if automatic speech recognition has been turned on by your voice mail administrator) or using touchtone inputs on your telephone keypad. You can also use Outlook Voice Access to listen to details about a group, including the members included in the group.

Note:
When sending a message to a public group in your shared address list, or a group in your personal Contacts folder that doesn’t include any members, the voice mail system won't give you the option to send or forward the message or meeting request. However, if you try to add a group as one of the recipients of a message or meeting request that you are

creating over the phone, the voice mail system will not add the group and say "The message could not be sent because the contact does not appear to have a valid e-mail address" because the group doesn't contain any valid e-mail addresses.

Choosing a Language

You can't change the language that Outlook Voice Access uses to speak to you and to reply to you when you speak to it. The voice mail system will try to find and use the best match for the language you chose when you first signed in to Microsoft Office Outlook Web App or the language that you've chosen on the Regional tab in Outlook Web App. If the language you choose isn't supported by Outlook Voice Access, the voice mail system will use the same language that callers hear when they're prompted to leave a voice message for you.

Outlook Voice Access User Scenarios

Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging > Understanding Outlook Voice Access >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-11*

Outlook Voice Access is a feature in Microsoft Exchange Server 2010 Unified Messaging (UM) that enables users to retrieve e-mail messages from their mailbox using an analog, digital, or mobile telephone. They can then interact with their mailbox using touchtone or voice commands.

The Outlook Voice Access Quick Reference Guide includes a graphic representation of all the Outlook Voice Access menu options and how to navigate the menu system. To download a copy of the Quick Reference Guide, see the Microsoft Download Center.

When UM-enabled users access their Exchange 2010 mailbox using a telephone, they are presented with a series of voice prompts. These voice prompts help them navigate the Unified Messaging system and enable them to access their mailbox. Outlook Voice Access lets users do the following:

- Retrieve, listen to, reply to, create, and forward voice or e-mail messages.
- Listen to or change calendar information.
- Change personal options, such as changing a PIN, or call or send a voice message to a personal contact.

Contents

Reading and Reviewing E-Mail

Users can listen to, reply to, create, and forward unread e-mail messages using the telephone. For example, if users are expecting an important e-mail message, and do not have access to the Internet, they can use a mobile phone to dial the subscriber access number or the number that is used for Outlook Voice Access. After users enter their extension number, enter their PIN, and then say, "E-mail," the Unified Messaging server

will access the users' mailbox and read their unread e-mail. While the Unified Messaging server reads an e-mail message, the user can say one of the following:

- "Reply" to reply to the sender.
- "Reply all" to reply to all recipients on the e-mail message.
- "Forward" to forward the e-mail message to another user.
- "Flag" to flag the message for follow up.
- "Hide" to hide the conversation.

Listen to E-Mail Messages

To listen to e-mail messages using the voice user interface (VUI), users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "E-mail" to access e-mail.
2. The Unified Messaging server will read the name, subject, time, and priority of the first unread e-mail message.
3. The user can then say one of the following options:
   - "Next message" to mark the message as Read and go to the next e-mail message.
   - "Mark unread" to keep the message marked as Unread and go to the next message.
   - "End" to jump to the end of the message.
   - "Delete" to delete the message.

This process is shown in the following figure.

To listen to e-mail messages using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access e-mail.
2. The Unified Messaging server will read the name, subject, time, and priority of the first unread e-mail message.
3. The user can then press one of the following options:
   - Pound (#) key to mark the message as Read and go to the next e-mail message.
   - 9 to keep the message marked as Unread and go to the next message.
   - 33 to jump to the end of the message.
   - 7 to delete the message.

This process is shown in the following figure.

Return to top

Reply to E-Mail Messages

To listen to e-mail messages and then reply using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "E-mail" to access e-mail.
2. Say "Next message" repeatedly until they reach the e-mail message to which they want to reply.
3. Listen to the message or say "End" to go to the end of the message.

4. Say one of the following:
   - "Reply" to reply to the sender.
   - "Reply all" to reply to the sender and all other recipients.
   - "Forward" to forward the message to another user or group.
5. Record a reply and then hang up, remain silent, or press any key. To accept the reply message and send it, say "Send it."

This process is shown in the following figure.

To listen to e-mail messages and then reply using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access e-mail.
2. Press # repeatedly until they user reach the e-mail message to which they want to reply. Press 9 to mark the message as Unread.
3. Listen to the message or press 33 to go to the end of the message.
4. Press 8 to reply to the sender, press 88 to reply to the sender and all other recipients, or press 6 to forward the message to another user or group.
5. Record a reply, and then press #. To accept the reply message and send it, press 1.

This process is shown in the following figure.

Return to top

Listen to the Next Unread E-Mail Message

To listen to an e-mail message and then go to the next unread message using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "E-mail."
2. Say "Next unread." Say "Mark unread" if they want to mark the message as Unread.

This process is shown in the following figure.

To listen to an e-mail message and then go to the next Unread message using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access e-mail.
2. Press ## to listen to the next unread message. Press 9 to mark the message as Unread.

This process is shown in the following figure.

Return to top

Flag an E-Mail Message for Follow Up

To listen to e-mail messages and flag messages for follow up using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

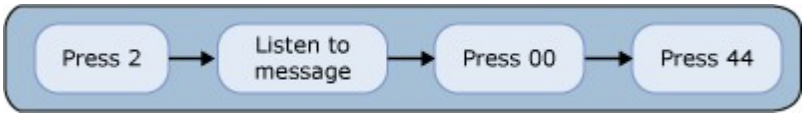
1. Say "E-mail" to access e-mail.
2. Say "Next message" repeatedly until they reach the e-mail message that they want to flag for follow up. Say "Mark unread" to mark the message as Unread.
3. Listen to the message or say "End" to go to the end of the message.
4. Say "Flag" or "Flag for follow up" to flag the message for follow up.

This process is shown in the following figure.

To listen to e-mail messages and flag messages for follow up using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access e-mail.
2. Press # repeatedly until they reach the e-mail message that they want to flag for follow up. Press 9 to mark the message as Unread.
3. Listen to the message or press 33 to go to the end of the message.
4. Press 0 (zero) twice to access more options.
5. Press 44 to flag the message for follow up.

This process is shown in the following figure.



Return to top

Hide a Conversation

To listen to e-mail messages and hide a conversation so that Unified Messaging will not continue to read other e-mail messages that are in the same e-mail conversation using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "E-mail" to open e-mail.
2. Say "Next message" repeatedly until they reach the e-mail message that they want. Say "Mark unread" to mark the message as Unread.
3. Listen to the message or say "End" to go to the end of the message.
4. Say "Hide" or "Hide conversation" to hide the conversation. The next e-mail message will be read.

This process is shown in the following figure.

To listen to e-mail messages and hide a conversation so that Unified Messaging will not continue to read other e-mail messages that are in the same e-mail conversation using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access e-mail.
2. Press # until they reach the e-mail message that they want to hide. Press 9 to mark the message as Unread.
3. Listen to the message or press 33 to go to the end of the message.
4. Press 99 to hide the conversation. The next e-mail message will be read.

This process is shown in the following figure.

Note:
When a conversation is hidden, it is hidden only for the current session. If users log off and then log on to their mailbox again, Unified Messaging will read e-mail messages that are in the same conversation.

Return to top

Managing Calendar Items

Users can listen to, reply to, create, and forward items in their calendar over the telephone.

For example, a user has a meeting at 10:00 A.M. However, because of some unexpected delays, the user will be 15 minutes late. The user can inform the other meeting attendees by calling the telephone number for Outlook Voice Access, logging on to the Exchange 2010 mailbox, and then accessing the list of meetings for that day in the calendar. After Unified Messaging reads the meeting request for the 10:00 A.M. meeting, the user can use the *I'll be late* feature to inform all the meeting attendees that the user will be 15 minutes late. Each attendee will receive an e-mail message that informs them that the user will be 15 minutes late. The user also has the option to attach a voice mail message.

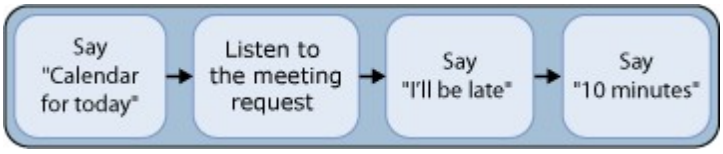
In another example, a user may have an important client who decides to schedule an all-day meeting on very short notice. The user must cancel all other meetings for that day in the simplest possible way. Using the *Clear my calendar* feature, users can quickly and easily clear their calendar for the whole day.

Send an I'll Be Late Message

To send an I'll be late message to meeting participants using the VUI, users must dial the Unified Messaging subscriber access number, enter their extension number and PIN, and then do the following:

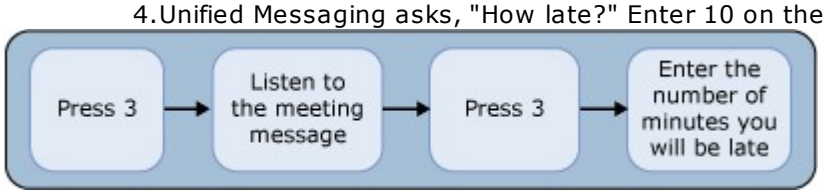
1. Say "Calendar for today."
2. Listen to the meeting request.
3. After the meeting request has been read, say "I'll be late."
4. Unified Messaging asks, "How late?" Say "10 minutes."
5. Unified Messaging asks, "Do you want to record a message?" Say "Yes." Record the message, and then say "Send it."

This process is shown in the following figure.



To send an I'll be late message to meeting participants using the touchtone interface, users must dial the Unified Messaging subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 3 to access their calendar.
2. Listen to the meeting requests to locate the meeting for which to send an I'll be late message.
3. After the meeting request has been read, press 3.
4. Unified Messaging asks, "How late?" Enter 10 on the telephone key pad.



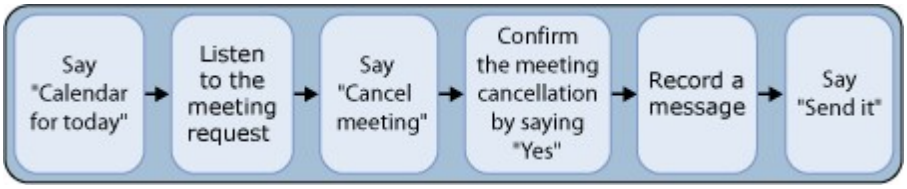
Return to top

Cancel a Meeting

To cancel a meeting, the user must be the meeting organizer. To cancel the meeting using the VUI, meeting organizers must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "Calendar for today" to access their calendar.
2. Listen to the meeting request.
3. After the meeting request has been read, say "Cancel meeting."
4. Confirm the meeting cancellation by saying "Yes."
5. After Unified Messaging asks whether the meeting organizer wants to attach a recorded message, say "Yes." Record the message, and then say "Send it."

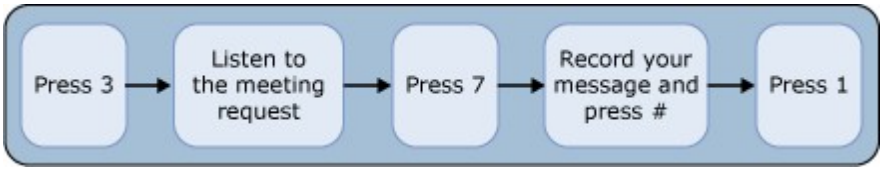
This process is shown in the following figure.



To cancel a meeting, the user must be the meeting organizer. To cancel the meeting using the touchtone interface, meeting organizers must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 3 to access their calendar.
2. Listen to the meeting requests to locate the meeting to cancel.
3. Press 7 to cancel the meeting.
4. If meeting organizers choose to send a voice message, they can then press one of the following options:
   - # to stop recording the message.
   - 1 to accept the recorded message.

This process is shown in the following figure.



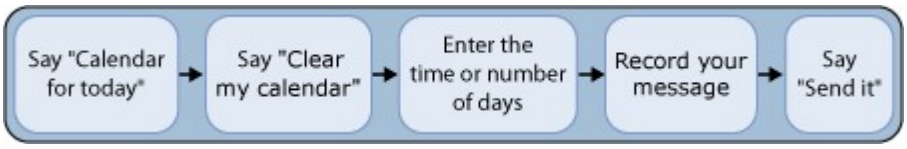
Return to top

Clear a Calendar

To clear their calendar using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "Calendar for today" to access their calendar.
2. Say "Clear my calendar."
3. Enter the time or the number of days to be cleared.
4. After Unified Messaging asks whether they want to attach a recorded voice message, they say "Yes," record the message, and then say "Send it." If they do not want to send an attached recorded voice message, they say "No."

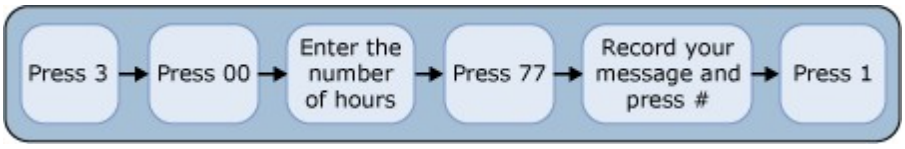
This process is shown in the following figure.



To clear their calendar using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 3 to access their calendar.
2. Press 00 to go to the More Options menu.
3. Press 77 to clear their calendar.
4. Enter the number of hours to clear from the calendar.
5. If users choose to send a voice message, they can do one of the following:
   - Press # to not send a voice message
   - Record the voice message when prompted, press # to stop recording the message, and then press 1 to accept the recorded message.

This process is shown in the following figure.



Return to top

Accept a Meeting Request

To accept a meeting request using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "E-mail" to access their e-mail.
2. Listen to the e-mail message that contains a meeting request.
3. Say "Accept" to accept the meeting request.

This process is shown in the following figure.

To accept a meeting request using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 2 to access their e-mail.
2. Listen to the e-mail message that contains a meeting request.
3. Press 4 to accept the meeting request.

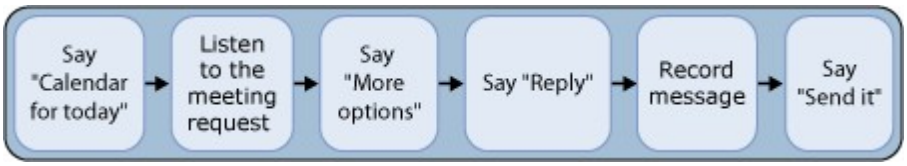
This process is shown in the following figure.

Reply to a Meeting Request

To reply to a meeting request using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

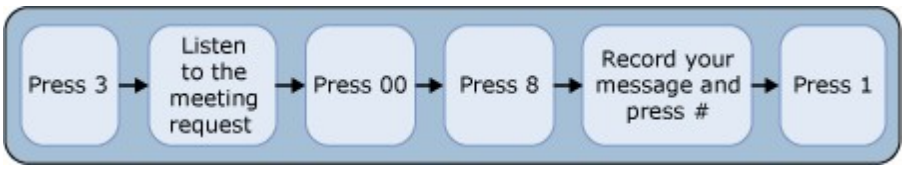
1. Say "Calendar for today."
2. Listen to the meeting requests to locate the meeting request to reply to.
3. Say "More options" to open the More Options menu.
4. Say "Reply" to reply to the meeting organizer.
5. Record a message.
6. Say "Send it."

This process is shown in the following figure.



1. To reply to a meeting request using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:
2. Press 3 to access their calendar.
3. Listen to the meeting requests to locate the meeting request to reply to.
4. Press 00 for more options.
5. Press 8 to reply to the meeting organizer.
6. Record a message, and then press #.
7. Press 1 to accept the recording and send the message.

This process is shown in the following figure.



Return to top

Managing Personal Options and Contacts

Users can manage their personal options and contacts using Outlook Voice Access. They can:

- Call a personal contact.
- Locate and call a user in the directory.
- Configure personal options, such as changing their PIN over the telephone.

When users first set up their mailbox, they must create personal and Away greetings that callers will hear when users are unable to answer their telephone. If, for example, users realize that they have forgotten to turn on an Away voice greeting that will give callers an alternative number to call if they have an immediate issue, users can use Outlook Voice Access to access their personal options and record and turn on an Away greeting from any telephone.

If a user has to contact an account manager with important information about a client, the user can call the number that is used for Outlook Voice Access, use the directory search feature to locate the account manager, and then place the call.

Note:

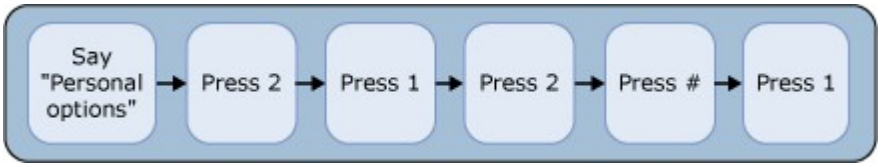
When users access the Personal Options menu, they must use the touchtone interface.

Record a Personal Greeting

To record a personal greeting using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

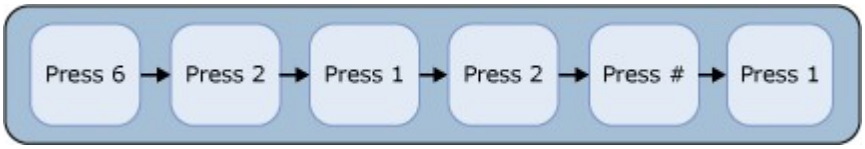
1. Say "Personal options" to access the Personal Options menu.
2. Press 2 to record greetings.
3. Press 1 to record a personal greeting.
4. Press # to stop recording the personal greeting.
5. If they have to re-record their personal greeting, they should press 2.
6. Press 1 to accept the personal greeting.

This process is shown in the following figure.



1. To record a personal greeting using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:
2. Press 6 to access personal options.
3. Press 2 to record greetings.
4. Press 1 to record a personal greeting.
5. Press 2 to re-record the personal greeting.
6. Press # to stop recording the personal greeting.
7. Press 1 to accept the personal greeting.

This process is shown in the following figure.



Note:

When users change their telephone greeting, they are also given the option to turn on or

off their e-mail automatic reply message.

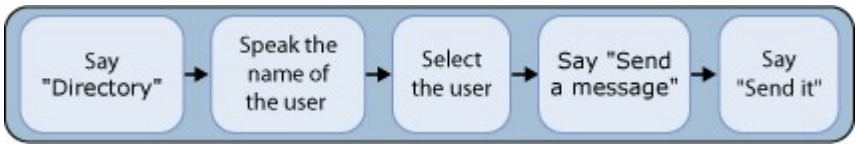
Return to top

Send a Voice Message to a User

Users can locate and send a voice message to another UM-enabled user. To send a voice message to another user using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

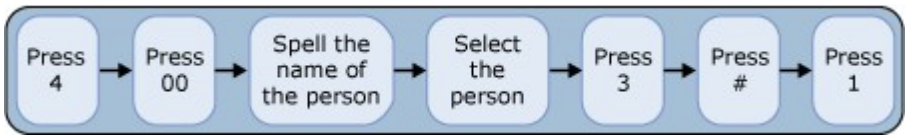
1. Say "Directory."
2. Say the name of the person to locate.
3. Select the correct person from the list.
4. Say "Send a message," and then record the voice message.
5. Say "Send it" to send the message.

This process is shown in the following figure.



1. Users can locate and send a voice message to another UM-enabled user. To send a voice message to another user using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:
2. Press 4 to search for a contact.
3. Press 00 to locate the person in the directory.
4. Spell the name of the person to locate using the telephone keypad.
5. Select the correct person from the list.
6. Press 3 to send a voice message to the person.
7. Record the voice message, and then press # to stop recording.
8. Press 1 to accept the voice message and send it.

This process is shown in the following figure.

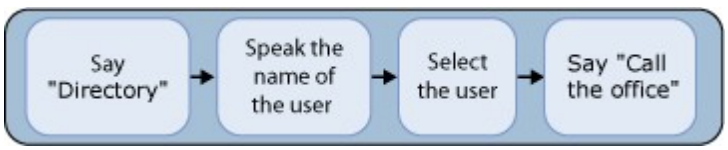


Locate and Call a User in the Directory

To locate and call a user in the directory using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "Directory."
2. Say the name of the person to locate.
3. Select the correct person from the list.
4. Say "Call the office."

This process is shown in the following figure.

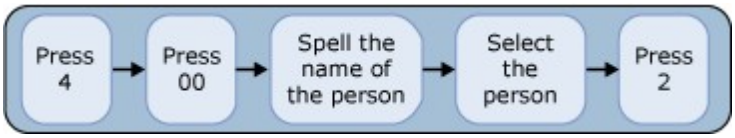


To locate and call a user in the directory using the touchtone interface, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Press 4 to access personal contacts.

2. Press 00 to locate a person in the directory.
3. Spell the name of the person to locate using the telephone keypad.
4. Select the correct person from the list.

This process is shown in the following figure.



Return to top

Change a PIN

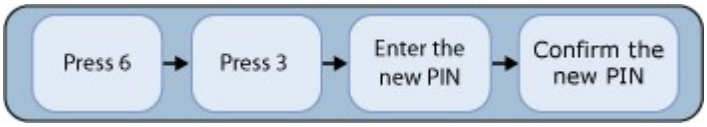
To change their PIN using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:

1. Say "Personal options."
2. Press 3 to change the PIN.
3. Enter the new PIN, and then press #.
4. Press # to confirm the new PIN.

This process is shown in the following figure.

1. To change their PIN using the VUI, users must dial the UM subscriber access number, enter their extension number and PIN, and then do the following:
2. Press 6 to change personal options.
3. Press 3 to change the PIN.
4. Enter the new PIN, and then press #.
5. Press # to confirm the new PIN.

This process is shown in the following figure.



Outlook Voice Access Quick Start Guide

Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging > Understanding Outlook Voice Access >

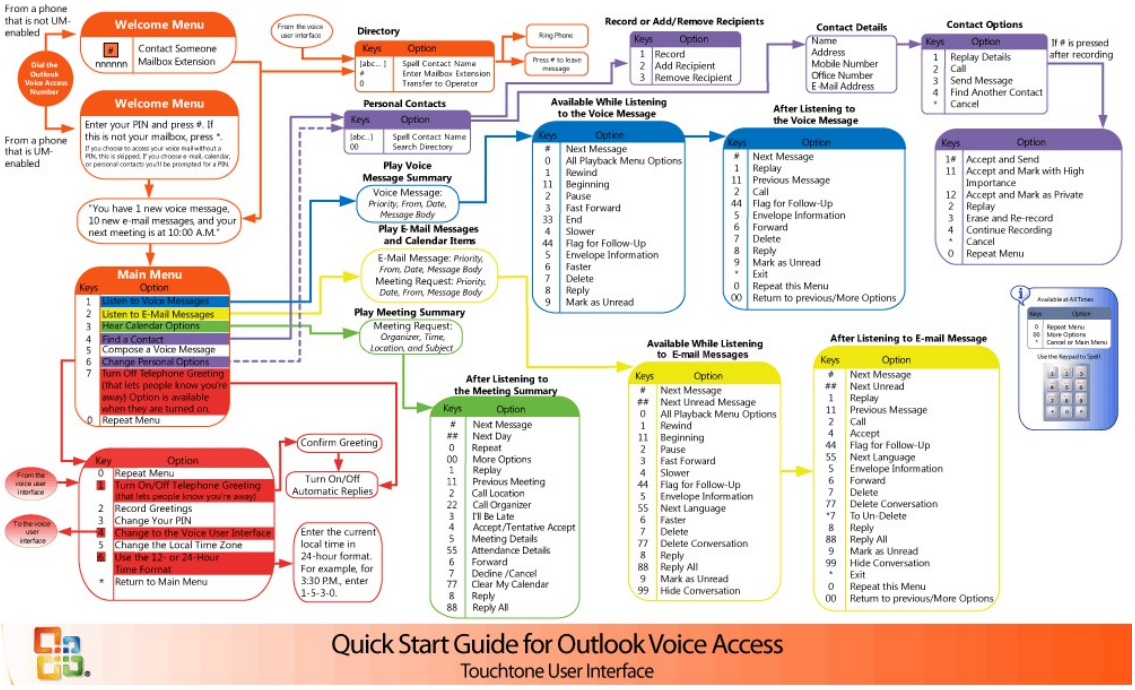
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

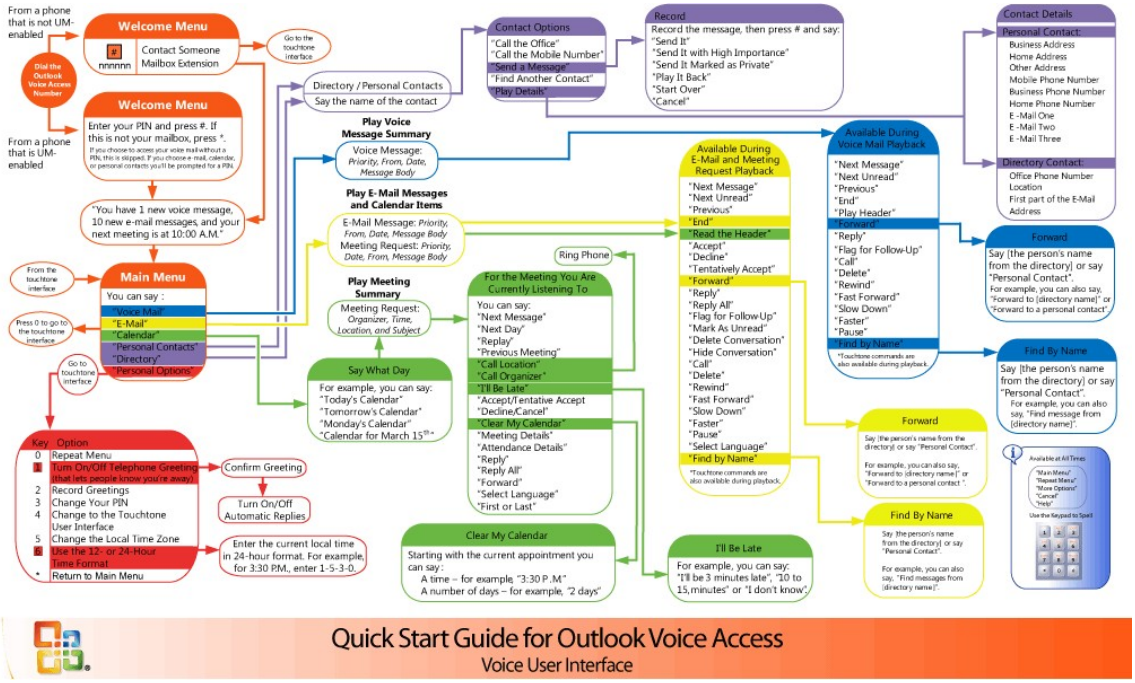
Topic Last Modified: *2009-09-15*

Outlook Voice Access lets Unified Messaging (UM)-enabled users access their Microsoft Exchange Server 2010 mailbox using analog, digital, or mobile telephones. Using the menu system found in Outlook Voice Access, UM-enabled users can read e-mail, listen to voice messages, interact with their Microsoft Outlook calendar, access their personal contacts, and manage personal options, for example, configuring their Outlook Voice Access PIN or recording their voice mail recordings. This quick start guide shows the navigation tree and the options that are available to UM-enabled users when they use Outlook Voice Access.

Outlook Voice Access Quick Start Guide

The following figures illustrate the touchtone interface and Voice User Interface (VUI) commands and menus that are used with Outlook Voice Access.





You can download a printable version of the Outlook Voice Access Quick Start Guide for Exchange 2010 Unified Messaging by visiting the Microsoft Download Center.

- For more information about the voice prompts that are used with subscriber access in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Audio Prompts.

Outlook Voice Access Command Reference

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Outlook Voice Access lets Unified Messaging (UM)-enabled users access their Microsoft Exchange Server 2010 mailbox using analog, digital, or mobile telephones. Using the menu system found in Outlook Voice Access, UM-enabled users can read e-mail, listen to voice messages, interact with their Outlook calendar, access their personal contacts, and manage personal options such as configuring their Outlook Voice Access PIN or recording their voice mail recordings. This topic contains a list of the commands and how they are used by Outlook Voice Access users when they call in to a subscriber access number to access their Exchange 2010 mailbox.

Outlook Voice Access User Interfaces

There are two Exchange 2010 Unified Messaging user interfaces available to subscribers: the Telephone User Interface (TUI) and the Voice User Interface (VUI). In Exchange 2010, these two interfaces together are called Outlook Voice Access. Outlook Voice Access can be used when subscribers access the Unified Messaging system from an external or internal telephone to access their personal e-mail, voice messages, contacts, and calendaring information in their Exchange 2010 mailbox.

For more information about the user interfaces that are used by Outlook Voice Access users, see the following topics:

- Understanding the DTMF Interface
- Understanding Automatic Speech Recognition Directory Lookups

E-Mail and Voice Mail Commands Reference

As an Outlook Voice Access user, when you dial in to a subscriber access number, you are presented with menu options that enable you to access your Exchange 2010 mailbox and manage your e-mail and voice mail. The following table lists the commands that are available for managing your e-mail and voice mail.

E-mail and voice mail commands

Voice command	Touchtone command	Description
"Play"		Plays the current e-mail or voice mail message.
"Next"	#	Reads the next e-mail or voice mail message.
"Next unread"	00 followed by ##	Reads the next unread e-mail message. Available only for e-mail.
"Delete"	7	Deletes the current e-mail or voice mail message.
"Reply"	8	Replies to the user who sent the current e-mail or voice mail message.
"Reply all"	00 followed by 88	Replies to the user of the current e-mail message. Not an available option for voice mail messages.
"Mark as unread"	9	Marks the e-mail message as Unread.
"End"	33	Stops reading and goes to the end of the current e-mail or voice mail message.
"More options"	00	Opens the More Options menu.
"Previous"	00 followed by 11	Reads the previous e-mail or voice mail message.
"Read the header"		Reads the header of the e-mail or voice mail message.
"Call sender"	00 followed by 2	Places a call to the user who sent the current e-mail or voice mail message.
"Forward"	00 followed by 6	Forwards the current e-mail or voice mail message to other e-mail recipients or groups.
"Flag for follow up"	00 followed by 44	Marks or flags the current e-mail or voice mail message for follow up.
"Find by name"		Uses the user's name to locate e-mail or voice mail messages in the user's mailbox.
"Delete conversation"	00 followed by 77	Deletes all the e-mail messages that are associated with an e-mail

		conversation. Available only for e-mail.
"Hide conversation"	00 followed by 99	Hides additional e-mail messages that are contained within the same e-mail conversation. Available only for e-mail.
"Envelope information"	00 followed by 5	Reads the envelope information for the e-mail or voice mail message.
"Select language"	00 followed by 55	Lets you select the language in which you want the e-mail or voice mail message to be read.
"Rewind" or "Repeat"	1	Rewinds or repeats the current e-mail or voice mail message. Available only while the message is being played.
"Pause"	2	Pauses the current e-mail or voice mail message. Available only while the message is being played.
"Fast forward"	3	Fast forwards the current e-mail or voice mail message. Available only while the message is being played.
"Slow down"	4	Plays or reads the current e-mail or voice mail message more slowly. Available only while the message is being played.
"Faster"	6	Plays or reads the current e-mail or voice mail message faster. Available only while the message is being played.
"Previous"	11	Reads the previous e-mail message from the beginning. Available only for e-mail.
"Replay"	00 followed by 1	Replays the current e-mail or voice mail message.
"Repeat"	0	Repeats the current menu options.
"Main menu"	*	Exits to the main menu.

Important:

If you need to access the e-mail message after you delete it using Outlook Voice Access, you can use Outlook Web App or Outlook to move the e-mail message back into the appropriate folder from the Deleted Items folder. You cannot use Outlook Voice Access to access the Deleted Items folder.

Calendar Options Command Reference

As an Outlook Voice Access user, when you dial in to a subscriber access number, you are presented with menu options that enable you to access your Exchange 2010 mailbox and manage your calendar. The following table lists the commands that are available for managing your calendar.

Calendar commands

Voice command	Touchtone command	Description
"Next"	#	Reads the next calendar appointment.
"Next day"	##	Opens and reads the calendar appointments for the next day.
"Repeat"	0	Repeats the menu options that are available. Or, if you are using the VUI, the system reads the calendar appointment again.
"More options"	00	Plays the more calendar options menu.
"Repeat"	1	Reads the calendar appointment again.
"Previous meeting"	00 followed by 11	Opens the previous meeting that is scheduled.
"Call location"	2	Calls the telephone number that is listed for the meeting location.
"Call organizer"	00 followed by 22	Calls the telephone number that is listed for the organizer of the meeting.
"I'll be late"	3	Sends an I'll be late message to all the meeting attendees.
"Accept" or "Tentative accept"	4	Accepts or tentatively accepts the meeting request.
"Meeting details"	5	Reads or plays back the details of the meeting that is currently being read.
"Attendance details"	00 followed by 55	Reads or plays the details of a meeting that is scheduled.
"Forward"	00 followed by 6	Forwards a meeting request for the meeting to another user.
"Decline" or "Cancel"	7	Declines or cancels the meeting request.
"Clear my calendar"	00 followed by 77	Clears your calendar for a

		specific time period for that day.
"Reply"	00 followed by 8	Replies to the meeting organizer.
"Reply all"	00 followed by 88	Replies to all the meeting attendees.
"Repeat menu"	5 followed by 0	Repeats the menu options that are available.
"Rewind"	5 followed by 1	Rewinds the meeting details.
	5 followed by 11	Returns to the beginning of the meeting details.
	5 followed by 2	Pauses and resumes playback of the meeting details.
"Fast forward"	5 followed by 3	Skips forward within the meeting details.
"End"	5 followed by 33	Skips to the end of the meeting details.
	5 followed by 4	Plays or reads the meeting details slower.
	5 followed by 55	Selects the language that will be used to read the meeting details.
	5 followed by 6	Plays or reads the meeting details faster.
"Main menu"	*	Exits to the main menu.

Personal Contacts Options Commands Reference

As an Outlook Voice Access user, when you dial in to a subscriber access number, you are presented with menu options that enable you to access your Exchange 2010 mailbox and call or send a message to a personal contact. If you choose to use the VUI, which is selected by default, and select the personal contacts menu option, the system will prompt you to input the name of the personal contact. However, to locate a user in the directory, you must use the touchtone or dual tone multi-frequency (DTMF) interface. The following table lists the commands that are available for managing your contacts.

Personal contact commands

Voice command	Touchtone command	Description
"Directory"	00	Searches the directory for a user.
"Play details"	1	Plays the details of the personal contact, such as the telephone numbers that are

		listed for the personal contact.
"Send a message"	3	Sends a message to the personal contact that is selected.
"Find another contact"	4	Finds another personal contact.
"Call the cell"	2 followed by 1	Calls the mobile telephone number that is listed for the personal contact.
"Call the office"	2 followed by 2	Calls the business or office telephone number that is listed for the personal contact.
"Call home"	2 followed by 3	Calls the home telephone number that is listed for the personal contact.
	##	Lets you enter the e-mail alias or name for the user in the directory if using the directory search feature.
"Main menu"	*	Exits to the main menu.

Personal Options Commands Reference

As an Outlook Voice Access user, when you dial in to a subscriber access number, you are presented with menu options that enable you to access your Exchange 2010 mailbox and manage your personal options. When you configure personal options using Outlook Voice Access, the DTMF or touchtone interface is the only interface that is available. The VUI or Automatic Speech Recognition (ASR) is not available for configuring personal options. The following table lists the commands that are available for managing your personal options.

Personal options commands

Voice command	Touchtone command	Description
	1	Turns on or off the telephone Out of Office greeting.
	2	Records the personal voice mail or Out of Office voice mail greeting.
	3	Changes the PIN that is used for Outlook Voice Access.
	4	Starts using the VUI or touchtone interface.
	5	Sets the local time zone to use.
	6	Chooses the 12-hour or 24-hour time format.

	*	Returns to the main menu.
	0	Repeats the menu options that are available.

For More Information

- For more information about subscriber access in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Subscriber Access.
- For more information about the voice prompts that are used with subscriber access in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Audio Prompts.
- For more information about client features in Exchange 2010 Unified Messaging, see Understanding Client Features in Unified Messaging.
- For more information about common user scenarios in Exchange 2010 Unified Messaging, see Outlook Voice Access User Scenarios.

1.9.1.3.22.2 Understanding Call Answering Rules

Understanding Call Answering Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-04-12*

Call Answering Rules is a new feature in Microsoft Exchange Server 2010. Using this feature, end users can dictate how their incoming call answering calls should be handled. Call answering rules are applied to incoming calls similar to the way Inbox rules are applied to incoming e-mail messages.

Call answering rules are stored in the mailboxes of users who are enabled for Exchange 2010 Unified Messaging. Nine call answering rules can be set up for each mailbox. These rules are independent of the Inbox rules that are set up by users and don't consume a part of the Inbox rules quota for the user. By default, no call answering rules are configured. If an incoming call is answered by a Unified Messaging (UM) server, the caller can be prompted to leave a voice message or if the caller doesn't prompt the system, the caller will also be able to leave a voice message for the called party.

Anatomy of Call Answering Rules

A call answering rule consists of two parts: conditions and actions. You can associate one or more conditions with a single call answering rule. The call answering rule will only be processed if all the conditions for the rule are met. You can also associate one or more actions with a single call answering rule. These actions determine what options will be offered to the caller when the call answering rule is processed.

Call Answering Rules support the following conditions:

- Who the incoming call is from
- The time of day
- Calendar free/busy status

- Whether automatic replies are turned on for e-mail

The following actions are supported:

- Find me
- Transfer the caller to someone else.
- Leave a voice message

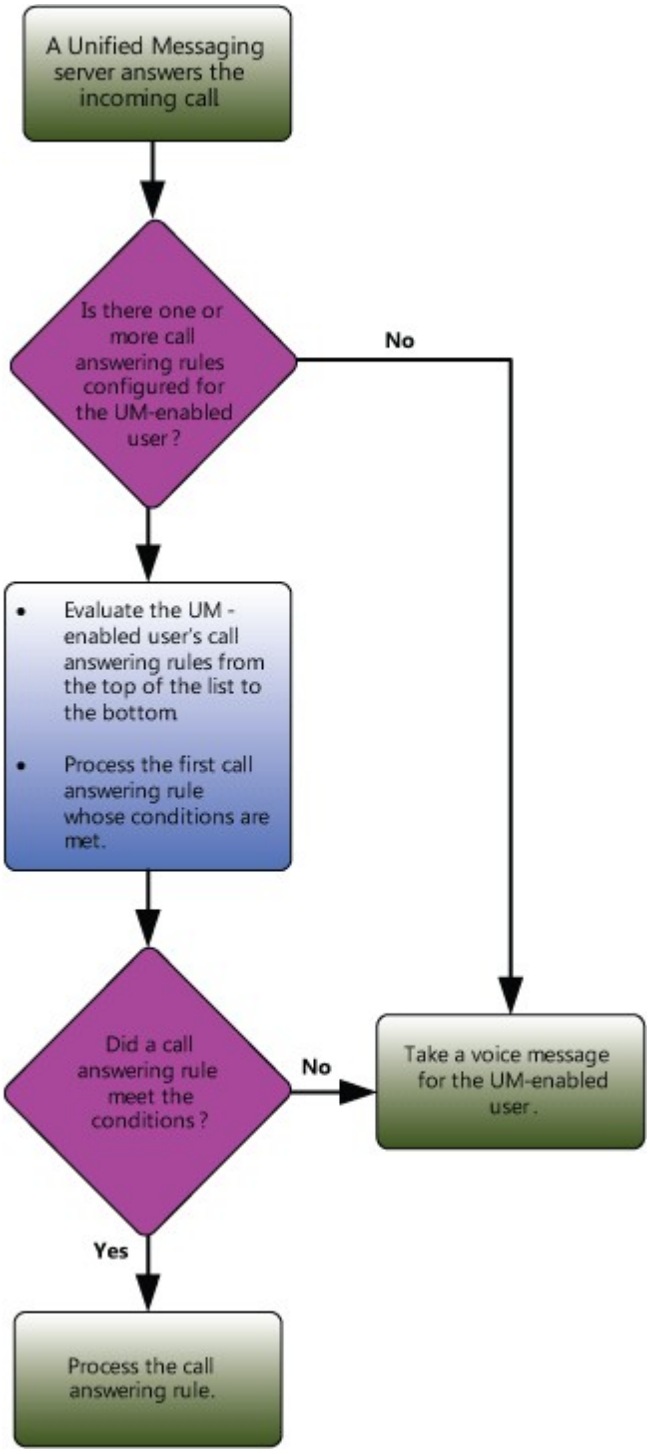
Note:
If a user records a custom greeting for a call answering rule, they must include the menu option as part of the custom greeting when they configure the call answering rule. If they don't, the Unified Messaging server won't generate a menu prompt that lets the caller know what his or her choices are. After UM plays the custom greeting, the server will wait for the caller's input. If the menu option isn't included in the greeting, the caller won't input anything and the server will prompt them, asking "Are you still there?"

For more information on the conditions and actions, see Call Answering Rules for the End User.

Selecting a call answering rule for each incoming call

As shown in the following diagram, when an incoming call is received for a UM-enabled user, UM will:

1. Determine whether the user has created any call answering rules. If not, UM will offer the caller the option of leaving a voice message.
2. If one or more call answering rules have been configured, UM will evaluate each of these rules. The first rule whose conditions are met will be processed.
3. After evaluating all the rules, if UM doesn't find a rule whose conditions are met, UM will ask the caller to leave a voice message.



Dialing Rules

Depending on how a call answering rule is configured, an incoming call may result in a call transfer. When this happens, the transfer target phone number will be subject to the dialing rules and restrictions on the UM mailbox policy that the called party is associated with. For more information about outdialing and dialing rules and restrictions, see the following topics:

- Configure Dialing Rule Groups on a UM Dial Plan
- Create a Dialing Rule Entry on a UM Dial Plan
- Enable Dialing Restrictions on a UM Mailbox Policy

Enabling/Disabling Call Answering Rules

By default, call answering rules are automatically enabled for UM-enabled users. However, you can disable call answering rules for users by disabling the feature on a UM dial plan, a UM mailbox policy, or the user's mailbox. For details about how to enable or disable call answering rules, see the following topics:

- Allow or Prevent Call Answering Rules on a UM Dial Plan
- Enable or Disable Call Answering Rules on a UM Mailbox Policy
- Enable or Disable Call Answering Rules for a UM-Enabled User

Important:
Call answering rules aren't available for UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 Mailbox server.

Call Answering Rules for the End User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-04-12*

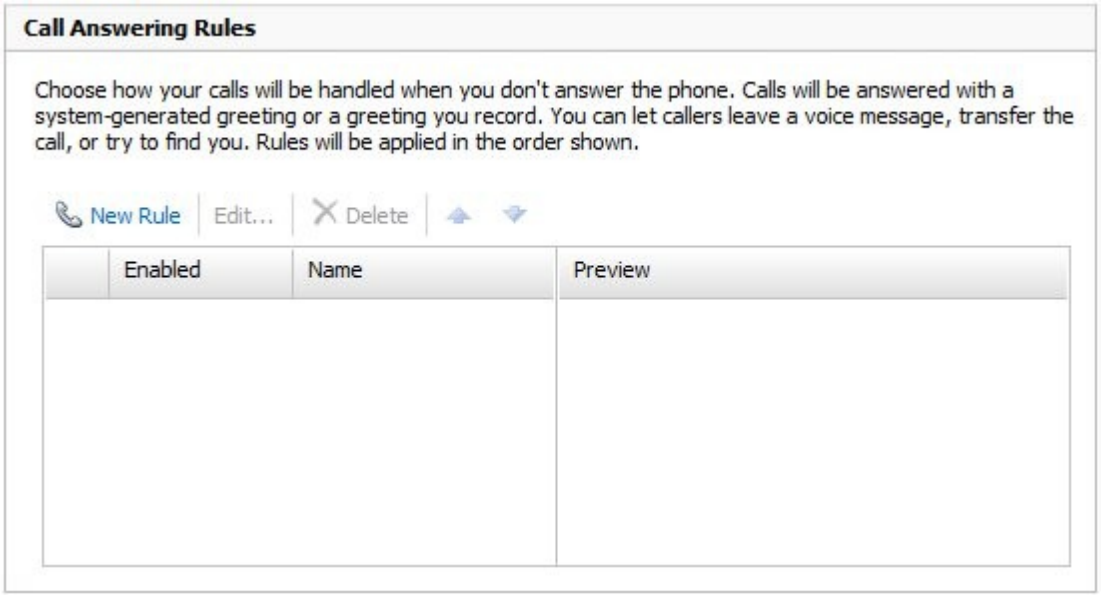
One of the main functions of Exchange Unified Messaging is to answer incoming calls, take a voice mail message, and send it to your Inbox. Call Answering Rules let you tell the voice mail system how to handle your incoming calls. You can set the voice mail system to just answer your incoming calls and record a voice message, or you can set up conditions and actions so that the incoming call will be handled in a different way.

Contents

Call Answering Rules Overview

If your mailbox is enabled for Exchange 2010 Unified Messaging, you can set up to nine call answering rules. These rules are different from the Inbox rules that you set up. By default, no call answering rules have been created for you. All callers will be prompted to leave you a voice message until you set up call answering rules. If you're satisfied with having the voice mail system just answer your incoming calls and record a voice message, you don't have to create any call answering rules. However, if you decide that you want to set up conditions or actions, you can set them up by using the **Call Answering Rules** section on the **Voice Mail** tab in Outlook Web App. Use the **Call Answering Rules** section,

shown below, to create, edit, and delete call answering rules.



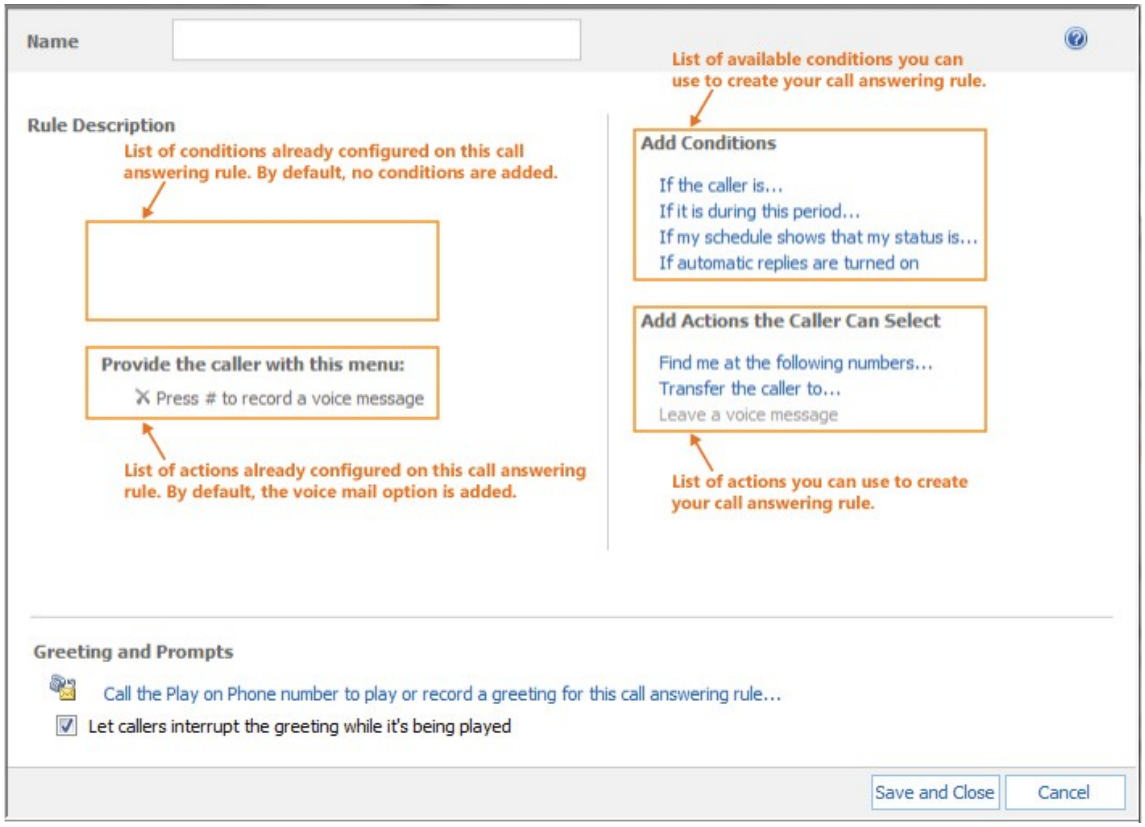
To create a new call answering rule, click New Rule.

Anatomy of a Call Answering Rule

Each call answering rule that you create contains two key parts:

- Conditions – The criteria that must be met before the rule can be applied to an incoming call.
- Actions – The options that should be presented to the caller when all the conditions are met. These actions will be read to the caller over the phone, and the caller can then choose what they want to do using the keypad on their phone.

The following figure shows the form for creating a call answering rule. The form is divided into two columns. The right column displays the list of available conditions and actions you can use to build the rule. The left column displays the list of conditions and actions that have been added to the rule.



Return to top

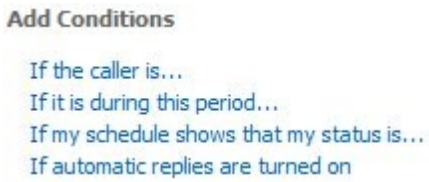
Conditions

Conditions are rules that you can apply to call answering rules. By using a combination of conditions, you can create multiple call answering rules that will trigger when the conditions are met. To create a default rule that will be applied to every call, you create a rule that doesn't contain any conditions.

There are four conditions that can be used when you set up call answering rules, including:

- Caller ID
- Time-of-the-day
- Free/busy status
- Automatic e-mail reply is enabled/disabled

Use one of the following options to add a condition for a call answering rule:



Actions

Actions are used to define what you want to happen when a condition is met. The three kinds of actions are:

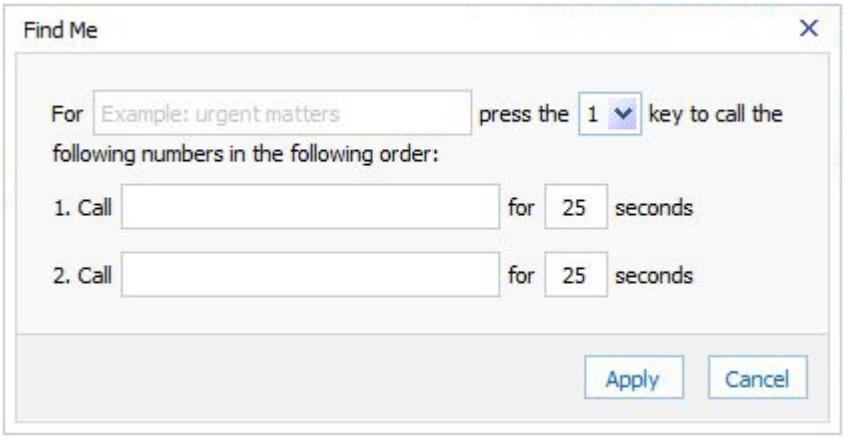
- Find-Me
- Call Transfer
- Leave a Voice Mail

Use one of the following options to add an action for a call answering rule:

Adding a Find-Me Action

When a caller selects Find-Me, the voice mail system will attempt to locate you at up to 2 different phone numbers, and then connect the caller to you if you're available at one of the phone numbers. To add Find-Me to your list of actions, click Find me at the following numbers...

In the Find-Me dialog box, specify the phone numbers and other settings. The settings that are available are listed below:



You can specify text that will be read to the caller. For example, if you enter "Urgent Matters" to inform your callers that they should only select this action if they have important things to discuss with you, the voice mail system will say "For Urgent Matters, press the 1 key."

You have to associate the Find-Me action with the number on the telephone keypad that the caller will have to press to select this action. In the example above, the **1** telephone key is the number callers will press to reach you at one of the phone number or numbers you specify.

Next you have to specify the one or two phone numbers that the voice mail system will dial. If you specify two telephone numbers, the second number will be dialed if you're not available at the first. Each phone number that you specify has an associated duration. The duration is the time period during which the voice mail system will try to dial the phone number before it moves on to the next number. Or, if you can't be contacted, the voice mail system will go back to the options menu.

After you've entered this information, click **Apply** to save the Find-Me settings.

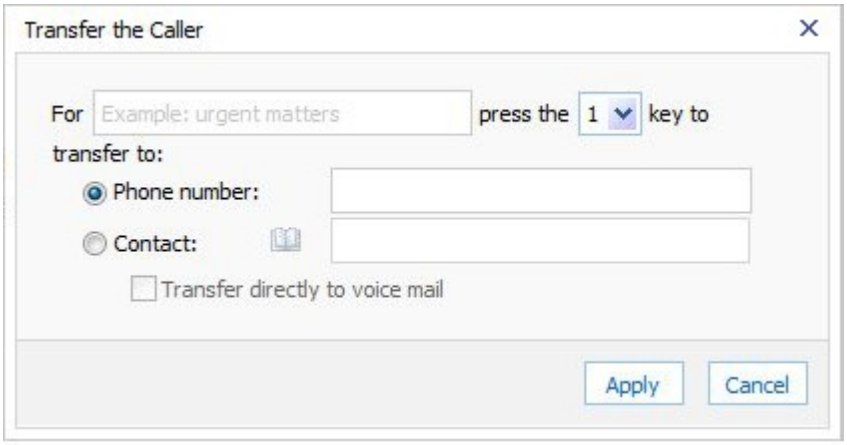
Return to top

Adding Call Transfer Options

By setting a Call Transfer action, you provide callers with the option to be transferred to another person's phone number. To add Call Transfer to your list of actions, click

Transfer the caller to...

There are several options that are available when you want to transfer an incoming call to another phone or Contact. The **Transfer the Caller** dialog box is shown below.



- You can specify text that will be read to the caller. For example, you can enter "Important Matters" to inform your callers that they should choose this option if they have an important matter to discuss and need to speak to someone.
- You have to associate the **Call Transfer** action with the number on the telephone keypad that the caller will have to press to select this action.
- When you choose the Call Transfer action, you have to specify a person or phone number for the caller to be transferred to. You can choose a phone number or select a Contact to be called when the caller presses the correct key on the telephone keypad. If you specify a contact who's within your company directory, the voice mail system will try to transfer the call to the extension number of that contact.
- In addition to specifying a person or number for the caller to be transferred to, you also need to specify the number on the telephone keypad that the caller will have to press to select the Call Transfer action.
- After you've entered this information, click **Apply** to save the Call Transfer settings.

Adding and Removing the Leave a Voice Mail Action

By default, the voice mail option is automatically added to each call answering rule. If you don't want to offer this option, you can remove it by clicking . Press the # key to record a voice message. If you've removed the option for receiving a voice message, you can add it back by clicking the Leave a voice message option.

Return to top

Recording a Personalized Voice Mail Greeting

You can record a custom greeting for each call answering rule you create. By default, Unified Messaging will generate a default greeting based on the actions you've configured. To record a custom greeting, you can click the

Call the Play on Phone number to play or record a greeting for this call answering rule...

in the **Call Answering Rule** window and the voice mail system will call you so you can

record a greeting. In your recording, you should include any actions you've configured on the rule itself. The voice mail system won't list the actions if you've recorded a custom greeting.

You can also allow callers to interrupt your voice mail greeting while it's being played for callers, or prevent them from doing so, by selecting or clearing the

check box.

Saving Your Call Answering Rules

Before you save your rule, you have to give it a meaningful name. After you do this, click **Save and Close** to create the rule. Next, you should test to make sure the call answering rule is working you want it to by trying to call your phone extension and waiting for the call to be answered by Unified Messaging.

1.9.1.3.22.3 Outlook 2007 Features for Exchange Unified Messaging

Outlook 2007 Features for Exchange Unified Messaging

Understanding Unified Messaging > Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-26*

When you enable users for Microsoft Exchange Server 2010 Unified Messaging (UM), users can receive e-mail, voice, and fax messages in their individual Exchange Inbox. This topic discusses the Microsoft Office Outlook 2007 features for Exchange 2010 Unified Messaging that let a UM-enabled user who is using Outlook 2007:

- Play a voice message from Microsoft Windows Media Player, which is integrated into an Outlook mail form, or from a message list.
- Play a voice message on a telephone.
- Configure individual voice mail settings.

Note:

Unified Messaging is only available for Exchange recipients who have mailboxes located on a server that's running Exchange 2010.

Third-Party Unified Messaging Solutions

In the past, with many third-party Unified Messaging solutions, voice mail was received and then stored in a single location. It was retrieved by a user who was using a telephone, or routed to the user's Inbox to be played from an Outlook or Outlook Web App client computer. Even if the Unified Messaging system was using a legacy version of Microsoft Exchange to store the voice mail data, the voice mail system and the client computer weren't closely integrated and therefore didn't provide a seamless voice mail experience for the user.

In voice mail environments such as these, when a user received a voice message, it arrived as an e-mail message with the voice mail message contained inside an attachment. Users had to open an instance of Windows Media Player or another media

player installed on the client computer to play and listen to their voice mail messages. Because the Outlook or Outlook Web App client computer and the third-party Unified Messaging system weren't integrated, in addition to having to open an individual instance of a media player application, users couldn't configure their individual voice mail settings from their e-mail client software. They had to change individual voice mail settings through a different software application or by using their telephone.

Legacy Clients and Exchange

When UM-enabled users use Outlook 2007 or the version of Outlook Web App that's included with Exchange 2010, they are given more voice mail options than Microsoft Exchange recipients who are using legacy versions of Outlook, Outlook Web App, or Exchange. Outlook or Outlook Web App users, or users who connect to a legacy version of Exchange, still receive their voice mail as a standard e-mail sound file attachment (*.wav or *.wma), and no voice mail configuration options are available to them.

Note:

When you use Microsoft Exchange ActiveSync on a mobile phone, you can listen to the attached *.wma file that contains the voice mail message. The advanced Unified Messaging features found in the Outlook Web App client, such as the voice mail configuration options, aren't available in the light version of Outlook Web App.

Caution:

When you use the light version of Outlook Web App and Pocket Internet Explorer on a mobile phone, you may be able to listen to the .wma attachment in a voice message. However, this is not a supported configuration.

Outlook 2007 Features for Exchange Unified Messaging

To offer a seamless voice mail experience for the user, Outlook 2007 and the version of Outlook Web App included with Exchange 2010 offer Exchange 2010 UM-enabled users a full set of voice mail features. These features include many voice mail configuration options, and the ability to play a voice message from either the reading pane using an integrated Windows Media Player or from the message list.

Note:

Users must use a version of Windows Media Player no earlier than Windows Media Player version 7.0 to use the integrated media player and controls. If you are running Outlook 2007 on a computer that's running Windows Server 2008 64-bit Edition, you must install the most recent version of the Windows Media Audio Voice Codec and the Windows Media Encoder. To install the most recent version of the Windows Media Audio Voice Codec, see FIX: Availability of the Windows Media Audio 9 Voice codec for x64-based computers. To install the most recent version of the Windows Media Encoder, see Windows Media Encoder 9 Series x64 Edition.

The Outlook 2007 features for Exchange Unified Messaging are included with the installation of Outlook 2007.After the Outlook 2007 software is installed and the user is UM-enabled, a voice mail tab with voice mail configuration settings will be made available to the user from the **Options** menu.

Note:

The Outlook features for Exchange Unified Messaging are available only with Outlook 2007 and are not available with earlier versions of Outlook.

Using the **Voice Mail** tab, the user can configure settings such as telephone access

numbers and the voice mail Play on Phone number, and can reset a voice mail access PIN.

Note:
The Outlook 2007 **Voice Mail** tab will only be available if the user is enabled for Unified Messaging.

With Outlook features for Exchange Unified Messaging, UM-enabled users can:

- Listen to voice messages without changing their context to another application.
- Configure individual voice mail settings.
- View all their voice mail in one location.
- Distinguish voice and fax messages from e-mail messages within their individual Inboxes using new icons. This includes unique notifications for new e-mail, voice, and fax messages.
- Determine whether a voice message has already been played.
- Add annotations to a voice mail message in a text box.
- Reply to a voice message with e-mail when the sender's contact information is known.
- Add received phone numbers to Contacts using the shortcut menu.

Note:
The Outlook features for Exchange Unified Messaging are included when you install Outlook 2007. However, the settings for the Unified Messaging features are maintained per user and not per computer.

The topics in the following list introduce and more fully discuss the Unified Messaging features found in Outlook 2007 and in Outlook Live in Exchange 2010:

- Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Form
- Outlook 2007 Features for Exchange Unified Messaging: Play on Phone
- Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Options

For More Information

- For more information about Exchange 2010 Unified Messaging, see Unified Messaging.
- For more information about how to enable users for Unified Messaging, see Enable a User for Unified Messaging.
- For more information about Outlook Live in Exchange 2010, see Managing Outlook Web App

Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Form

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-01*

This topic discusses the Outlook features for Microsoft Exchange Server 2010 Unified Messaging (UM) available with Microsoft Office Outlook 2007. Using the Outlook features for Exchange Unified Messaging, a UM-enabled user who is using Outlook 2007 can play a voice mail message from Microsoft Windows Media Player using an Outlook voice mail

form. After a voice message is received and opened, a voice mail form will be used. Other message types with voice attachments, for example, calendar replies, are treated as standard items and use default Outlook forms.

Contents

Voice Mail Form

The Outlook 2007 voice mail form resembles the default e-mail form, but gives users an interface for performing actions such as playing, stopping, or pausing voice messages, playing voice messages on a telephone, and adding and editing notes.

The voice mail form includes the embedded Windows Media Player and a notes field. The embedded Windows Media Player and notes field are displayed in either the preview pane when previewing a voice message or in a separate window when the voice message is opened by the user. If users aren't enabled for Unified Messaging or Outlook 2007 hasn't been installed on the client computer, users receive voice messages only as attachments, and the voice mail form isn't available.

Note:

To use the Windows Media Player in the voice mail form, users must use a version of Windows Media Player no earlier than Windows Media Player version 7.0. If the appropriate version of Windows Media Player isn't installed, the player won't be rendered in the form, but other Unified Messaging features will be available on the client computer.

Important:

If you're running Outlook 2007 on a computer running Windows Server 2008 64-bit Edition, you need to install the most recent version of the Windows Media Audio Voice codec and the Windows Media Encoder. To install the most recent version of the Windows Media Audio Voice codec, see FIX: Availability of the Windows Media Audio 9 voice codec for x64-based computers. To install the most recent version of the Windows Media Encoder, see Windows Media Encoder 9 Series x64 Edition.

Voice Mail Form Options

The following three options are available in the voice mail form options:

- **Play** Users can play and listen to voice messages using computer speakers or headphones. After **Play** is clicked, the Windows Media Player goes into play mode.
- **Play on Phone** Users send a request to the Unified Messaging server to play the selected voice message on the user's phone or send the voice message to another telephone number specified by the user. After **Play on Phone** is clicked, the **Play on Phone** dialog box appears so that the user can configure and control the Play on Phone operation.
- **Edit Notes** The user opens the voice message and can add or edit notes or comments in the **Notes** field.

Outlook 2007 Features for Exchange Unified Messaging: Play on Phone

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

After a voice mail message arrives, users can choose either to listen to the voice mail message through their computer speakers or headphones or to use the Play on Phone feature. The Play on Phone feature is included with the Outlook features for Microsoft Exchange Server 2010 Unified Messaging (UM) in Microsoft Office Outlook 2007. This topic discusses how a UM-enabled user can use the Play on Phone feature provided by Exchange 2010.

What Is Play on Phone?

The Play on Phone feature lets UM-enabled users play voice messages over a telephone. If a UM-enabled user works in an office cubicle, is using a public computer or a computer that isn't enabled for multimedia, or is listening to a voice message that's confidential, the user might not want to or be able to listen to a voice message through computer speakers. Alternatively, the user can play back the voice mail message using any telephone, including home, office, or mobile telephones.

The Play on Phone feature is available in Outlook 2007 and also in Exchange 2010 Outlook Web App.

When the user clicks the **Play on Phone** toolbar option in the Outlook 2007 voice mail form, the **Play on Phone** dialog box appears. The **Play on Phone** dialog box provides the controls for selecting or inputting the telephone number to use to play a voice message, for starting and ending the call, and for displaying a status message for monitoring the call.

Note:

Only one voice message can be played at one time. If the user tries to start a second Play on Phone call while a previous call is still in progress, an error message will appear.

Most Recently Used Telephone Number List

Users can see a list of telephone numbers they used most recently in the **Play on Phone** dialog box. The telephone number specified on the **Voice Mail** tab is always displayed as the top entry and is automatically selected for the user as the primary number. Users can use the menu options to select other telephone numbers to dial instead of the telephone number configured as the primary number.

Note:

To enable users who are using the Play on Phone feature to dial an external telephone number without using an outside line access code, for example 425-555-0123 instead of 9-425-555-0123, configure in-country/region dialing rules on a UM dial plan that include the following line: group1, 9xxxxxxxxxx, 91xxxxxxxxxx. After you configure the in-country/region dialing rules, add this list to the UM mailbox policy.

Play on Phone Buttons

The **Play on Phone** dialog box gives users the option to **Dial** and **Hang-up**. When the **Play on Phone** dialog box is first opened, the **Dial** button is enabled and the **Hang-up** button is disabled. After a call is placed, the **Dial** button becomes disabled until the call has ended. The call can be ended either by clicking the **Hang-up** button or by physically hanging up the telephone. Closing the **Play on Phone** dialog box using the **Close** button ends the call if one is in progress.

Subject, Sent, and Status Field

The bottom section of the **Play on Phone** dialog box displays the subject of the voice message, the date and time sent, and a message that displays the current state of the call. Any errors specific to the Play on Phone operation are displayed to the user in this section of the **Play on Phone** dialog box.

Phone Number Validation

Play on Phone only performs simple validation on your input into the **Play on Phone** dialog box. Play on Phone doesn't validate telephone numbers. If a telephone number isn't valid, the Microsoft Exchange Unified Messaging service returns a meaningful error code to the user.

For More Information

- For more information about the Outlook features for Exchange Unified Messaging, see Outlook 2007 Features for Exchange Unified Messaging.
- For more information about the Unified Messaging voice mail form, see Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Form.
- For more information about how to configure Unified Messaging voice mail options, see Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Options.

Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Options

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

A user who is enabled for Microsoft Exchange Server 2010 Unified Messaging (UM) can configure several voice mail options in the Outlook features for Exchange Unified Messaging available with Microsoft Office Outlook 2007. This topic discusses the Outlook 2007 Unified Messaging features that let a UM-enabled user who is using Outlook 2007 select and configure available voice mail options.

Note:

The voice mail configuration options on the **Voice Mail** tab in Outlook 2007 appear dimmed if a Unified Messaging server cannot be located on the network. These voice mail options are also unavailable if the user's mailbox is located on a server running an earlier version of Microsoft Exchange.

Note:
When you log on to a computer joined to a domain and you access the **Voice Mail** tab in Outlook 2007, you may be prompted to enter your credentials. This occurs because the default security settings in Microsoft Internet Explorer are configured to allow an automatic logon only for Web sites listed in the **Local intranet** zone. To correct this issue, add the fully qualified domain name (FQDN) of the Client Access server to the **Local intranet** zone or configure the user authentication to use an automatic logon using the current user credentials in Internet Explorer.

Telephone Access

Using the options in the **Telephone Access** section on the **Voice Mail** tab, users can set telephone access numbers, reset their voice mail PIN, and select the e-mail folder that they will access when they use Outlook Voice Access.

Telephone Access Numbers

The **Telephone Access Numbers** box specifies the telephone number or telephone numbers that users can dial to access their messages, calendar, and contacts using Outlook Voice Access. The numbers in this box are referred to as subscriber access numbers, pilot ID numbers, pilot IDs, or pilot numbers, and are configured on a UM dial plan. The telephone access numbers listed in this box are configured in the **Telephone access numbers** section on the **Subscriber Access** tab of a UM dial plan. These telephone numbers apply to all users who are members of the UM dial plan. For more information about how to configure a UM dial plan, see View or Configure the Properties of a UM Dial Plan.

Resetting Voice Mail PIN

The **Reset PIN** button lets users reset their voice mail PIN. The PIN is used to access their mailbox and calendar information.

Selecting an E-Mail Folder

The **Choose the folder to read when accessing e-mail messages from a phone** option lets users specify which e-mail folder to read e-mail, voice mail, or other messages from, when they use Outlook Voice Access. The **Change Folder** button lets users select which mailbox folder will be read. By default, the Inbox is selected as the folder to use when users access messages from a telephone using Outlook Voice Access.

Voice Mail

Users can configure several voice mail options in the **Voice Mail** section of the **Voice Mail** tab. These options include the Play on Phone telephone number and voice mail greetings.

Play on Phone Number

The telephone number in the **Play on Phone number** box determines the telephone number that the Unified Messaging system calls when the user is using the Play on Phone feature. By default, the telephone number is set to the user's extension number, but can be changed by the user.

Voice Mail Greetings

Users can use the **Choose the greeting played to callers when leaving a message** option on the **Voice Mail** tab to select the type of greeting that callers hear when they reach the user's voice mail.

- **Voice-mail greeting** is the default selection and is the regular voice mail greeting. It's the greeting used when the user is in the office but away from the desk for a short time.
- The **Out of Office voice mail greeting** is generally used when a user is not in the office or is away for an extended time.

Play or Record a Greeting on Your Telephone

Clicking the **Call** button calls the Play on Phone number and plays the greeting to users on their telephone. Users can also use this option to play or record a new greeting from a telephone.

Missed Call Notifications

Users can specify whether they want to receive missed call notification messages from the Exchange 2010 Unified Messaging server using the **Send an e-mail to my Inbox when I miss a phone call** check box. When this box is selected, users receive notifications when callers try to contact them but do not leave voice messages. By default, the **Send an e-mail to my Inbox when I miss a phone call** box is selected.

Note:
For many of the voice mail options included in Outlook 2007 and Exchange 2010 Outlook Web App to function correctly, the Client Access server role must be installed on a computer running Exchange 2010, and Autodiscover must be configured correctly.

Voice Mail Shortcut Keys

There are keyboard shortcuts to help users configure or select voice mail options. The following table lists the keyboard shortcuts available for voice mail options.

To do this	Press
Reset the telephone access PIN	ALT+R
Select the e-mail folder to read when you use Outlook Voice Access	ALT+F
Enter the Play on Phone number	ALT+P
Select the voice mail greeting	ALT+V
Select the Out of Office greeting	ALT+O
Dial the number to play or record a greeting on the telephone	ALT+D
Enable or disable Missed Call Notifications	ALT+S

For More Information

- For more information about the Unified Messaging voice mail form, see Outlook 2007 Features for Exchange Unified Messaging: Voice Mail Form.
- For more information about the Unified Messaging Play on Phone feature, see Outlook 2007 Features for Exchange Unified Messaging: Play on Phone.
- For more information about Outlook features for Exchange Unified Messaging, see Outlook 2007 Features for Exchange Unified Messaging.

Outlook 2010 and Outlook Web App Features in Unified Messaging

Understanding Unified Messaging > Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

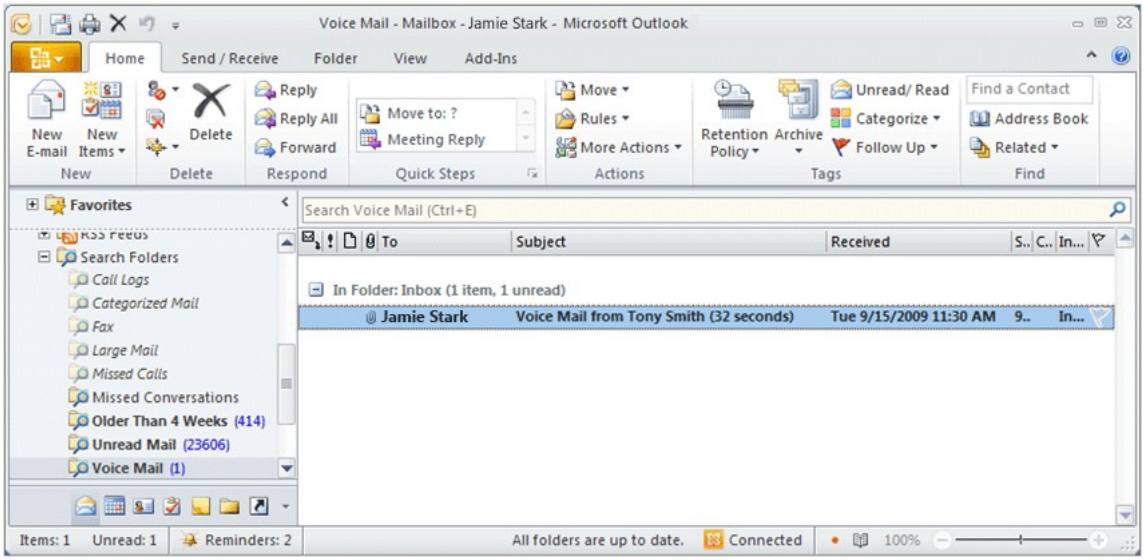
Topic Last Modified: *2010-04-15*

When you enable users for Microsoft Exchange Server 2010 Unified Messaging (UM), users can receive e-mail, voice mail, and fax messages in their individual Exchange Inbox. This topic discusses the Microsoft Outlook 2010 features for Exchange 2010 Unified Messaging that let a UM-enabled user who's using Outlook 2010 do the following:

- See the transcription for voice messages.
- Play a voice message from Windows Media Player, which is integrated into an Outlook mail form, or from a message list.
- Play a voice message on a telephone.
- Configure individual voice mail settings.
- Reply to a voice message with e-mail when the sender's contact information is known.
- Add received phone numbers to Contacts using the shortcut menu.

To offer a seamless voice mail experience for the user, Outlook 2010 and Microsoft Office Outlook Web App in Exchange 2010 offer Exchange 2010 UM-enabled users a full set of voice mail features. These features include many voice mail configuration options, Voice Mail Preview, and the ability to play a voice message from either the Reading Pane using an integrated Windows Media Player or from the message list.

- The Outlook 2010 features for Exchange Unified Messaging are installed with Outlook 2010. After Outlook 2010 is installed and a user is enabled for Unified Messaging, a Voice Mail tab with voice mail configuration settings is available to the user from the **Options** menu and they can receive their voice mail in their mailbox.
- When the UM-enabled user receives a voice message, the voice message will be sent to the **Voice Mail** search folder in their Outlook 2010 **Search Folders**. The following screenshot shows a new voice message that's been sent to the **Voice Mail** search folder:



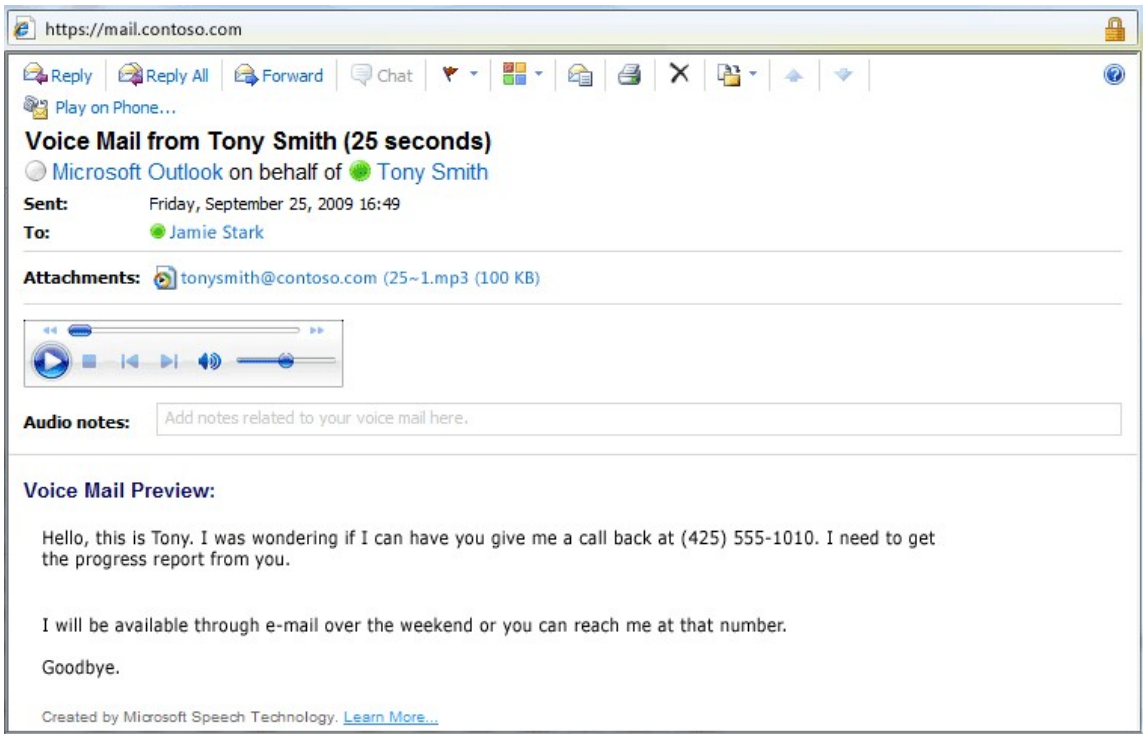
Voice Mail Message Form and Voice Mail Preview

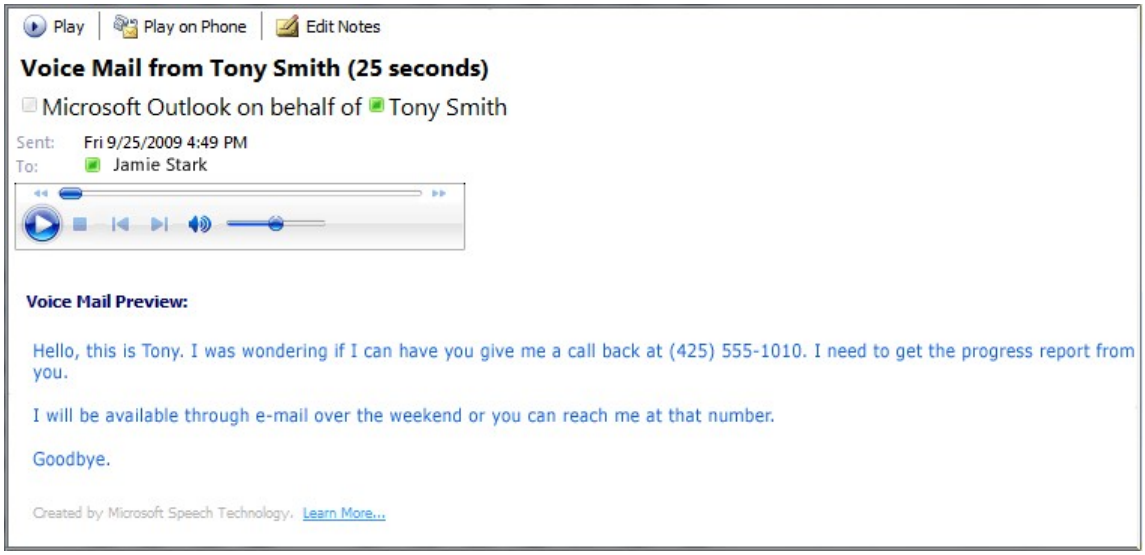
The Outlook 2010 and Outlook Web App voice mail form resembles the default e-mail form, but gives users an interface for performing actions such as playing, stopping, or pausing voice messages, playing voice messages on a telephone, and adding and editing notes.

The voice mail form includes the embedded Windows Media Player and a notes field. The embedded Windows Media Player and notes field are displayed in either the Reading Pane when the user previews a voice message or in a separate window when they open a voice message. If users aren't enabled for Unified Messaging, they won't receive voice mail in their mailbox. Or, if they don't have Outlook 2010 installed, they'll receive voice messages only as attachments, and the voice mail form won't be available.

Voice Mail Form Options

The voice mail form options are available when a user accesses their voice mail using Outlook Web App or Outlook 2010. The following screenshots show the voice mail form in Outlook Web App and Outlook 2010.





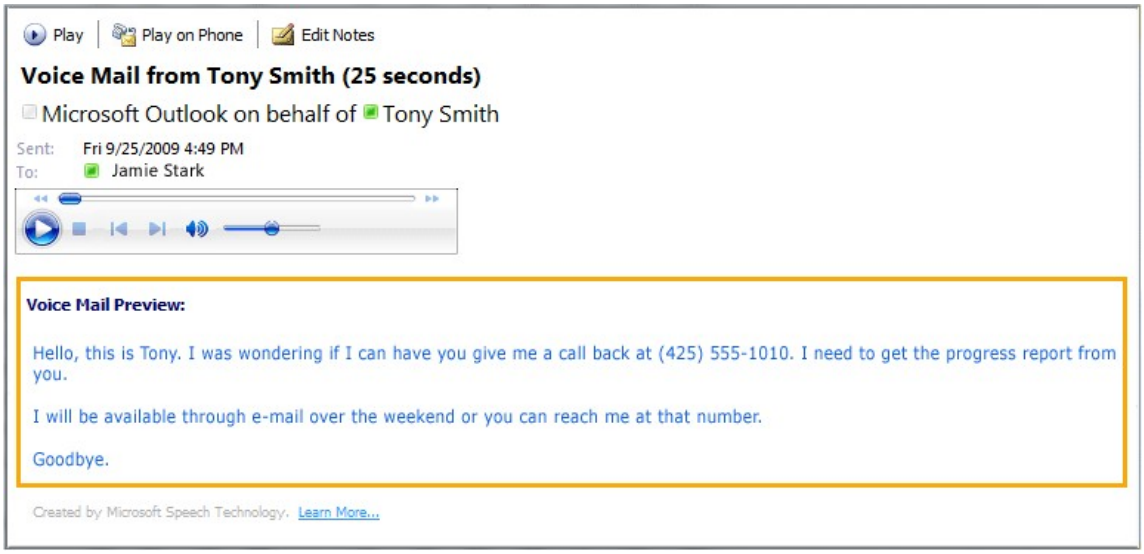
In both Outlook Web App and Outlook 2010, the following three options are available in the voice mail form:

- **Windows Media Player Controls** Users can play and listen to voice messages using computer speakers or headphones. After **Play** is clicked, the Windows Media Player goes into play mode.
- **Play on Phone** Users send a request to the Unified Messaging server to play a selected voice message on their phone or send the voice message to another telephone number they specify. After **Play on Phone** is clicked, the **Play on Phone** dialog box appears so that the user can configure and control the Play on Phone operation.
- **Voice Mail Preview** The user can view the text transcription of the actual voice mail message that was left by a caller.
- **Audio Notes** The user opens the voice message and can add or edit notes or comments in the **Audio notes** field.

Return to top

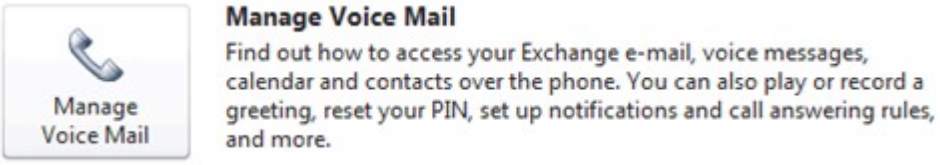
Voice Mail Preview

When users receive a voice mail, they receive a message that contains not just a recording, but also text that's been created from the voice recording. Users see the voice mail text displayed in the e-mail message within Outlook Web App or in the next version of Outlook. The following screenshot shows an example of a voice mail preview for a voice message:



Voice Mail Settings

After a user has been enabled for voice mail access, they can change settings for Call Answering Rules, Outlook Voice Access, text message and e-mail notifications, and Voice Mail Preview. They can click the button shown next to the **Manage Voice Mail** option in the following figure to view and set up their voice mail settings.



Call Answering Rules

Using the options in the **Call Answering Rules** section, users can create rules that specify how they want incoming calls to be handled. They can set up call answering rules to handle calls based on a condition such as the time of the day, transfer an incoming call to another phone number, or use the Find Me feature to call other phone numbers that they set up.

If they don't create call answering rules, incoming callers will be sent directly to their voice mail.

New Rule	• The **New Rule** button is used to add a new call answering rule. By default, no rules are set up, so all callers will be forwarded to their voice mail when they're not available.
Edit...	• The **Edit** button is used to change an existing call answering rule.
Delete	• The **Delete** button is used to remove an existing call answering rule.
	• This arrow is used to move a call answering rule up in the processing order.
	• This arrow is used to move a call

	answering rule down in the processing order.

Reset PIN

You can use this option to reset your Outlook Voice Access PIN.

Reset my Voice Mail PIN...	• Use this setting to reset your voice mail PIN. After you do this, you'll receive a new temporary PIN in your Inbox. You use your PIN to access your mailbox and calendar information.

Outlook Voice Access

Using the options in the **Outlook Voice Access** section on the **Voice Mail** tab, you can set telephone access numbers, reset your voice mail PIN, and select the e-mail folder that you'll access when you use Outlook Voice Access.

You can access your new voice messages in the order of your prefer. (•) From newest to oldest ( ) From oldest to newest	• You can access your new voice messages in the order in which you want to hear them read. This option lets you play unread voice messages from the newest to the oldest or from the oldest to the newest.
Read this folder: Inbox	• Use this setting to select which e-mail folder to read e-mail, voice mail, or other messages from when you use Outlook Voice Access • If you want Outlook Voice Access to read from a different folder than the one that's currently specified, click the name of the folder next to **Read this folder**. Then, in the **Select Folder** window, select the folder you want from the list. Or, you can click **Create New Folder** to create a different folder for Outlook Voice Access to read from. After you've

	selected the correct folder, click **OK**.

Greetings

You can choose which greeting will be played to callers when you're not available or you don't answer your phone. To record a greeting, call the Play on Phone number.

Default voice mail greeting	• Use this setting to select the default voice mail greeting to use when you don't answer your phone.
Inform callers that you will be away for an extended period of time	• Use this setting to select a voice mail greeting that lets people know you're away for an extended period of time. For example, you would use this setting when you're on vacation or away on business.
Call me to play or record the selected greeting...	• Use this setting to call the Play on Phone number and play the default voice mail greeting or the greeting you use when you'll be away for an extended period of time to you over a phone. • You can use this setting to play or record a new greeting from a telephone.

Play on Phone

Use Play on Phone to have the voice mail system call you at the number that you define in this box.

The voice mail system calls this number when you click the Play on Phone button to listen to a voice message. 11111	• The telephone number you add in this box determines the telephone number that the voice mail system calls when you use Play on Phone and click **Call me on my Play on Phone number to play or record the selected greeting**. • By default, this telephone number is your extension number, but you can change it.

	• If this box contains something other than a phone or extension number, such as an e-mail address, the call will be sent to you where you're signed in.

Return to top

Notifications

Users can receive notifications about missed calls and voice messages on their mobile or office phone. They can receive an e-mail notification when someone calls them on their office or mobile phone but doesn't leave a voice message. They can also receive a text message notification to alert them when they miss a phone call or receive a voice message on their mobile phone.

The following settings allow users to set up notifications for missed calls and voice mail messages they receive:

	• If this check box is selected, the user will receive an e-mail notification in their Inbox when a caller tries to contact them but doesn't leave a voice message. • In most cases, the user will also see a missed call notification on their mobile phone from their mobile phone provider. • By default, this box is selected.
	• When a user selects this option button, they won't receive a text message notification on their mobile phone when they miss a call or receive a voice message. • In most cases, they'll see a missed call notification on their mobile phone from their mobile phone provider, but they won't see a notification on their mobile phone that they have a voice message. • By default, the option to receive text message notifications isn't available until a user sets up text message notifications. They can set up text message notifications by clicking the **Set up notifications** link and following the

	required steps.
I only want to receive text message notifications when I have voice messages	• When a user selects this option button, they'll receive text message notifications on their mobile phone when they have a voice message but won't receive missed call notifications. • In most cases, they'll see a missed call notification on their mobile phone from their mobile service provider, but they won't see a notification from their mobile phone provider that they have a voice message. • By default, this option isn't available until the user sets up text message notifications. They can set up text message notifications by clicking the **Set up notifications** link and following the required steps.
I want to receive text message notifications about missed calls and voice messages	• When a user selects this option button, they'll receive missed call and voice message notifications in a text message on their mobile phone. • In most cases, they'll also see a missed call notification and a voice mail notification on their mobile phone from their mobile service provider. • By default, this option isn't available until the user sets up text message notifications. They can set up text message notifications by clicking the **Set up notifications** link and following the required steps.

Return to top

Voice Mail Preview

Users can preview the text of voice messages they receive. They can also have text previews included with voice messages they send. To turn on Voice Mail Preview, they select from the following options. Users can use the settings in the Voice Mail Preview section to turn on or turn off voice mail previews or to allow preview text to be sent using

Outlook Voice Access.

☑ Include preview text with voice messages I receive.	• When this check box is selected, the user will receive a text preview of the voice messages they receive in an e-mail message. • By default, this box is selected.
☑ Include preview text with voice messages I send through Outlook Voice Access	• When this check box is selected, a text preview will be sent along with voice messages that the user sends. • By default, this box is selected.

1.9.1.3.22.5 Voice Mail Preview for End Users

Voice Mail Preview for End Users

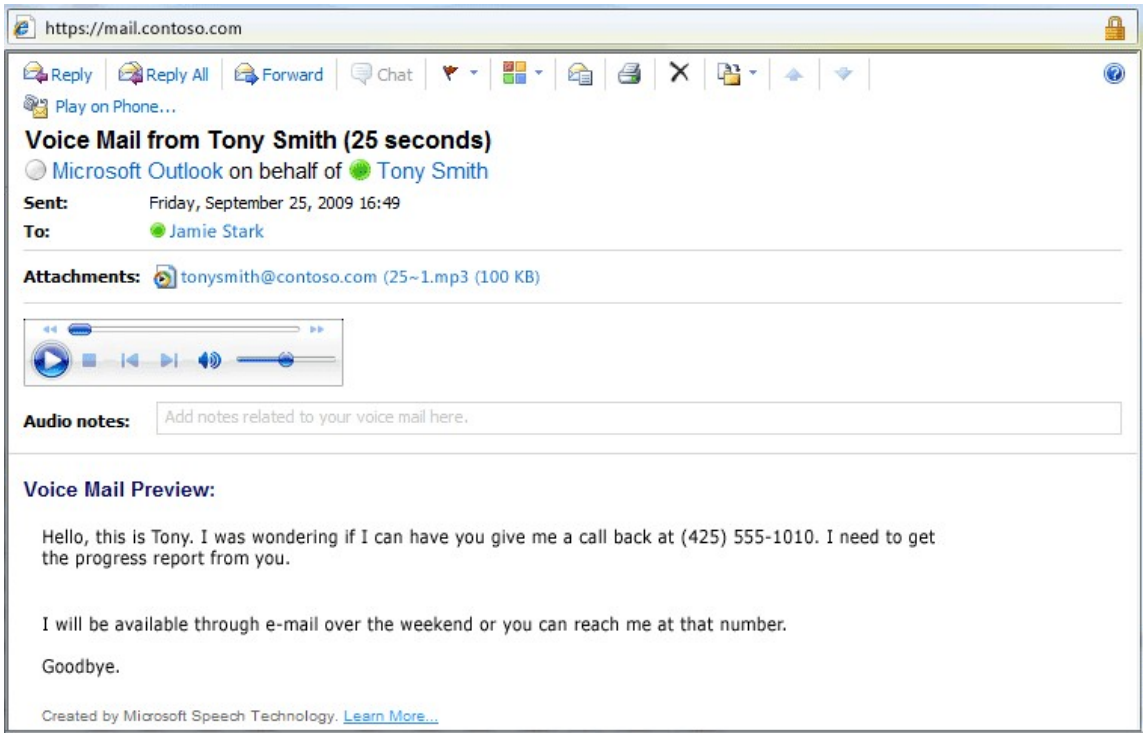
Understanding Unified Messaging > Understanding Unified Messaging Features > Understanding Client Features in Unified Messaging >

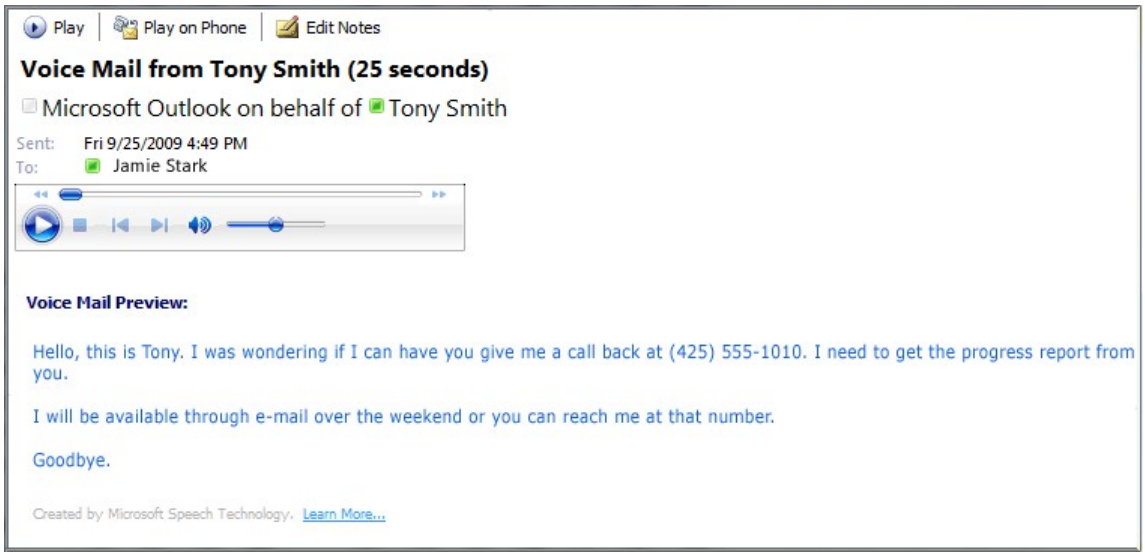
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-17*

Voice Mail Preview is a feature that's available to users who receive their voice mail messages from Microsoft Exchange Server 2010 Unified Messaging (UM). Voice Mail Preview enhances the existing UM voice mail functionality by providing a text version of audio recordings. The voice mail text is displayed in e-mail messages within Microsoft Office Outlook Web App, Outlook 2010, and in other e-mail programs. For more information, see Microsoft Speech Technologies.

The following examples show how Voice Mail Preview is displayed in Outlook Web App and Outlook 2010:





Do users need to use a specific e-mail program?

No. Voice Mail Preview is included in the message body text of any e-mail program, including mobile programs. Although users can use other e-mail programs to receive voice messages, Outlook and Outlook Web App provide a better experience. For example, in Outlook 2010, when a specific word is clicked in the Voice Mail Preview text, the audio playback of the voice message will start to play at that word. This is useful for listening to a specific part of a voice message.

Can users search for specific voice mail messages?

Yes. Words and phrases in the Voice Mail Preview text are automatically indexed, so voice messages will appear in search results. In Microsoft Office Outlook 2007 or later versions or in Outlook Web App in Exchange 2010, users can also use the **Audio Notes** field to add text about a voice message. These notes are also included in searches, to make it easier to locate a message.

Why is this feature called 'Voice Mail Preview'?

It’s important to set users’ expectations correctly. Voice Mail Preview doesn't necessarily produce text that’s the same as what callers say in their voice messages. In fact, it's usually inaccurate in some way. To call it transcription would suggest a more perfect result can generally be achieved. Preview suggests that the reader should be able to gain an idea of the voice content, which is closer to the real capability of the feature.

What makes the Voice Mail Preview text more or less accurate?

The accuracy of the Voice Mail Preview text is controlled by many factors and sometimes those factors can't be controlled. However, Voice Mail Preview text is likely to be more accurate when:

- The caller leaves a simple voice message that doesn't include slang terms, technical jargon, or unusual words or phrases.
- The caller uses a language that's easily recognized and translated by the voice mail system. Generally, voice messages left by callers who don't speak too quickly or too softly and who don't have strong accents will produce more accurate sentences and phrases.
- The voice message is free of background noise, echo, and the audio doesn't drop-out.

Which languages can be used with Voice Mail Preview?

Voice Mail Preview text is available in the following languages:

- English (US) (en-US)
- English (Canada) (en-CA)
- French (France) (fr-FR)
- Italian (it-IT)
- Polish (pl-PL)
- Portuguese (Portugal) (pt-PT)
- Spanish (Spain) (es-ES)

You can download the Exchange 2010 UM language packs from the Microsoft Download Center.

After you install a UM language pack on a UM server, the dial plans and auto attendants can be configured to use the language you've chosen. Many companies have only one UM dial plan. UM will try to create a voice mail preview in the default dial plan language, but

the default language must support Voice Mail Preview. A UM dial plan can only be configured to create voice mail previews in one language at a time.

To configure UM to provide voice mail previews in a language other than en-US, follow these steps:

1. Verify that Voice Mail Preview is supported in the language you want to use.
2. If so, download and install the appropriate UM language pack on each UM server that's associated with the dial plan. Downloading and installing the language pack doesn't configure the dial plan default language.
3. Configure the dial plan with the language that will be used for Voice Mail Preview. For more information, see Configure the Default Language on a UM Dial Plan.

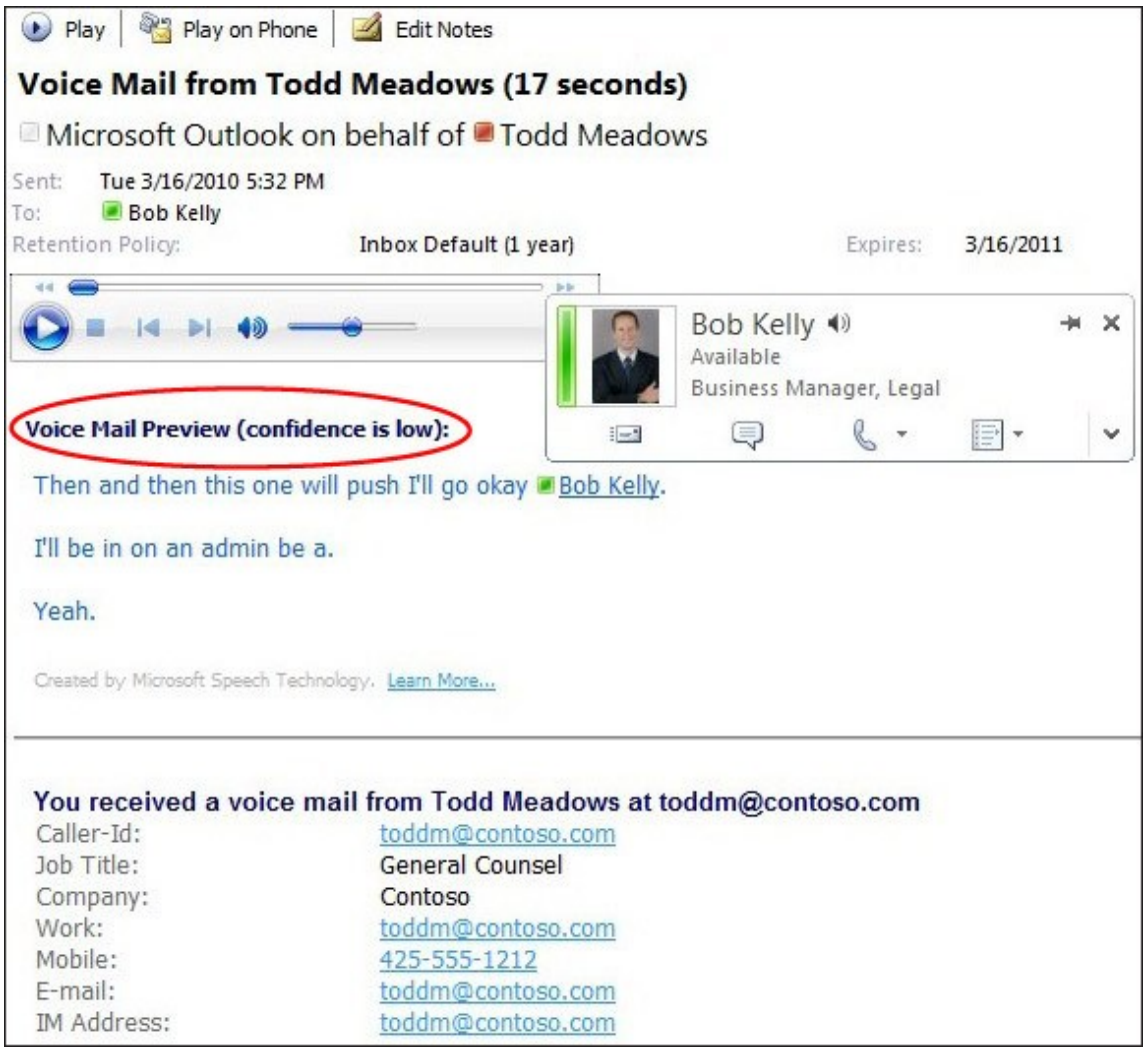
- How Voice Mail Preview displays text in the supported languages depends on the type of voice message that's sent. There are two types:
- **Voice messages that are recorded when the called party doesn't answer their phone**
  In this scenario, the language used for Voice Mail Preview is determined by the caller's spoken language and whether the language is supported. For example, if a caller leaves a voice message in Italian, the Voice Mail Preview text will appear in Italian if Italian has been configured on the dial plan. However, if a caller leaves a message in Japanese, no Voice Mail Preview text will be included with the message because Japanese isn't available.
- **Voice messages that are sent to by an Outlook Voice Access user**
  The language that's used for voice mail preview of messages sent by an Outlook Voice Access user is controlled by the voice mail administrator. Thus, the language used for Voice Mail Preview text will be in the same language of the voice mail system. However, if a caller speaking a language that's not supported for Voice Mail Preview uses Outlook Voice Access to leave a message, no Voice Mail Preview text will be included with the message. To learn more about Outlook Voice Access, see Understanding Outlook Voice Access.

For more information about UM language packs, see Understanding Unified Messaging Languages and Client Language Support for Unified Messaging.

Does the voice mail system know when a voice mail preview is inaccurate?

The voice mail system determines a confidence level for each voice mail preview included with a voice message. The voice mail system measures how well the sounds in the recording matched with words, numbers, and phrases. If the system was able to find matches easily, the confidence level will be high. A higher level of confidence is generally associated with a higher accuracy.

If the confidence level is determined to be lower than a certain value, the voice mail system includes the phrase **Voice Mail Preview (confidence is low)** above the Voice Mail Preview text. If the confidence level is low, it's likely that the Voice Mail Preview text will be inaccurate. The following is an example of a low confidence voice mail preview.



Unified Messaging uses Automatic Speech Recognition (ASR) to calculate its confidence in the preview, but it has no way to decide which words are wrong and which are correct.

However, the system does try to learn to improve accuracy of its voice mail previews. For example, Exchange 2010 Unified Messaging tries to match the caller's telephone number (if provided) with the user's personal Contacts and Active Directory. If the UM finds a match, it will include the name of the caller, along with its standard lists of names and words, when running ASR on the voice recording.

Can Voice Mail Preview be used if it isn't completely accurate?

Users may have a better experience with Voice Mail Preview if they don't try to read the preview too carefully, word by word. Instead, they should look for names, phone numbers, and phrases such as "Call me back" or "I need to talk" that may provide clues about the purpose of the call.

Voice Mail Preview isn't expected to dictate messages exactly, but it can help users answer questions such as the following:

- Is this voice message related to my work?
- Is this voice message important to me?
- Did the caller leave a number? Is it different from any numbers that I may have listed for them?
- Does the caller consider this voice message urgent?

- Should I step out of a meeting to call this person back?
- I was expecting a call to confirm my request. Is this the confirmation call?

Can Voice Mail Preview be turned on or off?

Yes. If you've enabled Voice Mail Preview, users can turn it on or off using Outlook 2010 or Outlook Web App. However, the dial plan language must support Voice Mail Preview and the UM language pack for that language must be installed.

Although Voice Mail Preview settings are the same whether a user is using Outlook 2010 or Outlook Web App, they'll access them differently:

Outlook 2010

To access the Voice Mail Preview settings in Outlook 2010, on the **File** tab, they click **Manage Voice Mail**.

Manage Voice Mail
Find out how to access your Exchange e-mail, voice messages, calendar and contacts over the phone. You can also play or record a greeting, reset your PIN, set up notifications and call answering rules, and more.

Outlook Web App

To access the Voice Mail Preview settings in Outlook Web App, they click **Options** > Go to **Options** > **Phone** > **Voice Mail**. On the **Voice Mail** tab, the following settings are available in the **Voice Mail Preview** window.

☑ Include preview text with voice messages I receive.	When this check box is selected, the user will see a text preview of the voice messages they receive. By default, this box is selected.
☑ Include preview text with voice messages I send through Outlook Voice Access	When this check box is selected, a text preview will be sent along with voice messages that the user sends. By default, this box is selected.

By default, both Voice Mail Preview options are enabled when a user is enabled for Unified Messaging. If the UM dial plan is configured to use a UM language pack that supports Voice Mail Preview, a UM server will create voice mail previews for users when:

- A caller leaves a voice mail message because the called party doesn't answer their phone.
- A UM-enabled user signs in to Outlook Voice Access and records a voice message to one or more recipients.

When a caller leaves a voice message, and **Include preview text with voice messages I receive** is enabled, the UM server will create a voice mail preview in the e-mail message, attach the audio file, and send it to the recipient's mailbox. You may want to disable this option if the language that's configured on the dial plan doesn’t include Voice Mail Preview support and you don't want voice mail previews included in voice mail messages.

When users sign in to Outlook Voice Access and they send a voice message to another

user, they may want to disable the **Include preview text with voice messages I receive through Outlook Voice Access** option. For example, they might want to do this it if they're sending voice messages in a language that Voice Mail Preview doesn't support or if they don't want to include the voice mail preview with the voice message because it's too long.

1.9.1.4 Understanding Unified Messaging Call Processing

Understanding Unified Messaging Call Processing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Call processing is a term that describes how incoming calls are answered and handled by a Microsoft Exchange Server 2010 Unified Messaging server in different incoming call scenarios.

Unified Messaging handles the following sorts of incoming calls:

- Voice
- Outlook Voice Access
- Play on Phone
- Auto attendant

Incoming Calls Overview

When an incoming call is received by a Unified Messaging server, the call is answered and then routed using a message transport, for example, SMTP, MAPI, remote procedure call (RPC), or LDAP. The message transport protocol used to route messages depends on the type of incoming call the Unified Messaging server answers.

Unified Messaging depends on the Active Directory directory service to route incoming calls. Each UM-enabled recipient must have a telephone extension number listed in Active Directory for call answering to function correctly. The extension number for the recipient is listed in Active Directory and is mapped to the extension number that's configured on the user's UM-enabled Exchange mailbox. When a Unified Messaging server answers a call, an Active Directory lookup is performed to locate the appropriate UM-enabled recipient and the message is routed to the recipient's mailbox.

Message Flow

Message flow in Unified Messaging is the process by which a message received by a Unified Messaging server is routed in an Exchange 2010 organization.

Note:

In earlier versions of Exchange, routing groups were used to route messages between bridgehead servers—known in Exchange 2007 and Exchange 2010 as Hub Transport servers. There are no routing groups in Exchange 2010.

For example, in an incoming call scenario that includes incoming voice messages, a Hub Transport server uses the SMTP transport protocol to submit the voice mail message to the Mailbox server. In a routing scenario that includes multiple Hub Transport servers, the incoming voice mail message is first submitted to the closest Hub Transport server and is

then routed to the Mailbox server that contains the UM-enabled mailbox.

Note:
The Unified Messaging servers use a spooling or retry algorithm to make sure all incoming messages are transmitted and delivered to UM-enabled recipients. They try to connect to a Hub Transport server every 30 seconds to submit all messages stored on the Unified Messaging server.

For more information about how the Unified Messaging server handles incoming calls and how messages flow in Unified Messaging, see the following topics:

- Unified Messaging Voice Call Processing
- Unified Messaging Outlook Voice Access Call Processing
- Unified Messaging Auto Attendant Call Processing
- Unified Messaging Play on Phone Call Processing

1.9.1.4.1 Unified Messaging Voice Call Processing

Unified Messaging Voice Call Processing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

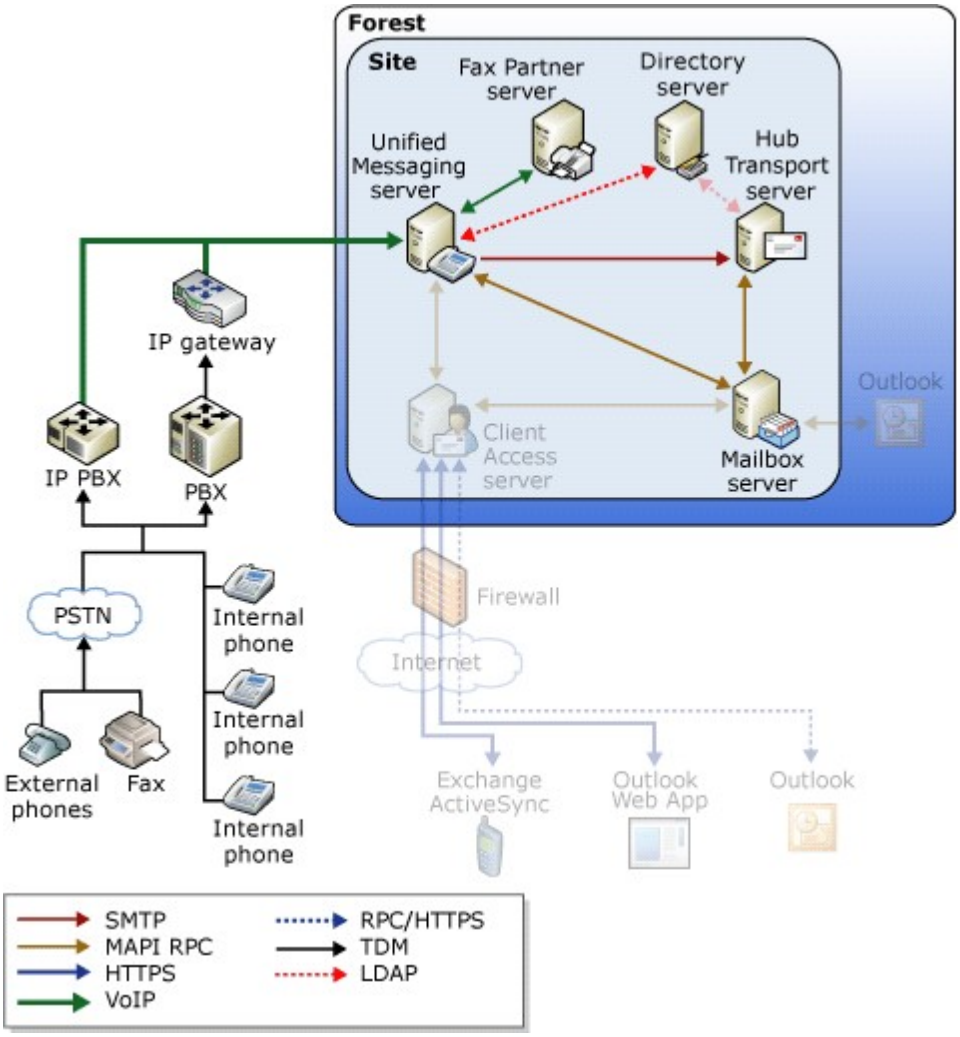
Topic Last Modified: *2011-04-28*

Incoming voice messages are received by your organization's telephony network and then passed to a Microsoft Exchange Server 2010 Unified Messaging (UM) server that handles and routes the incoming call. This topic discusses the message flow for incoming voice messages received by a Unified Messaging server.

Voice Incoming Messages

Voice calls that come in to an Exchange 2010 organization can be received from users who are inside or outside the organization. When a caller places a call to a UM-enabled user's telephone extension and the user is unavailable to answer the call, the Private Branch eXchange (PBX) forwards or routes the incoming call to an IP gateway and then to the Unified Messaging server. In a Unified Messaging system that uses an IP PBX, the IP PBX forwards the incoming message to the Unified Messaging server. The IP gateway or the IP PBX translates or converts the incoming stream into a Voice over IP (VoIP) protocol such as the Session Initiation Protocol (SIP) for incoming voice messages. The stream of IP data is then passed on to the Unified Messaging server. After the Unified Messaging server receives the call, the Unified Messaging server processes the message and determines how to route the message.

The following figure illustrates how incoming voice messages flow in an Exchange 2010 organization.



1.9.1.4.2 Unified Messaging Outlook Voice Access Call Processing

Unified Messaging Outlook Voice Access Call Processing

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Call Processing >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When an authenticated UM-enabled user calls in to the Microsoft Exchange Server 2010 Unified Messaging (UM) system, the call is received by your organization's telephony network and then passed to an Exchange 2010 Unified Messaging server that handles and routes the incoming call. This topic discusses the message flow for incoming Outlook Voice Access calls to an Exchange 2010 Unified Messaging server.

Outlook Voice Access

With Exchange 2010 Unified Messaging, UM-enabled users or subscribers can access their e-mail, contacts, and calendaring information using a standard analog, digital, or mobile

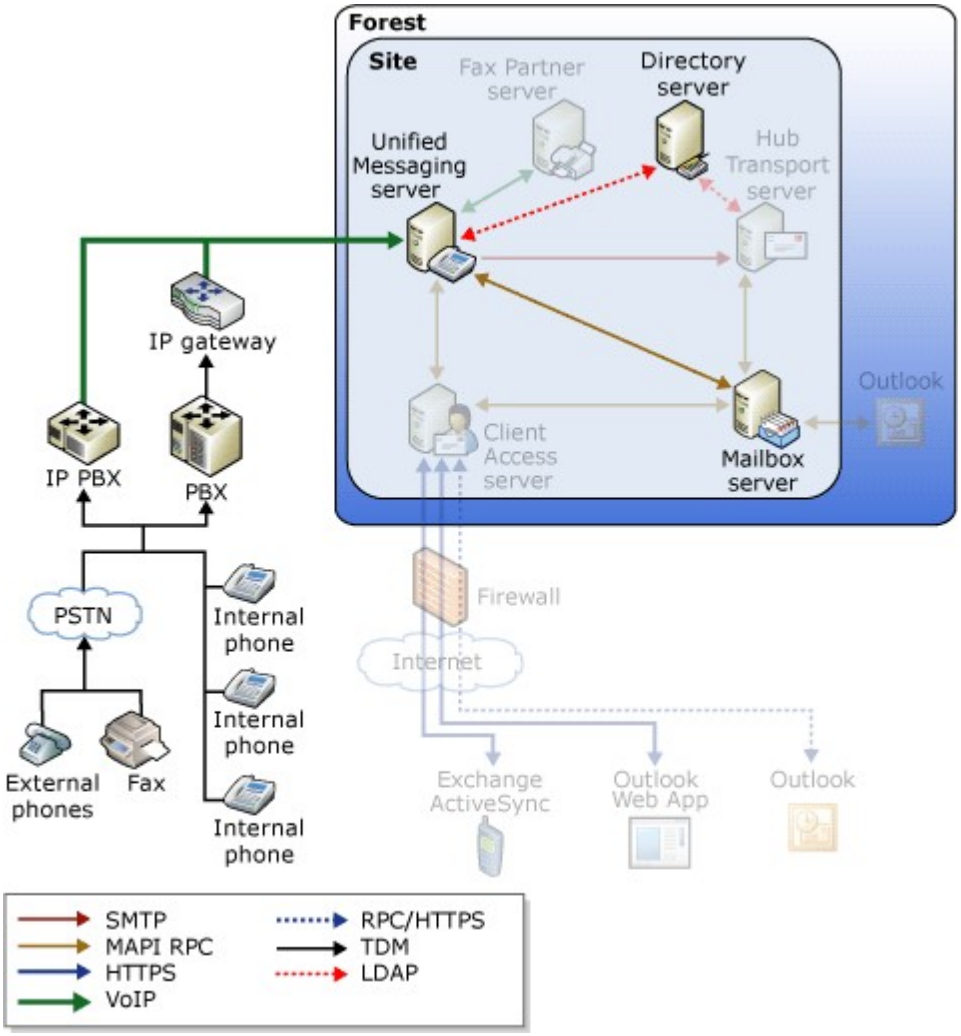
telephone. When UM-enabled users use Outlook Voice Access, they can perform the following tasks:

- Listen to new and saved e-mail and voice mail messages.
- Forward, reply, save, and delete e-mail and voice mail messages.
- Interact with their calendar.
- Locate a person in the global address list or personal contacts.
- Send a voice message to a person.
- Change their PIN, spoken name, or greetings.
- For more information about subscriber access in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Subscriber Access.

Outlook Voice Access Message Flow

Outlook Voice Access incoming calls and messages created using Outlook Voice Access are routed to an Exchange 2010 Unified Messaging server and then to the Mailbox server. However, if a message is submitted using Outlook Voice Access, for example, a change in the schedule of a meeting from a subscriber, the message is submitted to a Hub Transport server before it's routed to the appropriate mailbox for the Exchange 2010 recipient or recipients.

The following figure illustrates how incoming calls and messages placed by subscribers or UM-enabled users flow in an Exchange 2010 organization.



1.9.1.4.3 Unified Messaging Auto Attendant Call Processing

Unified Messaging Auto Attendant Call Processing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Incoming calls received by a Unified Messaging (UM) auto attendant are first passed through your organization's telephony network and then to a Microsoft Exchange Server 2010 Unified Messaging server that handles and routes the incoming call. This topic discusses the message flow for incoming messages received by an Exchange 2010 Unified Messaging auto attendant.

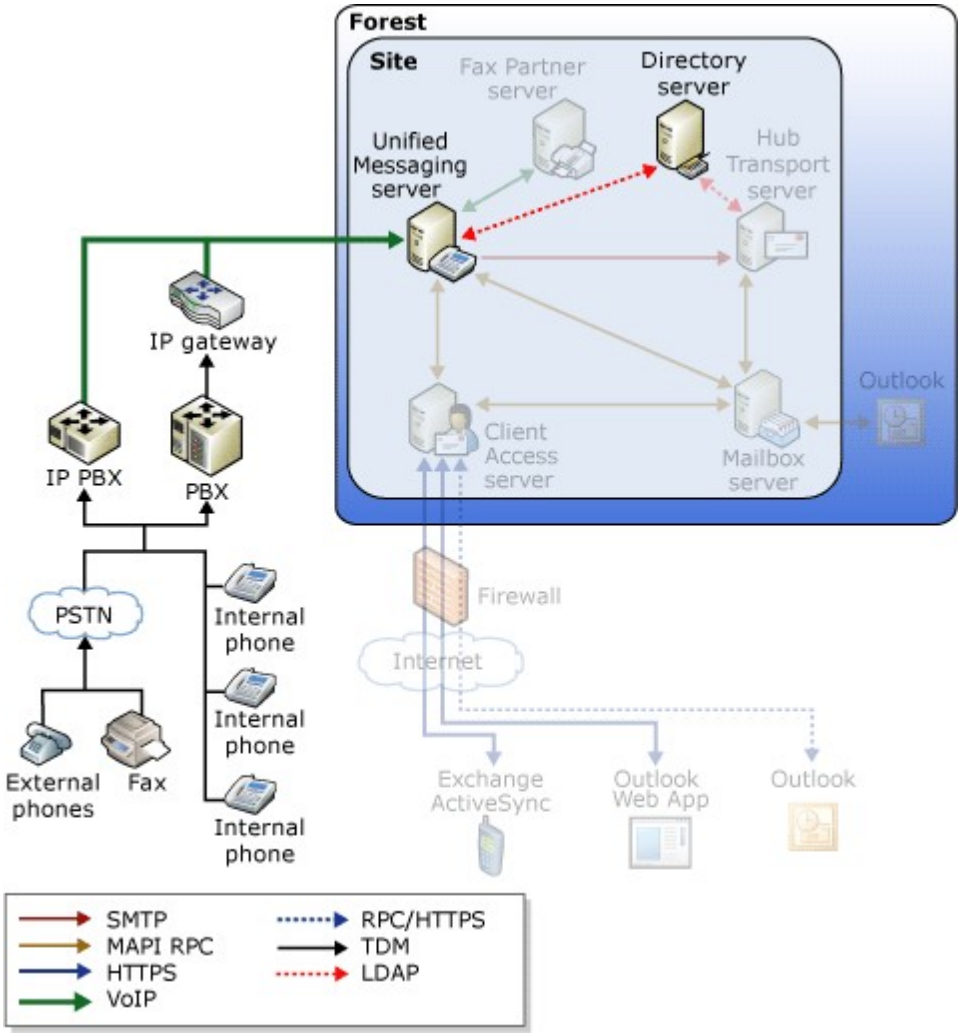
UM Auto Attendants

When external or anonymous callers place a call using an external business telephone number, or an internal anonymous caller places a call to an internal extension number, they are presented with voice prompts to help them navigate the Unified Messaging menu system. The UM auto attendant is a set of voice prompts or .wav files played to callers in place of a human operator or receptionist when they call into an organization that has Exchange 2010 Unified Messaging. Exchange 2010 Unified Messaging enables you to create one or more auto attendants depending on the needs of your organization. For more information about UM auto attendants, see Understanding Unified Messaging Auto Attendants.

Auto Attendant Message Flow

When a call is received by an Exchange 2010 Unified Messaging server, the Unified Messaging server performs an LDAP query to an Active Directory directory service domain controller to determine how to handle the incoming call.

The following figure illustrates the message flow process when Unified Messaging auto attendants are used in an Exchange 2010 organization.



1.9.1.4.4 Unified Messaging Play on Phone Call Processing

Unified Messaging Play on Phone Call Processing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Incoming calls placed by users using the Play on Phone feature are received and routed by a Microsoft Exchange Server 2010 Unified Messaging server.

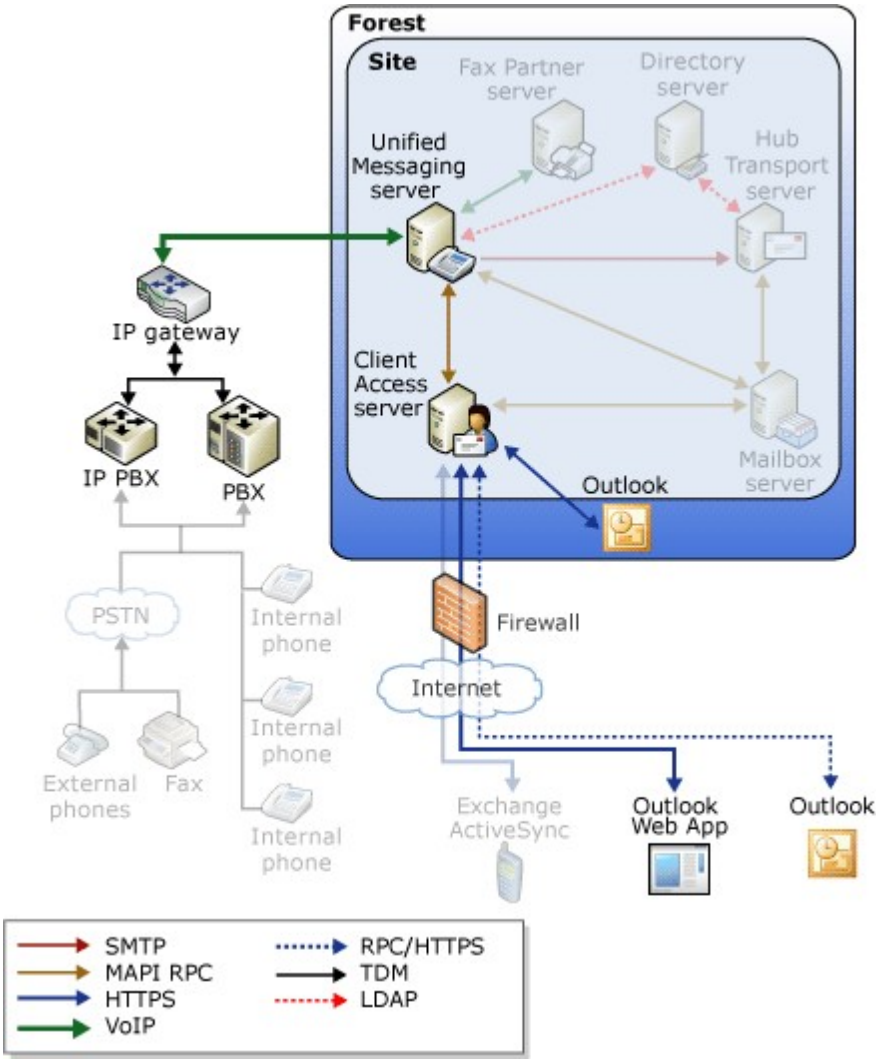
Play on Phone

The Exchange 2010 Unified Messaging Play on Phone feature enables UM-enabled users to access a voice mail message. However, instead of playing the media file over their computer speakers, they can listen to the message on a telephone.

When UM-enabled users work in office cubicles, use a public computer, have a computer

that isn't enabled for multimedia, or have a voice message that's confidential, they may not want to or may be unable to play a voice message over their computer speakers. The Play on Phone feature lets UM-enabled users play the voice message over a telephone. The Play on Phone feature is available in Exchange 2010 Outlook Web App and in Microsoft Office Outlook 2007.

The following figure illustrates how Exchange 2010 Unified Messaging routes the incoming calls for UM-enabled users who use the Play on Phone feature.



The Unified Messaging Web services are installed on Client Access server. Unified Messaging Web services enable Session Initiation Protocol (SIP) functionality on a Client Access server. This functionality enables a user to record a voice mail greeting or use the Play on Phone feature. The Unified Messaging server uses only SIP to communicate. Therefore, the UM Web service is installed on a computer running the Client Access server role and is required to enable the Client Access server to communicate with the Unified Messaging server.

Important:

By default, SIP data, which includes Unified Messaging server settings and other call information sent from a Unified Messaging server to a Client Access server, isn't encrypted. This could pose a security threat. To help protect all SIP traffic, use Transport

Layer Security (TLS) to encrypt the traffic between a Client Access server and a Unified Messaging server by configuring TLS security settings on the UM dial plan. For more information about SIP security and TLS, see Understanding Unified Messaging VoIP Security.

1.9.1.4.5 Call Routing with Office Communications Server 2007

Call Routing with Office Communications Server 2007

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-07*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) or later Unified Messaging (UM) combines voice messaging and e-mail messaging into a single messaging infrastructure. Enterprise Voice in Microsoft Office Communications Server 2007 takes advantage of the UM infrastructure to provide call answering, subscriber access, call notification, and auto-attendant services. Implementing these services requires integration of Exchange UM and Communications Server 2007 in a shared Active Directory topology. Working together, Unified Messaging and Communications Server 2007 provide call answering, Outlook Voice Access, and auto-attendant services to Enterprise Voice deployments.

Deploying Exchange UM for Communications Server requires you to install the Exchange Mailbox, Hub Transport, Client Access, and Unified Messaging server roles in each forest where Unified Messaging is deployed. Exchange 2010 Unified Messaging requires that all Enterprise Voice users be configured with a Microsoft Exchange Server 2007, Exchange 2007 Service Pack 3 (SP3), or Exchange 2010 SP1 or later mailbox.

If you plan to move users from an existing telephony infrastructure to Enterprise Voice, moving them to Unified Messaging is the last step in the migration process.

Routing Components for Enterprise Voice

Enterprise Voice functionality is handled by services running on Communications Server 2007 Enterprise Edition and Communications Server 2007 Standard Edition. When a user is enabled for Enterprise Voice, Microsoft Office Communicator 2007 or Communicator Phone Edition becomes the user's primary phone, instead of his or her PBX phone. A unique phone number will be assigned to Communicator. In combination with a recommended USB audio device, Communicator will handle both the call control (or signaling) and the media (audio and video). In this scenario, Communications Server 2007 routes calls among Communicator endpoints on the IP network (IP-IP calls) and routes those calls to the Public Switched Telephone Network (PSTN).

To download the reference and Help documentation for Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

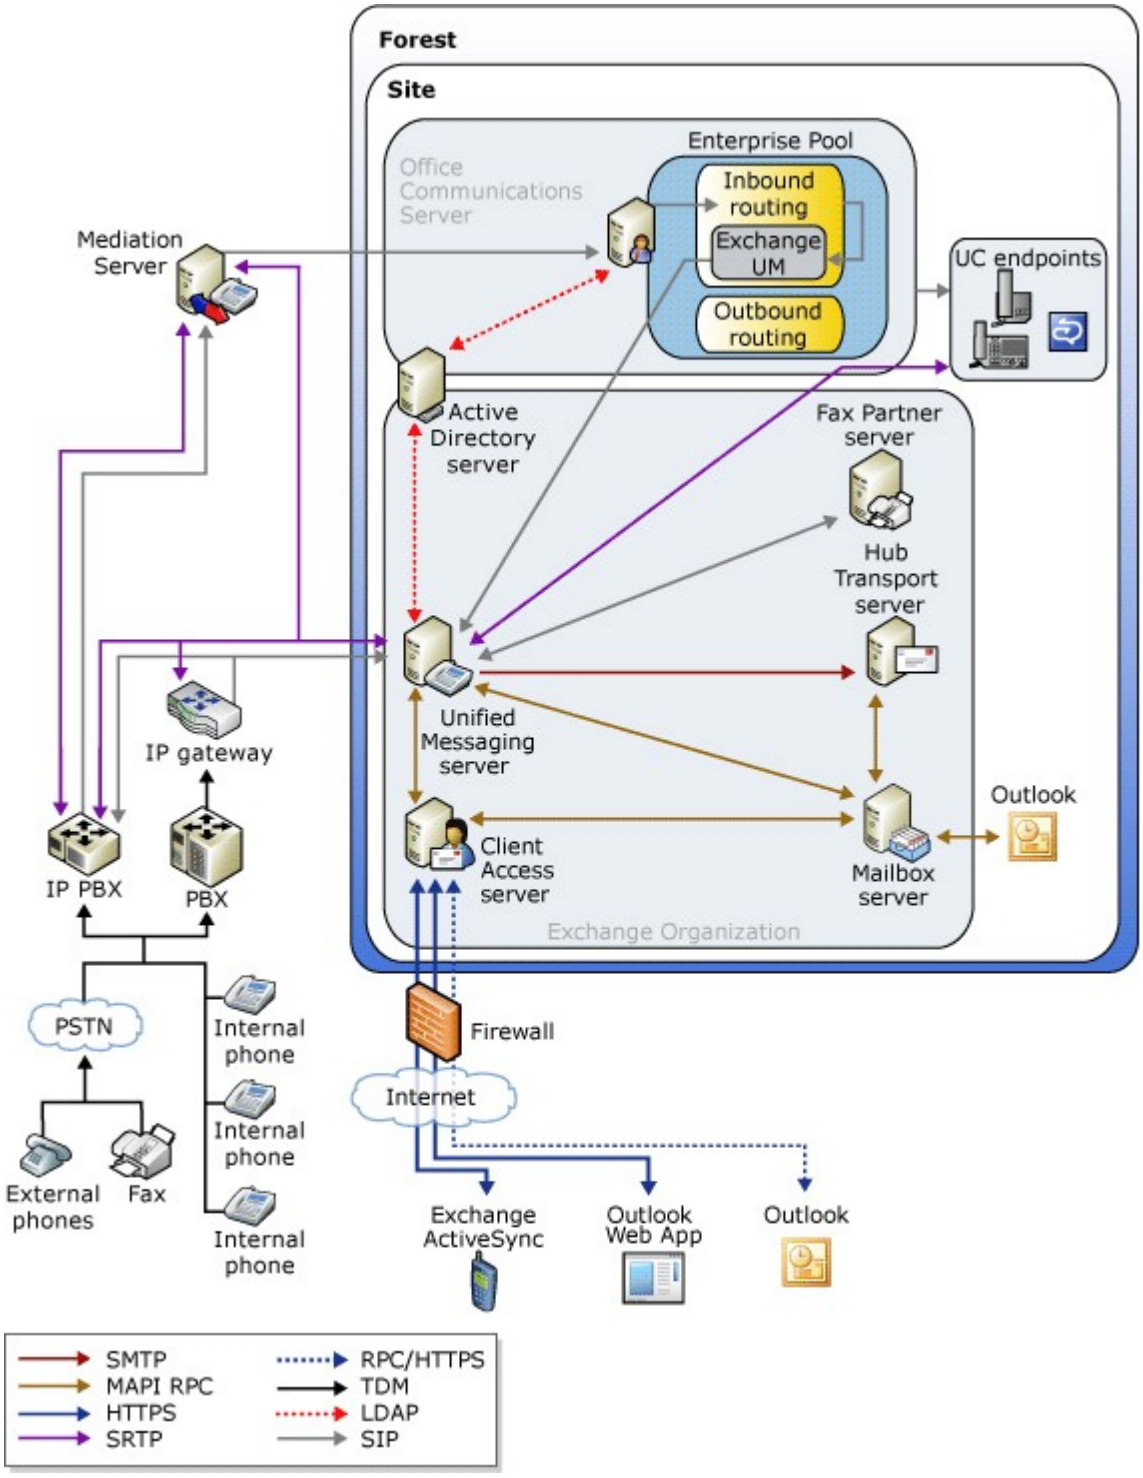
Enterprise Voice services include an Inbound Routing component. By default, the Inbound Routing component is installed on all Communications Server 2007 Standard Edition servers and Enterprise Edition front-end servers and is needed for routing incoming calls for Enterprise Voice users. Enterprise Voice services include the following, which control inbound and outbound calling:

Service	Description
Inbound Routing Component	Applies the target user's calling preferences.

Exchange Unified Messaging	Forwards the request to voice mail, as needed.
Outbound Routing Component	Determines the optimal route, based on URI and user policy.
Translation Service	Applies normalization rules, based on the location profile or phone context.
User Services	Performs reverse number lookup on the target phone number.

Inbound Routing and Exchange Unified Messaging

The Inbound Routing component determines how incoming calls to the server should be routed. When this component is used with Exchange UM, it enables voice mail services for Enterprise Voice enabled users. The following figure shows how the Inbound Routing component in Communications Server 2007 is used to send an incoming call to an Exchange Unified Messaging server.



The Inbound Routing component handles incoming calls largely according to preferences that are specified by users on their Enterprise Voice clients. For example, users specify whether unanswered calls are forwarded or only logged for notification. If call forwarding is enabled, users can specify whether unanswered calls should be forwarded to another number or to an Exchange 2007 SP3 or Exchange 2010 Unified Messaging server that's been configured to provide call answering.

The Inbound Routing component controls many options for Enterprise Voice users including options for voice mail such as:

- **Route Unanswered Calls to Voicemail** This is the default if the user is enabled for voice mail. The call is routed according to Inbound Routing rules.
- **Generate Missed Call Notifications when caller hangs up before call reaches voicemail** Notifies Exchange UM when this type of missed call is received.

Inbound routing rules specify how calls to a user should be routed in the presence or absence of registered clients in the system. The Inbound Routing component also takes care of applying presence-based rules to incoming calls. For example, it can send incoming calls to voice mail if the user has set the presence state to Do Not Disturb. Inbound routing is aware of the presence container levels and automatically rejects calls from users in blocked containers.

Inbound routing rules are uploaded to the server as an XML schema as part of an Enterprise Voice user's self-provisioning information. By default, if the incoming call isn't answered within the ring duration, the unanswered call is sent to voice mail. The user can choose to modify the default configuration by choosing whether to forward to a number immediately, forward to another person, or to send the caller directly to voice mail.

1.9.1.5 Understanding Unified Messaging Server Topologies

Understanding Unified Messaging Server Topologies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

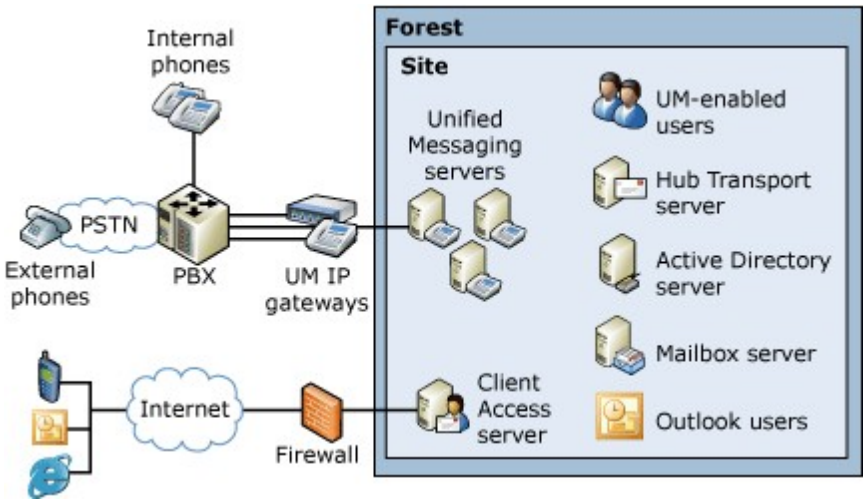
Topic Last Modified: *2010-05-13*

Microsoft Exchange Server 2010 supports a server architecture that distributes server tasks among different server roles. In this kind of architecture, a Unified Messaging (UM) server accepts incoming calls. The Unified Messaging server then routes the messages to the appropriate server for processing. This could be the Client Access server, the Mailbox server, or the Hub Transport server. The server that has the Hub Transport server role installed was formerly known as a bridgehead server.

This topic describes the relationship between the Unified Messaging servers on a typical network and the telephony components in an organization.

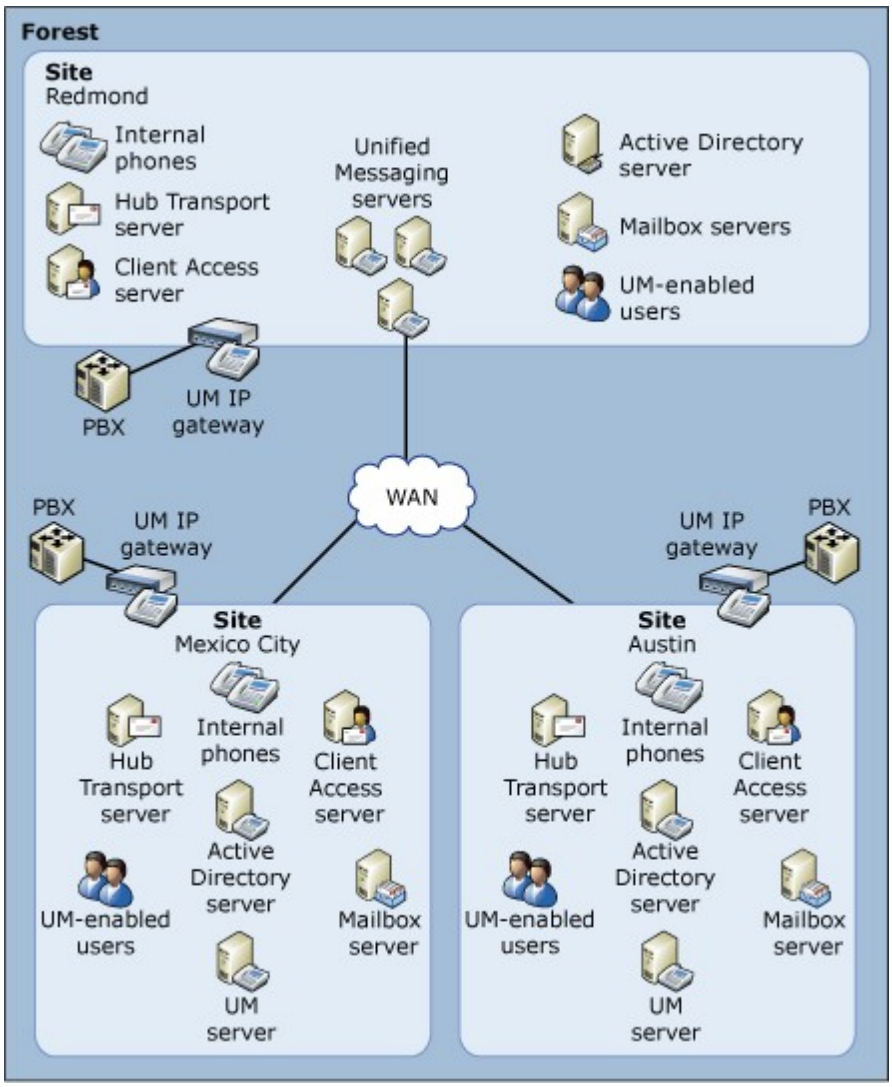
UM Topology That Has a Single PBX

The following figure illustrates an Exchange Server 2010 Unified Messaging topology that contains a single Private Branch eXchange (PBX).



UM Topology That Has Multiple PBXs

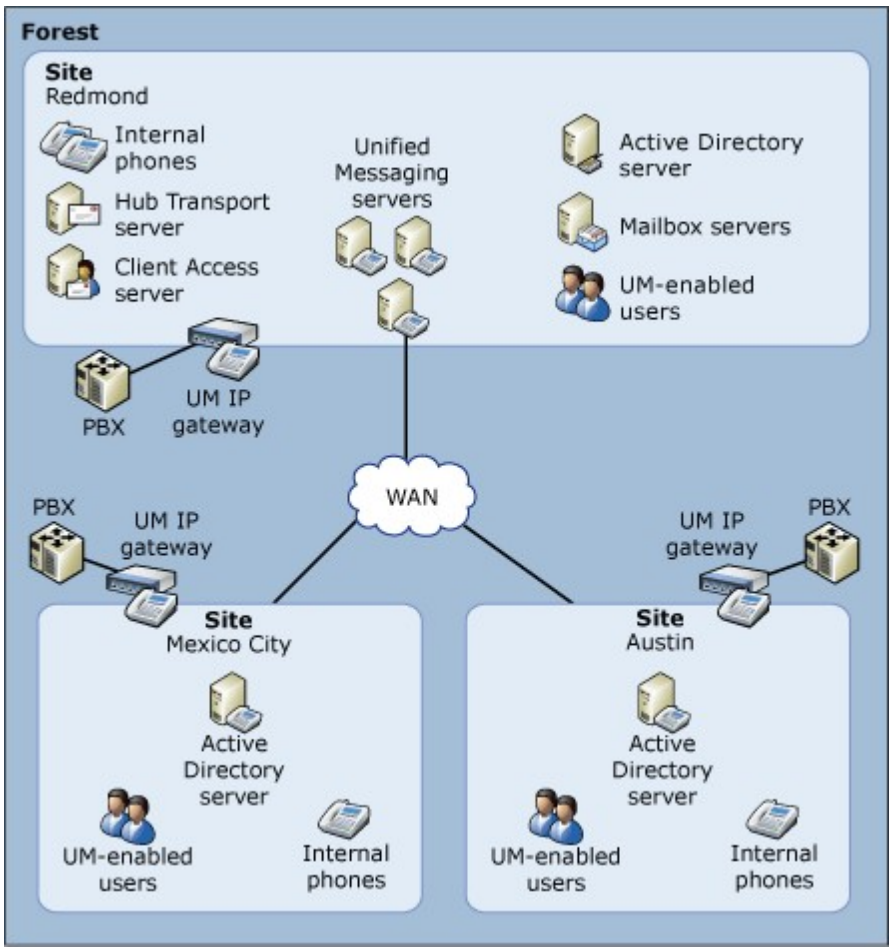
The following figure illustrates an Exchange 2010 Unified Messaging topology that contains multiple PBXs.



The following figure illustrates centralized management system for an Exchange 2010 Unified Messaging topology that contains multiple PBXs. This configuration enables the placement of all Unified Messaging servers in a single location. IP gateways are deployed in each branch office, and replace the legacy voice messaging system for each branch office. Because IP gateways are close to the PBX, the Hub Transport, Client Access, and the Mailbox servers can be removed from both the Mexico City and the Austin sites.

Note:

The round trip time between the IP gateways and UM servers should not be more than 300 milliseconds.



1.9.1.6 Understanding Unified Messaging and Communications Server 2007 R2

Understanding Unified Messaging and Communications Server 2007 R2

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 Unified Messaging (UM) can use the Microsoft Office Communications Server 2007 platform to combine voice messaging, instant messaging, enhanced presence, audio/video conferencing, and e-mail into a familiar, integrated communications experience. This communication method has the following benefits:

- Enhanced presence notifications across a variety of applications that keep users informed of the availability of contacts.
- Integration of instant messaging, voice messaging, conferencing, e-mail, and other communication modes that enables users to select the most appropriate mode for the task. Users can also switch from one mode to another as needed.
- Availability of communications alternatives from any location where an Internet connection is available.
- A smart client (Microsoft Office Communicator 2007) for telephony, instant

messaging, and conferencing.
- Continuity of user experience across multiple devices.

This topic discusses how Exchange 2010 Unified Messaging and Communications Server 2007 can be deployed together to provide voice messaging, instant messaging, enhanced presence, audio/video conferencing, and e-mail into an integrated communication experience for users in your organization.

Caution:
To use the features described in this topic, Exchange 2010 must be installed on the computers that have the Unified Messaging server role installed.

Contents

Overview

All Communications Server 2007 topologies support Enterprise Voice. Enterprise Voice is an implementation of IP telephony that uses Session Initiation Protocol (SIP) for signaling and Realtime Transport Protocol (RTP) for voice messaging. SIP is an industry standard, application layer signaling protocol for starting, controlling, and ending communication sessions in an IP-based network. SIP is formally described in the International Engineering Task Force (IETF) reference specification RFC 3261.

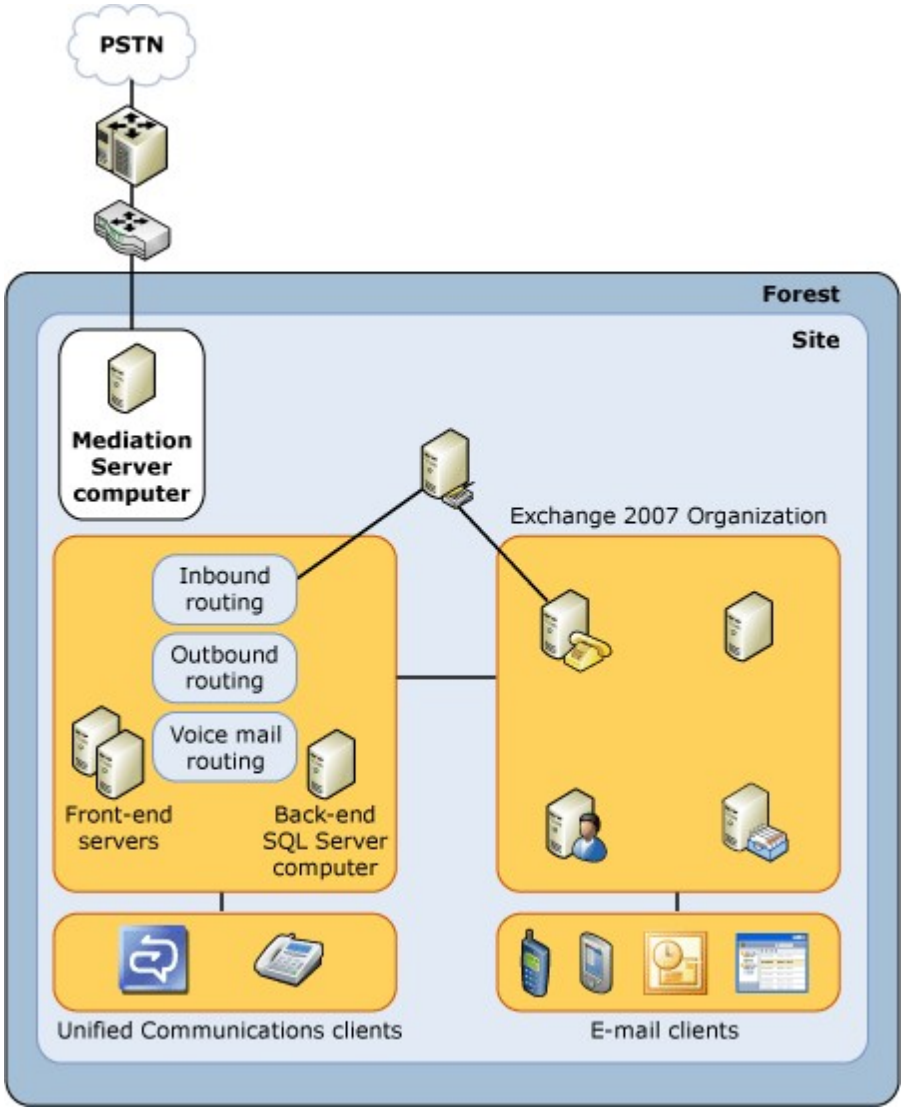
In Communications Server 2007, SIP is used for instant messaging, conferencing, presence subscriptions, video, and voice messaging. SIP enables Enterprise Voice clients to provide a common user experience across all these communication modes. Enterprise Voice uses RTP for media. Like SIP, RTP is an IETF standard. It defines a packet format for carrying audio and video over IP networks.

When a user places a call from an Enterprise Voice client to a Public Switched Telephone Network (PSTN) destination, the call moves through the Enterprise Voice infrastructure as follows:

1. The user places a call from an Enterprise Voice client by dialing the number or by clicking the name of a contact in Communicator or Microsoft Office Outlook 2007.
2. The Communications Server 2007 server normalizes the telephone number to E.164 format, and then uses the routing rules based on location profile and user policy to direct the call to the correct mediation server.
3. The Communications Server 2007 mediation server performs any necessary media translation and routes the call to the IP gateway.
4. The IP gateway applies local dialing rules or Private Branch eXchange (PBX) dialing rules and passes the call to the PSTN, PBX, or IP PBX.

The following figure illustrates a simple Unified Messaging and Communications Server 2007 topology.

Exchange 2010 Unified Messaging and Communications Server 2007 simple topology



Communications Server 2007 Overview

Communications Server 2007 Enterprise Voice takes advantage of the Unified Messaging infrastructure to provide voice mail, subscriber access, call notification, and auto attendant services. These include the following:

- **Phone number normalization** Phone number normalization translates number strings entered in various formats into a single standard format. Normalization rules specify how to convert telephone numbers dialed in various formats to standard E.164 format.
- **Location profiles** A location profile is a named set of normalization rules that translates telephone numbers for a location to a single standard (E.164) format for telephone authorization and call routing. The name of each location profile must match the fully qualified domain name (FQDN) of its corresponding Exchange 2010 UM dial plan.
- **Phone usage records** Phone usage records provide a quick, easy way to assign call permissions to users. To enable phone usage records to function correctly, you must assign a voice policy for the call to be correctly routed to the voice user.
- **Voice policies** Enterprise Voice policies are collections of phone usage

records assigned to one or more users. Most organizations will have multiple voice policies. Typically, organizations have a global policy that applies to all users and special policies applied on a per-user basis.

- **Call routing** The core routing components for Communications Server 2007 are the Inbound and Outbound Routing Components, as follows:
  - **Inbound Routing Component** The Inbound Routing Component handles incoming calls largely according to preferences specified by users on their Enterprise Voice clients. Users specify whether unanswered calls are forwarded or logged for notification.
  - **Outbound Routing Component** The Outbound Routing Component handles calls placed by Enterprise Voice users either to telephone numbers owned and managed by the enterprise or to telephone numbers on the PSTN or mobile networks. When an enterprise user places a call, the Outbound Routing Component looks up the target number in the Realtime Communication (RTC) database. If the dialed number matches a SIP Uniform Resource Identifier (URI) for an enterprise user, the call is routed through all SIP endpoints for that user.

Important:

When you are integrating Exchange Unified Messaging and Office Communications Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange Unified Messaging. Office Communications Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Exchange Unified Messaging on behalf of users.

- **Services** The setup routing for Communications Server 2007 installs services that provide support for voice messaging with Exchange 2010 Unified Messaging, including the following:
  - **Translation Service** The Translation Service is the application responsible for translating the dialed number into an E.164 number based on the normalization rules defined by the administrator.
  - **Enterprise Services** Enterprise Services performs reverse number lookup on the target telephone number of each incoming call, matches that number to the SIP URI of the destination user, and sends the call to that user's SIP endpoints.
  - **User Replicator** The User Replicator extracts user telephone numbers from the Active Directory directory service and writes them to tables in the RTC database, where they are available to Enterprise Services and the Address Book Service.
  - **Address Book Service** The Address Book Service normalizes enterprise user telephone numbers written to the RTC database to E.164 format to provision user Contacts in Communicator.

To download the reference and Help documentation for Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

Return to top

Exchange 2010 Unified Messaging

The Unified Messaging server role is one of several Exchange 2010 server roles that you can install and configure on a computer running Exchange 2010. For Enterprise Voice users, Unified Messaging combines voice messaging and e-mail messaging into a single store that can be accessed from a telephone or a computer. Unified Messaging and Communications Server 2007 work together to provide voice mail, subscriber access, and auto attendant services to Enterprise Voice deployments, including the following:

- **Voice mail** Voice mail includes answering an incoming call on behalf of a user, playing a personal greeting, recording a message, and submitting it for

delivery to the user's Inbox as an e-mail message. Notification of unanswered calls is sent to the user's Outlook and Outlook Web App Inboxes. The subject and priority of calls can be displayed in a way that resembles the way they are displayed for e-mail.

- **Subscriber access** A subscriber is an internal business user or network user who is enabled for Exchange 2010 Unified Messaging. Subscriber access is used by users to access their individual mailboxes to retrieve e-mail, voice messages, contacts, and calendaring information. Outlook Voice Access is an Exchange 2010 Unified Messaging feature that lets subscribers access their Exchange 2010 mailbox. Subscriber access enables an Enterprise Voice user to access voice mail, calendar, and contacts from a telephony interface. A subscriber access number is configured by you on a UM dial plan. For more information about Outlook Voice Access, see Understanding Unified Messaging Subscriber Access.
- **Auto attendant** In telephony or Unified Messaging environments, an automated attendant or auto attendant menu system transfers callers to the extension of a user or department without the intervention of a receptionist or an operator. In many auto attendant systems, a receptionist or operator can be reached by pressing or saying zero. The automated attendant is a feature in most modern PBXs and Unified Messaging solutions. For more information about auto attendants in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Auto Attendants.

For more information about Exchange 2010 Unified Messaging, see Unified Messaging.

There are four user scenarios in which Communications Server 2007 and Exchange 2010 Unified Messaging can be used together. These are:

- **Call notification** User 1 calls User 2. User 2 doesn't answer the call. User 1 hangs up. User 2 receives an e-mail message in the Exchange 2010 mailbox that User 1 called. Call notifications are also sent when an inbound call is forwarded. User 1 calls User 2. User 2 sets call forwarding to User 3. User 1 calls User 2. The call is forwarded to User 3, and User 2 receives a call notification that the call was forwarded.
- **Leave a voice mail message** User 1 calls User 2. User 2 doesn't answer the call. Because User 2 hasn't configured call forwarding to another telephone number, the call from User 1 is diverted to the voice mail for User 2. User 1 is invited to leave a voice message for User 2. The voice mail greeting previously recorded by User 2 is played, inviting User 1 to leave a voice message for User 2. User 2 receives a voice mail message recorded by User 1.
- **Subscriber access** User 2 dials in to a subscriber access number and accesses the Exchange 2010 mailbox to check for voice messages. User 2 can listen to e-mail or voice mail messages or access the calendar. After listening to the voice message from User 1, User 2 decides to return the call from User 1. User 2 accesses the options menu and uses the callback option to place a call to User 1.
- **Auto attendant** User 1 doesn't know the extension number for User 2. User 1 dials in to a telephone number configured on a UM auto attendant. The welcome greeting and prompts configured on the auto attendant are played to User 1. User 1 uses the directory search feature to locate User 2 in the directory and places a call to the extension number for User 2.

Note:

Both subscriber access and those auto attendant services offered by Exchange 2010 Unified Messaging require users to dial specific telephone numbers. These numbers must be routable by Enterprise Voice. This means that each number must be mapped to a SIP address. Communications Server 2007 can route the SIP address to an address configured on the server that has the Exchange 2010 Unified Messaging server role installed.

Return to top

Exchange 2010 Unified Messaging Active Directory Objects

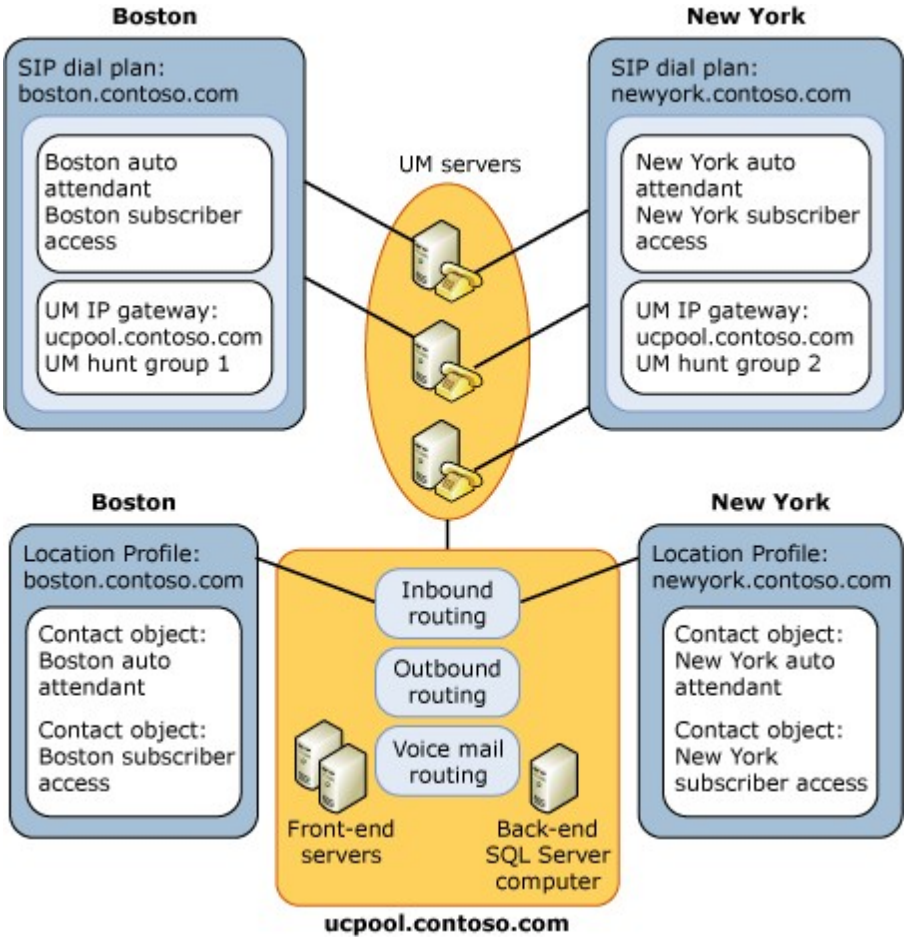
Exchange Unified Messaging Active Directory objects enable Exchange 2010 Unified Messaging to integrate with the Communications Server 2007 Enterprise Voice infrastructure. To successfully deploy Exchange 2010 Unified Messaging in your organization, you must fully understand the relationship between each of following UM Active Directory objects and their counterparts in Enterprise Voice:

- **UM Dial Plan object** A UM Dial Plan object is the basic unit of configuration in Exchange Unified Messaging. A UM dial plan can be of the following types: Telephone Extension, SIP URI, or E.164. When Exchange Unified Messaging is deployed with Communications Server 2007, the dial plan type is always SIP URI. Users in a UM dial plan reach all other users in the plan using SIP URIs or SIP addresses. Each SIP address must be unique within a specific SIP URI dial plan. Each dial plan must correspond to an Enterprise Voice location profile. The name of each location profile must match the forest FQDN of the SIP URI dial plan.
- **UM IP Gateway object** A UM IP Gateway object is a logical representation of a physical IP gateway or SIP-enabled IP PBX. The UM IP Gateway object logically represents each Communications Server 2007 pool and front-end server as if it were a physical IP gateway. Each UM IP Gateway object encapsulates configuration elements related to the corresponding pool or server. After a UM IP Gateway object is created, it's associated with one or more UM hunt groups.
- **UM Hunt Group object** The UM Hunt Group object associates a UM IP gateway with a UM dial plan. By creating multiple UM Hunt Group objects, you can associate a single UM IP gateway with multiple UM dial plans and, therefore, with multiple Enterprise Voice location profiles.

For more information about the Active Directory objects included in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Components.

The following figure illustrates the relationships between Exchange 2010 Unified Messaging objects and Communications Server 2007 objects.

Unified Messaging and Communications Server 2007 objects and their relationships



Exchange 2010 Unified Messaging combines voice messaging and e-mail messaging into a single messaging infrastructure. Communications Server 2007 Enterprise Voice takes advantage of the Unified Messaging infrastructure to provide voice mail, subscriber access, call notification, auto attendant services and other enhanced features that include voice messaging, instant messaging, enhanced presence, audio/video conferencing, and e-mail into an integrated communication experience for users in your organization. Implementing these services requires integrating Unified Messaging and Communications Server 2007 in a shared Active Directory topology. For more information about the configuration steps required to correctly deploy and integrate Exchange 2010 Unified Messaging and Communications Server 2007, see Deploy Unified Messaging and Communications Server 2007 R2.

To download the reference and Help documentation for Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

1.9.1.7 Understanding Unified Messaging Performance and Scalability

Understanding Unified Messaging Performance and Scalability

Exchange Server 2010 > Unified Messaging > Understanding Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-30*

In many organizations today, the ability to access e-mail and voice mail is critical to the success of daily operations. To provide continuous access to e-mail and voice mail, you must correctly plan and implement a solution for Microsoft Exchange Server 2010 that will ensure the availability of the servers that provide these services. To provide a highly scalable solution in Exchange 2010 Unified Messaging (UM), you have to understand how the UM components can be scaled to support your users.

Unified Messaging Server Scalability

Scalability is defined as the capability to increase resources to increase the capacity of a given service. There are two types of scalability that can be used to increase the capacity of UM servers in your organization: horizontal and vertical. In Unified Messaging, when you scale vertically, you add hardware resources to a single UM server or multiple UM servers, by, for example:

- Adding more hard disk space for message storage
- Increasing the speed or number of processors
- Increasing the amount or speed of RAM
- Increasing the number of network adapters or increasing the number of local area network ports in a single network adapter

In Unified Messaging, when you scale horizontally, you install the Unified Messaging server role on new UM servers and add more UM servers to a dial plan to increase the number of incoming concurrent calls the system can accept. To scale your UM environment horizontally, you can also increase the number of IP gateways. This increases the number of ports available to be used for incoming calls.

Unified Messaging provides an efficient and simple deployment model that's highly scalable without increasing the complexity of the deployment. There are many deployment models for Unified Messaging in your organization. But the recommended deployment model for Unified Messaging is to centralize your UM servers. All the available deployment options for Unified Messaging have several steps in common that are required to create a scalable system to support large numbers of UM users. These steps are as follows:

1. **Provision PBX lines** The first step in building a highly scalable UM solution is to provision PBX lines.
2. **Organize channels** After you've provisioned PBX-based voice channels, you can organize the channels as hunt groups.
3. **Deploy IP gateways** After you've organized your voice channels as hunt groups, you end these channels at IP gateways. IP gateways are used with a legacy PBX to convert the circuit-switched protocols found on a telephony network to IP-based packet-switched protocols.
4. **Add more Unified Messaging servers to a dial plan** If you have to increase the number of calls that can be handled by Unified Messaging, you can install and set up additional UM servers and add them to a dial plan. In most cases, IP gateways will use DNS to load balance between the existing UM servers and the additional UM servers that have been installed.

Return to top

Network Traffic

Every incoming call received from an IP gateway will generate IP-based network traffic and consume some amount of your available network bandwidth. Before you deploy Unified Messaging, you should perform an analysis of the network traffic to determine current usage patterns and find any potential issues. On most networks, bandwidth demand isn't evenly distributed throughout business hours. Because all the IP-based calls are routed directly to your UM servers from the IP gateways on your network and this IP-

based network traffic consumes some available bandwidth, you should follow these recommendations and guidelines:

- Place your PBXs physically close to your IP gateways.
- Place your IP gateways and your UM servers on the same well-connected network or within the same physical site.
- Place your UM servers on the same well-connected network or within the same physical site as other computers that have Exchange 2010 server roles installed, including Mailbox, Hub Transport, and Client Access servers.
- End your Wide Area Network (WAN) connections close to where your telephony equipment is located.
- In branch office scenarios or over WAN connections, use the G.723.1 codec instead of the G.711u or G.711A codec to minimize the network traffic that's passed between your IP gateways and your UM servers.

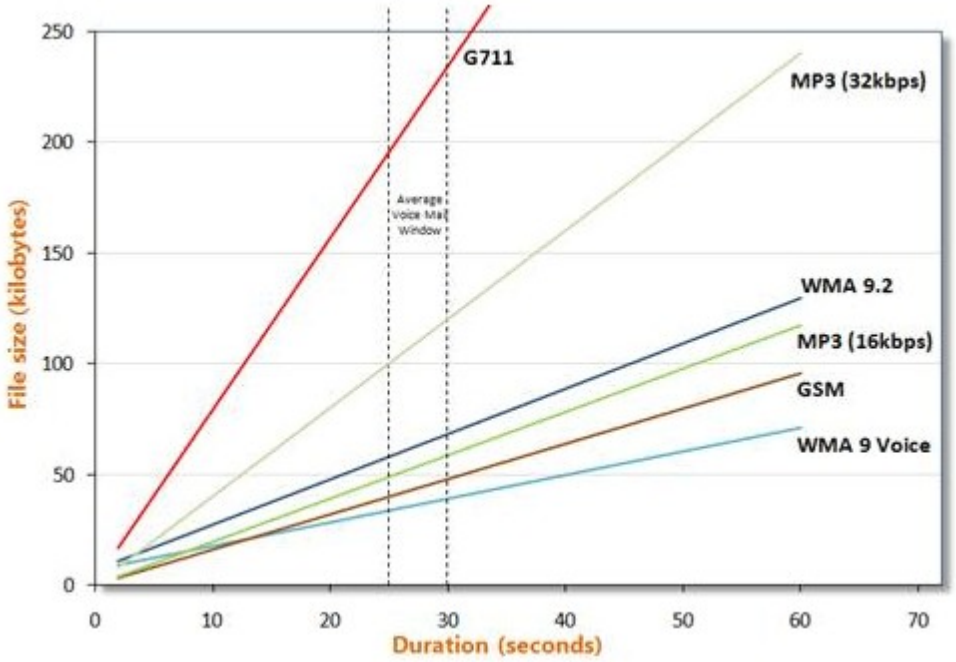
UM Servers

Generally, Unified Messaging scalability is determined by the number of concurrent calls. By default, a single UM server can accept a maximum of 100 concurrent voice calls. These calls can be either incoming or outgoing, and can be generated when a user leaves a voice mail message, when an Outlook Voice Access user accesses their Exchange 2010 mailbox, or when a user uses the Play on Phone feature to listen to their voice messages. Although the number of concurrent calls is an important factor to consider when you build a scalable UM infrastructure, you also have to determine the best codec to use to encode the voice messages and the types and number of users who you have to support.

- **Number of concurrent calls** Although, by default, a UM server can accept 100 concurrent voice calls, a single UM server can be set up to accept a maximum of 200 concurrent voice messages. The more you increase the number of concurrent connections on a single UM server, the more resources will be required. It's especially important to decrease this setting on low-end, slower computers on which the UM server role is installed. Performance counters are available, and the **Get-UMActiveCalls** cmdlet can also be used to monitor the number of calls that are currently connected to a UM server.
  If the number of concurrent calls required by your organization is larger than the number that's supported by a single UM server, you can scale horizontally and increase the capacity of concurrent calls by installing the Unified Messaging server role on an additional server and then adding the new UM server to the same dial plan.
- **Voice mail storage codec** The term "codec" is a combination of the words "coding" and "decoding" and relates to digital data. A codec is a computer program or software that transforms digital data into an audio file format or streaming audio format.
  In Microsoft Exchange Unified Messaging, there are two general types of codecs: the codec that's used between IP gateways and the codec that's used to encode voice messages. The MP3, Windows Media Audio (WMA), Group System Mobile (GSM) 06.10, and G.711 Pulse Code Modulation (PCM) Linear audio codecs are used to create mp3, .wma and .wav audio files for voice messages. But the file type that's used depends on the audio codec that's used to create the voice message audio file. In Microsoft Exchange Unified Messaging, the MP3 audio codec creates .mp3 audio files, the WMA audio codec creates .wma audio files, and the GSM 06.10 and G.711 PCM Linear audio codecs produce .wav audio files. Depending on the codec that's used, an audio file in .wma or .wav format is sent together with the e-mail message to the intended voice mail recipient. The size of UM voice messages depends on the size of the attachment that holds the voice data. Additionally, the size of the attachment depends on the following factors:
  - The duration of the voice mail recording
  - The audio codec that's used
  - The audio file storage format

  The following figure shows the four audio codecs you can use in Unified Messaging and how the size of the audio file depends on the duration of the

voice mail recording.



The sample bit rate (bit/sec) and compression properties for each audio codec that's used in Unified Messaging are as follows:

- MP3 - 16 bit - compressed file
- WMA – 16-bit – compressed file
- G.711 – 16-bit – uncompressed file
- GSM – 8-bit – compressed file

By default, the MP3 format is selected. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phones and devices and different computer operating systems.

When the WMA codec is used, we estimate that each UM server can handle 60 to 75 concurrent IP-based calls. This estimate is based on the assumption that 14 percent of all the IP-based calls arrive during the single busiest hour of a day. Based on the following assumptions:

- The WMA codec is used
- 14 percent of all IP-based calls arrive during the single busiest hour of a day
- Your users access their voice messages frequently using Outlook Voice Access

we estimate that each UM server can support between 2,000 and 10,000 users.

Generally, you should allow for the following number of concurrent calls per UM server:

- 60, if the default dial plan codec is WMA
- 75, if the default dial plan codec is GSM

- **Types of users** There are two types of users who access the UM system and consume UM resources: authenticated users and unauthenticated users. When you build a scalable UM environment, you have to consider the effect these users will have and the resources each of these users will consume.
  - **Authenticated** Authenticated users are UM-enabled and can access their mailbox using Outlook Voice Access. Authenticated users consume UM server resources in several ways, for example, by directly calling in to a subscriber access number, signing in to their mailboxes, accessing their messages, calendar, contacts, or the directory, and using a UM server to play voice

messages over a telephone with the Play on Phone feature. They can also indirectly consume resources by transferring a call, sending a voice message, or calling a user's extension number and leaving a voice message.

- **Unauthenticated** Users who call in to a UM auto attendant or call in to a subscriber access number but don't sign in to their mailbox are unauthenticated callers. UM resources are used to service their requests every time they call in to a UM auto attendant or use a subscriber access number. Even though they don't sign in to their mailbox, they still consume resources by transferring a call, sending a voice message, transferring to another auto attendant, transferring to another telephone number, or listening to recorded audio prompts.

IP Gateways

Unified Messaging relies on the ability of the IP gateway to translate TDM or telephony circuit-switched based protocols, such as Integrated Services Digital Network (ISDN) or QSIG, from a PBX to protocols based on VoIP or IP, such as SIP, RTP, or T.38 for real-time facsimile transport.

IP gateways are available from multiple manufacturers in sizes and models that range from 4 ports to 32 ports. You can deploy as many IP gateways as necessary to provide for capacity and fault tolerance. If the number of calls or ports required is larger than the number of calls or ports supported by a single IP gateway, you can scale horizontally and increase the number of calls that can be accepted or the number of ports by installing and setting up additional IP gateways, creating the UM IP gateway object, and setting up the appropriate hunt groups to support your environment.

It's equally important to match the number of IP gateways you have in your environment to the number of UM servers that are available. For example, you shouldn't set up 10 IP gateways that are each connected with a T-1 line to a single UM server. This would mean that the UM server would have to support 240 concurrent incoming calls. You should consider this and scale your IP gateways to UM servers appropriately.

Return to top

1.9.1.8 Understanding Unified Messaging Availability

Understanding Unified Messaging Availability

Exchange Server 2010 > Unified Messaging > Understanding Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-03*

In many organizations today, accessing e-mail and voice mail is critical to the success of daily operations. To provide continuous access to e-mail and voice mail, you have to correctly plan and implement a solution for Microsoft Exchange Server 2010 that will ensure the availability of the servers that provide these services. You need to understand how to implement a solution that will make your Unified Messaging servers highly available.

Unified Messaging Availability

Minimum uptime requirements may vary among organizations. But every organization wants to achieve a high level of up time, especially for their telephony system. An

organization's telephony system is frequently business-critical and must be highly available to users. One of the factors you need to consider when you deploy a UM system is the ability for the system to provide services for users when a key component, for example, a UM server or an IP gateway, becomes unavailable.

To provide a highly available UM system, you must include additional key components to protect against hardware failures for the following:

- **UM servers** Unified Messaging runs as a service and a worker process. This means that if the service is using lots of system resources or has become unresponsive, the worker process can be recycled. The UM worker process is responsible for dealing with outages in Mailbox servers, Hub Transport servers, and domain controllers. If, for example, a Mailbox server for a user is unavailable, the UM server will continue to accept calls on behalf of the user. But the user's custom greeting won't be played. Instead, a standard greeting will be used for calls to that user. Additionally, if the Hub Transport server is unavailable, the UM server will continue to accept calls and queue the calls, depending on how you've set up the queuing limit, until the Hub Transport server is available. In a situation where all domain controllers are unavailable, the UM server will be unable to accept calls.
  UM deployments can be made more resilient and more available by adding UM servers to a single dial plan in an N+1 configuration. This means that, if you need two UM servers, you'd install and set up an additional UM server so you'd have a UM server to take the place of a UM server that's failing or has to be taken offline.
  When you add multiple servers to a single dial plan, the IP gateway will try to connect to a UM server that's listed in the configuration on the IP gateway by IP address, or by fully qualified domain name for TLS deployments. If the UM server is unavailable, the IP gateway will try to connect to the UM server again after 5 seconds. If there is no response from the UM server, the IP gateway will try to connect to the next UM server in the list that's set up on the IP gateway.
- **IP gateways** If you want to create redundancy to provide for IP gateway availability, you should add multiple IP gateways in an N+1 configuration. This means that, if you need two IP gateways, you'd install and set up an additional IP gateway so that you'd have an IP gateway to take the place of an IP gateway that's failing or has to be taken offline.
  You have to set up your PBX to send the incoming calls it receives to different IP gateways. After you set up the PBX, the PBX will detect a failure or no signal or that a port isn't answering calls. This lets the PBX redirect calls to an IP gateway that can answer incoming calls.
  The IP gateways supported by Unified Messaging can be set up to route calls to UM servers in a round-robin manner. To enable an IP gateway, you need to set up each IP gateway with the IP addresses for your UM servers that will be answering calls from the IP gateway. These are the UM servers associated with the same dial plan as the UM IP gateway object that logically represents the IP gateway. This will let all the UM IP gateways to forward incoming calls to the UM servers associated with the same dial plan. Then, if an IP gateway fails, the PBX will send the call to an IP gateway that can answer the call. The IP gateway, in turn, will forward the call to a UM server within the same dial plan. If the call is sent to a UM server that isn't available, the IP gateway will try to contact the UM server again. If it's unsuccessful in contacting the UM server, it will then use the next UM server in the list that's set up on the IP gateway to answer the call. But not all supported IP gateways can be set up to support both load balancing and detecting when a server has been taken offline or is failing.

Return to top

Load Balancing in Unified Messaging

Unified Messaging deployments can be made more resilient by deploying multiple UM

servers to a single dial plan to balance the load of incoming calls. The IP gateways supported by Unified Messaging can be set up to route calls in a round-robin manner to balance the load between multiple UM servers in a dial plan.

Round robin is a method for distributing the workload among multiple servers. However, round robin doesn't by itself enable an IP gateway to detect a server failure. If one of the UM servers fails and if the IP gateway can't detect that a UM server is unavailable, the IP gateway will continue to send incoming calls to the UM server until you detect the failure and remove the server from the dial plan. After you remove the UM server from the dial plan, you should also remove the IP address or FQDN for the UM server from the configuration on the IP gateway.

Unified Messaging doesn't use round-robin DNS or Network Load Balancing to distribute incoming calls. Round-robin DNS can be used on multi-homed computers and can be used to distribute the load for other services, but not for Unified Messaging. NLB is used with other services to distribute client requests and to automatically detect whether a server is unavailable, and then to redistribute other client requests to the remaining server. But it also can't be used with Unified Messaging. The only way to distribute or balance the load between Unified Messaging servers in a dial plan is for the IP gateway to be set up with the IP addresses or FQDNs of the UM servers in the dial plan. The IP gateway will use the list to distribute the load across all the UM servers in the dial plan and can also detect a server failure if the IP/VoIP supports this functionality.

Another way to load balance your UM deployment is to set up PBX hunt groups to connect to multiple IP gateways and then set up the hunt groups to load balance across the IP gateways.

1.9.1.9 Understanding System Requirements for Unified Messaging

Understanding System Requirements for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-10*

To provide continuous access to e-mail and voice mail, you must correctly plan and implement a high performance, highly available, and scalable solution for Microsoft Exchange Server 2010. To implement a high performance voice mail solution that's highly available and scalable, you must understand the system requirements for Exchange Unified Messaging (UM) in Exchange 2010. This will help you to select the UM servers and other voice mail components that will have the greatest effect on system performance, scalability, and availability for your deployment.

As you plan your deployment, you can use this topic and other topics in this section to help design your Unified Messaging environment. For details, see Exchange 2010 System Requirements.

Unified Messaging System Hardware Overview

Choosing the correct system hardware is one of the most important steps when in planning and implementing voice mail solution. You must ensure that the hardware you choose will meet or even exceed the system requirements. You must consider the following when you plan and deploy Unified Messaging 2010:

- How to tune your high-performing UM servers for optimum performance

- How to make your Unified Messaging deployment scalable
- How to make your Unified Messaging deployment highly available

Performance

Tuning a Unified Messaging server for optimum performance is an ongoing process. You must understand all the variables that affect your system, including user profile, architecture, and the hardware that's used on a Unified Messaging server. When you know your requirements for a Unified Messaging server, you can establish baseline metrics for the server and make adjustments to improve overall system performance.

Generally, the maximum level of performance for a Unified Messaging server is determined by the component that has the lowest level of performance, which can cause a bottleneck in the system. The key to improving performance is learning to identify bottlenecks in your Unified Messaging system, determine the cause of the system bottlenecks, and then take the appropriate action or actions.

There are several tools you can use to measure performance of Exchange 2010 Unified Messaging, including Jetstress and Load Generator (LoadGen). For details, see Tools for Performance and Scalability Evaluation. The Windows Server 2008 operating system also includes some general performance tools, including Windows Performance Monitor.

Also, you should analyze your current loads to establish minimum server requirements. One of the biggest challenges in determining minimum server requirements is understanding how your users use your voice mail system. After you determine your hardware requirements, you should conduct a pilot test to make sure the Unified Messaging server performance levels are acceptable.

Availability

To provide a highly available UM system, you must protect against hardware failures for the following:

- **UM servers** Unified Messaging runs as a service and a worker process. This means that if the service is using lots of system resources or has become unresponsive, the worker process can be recycled to bring the Unified Messaging service back online. Having the UM worker process recycle allows for a more highly available system and prevents the Unified Messaging service from being down for extended periods of time. The UM worker process is responsible for dealing with outages in Mailbox servers, Hub Transport servers, and domain controllers. For example, if a Mailbox server for a user is unavailable, the UM server will continue to accept calls on behalf of the user. However, the user's custom greeting won't be played. Instead, a standard greeting will be used for calls to that user. Additionally, if the Hub Transport server is unavailable, the UM server will continue to accept calls and queue the calls, depending on how you've set up the queuing limit, until the Hub Transport server is available. In a situation where all domain controllers are unavailable, the UM server will be unable to accept calls.
- **IP gateways** If you want to create redundancy to help ensure that IP gateways are always available, add multiple IP gateways in an N+1 configuration. For example, if you need two IP gateways, install and set up an additional IP gateway so that you have an IP gateway to take the place of an IP gateway that fails or must be taken offline.

For details, see Understanding Unified Messaging Availability.

Scalability

Minimum requirements for uptime may vary among organizations. But every organization wants to achieve a high level of uptime, especially for their telephony system. An organization's telephony system is frequently business-critical and must be highly available to users. One of the factors you need to consider when you deploy a UM system is the ability of the system to provide service to users when a key component, for example, a UM server or an IP gateway, becomes unavailable.

Scalability is defined as the capability to increase resources to increase the capacity of a given service. There are two types of scalability that can be used to increase the capacity of UM servers in your organization: horizontal and vertical. In Unified Messaging, when you scale vertically, you add hardware resources to a single UM server or multiple UM servers by, for example:

- Adding more hard disk space for message storage.
- Increasing the speed or number of processors.
- Increasing the amount or speed of RAM.
- Increasing the number of network adapters or the number of local area network ports in a single network adapter.

For details, see Understanding Unified Messaging Performance and Scalability.

Hardware Requirements

When selecting hardware for your Unified Messaging servers, you must consider several components, including disk storage, memory, processor, and network hardware. The hardware that you select for your Exchange Unified Messaging deployment will have an effect on performance. Because many variables affect performance, including the hardware, it's difficult to predict the effect that any particular hardware component will have.

When you're selecting the hardware components for a Unified Messaging server, consider the following definitions:

- **Minimum** This is the minimum processor and memory configuration that's suitable for specific Exchange 2010 server roles. Minimum hardware requirements must be met before you can receive help from Microsoft Customer Service and Support.
- **Maximum** This is the maximum recommended processor and memory configuration for specific Exchange 2010 server roles. Maximum is defined as the upper limit of the processor and memory configurations for Exchange 2010, based on the price and performance. Maximum is a guideline and not a support criterion. It doesn't take into account the resource requirements of third-party applications. The recommended maximum may change over time, based on price changes and technology advancements.
- **Recommended** This is the recommended processor and memory configuration for specific Exchange 2010 server roles. Recommended can be defined as the best configuration based on price and performance. The recommended configuration also provides a balance between processor and memory capacity. The goal is to match the memory configuration to the processor configuration so that the system will use the processors effectively without causing a bottleneck in memory or vice versa.

Disk Storage Requirements

Here are a few helpful guidelines for selecting a storage configuration that provides good performance and capacity for Exchange 2010. Considerations of capacity and performance are often at odds with each other when it comes to selecting a storage solution, and you must consider both before you make a purchase. Generally, you should make sure that:

- There will be enough space to store all the data. Determining your capacity needs is a relatively straightforward process.
- The solution provides acceptable disk latency and a responsive user experience. You determine this by measuring or predicting transactional input/output (I/O) delivered by the solution.
- Non-transactional I/O has both enough time to complete and enough disk throughput to meet your service-level agreements.

The goal is to balance these factors so that you can design the hardware solution for your

servers.

UM doesn't really require much storage because each message is converted and forwarded as soon as a Hub Transport server is available. However, for Unified Messaging, each UM server requires storage for the following:

- Any UM language packs that are installed along with the en-US UM language pack
- Custom audio prompts for UM dial plans and auto attendants that are stored in a system mailbox
- UM messages that are queued when Hub Transport servers are unavailable, such as:
  - Missed call notifications
  - E-mail messages when a user has been UM-enabled
  - Voice mail messages with an audio attachment
  - Fax messages with an attachment

Note:
If no Hub Transport servers are available, a Unified Messaging server will queue 100 voice messages before shutting down the Microsoft Exchange Unified Messaging service.

To determine the maximum amount of storage required to accommodate these language packs, audio prompts, and queued messages, take the maximum message size of a voice message, based on the audio codec that's used and the message length, and then multiply it by 1,000 bytes. For example, if an average voice message is approximately 30 seconds, which is usually under 100 KB in size, take that number times 100 voice mails.

Memory Requirements

When you select hardware for Exchange 2010, we recommend that you consider the maximum memory limits of the server. Different server architectures have different memory limits. We recommend that you check the following technical specifications of the server to determine the most cost-efficient maximum memory limits for your servers:

- **Memory speed** Some server architectures require slower memory modules to scale to the maximum supported amount of memory. For example, maximum server memory could be limited to 32 GB with PC3 10666 (DDR3 1333) or 128 GB using PC2 6400 (DDR2 800). Check with the manufacturer to ensure that the memory configuration target for Exchange 2010 is compatible in terms of speed.
- **Memory module size** Consider the largest memory module size that the server will support. Generally, the larger the memory module, the more expensive it is. For example, two 2 GB DDR SDRAM memory modules generally cost much less than one 4 GB DDR SDRAM memory module, and two 4 GB DDR SDRAM memory modules generally cost much less than one 8 GB DDR SDRAM memory module. Make sure the size of the maximum memory module allows you to meet your target memory requirements for Exchange 2010.
- **Total number of memory slots** Consider how many memory modules a specific server will support. The total number of slots multiplied by the maximum memory module size provides the maximum memory for the server. Remember that memory modules must sometimes be installed in pairs.

Thus, the recommended minimum of 4 GB of memory installed with a recommended maximum of 2 GB per processor which would equal 4 GB minimum. However, there are several other factors that must be considered when you determine the amount of memory needed for each Unified Messaging server. These include:

- The size of the global address list or the combined size of all address lists.
- The UM language packs that are installed and available.
- Whether Voice Mail Preview is enabled or disabled.
- The number of incoming calls.

The following table shows the minimum supported and recommended maximum memory configurations for Exchange 2010.

Number of users	Recommended memory per UM server
25,000	250 MB
50,000	500 MB
100,000	1 GB

After the required number of processors has been estimated for a specific server role, baseline memory recommendations can be applied. Exchange 2010 on the 64-bit edition of the Windows Server 2008 operating system can efficiently use more than 64 GB of memory.

With effective planning and an understanding of the basic processor and memory requirements for specific Exchange 2010 server roles, you can create a balanced and cost-effective topology.

For more information about how different memory configurations perform, see Understanding Memory Configurations and Exchange Performance.

Processor Requirements

There are significant benefits to be gained by running Exchange 2010 on multiple processors. The performance benefit depends upon the specific processor that's used. Check with your server hardware vendor to see whether the benefits of processors are Exchange-specific for a given hardware architecture.

The processor on a server should maintain a load of about 60 percent during peak working hours. This percentage level allows for periods of extreme load. If the processor usage is consistently greater than 75 percent, processor performance is considered a bottleneck.

There are several ways that server CPU can affect performance. These include:

- The processor clock speed, measured in megahertz (MHz) or gigahertz (GHz)
- The number of processors used
- The type of processors used
- Whether Voice Mail Preview is enabled or disabled

Exchange can make full use of multiple processors, so using servers with more processors improves performance. However, the relationship between the number of processors, the number of processor cores, and performance is complex. The optimum number of processors and cores is partly determined by the Exchange server roles deployed on the server and whether the Unified Messaging server role is also deployed on the same physical server as other server roles.

Network Requirements

Much of the network interface subsystem is tuned automatically. Server-based network adapters are capable of detecting the type and level of traffic that passes through the network interface, and they self-tune to reflect this information. We recommend that you ensure that the latest device drivers are maintained on the server.

Every incoming call that's received from an IP gateway will generate IP-based network traffic and consume some of your available network bandwidth. Before you deploy Unified Messaging, you should perform an analysis of the network traffic to determine current usage patterns and find any potential issues. On most networks, bandwidth demand isn't evenly distributed throughout business hours. Because all the IP-based calls are routed directly to your UM servers from the IP gateways on your network, and because this IP-based network traffic consumes some available bandwidth, you should follow these

recommendations and guidelines:

- Place your PBXs physically close to your IP gateways.
- Place your IP gateways and your UM servers on the same well-connected network or within the same physical site.
- Place your UM servers on the same well-connected network or within the same physical site as other computers that have Exchange 2010 server roles installed, including Mailbox, Hub Transport, and Client Access servers.
- End your wide area network (WAN) connections close to where your telephony equipment is located.
- In branch office scenarios or over WAN connections, use the G.723.1 codec instead of the G.711u or G.711A codec to minimize the network traffic that's passed between your IP gateways and your UM servers.

The network requirements or recommendations for UM servers are as follows:

- UM servers using gigabit (1,000 megabits per second (Mbps)) or 1 gigabit per second (Gbps) Ethernet adapters.
- UM servers connected to multiple-switched, fast Ethernet networks of gigabit Ethernet connections.
- A round trip time from the IP gateway or IP PBX of less than 300 milliseconds.

Note:

Performance-related issues may arise because your hardware, firmware, or software drivers aren't designed to work in your configuration. For more information, see the Products Designed for Microsoft Windows Web site.

1.9.1.10 Fax Advisor for Exchange 2010

Fax Advisor for Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-19*

Microsoft Exchange Server 2010 Unified Messaging (UM) relies on certified fax partner solutions for enhanced fax functionality such as outbound fax or fax routing. By default, when you install the Unified Messaging server role, the server isn't configured to allow incoming fax messages to be delivered to a UM-enabled user. Instead, the UM server redirects incoming fax calls to a certified fax partner solution. The fax partner's server receives the fax data and then sends it to the recipient's mailbox in an e-mail message with the fax included as a .tif attachment. For details, see Understanding Faxing in Unified Messaging.

The Exchange 2010 Unified Messaging server ensures that the final message delivered to the user is identical to the fax messages generated by Microsoft Exchange Server 2007 Unified Messaging. However, the fax partner solution must meet a set of requirements to interoperate with Exchange 2010 Unified Messaging.

Important:

We recommend that all customers who plan to deploy Unified Messaging obtain the assistance of a Unified Messaging specialist. A Unified Messaging specialist helps you ensure that there's a smooth transition to Exchange 2010 Unified Messaging from a legacy voice mail system. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about PBXs and Exchange 2010 Unified Messaging. For more information about how to contact a Unified Messaging specialist, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Exchange 2010 Unified Messaging Fax Partner Program

In order to become a fax partner certified for interoperability with Exchange 2010 UM, the partner must implement the requirements contained in the Fax Partner Interoperability Specification and the fax solution must be certified by an independent certification vendor. For more information about certifying a fax product to work with Exchange 2010 Unified Messaging, submit a request to Fax Partners for Exchange 2010 Unified Messaging.

Fax Partner Solutions Certified As Interoperable with Exchange 2010 Unified Messaging

If you've already deployed Exchange 2010 Unified Messaging, and you're looking for a fax partner solution to set up incoming fax processing for your organization, see Microsoft PinPoint for available partners. These fax solution partners have been certified as interoperable with Exchange 2010. Among other services, they provide certified software solutions for Unified Messaging.

IP or Media Gateways and IP PBX Support

Correctly configuring IP gateways for your organization is a difficult deployment task that must be completed to successfully deploy Exchange 2010 Unified Messaging with incoming faxing. To help answer questions and give you the most up-to-date IP gateway configuration information, see Telephony Advisor for Exchange 2010. That topic provides IP gateway configuration notes and files that you must have to correctly configure your organization's IP gateways to work with Exchange 2010 Unified Messaging.

Interoperability testing of Exchange 2010 Unified Messaging with IP gateways is now integrated with the Microsoft Unified Communications Open Interoperability Program. For more information, see Microsoft Unified Communications Open Interoperability Program.

The Microsoft Unified Communications Open Interoperability Program qualification program for IP gateways and IP PBXs ensures that customers have a seamless setup and support experience when they're using qualified telephony gateways and IP-PBXs with Microsoft Unified Communications software.

Important:

Sending and receiving faxes using T.38 or G.711 isn't supported in an environment where Unified Messaging and Communications Server 2007 are integrated.

Deploying and Configuring Faxing

Exchange 2010 UM forwards incoming fax calls to a dedicated fax partner solution, which then establishes the fax call with the fax sender and receives the fax on behalf of the UM-enabled user. However, to allow UM-enabled users to receive fax messages in their mailbox, you must first run Exchange 2010 Unified Messaging setup and configure the Fax Partner server, and then configure the UM dial plans, UM mailbox policies, and enable UM-enabled users to receive faxes. For details, see Deploy and Configure Incoming Faxing.

1.9.1.11 Voice Mail Preview Advisor for Exchange 2010

Voice Mail Preview Advisor for Exchange 2010

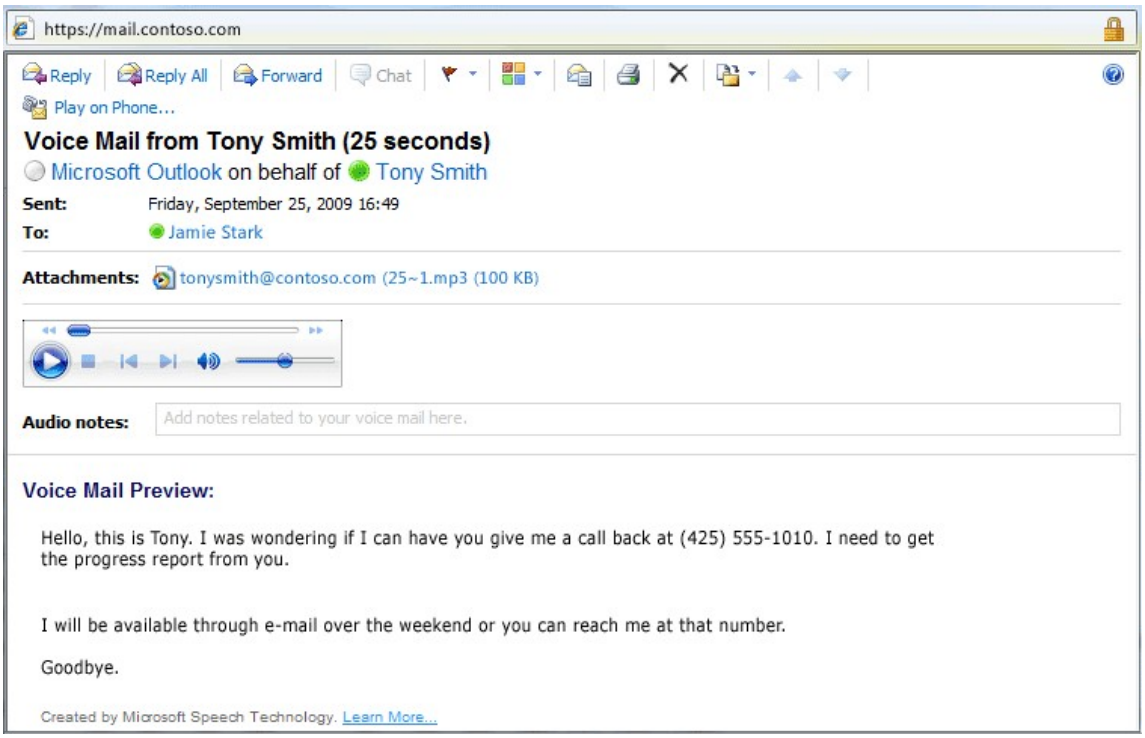
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

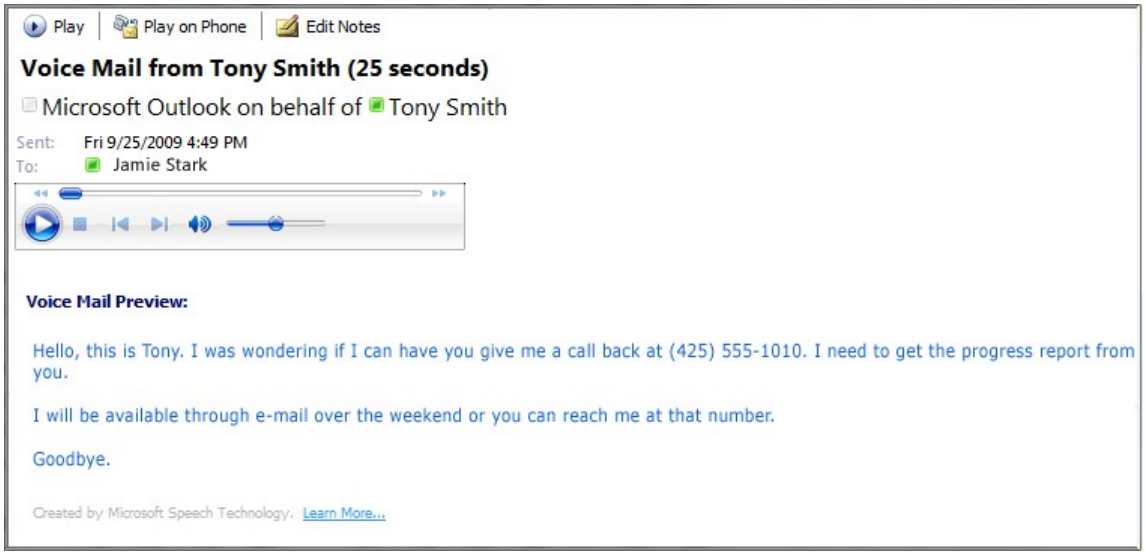
Topic Last Modified: *2012-10-30*

In Microsoft Exchange Server 2010, the Unified Messaging (UM) server role delivers a feature called Voice Mail Preview that uses automatic speech recognition (ASR) to add a text version of the voice mail audio file to voice mail messages. ASR isn't entirely accurate, especially when it's used to record audio over a phone that contains unknown voices and noises. Some organizations require consistently error-free (or near-error-free) transcripts of voice mail messages for some -- if not all -- of their users. The Voice Mail Preview Partner Program helps such organizations meet those requirements.

Voice Mail Preview uses Microsoft speech technologies to provide a text version of audio recordings. The voice mail text is displayed in e-mail messages within Microsoft Office Outlook Web App, Outlook 2010, and in other e-mail programs.

The following examples show how Voice Mail Preview is displayed in Outlook Web App and Outlook 2010:





By default, when you install the Exchange 2010 Unified Messaging server role, the server will send voice mail previews to UM-enabled users if a supported UM language pack is installed.

There are Exchange 2010 Unified Messaging Voice Mail Preview partners that offer enhanced transcription support for the Voice Mail Preview feature. These partners employ people to correct voice mail transcriptions that were created using Automatic Speech Recognition (ASR). Each Voice Mail Preview partner must meet a set of requirements to be certified to interoperate with Exchange 2010 Unified Messaging.

If you determine that the voice mail previews sent to your users aren't accurate enough, you can contact one of the certified Voice Mail Preview partners listed on the Microsoft PinPoint web page and sign up with them at an additional cost.

Overview

When an Exchange 2010 Unified Messaging server records the audio for a voice mail message, it uses ASR to create voice mail preview text from the audio file, and then submits the whole voice message to a Hub Transport server for delivery to the user. For each voice message that's created, a Unified Messaging server determines a confidence level for the voice mail preview included with the message. The voice mail system measures how well the sounds in the recording match the words, numbers, and phrases. If the system finds matches easily, the confidence level will be high. A higher level of confidence is generally associated with a higher accuracy.

The accuracy of Voice Mail Preview text is controlled by many factors, and sometimes those factors can't be controlled. However, the text is likely to be more accurate when:

- A simple voice mail is left, and the caller doesn't use slang terms, technical jargon, or unusual words or phrases.
- The caller uses a language that's easily recognized and translated by the voice mail system. Generally, voice messages left by callers who don't speak too quickly or too softly and who don't have strong accents will produce more accurate sentences and phrases.
- The voice message is free of background noise, echoes, and the audio doesn't drop out.

Most customers who deploy Exchange 2010 Unified Messaging find that the voice mail previews are accurate enough for their users. However, when ASR is applied to recordings made over the phone by unknown voices and background noises, the voice

mail preview text usually isn't completely accurate. If the level of confidence is consistently low or the voice mail previews that are received aren't very accurate, you can increase the accuracy of the Voice Mail Previews that users receive as follows:

- Sign up for a voice transcription service from a Voice Mail Preview partner. For more information about where to find a Voice Mail Preview partner, see the section "Voice Mail Preview Partners Certified for Exchange 2010 Unified Messaging" later in this topic.
- After you've signed up with a Voice Mail Preview partner, use the information provided by the partner to set it up to work with Unified Messaging. For more information, about how to configure UM for a Voice Mail Preview partner, see Configure a Voice Mail Preview Partner on a UM Mailbox Policy.

When you've signed up with a Voice Mail Preview partner, the UM server redirects voice mail messages with the audio file attached to a Voice Mail Preview partner instead of generating Voice Mail Preview text for voice messages and submitting the voice messages to a Hub Transport server. The e-mail message with the Voice Mail Preview text produced by the Voice Mail Preview partner is then submitted to the Hub Transport server for delivery to the recipient's mailbox.

Important:

We recommend that all customers who plan to deploy Unified Messaging obtain the assistance of a Unified Messaging specialist. A Unified Messaging specialist helps you ensure that there's a smooth transition to Exchange 2010 Unified Messaging from a legacy voice mail system. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about PBXs and Exchange 2010 Unified Messaging. For more information about how to contact a Unified Messaging specialist, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Exchange 2010 Unified Messaging Voice Mail Partner Program

To become certified as a Voice Mail Preview partner that interoperates with Exchange 2010 UM, the partner must implement the requirements contained in the Voice Mail Preview Interoperability Specification, and the partner solution must be certified by an independent certification vendor. If you're interested in certifying your transcription service to work with Exchange 2010 Unified Messaging, submit a request to Voice Mail Preview Partners for Exchange 2010 Unified Messaging.

Voice Mail Preview Partners Certified for Exchange 2010 Unified Messaging

If you've already deployed Exchange 2010 Unified Messaging in your organization and you're looking for a certified Voice Mail Preview partner to provide transcription support services, see Independent Software Vendors. These software vendors have been certified as interoperable with Exchange Server 2010.

Configuring Voice Mail Preview Partners

The Exchange 2010 UM server forwards voice mail message with the audio to a dedicated Voice Mail Preview partner solution, which then takes the audio file and creates the Voice Mail Preview text. However, to allow UM-enabled users to receive the Voice Mail Preview with their voice mail message in their mailbox, you must configure a UM mailbox policy, associate users with the UM mailbox policy, and then have the UM-enabled users verify that they can receive voice mail previews in their voice mail messages in Outlook 2010 or

Outlook Web App. For more information about Voice Mail Preview with Outlook 2010 and Outlook Web App, see Outlook 2010 and Outlook Web App Features in Unified Messaging. For more information, about how to configure UM for a Voice Mail Preview partner, see Configure a Voice Mail Preview Partner on a UM Mailbox Policy.

IP or Media Gateways and IP PBX Support

Configuring IP gateways and IP PBXs for your organization is a difficult deployment task that must be completed correctly to successfully deploy Exchange 2010 Unified Messaging with a Voice Mail Preview partner. For information that can help you configure your IP gateways and IP PBXs and for the most up-to-date information about how to configure them, see Telephony Advisor for Exchange 2010.

Testing interoperability of Exchange 2010 Unified Messaging with IP gateways has been integrated with the Office Unified Communications Open Interoperability Program. For more information, see Microsoft Unified Communications Open Interoperability Program.

1.9.1.12 Telephony Advisor for Exchange 2010

Telephony Advisor for Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-13*

Unified Messaging (UM) requires that you integrate Microsoft Exchange Server 2010 with the existing telephony system for your organization. A successful deployment requires you to make a careful analysis of your existing telephony infrastructure and to perform the correct planning steps to deploy Unified Messaging.

The planning phase can be a significant challenge to Exchange administrators who have little or no experience with a telephony network. To help address this challenge, see Resources to Help with Your UM Deployment later in this topic.

To see the supported IP gateways for Unified Messaging, determine whether your PBX is supported using a specific IP gateway model or manufacturer, whether your IP PBX is supported using a direct SIP connection, or to see supported session border controllers (SBCs) for Exchange Online UM, click one of the following links:

- Supported IP Gateways
- Supported PBXs When Using an AudioCodes IP Gateway
- Supported PBXs Using a Dialogic IP Gateway
  - PBXs Supported Using a DMG1000 Series Media Gateway
  - PBXs Supported Using a DMG 2000 Series Media Gateway
  - PBXs Supported Using a DMG3000 Series Media Gateway
- Supported IP PBXs
- Supported IP PBXs Using SIP Media Gateways
- Session Border Controllers Tested with Exchange Online UM
- Exchange Unified Messaging, and Office Communications Server 2007 R2, and Lync Server 2010

Resources to Help with Your UM Deployment

It's challenging to create guidelines for deploying telephony networks. They can be very different from one another because they can include IP gateways, IP PBXs, and PBXs with different configuration settings, firmware, and requirements. This diversity makes planning and deploying Unified Messaging somewhat challenging. However, several resources are available to help you successfully deploy Unified Messaging:

- **Unified Messaging specialists** UM specialists are systems integrators who have received technical training about Exchange 2010 Unified Messaging conducted by the Exchange engineering team. To help ensure a smooth transition to Exchange 2010 Unified Messaging from legacy voice mail systems, Microsoft recommends that all customers engage a UM specialist. For contact information, visit Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists.
- **PBX configuration notes** PBX configuration notes contain configuration settings and other information that's very useful when you're configuring IP gateways, IP PBXs, and PBXs to communicate with the Unified Messaging servers that are on your network. For more information, see PBX Configuration Notes Tested by Microsoft or IP Gateway Vendor Partners for Exchange 2010 Unified Messaging.

Before you engage a Unified Messaging specialist, you should be able to answer key questions that they'll ask. Having the answers to the following questions will help make the conversation between you and the UM specialist productive:

- How many existing telephone or voice mail users, or both, are in your organization?
- How many users do you intend to provide with Exchange 2010 Unified Messaging?
- Which PBX or PBXs do you intend to use for integration with Exchange 2010 Unified Messaging?
- How many PBXs does your organization have? Specify the vendors, types (circuit- or IP-based), models, and firmware versions.
- Are the PBXs networked, and are they centralized or located in multiple locations?
- What voice mail system or systems does your organization currently use? Specify the vendors, types, models, and firmware versions.
- How are the voice mail systems integrated into your PBXs (Analog, T1/E1, PRI, Digital set emulation, VoIP, other)?
- Are you currently using voice networking?
- What type of fax system or systems does your organization use, and does the fax system or systems support inbound fax routing to Exchange?
- Does your organization use automated attendants?
- Do you need support for phone-only users, that is, users who won't have e-mail access?

Supported IP Gateways

Integrating Exchange 2010 Unified Messaging with PBXs requires you to use one or more IP gateways to translate the circuit-switched protocols that are used by TDM-based PBXs to IP-based, packet-switched protocols that are used by Exchange 2010 Unified Messaging. IP gateway vendors with several models of IP gateways have been tested and are supported for Exchange 2010 Unified Messaging.

Interoperability testing of Exchange 2010 Unified Messaging with IP gateways is now integrated with the Microsoft Unified Communications Open Interoperability Program. For more information, see Microsoft Unified Communications Open Interoperability Program.

The Microsoft Unified Communications Open Interoperability Program qualification program for IP gateways and IP PBXs ensures that customers have a seamless setup and support experience when they're using qualified telephony gateways and IP-PBXs with Microsoft Unified Communications software. Only products that meet rigorous and extensive testing

requirements and conform to the specifications and test plans receive qualification.

Interoperability was verified for the following IP gateway vendors in the following years:

- AudioCodes
- Dialogic
- The following table shows the IP gateway vendor, the IP gateway model, and the protocols that are supported by each model.

Supported IP gateways for Unified Messaging

Vendor	Model	Supported protocols
AudioCodes	MediaPack 114/8 FXO	• Analog with In-Band DTMF • Analog with SMDI
AudioCodes	Mediant 1000	• Analog with In-Band DTMF • Analog with SMDI • BRI Q.SIG • T1/E1 Q.SIG • IP-to-IP
AudioCodes	Mediant 2000	• T1/E1 CAS • T1/E1 Q.SIG • IP-to-IP
Dialogic	DMG1000PBXDNIW	Digital Set Emulation
Dialogic	DMG1000LSW	• Analog with In-Band DTMF • Analog with SMDI
Dialogic	DMG2000	• T1 CAS • T1/E1 Q.SIG
Dialogic	DMG3000	• BRI Q.SIG
NET	VX1200	• T1 Q.SIG
Quintum	Tenor DX Series	• T1 Q.SIG

Supported PBXs When Using an AudioCodes IP Gateway

The following table shows the PBXs that are supported using AudioCodes IP gateways including MediaPack-114 FXO, MediaPack-118 FXO, and Mediant 2000.

PBXs Supported with an AudioCodes IP gateway

PBX manufacturer	PBX model/type	AudioCodes model "x" - replace with 4 or 8 per need "y" - replace with 1, 2, 4, 8 or 16 per need
Alcatel	OmniPCX 4400	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP
Aastra	M1000, M2000	• Mediant2000/ySpans/SIP
Avaya	Definity G3	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	Magix/Merlin	• MediaPack 11x/FXO/AC/SIP-0

Avaya	S8300	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	S8700	• MediaPack 11x/FXO/AC/SIP-0 • Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Avaya	IP Office	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP
Cisco	CallManager 4.x	• Mediant1000/IP-to-IP • Mediant2000/IP-to-IP
NEC	Electra Elite	• MediaPack 11x/FXO/AC/SIP-0
NEC	NEAX2400	• MediaPack 11x/FXO/AC/SIP-0 • Mediant2000/ySpans/SIP/RS232
NeXspan	S	• MediaPack 11x/FXO/AC/SIP-0
Nortel	Communication Server-1000M, 1000S, 1000E	• Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Nortel	Meridian 11c, 51c, 61c, 81c	• Mediant1000/ySpans/SIP • Mediant2000/ySpans/SIP
Panasonic	KX-TES824, KX-TEA308	• MediaPack 11x/FXO/AC/SIP-0
Panasonic	KX-TDA30, KX-TDA100, KX-TDA200, KX-TDA600	• MediaPack 11x/FXO/AC/SIP-0

Supported PBXs Using a Dialogic IP Gateway

Each Dialogic IP gateway model supports different PBXs. The following tables show the PBX manufacturer and model and which Dialogic IP gateway can be used. Each IP gateway uses different signaling methods, densities, and protocols.

PBXs Supported Using a DMG1000 Series Media Gateway

The following table shows the PBXs that are supported with the low-density Dialogic

Media Gateway (DMG1000). However, when an analog DMG1000 is used, supplemental signaling (RS232 SMDI, MD110, MCI protocols, or Inband DTMF signaling) is required.

PBXs supported using a low-density Dialogic DMG1000 series IP gateway

PBX manufacturer	PBX model/type	DMG model and additional signaling
Aastra	Aastra MD110 (formerly Ericsson MD110)	DMG1008LSW Analog connectivity using the MD110 RS232 protocol
Alcatel	Omni PCX 4400	DMG1008LSW
Avaya	Definity G3 S8100, S8300, S8700, and S8710 (Communications Mgr SW V2.0 or later versions)	DMG1008DNIW
Intercom		DMG1008LSW Analog connectivity using SMDI serial protocol
Mitel	SX-200D, SX-200 Light, SX-2000 Light, SX-2000 S, SX-2000 VS, SX-200 ICP	DMG1008MTLDNIW
NEC	2000, 2400, 2400 IPX	DMG1008DNIW
Nortel	Meridian 1 - Option 11, 21, 21A, 51, 61, 71, and 81 Meridian SL1 - Generic X11, Release 15 or later versions Nortel Communication Server - 1000M, 1000S, 1000E with V3.0 or later versions	DMG1008DNIW
Nortel	SL 100	DMG1008LSW Analog connectivity using SMDI serial protocol
Siemens	HiCom 300E CS	DMG1008DNIW
Siemens	HiCom 300E (European)	DMG1008LSW Analog connectivity using Inband DTMF signaling
Siemens/ROLM	8000 (SW release 80003 or later versions) 9000 (All versions) 9751 (All versions of SW release 9005) 9751 (SW release 9006.4 or later versions)	DMG1008RLMDNIW

Siemens	HiPath 4000	DMG1008LSW
Toshiba	CTX (SW version AR1ME021.00)	DMG1008LSW
Others	Various	DMG1008LSW Analog connectivity using either Inband DTMF or SMDI

PBXs Supported Using a DMG 2000 Series Media Gateway

The following table shows the PBXs that are supported with the T1/E1 Dialogic Media Gateway (DMG2000). The DMG2000 gateway, which comes in single span (DMG2030DTIQ), dual span (DMG2060DTIQ), or quad span (DMG2120DTIQ) densities, supports the following protocols:

- T1 CAS
- T1 Q.SIG
- E1 Q.SIG
- T1 NI-2
- T1 5ESS
- T1 DMS100

If Channel Associated Signaling (CAS) signaling is used, supplemental signaling (RS232 SMDI, MD110, MCI protocols, or Inband DTMF signaling) is required. If Q.SIG signaling is used, the PBX must support the supplemental services that are associated with calling and called party Information and the call transfer capabilities required by Exchange 2010 Unified Messaging.

PBXs supported with the DMG2000 Media Gateway

PBX manufacturer	PBX model/type	Required software version	Protocol and additional signaling
Alcatel	Omni PCX 4400	Version 3.2.712.5	T1 Q.SIG E1 Q.SIG
Avaya	Definity G3	Version 3 or later	T1 CAS
Avaya	S8500	Manager SW V2.0 or later versions	T1 CAS T1 Q.SIG E1 Q.SIG
Ericsson	MD110	Release MX1 TSW R2A (BC13)	E1 Q.SIG
Intercom			CAS (w/ SMDI serial protocol)
NEC	2400 IMX	Release 5200 Dec. 92 1b or later versions	CAS (w/ MCI serial protocol)
NEC	2400 IPX	R17 Release 03.46.001	T1 Q.SIG
Nortel	Meridian 1 - Option 11	Release 15 or later versions, and options 19 and 46 are required	T1 Q.SIG E1 Q.SIG

Nortel	Communication Server 1000	Version 2121, Release 4	T1 Q.SIG E1 Q.SIG
Siemens	HiCom 300E CS	Release 9006.4 or later (Note: North American software load only)	T1 CAS
Siemens	HiPath 4000	V2 SMR 9 SMPO	T1 Q.SIG E1 Q.SIG
Mitel	SX-2000 S, SX-2000 VS	LW 34	T1 Q.SIG E1 Q.SIG
Mitel	3300	Version 5.1.4.8	T1 Q.SIG E1 Q.SIG

PBXs Supported Using a DMG4008BRI Series Media Gateway

The DMG4000 series Media Gateway comes with several TDM interface options. The DMG4008BRI supports 4-port/8-channel densities and supports the following protocols:

- ISDN BRI Q.SIG
- ETSI-DSS1 (Euro ISDN)
- NET 3 (Belgium)
- VN3 (France)
- 1TR6 (Germany)
- INS-64 (Japan)
- 5ESS Custom (North America - AT&T)
- National ISDN (NI1 - North America)

The following table shows the PBXs that are supported using a Dialogic 4000 Media Gateway Series (DMG4008).

PBXs supported using a DMG4008BRI Media Gateway

PBX manufacturer	PBX model/type	Required software version	Protocol and additional signaling
Siemens	HiCom 300	SA300-V3.05	BRI-Q.SIG (ECMAV2)
Siemens	HiPath 4000	S.0 B4400	BRI-Q.SIG (ECMAV2)

Supported IP PBXs

IP PBXs are also supported by Exchange 2010 Unified Messaging. The following table shows the IP PBXs that are supported using a direct SIP connection to Exchange 2010 Unified Messaging.

IP PBXs supported using a direct SIP connection

PBX manufacturer	PBX model/type	Required software version
Aastra	MX-ONE	4.0
Avaya	Aura	5.2.1 with Service Pack 5 (SP5)

Avaya	Communication Server 2100	CS2100 SE13
Cisco	Call Manager, Unified Communications Manager	5.1, 6.x, 7.0 and8.0

Supported IP PBXs Using SIP Media Gateways

IP PBXs using SIP media gateways are also supported by Exchange 2010 Unified Messaging. The following table shows the IP PBXs that are supported using IP to IP capabilities of SIP media gateways to connect to Exchange 2010 Unified Messaging.

IP PBXs supported using a SIP Media Gateway

PBX manufacturer	PBX model/type	SIP Gateway Model
Cisco	Call Manager 4.x	AudioCodes Mediant 1000/2000 (IP-to-IP enabled)

Exchange Unified Messaging, and Office Communications Server 2007 R2, and Lync Server 2010

Exchange 2010, Microsoft Office Communications Server 2007 R2, and Microsoft Lync Server 2010 can be deployed together to provide voice messaging, Instant Messaging (IM), enhanced user presence, audio-video conferencing, and an integrated e-mail and messaging experience for users in your organization. For more information, see:

- Office Communications Server 2007 Document: Enterprise Voice Planning and Deployment Guide
- Understanding Unified Messaging and Communications Server 2007 R2
- Deploy Unified Messaging and Communications Server 2007 R2
- Lync Server 2010

To find out more about the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure, including finding qualified SIP PSTN gateways and IP PBXs and the process for telephony infrastructure vendors to join and participate in the program, see Microsoft Unified Communications Open Interoperability Program.

1.9.1.12.1 PBX Configuration Notes Tested by Microsoft or IP Gateway Vendor Partners for Exchange 2010 Unified Messaging

PBX Configuration Notes Tested by Microsoft or IP Gateway Vendor Partners for Exchange 2010 Unified Messaging

Unified Messaging > Understanding Unified Messaging > Telephony Advisor for Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-20*

This page provides links to configuration notes that have been created and tested by Microsoft or an IP gateway partner. When Microsoft or a partner deploys Exchange Server

2010 Unified Messaging with a new IP gateway and PBX or IP PBX configuration, the prerequisites and configuration settings are documented. This information is used to create a configuration note.

Each PBX configuration note contains information about how to deploy Exchange 2010 Unified Messaging with a specific telephony configuration, and includes the manufacturer, model, and firmware version for the IP gateways, IP PBXs, or PBXs. In addition, each PBX configuration note includes other information, such as:

- Contributors in authoring the configuration note.
- Detailed prerequisites, including the following:
  - Features that have to be enabled or disabled on the PBX.
  - Specialized hardware that has to be installed.
  - Whether an IP gateway is required.
  - Features that must be present on the IP gateway, if one is needed.
  - Specific cabling requirements between an IP gateway and a PBX.
  - A list of Unified Messaging features that may not be available with a given telephony configuration.

To find out more about the Microsoft Unified Communications Open Interoperability Program for enterprise telephony infrastructure, including finding qualified SIP PSTN gateways and IP PBXs and the process telephony infrastructure vendors can use to join and participate in the program, see Microsoft Unified Communications Open Interoperability Program.

IP Gateway, IP PBX, and PBX Configuration Notes

Microsoft is working with IP gateway partners, AudioCodes and Dialogic, to add to the list of PBXs that are tested. Because we are currently testing many combinations of telephony components, this topic is updated frequently. Please check back if you can't locate the appropriate configuration note for your deployment.

The following configuration notes are available:

- Aastra
- Alcatel
- Avaya
- Cisco
- Inter-Tel
- Intecom
- Mitel
- NEC
- NeXspan
- Nortel
- Panasonic
- Rolm
- ShoreTel
- Siemens
- Tadiran
- Toshiba

1.9.1.13 Unified Messaging Terminology

Unified Messaging Terminology

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-10*

The following table contains the terms and definitions that are used with Microsoft Exchange Server 2010 Unified Messaging.

audio codec

A digital encoding of an analog voice signal. Most audio codecs provide compression of the data, at the cost of some loss of fidelity when the data is recovered. Audio codecs vary in their perceived sound quality, the bandwidth that is required to use them, and the system requirements that are needed to do the encoding.

Audio notes

Text-based notes that can be added to a voice mail message that has been received

in Office Outlook 2007, Outlook 2010, or Outlook Web App.

auto attendant

A software system that answers calls, plays prompts or instructions, and then collects input from the caller as touch tones or speech. Auto attendants can direct a call to telephone numbers or named users or to entities (for example, departments) that the caller specifies, without intervention from a human operator.

Automatic Speech Recognition (ASR)

A technology that enables a computer to match human speech to a predefined set of words or phrases.

call answering

The process by which a caller interacts with a voice mail system if the number they originally called isn't answered. Typically, the system will play a greeting or other prompt, and allow the caller to record a voice message.

Call Answering Rules

A form of call answering in which the user for whom the call is being answered can specify rules to determine the behavior callers experience. The user can specify conditions to be evaluated, greetings, and choices to be provided to the caller, and actions (for example, transfer or leave a message) to be taken as a result of the caller's choice.

conditional call forwarding

A set of conditions that are chosen by a user to be used when they receive an incoming call. The call is redirected based on the conditions that are set.

Dial by Name

A feature that enables a caller to spell a person’s name using the keys on a telephone (ABC=2, DEF=3, etc.).

dial plan

For Exchange Unified Messaging, this is a set of telephony-capable endpoints that share a common numbering plan. The details of the plan are determined by the telephone system to which UM is connected. In the simplest case, this can be a private branch exchange (PBX) with its extensions, each with a unique, fixed-length number.

dialing rule group

Dialing rule groups are created to enable telephone numbers to be modified before they're sent to the PBX or IP PBX for outgoing calls. Dialing rule groups may remove digits from or add digits to telephone numbers that are being used to place calls by a Unified Messaging server.

Each dialing rule group contains dialing rule entries that determine the types of in-country/region and international calls that users within a dialing rule group can make. Each dialing rule group must contain at least one dialing rule entry.

fax partner

UM fax partners provide applications or services that can accept calls handed off by UM when a fax tone is detected. The partner's product or service then receives the fax data, creates a message, and delivers it to the UM-enabled user as an e-mail with a .tif attachment. These messages will appear in the Fax search folder in Office Outlook 2007, Outlook 2010, and Outlook Web App.

hunt group

A set of extensions that are organized into a group, over which the PBX or IP PBX “hunts” to find an available extension. A hunt group is used to direct calls to identically-capable endpoints or to an application, such as voice mail.

In-Country/region number format

The In-Country/region number format specifies how a user's telephone number should be dialed by the Unified Messaging server from a different dial plan that has the same country code. This is used by an auto attendant and when an Outlook Voice Access subscriber searches and tries to call the user in the directory.

This entry consists of a number prefix and a variable number of characters (for example, 020xxxxxxx).

informational announcement

An audio message that is played when a caller first dials in to a Unified Messaging system, which may describe some interest.

International Access Code

The prefix that is used to direct a call internationally. The International Access Code is 011 in the United States and 00 in much of the rest of the world.

International Number Format

The string of digits that is used to define how to dial someone from outside a specific country.

Internet Protocol Private Branch eXchange (IP PBX)

A telephone switch that natively supports voice over IP (VoIP). An IP PBX uses VoIP-based protocols to communicate with IP-based hosts such as VoIP telephones over a packet-switched network. Some IP PBXs can also support the use of traditional analog and digital phones.

IP gateway

1. A third-party hardware device or product that connects a legacy PBX to a LAN. An IP gateway translates or converts TDM or telephony circuit-switched protocols to packet switched protocols that can be used on a VoIP-based network.
2. The Exchange Unified Messaging representation of any SIP peer with which it can communicate using VoIP protocols. It may represent a device that interfaces with a legacy PBX, or an IP PBX, or Microsoft Office Communications Server.

matched name selection method

The mechanism used to help a caller differentiate between users with names that match the touchtone or speech input.

message waiting indicator

A signal that indicates the presence of one or more unread voice messages. For voice mail systems, this is often a lamp on the phone or a stutter dial tone.

Microsoft Exchange Unified Messaging service

A service that implements Unified Messaging capabilities for UM-enabled users.

missed call notification

An e-mail message that is sent to a UM-enabled user that indicates that someone called but did not leave a voice message.

National Number Prefix

A prefix that is used to direct a call as an in-country call. In the United States, this prefix is 1. In the United Kingdom and most the rest of the world, this prefix is 0.

number mask

A set of numbers and wildcard characters that is used to determine the telephone number that the Unified Messaging server will dial. An 'X' represents a single digit (0 … 9). A '*' represents any number of such digits.

numeric extension

A string of digits that doesn't contain a '+' or a country/region code. In dial plans, extensions are required to have a specified length.

outdialing

A process in which Unified Messaging (UM) dials or transfers calls. Unified Messaging generally receives calls, but sometimes dials calls. For example, outdialing occurs when a Unified Messaging auto attendant transfers a call to a user's extension, or when a UM-enabled user uses Play on Phone from Outlook.

Outlook Voice Access

A series of voice prompts that allows authenticated callers to access their e-mail, voice mail, calendar, and contact information using a standard analog, digital, or mobile telephone. Outlook Voice Access also enables authenticated callers to navigate their personal information in their mailbox, place calls, locate users, and navigate the system prompts and menus using DTMF, also known as touchtone, or voice inputs.

Outside Line Access Code

The prefix that is used by UM (or a person using an internal extension on the PBX) to access an outside line. This prefix is typically 9.

pilot identifier

A telephone number that points to a hunt group and is the access number for calls that are routed to Unified Messaging servers. This is also sometimes called a pilot number.

PIN

A passcode that a user enters on the telephone to access their Exchange mailbox.

Play on Phone

A Unified Messaging feature that users can use to play their voice messages or play and record personalized voice mail greetings over a telephone.

Private Branch eXchange (PBX)

A private telephone network in an organization. Individual telephone numbers or extension numbers are supported, and calls are automatically routed to them. Users can call each other using extensions, even across distributed locations.

prompt

An audio message played over the telephone to explain valid options to users.

Protected Voice Mail

A UM feature that uses information rights management to encrypt the contents of voice messages and specify the operations permitted on them. Protection can be caused by caller action (marking the message as private), or by system policy.

reset

When a PIN or a password is reset, the system randomly chooses a new, temporary PIN or password. The user is required to change the temporary PIN the next time that they sign in to Outlook Voice Access.

reverse number lookup (RNL)

A method used to try to locate the name of a person, from a directory or other information store, based on a telephone number.

RTAudio codec

An advanced speech codec that is designed for real-time two-way VoIP applications such as gaming, audio conferencing, and wireless applications over IP. RTAudio is the preferred Microsoft audio codec and is the default codec for Microsoft Unified

Communications platforms.

SIP notification

A SIP notification is a SIP message sent from one SIP peer to another to advise it of a change.

SIP peer

A SIP-enabled device that provides telephony communications between an IP gateway or SIP-enabled IP PBX and a Unified Messaging server.

star out

An action a caller can perform when they are dialed in to a Unified Messaging auto attendant but they want to be able to get to Outlook Voice Access to get their e-mail and voice mail. To do this, they press the star key while the auto attendant prompts are being played.

subscriber access number

A number that is configured in a PBX and on a UM dial plan that allows users to access their Exchange mailbox using Outlook Voice Access. In some cases, this may be configured to be the same number as the pilot number (also called a pilot identifier) on the PBX or IP PBX and the UM hunt group.

system prompt

A short audio recording, installed on the Unified Messaging server, which is played to callers by the server. System prompts are used to welcome callers and to inform them of their options when they use the Unified Messaging system.

telephone user interface (TUI)

An interface that is used to navigate the menus of a Unified Messaging system using DTMF, also known touchtone, inputs.

Text-to-Speech (TTS)

Technologies for translating or converting typewritten text into speech.

UM IP gateway

(See IP gateway.) A UM IP gateway is the Exchange Unified Messaging representation of any SIP peer with which it can communicate using VoIP protocols. It may represent a device that interfaces with a legacy PBX, or an IP PBX, or Microsoft Office Communications Server.

UM worker process

A process that's created during the startup of the Microsoft Exchange Unified Messaging service. The UM service, on receiving a request to handle an incoming call, immediately redirects the request to a UM worker process, which carries out all subsequent interactions with the caller.

UM Worker Process Manager

A component that handles the creation and monitoring of all the UM worker processes that are created.

Unified Messaging

An application that consolidates a user’s voice mail and e-mail into one mailbox, so that the user only needs to check a single location for messages, regardless of type. The e-mail server is used as the platform for all types of messages, making it unnecessary to maintain separate voice mail and e-mail infrastructures.

Unified Messaging server role

A set of components and services that enable voice and e-mail messages to be stored in a user’s single mailbox. Users can also access their Exchange mailbox from a

telephone or a computer. The Unified Messaging server role is included in Exchange Server 2007 and Exchange 2010.

voice mail

A system that records and stores telephone messages in a user mailbox.

Voice Mail Preview

A feature that provides text, transcribed from the audio recording, on a voice message when it is delivered.

voice message

An electronic message with a primary content of digitized audio.

Voice over IP (VoIP)

The practice of using an IP data network to transmit voice calls.

VoIP gateway

A computer device that converts between circuit-switched telephony protocols and VoIP protocols.

voice user interface (VUI)

An interface that is used to navigate the menus of a Unified Messaging system using speech inputs.

welcome greeting

A greeting that is played when an external caller calls in to a UM auto attendant or when an Outlook Voice Access user or another caller calls a subscriber access number that is configured on a UM dial plan. The default welcome greetings can be changed by a customer to make them specific to an organization or location.

1.9.1.14 Virtualization of the Unified Messaging Role in Exchange 2010 SP1

Virtualization of the Unified Messaging Role in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-03-07*

Many organizations today rely on some degree of virtualization to run Microsoft Exchange Server 2010. Virtualization of the Unified Messaging (UM) role on the 64-bit edition of Windows Server 2008 R2 is supported starting in Microsoft Exchange Server 2010 Pack 1 (SP1).

Required hardware and software

The virtualized UM server must be running as the guest operating system under Windows Server 2008 R2 Hyper-V. Windows Server 2008 R2 Hyper-V is a powerful virtualization technology that lets organizations take advantage of the benefits of virtualization without having to buy third-party software. By deploying Exchange 2010 together with Windows Server 2008 R2 Hyper-V technology, an organization of any size can avoid the complications that can arise from dealing with third-party virtualization software vendors.

An Exchange 2010 SP1 server that is running the UM server role must be the only Exchange role within a single virtualized server or Hyper-V environment. Other Exchange

2010 server roles, such as Client Access, Edge Transport, Hub Transport, and Mailbox, are not supported in the same virtualized server as the UM server role.

We recommend that the computer that is running the virtualized UM server have at least four CPU cores, and at least 16 GB of memory. For virtualizing UM, the essential requirement is a 1-to-1 mapping of physical cores to virtual cores, and no overbooking. We recommend that the virtualized UM be configured to use at least 2 GB of RAM per core.

In this configuration, a virtualized UM server that experiences a typical mixture of user and caller interactions can handle fewer concurrent calls than a physical UM server that has the same specifications. Under a sustained load, tests show that a virtualized UM server that is configured as described can handle 40 concurrent calls if Voice Mail Preview is active for all UM users, and it can handle 65 concurrent calls if Voice Mail Preview is not in use.

UM does some media (audio) I/O and processing. For the production and consumption of this media, the UM role must be able to keep up with the demands of other endpoints or the user experience will suffer. For example, users may notice audio dropout, either directly for playback or indirectly if speech recognition accuracy is affected.

Facts to consider before deploying UM in a virtualized environment

When you deploy UM servers in both a physical and a virtualized environment, you must consider multiple factors that can affect your Exchange environment:

- The number of mailboxes that are enabled for UM
- The number of incoming calls that are processed
- Whether Voice Mail Preview is enabled for UM-enabled users
- The amount of RAM and the number of processor cores per UM server

In typical UM deployments, the ratio of UM-enabled mailboxes that are served to concurrent calls is at least 100:1. This is because the amount of time that a UM server spends in servicing requests (such as recording messages or using Outlook Voice Access) for any given user usually amounts to a few minutes per day. Therefore, a UM server role, virtualized as described, supports about 4,000 UM-enabled mailboxes if they all have Voice Mail Preview enabled, and about 6,500 mailboxes if Voice Mail Preview is not enabled.

A virtualized UM server role can handle fewer concurrent incoming calls than a physical UM server with the same specifications. Concurrent incoming calls include incoming calls such as call answering or voice mail calls, fax calls, Outlook Voice Access calls, and calls that are answered by UM auto attendants.

A virtualized UM server that is running under Hyper-V can process approximately 40 concurrent incoming calls when Voice Mail Preview is active for all UM-enabled users, and can handle 65 concurrent calls if Voice Mail Preview is not active.

Voice Mail Preview is a UM feature that provides users a text version of their voice messages. The text is generated by automatic speech recognition, and is included with the voice message when it is delivered. Voice Mail Preview is supported in 7 UM language packs (US English, Canadian English, French, Italian, Spanish, Portuguese, and Polish).

If Voice Mail Preview is used, a UM server throttles Voice Mail Previews if the UM server is too busy or is overloaded with incoming calls. Therefore, the percentage of voice messages that include a transcription may be less than 100 percent, depending on the UM configuration and the environment. To be reasonably sure that all average-length voice messages contain voice mail preview text, we recommend that you set the number of concurrent incoming calls to be processed by a virtualized UM server to about 25 instead of 40.

Administrators who must run UM in an environment in which voice mail usage is much heavier than usual should reduce these values. If users receive an average of 10 or more voice messages per day, or use Outlook Voice Access for more than five minutes per day, the ratio of UM-enabled mailboxes that are served to concurrent calls will be nearer to 30:1.

Generally, a UM server role, virtualized as described, should support about 4,000 UM-enabled mailboxes if the mailboxes all have Voice Mail Preview enabled, and about 6,500 mailboxes if Voice Mail Preview is not enabled.

More Information

The Exchange 2010 UM role provides voice mail services, and consolidates voice mail and email messages into a user's Inbox. For more information about the UM server role, see Voicemail with Unified Messaging in Exchange 2010.

An organization might have many different reasons to want to virtualize an Exchange environment. The most common reasons for most organizations are as follows:

- To consolidate underused Exchange servers onto one physical server for increased hardware utilization.
- To consolidate Exchange Client Access server (CAS) and HUB server roles into a virtualized environment together with other server roles on the same or different physical servers (especially useful for small and medium-sized organizations or for branch offices of large organizations).
- To save space, power, and cooling for the servers that are running Exchange.

Exchange can be virtualized on one or more servers. A small organization can have a single server that provides all the required Exchange roles and functionality. A large organization requires a more complex configuration in which the Exchange roles are installed on multiple servers for the CAS, Hub Transport, Edge, Mailbox, and UM roles. Each of these roles includes its own unique workload characteristics. Typically, the different server roles work most intensively with the following components:

- Mailbox: processor, memory, disk
- CAS: processor, memory
- Hub Transport: memory, disk
- UM: processor, disk

You must perform careful planning and workload balancing for all of the server roles to determine the optimum configurations. All server roles can be expanded to additional servers to provide high availability and failover for your Exchange environment.

Install the Exchange 2010 Unified Messaging Server Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use several methods to install the Unified Messaging (UM) server role on a computer running Microsoft Exchange Server 2010. The Unified Messaging server role can be installed on a single computer that has no other Exchange 2010 server roles installed or on a computer running another Exchange 2010 server role. This topic discusses the methods you can use to install the Unified Messaging server role.

Important:

After you install the Unified Messaging server role, you must perform other tasks before the Unified Messaging server can process incoming calls. To complete the steps required to enable and configure Unified Messaging, see Deploy a New Exchange 2010 RTM UM Environment.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the Setup wizard to install the UM server role

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

You can use the Setup wizard on the Exchange 2010 installation DVD to install the Unified Messaging server role. For more information about how to install the Unified Messaging server role using the Setup wizard, see Install Exchange 2010 Using the Custom Installation Type.

Use the command prompt to perform an unattended installation of the UM server role

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

You can perform an unattended installation of the Unified Messaging server role at a command prompt. For more information about how to perform an unattended installation of the Unified Messaging server role, see Install Exchange 2010 in Unattended Mode.

Use Setup.com to add or remove a UM Server Role

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

You can use Setup.com to add or remove the Unified Messaging server role to an existing

Exchange 2010 server. Setup.com supports command-line switches for performing scripted or quiet installations of Exchange 2010.

Important:

After you install the Unified Messaging server role, you must restart the system to allow the Unified Messaging service to reserve the TCP ports required.

Other Tasks

After you install the Unified Messaging server role you may also want to:

- Create a UM Dial Plan
- Create a UM IP Gateway

1.9.2.1.2 Uninstall the Unified Messaging Server Role in Exchange 2010

Uninstall the Unified Messaging Server Role in Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove the Unified Messaging server role from a computer running Microsoft Exchange Server 2010. When you uninstall or remove the Unified Messaging server role from an Exchange 2010 server, the server can no longer answer and process incoming calls.

In certain situations, you may have to remove the Unified Messaging server role from an Exchange 2010 server. If the Unified Messaging server role has been installed on the same server as another Exchange 2010 server role, you can remove the Unified Messaging server role using Setup.com.

Prerequisites

You must ensure that each of the Exchange 2010 server roles meets the appropriate prerequisites and system requirements before you begin the modification or uninstall process. For more information about server roles, see Overview of Exchange 2010 Server Roles. To understand the prerequisites for all server roles, see Exchange 2010 Prerequisites. For more information about system requirements, see Exchange 2010 System Requirements.

Remove the Unified Messaging server role

To perform the following procedure you must log on by using an account that's a member of the local Administrators group on the computer you're performing the procedures on. Or, the account you use must be a member of the Delegated Setup role group.

You can either run Exchange 2010 Setup.exe or navigate to Control Panel to modify or remove the Exchange 2010 Unified Messaging server role. In Control Panel, you can either remove the specific server role or the entire installation.

1. The Exchange Server 2010 Setup wizard begins the process of changing or removing your Exchange installation on the **Exchange Maintenance Mode**

page. Click **Next** to continue.
2. On the **Server Role Selection** page, select **Unified Messaging Role**. Click **Next** to continue.
3. On the **Readiness Checks** page, view the status to determine whether the organization and server role prerequisite checks completed successfully. If the prerequisite checks didn't complete successfully, review the **Summary** page to help troubleshoot and fix any issues that are preventing Setup from completing. If the checks completed successfully, click **Uninstall** to remove the Unified Messaging server role.

4. On the **Completion** page, click **Finish**.

1.9.2.1.3 View or Configure the Properties of a UM Server

View or Configure the Properties of a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you install the Unified Messaging (UM) server role, you first need to add the Unified Messaging server to a UM dial plan to allow it to process incoming calls. You can also configure several options including the number of concurrent calls that the Unified Messaging server can answer.

Looking for other management tasks related to Unified Messaging servers? Check out Managing Unified Messaging Servers.

What Do You Want to Do?

- Use the EMC to view or configure Unified Messaging server properties
- Use the Shell to configure Unified Messaging server properties
- Use the Shell to view Unified Messaging server properties

Use the EMC to view or configure Unified Messaging server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM servers" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Unified Messaging**.
2. In the work pane, select the Unified Messaging server that you want to configure.
3. In the action pane, click **Properties**.

4. On the **General** tab, you can view general information about the server:
   - **Version** This field displays the version of Exchange installed on the server.
   - **Edition** This field displays the Exchange Server edition. The edition is either Standard Edition or Enterprise Edition.
   - **Role(s)** This field displays the Exchange server roles installed on the server.
   - **Product ID** This field displays the product ID for the Exchange server. If

you haven't yet entered the product key for the server, the product ID displayed is **Unlicensed**. To license an unlicensed version of Exchange, see Enter Product Key.

- **Modified** This field displays the last date and time that a configuration change was made on this server.

5. On the **System Settings** tab, view the domain controller servers and global catalog servers. You can also enable an error reporting feature:
   - **Domain controller servers being used by Exchange** This read-only box displays a list of domain controller servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.

   - **Global catalog servers being used by Exchange** This read-only box displays a list of global catalog servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.

   - **Automatically send fatal service error report to Microsoft** Select this check box if you want to enable the error reporting feature and automatically send an error report to Microsoft in the event of a fatal error.
     If you enable the error reporting feature, information about fatal service errors is sent to Microsoft over encrypted channels. The information is used to improve Microsoft products.
     When this feature is enabled and the issue reported has a known solution, the server receives feedback from Microsoft. This feedback contains a link to information that may help resolve the problem.

6. On the **Customer Feedback Options** tab, you can enroll the selected server into the Customer Experience Improvement Program. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.

7. Use the **UM Settings** tab to view and configure settings for the Unified Messaging (UM) server. This tab is available only on servers that have the Unified Messaging server role installed.
   - **Associated Dial Plans** Use this box to view the UM dial plans associated with the Unified Messaging server. When you install the Unified Messaging server role on a computer running Exchange Server 2010, the server is left in an enabled state. However, for the UM server to answer and process incoming calls, you must also associate a UM dial plan with the UM server. Click **Add** to select a UM dial plan.
     An Exchange 2010 UM server can be associated with multiple UM dial plans that have different Voice over IP (VoIP) security settings at the same time. After you associate the UM server with a UM dial plan, the UM server will process incoming calls for users who are associated with the UM dial plan.
   - **Prompt languages** Use this text box to view the languages supported by the UM server. The languages listed in this box are the languages or language packs installed on the UM server.
     By default, when you install the Unified Messaging server role, the U.S. English (en-US) language is installed even if you chose to install other languages when you installed Exchange 2010, and it can't be removed. However, after you've downloaded the appropriate UM language packs, you can add language packs for UM by using the **Setup.com /AddUMLanguagePack** or run the *<UMLanguagePack>*.exe installation program after you've downloaded the UM language pack from Exchange Server 2010 UM Language Packs. For details about how to add UM languages, see Managing Unified Messaging Servers.

- **Startup mode** Use this list to specify whether the Microsoft Exchange Unified Messaging service on a Unified Messaging server will start in **TCP**, **TLS**, or **Dual** mode. If the UM server is being added to UM dial plans that have different security settings, you should select Dual mode. In Dual mode, the UM server can listen on ports 5060 and 5061 simultaneously. If you change the startup mode, you must restart the Microsoft Exchange Unified Messaging service for the change to take effect.
- **Maximum concurrent calls** Use this box to specify the number of concurrent incoming voice call connections that the UM server will accept. When you increase the number of concurrent connections on a UM server, more system resources are required than if you decrease the number of concurrent voice call connections. Decreasing this setting is especially important on low-end, slower UM servers.

  The range for this setting is from 0 through 200. The default setting is 100. There are performance counters that you can use to monitor the current number of voice calls connected to a UM server.

Use the Shell to configure Unified Messaging server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM servers" entry in the Unified Messaging Permissions topic.

This example prevents a Unified Messaging server named `MyUMServer` from accepting new calls.

```
Set-UMServer -Identity MyUMServer -Status NoNewCalls
```

This example removes a Unified Messaging server named `MyUMServer` from all UM dial plans.

```
Set-UMServer -Identity MyUMServer -DialPlans $null
```

This example adds the Unified Messaging server named `MyUMServer` to a UM dial plan named `MyUMDialPlanName` and also sets the maximum number of incoming voice calls.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlanName -MaxCalls 50
```

This example changes the grammar generation schedule to 02:30 to 03:00 (2:30 A.M. to 3:00 A.M.) every day on a Unified Messaging server named `MyUMServer`.

```
Set-UMServer -Identity MyUMServer -GrammarGenerationSchedule 1.02:30-1.03:00, 2.0
```

For more information about syntax and parameters, see Set-UMServer.

Use the Shell to view Unified Messaging server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM servers" entry in the Unified Messaging Permissions topic.

This example displays a list of all the Unified Messaging servers in the Active Directory forest.

```
Get-UMServer
```

This example displays a formatted list of properties for the Unified Messaging server named MyUMServer.

```
Get-UMServer -Identity MyUMServer | Format-List
```

For more information about syntax and parameters, see Get-UMServer.

Other Tasks

After configuring a Unified Messaging server, you may also want to:

- Install a Unified Messaging Language Pack on a UM Server
- Configure the Default Language on a UM Dial Plan
- Enable a User for Unified Messaging

For More Information

Understanding Unified Messaging Servers

1.9.2.1.4 Enable Unified Messaging on Exchange 2010

Enable Unified Messaging on Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable Unified Messaging (UM) in Microsoft Exchange Server 2010. You must enable the Exchange computer running the Unified Messaging server role before the Unified Messaging server can process calls for UM-enabled Exchange 2010 recipients in your Exchange organization. However, the Unified Messaging server also must be added to a UM dial plan before it can process calls for Unified Messaging.

Although, by default, the Unified Messaging server is in an enabled state after the Unified Messaging server role is installed, the Unified Messaging server also has a status parameter that can be used to enable or disable the Unified Messaging server functions. The Unified Messaging server status is controlled by the **Enable-UMServer** and **Disable-UMServer** commands.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- The Unified Messaging server status is set to disabled. For detailed steps, see Disable Unified Messaging on Exchange 2010.

Use the EMC to enable Unified Messaging on an Exchange 2010 server

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration** > Unified Messaging.
2. In the result pane, select the Unified Messaging server to enable.
3. In the action pane, click **Enable UM Server**.

Use the Shell to enable Unified Messaging on an Exchange 2010 server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example enables a UM server named MyUMServer to answer incoming calls.

```
Enable-UMServer -Identity MyUMServer
```

For more information about syntax and parameters, see Enable-UMServer.

Other Tasks

After you enable Unified Messaging on an Exchange 2010 server, you may also want to:

- Add a UM Server to a Dial Plan
- Configure the Startup Mode on a UM Server

1.9.2.1.5 Disable Unified Messaging on Exchange 2010

Disable Unified Messaging on Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use disable a Unified Messaging (UM) server in Microsoft Exchange Server 2010. When you disable Unified Messaging in Exchange 2010, you prevent the Unified Messaging server from answering Unified Messaging incoming calls. You can choose to disconnect all calls immediately or else wait for existing calls to be processed before disabling the Unified Messaging server.

After you disable the Unified Messaging server, it will no longer:

- Answer any incoming calls.
- Respond to Play on Phone requests from a Client Access server.
- Be used to manage UM-enabled mailboxes.
- Be queried when a diagnostic task is used.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the EMC to disable Unified Messaging

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server to disable.
3. In the action pane, click one of the following:
   3.a. When you select the **Disable Immediately** option, the Unified Messaging server disconnects all calls connected to the Unified Messaging server.
   3.b. When you select the **Disable After Completing Calls** option, the Unified Messaging server won't accept new calls and won't be disabled until all calls have been processed.
4. In the confirmation dialog box, click **Yes** to continue.

Use the Shell to disable Unified Messaging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example disables Unified Messaging on the Unified Messaging server named MyUMServer but doesn't disconnect calls that are being processed.

```
Disable-UMServer -Identity MyUMServer
```

This example disables Unified Messaging on the Unified Messaging server named MyUMServer and disconnects all calls being processed.

```
Disable-UMServer -Identity MyUMServer -Immediate $true
```

For information about syntax and parameters, see Disable-UMServer.

Other Tasks

After you disable Unified Messaging, you may also want to:

- Enable Unified Messaging on Exchange 2010
- Configure the Startup Mode on a UM Server
- Add a UM Server to a Dial Plan

1.9.2.1.6 Add a UM Server to a Dial Plan

Add a UM Server to a Dial Plan

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you install the Unified Messaging (UM) server, it's left in an enabled state. However, before the UM server can answer and process incoming calls, you must add the UM server to a UM dial plan. You can add a Microsoft Exchange Server 2010 UM server to one or more UM dial plans with different security settings at the same time.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

Before you perform these procedures, confirm that a UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to add a UM server to a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Server Configuration**.
2. In the result pane, select the Unified Messaging server.
3. In the action pane, click **Properties**.
4. On the **UM Settings** > **Associated Dial Plans**, click **Add**.
5. In the **Select Dial Plan** window, select the dial plan you want to add from the list of available dial plans, and then click **OK**.
6. Click **OK** again to accept your changes.

Use the Shell to add a UM server to a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example adds a Unified Messaging server to a dial plan named `MyUMDialPlan` and prevents the UM server from accepting new calls. It also sets the start up mode to dual mode, which enables the UM server to accept TCP and TLS requests.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlan -Status Disabled -UMSta
```

This example adds the Unified Messaging server named `MyUMServer` to two UM dial plans, named `MyUMDialPlan` and `MyUMDialPlan2`, and also sets the maximum number of incoming voice and fax calls.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlan, MyUMDialPlan2 -MaxCall
```

For more information about syntax and parameters, see Set-UMServer.

Other Tasks

After you've added a UM server to a dial plan, you may also want to:

- Install a Unified Messaging Language Pack on a UM Server
- View or Configure the Properties of a UM Server

1.9.2.1.7 Remove a UM Server from a Dial Plan

Remove a UM Server from a Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove an Microsoft Exchange Server 2010 Unified Messaging server from a UM dial plan. When you remove a Unified Messaging server from a UM dial plan, the Unified Messaging server will no longer answer calls or process UM calls for UM-enabled recipients.To process calls, a Unified Messaging server must be added to at least one UM dial plan. However, a Unified Messaging server can be added to multiple UM dial plans.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- The Unified Messaging server has been added to at least one UM dial plan. For detailed steps, see Add a UM Server to a Dial Plan.

Use the EMC to remove an Exchange 2010 server from a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, select the Unified Messaging server.
3. In the action pane, click **Properties**.
4. On the **UM Settings** tab, in the **Associated Dial Plans** section, click **Remove**.
5. In the confirmation dialog box, click **Yes** to confirm the deletion of the Exchange 2010 server from the UM dial plan.
6. Click **OK** to close the properties window.

Use the Shell to remove an Exchange 2010 server from a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example removes a UM server named `MyUMServer` from the dial plan named `MyUMDialPlan`.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlan
```

For more information about syntax and parameters, see Set-UMServer.

Other Tasks

After you remove an Exchange 2010 server from a dial plan, you may also want to:

- Disable Unified Messaging on Exchange 2010
- Uninstall the Unified Messaging Server Role in Exchange 2010

1.9.2.1.8 Install a Unified Messaging Language Pack on a UM Server

Install a Unified Messaging Language Pack on a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

To make a language available in the list of available Unified Messaging languages on the **Settings** tab of a UM dial plan, you must first install the appropriate UM language pack. You install the language pack on a Unified Messaging server by using the language-specific self-extracting executable file or the **setup.com /AddUmLanguagePack** command. Before you can install a UM language pack, you must first download it to a local folder on the UM server. You can download UM language packs from Exchange Server 2010 SP2 UM Language Packs.

After you install the appropriate UM language pack, you can view the list of installed UM language packs by viewing the properties on the **UM Settings** tab of a Unified Messaging server. You can also configure the default language to be a language other than English (en-US) on UM dial plans and auto attendants.

Caution:

The UM language packs for Microsoft Exchange Server 2007 or Exchange 2007 Service Pack 1 (SP1), SP2, or SP3 can't be used on an Exchange 2010 Unified Messaging server. The UM language packs for Exchange Server 2010 RTM or SP1 can’t be installed on a UM server running Exchange 2010 SP2.

Looking for other management tasks related to Unified Messaging servers? Check out Managing Unified Messaging Servers.

What Do You Want to Do?

- Use the UM Language Pack Installation file to install a UM language pack
- Use setup.com to install a UM language pack

Use the UM Language Pack Installation file to install a UM language pack

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. From the Microsoft Download Center, download the language-specific UM language pack file into a local folder on the UM server.
2. Double-click the UMLanguagePack.*<CultureCode>.exe* file. For example, for the German UM language pack, you would download the file named UMLanguagePack.de-DE.exe.

3. In the Exchange Server 2010 Setup wizard, on the **License Agreement** page, read the terms of the agreement, select **I accept the terms in the license agreement**, and then click **Next**.

4. On the **Unified Messaging Language Pack** page, verify that the correct language is listed in the **The following Unified Messaging Language Pack (s) will be installed** window, and then click **Install**.

5. On the **Completion** page, confirm whether the UM language pack was successfully installed.
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the installation of the UM language pack.

Use setup.com to install a UM language pack

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example installs the Japanese (ja-JP) UM language pack that's been downloaded to the D:\Exchange\UMLanguagePacks folder on a Unified Messaging server.

```
setup.com /AddUmLanguagePack:ja-JP /s:d:\Exchange\UMLanguagePacks
```

This example installs the Mexican Spanish (es-MX) and German (de-DE) UM language packs that have been downloaded to the D:\Exchange\UMLanguagePacks folder on a UM server.

```
setup.com /AddUmLanguagePack:es-MX,de-DE /s:d:\Exchange\UMLanguagePacks
```

For more information about available UM languages and the culture codes, see Understanding Unified Messaging Languages.

Other Related Tasks

After you install a Unified Messaging language pack, you may also want to:

- Configure the Default Language on a UM Dial Plan
- Add a UM Server to a Dial Plan

For More Information

Understanding Unified Messaging Languages

1.9.2.1.9 Remove a Unified Messaging Language Pack from a UM Server

Remove a Unified Messaging Language Pack from a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In Microsoft Exchange Server 2010, you can manage UM languages on Unified Messaging servers using the Exchange Management Console or the Exchange Management Shell. However, to remove a language from the list on a UM dial plan, you must remove the appropriate UM language pack from the Unified Messaging server by using the **Setup.com /RemoveUmLanguagePack** command. After you remove the UM language pack from the Unified Messaging server, the language won't be available when you configure a UM dial plan. You can view the UM language packs that are installed by viewing the properties of the Unified Messaging server or using the **Get-UMServer** cmdlet.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use Setup.com to remove a UM language pack

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

At a command prompt, run the following command:

```
Setup.com /RemoveUmLanguagePack:<UmLanguagePackName> /s: d:\<MyLocalFolder>
```

In the previous command, *<UmLanguagePackName>* is the name of the UM language pack, for example, fr-FR.

Caution:

You can't use the Setup.com file that's located in the \Bin folder to remove a UM language pack after you've installed any updates for Exchange 2010. You must use the Setup.com file from the Exchange 2010 DVD or the downloaded source files. If you don't, you'll see the following error: There is a version mismatch between the running application and the installed application.

Other Tasks

After you remove a UM language pack, you may also want to:

- Configure the Default Language on a UM Dial Plan
- Configure the Language Setting on a UM Auto Attendant

1.9.2.1.10 Configure the Startup Mode on a UM Server

Configure the Startup Mode on a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the startup mode for the Microsoft Exchange Unified Messaging service on a Unified Messaging (UM) server. By default, the UM server will startup in TCP mode, but if

you are using Transport Layer Security (TLS) to encrypt Voice over IP (VoIP) traffic you must configure the UM server to use TLS or Dual mode. A UM server can be added to UM dial plans that have different security settings. If the UM server has been added to dial plans with different security settings, you should select Dual mode. If you change the startup mode, you must restart the Microsoft Exchange Unified Messaging service for the change to take effect

Important:

When Exchange Server 2010 is installed, static Windows Firewall rules are added for Exchange. If you change the TCP ports that are used by the Unified Messaging server role, you may also need to reconfigure the Windows Firewall rules to allow Unified Messaging to work correctly.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the EMC to configure the startup mode

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. In the console root, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, click to select the Unified Messaging server you want to set up.
3. In the action pane, click **Properties**.
4. On the **UM Settings** tab, in the **Startup Mode** drop-down list, select one of the following settings:
   - 4.a. **TCP** Use this setting if the UM server is being added to only UM dial plans that are set to **Unsecured** but won't be added to dial plans that are set to **SIP Secured** or **Secured**. In TCP mode, the UM server will only listen on TCP port 5060 for SIP requests. By default, the UM server will startup in TCP only mode.
   - 4.b. **TLS** Use this setting if the UM server is being added to UM dial plans that are set to **SIP Secured** or **Secured** but won't be added to dial plans that are set to **Unsecured**. In TLS mode, the UM server will only listen on TCP port 5061 for SIP requests.
   - 4.c. **Dual** Use this setting if the UM server is being added to UM dial plans that have different security settings. In Dual mode, the UM server can listen on ports 5060 and 5061 simultaneously.

     Note:

     If you change the startup mode, you must restart the Microsoft Exchange Unified Messaging service for the change to take effect.
5. Click **OK**.

Use the Shell to configure the startup mode

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example sets the startup mode for a UM server named `MyUMServer1` to Dual mode.

```
Set-UMServer -Identity MyUMServer1 -UMStartUpMode Dual
```

This example sets the startup mode for a UM server named MyUMServer1 to TCP mode.

```
Set-UMServer -Identity MyUMServer1 -UMStartUpMode TCP
```

For more information about syntax and parameters, see Set-UMServer.

Other Tasks

After you configure the startup mode, you may also want to:

- Configure VoIP Security on a UM Dial Plan
- View the Number of Active Calls for a UM Server

1.9.2.1.11 Configure the Number of Concurrent Calls on a UM Server

Configure the Number of Concurrent Calls on a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You configure the number of incoming concurrent voice call connections that a Unified Messaging (UM) server accepts in Microsoft Exchange Server 2010. When you increase the number of concurrent connections on a Unified Messaging server, more system resources are required than if you decrease the number of concurrent voice call connections. Decreasing this setting is especially important on low-end, slower computers on which Unified Messaging is installed.

Note:

The range for the number of concurrent voice calls is 0 to 200. The default setting is 100.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Unified Messaging Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Unified Messaging**.
2. In the result pane, click to select the Unified Messaging server you want to set up.
3. In the action pane, click **Properties**.
4. On the **UM Settings** tab, in the **Maximum concurrent calls** text box, type the maximum number of concurrent voice calls.
5. Click **OK**.

Use the Shell to set up the number of concurrent connections on a Unified Messaging server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example sets the number of incoming calls that can be accepted by a UM server named MyUMServer1 to 50.

```
Set-UMServer -Identity MyUMServer1 -MaxCallsAllowed 50
```

For more information about syntax and parameters, see Set-UMServer.

Other Tasks

After you configure the number of concurrent calls, you may also want toView the Number of Active Calls for a UM Server.

1.9.2.1.12 Start the Microsoft Exchange Unified Messaging Service

Start the Microsoft Exchange Unified Messaging Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Services snap-in in Microsoft Management Console (MMC) or cmd.exe at a command prompt to start the Microsoft Exchange Unified Messaging service. By default, the Microsoft Exchange Unified Messaging service is started after the Unified Messaging server role is installed on a computer running Microsoft Exchange Server 2010. However, there may be times when you must restart the Microsoft Exchange Unified Messaging service manually, for example, when you've taken the Unified Messaging server offline and have to bring it back online.

When the Microsoft Exchange Unified Messaging service is started on a Unified Messaging server, the Unified Messaging server is available to process incoming UM calls.

Note:

The default startup time for the Microsoft Exchange Unified Messaging service is 120 seconds. You can increase this time-out value by editing the Msexchangeum.config file located in the \Program Files\Microsoft Exchange\V14\bin folder.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the MMC Services snap-in to start the Microsoft Exchange Unified Messaging service

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, and then click **Control Panel**.
2. In **Control Panel**, double-click **Administrative Tools**.
3. In **Administrative Tools**, double-click **Services**.
4. In the **Services** result pane, right-click **Microsoft Exchange Unified Messaging**, and then click **Start**.

Use a command prompt to start the Microsoft Exchange Unified Messaging service

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, and then click **Run**.
2. In the **Open** box, type the following command, and then press **ENTER**.

```
net start MSExchangeUM
```

Other Tasks

After you start the Microsoft Exchange Unified Messaging service, you may also want to:

- Configure the Startup Mode on a UM Server
- Stop the Microsoft Exchange Unified Messaging Service

1.9.2.1.13 Stop the Microsoft Exchange Unified Messaging Service

Stop the Microsoft Exchange Unified Messaging Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can stop the Microsoft Exchange Unified Messaging service using the Services snap-in in Microsoft Management Console (MMC) or at a command prompt. There may be times when you need to stop this service, for example, when you must take the Unified Messaging server offline. When you stop the Microsoft Exchange Unified Messaging service, the Unified Messaging server won't be able to accept and process incoming calls.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the MMC Services snap-in to stop the Microsoft Exchange Unified Messaging service

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, and then click **Control Panel**.
2. In **Control Panel**, double-click **Administrative Tools**.
3. In **Administrative Tools**, double-click **Services**.
4. In the **Services** details pane, right-click **Microsoft Exchange Unified Messaging**, and then click **Stop**.

Use a command prompt to stop the Microsoft Exchange Unified Messaging service

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, and then click **Run**.
2. In the **Open** box, type the following command, and then press **ENTER**.

```
net stop MSExchangeUM
```

Other Tasks

After you stop the Microsoft Exchange Unified Messaging service, you may also want to:

- Start the Microsoft Exchange Unified Messaging Service
- Configure the Startup Mode on a UM Server

1.9.2.1.14 View the Number of Active Calls for a UM Server

View the Number of Active Calls for a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view the number of active Unified Messaging (UM) calls being processed. You can view the number of active calls for a UM dial plan, a Unified Messaging server, or all calls for a UM IP gateway. If you use the **Get-UMActiveCalls** cmdlet to view the number of active calls for dial plans or IP gateways, the cmdlet uses Active Directory to determine which Unified Messaging servers must be contacted.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the Performance console to view the number of active calls

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, click **Programs**, click **Administrative Tools**, and then click **Performance**.
2. In the **Performance** console, right-click the details pane, and then select **Add Counters** from the menu. You can also press CTRL+I to open the **Add Counters** window.
3. In the **Add Counters** window, in the **Performance object** list, select **MSExchangeUMGeneral**.
4. In **Select Counters from list**, select **Current Calls**, click **Add**, and then click **Close**.
5. In the **Performance** console, in the details pane, select the **Current Calls**

counter to display the number of current calls.

Use the Shell to view the number of active calls for a Unified Messaging server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example displays the details of all active calls on the local Unified Messaging server.

```
Get-UMActiveCalls
```

This example displays the details of all active calls on a Unified Messaging server named MyUMServer.

```
Get-UMActiveCalls -Server MyUMServer
```

This example displays the details of all active calls being processed by a UM IP gateway named MyUMIPGateway.

```
Get-UMActiveCalls -IPGateway MyUMIPGateway
```

This example displays a list of active calls associated with the UM dial plan named MyUMDialPlan.

```
Get-UMActiveCalls -DialPlan MyUMDialPlan
```

Note:

When a Unified Messaging server is process cycling, the **Get-UMActiveCalls** cmdlet won't return a list of all calls for the retired process and the active process. It returns the active calls only for the new process.

For more information about syntax and parameters, see Get-UMActiveCalls.

Other Tasks

After you view the number of active calls for a Unified Messaging server, you may also want to:

- Testing Unified Messaging Server Functionality
- Test Unified Messaging Server Operation

1.9.2.1.15 View Call Statistics for a UM Server

View Call Statistics for a UM Server

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the **Call Statistics** tool, available in Exchange Server 2010 Service Pack 1 (SP1), to provide aggregated statistical information about calls that are forwarded to or

placed by UM servers. This information is helpful for administrators who are interested in overall statistics for the Exchange 2010 Unified Messaging (UM) servers in their organization. Call statistics reports that you initiate in the EMC are displayed in the Exchange Control Panel (ECP) user interface. For more information, see New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1.

Reports can be filtered to show call statistics by month, by day, for the past 90 days, or since UM was deployed in your organization. You can then filter these results by UM dial plan and UM IP gateway within your organization.

Call statistics reports display:

- The total number of calls, organized by type of call (for example, missed calls, Outlook Voice Access calls, or fax calls).
- The average audio quality metrics for the selected month, day, or all calls placed or forwarded since UM was deployed in your organization.

For more information about the **Call Statistics** tool, see Using Unified Messaging Tools.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM server has been added to a UM dial plan. For detailed steps, see Add a UM Server to a Dial Plan.

Use the EMC to view the call statistics for a UM server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM call data and summary reports" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Toolbox**, then **Call Statistics**, and then click **Open Tool** from the **Actions** menu. If you receive the error message "There is a problem with this website's security certificate", click **Continue to this website (not recommended)**.
2. In the **Outlook Web App** window, enter the correct user account (in the format Domain\user name) and password, and then click **Sign in**.
3. If this is your first time signing in to the ECP, select your language and time zone, and then click **OK**.
4. In the **Call Statistics** window, specify the following:
   4.a. **Show** Select the time period to show for incoming calls.
   4.b. **UM dial plan** Select the UM dial plan you want call statistics for.
   4.c. **UM IP gateway** Select the UM IP gateway you want call statistics for.
5. The call details will be listed in the table that's displayed in the window.

Use the Shell to view the call statistics for a UM server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM call data and summary reports" entry in the Unified Messaging Permissions topic.

This example displays the statistics for all calls received by or placed by Unified Messaging servers in an organization.

```
Get-UMCallSummaryReport -GroupBy Total
```

This example displays the statistics for all calls received by or placed by Unified Messaging servers in an organization over the last 12 months.

```
Get-UMCallSummaryReport -GroupBy Month
```

This example displays the statistics for all calls received by or placed by Unified Messaging servers in the organization over the last 90 days.

```
Get-UMCallSummaryReport -GroupBy Day
```

This example displays the statistics for calls received or placed by Unified Messaging servers for the UM dial plan MyUMDialPlan.

```
Get-UMCallSummaryReport -GroupBy Month -UMDialplan MyUMDialPlan
```

For more information about syntax and parameters, see Get-UMCallSummaryReport.

Other Tasks

After you view the call statistics for a UM server, you may also want to:

- View the Number of Active Calls for a UM Server
- View Call Logs for a UM-Enabled User
- Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool
- Test-UMConnectivity

1.9.2.1.16 Update the Speech Grammar Files on a UM Server

Update the Speech Grammar Files on a UM Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can update the Automatic Speech Recognition (ASR) grammar files for Microsoft Exchange Server 2010 Unified Messaging (UM). Speech grammar files have a file name extension of .cfg and are used by Unified Messaging to enable callers to use speech inputs to perform directory lookups. A folder for each UM language is created in the <Program Files>\Microsoft\Exchange Server\V14\UnifiedMessaging\grammars folder. Each UM language-specific folder contains the grammar files for the given language that are used for Outlook Voice Access. The language-specific folders also contain the grammar files generated by the Microsoft Exchange Unified Messaging service for the global address list, custom address lists, UM dial plans, and UM auto attendants.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Use the galgrammargenerator.exe program to update the speech grammar files on a Unified Messaging server

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

This example creates a grammar file for each UM dial plan to which the specified UM server belongs.

```
Galgrammargenerator.exe -s MyUmServer
```

This example creates a grammar file for the UM-enabled users who belong to the UM dial plan named `MyUMDialPlan`.

```
Galgrammargenerator.exe -d MyUMDialPlan
```

This example creates or updates DTMF maps for users who are enabled for UM and who aren't enabled for UM.

```
Galgrammargenerator.exe -u
```

For more information about syntax and parameters, at the command prompt, type galgrammargenerator.exe -?

Other Tasks

After you update the speech grammar files on a Unified Messaging server, you may also want to:

- Enable or Disable Automatic Speech Recognition on a UM Auto Attendant
- Install a Unified Messaging Language Pack on a UM Server

1.9.2.1.17 Configure Quality of Service (QoS) for Unified Messaging

Configure Quality of Service (QoS) for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 Unified Messaging supports DiffServ through Differentiated Services Code Point (DSCP) marking. In Microsoft Windows Server 2008, TCP/IP performs DiffServ marking when you've installed the Quality of Service (QoS) Packet Scheduler. When you install the Unified Messaging server role on a computer that's running Windows Server 2008 with the QoS Packet Scheduler installed, all outgoing Unified Messaging packets will be marked with a DSCP value that's configured using Group Policy. If you're integrating Exchange Unified Messaging and Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010, you can also configure QoS using DiffServ.

Note:
Layer 3 network devices, such as routers, must also support DiffServ.

When you create a QoS policy on Windows Server 2008, it will be applied to all UDP packets that are set by the Microsoft Unified Communications Managed API v. 2.0 (UCMA). For more information about how to configure Policy-based QoS, see Policy-based Quality of Service (QoS).

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

The Unified Messaging server role is installed. For detailed steps, see Install the Exchange 2010 Unified Messaging Server Role.

Enable QoS for Unified Messaging

To perform the following procedures, you must log on to the Unified Messaging server by using an account that's a member of the local Administrators group on that computer.

1. Click **Start**, click **Run**, type **gpedit.msc** in the **Open** dialog box, and then click **OK**.
2. In the **Group Policy Object Editor** window, locate Computer Configuration/Policies/Administrative Templates/Network/QoS Packet Scheduler/DSCP value of conforming packets.
3. In the result pane, double-click **Controlled load service type**.
4. In the **Controlled load service type Properties** window, click **Enable**.
5. In the **DSCP value** dialog box, verify that the DSCP value **24** is selected, and then click **OK**.
6. In the result pane, double-click **Guaranteed service type**.
7. In the **Guaranteed service type Properties** window, click **Enable**.
8. In the **DSCP value** dialog box, verify that the DSCP value **40** is selected, and then click **OK**.
9. Close the **Group Policy Object Editor** window.
10. If you want to verify that the DSCP values are set correctly, performing these steps:

    Caution:
    Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

    10.a. Start Registry Editor (regedit).
    10.b. Locate the following key: **HKLM\Software\Policies\Microsoft\Windows\Psched\DiffservByteMappingConforming**
    10.c. The following default values will be set:
    SERVICETYPE_GUARANTEED (DSCP 40, 0x28)
    SERVICETYPE_CONTROLLEDLOAD (DSCP 24, 0x18)
11. Regardless of whether your environment is integrated with Office Communications Server 2007 R2 or Microsoft Lync Server 2010, configure the registry key to enable QoS marking of IP packets sent by setting the. **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\RTC\Transport\QoSEnabled** key to **1**. Then restart the Communications Server 2007 server or the Lync Server 2010 server to load the QoS settings that are stored in the registry.

Enable QoS for Unified Messaging and Office Communications Server 2007 R2 or Microsoft Lync Server 2010

To perform the following procedures, you must log on to the Unified Messaging server by using an account that's a member of the local Administrators group on that computer.

1. Enable the **QoS Packet Scheduler** service on servers and clients. By default, the **QoS Packet Scheduler** service is enabled on Windows Server 2008 computers. However, by default, it isn't enabled on Windows Server 2003 computers. QoS marking isn't enabled by default in Communications Server 2007 R2 or Lync Server 2010 because Communications Server 2007 R2 and Lync Server 2010 only run on Windows Server 2008 and QoS marking depends on the **QOS Packet Scheduler** service running on both server and client computers.
2. Configure the registry key to enable QoS marking of IP packets sent to and from the Communications Server 2007 server or the Lync Server 2010 server by setting the **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\RTC\Transport\QoSEnabled** key to **1**. Then restart the Communications Server 2007 R2 or Lync Server 2010 server to load the QoS settings that are stored in the registry.
3. Use Group Policy to set DSCP values that mark the IP packets if you need values other than the defaults for Guaranteed service type packets (used for audio) and Controlled load service type packets (used for video). By default, the following settings are applied when you set the **QoSEnabled** DWORD value:
   - SERVICETYPE_GUARANTEED (DSCP 40, 0x28)
   - SERVICETYPE_CONTROLLEDLOAD (DSCP 24, 0x18)

For more information about QoS and Communications Server 2007 R2, see Voice QoS.

Other Tasks

After you enable Unified Messaging on an Exchange 2010 server, you may also want to:

- Configure the Startup Mode on a UM Server
- Start the Microsoft Exchange Unified Messaging Service
- Stop the Microsoft Exchange Unified Messaging Service

1.9.2.1.18 Create a Certificate for Enabling Mutual TLS in Unified Messaging

Create a Certificate for Enabling Mutual TLS in Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable Voice over IP (VoIP) security for a Unified Messaging (UM) dial plan. By default, when a UM dial plan is created, it will use Unsecured mode or no encryption. When you configure the UM dial plan to use Session Initiation Protocol secured (SIP

Secured) or Secured mode, the Unified Messaging servers that are associated with the UM dial plan will encrypt the SIP signaling traffic or the Realtime Transport Protocol (RTP) media channels and the SIP signaling traffic.

To enable a UM server to encrypt data that's sent between IP gateways and IP PBXs you must:

- Create a new self-signed or public certificate that you can use for mutual TLS.
- Associate a certificate with the UM server.
- Configure the UM dial plan as SIP Secured or Secured.
- Configure the startup mode on the UM server.
- Configure the listening port on the UM IP gateways to use TCP port 5061.
- Import the certificate on your IP gateways or IP PBXs.

Prerequisites

After you've installed the Unified Messaging server role, you'll have to create a certificate that can be used to encrypt data between a UM server and IP gateways or IP PBXs.

Use the EMC to create a new Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic. You must also log on by using an account that's a member of the local Administrators group on that computer.

1. In the console tree, click **Server Configuration**.
2. In the action pane, click **New Exchange Certificate** to open the New Exchange Certificate wizard.
3. On the **Introduction** page, enter a friendly name for your certificate.
4. On the **Domain Scope** page, don't select the **Enable wildcarding for this certificate** check box.
5. On the **Exchange Configuration page > expand Unified Messaging server**.
6. Select **Self-signed certificate** or **Public certificate**, enter the fully qualified domain name (FQDN) of your UM server in the **Fully qualified domain name (FQDN) of your UM servers** box, and then click **Next**.
7. On the **Organization and Location** page, enter information about your Exchange organization.
8. On the **Certificate Completion** page, verify that all the information you've entered is correct. If it is correct, click **New**.
9. On the **Completion** page, follow the steps that are listed there to complete your request. This page also contains the cmdlet syntax necessary to create a new certificate.

Use the Shell to create a new Exchange certificate

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic. You must also log on by using an account that's a member of the local Administrators group on that computer.

This example creates a new Exchange certificate request for a UM server named `MyUMServer` with a friendly name of `UMCert`.

```
New-ExchangeCertificate -FriendlyName 'UMCert' -GenerateRequest -PrivateKeyExport
```

Other Tasks

After you create a certificate for Unified Messaging, you may also want to:

- Assign Services to a Certificate
- Configure the Startup Mode on a UM Server
- Configure VoIP Security on a UM Dial Plan

1.9.2.2 Managing Unified Messaging Users

Managing Unified Messaging Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-18*

Enable a User for Unified Messaging

Disable Unified Messaging for a User

View or Configure the Properties of a UM-Enabled User

View Call Logs for a UM-Enabled User

Configure the UM Mailbox Policy Assigned to a UM-Enabled User

Enable or Disable Automatic Speech Recognition for a UM-Enabled User

Enable or Disable Calls from Users Who Are Not UM-Enabled for a UM-Enabled User

Enable a UM-Enabled User to Receive Faxes

Prevent a UM-Enabled User from Receiving Faxes

Allow or Prevent Calls Without a Caller ID to Leave a Voice Message

Enable or Disable Call Answering Rules for a UM-Enabled User

Enable or Disable a Personal Operator for a UM-Enabled User

1.9.2.2.1 Enable a User for Unified Messaging

Enable a User for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you enable a user for Unified Messaging (UM), a default set of UM properties are applied to the user, and the user will be able to use the Unified Messaging features. When you enable a user for Unified Messaging, you have the option to add a Session Initiation Protocol (SIP) or E.164 address for the user. However, the user must still have an extension number configured.

You can configure the extension number automatically or manually using the Enable Unified Messaging wizard. An extension number is required for each UM-enabled user associated with a telephone extension, SIP Uniform Resource Identifier (URI), or E.164 dial plan. The extension number must be the correct number of digits, as specified in the UM dial plan for the UM mailbox policy. If the user is associated with an E.164 dial plan, you can manually configure an E.164 address for a user using the Enable Unified Messaging wizard. If you associate a user to a SIP URI or E.164 dial plan, you must manually enter an extension number and the SIP or E.164 address for the user.

Note:

You must add, remove, or modify the Exchange Unified Messaging proxy addresses (EUM addresses) for a user using the **EUM Address** menu item on the **E-mail Addresses** tab on the user's mailbox properties.

Looking for other management tasks related to UM-enabled users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

What Do You Want to Do?

- Use the EMC to enable a user for Unified Messaging
- Use the Shell to enable a user for Unified Messaging

Use the EMC to enable a user for Unified

Messaging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user mailbox that you want to enable for Unified Messaging.
3. In the action pane, click **Enable Unified Messaging**.
4. In the Enable Unified Messaging wizard, on the **Introduction** page, complete the following fields:
   - **Unified Messaging Mailbox Policy** Use this text field to select the UM mailbox policy that you want to associate with a user's mailbox.
     UM mailbox policies define settings such as PIN policies, dialing restrictions, and message text for Unified Messaging messages sent to the user. Each UM-enabled user is required to be associated with at least one UM mailbox policy. However, the UM-enabled user can be associated with only one UM mailbox policy.
   - **Automatically generate PIN to access Outlook Voice Access** Click this button to automatically generate a PIN for the UM-enabled user. This is the default setting. If this option is selected, a PIN is automatically generated based on the PIN policies configured on the UM mailbox policy associated with the recipient. We recommend that you use this setting to help protect the user's PIN.
   - **Manually specify PIN** Click this button to manually specify a PIN that a recipient will use to access the Unified Messaging system.
     The PIN must comply with the PIN policy settings configured on the UM mailbox policy associated with this recipient. For example, if the UM mailbox policy is configured to accept only PINs that contain seven or more digits, the PIN you enter in this text box must be at least seven digits.
   - **Require user to reset PIN on first telephone logon** Select this check box to force the user to reset a Unified Messaging PIN when the user accesses the Unified Messaging system from a telephone.
     It's a security best practice to force UM-enabled users to change their PIN at their first logon to help protect against unauthorized access to their data and Inbox. This is the default setting.
5. In the Enable Unified Messaging wizard, on the **Extension Configuration** page, complete the following fields:
   - **Automatically generated mailbox extension** Click this button if you want the extension number for the user's mailbox to be automatically generated from the telephone number specified in the Active Directory directory service and used to populate the field. By default, this setting is enabled. This option will be unavailable if the user is being associated with a SIP URI or E.164 dial plan.
     For the user's extension number to populate this field, you can enter the telephone number in the **Business** field on the **Address and Phone** tab in the user properties in the EMC. You can also configure a telephone number for a user by configuring the **Telephone number** field on the **General** tab on the user account using Active Directory Users and Computers.
     If you select this option, the extension number generated automatically for the user will comply with the number of digits specified for the dial plan with which the UM mailbox policy that you selected is associated. For example, if the dial plan is

configured to use 5-digit extension numbers, the Unified Messaging server will take the last 5 digits of the user's telephone number and use those digits to populate this field. UM dial plans are typically configured to have extensions three through seven digits long.

- **Manually entered mailbox extension** Click this button if you want to manually configure the extension number for the user's mailbox.

  If you select this option, you must supply the extension number for the user. If you select this option, you must provide a valid extension number for the user and must match the number of digits specified on the dial plan. You can configure this field to contain a value range of numeric characters or digits from 1 through 20. The typical extension number is from 3 through 7 digits and is configured on the dial plan with which the UM mailbox policy is associated.

  If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions. The number of digits that you specify is the default setting after a UM mailbox policy is selected.

- **Automatically generated SIP resource identifier** Click this button if you want the SIP resource identifier or SIP address for the user's mailbox to be automatically generated. If you have deployed Microsoft Office Communications Server 2007, the user's SIP address is taken from the **msRTCSIP-PrimaryUserAddress** attribute in Active Directory. If this attribute isn't populated, the user's primary SMTP address will be used for the SIP address. By default, this setting is enabled, for example, tony.smith@contoso.com.

  This option is available only if the user that you enable for Unified Messaging is associated with a SIP URI dial plan. This option will be unavailable if you configure a user's mailbox to be associated with an E.164 dial plan.

  If you associate a user with a SIP URI dial plan, you must also manually enter a mailbox extension for the user. This extension number is used when users use Outlook Voice Access to access their Exchange 2010 mailbox. The number of digits that you configure in this field must match the number of digits configured on the SIP URI or E.164 dial plan.

  This option will not be available if the user is being associated with a telephone extension dial plan.

- **Manually entered SIP resource identifier** Click this button if you want to manually enter the SIP or E.164 address for the user. This option is available if the user that you enable for Unified Messaging is associated with either a SIP URI or E.164 dial plan. If you deployed Communications Server 2007, the user's SIP address is taken from the **msRTCSIP-PrimaryUserAddress** attribute in Active Directory. If this attribute isn't populated, the user's primary SMTP address is used for the SIP address, for example, tony.smith@contoso.com. This option isn't available if the user is associated with a telephone extension dial plan.

  If you associate the user with an E.164 dial plan, you must manually enter an E.164 address for the user. The number entered must be in the correct E.164 format, for example, +14255551234.

  If you associate the user with a SIP or E.164 dial plan, you must also manually enter a mailbox extension number for the user. This extension number is used when users use Outlook Voice Access to access their Exchange 2010 mailbox. The number of digits that you configure in this field must match the number of digits configured on the SIP URI or E.164 dial plan.

6. On the **Enable Unified Messaging** page, review your configuration settings. Click **Enable** to enable the user for Unified Messaging. Click **Back** to make configuration changes.

7. On the **Completion** page, confirm whether the user was successfully enabled for Unified Messaging:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
8. Click **Finish** to complete the Enable Unified Messaging wizard.

Use the Shell to enable a user for Unified Messaging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example enables Unified Messaging on the mailbox for tonysmith@contoso.com, sets the extension and PIN for the user, and then assigns a UM mailbox policy named MyUMMailboxPolicy to the user's mailbox.

```
Enable-UMMailbox -Identity tonysmith@contoso.com -UMMailboxPolicy MyUMMailboxPoli
```

This example enables Unified Messaging on a SIP-enabled mailbox for tonysmith@contoso.com, associates a UM mailbox policy named MyUMMailboxPolicy, and sets the extension number, SIP resource identifier, and PIN for the user.

```
Enable-UMMailbox -Identity tonysmith@contoso.com -UMMailboxPolicy MyUMMailboxPoli
```

For more information about syntax and parameters, see Enable-UMMailbox.

Other Tasks

After you have enabled a user for Unified Messaging, you may also want to:

- View or Configure the Properties of a UM Mailbox Policy
- Set PIN Policies for UM-Enabled Users

For More Information

Understanding Unified Messaging Users

1.9.2.2.2 Disable Unified Messaging for a User

Disable Unified Messaging for a User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable Unified Messaging (UM) for a UM-enabled user. When you disable a user

for Unified Messaging, the user is no longer able to use the UM features found in Microsoft Exchange Server 2010. If you prefer, you can keep the UM settings for the user after the user is disabled.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient has an Exchange mailbox.
- The existing user is currently enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to disable Unified Messaging for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user whose mailbox you want to disable for Unified Messaging.
3. In the action pane, click **Disable Unified Messaging**.
4. In the confirmation dialog box, click **Yes** to confirm that Unified Messaging will be disabled for the user.

Use the Shell to disable Unified Messaging for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example disables Unified Messaging for the user tonysmith@contoso.com but keeps the UM mailbox settings.

```
Disable-UMMailbox -Identity tonysmith@contoso.com -KeepProperties False
```

For more information about syntax and parameters, see Disable-UMMailbox.

Other Tasks

After you disable Unified Messaging for a user, you may also want to:

- Enable a User for Unified Messaging
- Configure the UM Mailbox Policy Assigned to a UM-Enabled User

1.9.2.2.3 View or Configure the Properties of a UM-Enabled User

View or Configure the Properties of a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view or configure the Unified Messaging (UM) properties for an existing user who's enabled for Unified Messaging. When you change a user's UM properties, you can control their access to various UM features. For example, you can enable or disable Automatic Speech Recognition (ASR) or associate the user's mailbox with a different UM mailbox policy.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange user has been enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to view or configure a UM-enabled user's properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the work pane, select the UM-enabled user that you want to view or configure.
3. In the action pane, click **Properties**.
4. In the UM-enabled user's mailbox properties window, click the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. Use the **Unified Messaging Properties** page to view or change the UM properties for an existing UM-enabled user:
   - **UM Mailbox Status** This display-only field shows the status of the user's mailbox. By default, when a user is UM-enabled, the mailbox status is listed as **Not locked out**. However, if the user has input an incorrect Outlook Voice Access PIN multiple times, the status is listed as **Locked Out**.
   - **Unified Messaging Mailbox Policy** This display-only field shows the name of the UM mailbox policy associated with the UM-enabled user. You can specify the UM mailbox policy to be associated with this UM mailbox by clicking the **Browse** button.
   - **UM Extensions** This box displays the extension numbers and the Session Initiation Protocol (SIP) and E.164 addresses after the user has been enabled for Unified Messaging. If you've associated the user with a **Telephone Extension** dial plan, only the extension number configured for the user appears in this box.

     If you've associated the UM-enabled user with a SIP dial plan, an extension number and SIP address are listed. If you've associated the UM-enabled user with an E.164 dial plan, an

extension number and E.164 address are listed.

- **Enable for Automatic Speech Recognition** Select this option to specify whether users can use ASR when they sign in to their mailbox. By default, UM-enabled users can use voice commands when they use Outlook Voice Access to access their mailbox.

  Even if Outlook Voice Access users are speech-enabled, they must still use the keypad to enter their extension number, PIN, and personal options.
- **Allow UM Calls from non-users** Select this option to specify whether to allow incoming calls from unauthenticated callers through an auto attendant to be transferred to the UM-enabled user. By default, this setting is enabled. Enabling this setting allows callers from outside an organization to be transferred to a user inside an organization.

  The user's mailbox can still be accessed using directory searches. However, if an external caller tries to transfer to a user for whom this setting is disabled, the system will say, "I'm sorry, I am unable to transfer the call to this user." The caller is then transferred to the operator configured on the auto attendant.

  This setting doesn't apply to callers who've signed in to their mailbox using Outlook Voice Access and are sending a voice message to a user.
- **Allow faxes to be received** Select this option to specify whether a user is allowed to receive incoming faxes. By default, this setting is enabled. However, it can be disabled if you don't want the user to receive incoming faxes.

  This setting is also configured on dial plans. If you enable this setting for a UM-enabled user, but the dial plan is configured to disable fax receiving, the UM-enabled user is unable to receive faxes.
- **Diverted calls without a caller ID can leave a message** Select this option to specify whether, for diverted calls without a caller ID, the caller is allowed to leave a message. By default, this option is enabled. This enables the UM-enabled user to accept anonymous calls from callers.
- **Allow users to configure personal auto attendants** Select or clear this check box to allow or prevent a user from creating personal auto attendants. If this option is disabled on the UM dial plan or the UM mailbox policy, this feature isn't available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users that have a mailbox on an Exchange UM server. The default setting is enabled.
- **Personal operator extension** Use this field to specify the operator extension number for the user. By default, an extension number isn't configured. The range for the extension number is from 1 through 20 characters. This enables incoming calls for the UM-enabled user to be forwarded to the extension number that you specify in this field.

  You can configure other types of operator extension numbers on dial plans and auto attendants. However, those extensions are generally meant for company-wide receptionists or operators. The personal operator extension setting could be used when an administrative assistant or personal assistant answers incoming calls before they're answered for a particular user.

Use the Shell to configure a UM-enabled user's properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example disables Play on Phone and missed call notifications, but enables text message (SMS) notifications.

```
Set-UMMailbox -Identity tony@contoso.com -UMEnabled $true -UMMailboxPolicy AdminP
```

This example prevents a user from accessing the calendar, but enables access to e-mail when the user is using Outlook Voice Access.

```
Set-UMMailbox -Identity tony@contoso.com -UMEnabled $true -UMMailboxPolicy AdminP
```

This example prevents a user from accessing the calendar and e-mail when the user is using Outlook Voice Access.

```
Set-UMMailbox -Identity tony@contoso.com -TUIAccessToCalendarEnabled $false -TUIA
```

For more information about syntax and parameters, see Set-UMMailbox.

Use the Shell to view a UM-enabled user's properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example displays a list of all the UM-enabled mailboxes in the Active Directory forest in a formatted list.

```
Get-UMMailbox | Format-List
```

This example displays the UM mailbox properties for tonysmith@contoso.com.

```
Get-UMMailbox -Identity tonysmith@contoso.com
```

For more information about syntax and parameters, see Get-UMMailbox.

Other Tasks

After you configure the properties for a UM-enabled user, you may also want to:

- Configuring PIN Security for a UM-Enabled User
- View or Configure the Properties of a UM Mailbox Policy

1.9.2.2.4 View Call Logs for a UM-Enabled User

View Call Logs for a UM-Enabled User

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the **User Call Logs** tool, available in Exchange Server 2010 Service Pack 1 (SP1), to display the call statistics for a UM-enabled user you specify. The report that's

generated is displayed in the Exchange Control Panel (ECP). It includes information about calls made by and received by the user, and can help you diagnose and fix issues with a user's voice mail. For more information, see New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1.

After you click the **Select a user** button and specify the user, the following information will be displayed about the user's calls:

- Date and time
- Duration of the call
- Type of call
- The calling number
- The called number
- The UM IP gateway
- Audio quality

You can copy the user's call statistics to the Clipboard and then paste them into another application. You can use the **Audio Quality Details** button to display more specific information about the call. For details on **User Call Logs** tool, see Using Unified Messaging Tools.

Looking for other management tasks related to Unified Messaging (UM) servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user whose call logs you want to view has been enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM server has been added to a UM dial plan. For detailed steps, see Add a UM Server to a Dial Plan.

Use the EMC to view the call logs for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM call data and summary reports" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Toolbox**, click **User Call Logs**, and then click **Open Tool** from the **Actions** menu.
2. In the **Outlook Web App** window, enter the correct user account (in the format Domain\user name) and password, and then click **Sign in**.
3. If this is your first time signing in to the ECP, select your language and time zone, and then click **OK**.
4. In the **User Call Logs** window, click **Select a user**. In the pop-up window, select the UM-enabled user whose call logs you want to view, and then click **OK**.
5. The call details for the UM-enabled user will be listed in the table that's displayed in the window.

Use the Shell to view the call logs for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM call data and summary reports" entry in the Unified Messaging Permissions topic.

This example displays the UM call data records for the UM-enabled user Tony.

```
Get-UMCallDataRecord -Mailbox tony@contoso.com
```

For more information about syntax and parameters, see Get-UMCallDataRecord.

Other Tasks

After you view the call logs for a UM-enabled user, you may also want to:

- View the Number of Active Calls for a UM Server
- View Call Statistics for a UM Server
- Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool
- Test-UMConnectivity

1.9.2.2.5 Configure the UM Mailbox Policy Assigned to a UM-Enabled User

Configure the UM Mailbox Policy Assigned to a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you enable a user for Microsoft Exchange Server 2010 Unified Messaging (UM), you must select the UM mailbox policy that will be associated with the user's mailbox. However, you can change the UM mailbox policy associated with the user's mailbox after the user has been enabled for Unified Messaging.

You create UM mailbox policies to apply a common set of policies or security settings to a collection of mailboxes of UM-enabled users. You can use UM mailbox policies to apply settings such as the following:

- PIN policies
- Dialing restrictions
- Other general UM mailbox policy properties

Note:

A default UM mailbox policy is created every time you create a UM dial plan. However, you can either delete the default UM mailbox policies or create additional UM mailbox policies based on the needs of your organization.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to change the UM mailbox policy assigned to a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, on the **Mailbox** page, select the UM-enabled user for whom you want to change the UM mailbox policy, and then click **Properties** in the action pane.
3. On the user **Properties** page, on the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
4. On the **Unified Messaging Properties** page, under **Unified Messaging Mailbox Policy**, click **Browse**.
5. On the **Select UM Policy** page, select the UM mailbox policy that you want to use, and then click **OK**.
6. Click **OK** to save your changes.

Use the Shell to change the UM mailbox policy assigned to a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example associates a UM-enabled user named Tony Smith with a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailbox -Identity tonysmith@contoso.com -UMMailboxPolicy MyUMMailboxPolicy
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you change the UM mailbox policy assigned to a UM-enabled user, you may also want to:

- Configuring PIN Security for a UM-Enabled User
- View or Configure the Properties of a UM-Enabled User

1.9.2.2.6 Enable or Disable Automatic Speech Recognition for a UM-Enabled User

Enable or Disable Automatic Speech Recognition for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure Automatic Speech Recognition (ASR) for a Microsoft Exchange Server 2010 user who's enabled for Unified Messaging. When ASR is enabled on the mailbox of an Outlook Voice Access user, the user can move through the mailbox menus using voice commands. If ASR is disabled, the user must use dual tone multi-frequency (DTMF), also known as touchtone, inputs to move through the menus.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure ASR for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user's mailbox that you want to view.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, select **Enable for Automatic Speech Recognition**.
6. Click **OK** to accept your changes.

Use the Shell to configure ASR for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example enables Automatic Speech Recognition (ASR) for a UM-enabled user named Tony.

```
Set-UMMailbox -Identity tony@contoso.com -AutomaticSpeechRecognitionEnabled $true
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you configure ASR for a UM-enabled user, you may also want to:

- Configure a UM-Enabled User's TUI Settings
- View or Configure the Properties of a UM-Enabled User

1.9.2.2.7 Enable or Disable Calls from Users Who Are Not UM-Enabled for a UM-Enabled User

Enable or Disable Calls from Users Who Are Not UM-Enabled for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable calls from users who aren't enabled for Unified Messaging (UM). By default, Unified Messaging allows incoming calls from unauthenticated callers through an auto attendant to be transferred to UM-enabled users. With this option enabled, users from outside an organization can transfer calls to UM-enabled users.

If this setting has been disabled for a UM-enabled user, the user's mailbox can still be located using a directory search. However, if an external caller tries to transfer to the user, the system says, "I'm sorry, I am unable to transfer the call to this user." The caller is then transferred to the operator, if an operator has been configured on the auto attendant. If no operator has been configured on the auto attendant, the call is transferred to a dial plan operator, if one has been configured. If no operator extension has been configured on the speech-enabled auto attendant, the dual tone multi-frequency (DTMF) fallback auto attendant, or the dial plan, the system responds by saying, "Sorry. Neither the operator or the touchtone service are available."

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to enable or disable calls from users who aren't UM-enabled to a user who is UM-enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user's mailbox.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, do one of the following:
   - To enable calls from users who aren't UM-enabled, select the check box next to **Allow UM calls from non-users**.

- To disable calls from users who aren't UM-enabled, clear the check box next to **Allow UM calls from non-users**.

6. Click **OK** to accept your changes.

Use the Shell to enable or disable calls from users who aren't UM-enabled to a user who is UM-enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example prevents Tony Smith from receiving voice mails from callers who aren't UM-enabled.

```
Set UMMailbox -Identity tony@contoso.com -AllowUMCallsFromNonUsers None
```

This example allows Tony Smith to receive voice mails from callers who aren't UM-enabled.

```
Set UMMailbox -Identity tony@contoso.com -AllowUMCallsFromNonUsers SearchEnabled
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you enable or disable calls from users who aren't UM-enabled to a user who is UM-enabled, you may also want to:

- Configure an Operator Extension on a UM Auto Attendant
- Configure an Operator Extension on a UM Dial Plan

1.9.2.2.8 Enable a UM-Enabled User to Receive Faxes

Enable a UM-Enabled User to Receive Faxes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a Unified Messaging (UM) user to receive faxes. By default, when you enable a user for Unified Messaging, they will be able to receive faxes. Faxing can be enabled or disabled on UM dial plans, UM mailbox policies, or the UM-enabled user's mailbox. By default, although the user's mailbox allows incoming faxes, you must first enable inbound faxing on the UM mailbox policy that's associated with the UM-enabled user and enter the fax partner's URI.

For a specific user to be able to receive fax messages in their Microsoft Exchange 2010 mailbox, each Unified Messaging server that's associated with the dial plan that the user is associated with must be configured to accept incoming fax calls. In addition, the UM dial plan must also be configured to allow faxes to be sent to UM-enabled users.

Looking for other management tasks related to UM users? Check out Managing Unified

Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable a UM user to receive faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the user mailbox that you want to modify.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, select the check box next to **Allow the user to receive faxes**.
6. Click **OK** to save your changes.

Use the Shell to enable a UM user to receive faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example enables Tony Smith to receive incoming faxes.

```
Set-UMMailbox -Identity tonysmith@contoso.com -FaxEnabled $true
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you enable a UM user to receive faxes, you may also want to:

- Enable or Disable Inbound Faxing on a UM Mailbox Policy
- Enable UM-Enabled Users to Receive Faxes on a UM Dial Plan
- Add an Extension Number for a UM-Enabled User

1.9.2.2.9 Prevent a UM-Enabled User from Receiving Faxes

Prevent a UM-Enabled User from Receiving Faxes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can prevent a Microsoft Exchange Server 2010 Unified Messaging (UM) user from receiving faxes. By default, when you enable a user for Unified Messaging, the user will receive faxes. However, you can prevent a user from being able to receive faxes after they've been enabled for Unified Messaging. You can also prevent multiple users from receiving faxes by disabling delivery of faxes to users who are associated with the UM dial plan.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The UM-enabled user is enabled for faxing. For detailed steps, see Enable a UM-Enabled User to Receive Faxes.

Use the EMC to prevent UM-enabled users from receiving faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the UM-enabled user's mailbox that you want to modify.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, clear the check box next to **Allow the user to receive faxes**.
6. Click **OK** to save your changes.

Use the Shell to prevent UM-enabled users from receiving faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example prevents a UM-enabled user named Tony from receiving fax messages in his mailbox.

```
Set-UMMailbox -Identity tony@contoso.com -FaxEnabled $false
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you prevent UM-enabled users from receiving faxes, you may also want to:

- Prevent UM-Enabled Users from Receiving Faxes on a UM Dial Plan.
- Add an Extension Number for a UM-Enabled User

1.9.2.2.10 Allow or Prevent Calls Without a Caller ID to Leave a Voice Message

Allow or Prevent Calls Without a Caller ID to Leave a Voice Message

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can allow or prevent UM-enabled users to receive voice messages from anonymous callers or to prevent them from doing so. By default, when users are enabled for Unified Messaging (UM), they can receive calls that are anonymous and don't contain caller ID information.

In most cases, calls received by a Unified Messaging server contain a caller ID that can be used to determine the source of the incoming call. However, incoming calls may not include caller ID information for the following reasons:

- Your organization's telephony equipment is configured not to include caller ID information.
- The incoming call is from a mobile or external telephone.
- Callers have disabled caller ID on their telephone.

Because the **Allow diverted calls without a caller ID to leave a message** option is enabled by default, a UM-enabled user can receive a voice message even if caller ID information isn't included. If the **Allow diverted calls without a caller ID to leave a message** option is disabled, and the UM-enabled user receives a call that doesn't include a caller ID, the call will be identified as anonymous, and the UM-enabled user won't receive a voice message.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable voice messages from anonymous callers for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user's mailbox.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, do one of the following:
   - To enable voice messages from anonymous callers, select the **Allow diverted calls without a caller ID to leave a message** check box.
   - To disable voice messages from anonymous callers, clear the **Allow diverted calls without a caller ID to leave a message** check box.
6. Click **OK** to accept your changes.

Use the Shell to enable or disable voice messages from anonymous callers for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example allows UM-enabled users to receive voice mail from calls that don't contain caller ID information.

```
Set-UMMailbox -Identity tonysmith@contoso.com -AnonymousCallersCanLeaveMessages $
```

This example prevents UM-enabled users from receiving voice mail from calls that don't contain caller ID information.

```
Set-UMMailbox -Identity tonysmith@contoso.com -AnonymousCallersCanLeaveMessages $
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you enable or disable voice messages from anonymous callers for a UM-enabled user, you may also want to:

- Enable or Disable Call Transfers to Users on a UM Dial Plan
- Configure the Scope of Users Who Callers Can Contact on a UM Dial Plan

1.9.2.2.11 Enable or Disable Call Answering Rules for a UM-Enabled User

Enable or Disable Call Answering Rules for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify whether you want individual users to be able to create and manage their

own call answering rules by configuring their mailbox properties. You can also allow or prevent them from creating call answering rules by allowing or preventing Call Answering Rules on a Unified Messaging (UM) dial plan or UM mailbox policy that's associated with a user.

You can enable or disable call answering rules for multiple UM-enabled users by configuring Call Answering Rules on a UM dial plan or UM mailbox policy.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to enable or disable call answering rules for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user's mailbox that you want to view.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, select or clear the check box next to **Allow users to configure call answering rules**.
6. Click **OK** to accept your changes.

Use the Shell to enable or disable call answering rules for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example disables Call Answering Rules for the user tony@contoso.com.

```
Set-UMMailbox -Identity tony@contoso.com -CallAnsweringRulesEnabled $false
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you enable or disable call answering rules for a UM-enabled user, you may also want to:

- Allow or Prevent Call Answering Rules on a UM Dial Plan
- Enable or Disable Call Answering Rules on a UM Mailbox Policy

1.9.2.2.12 Enable or Disable a Personal Operator for a UM-Enabled User

Enable or Disable a Personal Operator for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The personal operator extension setting on a mailbox that's enabled for a Unified Messaging (UM) user can be used when an administrative assistant or personal assistant will answer incoming calls for a specific user instead of a voice mail message being generated for the user. For example, when a UM-enabled user will be out of the office and wants callers to have the option to talk to a human operator or leave a voice message. By default, an extension number isn't defined.

You can enter an internal or external telephone number that has from 1 through 20 digits in the **Personal operator extension** field available on the UM-enabled user's mailbox properties. If you use an external telephone number, you must verify that you've correctly configured the appropriate outdialing rule groups and entries to enable this functionality.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The extension number assigned to the UM-enabled user is valid according to the UM dial plan defined.

Use the EMC to configure a personal operator for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user's mailbox that you want to view.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. On the **Unified Messaging Properties** page, in the **Personal operator extension** field, enter the extension number for the personal operator that will be used for this user.
6. Click **OK** to accept your changes.

Important:

After you accept the changes that you made using this procedure, you must set the AllowExtensions parameter to True using the **Set-UMDialPlan** cmdlet. For the correct syntax, see the following procedure. You can't set the AllowExtensions parameter to True using the EMC.

Use the Shell to configure a personal operator for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example allows extensions on a UM dial plan named MyUMDialPlan and enables a personal operator extension 12345 for a UM-enabled user named Tony Smith.

```
Set-UMMailbox -identity tonysmith@contoso.com -OperatorNumber 12345
Set-UMDialPlan -identity MyUMDialPlan -AllowExtensions $true
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you configure a personal operator for a UM-enabled user, you may also want to:

- Create a Dialing Rule Entry on a UM Dial Plan
- Configure Dialing Rule Groups on a UM Dial Plan

1.9.2.2.13 Add an Extension Number for a UM-Enabled User

Add an Extension Number for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you enable a user for Unified Messaging (UM), you must define at least one extension number that Unified Messaging will use when voice mail is submitted to the user's Microsoft Exchange Server 2010 mailbox. After you enable the user for Unified Messaging, you can add extension numbers to the user's mailbox by configuring the Exchange Unified Messaging proxy address (EUM proxy address) on the user's mailbox.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM

Mailbox Policy.

- The extension number that will be assigned to the UM-enabled user is valid according to the UM dial plan associated with the UM-enabled user.

Use the EMC to add an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to add an extension number.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox User> Properties**, click the **E-Mail Addresses** tab.
5. Click the drop-down arrow located next to **Add**, and then click **EUM Address**. In **UM Address (Extension)**, in the **Address/Extension** box, type the extension number.
6. In the **Dial plan (Phone context)** box, click **Browse** to locate the dial plan for the user.
7. Click **Apply**, and then click **OK**.

Use the Shell to add an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example adds an extension number for Tony Smith, a UM-enabled user.

```
$mbx=Get-Mailbox tony.smith
$mbx.EmailAddresses +="eum:22222;phone-context=MyDialPlan.contoso.com"
Set-Mailbox tony.smith -EmailAddresses $mbx.EmailAddresses
```

For more information about syntax and parameters, see Set-Mailbox or Get-Mailbox.

Other Tasks

After you add an extension number, you may also want to:

- Modify an Extension Number for a UM-Enabled User
- Remove an Extension Number for a UM-Enabled User

1.9.2.2.14 Remove an Extension Number for a UM-Enabled User

Remove an Extension Number for a UM-Enabled User

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you enable a user for Unified Messaging (UM), you must define at least one extension number that Unified Messaging will use when voice mail is submitted to the user's Microsoft Exchange Server 2010 mailbox. After you enable the user for Unified Messaging, you can remove extension numbers from the user's mailbox by configuring the Exchange Unified Messaging proxy address (EUM proxy address) on the user's mailbox.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to remove an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to remove an extension number.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox User> Properties**, click the **E-Mail Addresses** tab.
5. To remove an existing EUM proxy address, select the EUM proxy address, and then click  .
6. Click **Apply**, and then click **OK**.

Use the Shell to remove an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example removes the extension number 12345 from the mailbox of Tony Smith, a UM-enabled user.

```
$mbx = Get-Mailbox tony.smith
$mbx.EmailAddresses.Item(1) -="eum:12345;phone-context=MyDialPlan.contoso.com"
Set-Mailbox tony.smith -EmailAddresses $mbx.EmailAddresses
```

For more information about syntax and parameters, see Set-Mailbox or Get-Mailbox.

Other Tasks

After you remove the extension number, you may also want to:

- Add an Extension Number for a UM-Enabled User
- Modify an Extension Number for a UM-Enabled User

1.9.2.2.15 Modify an Extension Number for a UM-Enabled User

Modify an Extension Number for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can modify an extension number that was assigned to a user when you enabled the user for Unified Messaging (UM). A single extension number is required when you enable a user for Unified Messaging. However, if you need to, you can change this extension number.

Looking for other management tasks related to Unified Messaging users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to modify an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to add a new extension number.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox User> Properties**, click the **E-Mail Addresses** tab.
5. Select the appropriate Exchange Unified Messaging proxy address (**EUM** address), and then click **Edit**. In **UM Address (Extension)**, in the **Address/ Extension** box, type the new extension number.
6. In the **Dial plan (Phone context)** box, click **Browse** to locate a new dial plan for the user.
7. Click **Apply**, and then click **OK**.

Use the Shell to modify an extension number for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example changes the extension number to 22222 for Tony Smith, a UM-enabled user.

Note:
You must determine the position of the EUM address that you want to modify. To determine the position of the EUM address, use the **$mbx.EmailAddresses** command. The first proxy address in the list will be 0.

```
$mbx=Get-Mailbox tony.smith
$mbx.EmailAddresses.Item(0)="eum:22222;phone-context=MyDialPlan.contoso.com"
Set-Mailbox tony.smith -EmailAddresses $mbx.EmailAddresses
```

For more information about syntax and parameters, see Set-Mailbox or Get-Mailbox.

Other Tasks

After you modify the extension, you may also want to:

- Add an Extension Number for a UM-Enabled User
- Remove an Extension Number for a UM-Enabled User

1.9.2.2.16 Modify a SIP Address for a UM-Enabled User

Modify a SIP Address for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you enable a user for Unified Messaging (UM), you must define at least one extension number that will be used by Unified Messaging when voice mail is submitted to the user's Microsoft Exchange Server 2010 mailbox. After you enable the user for Unified Messaging, you can modify the Session Initiation Protocol (SIP) address by configuring the Exchange Unified Messaging proxy address (EUM proxy address) on the user's mailbox.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to modify a SIP address for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions

topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to modify an e-mail address.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox User> Properties**, click the **E-Mail Addresses** tab.
5. Select the appropriate **EUM** address, and then click **Edit**. In **UM Address (Extension)**, in the **Address/Extension** box, type the new SIP address.
6. In the **Dial plan (Phone context)** box, click **Browse** to locate a new dial plan for the user.
7. Click **Apply**, and then click **OK**.

Use the Shell to modify a SIP address for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example changes a SIP address for Tony Smith, a UM-enabled user.

Note:

You must determine the position of the EUM address that you want to modify. To determine the position of the EUM address, use the **$mbx.EmailAddresses** command. The first proxy address in the list will be 0.

```
$mbx=Get-Mailbox tony.smith
$mbx.EmailAddresses.Item(1)="eum:tsmith;phone-context=MyDialPlan.contoso.com"
Set-Mailbox tony.smith -EmailAddresses $mbx.EmailAddresses
```

For more information about syntax and parameters, see Set-Mailbox or Get-Mailbox.

Other Tasks

After you modify a SIP address, you may also want to:

- Modify an E.164 Address for a UM-Enabled User
- Modify an Extension Number for a UM-Enabled User

1.9.2.2.17 Modify an E.164 Address for a UM-Enabled User

Modify an E.164 Address for a UM-Enabled User

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you enable a user for Unified Messaging (UM), you must define at least one extension number that will be used by Unified Messaging when voice mail is submitted to the user's Microsoft Exchange Server 2010 mailbox. However, you have the option to modify an E.164 address for a user if the user is associated with an E.164 dial plan. After you enable the user for Unified Messaging, you can modify E.164 addresses for the user's mailbox by configuring the Exchange Unified Messaging proxy address (EUM proxy

address) on the user's mailbox.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to modify an E.164 address for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to modify an E.164 address.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox User> Properties**, click the **E-Mail Addresses** tab.
5. Select the appropriate **EUM** address, and then click **Edit**. In **UM Address (Extension)**, in the **Address/Extension** box, type the new E.164 address.
6. In the **Dial plan (Phone context)** box, click **Browse** to locate the dial plan for the user.
7. Click **Apply**, and then click **OK**.

Use the Shell to modify an E.164 address for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example modifies an E.164 address for Tony Smith, a UM-enabled user.

Note:

You must determine the position of the EUM address that you want to modify. To determine the position of the EUM proxy address, use the **$mbx.EmailAddresses** command. The first proxy address in the list will be 0.

```
$mbx=Get-Mailbox tony.smith
$mbx.EmailAddresses.Item(1)="eum:+14255550123;phone-context=MyDialPlan.contoso.co
Set-Mailbox tony.smith -EmailAddresses $mbx.EmailAddresses
```

For more information about syntax and parameters, see Set-Mailbox or Get-Mailbox.

Other Tasks

After you modify the E.164 address, you may also want to:

- Modify a SIP Address for a UM-Enabled User

- Modify an Extension Number for a UM-Enabled User

1.9.2.2.18 Configure a UM-Enabled User's TUI Settings

Configure a UM-Enabled User's TUI Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Telephone user interface (TUI) settings are used when the user accesses the Unified Messaging (UM) system by using Outlook Voice Access. When you modify the UM-enabled user's TUI configuration settings, you modify properties and their values on the UM-enabled user's mailbox.

The following is a list of the TUI settings that you can modify for a UM-enabled user:

- Allow subscriber access
- Allow TUI access to the calendar
- Allow TUI access to e-mail
- Allow Automatic Speech Recognition

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to modify a UM-enabled user's TUI settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, click the user's mailbox.
3. In the action pane, click **Properties**.
4. In the mailbox properties, click the **Mailbox Features** tab.
5. On the **Mailbox Features** tab, select **Unified Messaging**, and then click **Properties**.
6. On the **Unified Messaging Properties** page, select the appropriate option, and then click **OK**.

Important:

There are multiple TUI settings that can be modified only by using the Shell.

Use the Shell to modify a UM-enabled user's TUI settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example enables calendar and e-mail access using the TUI for a UM-enabled user named Tony Smith.

```
Set-UMMailbox -Identity tony@contoso.com TUIAccessToCal True -TUIAccessToEmail Tr
```

Note:

TUI settings for users are also available on UM dial plans. Modifying TUI settings on a UM dial plan affects all users who belong to the UM dial plan. For more information about how to modify TUI settings on a UM dial plan, see Configure TUI Settings on a UM Mailbox Policy.

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you modify a UM-enabled user's TUI settings, you may also want to Configure TUI Settings on a UM Mailbox Policy.

1.9.2.2.19 Configuring PIN Security for a UM-Enabled User

Configuring PIN Security for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When a subscriber or a Microsoft Exchange Server 2010 Unified Messaging (UM) user uses a telephone to connect to a Unified Messaging server, the user uses Outlook Voice Access to navigate the Unified Messaging menu system. However, before users can access the Unified Messaging system, the system prompts them to input their PIN. As the administrator, you can configure PIN settings and requirements and perform PIN management tasks. After a user has been enabled for Unified Messaging and a PIN has been generated or created, a hash that's a mathematical computation of the user's PIN is stored in the user's mailbox. The checksum for the PIN is stored in Active Directory in an attribute called **ExUMPINChecksum**.

Note:

Subscribers must use touchtone or dual tone multi-frequency (DTMF) inputs to input their PIN to access their UM-enabled mailbox. Speech recognition is not enabled for PIN input.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Contents

PIN Requirements

Managing Unified Messaging PINs

PIN Overview

A PIN is a numeric string that's used in certain systems, including Unified Messaging systems, so that a user can be authenticated and gain access. A PIN is a passcode that users enter on the telephone to access their Exchange Server mailbox. The strength of the PIN depends on its length, how well it's protected, and how difficult it's to guess.

PINs are most frequently used for automatic teller machines (ATMs). However, they are also used for Unified Messaging systems instead of alphanumeric passwords. In Exchange 2010 Unified Messaging, the PIN is entered over an analog, digital, or mobile telephone and is used to gain access to the user's mailbox that includes e-mail, voice mail, and calendaring information.

In Exchange 2010 Unified Messaging, PIN policies are defined and configured on a UM mailbox policy. Multiple UM mailbox policies can be created depending on your requirements. When you enable a user for Exchange 2010 Unified Messaging, you associate or link the user to an existing UM mailbox policy. The UM PIN policies that are configured on the UM mailbox policy should be based on the security requirements of your organization.

PIN Requirements

The following are several PIN configuration settings that you can set on a UM mailbox policy in Exchange 2010.

Minimum PIN Length

The Minimum PIN Length setting specifies the minimum number of digits that a mailbox PIN can be. The range is 4 through 24, and the default is 6. If you enter 0, users aren't required to enter a PIN.

Important:

Configuring this setting with zero isn't a recommended practice. By configuring this setting to zero, you greatly decrease the level of security for your network.

If you change the minimum password length to a higher value, existing subscribers are prompted to enter a new PIN that contains the new minimum number of digits before they can continue.

Note:

Increasing this number creates a more secure UM environment. However, setting it too high can result in users forgetting their PIN.

PIN Lifetime

The PIN Lifetime setting controls the time interval, in days, from the date subscribers last changed their PIN to the date they'll be forced to change their PIN again. The range is 0 through 999, and the default is 60 days. If 0 is entered, the PIN won't expire.

Note:

Unified Messaging won't notify users when their PIN is about to expire.

Logon Failures Before PIN Reset

The Logon Failures Before PIN Reset setting specifies the number of sequential unsuccessful logon attempts before the mailbox PIN is automatically reset. To disable this feature, set this setting to unlimited. Otherwise, it must be set to a number lower than

the Maximum Logon Attempts setting. The range is 1 through 998, and the default is 5.

Note:
To increase security for UM-enabled users, enter a number that's less than 5.

Maximum Logon Attempts

The Maximum Logon Attempts setting specifies how many PIN entry errors in successive calls subscribers can make before they're locked out of their mailbox. By default, after 5 attempts are made, the PIN is automatically reset. The range is 1 through 999, and the default is 15.

Note:
To increase security, decrease the number of failed attempts. But remember that decreasing it to a number much lower than the default may result in users being locked out unnecessarily. Unified Messaging will generate warning events that can be viewed using Event Viewer if PIN authentication fails for a UM-enabled user or the user is unsuccessful in trying to log on to the system.

Allow Common Patterns

The Allow Common Patterns setting is used to either enable or disable the use of common number patterns used in creating a PIN. By default, this setting is disabled and won't allow users to input the following number patterns in the following list:

- **Sequential numbers** PIN values that consist completely of consecutive numbers. Examples of sequential numbers for a PIN are 1234 and 65432.
- **Repeated numbers** PIN values that consist of repeated numbers. Examples of repeated numbers are 11111 and 22222.
- **Suffix of mailbox extension** PIN values that consist of the suffix of your mailbox extension. If your mailbox extension is 36697, your PIN cannot be 6697.

PIN History Count

The PIN History Count setting configures the number of different PINs a user must use before any PINs that were previously used can be reused. The range is 1 through 20, and the default is 5.

Managing Unified Messaging PINs

When planning for UM PINs, you must make sure that you choose the appropriate levels of security for your organization. You must carefully consider the UM PIN requirements and how your PIN security settings meet or exceed your organization's security policy.

Important:
It's a security best practice to implement strong PIN requirements for Unified Messaging users. This can be enforced by creating Unified Messaging PIN policies that require six or more digits for PINs and increases the level of security for your network.

After you set the PIN requirements that meet the security requirements for your organization, you must create and configure a UM mailbox policy to enforce your organizational PIN requirements. For more information about how to create and manage a UM mailbox policy, see Managing UM Mailbox Policies.

Note:
After you create the UM mailbox policy, you must associate the UM-enabled user or users with the appropriate UM mailbox policy. You can perform this task by using the **Enable-UMMailbox** Exchange Management Shell command. For more information about the Exchange Management Shell command, see the Enable-UMMailbox reference topic.

There are situations in which UM users forget their PIN or are locked out of UM access to their mailbox. In either case, it may be necessary for you to reset a UM-enabled user's

PIN. For more information about how to reset a user's PIN, see Reset a Unified Messaging PIN for a UM-Enabled User.

1.9.2.2.19.1 Set PIN Policies for UM-Enabled Users

Set PIN Policies for UM-Enabled Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can set PIN policies on a Unified Messaging (UM) mailbox policy. UM mailbox policies can be configured to increase the level of security for UM-enabled users by requiring users to comply with the predefined PIN policies for your organization.

To set PIN policies for UM users, you can either create a new UM mailbox policy or modify an existing UM mailbox policy. After a new UM mailbox policy is created, you can then configure the UM mailbox policy by configuring the following PIN settings:

- `MinPasswordLength`
- `PINLifetime`
- `LogonFailuresBeforePINReset`
- `MaxLogonAttempts`
- `AllowCommonPatterns`
- `PINHistoryCount`

It's a security best practice to implement strong PIN requirements for UM users. This can be enforced by creating UM PIN policies that require 6 or more digits for PINs and increase the level of security for your network.

When you change the PIN policy, the new PIN setting is applied to users who are currently associated with the UM mailbox policy. For example, if you modify the UM mailbox policy and change the minimum PIN length from 7 to 10 digits, the next time users log on they'll be forced to change their PIN to comply with the changed PIN requirement.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to set PIN policies for UM users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic

1. In the console tree, navigate to **Organization Configuration** > **Unified**

Messaging.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. Click the UM mailbox policy that you want to change. This is the UM mailbox policy that's associated to the UM-enabled user.
4. In the action pane, click **Properties**.
5. In the UM mailbox policy **Properties** window, click the **PIN Policies** tab.
6. On the **PIN Policies** tab, configure the PIN settings for the UM mailbox policy, and then click **OK** to accept your changes.

Use the Shell to set PIN policies for UM users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic

This example sets the PIN settings for users associated with the UM mailbox policy `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 8 -M
```

For information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you set PIN policies for UM users, you may also want to:

- Include Text with the E-Mail Message Sent When a PIN Is Reset
- Reset a Unified Messaging PIN for a UM-Enabled User

1.9.2.2.19.2 Retrieve PIN Information for a UM-Enabled User

Retrieve PIN Information for a UM-Enabled User

Managing Unified Messaging > Managing Unified Messaging Users > Configuring PIN Security for a UM-Enabled User >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can retrieve PIN information for a user who is enabled for Microsoft Exchange Server 2010 Unified Messaging (UM). After a user has been enabled for Unified Messaging and a PIN is generated or created, the PIN is stored in the user's mailbox as a salted hash, and the checksum for the PIN is stored in an attribute called **ExUMPINChecksum** in the Active Directory directory service.

When you retrieve PIN information for a UM-enabled user, the information returned to you is calculated by using the PIN data stored in an encrypted format in the user's mailbox. This lets you view information from the user's mailbox and also indicates whether the user has been locked out of the mailbox.

Important:

When a UM-enabled user enters a PIN, the PIN data is passed in a format that isn't encrypted from an IP gateway over the IP-based network to Unified Messaging servers.

To increase the security for a user's PIN, use Internet Protocol security (IPsec) and Transport Layer Security (TLS)/Secure Realtime Transport Protocol (SRTP) to encrypt the PIN data.
After the PIN for a UM-enabled user is received by a Unified Messaging server and is passed from the Session Initiation Protocol (SIP)/RTP transport stack to the UM code, the PIN is temporarily held in a memory buffer in a form that isn't encrypted. Although this poses a small security risk, there's still the potential for an attacker to view the PIN while it isn't encrypted in the memory buffers on the Unified Messaging server.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user's mailbox has been UM-enabled. For detailed steps, see Enable a User for Unified Messaging.

Use the EMC to retrieve PIN information for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the user mailbox that you want to view.
3. In the action pane, click **Properties**.
4. On the **Mailbox Features** tab, click **Unified Messaging**, and then click **Properties**.
5. In the **UM Mailbox Status** section, view the **Lockout status** for the user.

Use the Shell to retrieve PIN information for a UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example displays the user ID, whether a PIN is expired, the UM mailbox is locked out and whether Tony is a first time user.

```
Get-UMMailboxPIN -identity tony@contoso.com
```

For more information about syntax and parameters, see Get-UMMailboxPIN.

Other Tasks

After you retrieve PIN information for a UM-enabled user, you may also want to:

- Configuring PIN Security for a UM-Enabled User
- Reset a Unified Messaging PIN for a UM-Enabled User
- Managing UM Mailbox Policies

1.9.2.2.19.3 Reset a Unified Messaging PIN for a UM-Enabled User

Reset a Unified Messaging PIN for a UM-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When a UM-enabled user is locked out of their mailbox because they tried to sign in using an incorrect PIN multiple times or they forgot their PIN, you can use one of the following procedures to reset the user's PIN. When you reset a user's Outlook Voice Access PIN, you can configure Unified Messaging (UM) to automatically generate a PIN or you can manually specify the PIN. The new PIN is e-mailed to the user. If you prefer, you can specify additional PIN options when resetting the user's PIN. Users can also reset their UM PIN using Outlook or Outlook Web App.

Note:

To access their UM-enabled mailbox, subscribers need to use touchtone, also known as dual tone multi-frequency (DTMF), inputs. Speech recognition isn't available for PIN input.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Use the EMC to reset a Unified Messaging PIN

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the UM-enabled user's mailbox that you want to reset their PIN for.
3. In the action pane, under the mailbox name, click **Reset Unified Messaging PIN**.
4. Use the **Reset Unified Messaging PIN** windows to reset the UM-enabled user's PIN:
   - **Automatically generate PIN to access Outlook Voice Access** Use this option to automatically generate the PIN that's used by the user to gain access to their mailbox using Outlook Voice Access. By default, this setting is enabled.

     The automatically generated PIN will be sent in an e-mail message to the user's mailbox. After they receive the PIN and sign in to their mailbox, they'll be prompted to change the PIN to a PIN that's more familiar to them.
     Outlook Web App for Microsoft Exchange Server 2010 and Office Outlook 2007 let the user reset their PIN. The PIN is automatically generated based on the PIN policies that are configured on the UM mailbox policy that is associated with the user's mailbox. We recommend that you automatically generate PINs for Outlook Voice Access users.

- **Manually specify PIN** Use this option to manually specify a PIN for an Outlook Voice Access user. By default, this setting is disabled.
  If you specify a PIN for a user, the PIN will be sent in an e-mail message to the user's mailbox. After they receive the PIN and sign in to their mailbox, they can change the PIN by configuring personal options in Outlook Voice Access. However, in Outlook Web App for Exchange 2010 and Outlook 2007, there is no option to manually specify a PIN.
- **Require user to reset PIN at first logon** Use this option to require the user to reset their PIN when they first sign in to Outlook Web App. By default, this option is disabled.
  If you select the option to automatically generate a PIN for a user, you can enable this option to require users to change their PIN when they first sign in to Outlook Voice Access. This helps protect the user's PIN.

5. Click **Apply**, and then click **OK**.

Use the Shell to reset a Unified Messaging PIN

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example resets the voice mail PIN for Tony Smith to 1985848. However, this PIN must be changed when the user first signs in to Outlook Voice Access.

```
Set-UMMailboxPIN -Identity tonysmith@contoso.com -PIN 1985848 -PinExpired $true
```

Other Tasks

After you reset a Unified Messaging PIN, you may also want to:

- Retrieve PIN Information for a UM-Enabled User
- Set PIN Policies for UM-Enabled Users
- Configuring PIN Security for a UM-Enabled User

1.9.2.2.20 Change the UM Dial Plan for a UM-Enabled User

Change the UM Dial Plan for a UM-Enabled User

Unified Messaging > Managing Unified Messaging > Managing Unified Messaging Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

There are specific scenarios in which you may need to move a user who is enabled for Unified Messaging (UM) to a different UM dial plan or to change the dial plan that's associated with the UM-enabled user. For example, if you want to move a UM-enabled user from a Telephone Extension to a SIP URI dial plan or if you have a Microsoft Exchange Server 2010 organization that's integrated with Microsoft Office Communications Server 2007 but the Mediation Server is down, you'll have to disable the user for Unified Messaging and then enable the user for Unified Messaging on the new UM dial plan. This is because different dial-plans may have different settings and

requirements, such as different extension length, different URI type. For example, a SIP URI dial plan requires a SIP Resource Identifier to be assigned to each UM-enabled mailbox, but Telephone Extension dial plans don't. Also, each UM mailbox contains references to both the UM dial plan and UM mailbox policy. The UM mailbox policy, in turn, also contains references to the UM dial plan. If you change the primary proxy address for a UM-enabled user to point to a different dial plan, the UM mailbox is now in an inconsistent state.

Important:

Although it's possible to add a secondary EUM proxy address with a secondary dial plan for a UM-enabled user, the user can receive new voice mails on the secondary dial plan. Adding a secondary EUM proxy address is designed to support call answering scenarios only when a user has two phones, for example, a Unified Communications and a legacy PBX phone, but wants all their voice mails to be sent to the same Exchange 2010 mailbox. However, adding a secondary EUM proxy address for a UM-enabled user when you're changing the primary UM dial plan that's associated with a UM-enabled user isn't a supported configuration.

Looking for other management tasks related to UM users? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The existing Exchange recipient is enabled for Unified Messaging. For detailed steps, see Enable a User for Unified Messaging.

Change the UM Dial Plan for a UM-enabled User

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

1. Create the new dial plan that be used. For detailed steps, see Create a UM Dial Plan.

   Important:

   If you're migrating UM-enabled users without Office Communications Server 2007to an integrated Communications Server 2007 environment, you must first create a SIP URI dial plan.

2. Disable the UM-enabled user for Unified Messaging. For detailed steps, see Disable Unified Messaging for a User.
3. Enable the user for Unified Messaging on the new dial plan. For detailed steps, see Enable a User for Unified Messaging.

Important:

If you are moving users to an environment with Office Communications Server 2007, you must also include a SIP Resource Identifier for the user when you enable the user for UM. You must also select the UM mailbox policy that's associated with a SIP dial plan.

Other Tasks

After you change the UM dial plan for a UM-enabled user, you may also want to:

- View or Configure the Properties of a UM-Enabled User

- Modify a SIP Address for a UM-Enabled User

1.9.2.2.21 Disable Selected Outlook Voice Access Features for UM-Enabled Users

Disable Selected Outlook Voice Access Features for UM-Enabled Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Outlook Voice Access contains two interfaces: the telephone user interface (TUI) and the voice user interface (VUI). By default, when users dial in to Outlook Voice Access, they can access their calendar, e-mail, and personal Contacts, and search the directory. You can use the Shell to prevent users from accessing one or more of these features when they use Outlook Voice Access to access their mailbox in Microsoft Exchange Server 2010. When you modify Outlook Voice Access features on a Unified Messaging (UM) mailbox policy, your changes affect all users who are associated with the UM mailbox policy.

You can disable users' access to the following Outlook Voice Access features on a UM mailbox policy:

- Calendar
- Directory
- E-mail
- Personal contacts

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

You can also use the Shell to disable Outlook Voice Access features on the mailbox of a single UM-enabled user. When you do this, the features will be disabled only for that user. Although you can't disable all the Outlook Voice Access features that are found on a UM mailbox policy for a single user, you can disable access to their calendar and to their e-mail.

Looking for other management tasks related to UM mailboxes? Check out Managing Unified Messaging Users.

Note:
You can only use the Shell to modify the Outlook Voice Access features for UM-enabled users on a UM mailbox policy or on the mailbox of a single UM-enabled user.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A user has been enabled for UM. For detailed steps, see Enable a User for Unified Messaging.

Use the Shell to disable selected Outlook Voice Access features for UM-enabled users on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example prevents users associated with a UM mailbox policy named MyUMMailboxPolicy from accessing their calendar when they dial in to Outlook Voice Access.

```
Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowTUIAccessToCalendar $false
```

This example prevents users associated with the UM mailbox policy named MyUMMailboxPolicy from accessing the directory when they dial in to Outlook Voice Access.

```
Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowTUIAccessToDirectory $false
```

This example prevents users associated with the UM mailbox policy named MyUMMailboxPolicy from accessing their e-mail when they dial in to Outlook Voice Access.

```
Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowTUIAccessToEmail -$false
```

This example prevents users associated with the UM mailbox policy named MyUMMailboxPolicy from accessing personal contacts when they dial in to Outlook Voice Access.

```
Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowTUIAccessToPersonalContacts $fals
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Use the Shell to disable selected Outlook Voice Access features on the mailbox of a single UM-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example disables access to the calendar on a UM mailbox named tony@contoso.com when the user dials in to Outlook Voice Access.

```
Set-UMMailbox -id tony@contoso.com -TUIAccessToCalendarEnabled
```

This example disables access to e-mail on a UM mailbox named tony@contoso.com when the user dials in to Outlook Voice Access.

```
Set-UMMailbox -id tony@contoso.com -TUIAccessToEmailEnabled $false
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you disable selected Outlook Voice Access features, you may also want to:

- Enable or Disable Outlook Voice Access on a UM Mailbox Policy
- Configure the UM Mailbox Policy Assigned to a UM-Enabled User
- Enable or Disable Sending Voice Messages on a UM Dial Plan
- Enable PIN-less Logons for UM-Enabled Users

1.9.2.2.22 Enable PIN-less Logons for UM-Enabled Users

Enable PIN-less Logons for UM-Enabled Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In Microsoft Exchange Server 2010, you can set up Unified Messaging (UM) so that your users can log on to their voice mail without using a PIN. By default, Outlook Voice Access users are prompted to enter a PIN to log on to their mailbox and access their voice mail, e-mail, calendar, personal Contacts, the directory, and personal options.

To enable PIN-less logons, you must set the parameter *AllowPinlessVoiceMailAccess* to `$true` on the UM mailbox policy and set the parameter *PinlessAccessToVoiceMailEnabled* to `$true` on the UM mailbox. By default, both parameters are set to `$false`, which requires an Outlook Voice Access user to enter their PIN when they access their voice mail.

Setting both parameters to `$true` allows you to enable PIN-less logons for a large group of users who are associated with a UM mailbox and also enable PIN-less logons for a single UM mailbox or a subset of UM mailboxes. Even if you enable PIN-less logons for a group of UM-enabled users or a single UM-enabled user, when they access their e-mail, calendar, personal Contacts, the directory, or personal options, they'll be prompted to enter their PIN.

To enable PIN-less logons to voice mail for a user, the following conditions must be met:

- You must have run the following cmdlet on the UM mailbox policy: `Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowPinlessVoiceMailAccess $true`
- You must have run the following cmdlet on the mailbox of the UM-enabled user: `Set-UMMailbox -id tonys@contoso.com -PinlessAccessToVoiceMailEnabled $true`
- The UM-enabled user is associated with the same UM mailbox policy for which you enabled PIN-less logons.
- The UM-enabled user dials in to Outlook Voice Access from a phone number that’s been assigned to them.

Note:

You can only use the Shell to modify the PIN-less logon settings for a group of UM-enabled users on a UM mailbox policy or on a single UM-enabled user's mailbox.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Looking for other management tasks related to UM mailboxes? Check out Managing Unified Messaging Users.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- The user or users have been enabled for UM. For detailed steps, see Enable a User for Unified Messaging.

Use the Shell to enable PIN-less access to voice mail for UM-enabled users on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example enables PIN-less voice mail access on a UM mailbox policy named MyUMMailboxPolicy for users associated with the mailbox policy who dial in to Outlook Voice Access.

```
Set-UMMailboxPolicy -id MyUMMailboxPolicy -AllowPinlessVoiceMailAccess $true
```

For information about syntax and parameters, see Set-UMMailboxPolicy.

Use the Shell to enable PIN-less access to voice mail on a UM-enabled user's mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailboxes" entry in the Unified Messaging Permissions topic.

This example enables PIN-less voice mail access for the user who dials in to Outlook Voice Access to reach the mailbox named tonys@contoso.com.

```
Set-UMMailbox -id tonys@contoso.com -PinlessAccessToVoiceMailEnabled $true
```

For more information about syntax and parameters, see Set-UMMailbox.

Other Tasks

After you enable PIN-less logons for voice mail, you may also want to:

- View or Configure the Properties of a UM-Enabled User
- Configure the UM Mailbox Policy Assigned to a UM-Enabled User
- Set PIN Policies for UM-Enabled Users

Create a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

After you create a Unified Messaging (UM) auto attendant, incoming calls to an external telephone number that a human operator would ordinarily answer are answered by the auto attendant. Unlike for other Unified Messaging objects, such as UM dial plans and UM IP gateways, you aren't required to create UM auto attendants. However, auto attendants help internal and external callers locate users or departments that exist in an organization and transfer calls to them.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

What Do You Want to Do?

- Use the EMC to create a UM auto attendant
- Use the Shell to create a UM auto attendant

Use the EMC to create a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. In the action pane, click **New UM Auto Attendant**.
4. In the New UM Auto Attendant wizard, complete the following fields:
   - **Name** Use this text box to create the display name for the UM auto attendant. A UM auto attendant name is required and must be unique. However, it's used only for display purposes in the EMC and the Shell.
     If you have to change the display name of the auto attendant after it's created, you must first delete the existing UM auto attendant and then create another auto attendant that has the appropriate name. If your organization uses multiple UM auto attendants, we recommend that you use meaningful names for your UM auto attendants. The maximum length of a UM auto attendant name is 64 characters, and it can include spaces. Although you can include spaces in the name of a new UM auto attendant, the name cannot include spaces if you integrate Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server. Therefore, if you created an auto attendant that has spaces in the display name, and if you are integrating with Office Communications Server 2007 R2 or Microsoft Lync Server, you must first delete that auto attendant and then create another by using a display name that does not include spaces.
   - **Select associated dial plan** Click **Browse** to select the UM dial plan to associate with this UM auto attendant. Selecting and associating a UM dial plan with the auto attendant is required. A UM auto attendant can be associated with only one UM dial plan.
   - **Pilot identifier list** Use this field to enter the extension numbers or pilot numbers that callers will use to reach the auto attendant. Type an extension number or pilot identifier in the box, and then click **Add** to add the number to the list. The number of digits in the extension number or pilot identifier that you provide doesn't have to match the number of digits for an extension number configured on the associated UM dial plan. This is because direct calls are allowed to UM auto attendants.
     The number of extension numbers or pilot identifiers entered is unlimited. However, you may create the new auto attendant without an extension number listed. An extension number or pilot identifier isn't required.
     You can edit or remove an existing extension number or pilot identifier. To edit an existing extension number or pilot identifier, click **Edit**. To remove an existing extension number or pilot identifier from the list, click **Remove**.

- **Create auto attendant as enabled** Select this option to enable the auto attendant to answer incoming calls when you complete the New UM Auto Attendant wizard. By default, a new auto attendant is created as disabled.
  If you decide to create the UM auto attendant as disabled, you can use the EMC action pane or the Shell to enable the auto attendant after you finish the wizard.
- **Create auto attendant as speech-enabled** Select this check box to speech-enable the UM auto attendant. By speech-enabling the auto attendant, callers can respond to the system or custom prompts used by the UM auto attendant using touchtone or voice inputs. By default, the auto attendant won't be speech-enabled when it's created.
  For callers to use a speech-enabled auto attendant, you must install the appropriate Unified Messaging language pack that contains Automatic Speech Recognition (ASR) support and configure the properties of the auto attendant to use this language.

5. On the **Completion** page, confirm whether the UM auto attendant was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM Auto Attendant wizard.

Use the Shell to create a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example creates a UM auto attendant named `MyUMAutoAttendant` that can accept incoming calls but isn't speech-enabled.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan MyUMDialPlan -PilotIdenti
```

This example creates a speech-enabled UM auto attendant named `MyUMAutoAttendant`.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan MyUMDialPlan -PilotIdenti
```

For more information about syntax and parameters, see New-UMAutoAttendant.

Other Tasks

After you create an auto attendant, you may also want to:

- Enable Business Hours Key Mappings on a UM Auto Attendant
- Enable Non-Business Hours Key Mappings on a UM Auto Attendant

For More Information

Understanding Unified Messaging Auto Attendants

View or Configure the Properties of a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you create a Unified Messaging auto attendant, you can view or configure a variety of settings. For example, you can add, remove, and edit extension numbers associated with the auto attendant. You can also enable or disable Automatic Speech Recognition (ASR) for the auto attendant and change the greetings used for business and non-business hours.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

What Do You Want to Do?

- Use the EMC to view or configure UM auto attendant properties
- Use the Shell to configure UM auto attendant properties
- Use the Shell to view UM auto attendant properties

Use the EMC to view or configure UM auto attendant properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab, and then select the UM auto attendant that you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view display-only information about the UM auto attendant and to perform management tasks on a UM auto attendant, as follows:
   - **Status** This box shows whether the UM auto attendant is enabled or disabled. To enable or disable the auto attendant, close the **General** tab and use the action pane commands to enable or disable the auto attendant.
   - **Associated dial plan** This box displays the UM dial plan associated with the auto attendant. After you create an auto attendant, the dial plan associated with the auto attendant can't be changed. If you need to associate an auto attendant with a different dial plan, you must delete the dial plan and then associate the auto attendant with the correct dial plan after you re-create it.

- **Modified** This box shows the last date and time the auto attendant settings were modified.
- **Pilot identifier list** Use this box to enter the extension numbers or pilot numbers that, when it's called, leads callers to the auto attendant. By default, no extension numbers are configured when you create an auto attendant.

  The number of digits in the extension number or pilot numbers you provide must match the number of digits for an extension number configured on the UM dial plan associated with the UM auto attendant. You can also add a Session Initiation Protocol (SIP) address to this box. A SIP address is used by some IP Private Branch eXchanges (PBXs).

  However, you can create the new auto attendant without listing an extension number or pilot number. An extension number isn't required. To add an extension, type the number in this box, and then click **Add**. You can associate more than one number with an auto attendant. You can also edit or remove an existing extension number. To edit an existing extension number, click the **Edit** button. To remove an existing extension number from the list, click the **Remove** button.
- **Auto attendant is speech-enabled** Use this option to enable callers to respond verbally to auto attendant prompts to navigate the menu system. By default, when an auto attendant is created, it isn't speech-enabled.

  If you decide to create the UM auto attendant but not to speech-enable it, you can use the EMC or the Shell to speech-enable it after you finish using the New UM Auto Attendant wizard. You can then view the properties of the auto attendant and enable this option.
- **Use this DTMF fallback auto attendant** Select this check box to enable the UM auto attendant to use a dual tone multi-frequency (DTMF) fallback auto attendant. A DTMF fallback auto attendant can be used only if the **Auto attendant is speech-enabled** option is selected. You must first create a DTMF fallback auto attendant, and then click the **Browse** button to locate the appropriate DTMF auto attendant.

  A DTMF fallback auto attendant is used when the UM speech-enabled auto attendant can't understand or recognize the speech inputs from the caller. If the DTMF auto attendant is used, the caller is required to use DTMF inputs to navigate the menu system, spell a user's name, or use a custom menu prompt. A caller won't be able to use voice commands to navigate this auto attendant.

  If you don't configure a DTMF fallback auto attendant, we recommend that you configure an operator extension number on the auto attendant. If you don't configure an operator extension number, when callers use a speech-enabled auto attendant and the system doesn't recognize their voice inputs, they won't be able to navigate the system or be transferred to an operator for help.

  Although not required, we recommend that you configure the DTMF fallback auto attendant to have the same configuration as the speech-enabled auto attendant. The DTMF fallback auto attendant shouldn't be speech-enabled.
- **Auto attendant is enabled for directory lookups** Select this check box to enable the UM auto attendant to look up names in the directory for callers. This setting is enabled by default. If this setting is disabled, callers won't be able to search the directory for a specific person using touchtone or voice commands.

5. Use the **Greetings** tab on the auto attendant's **Properties** sheet to manage recorded greetings for the current UM auto attendant. You can select default

greetings or previously recorded custom greetings for business hours and non-business hours. You can configure the following:

- **Business hours greeting** This is the initial greeting played when a caller calls the auto attendant during your organization's business hours. By default, it's a system prompt that says, "Welcome to the Exchange auto attendant." This greeting plays during your organization's business hours. The business and non-business hours are configured on the auto attendant **Times** tab.

  You may want to customize this greeting to represent your company, for example, "Thank you for calling Woodgrove Bank." You can configure a customized business hours greeting by clicking **Modify** to select a previously recorded custom greeting file. You can select the following:

  Use default greeting Use this option to enable the default business hours greeting to be played to callers. By default, this option is enabled.

  Use custom greeting file Use this option when you want to enable a custom business hours greeting file to be played to callers. Click **Browse** to locate a custom business hours greeting file that was previously recorded.
- **Non-Business hours greeting** This is the initial greeting played when a caller calls the auto attendant during your organization's non-business hours. By default, no business or non-business hours are configured. Therefore, there is no default non-business hours greeting. You can configure the business and non-business hours on the auto attendant **Times** tab.

  You may want to customize this greeting to represent your company, for example, "Thank you for calling Woodgrove Bank but we are now closed." You can configure a customized business hours greeting by clicking **Modify** to select a previously recorded custom greeting file.

  This is the initial greeting played when a caller calls the auto attendant during your organization's non-business hours. There's no default non-business hours greeting because, by default, there are no business or non-business hours configured. However, you may want to provide a customized non-business hours greeting specific to your company, for example, "You have reached Contoso, Ltd. after business hours. Our business hours are from 8:00 A.M. until 5:00 P.M., Monday through Friday." You can select the following:

  Use default greeting Use this option to enable the default non-business hours greeting to be played to callers when a business hours schedule has been configured on the auto attendant. By default, this option is enabled.

  Use custom greeting file Use this option when you want to enable a custom non-business hours greeting file to be played to callers. Click **Browse** to locate a custom non-business hours greeting file that was previously recorded.
- **Informational announcement** When enabled, this optional recording plays immediately after the business or non-business hours greeting. An informational announcement may state the organization's hours of operation, for example, "Our business hours are 8:30 A.M. to 5:30 P.M., Monday through Friday and 8:30 A.M. to 1:00 P.M. on Saturday." An informational announcement can also provide information required for compliance with company policy, for example, "Calls may be monitored for training purposes." If it's important that callers hear the whole informational announcement, it can be marked as uninterruptible.

  By default, there's no informational announcement configured on UM dial plans or auto attendants. Use the following options to enable an informational announcement and use a custom

audio file specific to your organization. The recordings must already have been recorded as .wav files. You can select the following:

Disable announcement Use this option to disable an informational announcement. By default, this option is configured.

Informational announcement file Use this option when you want to enable an informational announcement to be played to callers. Click **Browse** to locate a custom informational announcement file previously recorded.

Allow informational announcement to be interrupted Use this option to enable the informational announcement to be interrupted by the caller. This should be enabled if you have long informational announcements. Callers may become frustrated if the informational announcement is long and they can't interrupt the informational announcement to access the options provided by the UM dial plan or auto attendant.

- **Business hours main menu prompt** The business hours main menu prompt for an auto attendant is the list of options callers hear during business hours defined on the **Times** tab. For example, "For technical support, press or say 1. For corporate offices and administration, press or say 2. For sales, press or say 3."

  To enable a business hours main menu prompt, you must perform the following steps:

- Specify a custom menu prompt audio file. To use a custom business hours menu prompt, click **Modify** to select the default prompt or to specify a previously recorded prompt.
- Configure the appropriate business hours using the **Business hours** option on the **Times** tab.
- Enable business hours key mappings and configure key mappings on the **Key Mapping** tab for the auto attendant.

  By default, if you enabled and defined business hours key mappings on the **Key Mapping** tab on the UM auto attendant, the Unified Messaging Text-to-Speech (TTS) engine will synthesize a business hours main menu prompt. Alternatively, you can create a customized audio file that can be used for the business hours main menu prompt for a speech-enabled auto attendant that would say, for example, "For sales, say 1. For technical support, say 2. For administration, say 3. To reach an operator, press zero." You can select the following:

  Use default greeting Use this option to enable the default business hours main menu prompt to be played to callers when a business hours schedule has been configured on the auto attendant. By default, this option is enabled.

  Use custom greeting file Use this option when you want to enable a custom business hours main menu prompt file to be played to callers. Click **Browse** to locate a previously recorded custom business hours greeting file. The recordings must already have been recorded as .wav files.

- **Non-Business hours main menu prompt** The non-business hours main menu prompt for an auto attendant is the list of options callers hear during the non-business hours defined on the **Times** tab. For example, "Your call is very important to us. However, you have reached Woodgrove Bank after normal business hours. If you want to leave a message, please press or say 1 and we will return your call as soon as possible."

  To enable a non-business hours main menu prompt, you must perform the following steps:

  a. Specify a custom menu prompt audio file. To use a custom non-business hours main menu prompt, click **Modify** to select the default prompt or to specify a previously recorded prompt.

b. Configure the appropriate business hours using the **Business hours** option on the **Times** tab.
c. Enable non-business hours key mappings and configure key mappings on the **Key Mapping** tab for the auto attendant.
By default, if you enabled and defined non-business hours key mappings on the **Key Mapping** tab on the UM auto attendant, the Unified Messaging TTS engine will synthesize a non-business hours main menu prompt. Alternatively, you can create a customized audio file that can be used for the non-business hours main menu prompt for a speech-enabled auto attendant that would say, for example, "To leave a voice message for sales, say 1. To leave a voice message for technical support, say 2. To leave a voice message for administration, say 3. To reach an after hours operator, press zero." You can select the following:
Use default greeting Use this option to enable the default non-business hours main menu prompt to be played to callers when a non-business hours schedule has been configured on the auto attendant. By default, this option is enabled. The recordings must already have been recorded as .wav files.
Use custom greeting file Use this option when you want to enable a custom non-business hours main menu prompt file to be played to callers. Click **Browse** to locate a custom non-business hours greeting file that was previously recorded. The recordings must already have been recorded as .wav files.

6. Use the **Times** tab on the auto attendant **Properties** sheet to determine the organization's open business hours. During business hours, callers hear the default business hours greeting or a customized greeting and the business hours main menu prompt if the appropriate business hours key mappings are configured on the **Key Mapping** tab. You can configure the following:
   - **Business hours** Use this list to select a standard schedule, or you can click **Customize** to create your own user-defined schedule. **Always Run** is the default setting.
     If your business hours vary only slightly from one of the system-defined schedules, you can select a schedule, and then click **Customize** to refine your business hours schedule.
   - **Select time zone** Use this list to select your time zone. Consider whether the dial plan associated with the auto attendant covers more than one time zone when you set your schedule.
     By default, the time zone is configured using the local server's system time when the Unified Messaging server role was installed.
   - **Holiday Schedule** Use **Holiday Schedule** to define days, from 00:00 through 23:59 (12:00 A.M. through 11:59 P.M.), for which your organization will be closed for a holiday. Callers who reach the auto attendant during the times that you specify in the **Select Holiday** dialog box hear a custom holiday greeting audio file that you define. When you configure the holiday schedule, you must also define the **Holiday start date** and **Holiday end date**.

7. Use the **Features** tab on the auto attendant's **Properties** sheet to define the features available to callers who dial in to the UM auto attendant. For example, you can configure auto attendant features such as the language used when callers call in to the auto attendant and the ability for callers to transfer to an operator's extension number that you define on this property sheet. You can configure the following:
   - **Business name** Use this box to enter the name of the business. By default, no business name is entered. If you enter a business name in this box, a prompt with the business name will be played to callers instead of

the default greeting.

- **Business location** Use this box to enter the location of the business. By default, there is not a business location entered. If you enter the location of the business in this box, the business location will be played for callers.
- **Language** Use this list to select the language that callers hear when they reach the auto attendant. The default language is determined when you install Microsoft Exchange Server 2010. By default, when you install the Unified Messaging server role, U.S. English is used because the auto attendant uses the language setting on the UM dial plan. To have other language options available, you must install the UM language packs for the languages you want to include. For more information about how to install a UM language pack, see Install a Unified Messaging Language Pack on a UM Server.

  Although you can select a language other than the language selected on the UM dial plan associated with the auto attendant, we recommend that the language settings on the dial plan and the auto attendant match. If language settings don't match, when callers call an extension number defined on the dial plan, callers will be presented with prompts in one language, and when they dial an extension number associated with an auto attendant, they will be presented with prompts in a different language.

  The language selected in this list is used when callers call the extension number defined on the properties for the UM auto attendant.
- **Operator extension** Use this box to type the extension number used to call an operator. This extension number can also connect the caller to a human operator or a UM-enabled mailbox or can be configured to call an external telephone number. By default, an operator extension isn't included in this box.
- **Allow caller to transfer to users** Select this check box to enable callers to transfer calls to users. By default, this option is enabled, and lets users who are associated with the dial plan transfer calls to users in the same UM dial plan. After you select this check box, you can set the group of users to whom callers can transfer by selecting the appropriate option under the **Callers can contact** section on this page.

  If you disable this option and disable the **Allow callers to send voice message** option, the options under **Callers can contact** are also disabled.
- **Allow callers to send voice messages** Select this check box to enable callers to send voice messages to users. By default, this option is enabled, and lets users who are associated with the dial plan send voice messages to users in the same UM dial plan. After you select this check box, you can set the group of users to whom callers can send voice messages by selecting the appropriate option under the **Callers can contact** section on this page.

  If you disable this option and disable the **Allow caller to transfer to users** option, the options under **Callers can contact** are also disabled.

  If you disable this option, the auto attendant won't invite callers to send a voice message during a system prompt.
- **Callers can contact** Use these options to determine a grouping of users to use. By default, the **Users within dial plan** option is selected. However, you can change the grouping of users to allow callers to transfer calls or send voice messages to users who are located in the global address list (GAL) or to a specific set of users who are contained in custom address lists by choosing from the following:

  Users within dial plan Select this option to allow callers who connect to the UM auto attendant to locate and contact users who are in the dial plan associated with the UM auto attendant.

Anyone in the default global address list Select this option to allow callers who connect to the UM auto attendant to locate and contact anyone listed in the GAL. This includes all users who are mailbox-enabled.

Anyone in this address list Select this option to allow callers who connect to the UM auto attendant to locate and contact users who are in a defined custom address list. This includes all users who are mailbox-enabled.

Important:

The **All Address Lists** container is an empty container object and differs from the GAL container. If you choose the **All Address Lists** container when you browse for a custom address list, there will be no UM-enabled users for callers to contact. If you want to select all the address lists in your organization, choose the **Anyone in the default global address list** option.

- **Matched name selection method** Use this list to select the matched name selection method for the UM auto attendant. The matched name method is used when two or more users who have the same name exist in the directory. This is also called a disambiguation field. You can configure this setting on this property sheet, or you can leave the default setting on the auto attendant and configure this setting on the dial plan.

  By default, the auto attendant is set to inherit from the dial plan. However, by default, the auto attendant is unable to disambiguate between two or more users who have the same name because the default setting for the **Matched name selection method** on the dial plan is set to **None**.

  Select one of the following methods that provide the caller more information to help the caller select the correct user in the organization:

  Title Select this option to have the auto attendant include each user's title when listing matches.

  Department Select this option to have the auto attendant include each user's department when listing matches.

  Location Select this option to have the auto attendant include each user's location when listing matches.

  None Select this option to have no additional information given when listing matches.

  Prompt For Alias Select this option to have the auto attendant prompt the caller for the user's alias.

  Inherit From Dial Plan Select this option to have the auto attendant use the default setting from the dial plan associated with the auto attendant.

- **Allow transfer to operator during business hours** Select this check box to enable callers to be transferred to a human operator during business hours using the extension number that you configure in the **Operator extension** box on this property sheet. By default, this option is disabled.

  It's useful to enable this option so that when a caller is unsuccessful at using the menu prompts or directory search to locate the required person during business hours, the caller can leave a voice message or connect to a human operator. After you enable this option, you can configure the operator extension number on a UM-enabled mailbox that's monitored. The caller can leave a voice message, or a human operator who has the extension number can help the caller.

- **Allow transfer to operator after business hours** Select this check box to enable callers to be transferred to a human operator after business hours using the extension number that you configure in the **Operator extension** box on this property sheet. By default, this option is disabled.

  It's useful to enable this option so that when a caller is

unsuccessful at using the menu prompts or directory search to locate the required person after business hours, the caller can leave a voice message or connect to a human operator. After you enable this option, you can configure the operator extension number configured on a UM-enabled mailbox that's monitored. The caller can leave a voice message, or a human operator who has the extension number can help the caller.

8. Use the **Key Mapping** tab on the auto attendant's **Property** sheet to define the telephone keys that callers can press when they reach the UM auto attendant. You can define separate key mappings for business hours and non-business hours. A key mapping is defined as an entry in a table that has as many as nine entries. The 0 (zero) key is reserved for a transfer to the operator.
   For example, a key mapping used during business hours may enable a call transfer to another extension where a human operator or receptionist is available. For non-business hours, the option to transfer to another extension may not be available, or the call may be forwarded to a UM-enabled mailbox so the caller can leave a voice message. You can configure the following:
   - **Enable business hours key mapping** Select this check box to enable specific key mappings that will be used during business hours. When you enable business hours key mapping, you can add new key mappings for business hours.
   - **Enable non-business hours key mapping** Select this check box to enable specific key mappings that will be used during non-business hours. When you enable non-business hours key mapping, you can add new key mappings for non-business hours.

     For more information about configuring key mapping entries, see Configure Key Mapping Entries on a UM Auto Attendant.

9. Use the **Dialing Restrictions** tab on the UM auto attendant properties to configure dialing rules for callers who call in to a UM auto attendant. An auto attendant is the collection of voice prompts that callers hear instead of a human operator when they call in to an organization that has Exchange 2010 Unified Messaging. You can use these settings to control the extension numbers that can be reached from an auto attendant or control the telephone numbers that can be dialed by callers that have dialed into the auto attendant. You can configure the following:
   - **Allow calls to users within the same dial plan** Select this check box to allow users who call in to an auto attendant to place or transfer calls to an extension number associated with a UM-enabled user who is associated with the same dial plan as the auto attendant. By default, this setting is enabled.

     When you disable this setting, users who call in to an auto attendant can place or transfer calls to users who aren't UM-enabled or to other extension numbers not associated with a UM-enabled user. Users can't transfer calls to UM-enabled users who are associated with the same dial plan as the auto attendant. This is because the **Allow calls to extensions** setting is enabled by default.
   - **Allow calls to extensions** When this setting is disabled, users who call in to an auto attendant can't place calls to users who aren't UM-enabled or to other extension numbers not associated with a UM-enabled user. However, they can place calls or transfer calls to extension numbers associated with UM-enabled users. This is because the **Allow calls to users within the same dial plan** setting is enabled by default. The **Allow calls to extensions** setting is enabled by default.

     When this setting is enabled, users who call in to an auto attendant can place calls to users who aren't UM-enabled, to

other extension numbers not associated with a UM-enabled user, and to UM-enabled users. This is because the **Allow calls to users within the same dial plan** setting is enabled by default.
You can enable this setting in an environment where not all users have been UM-enabled. This setting is also useful when you want to allow users who call in to a telephone number configured on an auto attendant to call extension numbers not associated with a UM-enabled user.

- **Select allowed in-country/region rule groups from dial plan** Use this section to add or remove allowed in-country/region dialing rule groups. By default, there are no in-country/region dialing rule groups configured on UM auto attendants.
  In-country/region dialing rule groups are used to allow or restrict the telephone numbers within a country or region that any user who has dialed in to the UM auto attendant can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.
  To add in-country/region dialing rule groups, you must first create the appropriate in-country/region dialing rule groups on the dial plan associated with the UM auto attendant, and then add the appropriate dialing rule entries on the dialing rule group. After you create the required dialing rule groups on the dial plan, you must then add the dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the UM auto attendant.
  In-country/region dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers within a country or region. This is applied to any user who has called in to an auto attendant.
- **Select allowed international rule groups from dial plan** Use this section to add or remove allowed international dialing rule groups. By default, there are no international dialing rule groups configured on UM auto attendants.
  International dialing rule groups are used to allow or restrict the telephone numbers outside a country or region that any user who has dialed in to the UM auto attendant can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.
  To add international dialing rule groups, you must first create the appropriate international dialing rule groups on the dial plan associated with the UM auto attendant, and then add the appropriate dialing rule entries on the dialing rule group. After you create the required dialing rule groups on the dial plan, you must then add the dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the UM auto attendant.
  International dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers outside a country or region. This is applied to any user who has called in to an auto attendant.
  For more information about outdialing, see Understanding Outdialing.

Use the Shell to configure UM auto attendant properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging

Permissions topic.

This example configures a UM auto attendant named MySpeechEnabledAA to fall back to the MyDTMFAA auto attendant, sets the operators extension to 50100, and enables transfers to this extension number after business hours.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -DTMFFallbackAutoAttendant MyDTMF
```

This example configures a UM auto attendant named MyUMAutoAttendant that has: Business hours configured as 10:45 to 13:15 (10:45 A.M. to 1:15 P.M.) on Sunday, 09:00 to 17:00 (9:00 A.M. to 5:00 P.M.) on Monday, and 09:00 to 16:30 (9:00 A.M. to 4:30 P.M.) on Saturday; holiday times and their associated greetings configured as "New Year" on January 2, 2010; and "Building Closed for Construction" configured from April 24 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Use the Shell to view UM auto attendant properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example returns a formatted list of all UM auto attendants in the Active Directory forest.

```
Get-UMAutoAttendant | Format-List
```

This example displays the properties of a UM auto attendant named MyUMAutoAttendant.

```
Get-UMAutoAttendant -Identity MyUMAutoAttendant
```

For more information about syntax and parameters, see Get-UMAutoAttendant.

Other Tasks

After you configure Unified Messaging auto attendant properties, you may also want to:

- Configure Key Mapping Entries on a UM Auto Attendant
- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant

For More Information

Understanding Unified Messaging Auto Attendants

1.9.2.3.1.3 Delete a UM Auto Attendant

Delete a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can delete an existing Unified Messaging (UM) auto attendant. After you delete an existing UM auto attendant, the incoming calls that were answered by the UM auto attendant must be answered by a human operator. A UM auto attendant can't be deleted if it's associated with a UM dial plan as the default UM auto attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to delete a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to delete.
4. In the action pane, click **Remove**.
5. In the confirmation dialog box, click **Yes** to delete the UM auto attendant.

Use the Shell to delete a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example deletes a UM auto attendant named `MyUMAutoAttendant`.

```
Remove-UMAutoAttendant -Identity MyUMAutoAttendant
```

For more information about syntax and parameters, see Remove-UMAutoAttendant.

Other Tasks

After you delete an existing UM auto attendant, you may also want to Create a UM Auto Attendant.

Enable a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. By default, when a UM auto attendant is created, the status of the UM auto attendant is set to enabled. After you create the UM auto attendant, you can control its status using the status variable. If the status of a UM auto attendant is disabled, you'll have to enable the UM auto attendant so it can answer incoming calls.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant object you want to enable.
4. In the action pane, click **Enable**.

Use the Shell to enable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the UM auto attendant named `MyUMAutoAttendant` to answer incoming calls.

```
Enable-UMAutoAttendant -Identity MyUMAutoAttendant
```

For more information about syntax and parameters, see Enable-UMAutoAttendant.

Other Tasks

After you enable a UM auto attendant, you may also want to:

- View or Configure the Properties of a UM Auto Attendant
- Disable a UM Auto Attendant

1.9.2.3.1.5 Disable a UM Auto Attendant

Disable a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable a Unified Messaging (UM) auto attendant. By default, when a UM auto attendant is created, its status is set to enabled. After you create the UM auto attendant, you can control its status by changing the status variable. For example, you might want to disable the UM auto attendant when you're recording or re-recording customized prompts and messages. If the UM auto attendant is disabled, the UM auto attendant can't answer incoming calls.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.
- The status of the UM auto attendant is set to enabled.

Use the EMC to disable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the result pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to disable.
4. In the action pane, click **Disable**.

Use the Shell to disable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example disables a UM auto attendant named `MyUMAutoAttendant`.

```
Disable-UMAutoAttendant -Identity MyUMAutoAttendant
```

For more information about syntax and parameters, see Disable-UMAutoAttendant.

Other Tasks

After you disable a UM auto attendant, you may also want to:

- Enable a UM Auto Attendant
- View or Configure the Properties of a UM Auto Attendant

1.9.2.3.1.6 Add an Extension Number to a UM Auto Attendant

Add an Extension Number to a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure an extension number or multiple extension numbers on a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. When you add an extension number to a UM auto attendant, that number can be used by callers to access the auto attendant. Also, you may have to add extension numbers because there is more than one extension number that callers can use to access an auto attendant. By default, no extension numbers are configured when you create an auto attendant.

Note:
An extension number for a UM auto attendant is also known as a pilot identifier or pilot number.

You can create a new auto attendant without setting up an extension number for the auto attendant. You can also associate more than one telephone or extension number with a single auto attendant. You can either add the extension numbers when you create the UM auto attendant or add them after you configure the auto attendant. The number of digits in the extension number you configured on the UM auto attendant must match the number of digits for an extension number that's configured on the UM dial plan associated with the UM auto attendant.

Note:
You can also add a Session Initiation Protocol (SIP) address instead of adding an extension number. A SIP address is used by some IP Private Branch eXchanges (PBXs).

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM auto attendant has been created. For detailed steps, see Create a UM

Auto Attendant.

Use the EMC to configure an extension number on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **General** tab, under **Extension number to associate**, enter the number you want to associate with this auto attendant, and then click **Add**.
5. Click **OK** to save your changes.

Use the Shell to configure an extension number on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named `MyUMAutoAttendant` with multiple extension numbers.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -PilotIdentifierList "12345, 7200
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure an extension number on a UM auto attendant, you may also want to:

- Enable Dialing Restrictions on a UM Auto Attendant
- Configure an Operator Extension on a UM Auto Attendant

1.9.2.3.1.7 Enable or Disable Automatic Speech Recognition on a UM Auto Attendant

Enable or Disable Automatic Speech Recognition on a UM Auto Attendant

Managing Unified Messaging > Managing Unified Messaging Components > Managing UM Auto Attendants >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable your Microsoft Exchange Server 2010 Unified Messaging (UM) auto attendant for Automatic Speech Recognition (ASR). After you speech-enable a UM auto attendant, callers can respond verbally to auto attendant prompts and move through the

menu system of the auto attendant. By default, an auto attendant isn't speech-enabled when you create it. After you speech-enable the auto attendant, callers can use only voice commands to navigate the auto attendant menu system, and touchtone inputs can't be used.

Although it isn't required, we recommend that you configure a dual tone multi-frequency (DTMF) fallback auto attendant for each speech-enabled auto attendant so callers can use touchtone inputs if the speech-enabled auto attendant doesn't recognize or understand the words they say. If a DTMF fallback auto attendant is configured, callers can use DTMF inputs, also known as touchtone inputs, to navigate the auto attendant menu system, spell a user's name, or use a custom menu prompt. We don't recommend that you speech-enable a DTMF fallback auto attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to speech-enable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **General** tab, select **Auto attendant is speech-enabled**.
5. Click **OK** to save your changes.

Use the Shell to speech-enable a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables ASR on a UM auto attendant named `MySpeechEnabled AA`.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -SpeechEnabled $true
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you speech-enable a UM auto attendant, you may also want to:

- Install a Unified Messaging Language Pack on a UM Server
- Update the Speech Grammar Files on a UM Server

- Enable or Disable Automatic Speech Recognition for a UM-Enabled User

1.9.2.3.1.8 Configure a UM Auto Attendant with a DTMF Fallback Auto Attendant

Configure a UM Auto Attendant with a DTMF Fallback Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a speech-enabled Unified Messaging (UM) auto attendant that has a dual tone multi-frequency (DTMF) fallback auto attendant in Microsoft Exchange Server 2010. A DTMF fallback auto attendant is used when the UM speech-enabled auto attendant can't understand or recognize the speech inputs provided by a caller. If a DTMF fallback auto attendant has been configured, the caller has to use DTMF inputs, also known as touchtone inputs, to navigate the auto attendant menu system, spell a user's name, or use a custom menu prompt. If a DTMF fallback auto attendant hasn't been configured, and the maximum number of speech inputs has been exceeded because the system didn't understand what the caller said, the system will respond with this prompt: "Sorry, I couldn't help. Please call back later."

By default, an auto attendant isn't speech-enabled when you create it. After you speech-enable the auto attendant, callers can use only voice commands to navigate the auto attendant menu system, and touchtone inputs can't be used. Although it isn't required, we recommend that you configure a DTMF fallback auto attendant for each speech-enabled auto attendant so callers can use touchtone inputs if the speech-enabled auto attendant doesn't recognize or understand the words they say. We also recommend that you don't speech-enable a DTMF fallback auto attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM speech-enabled auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.
- A UM DTMF fallback auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure a speech-enabled auto attendant with a DTMF fallback auto attendant

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **General** tab, make sure the check box next to **Auto attendant is speech-enabled** is selected.
5. Select the check box next to **Use this DTMF fallback auto attendant**, and then click **Browse**.
6. On the **Select Auto Attendant** page, select the auto attendant you want to use as a DTMF fallback auto attendant, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to configure a speech-enabled auto attendant with a DTMF fallback auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named MySpeechEnabledAA to use a DTMF fallback auto attendant named MyDTMFAA.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -DTMFFallbackAutoAttendant MyDTMF
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure a speech-enabled auto attendant with a DTMF fallback auto attendant, you may also want to:

- Enable Business Hours Key Mappings on a UM Auto Attendant
- Configure Business Hours for a UM Auto Attendant
- Enable or Disable Automatic Speech Recognition on a UM Auto Attendant

1.9.2.3.1.9 Enable or Disable Directory Lookups for a UM Auto Attendant

Enable or Disable Directory Lookups for a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable directory lookups so that callers who call in to a Unified Messaging (UM) auto attendant can look up names in the directory. This setting is enabled by default. If this setting is disabled, callers won't be able to search the directory for a specific person

using touchtone or voice commands.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable or disable directory lookups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **General** tab, and then select or clear the **Auto attendant is enabled for directory lookups** check box.
5. Click **OK** to accept your changes.

Use the Shell to enable or disable directory lookups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example disables directory lookups on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -NameLookupEnabled $false
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable or disable directory lookups on a UM auto attendant, you may also want to:

- Enable Dialing Restrictions on a UM Auto Attendant
- Configure the Scope of Users that Callers Can Contact on a UM Auto Attendant

Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a custom business hours greeting for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. The business hours welcome greeting is the first thing callers hear when a UM auto attendant answers their call during business hours

You'll probably want to customize the greetings, informational announcements, and menu prompts used with UM dial plans and auto attendants. After the Unified Messaging server role is installed on the Exchange 2010 server, you can enable the UM dial plans and auto attendants to use these custom .wav audio files.

If you want to include the name of your organization or business as part of the default welcome greeting, you can enter the name in the Business Name field on the UM auto attendant. For details, see Configure a Business Name on a UM Auto Attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable a custom business hours greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change and then, in the action pane, click **Properties**.
4. On the **Greeting** tab, under **Business hours greeting**, click **Modify**.
5. On the **Business Hours Greeting** page, select from these options:
   - **Use default greeting**
   - **Use custom greeting file**
6. If you select the **Use custom greeting file** option, click **Browse**, locate the greeting file you've already created, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to enable a custom business hours greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the business hours welcome greeting that uses a custom greeting named `welcomegreetingfile.wav` for the UM auto attendant `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursWelcomeGreetingEnab
```

This example configures a UM auto attendant named `MyUMAutoAttendant` that has business hours configured to be 10:45 to 13:15 (Sunday), 09:00 to 17:00 (Monday), and 09:00 to 16:30 (Saturday) and holiday times and their associated greetings configured to be "`New Year`" on January 2, 2010, and "`Building Closed for Construction`" from April 24, 2010 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

This example configures a UM auto attendant named `MyAutoAttendant` and enables business hours key mappings so that when callers press 1, they are forwarded to another UM auto attendant named `SalesAutoAttendant`. When they press 2, they are forwarded to extension number 12345 for `Support`, and when they press 3, they are sent to another auto attendant that plays an audio file.

```
Set-UMAutoAttendant -Identity MyAutoAttendant - BusinessHoursKeyMappingEnabled $t
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable a custom business hours welcome greeting for a UM auto attendant, you may also want to:

- Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant
- Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

1.9.2.3.1.11 Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant

Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a custom non-business hours greeting for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. The non-business hours welcome greeting is the first thing callers hear when a UM auto attendant answers their call during non-business hours.

Unified Messaging includes a default system prompt for use during non-business hours.

Although the default system prompt mustn't be replaced or changed, you may want to provide an alternative greeting. You can create a custom welcome greeting in the .wav file format that can be used when callers call in to a UM auto attendant during non-business hours. For example, "You have reached Woodgrove Bank after hours."

If you want to include the name of your organization or business as part of the default welcome greeting, you can enter the name in the Business Name field on the UM auto attendant. For details, see Configure a Business Name on a UM Auto Attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable a custom non-business hours greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the **Greetings** tab, under **Non-business hours greeting**, click **Modify**.
5. On the **Non-Business Hours Greeting** page, select from these options:
   - **Use default greeting**
   - **Use custom greeting file**
6. If you select the **Use custom greeting file** option, click **Browse**, locate the greeting file you've already created, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to enable a custom non-business hours greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the non-business hours welcome greeting that uses a custom greeting named `welcomegreetingfile.wav` for the UM auto attendant `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -AfterHoursWelcomeGreetingEnabled
```

This example configures a UM auto attendant named `MyUMAutoAttendant` that has

business hours configured to be 10:45 to 13:15 (Sunday), 09:00 to 17:00 (Monday), and 09:00 to 16:30 (Saturday) and holiday times and their associated greetings configured to be "New Year" on January 2, 2010, and "Building Closed for Construction" from April 24, 2010 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

This example configures a UM auto attendant named MyAutoAttendant and enables business hours key mappings so that when callers press 1, they are forwarded to another UM auto attendant named SalesAutoAttendant. When they press 2, they are forwarded to extension number 12345 for Support, and when they press 3, they are sent to another auto attendant that plays an audio file.

```
Set-UMAutoAttendant -Identity MyAutoAttendant - BusinessHoursKeyMappingEnabled $t
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable a custom non-business hours greeting for a UM auto attendant, you may also want to:

- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant
- Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

1.9.2.3.1.12 Enable an Informational Announcement on a UM Auto Attendant

Enable an Informational Announcement on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable an informational announcement for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. When an informational announcement is enabled, it will play immediately after the business or non-business hours greeting. By default, an informational announcement isn't configured. To enable an informational announcement, create a .wav file to be used as the informational announcement, and then configure the auto attendant to use this .wav file.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable an informational announcement for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the **Greeting** tab, under **Informational announcement**, click **Modify**.
5. On the **Informational announcement** page, select from the following options:
   - **Disable announcement**
   - **Informational announcement file**
6. If you select the **Informational announcement file** option, click **Browse**, locate the informational announcement file you've already created, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to enable an informational announcement for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables an informational announcement that uses the MyInfoAnnouncement.wav file on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -InfoAnnouncementEnabled $true -I
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable an informational announcement for a UM auto attendant, you may also want to:

- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant
- Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant

1.9.2.3.1.13 Enable a Custom Non-Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

Enable a Custom Non-Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a custom non-business hours main menu prompt greeting for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. After you create a UM auto attendant, a default system prompt will be used for the non-business hours main menu prompt greeting heard by callers after the non-business hours welcome greeting is played. Although the system prompts mustn't be replaced or changed, you will probably want to customize the greetings and menu prompts used with UM auto attendants. Frequently, in addition to configuring a customized non-business hours welcome greeting, you will also want to create and configure a custom non-business hours main menu prompt greeting. After you configure a custom non-business hours main menu prompt greeting, you must enable key mappings on the UM auto attendant for non-business hours.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable a custom non-business hours main menu prompt greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the **Greetings** tab, under **Main Menu Prompt**, under **Non-Business hours main menu prompt**, click **Modify**.
5. On the **Non-Business Hours Main Menu Prompt** page, select from these options:
   - **Use default greeting**
   - **Use custom greeting file**
6. If you select the **Use custom greeting file** option, click **Browse**, locate the custom non-business hours main menu prompt file you've already created, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to enable a custom non-business hours main menu prompt greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named `MyUMAutoAttendant` that has business hours configured to be 10:45 to 13:15 (Sunday), 09:00 to 17:00 (Monday), and 09:00 to 16:30 (Saturday) and holiday times and their associated greetings configured to be "`New Year`" on January 2, 2010, and "`Building Closed for Construction`" from April 24, 2010 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

This example configures a UM auto attendant named `MyAutoAttendant` and enables business hours key mappings so that when callers press 1, they are forwarded to another UM auto attendant named `SalesAutoAttendant`. When they press 2, they are forwarded to extension number 12345 for `Support`, and when they press 3, they are sent to another auto attendant that plays an audio file.

```
Set-UMAutoAttendant -Identity MyAutoAttendant - BusinessHoursKeyMappingEnabled $t
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable a custom non-business hours main menu prompt greeting for a UM auto attendant, you may also want to:

- Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant
- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant
- Enable a Custom Non-Business Hours Welcome Greeting on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

1.9.2.3.1.14 Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a custom business hours main menu prompt greeting for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. After you create a UM auto attendant, a default system prompt will be used for the business hours main menu prompt greeting that's heard by callers after the business hours welcome greeting is played. Although the system prompts mustn't be replaced or changed, you will probably want to customize the greetings and menu prompts used with UM auto attendants. Frequently, in addition to configuring a customized business hours welcome greeting, you will want to create and configure a custom business hours main menu prompt greeting. After you configure a custom business hours main menu prompt greeting, you must enable key mappings on the UM auto attendant for business hours.

If you only want to include the name of your organization or business as part of the default welcome greeting, you can enter the name in the Business Name field on the UM auto attendant. For details, see Configure a Business Name on a UM Auto Attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable a custom business hours main menu prompt greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the **Greetings** tab, under **Main Menu Prompt**, under **Business hours main menu prompt**, click **Modify**.
5. On the **Business Hours Main Menu Prompt** page, select from these options:
   - **Use default greeting**
   - **Use custom greeting file**
6. If you select the **Use custom greeting file** option, click **Browse**, locate the custom business hours main menu prompt file you've already created, and then click **OK**.
7. Click **OK** to save your changes.

Use the Shell to enable a custom business hours main menu prompt greeting for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables a business hours main menu prompt and uses a custom prompt named `businesshoursprompts.wav` on the UM auto attendant `MyUMAutoAttendant`.

```
Command Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursMainMenuCus
```

This example configures a UM auto attendant named `MyUMAutoAttendant` that has business hours configured to be 10:45 to 13:15 (Sunday), 09:00 to 17:00 (Monday), and 09:00 to 16:30 (Saturday) and holiday times and their associated greetings configured to be "`New Year`" on January 2, 2010, and "`Building Closed for Construction`" from April 24, 2010 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

This example configures a UM auto attendant named `MyAutoAttendant` and enables business hours key mappings so that when callers press 1, they are forwarded to another UM auto attendant named `SalesAutoAttendant`. When they press 2, they are forwarded to extension number 12345 for `Support`, and when they press 3, they are sent to another auto attendant that plays an audio file.

```
Set-UMAutoAttendant -Identity MyAutoAttendant - BusinessHoursKeyMappingEnabled $t
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable a custom business hours main menu prompt greeting for a UM auto attendant, you may also want to:

- Enable a Custom Non-Business Hours Main Menu Prompt Greeting on a UM Auto Attendant
- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant
- Enable Business Hours Key Mappings on a UM Auto Attendant

1.9.2.3.1.15 Configure Business Hours for a UM Auto Attendant

Configure Business Hours for a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure business hours for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. When you configure business hours on a UM auto attendant, you define the hours of the day that your organization is open and the business hours greetings and menu prompts callers will hear when they call an extension number that's configured on the auto attendant. If a caller reaches the auto attendant during hours that are outside the business hours you defined, the caller will hear the non-business hours prompts and greetings.

Several default schedule options are available in the EMC. For example, most businesses are open from 8:00 A.M. to 5:00 P.M., Monday through Friday. Sometimes the default options won't fit your needs and you'll want to customize the schedule. If your business hours vary from one of the schedules defined by the system, you can define a customized schedule for the auto attendant.

By default, the **Always Run** setting is selected. If you leave the **Always Run** setting selected, the UM auto attendant will play the business hours prompts and greetings regardless of the time of day callers dial in to the auto attendant.

Note:

When you set the schedule for business and non-business hours on a UM auto attendant, make sure the time zone is configured correctly.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to specify business hours for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **Times** tab, under **Schedule Times**, under **Business hours**, select from the available options or select **Use Custom Schedule**.
5. If you select **Use Custom Schedule**, click **Customize**.
6. On the **Schedule** page, select the hours you want to use as your business hours for each day of the week, and then click **OK**.
7. Click **OK** again to save your changes.

Use the Shell to specify business hours for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the business hours for a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you specify business hours for a UM auto attendant, you may also want to:

- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant
- Enable Business Hours Key Mappings on a UM Auto Attendant

Configure the Time Zone on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, the Unified Messaging (UM) auto attendant uses the time zone of the Unified Messaging server on which it's created. However, there are situations where you may have to change the time zone for a UM auto attendant to a different time zone. For example, if you've two UM dial plans hosted on the same Unified Messaging server, and each dial plan represents a different time zone, you must configure one auto attendant to have the same time zone as the Unified Messaging server and the other auto attendant to have a time zone that differs from the Unified Messaging server.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure the time zone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Times** tab, and then use the **Select time zone** list to select the time zone for the auto attendant.
5. Click **OK** to accept your changes.

Use the Shell to configure the time zone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the time zone to the Pacific time zone on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -TimeZoneName Pacific
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure the time zone, you may also want to:

- Configure Business Hours for a UM Auto Attendant
- Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

1.9.2.3.1.17 Configure a Holiday Schedule for a UM Auto Attendant

Configure a Holiday Schedule for a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can define the dates and times your organization will be closed for holidays and other occasions. Between the start dates and the end dates you specify, callers who reach the Unified Messaging (UM) auto attendant will hear a holiday greeting you specify when you configure the holiday schedule. After the caller hears the holiday greeting you've specified, the non-business hours greeting and menu prompts will be played for the caller.

You can also create a holiday schedule within an existing holiday schedule. When you create multiple holiday schedules, Unified Messaging lets you overlap your scheduled holiday times. For example, you can define a holiday schedule from December 15th through December 31st when your organization will be closed for construction, and you can define another holiday schedule from December 24th through December 26th. When callers call in to the auto attendant from December 15th through December 23rd and from December 27th through December 31st, they'll be presented with the holiday greeting that you've specified for this schedule. For example, "We are currently closed for construction." When callers call in to the auto attendant from December 24th through December 26th, they'll be presented with another holiday greeting, such as "We are currently closed for business so that our employees can enjoy the holidays with their families."

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to specify a holiday schedule for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified**

Messaging.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **Times** tab, under **Holiday Schedule**, click **Add**.
5. On the **Select Holiday** page, configure the following:
   - **Holiday name** Enter a name for your holiday schedule.
   - **Holiday greeting file** Browse to the .wav file you want to use as your greeting. This is a required field.
   - **Holiday start date** Use this list to select the date you want the holiday to start. The holiday schedule will start at midnight on the date specified in this list.
   - **Holiday end date** Use this list to select the date you want the holiday to end. The holiday schedule will end at 11:59 P.M. on the date specified in this list.
6. After you've configured your holiday schedule, click **OK** twice to save your changes.

Use the Shell to specify a holiday schedule for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named `MyUMAutoAttendant` that has business hours configured to be 10:45 to 13:15 (Sunday), 09:00 to 17:00 (Monday), and 09:00 to 16:30 (Saturday) and holiday times and their associated greetings configured to be "New Year" on January 2, 2010, and "Building Closed for Construction" from April 24, 2010 through April 28, 2010.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessHoursSchedule 0.10:45-0.
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you specify a holiday schedule for a UM auto attendant, you may also want to:

- Configure Business Hours for a UM Auto Attendant
- Enable an Informational Announcement on a UM Auto Attendant

1.9.2.3.1.18 Configure a Business Name on a UM Auto Attendant

Configure a Business Name on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enter the name of the business. By default, no business name is entered. If you

enter a business name in this box, a prompt with the business name will be played to callers instead of the default greeting for the Unified Messaging (UM) auto attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure a business name

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Features** tab, and then in the **Business name** text box, type the name of the business.
5. Click **OK** to accept your changes.

Use the Shell to configure a business name

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the business name on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessName "Northwind Traders"
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure a business name on a UM Auto Attendant, you may also want to:

- Configure a Business Location on a UM Auto Attendant
- Configure Business Hours for a UM Auto Attendant
- Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

Configure a Business Location on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the location of a business on a UM auto attendant so that the location will be played for callers. By default, no business location is entered.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure a business location

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Features** tab, and then in the **Business location** text box, type the location of the business.
5. Click **OK** to accept your changes.

Use the Shell to configure a business location

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the business location on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -BusinessLocation 'Redmond'
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure the business location on a UM auto attendant, you may also want to:

- Configure a Business Name on a UM Auto Attendant
- Configure Business Hours for a UM Auto Attendant
- Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant

1.9.2.3.1.20 Configure the Language Setting on a UM Auto Attendant

Configure the Language Setting on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the language setting on a Unified Messaging (UM) auto attendant. The language setting available on a UM auto attendant enables you to configure the default prompt language on the auto attendant. When you're using the default system prompts for the auto attendant, this is the language that the caller will hear when the auto attendant answers the incoming call. This language setting affects only the default system prompts that are provided after the Unified Messaging server role is installed. However, this setting doesn't affect custom prompts that are configured on an auto attendant. The languages that are available are based on the Unified Messaging language packs that are installed on the Unified Messaging server.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure the default language setting

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **Auto Attendants** tab.
3. Click to select the UM auto attendant.
4. In the action pane, click **Properties**.
5. In the auto attendant **Properties** window, click the **Features** tab.
6. On the **Features** tab, in the **Language** list, select the language you want.

Use the Shell to configure the default

language setting

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the default language on the UM auto attendant MyUMAutoAttendant to English (Great Britain).

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -Language en-GB
```

This example sets the default language on the UM auto attendant MyUMAutoAttendant to German.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -Language de-DE
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure the default language setting, you may also want to:

- Install a Unified Messaging Language Pack on a UM Server
- Configure the Default Language on a UM Dial Plan

1.9.2.3.1.21 Configure an Operator Extension on a UM Auto Attendant

Configure an Operator Extension on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify an operator extension number for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. If you configure an operator extension number on a UM auto attendant, you let callers press 0 to reach an operator if they can't navigate the auto attendant menus or don't know which option to use from an auto attendant menu.

If you've created a speech-enabled auto attendant and configured an operator extension on the speech-enabled auto attendant, when a caller says "Operator", the auto attendant will forward the call to the number that's configured on the speech-enabled auto attendant. If the speech-enabled auto attendant is configured to use a dual tone multi-frequency (DTMF) fallback auto attendant but isn't configured to have an operator extension number, the operator extension number on the DTMF fallback auto attendant will be dialed.

At a minimum, we recommend that you configure either the auto attendant or the dial plan associated with the auto attendant to have an operator extension number to help callers find the user they're trying to reach.

Looking for other management tasks related to UM auto attendants? Check out Managing

UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to specify an operator extension for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the **Features** tab, enter a number for the operator extension in the **Operator extension** field.
5. Click **OK** to save your changes.

Use the Shell to specify an operator extension for a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named MySpeechEnabledAA with an operator extension of 50100.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -OperatorExtension 50100
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure an operator extension number on a UM auto attendant, you may also want to:

- Enable or Disable Operator Transfers After Business Hours on a UM Auto Attendant
- Enable or Disable Operator Transfers During Business Hours on a UM Auto Attendant

Enable or Disable Call Transfers to Users from a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable callers to transfer calls to users. By default, this option is enabled, and lets callers be transferred to users in the Unified Messaging (UM) dial plan that's associated with the UM auto attendant. When this option is enabled, callers can be transferred to UM-enabled users.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable or disable call transfers to users from a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Features** tab, and then select or clear the **Allow callers to transfer to users** check box.
5. If you select this check box, you can set the group of users to whom callers can transfer by selecting the appropriate option under the **Callers can contact** section on this page.

   Note:

   If you disable this option and disable the **Allow callers to send voice message** option, the options under **Callers can contact** are also disabled.

6. Click **OK** to accept your changes.

Use the Shell to enable or disable call transfers to users from a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example disables call transfers on a UM auto attendant named MyUMAutoAttendant.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -AllowDialPlanSubscribers $false
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you to have enabled or disabled call transfers from a UM auto attendant, you may also want to:

- Enable or Disable Voice Messages to Be Sent from a UM Auto Attendant
- Enable or Disable Call Transfers to Users on a UM Dial Plan

1.9.2.3.1.23 Enable or Disable Voice Messages to Be Sent from a UM Auto Attendant

Enable or Disable Voice Messages to Be Sent from a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable callers to send voice messages to users from a Unified Messaging (UM) auto attendant, or prevent them from doing so. By default, this option is enabled and lets callers send voice messages to users in the UM dial plan that's associated with the UM auto attendant. If you disable this option, the auto attendant won't invite callers to send a voice message during a system prompt.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable callers to send voice messages or prevent them from doing so

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified**

Messaging.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Features** tab, and then select or clear the **Allow callers to send voice messages** check box.
5. If you select this check box, you can set the group of users to whom callers can send voice messages by selecting the appropriate option under the **Callers can contact** section on this page.

Note:
If you disable this option and disable the **Allow caller to transfer to users** option, the options under **Callers can contact** are also disabled.

1. Click **OK** to accept your changes.

Use the Shell to enable callers to send voice messages or prevent them from doing so

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example prevents callers who call in to a UM auto attendant named `MyUMAutoAttendant` from sending voice messages.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -SendVoiceMsgEnabled $false
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable callers to send voice messages on a UM auto attendant or prevent them from doing so, you may want to:

- Enable or Disable Call Transfers to Users from a UM Auto Attendant
- Configure the Scope of Users that Callers Can Contact on a UM Auto Attendant

1.9.2.3.1.24 Configure the Scope of Users that Callers Can Contact on a UM Auto Attendant

Configure the Scope of Users that Callers Can Contact on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the grouping of users that callers can contact when calling into a Unified Messaging (UM) auto attendant. By default, callers can contact users within the same dial plan that's associated with the UM auto attendant. However, you can change the

grouping of users to allow callers to transfer calls or send voice messages to users who are located in the global address list (GAL) or to a specific set of users who are contained in custom address lists.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to configure the scope of users that callers can contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant.
3. In the action pane, click **Properties**.
4. In the auto attendant **Properties** window, click the **Features** tab and then, under **Callers can contact**, choose from the following options:
   Users within dial plan Select this option to allow callers who connect to the UM auto attendant to locate and contact users who are in the dial plan associated with the UM auto attendant.
   Anyone in the default global address list Select this option to allow callers who connect to the UM auto attendant to locate and contact anyone listed in the GAL. This includes all users who are mailbox-enabled.
   Anyone in this address list Select this option to allow callers who connect to the UM auto attendant to locate and contact users who are in a defined custom address list. This includes all users who are mailbox-enabled.

   Important:

   The **All Address Lists** container is an empty container object and differs from the GAL container. If you choose the **All Address Lists** container when you browse for a custom address list, there will be no UM-enabled users for callers to contact. If you want to select all the address lists in your organization, choose the **Anyone in the default global address list** option.
5. Click **OK** to accept your changes.

Use the Shell to configure the scope of users that callers can contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the scope of the users that callers can contact to all users in the Global Address List on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -ContactScope GlobalAddressList
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure the scope of users that callers can contact on a UM Auto Attendant, you may also want to:

- Enable Dialing Restrictions on a UM Auto Attendant
- Enable or Disable Directory Lookups for a UM Auto Attendant

1.9.2.3.1.25 Configure the Matched Name Selection Method on a UM Auto Attendant

Configure the Matched Name Selection Method on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the matched name selection method setting on the auto attendant's **Features** tab, or you can leave the default setting on the auto attendant and then configure this setting on the dial plan associated with the auto attendant. By default, an auto attendant can't disambiguate between two or more users who have the same name because the default setting for the matched name selection method on the dial plan is set to **None**.

Note:

For the matched name selection method to work correctly, you must populate the title, department, and location boxes on the recipients in your Microsoft Exchange organization.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created.
- A UM auto attendant has been created.

Use the EMC to configure the matched name selection method on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.

2. In the work pane, on the **UM Auto Attendants** tab, select the UM auto attendant you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, on the **Features** tab, under **Matched name selection method**, select one of the following values:
   - **Title** The auto attendant will include each user's title when it lists matches.
   - **Department** The auto attendant will include each user's department when it lists matches.
   - **Location** The auto attendant will include each user's location when it lists matches.
   - **None** The auto attendant won't include any additional information when it lists matches.
   - **Prompt For Alias** The auto attendant will prompt the caller for the user's alias.
   - **Inherit from dial plan** The auto attendant will use the default setting from the dial plan associated with the auto attendant.
4. Click **OK** to save your changes.

Use the Shell to configure the matched name selection method on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example sets the matched name selection method to Prompt for Alias for a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -MatchedNameSelectionMethod Promp
```

This example sets the matched name selection method to the title of the users, enables name lookups, and enables callers that dial into the auto attendant to press * to be presented with the Outlook Voice Access welcome greeting for a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -MatchedNameSelectionMethod Title
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you configure the matched name selection method setting on the auto attendant, you may also want to Configure the Matched Name Selection Method on a UM Dial Plan.

1.9.2.3.1.26 Enable or Disable Operator Transfers After Business Hours on a UM Auto Attendant

Enable or Disable Operator Transfers After Business Hours on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable users to transfer calls to an operator during non-business hours in Microsoft Exchange Server 2010 Unified Messaging (UM). You can also disable operator transfers during non-business hours. You enable users to transfer calls during non-business hours by configuring an operator extension number on a UM auto attendant, selecting the **Allow transfer to operator after business hours** setting, and configuring business hours on the **Times** tab on the UM auto attendant.

At a minimum, we recommend that you configure either the UM auto attendant or the UM dial plan associated with the auto attendant to have an operator extension number. This will help callers find the user they're trying to reach or navigate the menu system.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable callers to transfer calls to an operator after business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to change and then, in the action pane, click **Properties**.
4. On the **Features** tab, next to **Operator extension**, enter a number for your auto attendant operator.
5. Select the check box next to **Allow transfer to operator after business hours**.
6. Click **OK** to save your changes.

Use the EMC to prevent callers from transferring calls to an operator after business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant that you want to modify and then, in the action pane, click **Properties**.
4. Clear the check box next to **Allow transfer to operator after business hours**.
5. Click **OK** to save your changes.

Use the Shell to enable or disable operator transfers after business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables callers to transfer calls to an operator after business hours.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -OperatorExtension 50100 -AfterHo
```

This example prevents callers from transferring calls to an operator after business hours.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -AfterHoursTransferToOperatorEnab
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable or disable operator transfers after business hours, you may also want to:

- Configure an Operator Extension on a UM Auto Attendant
- Enable or Disable Operator Transfers During Business Hours on a UM Auto Attendant

1.9.2.3.1.27 Enable or Disable Operator Transfers During Business Hours on a UM Auto Attendant

Enable or Disable Operator Transfers During Business Hours on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable users to transfer calls to an operator during business hours in Microsoft Exchange Server 2010 Unified Messaging (UM), or prevent them from doing so. You enable users to transfer calls during business hours by setting up an operator extension number on a UM auto attendant and selecting the **Allow transfer to operator during business hours** setting.

At a minimum, we recommend that you configure either the UM auto attendant or the UM dial plan associated with the auto attendant to have an operator extension number. This will help callers find the user they're trying to reach or navigate the menu system.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

Also, before you perform these procedures, confirm the following:

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable callers to transfer calls to an operator during business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to change and then, in the action pane, click **Properties**.
4. On the **Features** tab, next to **Operator extension**, enter a number for your auto attendant operator.
5. Select **Allow transfer to operator during business hours**.
6. Click **OK** to save your changes.

Use the EMC to prevent callers from transferring calls to an operator during business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to change, and then, in the action pane, click **Properties**.
4. Clear the check box next to **Allow transfer to operator during business hours**.
5. Click **OK** to save your changes.

Use the Shell to enable or prevent operator transfers during business hours

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables callers to transfer calls to an operator during business hours.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -OperatorExtension 50100 -Busines
```

This example prevents callers from transferring calls to an operator during business hours.

```
Set-UMAutoAttendant -Identity MySpeechEnabledAA -BusinessHoursTransferToOperatorE
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable or disable operator transfers during business hours, you may also want to:

- Configure an Operator Extension on a UM Auto Attendant
- Enable or Disable Operator Transfers After Business Hours on a UM Auto Attendant

1.9.2.3.1.28 Enable Business Hours Key Mappings on a UM Auto Attendant

Enable Business Hours Key Mappings on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable business hours key mappings for a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. After you create a UM auto attendant, a default system prompt will be used for the business hours main menu prompt greeting callers hear after the business hours welcome greeting is played. The default business hours main menu prompt says, "Welcome to the Microsoft Exchange Auto Attendant." Because no key mappings are defined by default, no menu options are available to callers, and they hear only the default main menu prompt.

When you configure key mappings, you define the options and the operations that will be performed if a caller speaks a phrase while they're using a speech-enabled auto attendant or the caller presses the key on the keypad of the telephone while they're using an auto attendant that isn't speech-enabled.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable business hours key mappings on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane,

click **Properties**.
4. On the **Key Mapping** tab, select **Enable business hours key mapping**, and then click **Add**.
5. On the **Key Mapping Entry** page, in the **Name** field, type a name for the key mapping entry.
6. In **If the user does one of the following**, select one of these options:
   - **Presses this key**
   - **Presses no key (Time-out)**
   - **Or the user says this phrase**
7. In **This Action will occur**, select from these options:
   - **Play the following audio file**
   - **Transfer to extension**
   - **Run auto attendant**
8. Click **OK** to create the key mapping entry.
9. Click **OK** to save your changes.

Use the Shell to enable business hours key mappings on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named `MyAutoAttendant` and enables business hours key mappings so that when callers press 1, they're forwarded to another UM auto attendant named `SalesAutoAttendant`. When they press 2, they're forwarded to extension number 12345 for Support, and when they press 3, they're sent to another auto attendant that plays an audio file.

```
Set-UMAutoAttendant -Identity MyAutoAttendant - BusinessHoursKeyMappingEnabled $t
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable business hours key mappings on a UM auto attendant, you may also want to:

- Enable Non-Business Hours Key Mappings on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

1.9.2.3.1.29 Enable Non-Business Hours Key Mappings on a UM Auto Attendant

Enable Non-Business Hours Key Mappings on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable non-business hours key mappings for a Unified Messaging (UM) auto

attendant in Microsoft Exchange Server 2010. After you create a UM auto attendant, a default system prompt will be used for the non-business hours main menu prompt greeting that callers hear after the non-business hours welcome greeting is played. The default non-business hours main menu prompt says, "Welcome to the Microsoft Exchange After Hours Auto Attendant." Because no key mappings are defined by default, no menu options are available to callers and they hear only the default non-business hours main menu prompt.

When you configure key mappings, you define the options and the operations that will be performed if callers speak a phrase while they're using a speech-enabled auto attendant or callers press the key on the keypad of the telephone while they're using an auto attendant that isn't speech-enabled.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the EMC to enable non-business hours key mappings on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the **Key Mapping** tab, select **Enable non-business hours key mapping**, and then click **Add**.
5. On the **Key Mapping Entry** page, in the **Name** field, type a name for the key mapping entry.
6. In **If the user does one of the following**, select one of these options:
   - **Presses this key**
   - **Presses no key (Time-out)**
   - **Or the user says this phrase**
7. In **This Action will occur**, select one of these options:
   - **Play the following audio file**
   - **Transfer to extension**
   - **Run auto attendant**
8. Click **OK** to create the key mapping entry.
9. Click **OK** to save your changes.

Use the Shell to enable non-business hours key mappings on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example configures a UM auto attendant named `MyAutoAttendant` and enables non-business hours key mappings so that when callers say "After Hours" they will be forwarded to extension number 12345, and if they say "Directions" they will be forwarded to extension number 23456.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -AfterHoursKeyMappingEnabled $tru
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable non-business hours key mappings on a UM auto attendant, you may also want to:

- Enable Business Hours Key Mappings on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

1.9.2.3.1.30 Configure Key Mapping Entries on a UM Auto Attendant

Configure Key Mapping Entries on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the **Key Mapping Entry** dialog box to configure single or multiple key mappings for business or non-business hours main menu prompts for Unified Messaging (UM) auto attendants. You can define the operation that will be performed when the key on the telephone keypad is pressed, for example, transferring the call to an extension number or another auto attendant.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Use the EMC to configure UM auto attendant key mappings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

Use the **Key Mapping Entry** dialog box to configure key mappings for a UM auto attendant. You can configure the following:

- **Description** Use this field to type the name of the key mapping entry. The key mapping name is used for display purposes only. This is a required field, and you must provide a display name for the key mapping entry.
  Because you may want to specify multiple key mappings, we recommend that you use meaningful names for your key mappings. The maximum length of the

name for the key mapping is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

- **If the user does one of the following:**
  - **Press this key** Use this button to enable a key mapping. The key mapping is the number key that a caller presses to have the auto attendant perform a specific operation, for example, forwarding the caller to another auto attendant or to an operator. By default, no entries are defined.

    Use the text box to type the numeric key (from 1 through 9) that the caller must press. Zero (0) is reserved for the auto attendant operator.
  - **Presses no key (time-out)** Use this button to enable callers to be transferred to an extension number or to another auto attendant if they don't press a key on the telephone keypad. For example, "Please stay on the line and your call will be answered by the next available representative." By default, this option is disabled. The default setting is 5 seconds.

    If you enable this option, a blank key mapping will be created.
- **Or the user says this phrase** Use this field with speech-enabled auto attendants. This option enables you to define words or phrases that can be spoken by a caller. After the caller says the word or phrase, then the auto attendant will perform an action that you specify.
- **This action will occur** Use one of the following actions to define the action that you want the auto attendant to perform for the caller.
  - **Play the following audio file** Select this check box to enable an audio file to play when callers press the key specified in the **Key pressed** setting. By default, this setting is disabled. If you enable this option, specify an audio file:

    Click **Browse** to locate the audio file that you want to play. If you enable this option, the audio file that you specify here will be played to the caller after the business hours or non-business main menu prompt plays.
  - **Perform this additional action** Use one of the following actions to define additional actions that you want the auto attendant to perform for the caller.

    Transfer to extension Select this check box to enable calls to be transferred to an extension number or another auto attendant. If you enable this option, specify an extension or auto attendant.Use the text box to type the extension where the call will be transferred. This field allows only numeric characters. It can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

    Run auto attendant Click this button to transfer the call to an auto attendant. Click **Browse** to locate the auto attendant that you want to use. Before you enable this option, you must first create and configure the auto attendant. This option is used when you create a parent/child structure of UM auto attendants.

    Leave voice mail for Click this option to enable a caller to leave a voice mail message for a UM-enabled mailbox that's on the same dial plan as the UM auto attendant that you're configuring. When a caller chooses this option from an auto attendant menu, they'll be prompted to leave a voice mail for the UM-mailbox that was selected. Click **Browse** to locate the UM-enabled mailbox.

    Announce business location Click this option to enable a caller to choose an auto attendant menu option and hear the location of the business that's configured on the UM auto attendant. To enable this to work correctly, you must first enter the business location in the **Business location** box on the **Features** tab on the UM auto attendant.

    Announce business hours Click this option to enable a caller to choose an auto attendant menu option and hear the hours of

operation for the business that's configured on the UM auto attendant. To enable this to work correctly, you must first configure the business hours in the **Business hours** drop down list on the **Times** tab on the UM auto attendant. You can optionally choose preconfigured business times using the drop down or click the **Customize** button and configure other business times. It's also important to correctly configure the time zone using the **Select time zone** drop down for the auto attendant.

Use the Shell to configure UM auto attendant key mappings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables business hours key mappings so that:

- When callers press 1, they will be forwarded to another UM auto attendant named `SalesAutoAttendant`.
- When they press 2, they will be forwarded to extension number 12345 for Support.
- When they press 3, they will be sent to another auto attendant that will play an audio file.

```
Set-UMAutoAttendant -id MyAutoAttendant -BusinessHoursKeyMappingEnabled $true -Bu
```

This example sets key mappings defined in a comma-separated value (.csv) file. You must first create the .csv file with the following headings and the correct entry: <key>,<description>,[<extension>],[<autoattendant name>],[<promptfilenamepath>], [<asrphrase1;asrphrase2>],[<leavevoicemailfor>],[<transfertomailbox>]. The values in brackets are optional. After creating the .csv file, import the .csv file using the **Import-csv** cmdlet.

```
$o = Import-csv -path "C:\UMFiles\AutoAttendants\keymappings.csv"
Set-UMAutoAttendant MyAutoAttendant -BusinessHoursKeyMapping $o
```

This example exports key mappings from an existing UM auto attendant into a .csv file, and then imports the same key mappings into another UM auto attendant. You could also export the key mappings to a .csv file, edit or modify the key mappings in the .csv file, and then import those key mappings into another UM auto attendant.

```
$aa = Get-UMAutoAttendant -id MyAutoAttendant
$aa1 = Get-UMAutoAttendant -id MyAutoAttendant2
$aa.BusinessHoursKeyMapping | Export-csv -path "C:\UMFiles\AutoAttendants\keymapp
$aa1.BusinessHoursKeyMapping = (Import-csv -path "C:\UMFiles\AutoAttendants\keyma
```

Other Tasks

After you configure UM auto attendant key mappings, you may also want to:

- Enable Business Hours Key Mappings on a UM Auto Attendant
- Configure Business Hours for a UM Auto Attendant
- Enable Non-Business Hours Key Mappings on a UM Auto Attendant

Enable Dialing Restrictions on a UM Auto Attendant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable dialing restrictions on a Unified Messaging (UM) auto attendant in Microsoft Exchange Server 2010. Dialing restrictions are used to enable dialing rules that can be used to prohibit users who call into a UM auto attendant from making certain types of telephone calls that are known as outdialing. Outdialing is the process that happens when a Unified Messaging server places an outgoing call for users after they've called into a subscriber access number on a UM dial plan or into a UM auto attendant.

When you enable dialing restrictions, the following settings must be configured correctly:

- **Dialing group rules** Dialing group rules determine the types of calls users within a dial group can make.
- **Dialing rule entries** Dialing rule entries define the number that is dialed by the UM-enabled user and the actual number that will be dialed by the Private Branch eXchange (PBX) or IP PBX.
- **Dialing restrictions** Dialing restrictions determine the restrictions that will be applied to prevent users from incurring unnecessary telephone charges or from dialing long distance calls.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.
- A UM dialing rule group has been created. For detailed steps, see Configure Dialing Rule Groups on a UM Dial Plan.

Use the EMC to enable dialing restrictions on a UM auto attendant for in-country/region rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to change, and then, in the action pane, click **Properties**.
4. On the UM auto attendant **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed in-country/region rule groups from dial plan**, click **Add**.
5. On the **Select Allowed In-Country/Region Groups** page, select the dialing rule group that is enabled on the UM dial plan, and then click **OK**.

6. Click **OK** to save your changes.

Use the EMC to enable dialing restrictions on a UM auto attendant for international rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. Select the UM auto attendant you want to modify, and then, in the action pane, click **Properties**.
4. On the UM auto attendant **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed international rule groups from dial plan**, click **Add**.
5. On the **Select Allowed International Groups** page, select the dialing rule group that is enabled on the UM dial plan, and then click **OK**.
6. Click **OK** to save your changes.

Use the Shell to enable in-country/region and international dialing restrictions on a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the InCountry/RegionGroup1, InCountry/RegionGroup2. InternationalGroup1, and InternationalGroup2 dialing restrictions on a UM auto attendant named `MyUMAutoAttendant`.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -AllowedInCountryOrRegionGroups I
```

For more information about syntax and parameters, see Set-UMAutoAttendant.

Other Tasks

After you enable dialing restrictions on a UM auto attendant, you may also want to:

- Configure Dialing Rule Groups on a UM Dial Plan
- Create a Dialing Rule Entry on a UM Dial Plan

1.9.2.3.2.1 Create a UM Dial Plan

Create a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-10*

A Unified Messaging (UM) dial plan is created by using an organization-wide scope. This dial plan contains configuration information related to your telephony network. It also establishes a link from the telephone extension number of a Microsoft Exchange Server 2010 recipient in Active Directory to a UM-enabled mailbox.

When you create a UM dial plan, you can configure the number of digits in the extension numbers, the Uniform Resource Identifier (URI) type, and the Voice over IP (VoIP) security setting. Every time that you create a UM dial plan, a UM mailbox policy is also created. The UM mailbox policy is named *<DialPlanName>* Default Policy.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

What Do You Want to Do?

- Use the EMC to create a UM dial plan
- Use the Shell to create a UM dial plan

Use the EMC to create a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the action pane, click **New UM Dial Plan**.
3. In the New UM Dial Plan wizard, complete the following fields:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique. However, it's used only for display in the EMC and the Shell. If you have to change the display name of the dial plan after it's been created, you must first delete the existing UM dial plan and then create another dial plan that has the appropriate name. If your organization uses multiple UM dial plans, we recommend that you use meaningful names for your UM dial plans. The maximum length of a UM dial plan name is 64 characters. The name can't include any of the following characters:

     ```
     " / \ [ ] : ; | = , + * ? < >
     ```

     Although you can include spaces in the name of a new UM dial plan, the name cannot include spaces if you integrate Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server. Therefore, if you created a dial plan that has spaces in the display name, and if you are integrating with

Office Communications Server 2007 R2 or Microsoft Lync Server, you must first delete that dial plan, and then create another by using a display name that does not include spaces.

Important:

Although the field for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. If you try to create a dial plan name that contains more than 49 characters, you will receive an error message. The message will say that the dial plan name couldn't be created because a default UM mailbox policy name couldn't be generated because the UM dial plan name is too long. This happens because when you create a dial plan, a default UM mailbox policy is also created that has the name *<DialPlanName>* Default Policy. Therefore, the name of the UM mailbox policy is 15 characters longer than the name of the dial plan. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters. However, if the name of the dial plan is longer than 49 characters, the name of the default UM mailbox policy will be longer than 64 characters, and this isn't allowed by the system.

- **Number of digits in extension numbers** Enter the number of digits for the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a Private Branch eXchange (PBX). For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

  This is a required field that has a value range from 1 through 20. The typical extension length is from 3 through 7. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions.

  When you create a Session Initiation Protocol (SIP) or an E.164 dial plan and associate a UM-enabled user with the dial plan, you must still input an extension number to be used by the user. This number is used by Outlook Voice Access users when they access their Exchange 2010 mailbox.
- **URI Type** Use this drop-down list to select the URI type for the UM dial plan. A URI is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax, format, and the protocols for the call.

  You can select one of the following URI types for the dial plan:

  Telephone extension This is the most common URI type. The calling and called party information from the IP gateway or IP PBX will be listed in one of the following formats: Tel:512345 or 512345@*<IP address>*. This is the default URI type for dial plans.

  SIP URI Use this URI type if you need a SIP URI dial plan when an IP PBX supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 and Exchange Unified Messaging. The calling and called party information from the IP gateway or IP PBX will be listed as a SIP address in the following format: sip:*<username>*@*<domain* or *IP address>*:Port.

  E.164 E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country/region code, a national destination code, and a subscriber number. The calling and called party information sent from the IP gateway is listed in the following format: Tel:+14255550123.

Note:
After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP Security** Use this drop-down list to select the VoIP security setting for the UM dial plan. By default, when you create a UM dial plan, it communicates in unsecured mode. A Unified Messaging server can operate in any mode configured on a dial plan because the Unified Messaging server is configured to listen on TCP port 5060 for unsecured requests and on TCP port 5061 for secured requests at the same time.
  You can select one of the following security settings for the dial plan:
  Unsecured By default, when you create a UM dial plan, it communicates in unsecured mode, and the Unified Messaging servers associated with the UM dial plan send and receive data from IP gateways, IP PBXs, and other Exchange 2010 computers using no encryption. In unsecured mode, both the Realtime Transport Protocol (RTP) media channel and SIP signaling information aren't encrypted.
  SIP secured When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic.
  Secured When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. An encrypted signaling media channel that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data.
- **Country/Region code** Use this field to type the country/region code number used for outgoing calls. This number will precede the telephone number dialed. This field accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.

4. On the **Set UM Servers** page, click **Add**, and then, on the **Select UM Server** page, select the UM server that you want to add to the UM dial plan.

5. On the **Completion** page, confirm whether the dial plan was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM Dial Plan wizard.

Use the Shell to create a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example creates a new UM dial plan named `MyUMDialPlan` that uses four-digit extension numbers.

```
New-UMDialplan -Name MyUMDialPlan -NumberofDigits 4
```

This example creates a new UM dial plan named `MyUMDialPlan` that uses five-digit extension numbers and supports SIP URIs:

```
New-UMDialplan -Name MyUMDialPlan -UriType SIPName -NumberofDigits 5
```

For more information about syntax and parameters, see New-UMDialplan.

Other Tasks

After you enable a user for Unified Messaging, you may also want to:

- Add a UM Server to a Dial Plan
- Create a UM Auto Attendant

For More Information

Understanding Unified Messaging Dial Plans

Understanding Unified Messaging VoIP Security

1.9.2.3.2.2 View or Configure the Properties of a UM Dial Plan

View or Configure the Properties of a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

After you create a Unified Messaging (UM) dial plan, you can view and configure a variety of settings. For example, you can configure the level of Voice over IP (VoIP) security, the audio codec, and dialing restrictions. The settings that you configure on the UM dial plan affect all users who are associated with the dial plan through a UM mailbox policy.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

What Do You Want to Do?

- Use the EMC to view or configure UM dial plan properties
- Use the Shell to configure UM dial plan properties
- Use the Shell to view UM dial plan properties

Use the EMC to view or configure UM dial plan properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab, and then select the UM dial plan that you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to view specific dial plan settings or enable or disable

features for UM-enabled users:

- **Associated UM servers** This section displays the Unified Messaging servers associated with a dial plan. The Unified Messaging servers listed in this section process incoming calls for users who are associated with the dial plan. Unified Messaging servers can be associated with single or multiple dial plans. You must use the **UM Server Settings** properties tab in the Unified Messaging server's properties to add a Unified Messaging server to a dial plan.
- **Associated UM IP gateways** This section displays the UM IP gateways associated with a dial plan. The UM IP gateways listed in this section process incoming calls for users who are associated with the dial plan. A UM hunt group establishes a link between a UM dial plan and a UM IP gateway and can also be associated with a dial plan by first being associated with a UM IP gateway. You can associate a UM IP gateway with a dial plan when you create a UM hunt group.
- **URI type** A Uniform Resource Identifier (URI) is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax and format and the protocols for the call. After you create a UM dial plan, you won't be able to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type. You can select one of the following URI types for the dial plan:

  Telephone extension This is the most common URI type. The calling and called party information from the IP gateway or IP Private Branch eXchange (PBX) is listed in one of the following formats: Tel:512345 or 512345@<*IP address*>. This is the default URI type for dial plans.

  SIP URI Use this URI type if you must have a Session Initiation Protocol (SIP) URI dial plan such as an IP PBX that supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 and Microsoft Exchange Server 2010 Unified Messaging. The calling and called party information from the IP gateway or IP PBX is listed as a SIP address in the following format: sip:<*username*>@<*domain* or *IP address*>:Port.

  E.164 E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country code, a national destination code, and a subscriber number. The calling and called party information sent from the IP gateway is listed in the following format: Tel:+14255550123.
- **Number of digits in the extension** This is the number of digits in the extension numbers for users who are associated with this dial plan. For example, if a user associated with a dial plan dials a 4-digit extension to call another user in the same dial plan, select 4 as the number of digits in the extension.

  The number of digits for extension numbers is based on the telephony dial plan created on a PBX. This is a required field that has a value range from 1 through 20. The typical extension length is from 3 through 7 digits. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions when you create the UM dial plan.
- **Modified** This field shows the last date and time the dial plan settings were modified.
- **Allow users to receive faxes** Select this check box to allow fax messages to be received by users who are associated with the dial plan. If you don't select this check box, all users who are associated with the dial plan won't be able to receive fax messages in their Inbox. By default, this setting is enabled.
- **Allow user to configure call answering rules** Select this check box to

allow users associated with the dial plan through a UM mailbox policy to be able to create and configure call answering rules. When this setting is selected, UM-enabled users can create rules or actions and apply conditions to an incoming call to their phone number. They can transfer the call, have the caller leave a voice mail, or allow the caller to locate them at a different phone number.

- **VoIP security** Use this drop-down list to select the VoIP security setting for the UM dial plan. You can select one of the following security settings for the dial plan:

  Unsecured By default, when you create a UM dial plan, it communicates in an unsecured mode, and the Unified Messaging servers associated with the UM dial plan send and receive data from IP gateways, IP PBXs, and other Exchange 2010 computers using no encryption. In unsecured mode, both the Realtime Transport Protocol (RTP) media channel and SIP signaling information aren't encrypted.

  SIP secured When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic.

  Secured When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. A secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data. A Unified Messaging server can operate in any mode configured on a dial plan because the Unified Messaging server is configured to listen on TCP port 5060 for unsecured requests and TCP port 5061 for secured requests at the same time.

5. Use the **Subscriber Access** tab of the UM dial plan that you have selected to configure subscriber access settings for the UM dial plan. A subscriber is an internal business user or network user who is enabled for Exchange 2010 Unified Messaging. Outlook Voice Access enables subscribers to access their individual mailboxes to retrieve e-mail, voice messages, contacts, and calendaring information using a telephone. You can view or configure the following:

   - **Welcome greeting** This display-only field shows the name of the sound file that will be used for the welcome greeting. Click **Modify** to specify the audio (.wav) file to use for the welcome greeting. If you don't specify an audio file, callers will hear a default welcome greeting that says, "Welcome, you are connected to Microsoft Exchange."

     The welcome greeting is used when Outlook Voice Access users or another caller calls the subscriber access number. This audio file is the default greeting for a specific UM dial plan. However, you may want to change this greeting and provide another welcome greeting specific to your company, such as, "Welcome to Outlook Voice Access for Contoso, Ltd."

     If you decide to customize this greeting, you must first record the customized greeting, save it as a *.wav file, and then configure the dial plan to use this customized greeting. The file name and path must not exceed 255 characters.

     You can configure a customized business hours greeting by clicking **Modify** to select a previously recorded custom greeting file. You can select one of the following:

     Use default greeting Use this option to enable the default welcome greeting to be played to callers. By default, this option is enabled.

     Use custom greeting file Use this option when you want to enable a custom welcome greeting file to be played to callers. Click **Browse** to locate a custom welcome greeting file that was

previously recorded.

- **Informational announcement** When enabled, this optional recording plays immediately after the business or non-business hours greeting. An informational announcement may state the organization's hours of operation, for example, "Our business hours are 8:30 A.M. to 5:30 P.M., Monday through Friday and 8:30 A.M. to 1:00 P.M. on Saturday." An informational announcement can also provide information that's required for compliance with company policy, for example, "Calls may be monitored for training purposes." If it's important that callers hear the whole informational announcement, it can be marked as uninterruptible.

  By default, there's no informational announcement configured on UM dial plans or auto attendants. Use the following options to enable an informational announcement and use a custom audio file specific to your organization. The recordings must have already been recorded as .wav files. You can select the following:

  Disable announcement Use this option to disable an informational announcement. By default, this option is enabled.

  Informational announcement file Use this option when you want to enable an informational announcement to be played to callers. Click **Browse** to locate a custom informational announcement file that was previously recorded.

  Allow informational announcement to be interrupted Use this option to enable the informational announcement to be interrupted by the caller. This should be enabled if you have long informational announcements. Callers may become frustrated if the informational announcement is long and they can't interrupt the informational announcement to access the options provided by the UM dial plan or auto attendant.
- **Enter the telephone number to associate** Use this field to add a telephone number or extension that a user will call to access the Unified Messaging system using Outlook Voice Access. In most cases, you enter an extension number or an external telephone number. However, because this field accepts alphanumeric characters, a SIP URI can be used if you're using an IP PBX.

  By default, when a dial plan is created, no subscriber access numbers are configured. To enable subscriber access, you must configure at least one telephone number. The number of alphanumeric characters can't exceed 20.

  When you configure this number on the dial plan, this number will be displayed in the Microsoft Office Outlook 2007 and Outlook Web App for Exchange 2010 voice mail options.

6. Use the **Dial Codes** tab to configure the dial codes for a UM dial plan. Several dial code settings can be configured on the dial plan. These include incoming and outgoing calling options. You can configure the following:
   - **Outside line access code** Use this field to type the number or numbers used to access an outside telephone number for outgoing external calls. This number will precede the telephone number dialed. This is also called a trunk access code. This field accepts from 1 through 16 digits. For many organizations, this number is 9. By default, this field isn't populated.

     Frequently, this setting is used in telephony environments where a PBX is located onsite or maintained in an organization. It may not have to be configured if your organization's telephony environment is maintained by an external business or vendor.
   - **International access code** Use this field to type the number code used to access international telephone numbers for outgoing calls. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, the international

access code for the United States is 011. For Europe, it's 00.

- **National number prefix** Use this field to type the number code used to dial telephone numbers that are out of an area code but within the country/region. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, 0 is used in Europe, and 1 is used in North America.
- **Country/Region code** Use this field to type the country/region code number used for outgoing calls. This number will precede the telephone number dialed. By default, this field isn't populated. This field accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.
- **In-country/region number format** Use this field to specify how a user's telephone number should be dialed by the Unified Messaging server in a different dial plan, which has the same country code. This is used by an auto attendant and when an Outlook Voice Access subscriber searches and tries to call the user in the directory.

  This entry consists of a number prefix and a variable number of characters (for example, 020*xxxxxxx*).

  To determine the telephone number, Unified Messaging will append the last *x* digits from the telephone number specified in the directory to the prefix specified.
- **International number format** Use this field to specify how a user's telephone number should be dialed by the Unified Messaging server in a different dial plan, which has a different country code. This is used by an auto attendant and when an Outlook Voice Access subscriber searches and tries to call the user in the directory.

  This entry consists of a number prefix and a variable number of characters (for example, 4420*xxxxxxx*).

  To determine the telephone number, Unified Messaging will append the last *x* digits from the telephone number specified in the directory to the prefix specified.

7. Use the **Features** tab to configure the UM dial plan features. Several features can be configured on the UM dial plan. These include transferring calls and sending voice messages. You can configure the following:
   - **Allow callers to transfer to users** Select this check box to enable callers to transfer calls to users. By default, this option is enabled. This lets users associated with the dial plan transfer calls to users in the same UM dial plan. After you select this check box, you can set the group of users to whom callers can transfer by selecting the appropriate option under the **Callers can contact** section on this page.

     If you disable this option and disable the **Allow callers to send voice message** setting, the options under **Callers can contact** will also be disabled.
   - **Allow callers to send voice messages** Select this check box to enable callers to send voice messages to users. By default, this option is enabled. This lets users who are associated with the dial plan send voice messages to users in the same UM dial plan. After you select this check box, you can set the group of users to whom callers can send voice messages by selecting the appropriate option under the **Callers can contact** section on this page.

     If you disable this option and disable the **Allow callers to transfer users** setting, the options under **Callers can contact** will also be disabled.

     If you disable this option, the auto attendant won't invite callers to send a voice message during a system prompt.
   - **Callers can contact** Use these options to determine a grouping of users to use. By default, the **Users within this dial plan** option is selected. However, you can change the grouping of users to allow callers to transfer calls or send voice messages to users located in the global address list

(GAL) or to a specific set of users contained in a custom address list by choosing from the following:

Users within this dial plan Use this option to allow callers who connect to the UM auto attendant to locate and contact users who are within the dial plan associated with the UM auto attendant.

Anyone in the default global address list Use this option to allow callers who connect to the UM auto attendant to locate and contact anyone who is listed in the GAL. This includes all users who are mailbox-enabled.

Only this extension Use this option to allow callers to connect to an extension number that you specified in the field for this option. This field accepts only numeric digits. The number of digits that you define in this field must match the number of digits configured on the dial plan associated with the auto attendant.

Only this auto attendant Use this list to allow callers to connect to a UM auto attendant and then connect to another auto attendant. You must create this auto attendant to allow callers to be transferred to another auto attendant that's specified.

Anyone in this address list Use this option to allow callers who connect to the UM auto attendant to locate and contact users who are within a defined custom address list. This includes all users who are mailbox-enabled.

Important:

The **All Address Lists** container is an empty container object and differs from the GAL container. If you choose the **All Address Lists** container when you browse for a custom address list, there will be no UM-enabled users for callers to contact. If you want to select all the address lists in your organization, choose the **Anyone in the default global address list** option.

- **Matched name selection method** Use this field to select the method the dial plan uses to differentiate between users who have similar names. When a caller is prompted to enter letters to find a particular user in the organization, sometimes more than one name matches the caller's input. By default, all UM auto attendants associated with this dial plan inherit this setting. However, you can change this setting on each UM auto attendant created.

  Select one of the following methods for providing callers with more information to help them locate the correct user in the organization:

- **None** No additional information is given when matches are listed. By default, this method is selected.
- **Title** The auto attendant includes each user's title when matches are listed.
- **Department** The auto attendant includes each user's department when matches are listed.
- **Location** The auto attendant includes each user's location when matches are listed.
- **Prompt For Alias** The auto attendant prompts the caller for the user's alias.

8. Use the **Settings** tab to configure dial plan settings for Unified Messaging. When you configure settings on this tab, you can control how internal and external callers locate users in the system, the number of logon failures allowed when internal users try to access their voice mail, and the default language that the dial plan uses. You can configure the following:
   - **Dial by name primary method** Use this list to select the primary way that

callers can locate a user when they dial in to the system.

By default, **Last name, First name** is selected. This means that when users are searching for a user in the directory, they will enter the user's last name first and then the first name.

When a subscriber or a UM-enabled user uses the subscriber access number to access the Unified Messaging system, they can access the menu that enables them to spell the name or alias to locate a user in the system. The option selected is the default method used by UM-enabled users.

You must select one of the supported methods to be able to use the dial-by-name primary method. The following methods are supported:

Last First (default)
First Last
SMTP Address

- **Dial by name secondary method** Use this list to select the secondary way that callers can locate a user when they dial in to the system.

  By default, **SMTP address** is selected. This means that when users search for a user in the directory, they will enter the user's e-mail alias or SMTP address.

  When subscribers or UM-enabled users use the subscriber access number to access the Unified Messaging system, they can access the menu that enables them to spell the name or alias to locate a user in the system.

  You aren't required to select one of the four methods that are supported. However, if you don't select a secondary method, callers are given only one method to use to spell a user's name in the system. The following options are available:

  Last First
  First Last
  SMTP address (default)
  None

- **Audio codec** Use this list to select the audio codec that will be used by the dial plan. When a caller places a call to a user who is associated with the dial plan, Unified Messaging uses the audio codec that you select from this list to record voice messages that will be sent to UM-enabled users. The following audio codecs are supported:

  MP3 (default)
  WMA (Windows Media Audio)
  G711 (Pulse Code Modulation (PCM) Linear)
  GSM (Group System Mobile 06.10)

  By default, the MP3 format is selected. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phone and devices and various computer operating systems.

  WMA is used because it's highly compressed and has high quality format properties. G.711 PCM Linear is a telephone quality audio codec format that's the least compressed and has the lowest quality format. GSM 06.10 is an audio codec format that's used by mobile phone vendors and is the standard for digital mobile phone services.

  If you're concerned about users' disk quotas, select WMA as the audio codec. Voice files saved in .wma format are approximately half the size of the same voice recording made using one of the other audio codecs.

- **Operator extension** Use this text box to enter the telephone number or an extension number for the dial plan's operator.

  You can configure this setting to transfer calls to an auto

attendant if one is configured, to a human operator, to external telephone numbers, or to extension numbers.
When a caller who is using the telephone keypad presses 0, or says "reception" or "operator," or the number of **Input retries** threshold is exceeded, the caller is transferred to the telephone number that you specify in this text box.
This telephone number can be a number external to the organization or an internal telephone extension number. For example, if the extension number for the receptionist or operator is 81964 and your organization has only one dial plan, enter 81964.
By default, this setting is blank. If you don't enter a number in this text box, the ability to transfer calls to the operator is disabled and callers are politely disconnected because there's no one to answer the call.
We recommend that you populate this text box with a telephone number that transfers callers to an operator if they can't locate a specific user in the directory.

- **Logon failures before disconnect** Use this text box to enter the number of sequential unsuccessful logon attempts allowed before a caller is disconnected.
  The value of this setting can be from 1 through 20. Setting this value too low can frustrate users. For most organizations, this value should be set to the default of three attempts.
- **Maximum call duration (min)** Use this text box to enter the maximum number of minutes that an incoming call can be connected to the system without being transferred to a valid extension number before the call is ended. For most organizations, this value should be set to the default of 30 minutes.
  This setting applies to all kinds of calls. This includes incoming subscriber access calls, voice calls internal to your organization, and voice calls external to your organization.
  The value of this setting can be from 10 through 120. Setting this value too low can cause incoming calls to be disconnected before they are completed. For example, if your organization receives many large fax messages, you may want to consider increasing this value from the default so that all the pages for fax messages are received.
- **Maximum recording duration (min)** Use this text box to enter the maximum number of minutes allowed for each voice recording when a caller leaves a voice mail message. For most organizations, this value should be set to the default of 20 minutes.
  The value of this setting can be from 1 through 100. Setting this value too low can cause long voice messages to be disconnected before they are completed. Setting this value too high lets users save lengthy voice messages in their Inboxes. This setting is important if you have implemented strict disk quotas for users. This value must be less than the value set for the **Maximum call duration (min)** setting.
- **Recording idle time-out (sec)** Use this text box to enter the number of seconds of silence that the system allows when a voice message is being recorded before the call is ended. For most organizations, this value should be set to the default of 5 seconds.
  The value of this setting can be from 2 through 10. Setting this value too low can cause the system to disconnect callers before they are finished leaving their voice messages. Setting this value too high allows lengthy silences in voice messages.
- **Input failures before disconnect** Use this text box to configure the number of times that callers can enter incorrect data before they are disconnected. For most organizations, this value should be set to the

default of three attempts. This is an important setting for speech-enabled UM dial plans.

Examples of incorrect data include when a caller requests an extension number that isn't found in the system, the system can't locate the user's extension number to transfer the call, or the caller presses a menu option that isn't valid.

The value of this setting can be from 1 through 20. Setting this value too low may prematurely disconnect the caller.

- **Default language** Use this list to specify the default language used by callers. When a caller places a call to a user who is associated with a dial plan, this is the default language that the voice recorded operator uses. The system prompts that callers hear are also played in the default language. The language that is chosen on the UM dial plan is used to read e-mail, voice mail and calendar items; say the user's name if a personal greeting hasn't been recorded; transcribe a voice message using the Voice Mail Preview feature; enable Automatic Speech Recognition (ASR) to work correctly.

  By default, if you install U.S. English with Exchange 2010, only one language is listed in this list. To have other language options available, you must install the UM language pack for each language you want to include. For more information about how to install a UM language pack, see Install a Unified Messaging Language Pack on a UM Server.

  Adding other languages lets subscribers use a language other than U.S. English. For example, if a subscriber calls in to the Unified Messaging system using the subscriber access number from a desk telephone, the subscriber is greeted with a prerecorded operator's voice in English. Even if the same user selects a different language in Outlook Web App, such as French, the menus are still read in U.S. English. For the user to be able to hear the prerecorded operator menus in French, you must install the appropriate language.

9. Use the **Dialing Rule Groups** tab on the UM dial plan to specify dialing rule groups for in-country/region and international calls placed by UM-enabled users. Each dialing rule entry defined on the dialing rule group determines the types of calls that users within a specific dialing rule group can make. After you use the **Dialing Rule Groups** tab to configure a dialing rule group, you must configure the UM mailbox policy to use the appropriate dialing rule group. After you configure the UM mailbox to use a dialing rule group, the dialing restrictions configured apply to all UM-enabled users who are associated with the UM mailbox policy. For example, you can configure a dialing rule group that doesn't require users who are associated with the dial plan to dial an outside line access code when they place a call to an in-country/region telephone number. You can configure the following:
   - **In-Country/Region Rule Groups** Use this text box to add, remove, or edit in-country/region dialing rule groups used by UM mailbox policies.
   - **International Rule Groups** Use this text box to add, remove, or edit international dialing rule groups used by UM mailbox policies.
   - **Dialing Rule Entry** Use this dialog box to define the telephone numbers and number masks for in-country/region and international calls that will be made by UM-enabled users. Each dialing rule entry determines the types of calls that users within a dialing rule group can make. However, you must correctly configure the dialing rule entry with a number mask and a dial number. After you use the **Dialing Rule Entry** window to configure a dialing rule entry, you must configure the UM dial plan, mailbox policy, or auto attendant to use the appropriate dialing rule group. You can configure the following:

     Name Use this list to select a name of an existing dialing rule entry. Or, if you want to create a dialing rule entry, type the

name of the dialing rule entry. This is the display name for the dialing rule entry that will be displayed in the EMC. This field can contain only text characters. The display name for the dialing rule entry can contain up to 32 characters.

Number Mask Use this text box to define the number mask for the dialing rule entry. A number mask is used to define the telephone number format that a Unified Messaging server uses to determine what outgoing telephone number it will dial for a user. When an outgoing call is made to a number matched by the number mask on the dialing rule entry, the Unified Messaging server substitutes the digits matched into the dialed number. It then uses the digit string from this match to make the outgoing call. An example of a valid number mask is 91425*xxxxxxx*. This field can contain only numbers and the character *x*.

Dialed Number Use this text box to define the dialed number for the dialing rule entry. The dialed number is used to determine the actual dial string sent to the IP gateway. This number can be different from the number obtained by Unified Messaging for the outgoing call. However, your PBX can also be configured to omit the area code for local calls and can be configured for private voice numbering plans. Any wildcard characters (*x*) in the dial string are substituted with the digits from the original number that were matched by the number mask on the dialing rule entry. An example of a valid dialed number is 9*xxxxxxx*. This field can contain only numbers and the character *x*.

Comment Use this text box to input a comment or description for the dialing rule entry that you're adding or modifying. By default, this text box is blank.

Important:

If you've integrated Exchange Unified Messaging and Office Communications Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange Unified Messaging. Office Communications Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Exchange Unified Messaging on behalf of users.

10. Use the **Dialing Restrictions** tab on the UM dial plan properties to configure dialing rule entries for callers who call in to a subscriber access number configured on a UM dial plan. You can restrict the type of calls placed by callers when an unauthenticated user or an Outlook Voice Access user calls in to a subscriber access number configured on a dial plan by configuring dialing rule groups and dialing restrictions. You can configure the following:
    - **Allow calls to users within the same dial plan** Select this check box to let users who call in to a subscriber access number configured on a dial plan place or transfer calls to an extension number associated with a UM-enabled user who is within the same dial plan. By default, this setting is enabled.

      When you disable this setting, users who call in to the subscriber access number won't be able to place or transfer calls to any users who aren't UM-enabled, to other extension numbers, or to UM-enabled users who are associated with the same dial plan. This is because the **Allow calls to extensions** setting is disabled by default.
    - **Allow calls to extensions** When this setting is disabled, users who call in to a subscriber access number on the dial plan can't place calls to users who aren't UM-enabled or to other extension numbers not associated with

a UM-enabled user. However, they can place a call or transfer a call to extension numbers associated with UM-enabled users. This is because the **Allow calls to users within the same dial plan** setting is enabled by default. The **Allow calls to extensions** setting is disabled by default.

When this setting is enabled, users who call in to a subscriber access number configured on the dial plan can place calls to users who aren't UM-enabled, to other extension numbers not associated with a UM-enabled user, and to UM-enabled users. This is because the **Allow calls to users within the same dial plan** setting is enabled by default.

You can enable this setting in an environment where not all users have been UM-enabled. This setting is also useful when you want to allow users who call in to a subscriber access number configured on a dial plan to call extension numbers that aren't associated.

- **Select allowed in-country/region rule groups from dial plan** Use this section to add or remove allowed in-country/region dialing rule groups. By default, there are no in-country/region dialing rule groups configured on UM dial plans.

  In-country/region dialing rule groups are used to allow or restrict the telephone numbers within a country or region that any user who has dialed in to the subscriber access number can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.

  To add in-country/region dialing rule groups, you must first create the appropriate in-country/region dialing rule groups on the dial plan, and then add the appropriate dialing rule entries on the dialing rule groups. After you create the required dialing rule groups on the dial plan, you must then add the dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the dial plan.

  In-country/region dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers within a country or region. This is applied to all users who have called in to a subscriber access number.
- **Select allowed international rule groups from dial plan** Use this section to add or remove allowed international dialing rule groups. By default, there are no international dialing rule groups configured on UM dial plans.

  International dialing rule groups are used to allow or restrict the telephone numbers outside a country or region that any user who has dialed in to the subscriber access number can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.

  To add international dialing rule groups, you must first create the appropriate international dialing rule groups on the dial plan, and then add the appropriate dialing rule entries on the dialing rule groups. After you create the required dialing rule groups on the dial plan, you must then add the dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the dial plan.

  International dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers outside a country or region. This is applied to all users who have called in to a subscriber access number

Use the Shell to configure UM dial plan properties

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures a UM dial plan named MyDialPlan to use 9 for the outside line access code.

```
Set-UMDialplan -Identity MyDialPlan -OutsideLineAccessCode 9
```

This example configures a UM dial plan named MyDialPlan to use a welcome greeting.

```
Set-UMDialplan -Identity MyDialPlan -WelcomeGreetingEnabled $true -WelcomeGreetin
```

This example configures a UM dial plan named MyDialPlan with dialing rules.

```
$csv=import-csv "C:\MyInCountryGroups.csv"
Set-UMDialPlan -Identity MyDialPlan -ConfiguredInCountryGroups $csv
Set-UMDialPlan -Identity MyDialPlan -AllowedInCountryGroups "local, long distance
```

For more information about syntax and parameters, see Set-UMDialplan.

Use the Shell to view UM dial plan properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example displays a list of all the UM dial plans in the Active Directory forest.

```
Get-UMDialplan
```

This example displays a formatted list of properties for a UM dial plan named MyUMDialPlan.

```
Get-UMDialplan -Identity MyUMDialPlan | Format-List
```

For more information about syntax and parameters, see Get-UMDialplan.

Other Tasks

After you have configured a UM dial plan, you may also want to Add a UM Server to a Dial Plan.

For More Information

Understanding Unified Messaging Dial Plans.

1.9.2.3.2.3 Delete a UM Dial Plan

Delete a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can delete an existing Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. When you delete the UM dial plan, the UM dial plan will no longer be available to other UM objects such as Unified Messaging servers, UM IP gateways, UM mailbox policies, and UM hunt groups. You won't be able to delete a UM dial plan if it's referenced by or associated with other UM objects such as UM mailbox policies, UM auto attendants, UM IP gateways, UM hunt groups, or Unified Messaging servers.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to delete an existing UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Click to highlight the UM dial plan you want to delete.
4. In the action pane, click **Remove**.
5. In the confirmation dialog box, click **Yes**.

Use the Shell to delete an existing UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example deletes a UM dial plan named `MyUMDialPlan`.

```
RemoveUMDialplan -identity MyUMDialPlan
```

For more information about syntax and parameters, see Remove-UMDialplan.

Other Tasks

After you delete an existing UM dial plan, you may also want toView or Configure the Properties of a UM Dial Plan.

Prevent UM-Enabled Users from Receiving Faxes on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can prevent UM-enabled users who are associated with a Unified Messaging (UM) dial plan from receiving fax messages. By default, users who are enabled for Unified Messaging and are associated with a UM dial plan can receive fax messages. However, there may be times when you want to prevent users who are associated with a specific UM dial plan from receiving faxes.

You can prevent UM-enabled users from receiving faxes by configuring the UM dial plan, the UM mailbox policy, or by configuring the UM-enabled user's mailbox. If you disable incoming fax message delivery on a UM dial plan, all users who are associated with the dial plan will be prevented from receiving fax messages. Enabling or disabling faxing on a UM dial plan takes precedence over the settings for an individual UM-enabled user.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to prevent users who are associated with a dial plan from receiving faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Dial Plans** tab, select the UM dial plan for which you want to prevent UM-enabled users from receiving faxes, and then click **Properties** in the action pane.
3. On the dial plan Properties page, on the **General** tab, clear the check box next to **Allow users to receive faxes**.
4. Click **OK** to save your changes.

Use the Shell to prevent users who are associated with a dial plan from receiving faxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example prevents UM-enabled users associated with the UM dial plan named MyUMDialPlan from receiving faxes.

```
Set-UMDialPlan -Identity MyUMDialPlan -FaxEnabled $false
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you prevent users who are associated with a dial plan from receiving faxes, you may also want to:

- Enable or Disable Inbound Faxing on a UM Mailbox Policy
- Enable a UM-Enabled User to Receive Faxes
- Prevent a UM-Enabled User from Receiving Faxes

1.9.2.3.2.5 Enable UM-Enabled Users to Receive Faxes on a UM Dial Plan

Enable UM-Enabled Users to Receive Faxes on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable all users who are associated with a Unified Messaging (UM) dial plan to receive fax messages in their Microsoft Exchange Server 2010 mailbox. To allow UM-enabled users to receive fax messages in their mailbox, each Unified Messaging server that's associated with the dial plan must be configured to accept incoming fax calls. You must also enable fax messages to be received by users who are associated with the dial plan However, there may be times when these default settings have changed and UM-enabled users can't receive fax messages.

If you prevent fax messages from being received on a dial plan, all users who are associated with the dial plan won't be able to receive fax messages, even if you configure an individual user's properties to allow them to receive fax messages. Enabling or disabling faxing on a UM dial plan takes precedence over the settings for an individual UM-enabled user.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to enable faxes to be received by users who are associated

with a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Dial Plans** tab, select the UM dial plan for which you want to allow users associated with the dial plan to receive fax messages, and then, in the action pane, click **Properties**.
3. On the dial plan **Properties** page, on the **General** tab, select the check box next to **Allow users to receive faxes**.
4. Click **OK** to save your changes.

Use the Shell to enable faxes to be received by users who are associated with a dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example enables UM-enabled users who are associated with the UM dial plan named `MyUMDialPlan` to receive incoming faxes.

```
Set-UMDialPlan -Identity MyUMDialPlan -FaxEnabled $true
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you enable faxes to be received by users who are associated with a dial plan, you may also want to:

- Prevent a UM-Enabled User from Receiving Faxes
- Prevent UM-Enabled Users from Receiving Faxes on a UM Dial Plan

1.9.2.3.2.6 Allow or Prevent Call Answering Rules on a UM Dial Plan

Allow or Prevent Call Answering Rules on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can allow users associated with a Unified Messaging (UM) dial plan to create and configure call answering rules, or prevent them from doing so. When this setting is enabled, UM-enabled users can create rules or actions and apply conditions to an incoming call to their phone number. They can transfer the call, have the caller leave a

voice message, or allow the caller to locate them at a different phone number.

You can also allow users to create and configure call answering rules, or prevent them from doing so, by configuring the UM mailbox policy associated with the user or on the user's mailbox.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to allow or prevent users from configuring call answering rules

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **General** tab.
4. Under **Allow users to configure call answering rules**, clear or select the check box.
5. Click **OK** to save your changes.

Use the Shell to allow or prevent users from configuring call answering rules

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example allows users who are associated with a UM dial plan named `MyUMDialPlan` to configure call answering rules.

```
Set-UMDialPlan -identity MyUMDialPlan -CallAnsweringRulesEnabled $true
```

This example prevents users who are associated with a UM dial plan named `MyUMDialPlan` from configuring call answering rules.

```
Set-UMDialPlan -identity MyUMDialPlan -CallAnsweringRulesEnabled $false
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've allowed users to configure call answering rules on a UM dial plan or prevented them from doing so, you may also want to:

- Enable or Disable Call Answering Rules for a UM-Enabled User
- Enable or Disable Call Answering Rules on a UM Mailbox Policy

1.9.2.3.2.7 Configure VoIP Security on a UM Dial Plan

Configure VoIP Security on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable Voice over IP (VoIP) security for a Unified Messaging (UM) dial plan. By default, when a UM dial plan is created, it will use unsecured mode or no encryption. A Unified Messaging server can be associated with a single or multiple UM dial plans and can be associated with dial plans that have different VoIP security settings.

When you configure the UM dial plan to use Session Initiation Protocol (SIP) secured or secured mode, the Unified Messaging servers that are associated with the UM dial plan will encrypt the SIP signaling traffic or the Realtime Transport Protocol (RTP) media channels and the SIP signaling traffic.

Important:

When Microsoft Exchange Server 2010 is installed, static Windows Firewall rules are added for Exchange. If you change the TCP ports that are used by the Unified Messaging server role, you may also need to reconfigure the Windows Firewall rules to allow Unified Messaging to work correctly.

- Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure VoIP security on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab, select the UM dial plan that you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **General** tab.
4. Click the drop-down list next to **VoIP security**, and then select one of the following options:
   - SIP secured
   - Unsecured (default)
   - Secured

Click **OK** to save your changes.

Use the Shell to configure VoIP security on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures a UM dial plan named `MySecureDialPlan` to encrypt both SIP and RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity Secured
```

This example configures a UM dial plan named `MySecureDialPlan` to encrypt SIP but not encrypt RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity SIPsecured
```

This example configures a UM dial plan named `MySecureDialPlan` to not encrypt SIP and RTP traffic.

```
Set-UMDialPlan -identity MySecureDialPlan -VoIPSecurity Unsecured
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure VoIP security on a UM dial plan, you may also want to:

- Connect a Unified Messaging Server to a Supported IP Gateway
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Add a UM Server to a Dial Plan

For More Information

Import and Export Certificates

1.9.2.3.2.8 Enable a Custom Welcome Greeting on a UM Dial Plan

Enable a Custom Welcome Greeting on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable a custom welcome greeting on a Microsoft Exchange Server 2010 Unified Messaging (UM) dial plan. By default, each dial plan uses a system prompt or .wav file for its default welcome greeting. However, you can create a custom .wav file or custom prompt to use for the welcome greeting, and then enable the welcome greeting to be played to callers, including Outlook Voice Access users who dial in to a subscriber access number.

However, you might want to change this default welcome greeting and instead provide an alternative welcome greeting that's specific to your company, such as, "Welcome to

Outlook Voice Access for Woodgrove Bank." To do this, you record the customized welcome greeting and save it as a .wav file. Then you configure the dial plan to use the customized welcome greeting.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to enable a custom welcome greeting

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan that you want to manage.
3. In the action pane, click **Properties**.
4. On the dial plan **Properties** page, on the **Subscriber Access** tab, under **Welcome greeting**, click **Modify**.
5. On the **Welcome Greeting** page, under **Welcome greeting**, click **Use custom greeting file**, and then click **Browse** to locate the file that you want to use for your custom welcome greeting file.
6. Click **OK** to save your changes.

Use the Shell to enable a custom welcome greeting

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example enables a welcome greeting that uses the C:\UMPrompts\welcome.wav file on a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -Identity MyUMDialPlan -WelcomeGreetingEnabled $true -WelcomeGreet
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you enable a custom welcome greeting, you may also want to:

- Enable an Informational Announcement on a UM Dial Plan
- Configure a Subscriber Access Number on a UM Dial Plan
- Enable Custom Prompt Recording Using the Telephone User Interface

Enable an Informational Announcement on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable an informational announcement on a Microsoft Exchange Server 2010 Unified Messaging (UM) dial plan. By default, an informational announcement isn't played to callers, including Outlook Voice Access users who dial in to a subscriber access number. If you want an informational announcement to be played, you must create a .wav file to use for the informational announcement after you create a dial plan, and then enable the informational announcement on the dial plan.

You can use an informational announcement for general announcements that change more frequently than the welcome greeting does, or for announcements required by corporate compliance policies. When it's important that the whole informational announcement be heard, you can configure it to be uninterruptible. This prevents a caller from pressing a key or speaking a command to interrupt and stop the informational announcement.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to enable an informational announcement

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Dial Plans** tab, select the UM dial plan that you want to manage, and then click **Properties** in the action pane.
3. On the dial plan Properties page, under the **Subscriber Access** tab, under **Informational announcement**, click **Modify**.
4. On the **Informational Announcement** page, under **Informational announcement**, click **Informational announcement file**, click **Browse**, and then navigate to the .wav file that you want to use for your informational announcement.
5. (Optional) If you want to let your users interrupt the informational announcement, select the check box next to **Allow informational announcement to be interrupted**.
6. Click **OK** to save your changes.

Use the Shell to enable an informational announcement

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example enables an informational announcement that uses the informational.wav information announcement file on a UM dial plan named MyUMDialPlan.

```
Set-UMDialPlan -Identity MyUMDialPlan -InfoAnnouncementEnabled $true-InfoAnnounce
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you enable an informational announcement, you may also want to:

- Enable a Custom Welcome Greeting on a UM Dial Plan
- Enable an Informational Announcement on a UM Auto Attendant

1.9.2.3.2.10 Configure a Subscriber Access Number on a UM Dial Plan

Configure a Subscriber Access Number on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A subscriber access number lets a user who is enabled for Unified Messaging (UM) access a mailbox in Microsoft Exchange Server 2010 using Outlook Voice Access. When you configure a subscriber access number on a dial plan, UM-enabled users can call in to the subscriber access number, log on to their Exchange 2010 mailbox, and access their e-mail, voice mail, calendar, and personal contact information.

By default, when you create a UM dial plan, a subscriber access number isn't configured. To configure a subscriber access number, you first need to create the dial plan and then configure a subscriber access number on the dial plan's **Subscriber Access** tab. Although a subscriber access number isn't required, you need to configure at least one subscriber access number to enable a UM-enabled user to use Outlook Voice Access to access to their Exchange 2010 mailbox. You can also configure multiple subscriber access numbers for a single dial plan.

For more information about the menu options available for Outlook Voice Access users, see the Quick Reference Guide for Outlook Voice Access, which is available from the Microsoft Download Center.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure a subscriber access number

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Subscriber Access** tab.
4. Under **Associated Subscriber Access Numbers**, enter the subscriber access number in the box labeled **Enter the telephone number to associate**, and then click **Add**.
5. Click **OK** to save your changes.

Use the Shell to configure a subscriber access number

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the subscriber access number to 4255550100 for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -AccessTelephoneNumbers 4255550100
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure a subscriber access number, you may also want to:

- Configure the Dial by Name Primary Method on a Unified Messaging Dial Plan
- Configure the Dial by Name Secondary Method on a UM Dial Plan

1.9.2.3.2.11 Configure Dial Codes on a UM Dial Plan

Configure Dial Codes on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure dial codes for a Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. You can configure dial codes, national number prefixes, and in-country/region and international number formats used by a Unified Messaging server to dial incoming and outgoing calls for users who are enabled for Unified Messaging. In most

cases, you'll configure a dial plan with the dial codes and national number prefix currently configured on your telephony network.

Dial codes, national number prefixes, and formats are used by a Unified Messaging server to determine the correct number to dial for an outgoing call that's placed by a UM-enabled user. On the **Dial Codes** tab, you can also configure the Unified Messaging servers associated with the dial plan to match the incoming call number format for both in-country/region and international numbers. When you configure the in-country/region and international number formats, you can restrict incoming calls for users associated with a dial plan.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure dial codes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, on the **Dial Codes** tab, under **Outgoing Configuration**, configure these options:
   - Outside line access code
   - International access code
   - National number prefix
   - Country/Region code
4. Under **Incoming Configuration**, configure the following:
   - In-country/region number format
   - International number format
5. Click **OK** to save your changes.

Use the Shell to configure dial codes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures a UM dial plan named `MyUMDialPlan` with an In-Country or Region Number format and an International Number format and the following dial codes.

- 9 for the Outside Line Access Code
- 011 for the International Access Code
- 1 for the National Number Prefix
- 1 for the Country or Region code

```
Set-UMDialPlan -Identity MyUMDialPlan -OutsideLineAccessCode 9 -InternationalAcce
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure dial codes, you may also want to:

- Configure Dialing Rule Groups on a UM Dial Plan
- Create a Dialing Rule Entry on a UM Dial Plan

1.9.2.3.2.12 Enable or Disable Sending Voice Messages on a UM Dial Plan

Enable or Disable Sending Voice Messages on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable users who are enabled for Unified Messaging (UM) to send voice messages to other UM-enabled users who are associated with the same dial plan, or prevent them from doing so.

By default, this option is enabled. If you disable this setting and disable the **Allow callers to transfer users** setting, the options under **Callers can contact** will also be disabled. If you disable this option, an auto attendant associated with the UM dial plan won't invite callers to send a voice message when a system prompt is played.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to enable or prevent UM-enabled users from sending voice messages to users in the same dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan that you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Allow callers to send voice messages**, clear or select the check box. If you select this option, under **Callers can contact**, specify who users can transfer calls to.
5. Click **OK** to save your changes.

Use the Shell to enable or prevent UM-enabled users from sending voice messages to users in the same dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example prevents UM-enabled users associated with the UM dial plan named `MyUMDialPlan` from sending voice messages to users associated with the same dial plan.

```
Set-UMDialPlan -identity MyUMDialPlan -SendVoiceMsgEnabled $false
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've enabled or prevented users from sending voice messages to other UM-enabled users associated with the same UM dial plan, you may also want to:

- Enable or Disable Call Transfers to Users on a UM Dial Plan
- Configure the Scope of Users Who Callers Can Contact on a UM Dial Plan

1.9.2.3.2.13 Enable or Disable Call Transfers to Users on a UM Dial Plan

Enable or Disable Call Transfers to Users on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable call transfer to a user who's associated with a Unified Messaging (UM) dial plan. By default, this option is enabled, and lets users associated with the dial plan transfer calls to users in the same UM dial plan. After you select this check box, you can set the group of users to whom callers can transfer by selecting the option you want under the **Callers can contact** section on this page. If you disable the **Allow callers to transfer to users** option and disable the **Allow callers to send voice messages** setting, the options under **Callers can contact** will also be disabled.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to enable or disable call

transfer to users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Allow callers to transfer to users**, clear or select the check box. If you select this option, under **Callers can contact**, specify the people to whom users can transfer calls.
5. Click **OK** to save your changes.

Use the Shell to enable or disable call transfer to users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example prevents users from transferring calls for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -AllowDialPlanSubscribers $false>
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've enabled or disabled call transfer to users, you may also want to:

- Enable or Disable Sending Voice Messages on a UM Dial Plan
- Configure the Scope of Users that Callers Can Contact on a UM Auto Attendant
- Enable or Disable Call Transfers to Users from a UM Auto Attendant

1.9.2.3.2.14 Configure the Scope of Users Who Callers Can Contact on a UM Dial Plan

Configure the Scope of Users Who Callers Can Contact on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify which users will be able to receive transferred calls or voice messages from users who call in to a subscriber access number. By default, the **Users within this dial plan** option is selected. You can change this setting to allow callers to transfer calls or send voice messages to users located in the global address list, to a specific extension

number, to a UM auto attendant, or to a specific set of users contained in a custom address list.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the scope of users who callers can contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Features** tab.
4. Under **Callers can contact**, select one of the following options:
   - 4.a. **Users within this dial plan** Use this option to allow callers who call in to a subscriber access number to locate and contact users who are within the dial plan associated with the UM auto attendant.
   - 4.b. **Anyone in the default global address list** Use this option to allow callers who call in to a subscriber access number to locate and contact anyone who's listed in the global address list. This includes all users who are mailbox-enabled.
   - 4.c. **Only this extension** Use this option to allow callers to connect to an extension number that you specify. You can only use numeric digits for the extension. The number of digits that you define in this field must match the number of digits in the extension numbers that are configured on the UM dial plan.
   - 4.d. **Only this auto attendant** Use this option to allow callers who call in to a subscriber access number to connect to a specific auto attendant. You must create the auto attendant before you specify it here. This allows callers to be transferred to another auto attendant. The auto attendant you choose here can be a speech-enabled or non speech-enabled auto attendant.
   - 4.e. **Anyone in address list** Use this option to allow callers who call in to a subscriber access number to locate and contact users who are in a defined custom address list. This includes all users who are mailbox-enabled.
5. Click **OK** to save your changes.

Use the Shell to configure the scope of users who callers can contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the scope of the users who callers can contact for a UM dial plan named `MyUMDialPlan` to the global address list.

```
Set-UMDialPlan -Identity MyUMDialPlan -ContactScope 'GlobalAddressList' -UMAutoAt
```

This example sets the scope of the users who callers can contact for a UM dial plan named `MyUMDialPlan` to a custom address list named `MyAddressList`.

```
Set-UMDialPlan -Identity MyUMDialPlan -ContactScope MyAddressList -AllowDialPlanS
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the scope of users who callers can contact, you may also want to:

- Enable or Disable Call Transfers to Users on a UM Dial Plan
- Enable or Disable Sending Voice Messages on a UM Dial Plan

1.9.2.3.2.15 Configure the Matched Name Selection Method on a UM Dial Plan

Configure the Matched Name Selection Method on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the matched name selection method for a Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. The matched name selection method is used by Unified Messaging to differentiate between users who have the same or similar names. When a caller or an Outlook Voice Access user is prompted to enter letters to find a particular user, sometimes more than one name matches the caller's input. You can use one of the available methods for providing the caller with more information to help them locate the user they're trying to reach.

You can set the matched name selection method on UM dial plans and UM auto attendants. When a UM auto attendant is created, it inherits the matched name selection method from the dial plan associated with the auto attendant. By default, the matched name selection method isn't configured for dial plans.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the matched name selection method on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Select the dial plan you want to modify, and then, in the action pane, click **Properties**.
4. On the **Features** tab, under **Matched name selection method**, select from one of the following:
   - **Title** The dial plan operator or auto attendant will include each user's title when matches are listed.
   - **Department** The dial plan operator or auto attendant will include each user's department when matches are listed.
   - **Location** The dial plan operator or auto attendant will include each user's location when matches are listed.
   - **None** No additional information will be given when matches are listed. By default, this method is selected.
   - **Prompt For Alias** The dial plan operator or auto attendant will prompt the caller for the user's e-mail alias.
5. Click **OK** to save your changes.

Use the Shell to configure the matched name selection method on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the matched name selection method to prompt for the user's alias on a UM dial plan named `MyDialPlan`.

```
Set-UMDialplan -Identity MyDialPlan -MatchedNameSelectionMethod PromptForAlias
```

This example sets the matched name selection method to Department on a UM dial plan named `MyDialPlan`.

```
Set-UMDialplan -Identity MyDialPlan -MatchedNameSelectionMethod Department
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure the matched name selection method on a UM dial plan, you may also want to:

- Configure the Matched Name Selection Method on a UM Auto Attendant
- View or Configure the Properties of a UM Dial Plan

1.9.2.3.2.16 Configure the Dial by Name Primary Method on a Unified Messaging Dial Plan

Configure the Dial by Name Primary Method on a Unified Messaging Dial Plan

Managing Unified Messaging > Managing Unified Messaging Components > Managing UM Dial Plans >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you create a dial plan, you can configure the primary and secondary dial by name methods. These dial by name methods are used by callers use to look up names when they want to locate and contact a user when they call into an Outlook Voice Access number or when they call into a UM auto attendant that's associated with the dial plan. Callers can use either touchtone inputs or voice inputs to locate a UM-enabled user.

Note:

None isn't an available option for the dial by name primary method. When **None** is selected for the dial by name secondary method, only the dial by name primary method will be available to callers.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to change the primary dial by name method

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, on the **Settings** tab, select from the following options in the drop-down list next to **Dial by name primary method**:
   - Last First (default)
   - First Last
   - SMTP Address
4. Click **OK** to save your changes.

Use the Shell to change the primary dial by name method

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the primary dial by name method to `FirstLast`. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their first and then last name.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNamePrimary FirstLast
```

This example sets the primary dial by name method to `LastFirst`. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial

plan to search for a UM-enabled user by their last and then first name.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNamePrimary LastFirst
```

This example sets the primary dial by name method to SMTP address. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their SMTP address.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNamePrimary SMTPAddress
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the dial by name primary method, you may also want to:

- Configure the Dial by Name Secondary Method on a UM Dial Plan
- Configure the Matched Name Selection Method on a UM Dial Plan

1.9.2.3.2.17 Configure the Dial by Name Secondary Method on a UM Dial Plan

Configure the Dial by Name Secondary Method on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you create a dial plan, you can configure the primary and secondary dial by name methods. These dial by name methods are used by callers use to look up names when they want to locate and contact a user when they call into an Outlook Voice Access number or when they call into a UM auto attendant that's associated with the dial plan. Callers can use either touchtone inputs or voice inputs to locate a UM-enabled user.

Note:

If **None** is selected as the dial by name secondary method, only the dial by name primary method will be available to callers who want to locate users.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to change the secondary dial by name method

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, on the **Settings** tab, select from the following options in the drop-down list next to **Dial by name secondary method**:
   - Last First
   - First Last
   - SMTP address (default)
   - None
4. Click **OK** to save your changes.

Use the Shell to change the secondary dial by name method

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the secondary dial by name method to `FirstLast`. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their first and then last name.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNameSecondary FirstLast
```

This example sets the secondary dial by name method to `LastFirst`. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their last and then first name.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNameSecondary LastFirst
```

This example sets the secondary dial by name method to `SMTP address`. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their SMTP address.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNameSecondary SMTPAddress
```

This example sets the secondary dial by name method to `None` and the dial by name primary method to SMTP address. This enables callers who call the Outlook Voice Access number or a UM auto attendant associated with the dial plan to search for a UM-enabled user by their SMTP address only.

```
Set-UMDialPlan -Identity MyUMDialPlan -DialByNamePrimary SMTPAddress -DialByNameS
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the dial by name secondary method, you may also want to:

- Configure the Dial by Name Primary Method on a Unified Messaging Dial Plan
- Configure the Matched Name Selection Method on a UM Dial Plan

Configure the Audio Codec on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Unified Messaging (UM) servers can use one of four codecs for creating voice messages: MP3, Windows Media Audio (WMA), Group System Mobile (GSM) 06.10, and G.711 Pulse Code Modulation Linear. By default, when you create a UM dial plan, the UM dial plan uses the MP3 audio codec. However, after the UM dial plan is created, you can configure the UM dial plan to use the WMA, GSM 06.10 or G.711 PCM Linear audio codecs.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to change the audio codec on a Unified Messaging dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to modify.
3. In the action pane, click **Properties**.
4. On the dial plan **Properties** page, click the **Settings** tab.
5. On the **Settings** tab, use the **Audio codec** list to select the audio codec you want.
6. Click **OK** to accept your changes.

Use the Shell to change the audio codec on a Unified Messaging dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the audio codec on a UM dial plan named `MyUMDialPlan` to G.711.

```
Set-UMDialPlan -Identity MyUMDialPlan -AudioCodec G711
```

This example sets the audio codec on a UM dial plan named `MyUMDialPlan` to WMA.

```
Set-UMDialPlan -Identity MyUMDialPlan -AudioCodec Wma
```

For more information about syntax and parameters, see Set-UMDialplan.

1.9.2.3.2.19 Configure an Operator Extension on a UM Dial Plan

Configure an Operator Extension on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure an extension number for a Unified Messaging (UM) dial plan. You can set it to transfer calls to a UM auto attendant, if one is configured, a human operator, external telephone numbers, or extension numbers. When you configure an operator extension number on a UM dial plan, a caller can connect to the dial plan operator by doing one of the following:

- Pressing the zero (0) key
- Saying "Reception"
- Saying "Operator"

Note:
If the caller exceeds the maximum number of touchtone or voice input retries, they're transferred to the operator extension number, if you've defined an operator extension number and enabled business hours operator transfers.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure an operator extension

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to modify.
3. In the action pane, click **Properties**.
4. On the dial plan **Properties** page, click the **Settings** tab.
5. On the **Settings** tab, in the **Operator extension** text box, type the telephone number for the operator.
6. Click **OK** to accept your changes.

Use the Shell to configure an operator extension

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures an operator extension of 12345 on a UM dial plan named MyUMDialPlan.

```
Set-UMDialPlan -Identity MyUMDialPlan -OperatorExtension 12345
```

For more information about syntax and parameters, see Set-UMDialplan reference topic.

Other Tasks

After you configure an operator extension, you may also want to:

- View or Configure the Properties of a UM Dial Plan
- Configure an Operator Extension on a UM Auto Attendant

1.9.2.3.2.20 Configure the Number of Logon Failures Before Users Are Disconnected on a UM Dial Plan

Configure the Number of Logon Failures Before Users Are Disconnected on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the number of sequential unsuccessful sign-in attempts that are allowed before a caller is disconnected. The value of this setting can be from 1 through 20. Setting this value too low can frustrate users. For most organizations, this value should be set to the default of three attempts.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the number of sign-in failures before users are disconnected

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Logon failures before disconnect**, enter the number of sequential

unsuccessful sign-in attempts that are allowed before a caller is disconnected.

5. Click **OK** to save your changes.

Use the Shell to configure the number of sign-in failures before users are disconnected

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the number of sign-in failures before users are disconnected to 5 for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -LogonFailuresBeforeDisconnect 5
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the number of sign-in failures before users are disconnected on a dial plan, you may also want to:

- Configure the Input Failures Before Disconnect on a UM Dial Plan
- Configure the Recording Idle Time-Out Value on a UM Dial Plan

1.9.2.3.2.21 Configure the Maximum Call Duration on a UM Dial Plan

Configure the Maximum Call Duration on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the maximum number of minutes that an incoming call can be connected to the system without being transferred to a valid extension number before the call is ended. For most organizations, this value should be set to the default: 30 minutes. This setting applies to all calls, including incoming subscriber access calls, voice calls internal to your organization, and voice and fax calls placed from outside your organization.

This value can be set to a number from 10 through 120. Setting this value too low can cause incoming calls to be disconnected before they're completed. For example, if your organization receives many large fax messages, you may want to consider increasing this value from the default so that all the pages of fax messages are received.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the maximum call duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Maximum call duration (min)**, specify the maximum number of minutes that an incoming call can be connected to the system without being transferred to a valid extension before the call is ended.
5. Click **OK** to save your changes.

Use the Shell to configure the maximum call duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the maximum call duration to 10 minutes on a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -MaxCallDuration 10
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure the maximum call duration on a UM dial plan, you may also want to:

- Configure the Maximum Recording Duration on a UM Dial Plan
- Configure the Number of Logon Failures Before Users Are Disconnected on a UM Dial Plan

1.9.2.3.2.22 Configure the Maximum Recording Duration on a UM Dial Plan

Configure the Maximum Recording Duration on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the maximum number of minutes allowed for each voice recording when a caller leaves a voice mail message. This value can be set from 1 through 100. For most organizations, this value should be set to the default of 20 minutes. Setting this value too low can cause long voice messages to be disconnected before they're completed. Setting this value too high lets users save lengthy voice messages in their Inboxes.

This setting is important if you've implemented strict disk quotas for users. It must be set to a lower value than the one set for **Maximum call duration (min)**.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the maximum recording duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Maximum recording time duration (min)**, specify the maximum number of minutes allowed for each voice recording when a caller leaves a voice mail message.
5. Click **OK** to save your changes.

Use the Shell to configure the maximum recording duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the maximum recording duration to 10 minutes for a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -MaxRecordingDuration 10
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the maximum recording duration on a UM dial plan, you may also want to:

- Configure the Number of Logon Failures Before Users Are Disconnected on a UM Dial Plan

- Configure the Maximum Call Duration on a UM Dial Plan
- Configure the Recording Idle Time-Out Value on a UM Dial Plan

1.9.2.3.2.23 Configure the Recording Idle Time-Out Value on a UM Dial Plan

Configure the Recording Idle Time-Out Value on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the number of seconds of silence that the system allows when a voice message is being recorded before the call is ended. For most organizations, this value should be set to the default: 5 seconds.

This value can be set from 2 through 10. Setting this value too low can cause the system to disconnect callers before they've finished leaving their voice messages. Setting this value too high allows lengthy silences in voice messages.

Looking for other management tasks related to Unified Messaging (UM) dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the recording idle time-out value

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Recording idle time-out (sec)**, enter the number of seconds of silence that the system allows when a voice message is being recorded before the call is ended.
5. Click **OK** to save your changes.

Use the Shell to configure the recording idle time-out value

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the recording idle time-out value to 10 for a UM dial plan named MyUMDialPlan.

```
Set-UMDialPlan -identity MyUMDialPlan -RecordingIdleTimeout 10
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you've configured the recording idle time-out value, you may also want to:

- Configure the Maximum Recording Duration on a UM Dial Plan
- Configure the Maximum Call Duration on a UM Dial Plan

1.9.2.3.2.24 Configure the Input Failures Before Disconnect on a UM Dial Plan

Configure the Input Failures Before Disconnect on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the number of times that users who call in to a subscriber access number can enter incorrect data before they're disconnected. This setting applies to both Outlook Voice Access users and unauthenticated callers who use directory search.

The following are examples of types of data that are considered incorrect:

- A caller requests an extension number that isn't found in the system
- The system can't locate the user's extension number to transfer the call
- A caller presses a menu option that isn't valid.

The value of this setting can be from 1 through 20. For most organizations, this value should be set to the default of three attempts. Setting this value too low may prematurely disconnect callers.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the input failures before disconnect

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to manage, and then click **Properties** in the action pane.
3. On the dial plan **Properties** page, click the **Settings** tab.
4. Under **Input failures before disconnect**, enter the number of times that callers can enter incorrect data before they're disconnected.
5. Click **OK** to save your changes.

Use the Shell to configure the input failures before disconnect

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the input failures before disconnect to 5 on a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -identity MyUMDialPlan -InputFailuresBeforeDisconnect 5
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure the input failures before disconnect, you may also want to:

- Configure the Number of Logon Failures Before Users Are Disconnected on a UM Dial Plan
- Configure the Maximum Call Duration on a UM Dial Plan

1.9.2.3.2.25 Configure the Default Language on a UM Dial Plan

Configure the Default Language on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a Unified Messaging (UM) dial plan with a default language. Each dial plan and auto attendant you create will use English (en-US) as the default language. The English (en-US) language pack is installed by default on all versions of Microsoft Exchange Server 2010 and can't be removed.

If you want to select another language, such as German (de-DE), you must first download the German UM language pack .exe file from Exchange Server 2010 SP2 UM Language Packs and install the UM language pack on the UM server using the executable (UMLanguagePack.de-de.exe) installation file. After you've installed the UM language pack, you can set the default language to a language other than English (en-US) on UM dial plans and UM auto attendants.

Looking for other management tasks related to UM dial plans? Check out Managing UM

Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure the default language on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Dial Plans** tab, select the UM dial plan you want to modify.
3. In the action pane, click **Properties**.
4. On the dial plan **Properties** page, click the **Settings** tab.
5. On the **Settings** tab, in the **Language Settings** section, in the **Default language** option list, select the language you want to use.
6. Click **OK** to accept your changes.

Use the Shell to configure the default language on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example sets the default language on a UM dial plan named `MyUMDialPlan` to German.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage de-DE
```

This example sets the default language on a UM dial plan named `MyUMDialPlan` to Japanese.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage ja-JP
```

This example sets the default language on a UM dial plan named `MyUMDialPlan` to Australian English.

```
Set-UMDialPlan -Identity MyUMDialPlan -DefaultLanguage en-AU
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure the default language on a UM dial plan, you may also want to:

- View or Configure the Properties of a UM Dial Plan
- Install a Unified Messaging Language Pack on a UM Server
- Remove a Unified Messaging Language Pack from a UM Server

1.9.2.3.2.26 Configure Dialing Rule Groups on a UM Dial Plan

Configure Dialing Rule Groups on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure dialing rule groups for a Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. Dialing rule groups specify settings for in-country/region and international calls that will be placed by UM-enabled users from inside your organization. After you create a dialing rule group, you must add a dialing group entry. Each dialing rule entry that's defined in the dialing rule group determines the types of calls, in-country/region or international, that users within a specific dialing rule group can make when they place outgoing calls. By default, UM-enabled users aren't allowed to dial external telephone numbers from inside the organization. However, they're allowed to dial UM-enabled users who are associated with the same dial plan.

After you create the UM dial plan with an in-country/region or international dialing rule group and configure the dialing rule entries, you must add the dialing rule group to the dialing restrictions on the UM mailbox policy associated with the UM dial plan. When you add the dialing rule group to the dialing restrictions on the UM mailbox policy, the settings you use will apply to all UM-enabled users associated with the UM mailbox policy. For more information about how to create dialing rule entries, see Create a Dialing Rule Entry on a UM Dial Plan.

Important:

If you've integrated Exchange Unified Messaging and Office Communications Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange Unified Messaging. Office Communications Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Exchange Unified Messaging on behalf of users.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure in-country/region dialing rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Select the dial plan you want to modify, and then, in the action pane, click **Properties**.

4. On the **Dialing Rule Groups** tab, under **In-Country/Region Rule Groups**, do one of the following:
   - Click **Add** to add a dialing rule entry. On the **Dialing Rule Entry** page, enter the number mask and the number to be dialed for the dialing rule entry. A number mask is represented by a series of Xs or asterisks and replaces the number of digits that follow the prefix for a telephone number, for example, 91425xxxxxxx, or 91425*. If a number that's dialed by a caller matches the prefix configured in the dialing rule entry, the PBX will dial the number that was specified in the **Dialed number** field.
   - Click **Edit** to change the in-country/region dialing rule entry settings.
   - Click **Remove** to delete the in-country/region dialing rule entry.
5. Click **OK** to save your changes.

Use the EMC to configure international dialing rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Select the dial plan you want to modify, and then, in the action pane, click **Properties**.
4. On the **Dialing Rule Groups** tab, under **International Rule Groups**, do one of the following:
   - Click **Add** to add a dialing rule entry. On the **Dialing Rule Entry** page, enter the number mask and the number to be dialed for the dialing rule entry. A number mask is represented by a series of Xs or asterisks and replaces the number of digits that follow the prefix for a telephone number, for example, 91425xxxxxxx, or 91425*. If a number that's dialed by a caller matches the prefix configured in the dialing rule entry, the PBX will dial the number that was specified in the **Dialed number** field.
   - Click **Edit** to change the international dialing rule entry settings.
   - Click **Remove** to delete the international dialing rule entry.
5. Click **OK** to save your changes.

Use the Shell to configure in-country/region dialing rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures a UM dial plan named `MyDialPlan` with in-country or region dialing rules.

```
$csv=import-csv "C:\MyInCountryGroups.csv"
Set-UMDialPlan -Identity MyDialPlan -ConfiguredInCountryGroups $csv
Set-UMDialPlan -Identity MyDialPlan -AllowedInCountryGroups "local, long distance
```

Use the Shell to configure international dialing rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions

topic.

This example configures a UM dial plan named MyDialPlan with international dialing rules.

```
$csv=import-csv "C:\MyInternationalGroups.csv"
Set-UMDialPlan -Identity MyDialPlan -ConfiguredInternationalGroups $csv
Set-UMDialPlan -Identity MyDialPlan -AllowedInternationalGroups "local, long dist
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure dialing rule groups, you may also want to:

- Create a Dialing Rule Entry on a UM Dial Plan
- Enable Dialing Restrictions on a UM Mailbox Policy.

1.9.2.3.2.27 Create a Dialing Rule Entry on a UM Dial Plan

Create a Dialing Rule Entry on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can create a dialing rule entry for a dialing rule group on a Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. After you create an in-country/region or international dialing rule group on a UM dial plan, you must create a dialing rule entry for the dialing rule group.

A dialing rule entry defines the telephone numbers and number masks for in-country/region and international calls that can be made by UM-enabled users associated with a UM mailbox policy. Each dialing rule determines the types of calls users within a dialing rule group can make. However, you must correctly configure the dialing rule entry with a valid number mask and a dial number. After you create a dialing rule group and define the appropriate dialing rule entries on the **Dialing Group Rules** tab, you must add the appropriate dialing rule groups from the UM dial plan to a UM mailbox policy on the **Dialing Restrictions** tab.

Important:

If you've integrated Exchange Unified Messaging and Office Communications Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange Unified Messaging. Office Communications Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Exchange Unified Messaging on behalf of users.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

Use the EMC to configure a dialing rule entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Dial Plans** tab, select the UM dial plan you want to manage.
3. In the action pane, click **Properties**.
4. On the dial plan **Properties** page, under the **Dialing Rule Groups** tab, under **In-Country/Region Rule Groups** or **International Rule Groups**, click the **Add** button.
5. On the **Dialing Rule Entry** page for the **In-Country/Region Rule Groups** or **International Rule Groups**, enter the following information:
   - **Name** Use this list to select the name of an existing dialing rule group or, if you want to create a dialing rule group, type the name of the dialing rule group. This box can contain only text characters. The display name for the dialing rule entry can contain up to 32 characters.
   - **Number mask** Use this box to define the number mask for the dialing rule. A number mask defines the telephone number format that a Unified Messaging server will use to determine what outgoing telephone number it will dial for a user. An example of a valid number mask is 91425xxxxxxx. This box can contain only numbers and the letter "x."
   - **Dialed number** Use this box to define the dialed number for the dialing rule. The dialed number is used to determine the actual dial string that's sent to the IP gateway. This number can be different from the number that's obtained by Unified Messaging for the outgoing call. However, your Private Branch eXchange (PBX) can also be configured to omit the area code for local calls and can be configured for private voice numbering plans. Any wildcard (x) characters included in the dial string replace the digits from the original number that were matched by the number mask on the dialing rule. An example of a valid dialed number is 9xxxxxxx. This box can contain only numbers and the letter "x."
   - **Comment** Use this box to enter a comment or description for the dialing rule that you are adding or modifying. By default, this box is blank.
6. Click **OK** to save your changes.

Use the Shell to configure a dialing rule entry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example configures a dialing rule entry for an in-country/region rule group.

```
Set-UMDialPlan -Identity MyUMDialPlan -ConfiguredInCountryOrRegionGroups <name, a
```

This example configures a dialing rule entry for an international rule group.

```
Set-UMDialPlan -Identity MyUMDialPlan -ConfiguredInternationalGroups <name, allow
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you configure a dialing rule entry, you may also want to:

- Delete a UM Dial Plan
- Managing UM Auto Attendants
- Configure Business Hours for a UM Auto Attendant

1.9.2.3.2.28 Enable Dialing Restrictions on a UM Dial Plan

Enable Dialing Restrictions on a UM Dial Plan

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable dialing restrictions on a Unified Messaging (UM) dial plan in Microsoft Exchange Server 2010. Dialing restrictions are used to configure dialing rules that can be used to prohibit users who call in to a subscriber access number configured on a UM dial plan from making certain types of telephone calls. Dialing restrictions are also used when you want to allow users to place calls to in-country/region or international telephone numbers.

When you configure dialing restrictions and outdialing on a UM dial plan, the dialing restrictions that you configure will apply to all UM-enabled or Outlook Voice Access users associated with the UM dial plan and to anonymous callers when they call in to a subscriber access number configured on the UM dial plan.

For outdialing to work, the following settings must be configured correctly:

- **Dialing group rules** Dialing group rules determine the types of calls users within a dialing group can make. Dialing group rules include:
- **Dialing rule entries** Dialing rule entries define the number that is dialed by the user and the actual number that will be dialed by the Private Branch eXchange (PBX) or IP PBX.
- **Dialing restrictions** Dialing restrictions determine the restrictions that will be applied to prevent users from incurring unauthorized telephone charges or from dialing long distance calls.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.
- A UM dialing rule group has been created. For detailed steps, see Configure Dialing Rule Groups on a UM Dial Plan.

Use the EMC to enable dialing restrictions on a UM dial plan for in-country/region rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Select the UM dial plan you want to change, and then, in the action pane, click **Properties**.
4. On the UM dial plan **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed in-country/region rule groups from dial plan**, click **Add**.
5. On the **Select Allowed In-Country/Region Groups** page, select the dialing rule group configured on the UM dial plan, and then click **OK**.
6. Click **OK** to save your changes.

Use the EMC to enable dialing restrictions on a UM dial plan for international rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Dial Plans** tab.
3. Select the UM dial plan you want to change, and then, in the action pane, click **Properties**.
4. On the UM dial plan **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed international rule groups from dial plan**, click **Add**.
5. On the **Select Allowed International Groups** page, select the dialing rule group configured on the UM dial plan, and then click **OK**.
6. Click **OK** to save your changes.

Use the Shell to enable in-country/region and international dialing restrictions on a UM dial plan

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the InCountry/RegionGroup1, InCountry/RegionGroup2, InternationalGroup1, and InternationalGroup2 dialing restrictions on a UM dial plan named `MyUMDialPlan`.

```
Set-UMDialPlan -Identity MyUMDialPlan -AllowedInCountryOrRegionGroups InCountry/R
```

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you enable dialing restrictions on a UM dial plan, you may also want to:

- Create a Dialing Rule Entry on a UM Dial Plan
- Configure Dialing Rule Groups on a UM Dial Plan

1.9.2.3.2.29 Enable Custom Prompt Recording Using the Telephone User Interface

Enable Custom Prompt Recording Using the Telephone User Interface

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to record custom prompts and greetings for Unified Messaging (UM) dial plans and auto attendants using the telephone user interface (TUI). This can be useful when you can't create and edit a custom prompt or a greeting by using a computer, when you don't have access to a Unified Messaging server, or when there's an emergency such as an organization closure because of severe weather.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the Shell to enable a custom prompt or greeting recording using the TUI

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example enables you to manage custom prompt recording using the telephone user interface. You can record custom prompts and greetings by using the TUI if you follow these steps:

1. Create a domain user account that cannot log on interactively.
2. Delegate the Exchange Organization Administrator role to the domain user account.
3. Create an Exchange mailbox for the domain user.
4. Enable the domain user's mailbox for Unified Messaging.

Important:
Allow only those administrators who are managing prompts and greetings

access to the extension number and PIN for the domain user account. Use this domain user account only for managing prompts over the telephone.

5. Create a .wav file to be used for the custom greeting for the UM dial plan or auto attendant. Save the .wav file and upload it to a Unified Messaging server.
6. Run the following cmdlet:

```
Set-UMDialPlan -identity MyUMDialPlan -TUIPromptEditingEnabled $true
```

Note:
You must log on using the account that you'll use so that the mailbox is set up. If you don't first log on to the user's mailbox, you must log off and log back on to the system before you can hear the correct prompts and greetings when you use the TUI.

Perform TUI prompt provisioning on a UM auto attendant

1. Call the phone number that's been configured on the UM auto attendant.
2. While the welcome greeting for the auto attendant is being played, press the # key, then press the * key.
3. You'll be prompted to enter an extension number. Enter the extension number of the UM-enabled user who has permission to perform TUI prompt provisioning.
4. You'll be prompted for a PIN. Enter the user's PIN.

Perform TUI prompt provisioning on a UM dial plan

1. Call a pilot or subscriber access number you use to log on to Outlook Voice Access.
2. While the welcome greeting is being played, press the # and * keys.
3. If you're calling from a phone that's being used by a UM-enabled user, you'll be prompted for a PIN. Instead of entering the PIN, press the * key. You'll be prompted for an extension number.
4. If you're calling from a phone that's not used by a UM-enabled user, you'll automatically be prompted for an extension number. Enter the extension number of the UM-enabled user who has permission to perform TUI prompt provisioning.
5. You'll be prompted for a PIN. Enter the user's PIN.

For more information about syntax and parameters, see Set-UMDialplan.

Other Tasks

After you enable a custom prompt or greeting recording using the TUI, you may also want to:

- Enable a Custom Welcome Greeting on a UM Dial Plan
- Enable a Custom Business Hours Welcome Greeting on a UM Auto Attendant

1.9.2.3.2.30 Import and Export Custom Prompts for Unified Messaging

Import and Export Custom Prompts for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can import custom prompts into a system mailbox or export custom prompts from system mailboxes that are used with Unified Messaging (UM) dial plans and auto attendants in Microsoft Exchange Server 2010. Custom prompts are audio files used by Unified Messaging and include the following:

- UM dial plans: Customized welcome greetings and informational announcements.
- UM auto attendants: Customized after hours welcome greetings and menus, informational announcements, business hours and non-business hours welcome greetings and menus, and key mappings.

Custom prompts can be imported and exported by using the new cmdlet **Import-UMPrompt** and **Export-UMPrompt** cmdlets. The Microsoft Exchange Server 2007 Unified Messaging cmdlet **Copy-UMCustomPrompt** isn't supported in Exchange 2010 Unified Messaging for copying custom prompts.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.

Use the Shell to import custom prompts for UM dial plans and auto attendants

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM prompts" entry in the Unified Messaging Permissions topic.

This example imports the welcome greeting file welcomegreeting.wav from d:\UMPrompts into the UM dial plan `MyUMDialPlan`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts\welcomegreeting.wav" -Encoding Byte
Import-UMPrompt -UMDialPlan MyUMDialPlan -PromptFileName "welcomegreeting.wav" -P
```

This example imports the welcome greeting file welcomegreeting.wav from d:\UMPrompts into the UM auto attendant `MyUMAutoAttendant`.

```
[byte[]]$c = Get-content -Path "d:\UMPrompts\welcomegreeting.wav" -Encoding Byte
Import-UMPrompt -UMAutoAttendant MyUMAutoAttendant -PromptFileName "welcomegreeti
```

For more information about syntax and parameters, see Import-UMPrompt.

Use the Shell to export custom prompts from UM dial plans and auto attendants

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM prompts" entry in the Unified Messaging Permissions topic.

This example exports the welcome greeting for the UM dial plan MyUMDialPlan and saves it as the file welcomegreeting.mp3.

```
$prompt = Export-UMPrompt -PromptFileName "customgreeting.mp3" -UMDialPlan MyUMDi
set-content -Path "d:\DialPlanPrompts\welcomegreeting.mp3" -Value $prompt.AudioDa
```

This example exports the business hours welcome greeting used for the UM auto attendant MYUMAutoAttendant and saves it as the file BusinessHoursWelcomeGreeting.mp3.

```
$prompt = Export-UMPrompt -BusinessHoursWelcomeGreeting -UMAutoAttendant MyUMAuto
set-content -Path "d:\UMPrompts\BusinessHoursWelcomeGreeting.mp3" -Value $prompt.
```

For more information about syntax and parameters, see Export-UMPrompt.

Other Tasks

After you import and export custom prompts for UM dial plans and auto attendants, you may also want to:

- View or Configure the Properties of a UM Dial Plan
- View or Configure the Properties of a UM Auto Attendant
- Enable Custom Prompt Recording Using the Telephone User Interface

1.9.2.3.2.31 Import Custom Prompts from Exchange 2007 to Exchange 2010

Import Custom Prompts from Exchange 2007 to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the MigrateUMCustomPrompts.ps1 script to migrate a copy of all Microsoft Exchange Server 2007 Unified Messaging (UM) custom prompts to Exchange 2010 Unified Messaging. This includes all custom prompts in all Exchange 2007 UM dial plans and UM auto attendants. By default, the MigrateUMCustomPrompts.ps1 script is located in the *<Program Files>\Microsoft\Exchange Server\V14\Scripts* folder on a UM server running Microsoft Exchange Server 2010 Service Pack 1 (SP1).

System mailboxes are created when you install Exchange 2010 to support features such as message approval, and are also used in Exchange 2010 Unified Messaging to store dial plan and auto attendant custom prompts and Unified Messaging reports. You can import custom prompts from Exchange 2007 Unified Messaging into an Exchange 2010 system mailbox that's used with Unified Messaging dial plans and auto attendants in Exchange 2010. Custom prompts are audio files that are used by Unified Messaging, and include the following:

- UM dial plans: Customized welcome greetings and informational announcements.
- UM auto attendants: Customized after-hours welcome greetings and menus, informational announcements, business hours and non-business hours welcome greetings and menus, and key mappings.

Custom prompts can also be imported individually by using the cmdlet **Import-UMPrompt**. The Exchange 2007 Unified Messaging cmdlet **Copy-UMCustomPrompt** isn't supported for copying custom prompts in Exchange 2010 Unified Messaging.

Note:
The MigrateUMCustomPrompts.ps1 script is included with Exchange 2010 SP1. It must be run on an Exchange 2010 Unified Messaging server that has SP1 installed in the same organization with your Exchange 2007 UM servers.

Looking for other management tasks related to UM dial plans? Check out Managing UM Dial Plans.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM auto attendant has been created. For detailed steps, see Create a UM Auto Attendant.
- A custom prompt publishing point exists for the UM dial plans and UM auto attendants for the Exchange 2007 Unified Messaging servers.
- Custom prompts for UM dial plans and UM auto attendants have been created and saved in the custom prompt publishing point.

Use the MigrateUMCustomPrompts.ps1 script to migrate a copy of all custom prompts for UM dial plans and auto attendants

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM prompts" entry in the Unified Messaging Permissions topic.

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010** > **Exchange Management Shell**.
2. In the Shell, at the prompt, type the path to the script. For example, type **cd "D:\Program Files\Microsoft\Exchange Server\V14\Scripts"**, and then press Enter.
3. At the Shell prompt, type **".\MigrateUMCustomPrompt"**, and then press Enter.

For more information about syntax and parameters, see Import-UMPrompt.

Other Tasks

After you import custom prompts for UM dial plans and auto attendants, you may also want to:

- View or Configure the Properties of a UM Dial Plan
- View or Configure the Properties of a UM Auto Attendant
- Enable Custom Prompt Recording Using the Telephone User Interface
- Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging
- Import and Export Custom Prompts for Unified Messaging

1.9.2.3.3 Managing UM Mailbox Policies

Managing UM Mailbox Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-18*

Create a UM Mailbox Policy

Set the Voice Mail Preview Partner ID on a UM Mailbox Policy

Set the Maximum Message Duration for a Voice Mail Preview Partner on a UM Mailbox Policy

Set the Maximum Delivery Delay for a Voice Mail Preview Partner on a UM Mailbox Policy

1.9.2.3.3.1 Create a UM Mailbox Policy

Create a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can create a Unified Messaging (UM) mailbox policy to apply a common set of UM policy settings, such as PIN policy settings or dialing restrictions, to a collection of UM-enabled mailboxes. UM mailbox policies link a UM-enabled user with a UM dial plan and apply a common set of policies or security settings to a collection of UM-enabled mailboxes. UM mailbox policies are useful for applying and standardizing UM configuration settings for UM-enabled users.

By default, when a UM dial plan is created, a UM mailbox policy is also created. However, there are other times that you may have to create additional UM mailbox policies or modify existing UM mailbox policies after you deploy Unified Messaging in your Microsoft Exchange Server 2010 organization.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

What Do You Want to Do?

- Use the EMC to create a UM mailbox policy
- Use the Shell to create a UM mailbox policy

Use the EMC to create a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. In the action pane, click **New UM Mailbox Policy**.
4. In the New UM Mailbox Policy wizard, complete the following fields:
   - **Name** Use this text box to specify a unique name for the UM mailbox policy. This is a display name that appears in the EMC. If you must change the display name of the UM mailbox policy after it's been created, you must first delete the existing UM mailbox policy, and then create another UM mailbox policy that has the appropriate name. To delete the UM mailbox policy, there must not be any UM-enabled users who are associated with the UM mailbox policy.

     The UM mailbox policy name is required, but it is used for display purposes only. Because your organization may use multiple UM mailbox policies, we recommend that you use meaningful names for your UM mailbox policies. The maximum length of a UM mailbox policy name is 64 characters, and it can include spaces. However, it cannot include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Select associated dial plan** Click **Browse** to select the UM dial plan that will be associated with the UM mailbox policy. You must associate a UM mailbox policy with at least one UM dial plan. A single UM mailbox policy must be associated with at least one UM dial plan. However, you can also associate multiple UM mailbox policies with a single dial plan.
5. On the **Completion** page, confirm whether the UM mailbox policy was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM Mailbox Policy wizard.

Use the Shell to create a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example creates a UM mailbox policy named `MyUMMailboxPolicy` associated with a UM dial plan named `MyUMDialPlan`.

```
New-UMMailboxPolicy -Name MyUMMailboxPolicy -UMDialPlan MyUMDialPlan
```

For more information about syntax and parameters, see New-UMMailboxPolicy.

Other Tasks

After you have created a Unified Messaging Mailbox Policy, you may also want to:

- Configuring PIN Security for a UM-Enabled User
- Configure a UM-Enabled User's TUI Settings
- Enable a User for Unified Messaging

For More Information

Understanding Unified Messaging Mailbox Policies

1.9.2.3.3.2 View or Configure the Properties of a UM Mailbox Policy

View or Configure the Properties of a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you create a Unified Messaging (UM) mailbox policy, you can view and configure a variety of settings. For example, you can configure Unified Messaging features like Voice Mail Preview or Play on Phone and other security-related options such as Protected Voice Mail and PIN policy settings.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

What Do You Want to Do?

- Use the EMC to view or configure UM mailbox policy properties
- Use the Shell to configure UM mailbox policy properties
- Use the Shell to view UM mailbox policy properties

Use the EMC to view or configure UM mailbox policy properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab, and then select the UM mailbox policy that you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view and configure settings for a UM mailbox policy. For example, you can view the dial plans associated with the UM mailbox policy or disable missed call notifications for users who are associated with a specific UM mailbox policy.

When you modify the settings on a UM mailbox policy, the settings are applied to all users who are associated with the UM mailbox policy. UM mailbox policies let you apply a common set of settings to a collection or group of mailboxes. You must create a UM mailbox policy before you can enable users for Unified Messaging. You can view or configure the following:

- **Associated UM dial plan** Displays the name of the dial plan associated with the UM mailbox policy. This is the name of the dial plan displayed in the Shell.

  When a new UM mailbox policy is created, it must be associated with a dial plan. After the UM mailbox policy is created and associated with a dial plan, the settings defined on the mailbox policy are applied to the users who are associated with the dial plan. By default, when you create a UM dial plan using the Shell, it will also create a UM mailbox policy.

  A UM mailbox policy can't be changed after it's associated with a dial plan.
- **Modified** Displays the date of the last modification or change made to the UM mailbox policy.
- **Maximum greeting duration (minutes)** Use this text box to enter the maximum number of minutes that users who are associated with the UM mailbox policy can use when they record their voice mail greeting. You can modify this setting after the UM mailbox policy is created. Only numeric characters are allowed. The valid range for the greeting is from 1 through 10 minutes. The default setting is 5 minutes.
- **Allow missed call notifications** Select this check box to enable or disable missed call notifications for users associated with the UM mailbox policy.

  A missed call notification is an e-mail message sent to a user's mailbox when the user doesn't answer an incoming call. This is a different e-mail message than the e-mail message that contains the voice mail message left for a user.

  Typically, when a user misses an incoming call, the user receives two e-mail messages: an e-mail message that contains the voice mail message and a missed call notification message.

  By default, missed call notifications are enabled when a UM mailbox policy is created.
- **Allow Message Waiting Indicator** Select this check box to enable or disable Message Waiting Indicator for users associated with the UM mailbox policy. Message Waiting Indicator is a feature found in most legacy voice mail systems. In its most common form, it lights a lamp on the voice mail subscriber’s phone to indicate the presence of a new voice mail. Message Waiting Indicator can also be a text message sent to the UM-enabled user's mobile phone. If this option is disabled on the UM IP gateway, this feature isn't available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange 2007 server. The default setting is enabled.
- **Allow inbound faxes** Select this check box to enable or disable inbound faxes for users associated with the UM mailbox policy. By default, when you enable users for Unified Messaging, they can receive faxes. However, there may be situations when users can't receive faxes, because the ability to receive faxes has been disabled on their mailbox. If this option is disabled on the UM dial plan, UM-enabled users associated with the UM mailbox policy won't be able to receive faxes. The default setting is disabled.

  After you have enabled the **Allow inbound faxes** setting, you will need to specify the URI for the partner fax server. If the Unified Messaging mailbox policy is associated with UM servers that use TCP and TLS, you will need to enter URIs for both TCP and TLS.
- **Allow Voice Mail Preview** Select this check box to enable or disable the Voice Mail Preview feature for users associated with the UM mailbox policy.

Enabling this setting allows users to receive the text of a voice mail in the message body of an e-mail or text message. If this option is disabled on the UM dial plan, this feature won't be available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 Unified Messaging server. The default setting is enabled.

- **Allow Outlook Voice Access** Select this check box to enable or disable access to Outlook Voice Access for UM-enabled users who are associated with this UM mailbox policy. Outlook Voice Access is a feature used by UM-enabled users to access their Exchange 2007 or Exchange 2010 mailbox over a phone. By default, this setting is enabled.
- **Allow Play on Phone** Select this check box to enable or disable the Play on Phone feature for users associated with the UM mailbox policy. This option is enabled by default and allows users to play their voice mail messages over a phone. The phone can be any phone, including an office or mobile phone. This option isn't available to UM-enabled users who have a mailbox on an Outlook 2007 Unified Messaging server.
- **Allow users to configure call answering rules** Select this check box to allow users who are associated with the UM mailbox policy to create call answering rules. If this option is disabled on the UM dial plan, this feature won't be available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 Unified Messaging server. The default setting is enabled.

5. Use the **Message Text** tab to configure message text settings for users who are associated with a UM mailbox policy. For example, you can specify the e-mail message text sent to users after they reset their UM PIN. You can configure the following:
   - **Text sent when a UM Mailbox is enabled** The text entered in this text box appears in the e-mail message sent to users when they are enabled for Unified Messaging. When a recipient's mailbox is enabled for Unified Messaging, an e-mail message that welcomes the user to Unified Messaging is sent to the user. This text box is limited to 512 characters. By default, no text is defined in this text box.

     This welcome message contains welcome text and the PIN information that the user will use to access the Unified Messaging system. The text entered in this text box is included at the bottom of this welcome message. You can use this text box to include information such as the Unified Messaging technical support telephone numbers or subscriber access numbers.

     If text isn't entered in this text box, the default text generated by the Unified Messaging system is included in the e-mail message.

     The text that you provide in this text box can be plain. It can also contain simple HTML formatting tags if you want to emphasize text or add hyperlinks to other content.

     Example 1 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200.

     Example 2 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200 or visit our Web site at .
   - **Text sent when a PIN is reset** The text entered in this text box is included in the e-mail message sent to UM-enabled users when their UM PIN is reset.

     A PIN is reset by the Unified Messaging system if the number of failed logon attempts exceeds 10 (by default) or if users reset their PIN using the Unified Messaging features included with

Microsoft Office Outlook 2007, Exchange 2010, Outlook Web App, or Outlook Voice Access from a telephone. You can use this text box to include information such as security notices or other security-related information in the e-mail message.
If text isn't entered in this text box, the default text generated by the Unified Messaging system is included in the e-mail message.
This text box is limited to 512 characters. By default, no text is defined in this text box.
The text that you provide in this text box can be plain. It can also contain simple HTML formatting tags if you want to emphasize text or add hyperlinks to other content.
Example 1 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200.
Example 2 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200 or visit our Web site at .

- **Text included with a voice message** The text entered in this text box is included in the e-mail message sent to users when they receive a voice mail message from an incoming caller. For example, this text can include disclaimers that contain information about forwarding voice mail messages or system security policies that describe the correct way to handle voice mail messages in your organization.
  If text isn't entered in this text box, the default text generated by the system is included in the e-mail message. This text box is limited to 512 characters. By default, no text is defined in this text box.
  The text that you provide in this text box can be plain. It can also contain simple HTML formatting tags if you want to emphasize text or add hyperlinks to other content.
  Example 1 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200.
  Example 2 If you have any questions or suggestions about voice mail service, please call the help desk at extension 4200 or visit our Web site at .
- **Text included with a fax message** The text entered in this text box is included in the e-mail message sent to users when they receive an incoming fax message in their Inbox. You can use this text box to include disclaimers that contain information about forwarding fax messages or other system security policies about the correct way to handle fax messages in your organization.
  If text isn't entered in this text box, the default text generated by the system is included in the e-mail message. This text box is limited to 512 characters. By default, no text is defined in this text box.

6. Use the **PIN Policies** tab to configure PIN settings for users who are associated with a UM mailbox policy. Unified Messaging PINs enable users to access their Inboxes by using a telephone. By configuring settings on this page, you can specify the minimum number of digits for a UM PIN or the number of failed logon attempts before users are locked out of their UM mailbox.
   Make sure that you plan carefully for the UM PIN policies that you implement in your environment. If you don't plan and implement the appropriate UM PIN policies, you may introduce security threats and mistakenly allow unauthorized access to your network. You can configure the following:
   - **Minimum PIN length** Use this text box to specify the minimum number of digits that a UM user's PIN can contain. The default setting is six digits. The

range is from 4 through 24 numeric digits. This setting can't be disabled.

Increasing the number of digits required for a PIN increases the level of security for your Unified Messaging system. Decreasing the number of digits required for a PIN reduces the level of security for your network. The fewer the digits that are required in a PIN, the easier it is for a potential attacker to guess a user's PIN.

If this setting is set too high, users might have problems remembering their PINs. However, if the setting is too low, you risk unauthorized access to the Unified Messaging system.

- **PIN lifetime (days)** Use this text box to configure the number of days until the UM-enabled user's PIN expires. After the PIN expires, the user must create a new UM PIN. For most organizations, this value should be set to the default of 60 days.

  The value of this setting can be from 0 through 999. If it's set to 0, PINs never expire. Setting this value too low can frustrate users because they are required to create and memorize new PINS too frequently.
- **Number of previous PINs to disallow** Use this setting to set the number of unique PINs that users must use before they can reuse an old PIN. For most organizations, this value should be set to the default of 5, the number of PINs that the system will remember. PIN history can't be disabled.

  You can set this value from 1 through 20. Setting this value too high can frustrate users because it can be difficult to memorize many PINs. Setting it too low may introduce a security threat to your network.
- **Allow common patterns in PIN** Use this setting to set PIN complexity requirements for Unified Messaging. These complexity requirements are enforced on PIN changes or when new PINs are created.

  If this option is disabled, sequential and repeated numbers and the suffix of the mailbox extension will be rejected. If this option is enabled, only the suffix of the mailbox extension will be rejected.

  As a security best practice, we recommend that you disable this setting. If this setting is disabled, user PINs can't contain the following:

  Sequential numbers, such as 123456 or 456789.

  Repeated numbers, such as 111111 or 8888888.

  Suffix of the mailbox extension.
- **Number of incorrect PIN entries before PIN is automatically reset** Use this text box to enter the number of sequential unsuccessful or failed logon attempts that can occur before the Unified Messaging system automatically resets a user's PIN. For most organizations, this value should be set to the default of 5 attempts.

  The value of this setting can be from 0 through 999. If it's set to 0, this setting is disabled and the system won't automatically reset users' PINs. Setting this value too low can frustrate users; setting it too high gives malicious users more attempts to determine the PIN.

  This setting must be set to a number lower than the number configured in the **Number of incorrect PIN entries before UM mailbox is locked out** setting. This setting is designed to help prevent a brute force attack on user PINs.
- **Number of incorrect PIN entries before UM mailbox is locked out** Use this text box to enter the maximum number of sequential unsuccessful or failed logon attempts before users are locked out of their mailbox.

  For example, if a user tries to log on to the mailbox unsuccessfully five times, based on the **Failed logon attempts before automatic PIN reset** setting, the system will reset the

user's PIN. If the user tries to use the new PIN five more times unsuccessfully, the system will again reset the PIN. If the user tries to use this new PIN five more times unsuccessfully, the user is then locked out of the mailbox. After a user is locked out, an administrator must manually reset or unlock the mailbox for the user.
This value can be set from 1 through 999. Setting this value too low can frustrate users; setting it too high gives malicious users more attempts to determine the PIN. For most organizations, this value should be set to the default of 15 attempts.
This number must be greater than the number set in the **Number of incorrect PIN entries before PIN is automatically reset** setting. This setting is designed to help prevent a brute force attack on user PINs.

7. Use the **Dialing Restrictions** tab on the UM mailbox policy properties to configure dialing rules for UM-enabled users who are associated with this UM mailbox policy. UM mailbox policies are required to enable users for Unified Messaging. They are useful for applying and standardizing Unified Messaging configuration settings for UM-enabled users. You can create UM mailbox policies to apply a common set of policies or security settings to a collection of UM-enabled mailboxes.
   You can use these settings to control the extension numbers that can be reached by UM-enabled users who are associated with the UM mailbox policy or to control the telephone numbers that can be dialed by UM-enabled users who are associated with the UM mailbox policy. You can configure the following:
   - **Allow calls to users within the same dial plan** Select this check box to allow UM-enabled users who call in to a subscriber access number configured on a dial plan and successfully log on to their mailbox to place calls or transfer to users who have extension numbers associated with another UM-enabled user within the same dial plan. By default, this setting is enabled.
     When you disable this setting, UM-enabled users who call in to a subscriber access number configured on a dial plan and successfully log on to their mailbox can place calls or transfer calls to users who aren't UM-enabled or to other extension numbers not associated with a UM-enabled user. However, they can't transfer to UM-enabled users who are within the same dial plan. This is because the **Allow calls to extensions** setting is enabled by default.
   - **Allow calls to extensions** When this setting is enabled, users who call in to a subscriber access number configured on a dial plan and successfully log on to their mailbox can place calls to users who aren't UM-enabled, to other extension numbers not associated with a UM-enabled user, and to UM-enabled users within the same dial plan. This is because the **Allow calls to users within the same dial plan** setting is enabled by default.
     When this setting is disabled, users who call in to a subscriber access number configured on a dial plan and successfully log on to their mailbox can't place calls to users who aren't UM-enabled or to other extension numbers not associated with a UM-enabled user. However, they can place calls or transfer calls to extension numbers associated with UM-enabled users. This is because the **Allow calls to users within the same dial plan** setting is enabled by default. The **Allow calls to extensions** setting is enabled by default.
     You can enable this setting in an environment where not all users have been UM-enabled. This setting is also useful when you want to allow users who call in to a subscriber access number configured on a dial plan to call extension numbers not

associated with a UM-enabled user.

- **Select allowed in-country/region rule groups from dial plan** Use this section to add or remove allowed in-country/region dialing rule groups. By default, there are no in-country/region dialing rule groups configured on UM mailbox policies.

  In-country/region dialing rule groups are used to allow or restrict the telephone numbers within a country or region that Outlook Voice Access users can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.
  To add in-country/region dialing rule groups, you must first create the appropriate in-country/region dialing rule groups on the dial plan associated with the UM mailbox policy, and then add the appropriate dialing rule entries on the dialing rule group. After you create the required dialing rule groups on the dial plan, you must then add the dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the UM mailbox policy.
  In-country/region dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers within a country or region. This is applied to Outlook Voice Access users who have called in to a subscriber access number.
- **Select allowed international rule groups from dial plan** Use this section to add or remove allowed international dialing rule groups. By default, there are no international dialing rule groups configured on UM mailbox policies.

  To add international dialing rule groups, you must first create the appropriate international dialing rule groups on the dial plan associated with the UM mailbox policy, and then add the appropriate dialing rule entries on the dialing rule group. After you create the required dialing rule groups, you must add the dialing rule groups to the dialing restrictions on the UM mailbox policy.
  International dialing rule groups can be used to enable a Unified Messaging server to allow or restrict access to telephone numbers outside a country or region. This is applied to Outlook Voice Access users who have called in to a subscriber access number.
  International dialing rule groups are used to allow or restrict the telephone numbers outside a country or region that Outlook Voice Access users can dial. This helps prevent unnecessary or unauthorized telephone calls and charges.

8. Use the **Protected Voice Mail** tab to configure the following settings:
   - **Protect voice messages from unauthenticated callers** Select one of the following options from the drop-down list to determine whether an incoming call answered by a Unified Messaging server will protect voice messages. This setting applies to voice messages sent to UM-enabled users when they don't answer their phone. This setting also applies to voice messages sent directly to UM-enabled users when the caller uses a UM auto attendant. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 Unified Messaging server. You can configure the following:

     None Use this setting to not have protection applied to any voice messages sent to UM-enabled users.
     Private Use this setting when you want the Unified Messaging server to apply protection only to voice messages that have been marked as private by the caller.
     All Use this setting when you want the Unified Messaging server to apply protection to all voice messages including those

not marked as private.

- **Protect voice messages from authenticated callers** Select one of the following options from the drop-down list to determine whether an incoming call answered by a Unified Messaging server will protect voice messages. This setting applies to voice messages sent to UM-enabled users when they don't answer their phone. This setting also applies when callers log on to their mailbox using Outlook Voice Access, and then create and send a voice message. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 Unified Messaging server. You can configure the following:
  None Use this setting to not have protection applied to any voice messages sent to UM-enabled users.
  Private Use this setting when you want the Unified Messaging server to apply protection only to voice messages that have been marked as private by the caller.
  All Use this setting when you want the Unified Messaging server to apply protection to all voice messages including those not marked as private.
- **Allow multimedia playback of protected voice messages** Select this check box if you want to force users who receive protected voice messages to use the Play on Phone feature. Or, if the client software doesn't support rights management, users must use Outlook Voice Access. The Play on Phone feature only applies to clients using a version of Outlook that supports rights management. For Outlook 2007 and earlier versions that don't support rights management, and for Outlook Web App clients, Outlook Voice Access is the only way that users can listen to Protected Voice Mail.
  The default setting requires all users associated with the UM mailbox policy to use the Play on Phone feature to listen to voice messages that are protected. By doing this, it prevents other people from hearing the voice message using a media player over computer speakers or using a media player on a mobile phone to hear the voice message. Even if this is enabled, a UM-enabled user can still use Outlook Voice Access to hear the Protected Voice Mail.
  This is especially useful when UM-enabled users use public computers, laptops in public places, or their mobile phone's media player to listen to Protected Voice Mail that can contain private information. This option isn't available to UM-enabled users who have a mailbox on an Exchange 2007 Unified Messaging server.
- **Specify the text to display to voice mail recipients who have e-mail clients that don't support Windows Rights Management** Protected Voice Mail can only be accessed by e-mail clients that support Information Rights Management (IRM), or if a UM-enabled user uses Outlook Voice Access to access the Protected Voice Mail message.
  If a Protected Voice Mail is sent to an e-mail client that doesn't support IRM, the text that you include in this box will be sent to the user in an e-mail message. This information should include instructions about what to do to be able to receive the Protected Voice Mail.

Use the Shell to configure UM mailbox policy properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the PIN settings for users who are associated with a UM mailbox policy named MyUMMailboxPolicy.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 8 -M
```

This example selects the in-country or region groups and international groups from those configured on the UM dial plan associated with the UM mailbox policy. UM-enabled users associated with this UM mailbox policy will be able to place outbound calls according to the rules defined on these groups.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowDialPlanSubscribers $true -
```

This example configures the text of voice messages sent to UM-enabled users and the text included in an e-mail sent to a user who has been UM-enabled.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -UMEnabledText "You have been ena
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Use the Shell to view UM mailbox policy properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example returns a formatted list of all UM mailbox policies in the Active Directory forest.

```
Get-UMMailboxPolicy | Format-List
```

This example returns the properties and values for a UM mailbox policy named MyUMMailboxPolicy.

```
Get-UMMailboxPolicy -Identity MyUMMailboxPolicy
```

For more information about syntax and parameters, see Get-UMMailboxPolicy.

Other Tasks

After you configure settings on a UM mailbox policy, you may also want to configure PIN security. For details, see Configuring PIN Security for a UM-Enabled User.

For More Information

Understanding Unified Messaging Mailbox Policies

Understanding Outdialing

1.9.2.3.3.3 Delete a UM Mailbox Policy

Delete a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can delete or remove a Unified Messaging (UM) mailbox policy. When you delete a UM mailbox policy, the UM mailbox policy will no longer be available to be associated to the Microsoft Exchange Server 2010 recipients who are newly enabled for Unified Messaging. However, the UM mailbox policy can't be deleted if it's referenced by any UM-enabled mailboxes.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to delete a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. Click to highlight the UM mailbox policy you want to delete.
4. In the action pane, click **Remove**.
5. In the confirmation dialog box, click **Yes**.

Use the Shell to delete a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example deletes a UM mailbox policy named `MyUMMailboxPolicy`.

```
Remove-UMMailboxPolicy -Identity MyUMMailboxPolicy
```

For information about syntax and parameters, see the Remove-UMMailboxPolicy reference topic.

Other Tasks

After you delete a UM mailbox policy, you may also want to Create a UM Mailbox Policy.

Configure the Maximum Greeting Duration on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Maximum greeting duration setting enables you to enter the maximum number of minutes that users associated with the UM mailbox policy can use to record their voice mail greetings. This setting applies to both their standard voice mail and their Out of Office voice mail greetings. By default, the maximum greeting duration is set to 5 minutes. However, you can configure the maximum meeting duration to any setting between 1 and 10 minutes.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to change the maximum greeting duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, next to **Maximum greeting duration (minutes)**, enter the time, in minutes, for the maximum greeting duration for your UM users.
4. Click **OK** to save your changes.

Use the Shell to change the maximum greeting duration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example configures the maximum greeting duration on the UM mailbox policy `MyUMMailboxPolicy` to 3 minutes.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy MaxGreetingDuration 3
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

- After you change the maximum greeting duration, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.5 Enable or Disable Missed Call Notifications on a UM Mailbox Policy

Enable or Disable Missed Call Notifications on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable missed call notifications for a Unified Messaging (UM) mailbox policy in Microsoft Exchange Server 2010. A missed call notification is an e-mail message that's sent to a user's mailbox when the user doesn't answer an incoming call. This is a different e-mail message than the e-mail message that contains the voice message that's left for a user.

When you disable missed call notifications on a UM mailbox policy, you prevent all users associated with the UM mailbox policy from receiving an e-mail message when they don't answer an incoming call. By default, missed call notifications are enabled with each UM mailbox policy that's created.

Note:

By default, a UM mailbox policy is created every time you create a UM dial plan.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable missed call notifications for a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.

3. Select the UM mailbox policy that you want to change, and then, in the action pane, click **Properties**.
4. On the UM mailbox policy **Properties** page, click the **General** tab.
5. To enable missed call notifications, select the check box next to **Allow missed call notifications**.
6. To disable missed call notifications, clear the check box next to **Allow missed call notifications**.
7. Click **OK** to save your changes.

Use the Shell to enable or disable missed call notifications for a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example enables missed call notifications for a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowMissedCallNotifications $tr
```

This example disables missed call notifications for a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowMissedCallNotifications $fa
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable missed call notifications for a UM mailbox policy, you may also want to:

- Enable or Disable Message Waiting Indicator on a UM Mailbox Policy
- Allow or Prevent Message Waiting Indicator on a UM IP Gateway

Enable or Disable Message Waiting Indicator on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable the Message Waiting Indicator for users associated with a Unified Messaging (UM) mailbox policy. Message Waiting Indicator is a feature found in most legacy voice mail systems. In its most common form, it lights a lamp on a voice mail subscriber's phone to indicate the presence of a new voice mail message. Message Waiting Indicator can also be a text message sent to a UM-enabled user's mobile phone. The default setting is enabled.

If this option is disabled on the UM IP gateway, this feature isn't available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 server.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable Message Waiting Indicator

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow Message Waiting Indicator**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable Message Waiting Indicator

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example disables the Message Waiting Indicator for users associated with the UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowMessageWaitingIndicator $fa
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you've enabled or disabled Message Waiting Indicator on a UM mailbox policy, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.7 Enable or Disable Inbound Faxing on a UM Mailbox Policy

Enable or Disable Inbound Faxing on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable inbound faxes for users associated with a Unified Messaging (UM) mailbox policy. By default, when you enable users for Unified Messaging, this option is selected but users can't receive fax messages until you specify the URI for the fax partner server and deploy a fax partner server for your organization. If the Unified Messaging mailbox policy is associated with UM servers that use TCP and TLS, you'll need to enter URIs for both TCP and TLS. If the option to allow incoming faxes is disabled on the UM dial plan, UM-enabled users associated with the UM mailbox policy won't be able to receive faxes.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable inbound faxing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow inbound faxes**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable inbound faxing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example allows users who are associated with the UM mailbox policy `MyUMMailboxPolicy` to use inbound faxing.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowFax $true
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable inbound faxing on a UM mailbox policy, you may also want to

View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.8 Enable or Disable Voice Mail Preview on a UM Mailbox Policy

Enable or Disable Voice Mail Preview on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable the Voice Mail Preview feature for users associated with the Unified Messaging (UM) mailbox policy. Enabling this setting allows users to receive the text of a voice mail in the message body of an e-mail or text message. If this option is disabled on the UM dial plan, Voice Mail Preview won't be available to UM-enabled users associated with the UM mailbox policy. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 Unified Messaging server. The default setting is enabled.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable Voice Mail Preview

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow Voice Mail Preview**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable Voice Mail Preview

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example prevents users who are associated with the UM mailbox policy `MyUMMailboxPolicy` from using the Voice Mail Preview feature.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy - AllowVoiceMailPreview $false
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable Voice Mail Preview on a UM mailbox policy, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.9 Enable or Disable Outlook Voice Access on a UM Mailbox Policy

Enable or Disable Outlook Voice Access on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable access to Outlook Voice Access for UM-enabled users who are associated with a Unified Messaging (UM) mailbox policy. Outlook Voice Access is a feature used by UM-enabled users to access their Microsoft Exchange Server 2007 or Exchange Server 2010 mailbox over a phone. By default, this setting is enabled.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable Outlook Voice Access

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow Outlook Voice Access**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable Outlook Voice Access

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example prevents users who are associated with the UM mailbox policy MyUMMailboxPolicy from using Outlook Voice Access.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowSubscriberAccess $false
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable Outlook Voice Access on a UM mailbox policy, you may also want to:

- View or Configure the Properties of a UM Mailbox Policy
- Enable or Disable Play on Phone on a UM Mailbox Policy

1.9.2.3.3.10 Enable or Disable Play on Phone on a UM Mailbox Policy

Enable or Disable Play on Phone on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable the Play on Phone feature for users associated with the Unified Messaging (UM) mailbox policy. This option is enabled by default and allows users to play their voice mail messages over a phone. The phone can be any phone, including an office or a mobile phone. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 server.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable Play on Phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox

policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow Play on Phone**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable Play on Phone

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example disables the Play on Phone feature for users who are associated with the UM mailbox policy `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowPlayOnPhone $false
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

- After you enable or disable Play on Phone on a UM mailbox policy, you may also want to:
- View or Configure the Properties of a UM Mailbox Policy
- Enable or Disable Voice Mail Preview on a UM Mailbox Policy
- Enable or Disable Outlook Voice Access on a UM Mailbox Policy

1.9.2.3.3.11 Enable or Disable Call Answering Rules on a UM Mailbox Policy

Enable or Disable Call Answering Rules on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can allow users who are associated with a Unified Messaging (UM) mailbox policy to create call answering rules, or prevent them from doing so. If the option to create call answering rules is disabled on a UM dial plan, the Call Answering Rules feature won't be available to UM-enabled users associated with the UM mailbox policy. The default setting is enabled.

Call Answering Rules aren't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 Unified Messaging server.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial

Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable call answering rules on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **General** tab, select or clear the check box next to **Allow users to configure call answering rules**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable call answering rules on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example prevents users who are associated with the UM mailbox policy `MyUMMailboxPolicy` from creating call answering rules.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -AllowCallAnsweringRules $false
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable call answering rules on a UM mailbox policy, you may also want to:

- View or Configure the Properties of a UM Mailbox Policy.
- Allow or Prevent Call Answering Rules on a UM Dial Plan

1.9.2.3.3.12 Include Text with the E-Mail Message Sent When a Mailbox Is UM-Enabled

Include Text with the E-Mail Message Sent When a Mailbox Is UM-Enabled

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When a user's mailbox is enabled for Microsoft Exchange Server 2010 Unified Messaging,

an e-mail message is sent that welcomes the user to Unified Messaging. This message contains the PIN information the user will use to access the Unified Messaging system.

You can customize the text that's sent in the welcome e-mail message by adding text in the **Text sent when a UM mailbox is enabled** box on a UM mailbox policy. You can include such information as the UM technical support telephone numbers or subscriber access numbers. After you add the text, it will be included in the e-mail message sent when users associated with the UM mailbox policy are enabled for Unified Messaging.

Note:
The limit for custom text you add to the welcome message is 512 characters.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to customize the text sent when a mailbox is enabled for Unified Messaging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the mailbox policy Properties page, on the **Message Text** tab, under **Text sent when a UM mailbox is enabled**, enter the text you want to send to the user when a UM mailbox is enabled.
4. Click **OK** to save your changes.

Use the Shell to customize the text sent when a mailbox is enabled for Unified Messaging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example enables UM-enabled users who are associated with a UM mailbox policy to receive additional instructions about UM and the Outlook Voice Access number that they can use to access their mailbox over a phone.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -UMEnabledText "You've been enabl
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you customize the text sent when a mailbox is enabled for Unified Messaging, you may also want to:

- Include Text with the E-Mail Message Sent When a PIN Is Reset
- Enable a User for Unified Messaging
- Configure the UM Mailbox Policy Assigned to a UM-Enabled User

1.9.2.3.3.13 Include Text with the E-Mail Message Sent When a PIN Is Reset

Include Text with the E-Mail Message Sent When a PIN Is Reset

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can include additional text in the e-mail message that's sent to users when their Unified Messaging (UM) PIN is reset. You can customize the e-mail message sent to users when their UM PIN is reset by including custom text in the **Text sent when a PIN is reset** box on the **Message Text** tab.

By default, a PIN is reset by the Unified Messaging system if the number of failed logon attempts exceeds 5. Users can also reset their PINs using the UM features included with Microsoft Office Outlook 2007, the version of Outlook Web App that's included with Microsoft Exchange Server 2010, or by using Outlook Voice Access from a telephone. The customized text can include, for example, security-related information for UM-enabled users.

Note:

The text you enter in this box is limited to 512 characters.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to add text to the e-mail message sent to users when their PIN is reset

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the mailbox policy Properties page, on the **Message Text** tab, under **Text sent when a PIN is reset**, enter the text you want to send to users when their UM PIN is reset.
4. Click **OK** to save your changes.

Use the Shell to add text to the e-mail message sent to users when their PIN is reset

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example includes the additional text, "Do not share your PIN with other users. Doing so may result in disciplinary action", in the e-mail message sent to users who are associated with the UM mailbox policy `MyUMMailboxPolicy` when their PIN is reset.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -ResetPINText "Do not share your
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you add text to the e-mail message sent to users when their PIN is reset, you may also want to:

- Configure the Number of Incorrect PIN Entries Before a PIN Is Reset on a UM Mailbox Policy
- Reset a Unified Messaging PIN for a UM-Enabled User

1.9.2.3.3.14 Include Text with the E-Mail Message Sent When a Voice Message Is Received

Include Text with the E-Mail Message Sent When a Voice Message Is Received

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can include additional text in the e-mail message that's sent when a voice mail message is received by users who are enabled for Microsoft Exchange Server 2010 Unified Messaging (UM). By default, the text that's included with a voice message indicates only that the caller has received a voice message. However, you can create a custom message by adding text in the **Text included with a voice message** text box on a UM mailbox policy. For example, the text can include information about system security policies and describe the correct way to handle voice messages in your organization. After

you add the text, it will be included in each e-mail message that's sent when UM-enabled users associated with the UM mailbox policy receive a voice message.

Note:
The custom text that accompanies a voice message is limited to 512 characters.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to change the text included with a voice message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the mailbox policy Properties page, on the **Message Text** tab, under **Text included with a voice message**, enter the text you want to send to users when they receive a voice message.
4. Click **OK** to save your changes.

Use the Shell to change the text included with a voice message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example includes the additional text, "Do not forward voice message to users outside this organization", with voice messages sent to users who are associated with the UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -VoiceMailText "Do not forward vo
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you change the text included with a voice message, you may also want toInclude Text with the E-Mail Message Sent When a Fax Message Is Received.

Include Text with the E-Mail Message Sent When a Fax Message Is Received

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can include additional text in the e-mail message that's sent when a fax message is received by users who are enabled for Microsoft Exchange Server 2010 Unified Messaging (UM) and are fax-enabled, and when the UM mailbox policy has been configured correctly to use a fax partner provider. By default, the text included when a UM-enabled user receives a fax message indicates only that the caller has received a fax message. However, you can create a custom message by adding text in the **Text included with a fax message** text box on a UM mailbox policy. For example, the text can include information about system security policies and describe the correct way to handle fax messages in your organization. After you add the text, it will be included in each e-mail message that's sent when UM-enabled users who are associated with the UM mailbox policy receive a fax message.

Note:

The custom text that accompanies a fax message is limited to 512 characters.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to change the text included with a fax message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. On the **UM Mailbox Policies** tab, select the UM mailbox policy that you want to manage, and then click **Properties** in the action pane.
3. On the mailbox policy Properties page, on the **Message Text** tab, under **Text included with a fax message**, enter the text that you want to send to users when they receive a fax message.
4. Click **OK** to save your changes.

Use the Shell to change the text included with a fax message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging

Permissions topic.

This example enables UM-enabled users who are associated with a UM mailbox policy to receive additional instructions on how to open a fax message that they've received in their mailbox.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -FaxMessageText "To open this fax
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you change the text included with a fax message, you may also want to:

- Enable or Disable Inbound Faxing on a UM Mailbox Policy
- Enable UM-Enabled Users to Receive Faxes on a UM Dial Plan

1.9.2.3.3.16 Configure the Minimum PIN Length on a UM Mailbox Policy

Configure the Minimum PIN Length on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the minimum PIN length for your mail-enabled recipients in Microsoft Exchange Server 2010 who are enabled for Unified Messaging (UM). The PIN settings that you configure on a UM mailbox policy will apply to all UM-enabled users associated with the UM mailbox policy.

Outlook Voice Access is used by UM-enabled users so that they can access their voice mail, e-mail, calendar, and personal contact information located in their Exchange 2010 mailbox. However, before they can access their mailbox, they must enter a PIN so they can be authenticated by the system.

Note:

If you make a change to the minimum PIN length value, existing subscribers will be prompted to enter a new PIN that contains the new minimum number of digits before they can continue.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure the minimum

PIN length

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. Select the UM mailbox policy you want to manage, and then, in the action pane, click **Properties**.
4. On the UM mailbox policy **Properties** page, on the **PIN Policies** tab, next to **Minimum PIN length**, enter a value between 4 and 24.
5. Click **OK** to save your changes

Use the Shell to configure the minimum PIN length

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the minimum PIN length to 8 digits for UM-enabled users who are associated with the UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -MinPINLength 8
```

This example sets the minimum PIN length to 8 digits and sets the number of times a sign-in can fail before the user's PIN is reset to 3. This applies to UM-enabled users who are associated with the UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 3 -M
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you configure the matched name selection method on a UM dial plan, you may also want to:

- Enable or Disable Common PIN Patterns on a UM Mailbox Policy
- Configure the PIN Lifetime on a UM Mailbox Policy
- Set PIN Policies for UM-Enabled Users

1.9.2.3.3.17 Configure the PIN Lifetime on a UM Mailbox Policy

Configure the PIN Lifetime on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the PIN lifetime for users who are enabled for Unified Messaging (UM). The PIN lifetime is the maximum time that an Outlook Voice Access PIN will be valid for your UM-enabled recipients in Microsoft Exchange Server 2010. The PIN lifetime setting is configured on a UM mailbox policy and applies to all UM-enabled users associated with the UM mailbox policy.

Several PIN-related settings can be configured on a UM mailbox policy. The PIN lifetime setting controls the time interval, in days, from the date Outlook Voice Access users last changed their PIN to the date they'll be forced to change their PIN again. The range is 0 through 999, and the default is 60 days. If you enter 0, the user's PIN won't expire. But we don't recommend that you configure this setting to 0. By configuring this setting to 0, you greatly reduce the security of your network.

Important:

Unified Messaging doesn't notify users when their PIN is about to expire.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure the PIN lifetime

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then, in the action pane, click **Properties**.
3. On the UM mailbox policy **Properties** page, click the **PIN Policies** tab.
4. On the **PIN Policies** tab, next to **PIN lifetime (days)**, enter a value between 0 and 999.
5. Click **OK** to save your changes.

Use the Shell to configure the PIN lifetime

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the number of days that a PIN can be used for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy` to 30.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -PINLifetime 30
```

This example configures the following PIN related settings for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy`:

- Sets the number of logon failures before the user's PIN is reset to 3
- Sets the maximum number logon attempts to 5
- Sets the minimum PIN length to 9 digits.
- Sets the PIN to expire in 40 days.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 3
-MaxLogonAttempts 5 -MinPINLength 9 -PINLifetime 40
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you configure the number of logon failures before a mailbox is locked out, you may also want to:

- Configure the Number of Previous PINs to Disallow on a UM Mailbox Policy
- Configure the Minimum PIN Length on a UM Mailbox Policy
- Set PIN Policies for UM-Enabled Users

1.9.2.3.3.18 Configure the Number of Previous PINs to Disallow on a UM Mailbox Policy

Configure the Number of Previous PINs to Disallow on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When Outlook Voice Access users dial in to a subscriber access number, they're prompted to enter their PIN so that the Unified Messaging (UM) system in Microsoft Exchange Server 2010 can authenticate them. After they're authenticated, they can access the voice mail, e-mail, calendaring, and personal contact information in their Exchange 2007 mailbox from any telephone.

Several PIN-related settings can be configured on a UM mailbox policy. The **Number of previous PINs to disallow** setting specifies the number of unique PINs users need to use before they can reuse an old PIN. You can set the value of this setting between 1 and 20. For most organizations, this value should be set to the default, 5 PINs.Setting this value too high can frustrate users because it can be difficult for users to create and memorize many PINs. Setting it too low may introduce a security threat to your network.

Important:

The PIN history can't be disabled.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to change the number of

previous PINs to disallow

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, click the **PIN Policies** tab.
4. On the **PIN Policies** tab, next to **Number of previous PINs to disallow**, enter a value between 1 and 20.
5. Click **OK** to save your changes.

Use the Shell to change the number of previous PINs to disallow

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the PIN history on the UM mailbox policy `MyUMMailboxPolicy` to 10.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -PINHistoryCount 10
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you change the number of previous PINs to disallow, you may also want to:

- Configure the Number of Incorrect PIN Entries Before a PIN Is Reset on a UM Mailbox Policy
- Enable or Disable Common PIN Patterns on a UM Mailbox Policy

1.9.2.3.3.19 Enable or Disable Common PIN Patterns on a UM Mailbox Policy

Enable or Disable Common PIN Patterns on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable common Unified Messaging (UM) PIN patterns for Outlook Voice Access users in Microsoft Exchange Server 2010. If you enable or disable the common PIN patterns setting on a UM mailbox policy, the setting will apply to all UM-enabled users associated with the UM mailbox policy. By default, UM-enabled users can't use common patterns when they create a PIN.

You can configure several PIN-related settings on a UM mailbox policy. The **Allow**

Common Patterns setting is used to allow or prevent the use of common number patterns when users create a PIN. By default, this setting is disabled and prevents users from using the following number patterns:

- **Sequential numbers** These are PIN values that include only consecutive numbers. Examples of consecutive numbers for a PIN are 1234 and 65432.
- **Repeated numbers** These are PIN values that include only repeated numbers. Examples of repeated numbers are 11111 and 22222.
- **Suffix of mailbox extension** These are PIN values that include the suffix of a user's mailbox extension. For example, if a user's mailbox extension is 36697, the user's PIN cannot be 3669712.

Note:
If the **Allow Common Patterns** setting is enabled, only the suffix of the mailbox extension will be rejected.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable common PIN patterns

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to Organization Configuration node > Unified Messaging.
2. On the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, click the **PIN Policies** tab.
4. On the **PIN Policies** tab, select the check box **Allow common patterns in PIN** to enable common PIN patterns. Unselecting the check box prevents users from using common patterns in their Outlook Voice Access PINs.
5. Click **OK** to save your changes.

Use the Shell to enable or disable common PIN patterns

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example enables user's associated with the UM mailbox policy named `MyUMMailboxPolicy` to use PINs that contain common patterns.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -AllowCommonPatterns $true
```

This example prevents user's associated with the UM mailbox policy named `MyUMMailboxPolicy` from using PINs that contain common patterns.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -AllowCommonPatterns $false
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you enable or disable common PIN patterns, you may also want to:

- Configuring PIN Security for a UM-Enabled User
- Set PIN Policies for UM-Enabled Users

1.9.2.3.3.20 Configure the Number of Incorrect PIN Entries Before a PIN Is Reset on a UM Mailbox Policy

Configure the Number of Incorrect PIN Entries Before a PIN Is Reset on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the number of logon failures allowed before the PIN is reset for an Outlook Voice Access user. You can configure the number of logon failures allowed before a PIN is reset from 1 through 998. The default is 5. The number of logon failures allowed before a PIN is reset is configured on a Unified Messaging (UM) mailbox policy and applies to all UM-enabled users associated with the UM mailbox policy.

Note:

You can increase security by configuring the **Number of incorrect PIN entries before PIN is automatically reset** setting to a number less than 5. You decrease security if you configure it to a number more than 5.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure the number of logon failures before a PIN is reset

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox

policy you want to manage, and then, in the action pane, click **Properties**.
3. On the UM mailbox policy **Properties** page, click the **PIN Policies** tab.
4. On the **PIN Policies** tab, under **Failed Logons** next to **Number of incorrect PIN entries before PIN is automatically reset**, enter a value between 1 and 998.
5. Click **OK** to save your changes.

Use the Shell to configure the number of logon failures before a PIN is reset

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the number of logon failures before the user's PIN is reset to 3 for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 3
```

This example sets the number of logon failures before the user's PIN is reset to 3, the maximum number logon attempts to 5 and a minimum PIN length to 9 for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 3
-MaxLogonAttempts 5 -MinPINLength 9
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you configure the number of logon failures before a PIN is reset, you may also want to:

- Configure the Number of Previous PINs to Disallow on a UM Mailbox Policy
- Configure the PIN Lifetime on a UM Mailbox Policy
- Configure the Minimum PIN Length on a UM Mailbox Policy
- Set PIN Policies for UM-Enabled Users

1.9.2.3.3.21 Configure the Number of Incorrect PIN Entries Before a Mailbox Is Locked Out on a UM Mailbox Policy

Configure the Number of Incorrect PIN Entries Before a Mailbox Is Locked Out on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the number of logon failures allowed before Outlook Voice Access users are locked out of their mailbox in Microsoft Exchange Server 2010. The number of logon failures allowed before a mailbox is locked out is configured on a Unified Messaging (UM) mailbox policy and applies to all UM-enabled users associated with the UM mailbox policy.

To increase security, decrease the maximum number of failed attempts. However, remember that if you decrease it to a number much lower than the default, users may be locked out unnecessarily. Unified Messaging will generate warning events you can view using Event Viewer if PIN authentication fails for UM-enabled users or if users are unsuccessful when they try to log on to the system.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure the number of logon failures before a mailbox is locked out

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then, in the action pane, click **Properties**.
3. On the UM mailbox policy **Properties** page, click the **PIN Policies** tab.
4. On the **PIN Policies** tab, under **Failed Logons**, next to **Number of incorrect PIN entries before UM mailbox is locked out**, enter a value between 1 and 998.
5. Click **OK** to save your changes.

Use the Shell to configure the number of logon failures before a mailbox is locked out

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the maximum number logon attempts to 10 for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -MaxLogonAttempts 10
```

This example sets the number of logon failures before the user's PIN is reset to 3, the maximum number logon attempts to 5 and a minimum PIN length to 9 for UM-enabled users who are associated with a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -LogonFailuresBeforePINReset 3
-MaxLogonAttempts 5 -MinPINLength 9
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you configure the number of logon failures before a mailbox is locked out, you may also want to:

- Configure the Number of Previous PINs to Disallow on a UM Mailbox Policy
- Configure the PIN Lifetime on a UM Mailbox Policy
- Configure the Minimum PIN Length on a UM Mailbox Policy
- Set PIN Policies for UM-Enabled Users

1.9.2.3.3.22 Enable Dialing Restrictions on a UM Mailbox Policy

Enable Dialing Restrictions on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC and the Shell to enable dialing restrictions on a Unified Messaging (UM) mailbox policy in Microsoft Exchange Server 2010. A dialing restriction is used to configure dialing rules that can be used to prohibit users associated with a UM mailbox policy from making certain types of telephone calls.

Dialing restrictions are used when you configure outdialing for UM-enabled users and can be used when you want to enable users to place calls to in-country/region or international telephone numbers. When you configure a setting on a UM mailbox policy, that setting will apply to all UM-enabled users associated with the UM mailbox policy.

Outdialing enables UM-enabled users to initiate calls from inside an organization that has Unified Messaging. For outdialing to work correctly, certain settings must be configured correctly. These settings include:

- **Dialing group rules** Dialing group rules determine the types of calls users within a dial group can make.
- **Dialing rule entries** Dialing rule entries define the number dialed by the UM-enabled user and the actual number that will be dialed by the Private Branch eXchange (PBX) or IP PBX.
- **Dialing restrictions** Dialing restrictions determine the restrictions applied to prevent users from incurring unnecessary telephone charges or from dialing long distance calls.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.
- A UM dialing rule group has been created. For detailed steps, see Configure Dialing Rule Groups on a UM Dial Plan.

Use the EMC to enable dialing restrictions on a UM mailbox policy for in-country/region rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. Select the UM mailbox policy you want to change, and then, in the action pane, click **Properties**.
4. On the UM mailbox policy **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed in-country/region rule groups from dial plan**, click **Add**.
5. On the **Select Allowed In-Country/Region Groups** page, select the dialing rule group that's configured on the UM dial plan, and then click **OK**.
6. Click **OK** to save your changes.

Use the EMC to enable dialing restrictions on a UM mailbox policy for international rule groups

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. Select the UM mailbox policy you want to change, and then, in the action pane, click **Properties**.
4. On the UM mailbox policy **Properties** page, on the **Dialing Restrictions** tab, under **Select allowed international rule groups from dial plan**, click **Add**.
5. On the **Select Allowed International Groups** page, select the dialing rule group that's configured on the UM dial plan, and then click **OK**.
6. Click **OK** to save your changes.

Use the Shell to enable in-country/region and international dialing restrictions on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example enables the InCountry/RegionGroup1, InCountry/RegionGroup2, InternationalGroup1, and InternationalGroup2 dialing restrictions on a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -AllowedInCountryOrRegionGroups I
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you to enable dialing restrictions on a UM mailbox policy, you may also want to:

- Configure Dialing Rule Groups on a UM Dial Plan
- Create a Dialing Rule Entry on a UM Dial Plan

1.9.2.3.3.23 Configure Protected Voice Mail from Unauthenticated Callers on a UM Mailbox Policy

Configure Protected Voice Mail from Unauthenticated Callers on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can determine whether an incoming call answered by a Unified Messaging server will protect voice mail messages. Protected Voice Mail is encrypted. When a voice mail message is protected:

- The message is marked as Private in Microsoft Office Outlook and in Outlook Web App.
- The voice message can only be opened by the intended recipient of the voice message.
- The recipient can reply to the voice message, but can't forward it to someone who wasn't included on the original voice message.

This setting applies to voice messages sent to UM-enabled users when they don't answer their phone. This setting also applies to voice messages sent directly to UM-enabled users when the caller uses a UM auto attendant. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 Unified Messaging server.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure Protected Voice Mail from unauthenticated callers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **Protected Voice Mail** tab, next to **Protect voice messages from unauthenticated callers**, select **None**, **Private**, or **All**. You can configure the following:
   None Use this setting if you don't want protection applied to any voice messages sent to UM-enabled users.
   Private Use this setting when you want the Unified Messaging server to apply protection only to voice messages that have been marked as private by the caller.
   All Use this setting when you want the Unified Messaging server to apply protection to all voice messages, including those not marked as private.
4. Click **OK** to save your changes.

Use the Shell to configure Protected Voice Mail from unauthenticated callers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example protects all voice messages from all unauthenticated callers on the UM mailbox policy `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -ProtectUnauthenticatedVoiceMail
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you've configured Protected Voice Mail from unauthenticated callers on a UM mailbox policy, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.24 Configure Protected Voice Mail from Authenticated Callers on a UM Mailbox Policy

Configure Protected Voice Mail from Authenticated Callers on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can determine whether an incoming call answered by a Unified Messaging server will protect voice mail messages. Protected Voice Mail is encrypted. When a voice mail message is protected:

- The message is marked as Private in Microsoft Office Outlook and in Outlook Web App.
- The voice message can only be opened by the intended recipient of the voice message.
- The recipient can reply to the voice message, but can't forward it to someone who wasn't included on the original voice message.

This setting applies to voice messages sent to UM-enabled users when they don't answer their phone. This setting also applies when callers sign in to their mailbox using Outlook Voice Access, and then create and send a voice message. This option isn't available to UM-enabled users who have a mailbox on a Microsoft Exchange Server 2007 Unified Messaging server.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to configure Protected Voice Mail from authenticated callers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **Protected Voice Mail** tab, next to **Protect voice messages from authenticated callers**, select **None**, **Private**, or **All**.
   None Use this setting if you don't want protection applied to any voice messages sent to UM-enabled users.
   Private Use this setting when you want the Unified Messaging server to apply protection only to voice messages that have been marked as private by the caller.
   All Use this setting when you want the Unified Messaging server to apply protection to all voice messages, including those not marked as private.
4. Click **OK** to save your changes.

Use the Shell to configure Protected Voice Mail from authenticated callers

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example protects voice messages from all authenticated callers on the UM mailbox policy `MyUMMailboxPolicy`.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy ProtectAuthenticatedVoiceMail -Al
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you've configured Protected Voice Mail from authenticated callers on a UM mailbox policy, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.25 Enable or Disable Multimedia Playback of Protected Voice Messages on a UM Mailbox Policy

Enable or Disable Multimedia Playback of Protected Voice Messages on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can force users who receive protected voice messages to use the Play on Phone feature to listen to their messages. Or, if the client software doesn't support rights management, users must use Outlook Voice Access.

To listen to voice mail messages, UM-enabled users can use the Play on Phone feature or use multimedia software on a computer or mobile phone. Multimedia playback allows a UM-enabled user to use a media player over computer speakers or use a media player on a mobile phone to hear the voice message.

Note:

Protected voice mail is available only on clients that are using a version of Outlook that supports rights management. If the client software doesn't support rights management, users must use Outlook Voice Access to listen to their calls

By default, the value of the **RequireProtectedPlayOnPhone** property on a UM mailbox policy is set to false. This means that UM-enabled users that are associated with that UM mailbox policy can listen to protected voice mails by:

- Placing a call into Microsoft Exchange Server 2010 Unified Messaging and using Outlook Voice Access.
- Using the built-in media player or the Play on Phone button in Outlook 2010.
- Using the built-in media player or the Play on Phone button in Outlook Web App.

If this value is set to true, multimedia playback of protected voice mail isn't allowed. UM-enabled users associated with a UM mailbox policy on which this value is set to true can only listen to protected voice mails by:

- Placing a call into Exchange 2010 Unified Messaging and using Outlook Voice Access.
- Using the Play on Phone button in Outlook 2010.
- Using the Play on Phone button in Outlook Web App.

This setting is especially useful when UM-enabled users use public computers, laptops in public places, or their mobile phone's media player to listen to Protected Voice Mail that can contain private information.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to enable or disable multimedia playback of protected voice messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **Protected Voice Mail** tab, select or clear the **Allow multimedia playback of protected voice messages** check box.
4. Click **OK** to save your changes.

Use the Shell to enable or disable multimedia playback of protected voice messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example allows users who are associated with the UM mailbox policy `MyUMMailboxPolicy` to play back protected voice messages using a media player.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -RequireProtectedPlayOnPhone $fal
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you've enabled or disabled multimedia playback of protected voice messages on a UM mailbox policy, you may also want to View or Configure the Properties of a UM Mailbox Policy.

1.9.2.3.3.26 Specify the Text to Display for E-Mail Clients that Don't Support Windows Rights Management on a UM Mailbox Policy

Specify the Text to Display for E-Mail Clients that Don't Support Windows Rights Management on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can specify the text that will be sent to a called party when they receive a protected voice message but their e-mail client doesn't support Active Directory Rights Management Services (AD RMS), shown in the user interface as Windows Rights Management, and they're not using Outlook Voice Access to access the message. This text is set on the UM mailbox policy.

Protected Voice Mail can only be accessed by e-mail clients that support Windows Rights Management or when a Unified Messaging–enabled user uses Outlook Voice Access to access a protected voice message.

Protected Voice Mail is encrypted. When a voice message is protected:

- The message is marked as Private in Microsoft Office Outlook and in Outlook Web App.
- The voice message can only be opened by the intended recipient of the voice message.
- The recipient can reply to the voice message, but can't forward it to someone who wasn't included on the original voice message.

If a protected voice message is sent to someone whose e-mail client doesn't support Windows Rights Management and isn't accessing the message using Outlook Voice Access, an e-mail message will be sent to them that includes the text you specify. This text should include instructions about what the called party should do to be able to receive the protected voice message.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the EMC to specify the text to display for e-mail clients that don't support Windows Rights Management

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, on the **UM Mailbox Policies** tab, select the UM mailbox policy you want to manage, and then click **Properties** in the action pane.
3. On the UM mailbox policy **Properties** page, on the **Protected Voice Mail** tab, next to **Specify the text to display to voice mail recipients who have e-mail clients that don't support Windows Rights Management**, type the text that you want to display.
4. Click **OK** to save your changes.

Use the Shell to specify the text to display for e-mail clients that don't support

Windows Rights Management

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example specifies the text to display to users associated with the UM mailbox policy named `MyUMMailboxPolicy` who have e-mail clients that don't support Windows Rights Management.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -ProtectedVoiceMailText "Your e-m
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you specify the text to display for e-mail clients that don't support Active Directory Rights Management Services (AD RMS) on a UM mailbox policy, you may also want to:

- View or Configure the Properties of a UM Mailbox Policy
- Configure Protected Voice Mail from Unauthenticated Callers on a UM Mailbox Policy
- Configure Protected Voice Mail from Authenticated Callers on a UM Mailbox Policy

Configure TUI Settings on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Outlook Voice Access contains two interfaces: the telephone user interface (TUI) and a voice user interface (VUI). You can configure a UM-enabled user's TUI settings when the user accesses a mailbox using the Unified Messaging (UM) system in Microsoft Exchange Server 2010. When you modify a UM-enabled user's TUI settings on a UM mailbox policy, the changes affect all users who are associated with the UM mailbox policy. You can modify the following TUI settings on a UM mailbox policy including:

- PIN-less access to voice mail
- Voice responses to other messages
- TUI access to their calendar
- TUI access to the directory
- TUI access to their e-mail
- TUI access to their personal Contacts

Note:

You can only use the Shell to modify the Outlook Voice Access TUI settings for UM-enabled users.

Looking for other management tasks related to UM mailbox policies? Check out Managing

UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to modify TUI settings on a UM mailbox policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets TUI related settings on a UM mailbox policy named `MyUMMailboxPolicy`.

```
Set-UMMailbox -identity MyUMMailboxPolicy -AllowSubscriberAccess $true -AllowTUIA
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you modify TUI settings on a UM mailbox policy, you may also want to:

- Configure the UM Mailbox Policy Assigned to a UM-Enabled User
- Configure a Subscriber Access Number on a UM Dial Plan
- Enable or Disable Sending Voice Messages on a UM Dial Plan

1.9.2.3.3.28 Configure a Voice Mail Preview Partner on a UM Mailbox Policy

Configure a Voice Mail Preview Partner on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can configure a Voice Mail Preview partner on a Unified Messaging (UM) mailbox policy. After you've configured Voice Mail Preview partner settings, such as the Voice Mail Preview partner ID and Voice Mail Preview partner address, on a UM mailbox policy the settings you configure will apply to all UM-enabled users who are associated with that mailbox policy.

You must use the Exchange Management Shell to configure a Voice Mail Preview partner. You must be logged on to an Exchange server, or to a computer on which the Exchange system management tools have been installed. From the Start menu, choose **Exchange Management Shell** and then **Run as Administrator**.

For more information about the Voice Mail Preview partner program, see Voice Mail Preview Advisor for Exchange 2010.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to Configure a Voice Mail Preview Partner

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

Step 1: Sign Up with a Partner Service

To find the list of certified partners and detailed instructions for how to sign up, see Voice Mail Preview Advisor for Exchange 2010. After you've signed up, the Voice Mail Preview partner will provide you a partner ID and the SMTP address to use to forward the voice messages.

In Step 2, you'll apply the Partner ID and SMTP address you acquired in Step 1 to the required UM mailbox policies.

Step 2: Set the Voice Mail Preview Partner Address and ID

This example sets the Voice Mail Preview partner address to exumvmp@fabrikam.com and the Voice Mail Preview partner ID to CON123-2010 on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -VoiceMailPreviewPartnerAddress e
-VoiceMailPreviewPartnerAssignedID CON123-2010
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Step 3: Optional - Configure Advanced Voice Mail Preview Partner Settings

If the partner requires custom settings, you may want to set two additional parameters for a Voice Mail Preview partner as follows:

- *VoiceMailPreviewPartnerMaxMessageDuration*
- *VoiceMailPreviewPartnerMaxDeliveryDelay*

This example sets the maximum message duration to 300 seconds (5 minutes) and the maximum delivery delay to 600 seconds (10 minutes) on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -VoiceMailPreviewPartnerMaxMessag
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Step 4: Assign a UM-Enabled User to the UM Mailbox Policy for a Voice Mail Preview Partner

If you want to configure the Voice Mail Preview partner service for some, but not all, UM-

enabled users in a UM dial plan, you must create a new UM mailbox policy and configure the partner settings. When you've finished, you can apply the new policy to selected UM-enabled users. For more information about how to assign a UM-enabled user to a UM mailbox policy, see the following topics:

- Configure the UM Mailbox Policy Assigned to a UM-Enabled User
- Set-UMMailbox

For more information about Voice Mail Preview, see Voice Mail Preview for End Users.

Other Tasks

After you configure a Voice Mail Preview partner on a UM mailbox policy, you may also want to Enable or Disable Voice Mail Preview on a UM Mailbox Policy.

Set the Voice Mail Preview Partner Address on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set a Voice Mail Preview partner address on a Unified Messaging (UM) mailbox policy. After you've set the Voice Mail Preview partner address on a UM mailbox policy, the setting will apply to all UM-enabled users who are associated with that mailbox policy.

You must use the Exchange Management Shell to set a Voice Mail Preview partner address. You must be logged on to an Exchange server, or to a computer on which the Exchange system management tools have been installed. From the Start menu, choose **Exchange Management Shell** and then **Run as Administrator**.

For more information about the Voice Mail Preview partner program, see Voice Mail Preview Advisor for Exchange 2010.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to Set the Voice Mail Preview Partner Address on a UM Mailbox Policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the Voice Mail Preview partner address to exumvmp@fabrikam.com on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -VoiceMailPreviewPartnerAddress e
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you set the Voice Mail Preview partner address on a UM mailbox policy, you may also want to:

- Set the Voice Mail Preview Partner ID on a UM Mailbox Policy
- Set the Maximum Message Duration for a Voice Mail Preview Partner on a UM Mailbox Policy
- Set the Maximum Delivery Delay for a Voice Mail Preview Partner on a UM Mailbox Policy

Set the Voice Mail Preview Partner ID on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set a Voice Mail Preview partner ID on a Unified Messaging (UM) mailbox policy. After you've set the Voice Mail Preview partner ID on a UM mailbox policy, the setting will apply to all UM-enabled users who are associated with that mailbox policy.

You must use the Exchange Management Shell to set the Voice Mail Preview partner ID. You must be logged on to an Exchange server, or to a computer on which the Exchange system management tools have been installed. From the Start menu, choose **Exchange Management Shell** and then **Run as Administrator**.

For more information about the Voice Mail Preview partner program, see Voice Mail Preview Advisor for Exchange 2010.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to Set the Voice Mail Preview Partner ID on a UM Mailbox

Policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the Voice Mail Preview partner ID to CON123-2010 on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy
-VoiceMailPreviewPartnerAssignedID CON123-2010
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you set the Voice Mail Preview partner ID on a UM mailbox policy, you may also want to:

- Set the Voice Mail Preview Partner Address on a UM Mailbox Policy
- Set the Maximum Message Duration for a Voice Mail Preview Partner on a UM Mailbox Policy
- Set the Maximum Delivery Delay for a Voice Mail Preview Partner on a UM Mailbox Policy

Set the Maximum Message Duration for a Voice Mail Preview Partner on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set the message duration for a Voice Mail Preview partner on a Unified Messaging (UM) mailbox policy. After you've set the maximum message duration, the setting will apply to all UM-enabled users who are associated with that mailbox policy.

You must use the Exchange Management Shell to set the maximum message duration for a Voice Mail Preview partner. You must be logged on to an Exchange server, or to a computer on which the Exchange system management tools have been installed. From the Start menu, choose **Exchange Management Shell** and then **Run as Administrator**.

For more information about the Voice Mail Preview partner program, see Voice Mail Preview Advisor for Exchange 2010.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to Set the Maximum Message Duration for a Voice Mail Preview Partner

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the maximum message duration for a Voice Mail Preview partner to 300 seconds (5 minutes) on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy -VoiceMailPreviewPartnerMaxMessag
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you set the maximum message duration for a Voice Mail Preview partner, you may also want to:

- Set the Voice Mail Preview Partner Address on a UM Mailbox Policy
- Set the Voice Mail Preview Partner ID on a UM Mailbox Policy
- Set the Maximum Delivery Delay for a Voice Mail Preview Partner on a UM Mailbox Policy

Set the Maximum Delivery Delay for a Voice Mail Preview Partner on a UM Mailbox Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can set the maximum delivery delay for a Voice Mail Preview partner on a Unified Messaging (UM) mailbox policy. After you've set the maximum delivery delay, the setting will apply to all UM-enabled users who are associated with that UM mailbox policy.

You must use the Exchange Management Shell to set the maximum delivery delay for a Voice Mail Preview partner. You must be logged on to an Exchange server, or to a computer on which the Exchange system management tools have been installed. From the Start menu, choose **Exchange Management Shell** and then **Run as Administrator**.

For more information about the Voice Mail Preview partner program, see Voice Mail Preview Advisor for Exchange 2010.

Looking for other management tasks related to UM mailbox policies? Check out Managing UM Mailbox Policies.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to Set the Maximum Delivery Delay for a Voice Mail Preview Partner

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example sets the maximum delivery delay to 600 seconds (10 minutes) on a UM mailbox policy named *MyUMMailboxPolicy*.

```
Set-UMMailboxPolicy -identity MyUMMailboxPolicy - VoiceMailPreviewPartnerMaxDeliv
```

For more information about syntax and parameters, see Set-UMMailboxPolicy.

Other Tasks

After you set the maximum delivery delay for a Voice Mail Preview partner, you may also want to:

- Set the Maximum Message Duration for a Voice Mail Preview Partner on a UM Mailbox Policy
- Set the Voice Mail Preview Partner ID on a UM Mailbox Policy
- Set the Voice Mail Preview Partner Address on a UM Mailbox Policy

1.9.2.3.4 Managing UM IP Gateways

Managing UM IP Gateways

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-18*

Create a UM IP Gateway

View or Configure the Properties of a UM IP Gateway

Delete a UM IP Gateway

Enable a UM IP Gateway

Disable a UM IP Gateway

Configure the IP Address on a UM IP Gateway

Configure a Fully Qualified Domain Name for a UM IP Gateway

Enable or Disable Outgoing Calls on a UM IP Gateway

Allow or Prevent Message Waiting Indicator on a UM IP Gateway

Configure the TCP Listening Port on a UM IP Gateway

1.9.2.3.4.1 Create a UM IP Gateway

Create a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A Unified Messaging (UM) IP gateway establishes a logical link between the IP gateway device, a UM IP gateway, and single or multiple UM hunt groups. When you create a new UM IP gateway, you enable Unified Messaging servers to connect to a new IP gateway or an IP Private Branch eXchange (PBX) enabled for Session Initiation Protocol (SIP). Immediately after you create a UM IP gateway, you should create a new UM hunt group and then associate the UM hunt group with the UM IP gateway. You can associate the UM IP gateway with one or more UM dial plans by creating one or more UM hunt groups.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

What Do You Want to Do?

- Use the EMC to create a UM IP gateway
- Use the Shell to create a UM IP gateway

Use the EMC to create a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. In the action pane, click **New UM IP Gateway**.
4. In the New UM IP Gateway wizard, complete the following fields:
   - **Name** Use this text box to specify a unique name for the UM IP gateway. This is a display name that appears in the EMC. If you have to change the display name of the UM IP gateway after it's been created, you must first

delete the existing UM IP gateway, and then create another UM IP gateway that has the appropriate name. The UM IP gateway name is required, but it's used for display purposes only. When you're using the **Get-UMIPGateway** cmdlet, you can't enter the IP address that's configured on the UM IP gateway. You must use the name of the UM IP gateway. The name that's specified on the Identity parameter with the **Get-UMIPGateway** cmdlet can be the same as or different from the host name of the UM IP gateway. For example, **Get-UMIPGateway** *MyUMIPGateway*.

Because your organization may use multiple UM IP gateways, we recommend that you use meaningful names for your UM IP gateways. The maximum length of a UM IP gateway name is 64 characters, and it can include spaces.

- **IP address** You can configure a UM IP gateway with either an IP address or an FQDN. Use this field to specify the IP address configured on the IP gateway or SIP-enabled IP PBX.

  Although you can enter alphabetical and numeric characters in this text box, IPv4 addresses that are correctly formatted are required. IPv6 addresses aren't supported even though they can be entered into this field.
- **Fully qualified domain name (FQDN)** You can configure a UM IP gateway with either an IP address or an FQDN. Use this text box to enter the FQDN for the UM IP gateway or SIP-enabled IP PBX. This text box accepts only FQDNs that are valid and formatted correctly.

  If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any IP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: **Set-UMIPGateway -identity MyUMIPGateway -Port 5061**.
  If you use an FQDN, you must also make sure that you have correctly configured a DNS host record for the IP gateway so that the host name will be correctly resolved to an IP address. Also if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly in Active Directory.
- **Dial plan** Click the **Browse** button to select the UM dial plan that you want to associate with the UM IP gateway. When you select a UM dial plan to associate with a UM IP gateway, a default UM hunt group is also created and associated with the UM dial plan that you selected. If you don't select a UM dial plan, you must manually create a UM hunt group and then associate that UM hunt group with the UM IP gateway that you create.

5. On the **Completion** page, confirm whether the UM IP gateway was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM IP Gateway wizard.

Use the Shell to create a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging

Permissions topic.

This example creates a UM IP gateway named MyUMIPGateway that enables a Unified Messaging server to start accepting calls from an IP gateway that has an IP address of 10.10.10.1.

```
New-UMIPGateway -Name MyUMIPGateway -Address 10.10.10.1
```

This example creates a UM IP gateway named MyUMIPGateway that enables a Unified Messaging server to start accepting calls from an IP gateway that has an FQDN of MyUMIPGateway.contoso.com and listens on port 5061.

```
New-UMIPGateway -Name MyUMIPGateway -Address "MyUMIPGateway.contoso.com" -Port 50
```

For more information about syntax and parameters, see New-UMIPGateway.

Other Tasks

After you create a UM IP gateway, you may also want to:

- Create a UM Hunt Group
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Configure an IP Gateway to Communicate with a PBX

For More Information

Understanding Unified Messaging IP Gateways

1.9.2.3.4.2 View or Configure the Properties of a UM IP Gateway

View or Configure the Properties of a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After you create a Unified Messaging (UM) IP gateway, you can view or configure a variety of settings. For example, you can configure the IP address or a fully qualified domain name (FQDN), configure outgoing call settings, and enable or disable the Message Waiting Indicator. When you're using the **Get-UMIPGateway** cmdlet, you can't enter the IP address that's configured on the UM IP gateway. You must use the name of the UM IP gateway. The name that's specified on the Identity parameter with the **Get-UMIPGateway** cmdlet can be the same as or different from the host name of the UM IP gateway. For example, **Get-UMIPGateway** *MyUMIPGateway*.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.

What Do You Want to Do?

Use the EMC to view or configure UM IP gateway properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab, and then select the UM IP gateway that you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view and configure settings for the UM IP gateway. For example, you can configure the IP address that points to an IP gateway or Private Branch eXchange (PBX) enabled for Session Initiation Protocol (SIP) on your network. You can also change the display name of the UM IP gateway that was configured when the UM IP gateway was created. You can view or configure the following settings:
   - **Status** This display-only field shows the status of the UM IP gateway.
   - **Modified** This display-only field shows the date that the UM IP gateway was last modified.
   - **IP address** You can configure a UM IP gateway with either an IP address or an FQDN. Use this field to specify the IP address configured on the IP gateway or SIP-enabled IP PBX.

     Although you can enter alphabetical and numeric characters in this text box, IPv4 addresses that are correctly formatted are required. IPv6 addresses aren't supported even though they can be entered into this field.
   - **Fully qualified domain name (FQDN)** You can configure a UM IP gateway with either an IP address or an FQDN. Use this text box to enter the FQDN for the UM IP gateway or SIP-enabled IP PBX. This text box accepts only FQDNs that are valid and formatted correctly.

     If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any IP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: **Set-UMIPGateway -identity MyUMIPGateway -Port 5061**.
     If you use an FQDN, you must also make sure that you have correctly configured a DNS host record for the IP gateway so that the host name will be correctly resolved to an IP address. Also if you use an FQDN instead of an IP address, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that configuration information for the UM IP gateway is updated correctly in Active Directory.
   - **Allow outgoing calls through this UM IP gateway** Select this check box to allow the UM IP gateway to accept and process outgoing calls. This setting doesn't affect call transfers or incoming calls from an IP gateway.

By default, when the UM IP gateway is created, this setting is enabled. If you disable this setting, users associated with the dial plan won't be able to make outgoing calls through the IP gateway defined in the **Address** field.

- **Allow Message Waiting Indicator** Select this check box to allow voice mail notifications to be sent to users for calls taken by the UM IP gateway. This setting allows the UM IP gateway to receive and send SIP NOTIFY messages for users. The default setting is enabled by default and allows for message waiting notifications to be sent to users.

  Message Waiting Indicator is a feature found in most legacy voice mail systems. In its most common form, it lights a lamp on the voice mail subscriber's phone to indicate the presence of a new voice message.

  Message Waiting Indicator can refer to any mechanism that indicates the existence of a new message. The voice mail message could be a new or unheard voice message. The indication that a new voice message has arrived can be found in the Inbox in clients such as Outlook and Outlook Web App. It can take the form of a Short Messaging Service (SMS) or text message sent to a registered mobile phone, an outbound call made from an Exchange Unified Messaging server to a preconfigured number to play the new item, or a lighted desktop phone lamp for a user.

Use the Shell to configure UM IP gateway properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example modifies the IP address of a UM IP gateway named `MyUMIPGateway`.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1
```

This example prevents the UM IP gateway from accepting incoming calls and prevents outgoing calls.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1 -Status 2 -OutcallsAl
```

This example enables the UM IP gateway to function as an IP gateway simulator and can be used with the **Test-UMConnectivity** cmdlet.

```
Set-UMIPGateway -Identity MyUMIPGateway -Simulator $true
```

Important:

There is a period of latency before all changes that you make to the configuration of a UM IP gateway replicate to all Unified Messaging servers in the same UM dial plan as the UM IP gateway.

For more information about syntax and parameters, see Set-UMIPGateway.

Use the Shell to view UM IP gateway properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging

Permissions topic.

This example displays a formatted list of all the UM IP gateways in the Active Directory forest.

```
Get-UMIPGateway |Format-List
```

This example displays the properties for a UM IP gateway named MyUMIPGateway.

```
Get-UMIPGateway -Identity MyUMIPGateway
```

This example displays all the UM IP gateways including IP gateway simulators in the Active Directory forest.

```
Get-UMIPGateway -IncludeSimulator $true
```

For more information about syntax and parameters, see Get-UMIPGateway.

Other Tasks

After you configure UM IP gateway properties, you may also want to:

- Create a UM Hunt Group
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Configure an IP Gateway to Communicate with a PBX

For More Information

Understanding Unified Messaging IP Gateways

1.9.2.3.4.3 Delete a UM IP Gateway

Delete a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can delete a Unified Messaging (UM) IP gateway. When you delete the UM IP gateway, Unified Messaging servers are no longer able to accept incoming calls from the IP gateway or SIP-enabled IP PBX associated with the UM IP gateway.

Important:

Deleting a UM IP gateway should be performed only when you fully understand the implications of disabling communication with an IP gateway or a Session Initiation Protocol (SIP)–enabled IP Private Branch eXchange (PBX).

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP

Gateway.

Use the EMC to delete a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the result pane, click the **UM IP Gateways** tab.
3. In the work pane, click the UM IP gateway that you want to delete.
4. In the action pane, click **Remove**.
5. In the confirmation dialog box, click **Yes**.

Use the Shell to delete a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example removes or deletes the UM IP gateway named `MyUMIPGateway`.

```
Remove-UMIPGateway -Identity MyUMIPGateway
```

For more information about syntax and parameters, see Remove-UMIPGateway.

Other Tasks

After you delete a UM IP gateway, you may also want to:

- View or Configure the Properties of a UM IP Gateway
- Delete a UM Hunt Group

1.9.2.3.4.4 Enable a UM IP Gateway

Enable a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can to enable a Unified Messaging (UM) IP gateway. By default, when a UM IP gateway is created, the status of the UM IP gateway is set to enabled. After you create the UM IP gateway, you can control the operation and functionality of the UM IP gateway by setting its status variable.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial

Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to enable a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Select the UM IP gateway that you want to enable.
4. In the action pane, click **Enable**.

Use the Shell to enable a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example enables a UM IP gateway named `MyUMIPGateway`.

```
Enable-UMIPGateway -Identity MyUMIPGateway
```

For more information about syntax and parameters, see Enable-UMIPGateway.

Other Tasks

After you enable a UM IP gateway, you may also want to:

- View or Configure the Properties of a UM IP Gateway
- Disable a UM IP Gateway

1.9.2.3.4.5 Disable a UM IP Gateway

Disable a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable a Unified Messaging (UM) IP gateway. By default, when you create a UM IP gateway, the status of the UM IP gateway is enabled. However, after the UM IP gateway is created, you can disable the operation of the UM IP gateway by setting its status variable to disabled. After you disable the UM IP gateway, the IP gateway device with which it's associated no longer processes Unified Messaging incoming calls.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.
- The UM IP gateway status has been enabled. For detailed steps, see Enable a UM IP Gateway.

Use the EMC to disable a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the result pane, click the **UM IP Gateways** tab.
3. In the work pane, select a UM IP gateway that you want to disable.
4. In the action pane, click **Disable immediately**.
5. In the confirmation dialog box, click **Yes** to confirm.

Use the Shell to disable a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example disables a UM IP gateway named `MyUMIPGateway` and stops it from accepting incoming calls from the IP gateway.

```
Disable-UMIPGateway -Identity MyUMIPGateway
```

This example disables a UM IP gateway named `MyUMIPGateway` and disconnects all current calls immediately.

```
Disable-UMIPGateway -Identity MyUMIPGateway -Immediate $true
```

For more information about syntax and parameters, see Disable-UMIPGateway.

Other Tasks

After you disable a UM IP gateway, you may also want to:

- Enable a UM IP Gateway
- Configure the IP Address on a UM IP Gateway
- Configure a Fully Qualified Domain Name for a UM IP Gateway

1.9.2.3.4.6 Configure the IP Address on a UM IP Gateway

Configure the IP Address on a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you create a Unified Messaging (UM) IP gateway, you must define the IP address or the fully qualified domain name (FQDN) configured on the IP gateway or Session Initiation Protocol (SIP)-enabled IP Private Branch eXchange (PBX) that you're using. However, you can change the IP address after the UM IP gateway is created. The IP address configured on the UM IP gateway is the IP address configured on the network or LAN interface of the IP gateway or SIP-enabled IP PBX. If you create a UM IP gateway with an IP address and you view the properties of the UM IP gateway using the **Get-UMIPgateway** cmdlet, you can't use the IP address, you must use the name of the UM IP gateway. For example, **Get-UMIPGateway** *MyUMIPGateway*.

You can only configure a UM IP gateway with an IPv4 IP address. The **IP Address** field can accept an IPv6 address. However, IPv6 isn't supported.

Important:

If you create a UM IP gateway using an FQDN, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that the UM IP gateway's configuration information is updated correctly in the Active Directory directory service.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to configure the IP address on a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Select the UM IP gateway that you want to modify, and then in the action pane, click **Properties**.
4. On the UM IP gateway **Properties** page, under **IP Address**, enter the IP address for the IP gateway or IP PBX.

   Note:

   If you use an FQDN instead of an IP address on the UM IP gateway, verify that the correct DNS records have been created.

5. Click **OK** to save your changes.

Use the Shell to configure the IP address on a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example configures a UM IP gateway named `MyUMIPGateway` with an IP address of

10.10.10.1.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1
```

This example configures a UM IP gateway named MyUMIPGateway with an IP address of 10.10.10.10 and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.10 -Port 5061
```

For more information about syntax and parameters, see Set-UMIPGateway.

Other Tasks

After you've changed the IP address on a UM IP gateway, you may also want to:

- View or Configure the Properties of a UM IP Gateway
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Connect a Unified Messaging Server to a Supported IP Gateway

1.9.2.3.4.7 Configure a Fully Qualified Domain Name for a UM IP Gateway

Configure a Fully Qualified Domain Name for a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a Unified Messaging (UM) IP gateway with either an IP address or an FQDN. You can enter the FQDN for the UM IP gateway or SIP-enabled IP PBX. When you create a UM IP gateway, you must define the IP address or the fully qualified domain name (FQDN) configured on the IP gateway or Session Initiation Protocol (SIP)-enabled IP Private Branch eXchange (PBX) that you're using. However, you can change the IP address or FQDN after the UM IP gateway is created.

If you want to use mutual Transport Layer Security (mutual TLS) between a UM IP gateway and a dial plan operating in either SIP secured or Secured mode, you must configure the UM IP gateway with an FQDN. You must also configure it to listen on port 5061 and verify that any IP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -identity MyUMIPGateway -Port 5061`.

Important:

If you create a UM IP gateway using an FQDN, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that the UM IP gateway's configuration information is updated correctly in the Active Directory directory service.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to configure a FQDN

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Select the UM IP gateway that you want to modify, and then in the action pane, click **Properties**.
4. On the UM IP gateway **Properties** page, under **Fully qualified domain name (FQDN)**, enter the FQDN for the IP gateway or IP PBX.

   Note:
   If you use an FQDN instead of an IP address on the UM IP gateway, verify that the correct DNS records have been created.

5. Click **OK** to save your changes.

Use the Shell to configure a FQDN

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example configures a UM IP gateway named `MyUMIPGateway` with a FQDN of Contoso.com.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address Contoso.com
```

This example configures a UM IP gateway named `MyUMIPGateway` with FQDN of Contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address Contoso.com -Port 5061
```

For more information about syntax and parameters, see Set-UMIPGateway.

Other Tasks

After you configured a FQDN on a UM IP gateway, you may also want to:

- View or Configure the Properties of a UM IP Gateway
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Connect a Unified Messaging Server to a Supported IP Gateway

1.9.2.3.4.8 Enable or Disable Outgoing Calls on a UM IP Gateway

Enable or Disable Outgoing Calls on a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable outgoing calls for a Unified Messaging (UM) IP gateway in Microsoft Exchange Server 2010 Unified Messaging. When you select the **Allow outgoing calls through this UM IP gateway** check box on the properties for the UM IP gateway, you configure the UM IP gateway to accept and send outgoing calls to an IP gateway. If you clear the check box, you prevent the UM IP gateway from sending outgoing calls to an IP gateway. Although the **Allow outgoing calls through this UM IP gateway** setting controls whether the IP gateway is able to initiate outgoing calls for users, it doesn't affect call transfers or incoming calls from an IP gateway.

Outdialing is the term used to describe a situation in which a user in one UM dial plan initiates a call to another UM-enabled user in another dial plan or to an external telephone number

To allow outdialing for UM-enabled users, you must:

- Verify that the UM IP gateway allows outgoing calls.
- Create dialing rule groups by creating dialing rule entries on the UM dial plan associated with the UM IP gateway.
- Add the correct dialing rule groups to the list of dialing restrictions on the **Dialing Restrictions** tab on the UM dial plan and on the UM mailbox policy.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to enable or disable outgoing calls for a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Select the UM IP gateway that you want to modify, click **Properties** in the action pane, and then do one of the following:
   - To enable outgoing calls on a UM IP gateway, on the **UM IP Gateway Properties** page, select the check box next to **Allow outgoing calls through this UM IP gateway**.
   - To disable outgoing calls on a UM IP gateway, on the **UM IP Gateway Properties** page, clear the check box next to **Allow outgoing calls through this UM IP gateway**.
4. Click **OK** to save your changes.

Use the Shell to enable or disable

outgoing calls for a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example enables outgoing calls on a UM IP gateway.

```
Set-UMIPGateway -Identity MyUMIPGateway -OutcallsAllowed $true
```

This example disables outgoing calls on a UM IP gateway.

```
Set-UMIPGateway -Identity MyUMIPGateway -OutcallsAllowed $false
```

For more information about syntax and parameters, see Set-UMIPGateway.

Other Tasks

After you enable or disable outgoing calls for a UM IP gateway, you may also want to:

- Enable Dialing Restrictions on a UM Dial Plan
- Enable Dialing Restrictions on a UM Mailbox Policy

1.9.2.3.4.9 Allow or Prevent Message Waiting Indicator on a UM IP Gatew ay

Allow or Prevent Message Waiting Indicator on a UM IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can allow voice mail notifications to be sent to users for calls received by a Unified Messaging (UM) IP gateway. If you enable this setting, the UM IP gateway will be able to receive and send SIP NOTIFY messages for users. Message Waiting Indicator is enabled by default and allows message waiting notifications to be sent to users.

Message waiting indicator is a feature found in most legacy voice mail systems. In its most common form, it lights a lamp on the called party's phone to indicate the presence of a new voice message. Message waiting indicator can refer to any mechanism that indicates the existence of a new voice message or an unheard voice message.

The indication that a new voice message has arrived can be found in the Inbox in clients such as Outlook and Outlook Web App. It can take the form of a text (SMS) message sent to a registered mobile phone, an outgoing call made from an Exchange Unified Messaging server to number that's been configured for playing new messages, or it can be a lighted lamp on a user's desktop phone.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to allow or prevent Message Waiting Indicator from displaying

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Select the UM IP gateway that you want to modify and then, in the action pane, click **Properties**.
4. On the UM IP gateway **Properties** page, select or clear the **Allow Message Waiting Indicator** button.
5. Click **OK** to save your changes.

Use the Shell to allow or prevent Message Waiting Indicator from displaying

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example prevents the message waiting indicator from displaying for users who are associated with the UM IP gateway named `MyUMIPGateway` with an IP address of 10.10.10.1.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address 10.10.10.1 -MessageWaitingIndica
```

For more information about syntax and parameters, see Set-UMIPGateway.

Other Tasks

After you've allowed or prevented the message waiting indicator from displaying on a UM IP gateway, you may also want to:

- View or Configure the Properties of a UM IP Gateway
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Connect a Unified Messaging Server to a Supported IP Gateway

1.9.2.3.4.10 Configure the TCP Listening Port on a UM IP Gateway

Configure the TCP Listening Port on a UM IP Gateway

Managing Unified Messaging > Managing Unified Messaging Components > Managing UM IP Gateways >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure the TCP port that's used to listen for SIP requests on a Unified Messaging (UM) IP gateway. By default, when you create a UM IP gateway, the TCP SIP listening port number is set to 5060. The TCP SIP listening port can't be configured when you create a UM IP gateway or changed by using the EMC. You must configure the TCP SIP listening port number using the **Set-UMIPGateway** cmdlet.

You may have to configure the TCP listening port to 5061 if you want to:

- Set the VoIP security setting on a UM dial plan to SIP Secured.
- Set the VoIP security setting on a UM dial plan to Secured.
- Integrate Microsoft Exchange Server 2010 with Microsoft Office Communications Server.
- Use mutual Transport Layer Security (mutual TLS) to encrypt network data between a UM server and other Exchange servers, IP gateways, or IP PBXs.

If you want to use mutual TLS between a UM IP gateway and a dial plan operating in either SIP Secured or Secured mode, when you create the UM IP gateway you must configure it with an FQDN and then use the Exchange Management Shell to configure the UM IP gateway to listen on TCP port 5061. You must also verify that any IP gateways or IP PBXs have also been configured to listen for mutual TLS requests on port 5061.

Important:

If you create a UM IP gateway using an FQDN, and the DNS configuration for the UM IP gateway is changed, you must disable and then enable the UM IP gateway to make sure that the UM IP gateway's configuration information is updated correctly in Active Directory.

Looking for other management tasks related to UM IP gateways? Check out Managing UM IP Gateways.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the Shell to configure the TCP listening port on a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example configures a UM IP gateway named `MyUMIPGateway` with an FQDN of mTLS.MyUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address mTLS.MYUMIPGateway.contoso.com -
```

This example configures a UM IP gateway named `MyUMIPGateway` with an FQDN of SIPSecured.MyUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address SIPSecured.MyUMIPGateway.contoso
```

This example configures a UM IP gateway named MyUMIPGateway with an FQDN of MyOCSUMIPGateway.contoso.com and listens for SIP requests on TCP port 5061.

```
Set-UMIPGateway -Identity MyUMIPGateway -Address MyOCSUMIPGateway.contoso.com -Po
```

For more information about syntax and parameters, see Set-UMIPGateway.

Other Tasks

After you configure the TCP listening port for a UM IP gateway, you may also want to:

- Configure a Fully Qualified Domain Name for a UM IP Gateway
- View or Configure the Properties of a UM Dial Plan

1.9.2.3.5 Managing UM Hunt Groups

Managing UM Hunt Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-21*

Create a UM Hunt Group

View the Properties of a UM Hunt Group

Delete a UM Hunt Group

1.9.2.3.5.1 Create a UM Hunt Group

Create a UM Hunt Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you create a Unified Messaging (UM) hunt group, a UM Hunt Group object is created in the Active Directory directory service and is a logical representation of an existing Private Branch eXchange (PBX) or IP PBX hunt group. A UM hunt group acts as a connection or link between a UM IP gateway and a dial plan. After you create a UM hunt group, you can't change any of the settings that you defined. If you want to change the UM hunt group settings, you must delete the hunt group and then create another hunt group that has the appropriate settings.

Note:

If you associate a UM dial plan with the UM IP gateway when you create a UM IP gateway, a UM hunt group will also be created.

Looking for other management tasks related to UM hunt groups? Check out Managing UM Hunt Groups.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

What Do You Want to Do?

- Use the EMC to create a UM hunt group
- Use the Shell to create a UM hunt group

Use the EMC to create a UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. In the result pane, select a UM IP gateway.
4. In the action pane, click **New UM Hunt Group**.
5. In the New UM Hunt Group wizard, view or complete the following fields:
   - **Associated UM IP gateway** This display-only field shows the name of the UM IP gateway that will be associated with the UM hunt group.
   - **Name** Use this text box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EMC and the Shell. If you have to change the display name of the hunt group after it has been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name.

     If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Dial plan** Click the **Browse** button to select the dial plan that will be associated with the UM hunt group. Associating a hunt group with a dial plan is required. A UM hunt group can be associated with only one UM IP gateway and one UM dial plan.
   - **Pilot identifier** Use this text box to specify a string that uniquely identifies the pilot identifier or pilot ID configured on the PBX or IP PBX.

     An extension number or a Session Initiated Protocol (SIP) Uniform Resource Identifier (URI) can be used in this field. Alphanumeric characters are accepted in this field. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs can use SIP URIs.
6. On the **Completion** page, confirm whether the UM hunt group was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task

fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

7. Click **Finish** to complete the New UM Hunt Group wizard.

Use the Shell to create a UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

This example creates a UM hunt group named `MyUMHuntGroup` that has a pilot identifier of 12345.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier 12345  -UMDialplan MyUMDialP
```

This example creates a UM hunt group named `MyUMHuntGroup` that has multiple pilot identifiers.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier 5551234,55555 -UMDialplan My
```

For more information about syntax and parameters, see New-UMHuntGroup.

Other Tasks

After you configure dialing rule groups, you may also want to:

- View the Properties of a UM Hunt Group
- Create a UM Auto Attendant

1.9.2.3.5.2 View the Properties of a UM Hunt Group

View the Properties of a UM Hunt Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view Unified Messaging (UM) hunt group properties. When you view the properties for a UM hunt group, you can view the properties associated with a single UM hunt group or all UM hunt groups associated with a single UM IP gateway. If neither parameter is specified, all UM hunt groups in the forest will be returned.

After a UM hunt group has been created, the settings configured can't be changed. If you want to change a configuration setting such as the pilot identifier on a UM hunt group, you must delete the existing UM hunt group and create a new UM hunt group that has the correct settings. When you're using the **Get-UMHuntGroup** cmdlet, you can't only enter the name of the UM hunt group. You must also include the name of the UM IP gateway that's associated with the UM hunt group. For example, **Get-UMHuntGroup** *MyUMIPGateway\MyUMHuntGroup1*.

Looking for other management tasks related to UM hunt groups? Check out Managing UM Hunt Groups.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.

Use the EMC to view the properties of a UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

1. In the console root, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. On the **UM IP Gateways** tab, expand the UM IP Gateway object that contains the hunt group for which you want to review properties.
4. In the work pane, review the configuration settings of the UM hunt group by reviewing the **UM Dial Plans**, **Pilot Identifier**, **Address**, and **Status** columns.

Use the Shell to view the properties of a UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

This example displays all the UM hunt groups in the Active Directory forest.

```
Get-UMHuntGroup
```

This example displays the details of a UM hunt group named `MyUMHuntGroup` in a formatted list.

```
Get-UMHuntGroup -identity MyUMIPGateway\MyUMHuntGroup | Format-List
```

For more information about syntax and parameters, see Get-UMHuntGroup.

Other Tasks

After you view the properties of a UM hunt group, you may also want to:

- Delete a UM Hunt Group
- Create a UM Hunt Group

1.9.2.3.5.3 Delete a UM Hunt Group

Delete a UM Hunt Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can delete an existing Unified Messaging (UM) hunt group. After you delete the UM hunt group, the UM IP gateway associated with the UM hunt group will no longer service or answer incoming calls. If the deleted UM hunt group operation leaves the UM IP gateway without any remaining configured hunt groups, the UM IP gateway can't handle or process UM calls.

Looking for other management tasks related to UM hunt groups? Check out Managing UM Hunt Groups.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.
- A UM hunt group has been created. For detailed steps, see Create a UM Hunt Group.

Use the EMC to delete an existing UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. Under the name of the UM IP gateway, select a UM hunt group.
4. In the action pane, click **Remove**.
5. In the confirmation dialog box, click **Yes** to confirm the deletion of the UM hunt group.

Use the Shell to delete an existing UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

This example deletes a UM hunt group named `MyUMHuntGroup`.

```
Remove-UMHuntGroup -Identity MyUMHuntGroup
```

For information about syntax and parameters, see Remove-UMHuntGroup.

Other Tasks

After you delete an existing UM hunt group, you may also want to:

- Create a UM Hunt Group
- View the Properties of a UM Hunt Group

1.9.2.4 Managing IP Gateways

Managing IP Gateways

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2008-10-26*

Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server

Connect a Unified Messaging Server to a Supported IP Gateway

Configure an IP Gateway to Communicate with a PBX

1.9.2.4.1 Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server

Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-20*

You must configure the IP gateway devices correctly when you deploy Microsoft Exchange Server 2010 Unified Messaging (UM) for your organization. To do this, you need to configure the interface of the IP gateways to communicate with the Unified Messaging server.

Important:

When you perform administrative tasks on the IP gateway using a Web browser, the HTTP requests sent over the network when you configure an IP gateway device are not encrypted. To increase the level of security for the IP gateways on your network, use Internet Protocol security (IPsec) or Secure Sockets Layer (SSL) to help protect the administrative credentials and data transmitted over the network. We also recommend that you use a strong authentication mechanism and complex administrative passwords to protect the administrative credentials for the device.

IP Gateway Interface

There are several types of ports or interfaces that you must configure to enable communication between a Private Branch eXchange (PBX), IP gateway, and Unified Messaging servers on your network. When you configure an IP gateway, you must consider whether the IP gateway device is analog, digital, or analog and digital. If the IP gateway interface that connects to a PBX is analog, you must correctly configure the appropriate settings to enable the IP gateway to communicate with your Unified Messaging servers on your network. For your Unified Messaging servers to communicate with the IP gateways on your network, you must configure the interfaces to communicate with your PBXs, and you must configure the Local Area Network (LAN) connection or

network interface for the device.

The following is a list of suggested resources that contain information that can help you correctly configure your IP gateway interfaces and the network interface:

- **IP gateway, IP PBX, and PBX documentation** The Exchange TechCenter contains configuration files and setup information you can use when you configure IP gateways, IP PBXs, and PBXs. For more information, see Telephony Advisor for Exchange Server 2007.
- **Configuring an AudioCodes-based IP gateway** You can find the latest support and configuration information at the Microsoft AudioCodes Technical Resources for Exchange 2007 and 2010 Web site to help you configure AudioCodes-based IP gateways for use with Unified Messaging.
- **Configuring a Dialogic-based IP gateway** You can find the latest support and configuration information for Dialogic-based IP gateways at the Dialogic Technical Documentation Web site.

We also recommend that all customers who plan to deploy Exchange 2010 Unified Messaging obtain the assistance of a Unified Messaging specialist. A Unified Messaging specialist helps make sure that there is a smooth transition to Exchange 2010 Unified Messaging from a legacy voice mail system. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about PBXs and Exchange 2010 Unified Messaging. For more information about how to contact a Unified Messaging specialist, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

After you configure the IP gateway IP interface, you must create and configure a UM IP gateway. For more information about how to create a UM IP gateway, see Create a UM IP Gateway.

After you install the IP gateway, you must create an UM IP gateway object to represent the IP gateway. After you create a UM IP gateway object, the Unified Messaging server associated with the UM IP gateway sends a SIP OPTIONS request to the IP gateway to make sure that the IP gateway is responsive. If the IP gateway doesn't respond to the SIP OPTIONS request from the Unified Messaging server, the Unified Messaging server will log an event with ID 1088 stating that the request failed. To resolve this issue, make sure the IP gateway is available and online and the Unified Messaging configuration is correct.

A Unified Messaging server will communicate only with IP gateways or IP PBXs that are listed as a trusted Session Initiation Protocol (SIP) peer. An event with ID 1175 will be logged when multiple DNS hosts share the same IP address. This event may occur if you've configured you DNS zones with a fully qualified domain names (FQDN) for the IP gateways on your network. Unified Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web Services Virtual Directory that is located on the server that has the Client Access role installed and then uses the URL to build the list of FQDNs for the trusted SIP peers. After two FQDNs are resolved to the same IP address, this event will be logged.

Note:

You must restart the Microsoft Exchange Unified Messaging service if an IP gateway is configured to have an FQDN and the IP gateway's DNS record is changed after the service has been started. If you don't restart the service, the Unified Messaging server won't be able to locate the IP gateway. This occurs because a Unified Messaging server maintains a cache for all IP gateways in memory, and DNS resolution is performed only when the service is restarted or when an IP gateway's configuration has changed.

For More Information

Understanding Telephony Concepts and Components

Connect a Unified Messaging Server to a Supported IP Gateway

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You must configure the IP gateways and IP PBXs on your network to communicate with the Exchange 2010 Unified Messaging servers in your Exchange organization. You must also configure your Exchange 2010 Unified Messaging servers to communicate with the IP gateways and IP Private Branch eXchanges. After you've configured IP gateways or IP PBXs on your network, you then need to configure Active Directory and the computers on which the Unified Messaging server role is installed.

Note:

After you've connected the UM server to an IP gateway or IP PBX, you must also enable users for Unified Messaging.

Steps

Here are the basic steps for connecting IP Gateways or IP PBXs to a Unified Messaging server:

Step 1: Install the Unified Messaging server role

Step 2: Create and configure a UM IP gateway

Step 3: Create a new UM hunt group (possibly)

See the following sections for information about each step.

Step 1: Install the Unified Messaging server role

If you're installing the Unified Messaging server role on an Exchange 2010 server that is separate from the server on which the Mailbox and Hub Transport server roles are installed, use **Setup.exe**. If you're installing the Unified Messaging server role on the Exchange 2010 computer that currently has the Mailbox and Hub Transport server roles installed, you can use **Add or Remove Programs** or Setup.com.

For detailed steps, see Install the Exchange 2010 Unified Messaging Server Role.

Step 2: Create and configure a UM IP gateway

When you create a UM IP gateway, you can configure the UM IP gateway object to use an IP address or a fully qualified domain name (FQDN). If you use an FQDN, you must make sure you've correctly configured a DNS host record for the IP gateway so the host name will be correctly resolved to an IP address.

A Unified Messaging server will communicate only with IP gateways or IP PBXs listed as a trusted Session Initiation Protocol (SIP) peer. In some cases, if two IP gateways are configured to use the same IP address, an event with ID 1175 will be logged. Unified

Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web Services virtual directory that is located on the server that has the Client Access role installed and then uses the URL to build the list of FQDNs for the trusted SIP peers. When two FQDNs are resolved to the same IP address, this event will be logged.

Note:

You must restart the Microsoft Exchange Unified Messaging service if an IP gateway is configured to use an FQDN and the IP gateway's DNS record is changed after the service has been started. If you don't restart the service, the UM server won't be able to locate the IP gateway. This occurs because a UM server maintains a cache for all IP gateways in memory and DNS resolution is performed only when the service is restarted or when an IP gateway's configuration has changed.

After you install the IP gateway, you must create a UM IP gateway to represent the IP gateway. After you've created a UM IP gateway object, the UM server associated with the UM IP gateway will send a SIP OPTIONS request to the IP gateway to ensure that the IP gateway is responsive. If the IP gateway doesn't respond to the SIP OPTIONS request from the Unified Messaging server, the Unified Messaging server will log an event with ID 1088 stating that the request failed. To resolve this issue, make sure that the IP gateway is available and online and that the Unified Messaging configuration is correct.

Unified Messaging supports various IP gateway vendors and other vendors of IP PBXs. Each IP gateway is designed to connect to a variety of third-party PBX systems.

For detailed information about IP gateways, see the following topics:

- Create a UM IP Gateway
- View or Configure the Properties of a UM IP Gateway
- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server

Looking for other management tasks related to Unified Messaging? Check out Managing Unified Messaging Components.

Step 3: Create a new UM hunt group (possibly)

Depending on how you create the UM IP gateway, you may have to create a new UM hunt group. For more information about how to create a UM hunt group, see Create a UM Hunt Group.

Other Tasks

After you've connected the UM server to an IP gateway or IP PBX, you may also want to:

- Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server
- Configure an IP Gateway to Communicate with a PBX

Configure an IP Gateway to Communicate with a PBX

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-19*

When you configure your telephony and data networks for Microsoft Exchange Server 2010 Unified Messaging (UM), you must correctly configure the IP gateways so they communicate with the Unified Messaging servers running Exchange 2010. You must also correctly configure the IP gateways to communicate with the Private Branch eXchanges (PBXs) in your organization. You can use the information and links to configure an IP gateway to communicate with a PBX.

Note:

Exchange 2010 Unified Messaging supports only Session Initiation Protocol (SIP) over Transmission Control Protocol (TCP).

Configuring an IP Gateway

When you configure an IP gateway, you must consider whether the IP gateway device is analog, digital, or analog and digital. If the IP gateway interface that connects to a PBX is analog, you must correctly configure the appropriate settings to enable the IP gateway to communicate with a PBX. If the IP gateway interface that connects to a PBX is digital, there may be no additional configuration required to enable the digital interface to communicate with a PBX.

The following list of suggested resources contains information that can help you correctly configure your IP gateways:

- **IP gateway, IP PBX, and PBX documentation** The Exchange TechCenter contains configuration files and setup information you can use when you configure IP gateways, IP PBXs, and PBXs. For more information, see Telephony Advisor for Exchange Server 2007.
- **Configuring an AudioCodes-based IP gateway** You can find the latest support and configuration information at the Microsoft UM Specialist Resource Page to help you configure AudioCodes-based IP gateways for use with Unified Messaging.
- **Configuring a Dialogic-based IP gateway** You can find the latest support and configuration information for Dialogic-based IP gateways at the Dialogic Technical Documentation Web site.

We also recommend that all customers who plan to deploy Exchange 2010 Unified Messaging obtain the assistance of a Unified Messaging specialist. A Unified Messaging specialist will help make sure that there's a smooth upgrade to Unified Messaging from a legacy voice mail system. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about PBXs and Exchange 2010 Unified Messaging. For more information about how to contact a Unified Messaging specialist, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Important:

When you perform administrative tasks on the IP gateway using a Web browser, the HTTP requests sent over the network when you're configuring an IP gateway device aren't encrypted. To increase the level of security for the IP gateways on your network, use Internet Protocol security (IPsec) or Secure Sockets Layer (SSL) to help protect the administrative credentials and data transmitted over the network. We also recommend that you use a strong authentication mechanism and complex administrative passwords to protect the administrative credentials for the device.

Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server

Connect a Unified Messaging Server to a Supported IP Gateway

Understanding Telephony Concepts and Components

1.9.3 Securing Unified Messaging Servers

Securing Unified Messaging Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-23*

An important aspect of network security for your organization is correctly configuring security for your Microsoft Exchange Server 2010 Unified Messaging (UM) infrastructure. This includes using the security-related configuration options for your Unified Messaging servers and UM-enabled users. By increasing the level of security within your Unified Messaging environment, you increase the level of security for your whole network. This topic contains information and links to security-related topics that can help you increase the level of protection by doing the following:

- Configuring the appropriate PIN settings for users in your organization
- Enabling the security settings to help protect the Unified Messaging network data and servers in your organization
- Effectively assigning administrative permissions to manage your Unified Messaging environment

Unified Messaging Security

There are three security-related areas to consider when you deploy Unified Messaging. You can help increase the level of protection for your network if you correctly plan a Unified Messaging security strategy and then correctly configure the security settings that are available to administrators in the following areas:

- **UM-enabled user PIN security** When a subscriber or a UM-enabled user uses a telephone to connect to a computer that has the Unified Messaging server role installed, they use Outlook Voice Access to move through the Unified Messaging menu system. However, before users can access the Unified Messaging system, the system prompts them to input their PIN. As the administrator, you can configure PIN settings and requirements and perform PIN management tasks. For more information about how to configure PIN settings for UM-enabled users, see Configuring Security for Unified Messaging Users.
- **Securing Unified Messaging network traffic** There are several security methods that can help you protect the Unified Messaging servers and the network traffic in your organization. This includes traffic that's sent between your IP gateways and Unified Messaging servers and between your Unified Messaging servers and other Exchange 2010 servers in your organization. For more information about how to help secure the network traffic that's generated by Unified Messaging, see Securing Unified Messaging Network Traffic.

- **Configuring permissions for Unified Messaging** In many organizations, there are separate administrators for Microsoft Exchange, the Active Directory directory service, and the telecommunications equipment. Therefore, administrative functions must be delegated to maintain distinct boundaries between different levels of administrative permissions.

1.9.3.1 Configuring Security for Unified Messaging Users

Configuring Security for Unified Messaging Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

In Microsoft Exchange Server 2010 Unified Messaging (UM), PIN policies are defined and configured on a UM mailbox policy. Multiple UM mailbox policies can be created, depending on your requirements. When you enable a user for Unified Messaging, you associate or link the user to an existing UM mailbox policy. The UM PIN policies that are configured on the UM mailbox policy should be based on the security requirements of your organization.

Unified Messaging PIN Security

A PIN is a numeric string used in certain systems, including Unified Messaging systems, so a user can be authenticated and gain access. A PIN is a pass code users enter on the telephone to access their Exchange mailbox. The strength of the PIN depends on its length, how well it's protected, and how difficult it is to guess.

After you configure PIN settings for a UM-enabled user, you configure and manage PIN settings on the UM-enabled user's Exchange 2010 mailbox and on the UM mailbox policy associated with the UM-enabled user.

- When subscribers or a UM-enabled users use a telephone to connect to an Exchange 2010 Unified Messaging server, they use Outlook Voice Access to move through the Unified Messaging menu system. However, before users can access the Unified Messaging system, the system prompts them to input their PIN. As the administrator, you can configure PIN settings and requirements and perform PIN management tasks.

UM mailbox policies can be configured to increase the level of security for UM-enabled users by requiring users to comply with the predefined PIN policies for your organization.

When you modify a UM mailbox policy, you can change such settings as PIN policies, message text settings, and dialing restrictions for a single UM-enabled recipient or for multiple UM-enabled recipients. UM mailbox policies can be configured to increase the level of security for UM-enabled users.

You can increase the level of security for your network by correctly implementing and configuring the following PIN settings on a UM mailbox policy:

- The minimum number of digits required for a PIN
- The time, in days, a PIN is accepted by the system
- The number of times attempts to log on can fail before the user's PIN will be reset
- The maximum number of logon attempts before the user is locked out of their mailbox

- Whether to allow users to use common patterns in their PIN
- The number of past PIN entries the system should remember

Include Text with the E-Mail Message Sent When a PIN Is Reset

1.9.3.2 Securing Unified Messaging Network Traffic

Securing Unified Messaging Network Traffic

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

An important aspect of the overall network security for your organization is configuring security correctly for Microsoft Exchange Server 2010 Unified Messaging (UM) servers. Enabling Unified Messaging servers, IP gateways, and other servers running Exchange 2010 to communicate by using Transport Layer Security (TLS) or IP security increases the level of security for your whole network. The following information and links to security-related topics can help you increase the level of protection for your network.

Securing Network Traffic

Unified Messaging can communicate with IP gateways, IP Private Branch eXchanges (PBXs), and other Exchange 2010 computers in a secured or an unsecured mode, depending on how the UM dial plan is configured and whether the appropriate certificate trusts have been established between the IP gateways and Unified Messaging servers on your network. In Unsecured mode, the Voice over IP (VoIP) and Session Initiation Protocol (SIP) traffic isn't encrypted. However, the UM dial plans and the UM server associated with the UM dial plan can be configured using the *VoIPSecurity* parameter. The *VoIPSecurity* parameter configures the dial plan to encrypt the VoIP and SIP traffic using mutual Transport Layer Security (TLS) using SIP Secured or Secured mode..

There are several things you can do to help protect your UM servers and the network traffic that is sent between your IP gateways and UM servers and between your UM servers and other Exchange 2010 servers in your organization. To understand the

components that must be used in your UM environment to help protect the network data sent and received by UM servers in your organization, you need to first understand how to do the following:

- Use IPsec to protect UM network data.
- Use TLS to protect UM network data.
- Use the different types of certificates used with Unified Messaging to implement TLS.
- Correctly configure UM servers and IP gateways to use TLS.

UM Security Components

There are various components that must be configured to help enable the Unified Messaging server to communicate in a secure manner with other Exchange 2010 servers and IP gateways. The following components help secure the data that is passed over the network:

- **IPsec** IPsec uses cryptography-based protection services, security protocols, and dynamic key management. It provides the strength and flexibility to help protect communications between private network computers, domains, sites, remote sites, extranets, and dial-up clients. It can even be used to block receipt or transmission of specific types of traffic. For more information about the security options available to help secure UM traffic, see Understanding Unified Messaging VoIP Security.
- **TLS** After you've successfully imported and exported the required trusted certificates, an IP gateway will request a certificate from the UM server, and then it will request a certificate from the IP gateway. Exchanging the trusted certificates between the IP gateway and the UM server helps secure the channel over which the IP gateway and UM server communicate by using TLS. For more information about the security options available to help secure UM traffic, see Understanding Unified Messaging VoIP Security.
- **Certificates** Digital certificates are electronic files that work like an online passport to verify the identity of a user or computer. They're used to create an encrypted channel that is used to help protect data. A certificate is basically a digital statement issued by a certification authority (CA) that vouches for the identity of the certificate holder and enables the parties to communicate in a secure manner by using encryption. They can be issued by a trusted third-party CA, for example, using Certificate Services, or they can be self-signed. For more information about the security options that are available to help secure UM traffic, see Understanding Unified Messaging VoIP Security.
- **VoIP security** Unified Messaging can communicate with IP gateways, IP PBXs, and other Exchange 2010 computers in a secured or an unsecured mode depending on how the UM dial plan is configured. By default, UM dial plans communicate in an unsecured mode. You can use the **Get-UMDialPlan** cmdlet in the Exchange Management Shell to determine the security setting for a UM dial plan. For more information about how to enable VoIP security on a UM dial plan, see Configure VoIP Security on a UM Dial Plan.

1.9.4 Troubleshooting Reference for Unified Messaging Servers

Troubleshooting Reference for Unified Messaging Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-21*

After you've installed the Unified Messaging (UM) server role on a computer running Microsoft Exchange Server 2010, you may have to test the functionality of the server. The following are two situations in which you will use the diagnostic tools and commands included with Exchange 2010:

- Troubleshooting errors and events
- Testing the Unified Messaging server to make sure that an installation was successful

The following topics will help you test and troubleshoot a Unified Messaging server:

- Enable Tracing for Unified Messaging
- Enable Diagnostic Logging on a Unified Messaging Server
- Testing Unified Messaging Server Functionality
- Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool

1.9.4.1 Enable Tracing for Unified Messaging

Enable Tracing for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

There are several tracing options available for troubleshooting issues related to Microsoft Exchange Server 2010 Unified Messaging (UM). Tracing lets you troubleshoot, debug, and isolate problems on a computer. You can enable tracing, configure tracing settings, and gathering the appropriate information about an Exchange 2010 Unified Messaging server to help you diagnose problems or evaluate system performance. Although there are many tracing tools offered by Microsoft and third-party vendors that may offer more complex tracing options, Microsoft Exchange Analyzers and Network Monitor are tools that you can download to help you enable tracing on a Unified Messaging server. This topic discusses tracing tools and tracing options available for troubleshooting and diagnosing Unified Messaging issues.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

You can install these tools on a client computer running Microsoft .NET Framework 1.1.

For more information about Exchange Analyzers, see Overview: Microsoft Exchange Analyzers.

Use the Exchange Troubleshooting Assistant to create a network trace

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

The Exchange Troubleshooting Assistant includes several tools that can be used to troubleshoot Unified Messaging issues and gather information about different Unified Messaging services and components.

The Trace Control tool that's included in the Exchange Troubleshooting Assistant is a graphical user interface (GUI) that lets you enable and configure tracing on an Exchange 2010 Unified Messaging server. It can also be used to enable tracing on other Exchange 2010 servers in your organization. To enable tracing, select the trace type, component to trace, and any trace tags. When you're enabling tracing on a Unified Messaging server, you must enable the **MSExchangeUM** component listed under the **Components to Trace** section of the tool. Several features are available when you enable tracing using the Exchange Troubleshooting Assistant, including the following:

- Ability to display only enabled components and tags
- Ability to search components and tags
- Ability to display the current status of tracing on startup, including output file size, type, and location

The Microsoft Exchange Troubleshooting Assistant can be used to automatically determine what set of data is required to troubleshoot symptoms that you identify. It can also be used to collect configuration data, performance counters, event logs, and live tracing information from an Exchange 2010 Unified Messaging server in addition to Exchange 2010 servers in your organization running other Exchange 2010 server roles. The Exchange Troubleshooting Assistant analyzes each subsystem on a physical computer to determine individual bottlenecks and component failures. Then it aggregates the information to analyze the cause of the bottlenecks and failures. To download a copy of the Exchange Troubleshooting Assistant, see Microsoft Exchange Troubleshooting Assistant v1.1.

For more information about Exchange Analyzers, see Microsoft Exchange Analyzers

Important:

Tracing information and files can be very complex, depending on the operation and depth of tracing that has been completed. We recommend that after you enable tracing and collect the correct information, you contact Microsoft Enterprise Support.

Use Network Monitor to create a network trace

To perform the following procedures, you must log on by using an account that's a member of the local Administrators group on that computer.

You can use Network Monitor 3.3 to capture network traffic between a Unified Messaging server and an IP gateway or between Exchange 2010 servers running the Client Access, Mailbox, and Hub Transport server roles. A network monitor is a network protocol analyzer tool used to capture network data packets, which lets you analyze specific protocol information.

Network traffic to and from a Unified Messaging server may consist of the following protocols. However, there may be other protocols used, depending on the applications and devices. The following protocols can be used:

- **Session Initiation Protocol (SIP)** Used between an IP gateway, an IP Private Branch eXchange (PBX), or a Microsoft Office Communications Server 2007 front-end server and a Unified Messaging server to establish a communication session. By default, when SIP packets are sent over a network, they are not encrypted. However, you can use mutual Transport Layer Security (TLS) to encrypt the SIP packets.
- **Realtime Transport Protocol (RTP)** Used between media endpoints that send and receive audio packets such as an IP gateway, an IP-based phone, or

a Microsoft Office Communicator 2007 client and a Unified Messaging server. By default, when RTP packets are sent over a network, they are not encrypted. However, you can use mutual TLS to encrypt the SIP packets. If mutual TLS is used to protect the RTP packets, another protocol, Secure Realtime Transport Protocol (SRTP), will be used.

- **T.38** Used for the transmission of fax audio signals between a media endpoint and a Unified Messaging server.
- **SMTP** Used between a Unified Messaging server and a Hub Transport server.
- **LDAP** Used between a Unified Messaging server and an Active Directory domain controller.
- **MAPI RPC** Used between a Unified Messaging server and a Mailbox server.
- **Mutual TLS** Used between an IP gateway and a Unified Messaging server and between a Unified Messaging server and Hub Transport, Mailbox, and Client Access servers. Mutual TLS can be used with SIP, SMTP, or RTP to encrypt the protocol's content.

Note:
If mutual TLS transport is used, the Network Monitor parser will be unable to decode the packets because they are encrypted.

By default, the following parsers are available in Network Monitor 3.3 for protocols used specifically by a Unified Messaging server:

- RTP
- Session Description Protocol (SDP)
- SIP
- SMTP
- Interactive Connectivity Establishment
- To download a copy of Network Monitor 3.3, see Microsoft Network Monitor 3.3.

Other Tasks

After you enable Unified Messaging on an Exchange 2010 server, you may also want to read one or more of the following topics:

- Understanding Protocols, Ports, and Services in Unified Messaging
- Unified Messaging Voice Call Processing
- Unified Messaging Outlook Voice Access Call Processing
- Unified Messaging Auto Attendant Call Processing
- Unified Messaging Play on Phone Call Processing

1.9.4.2 Enable Diagnostic Logging on a Unified Messaging Server

Enable Diagnostic Logging on a Unified Messaging Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use EMC, Shell or a registry editing tool to enable diagnostic logging on a Microsoft Exchange Server 2010 Unified Messaging (UM) server. By default, diagnostic logging is enabled on a UM server but is set to the lowest level. However, if you're troubleshooting an issue on a UM server, you may have to increase the diagnostic logging

level to help you locate the source of the problem.

Event Viewer maintains logs about program, security, and system events on your computer. These logs include errors and events that occur on a UM server. You can use Event Viewer to view and manage the event logs, gather information about hardware and software problems, and monitor Unified Messaging errors and events. Although Event Viewer is a Microsoft Windows operating system tool and not a Microsoft Exchange tool, Event Viewer is useful when you troubleshoot problems with Unified Messaging. For more information about Unified Messaging errors and events, see Error and Event Reference for Unified Messaging Servers.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

What Do You Want to Do?

- Use the EMC to set logging levels
- Use the Shell to set logging levels
- Use the Registry to set logging levels

Use the EMC to set logging levels

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shell infrastructure permissions" section in the Exchange and Shell Infrastructure Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Mailbox**.
2. In the Actions pane, select **Manage Diagnostic Logging Properties**.
3. On the **Manage Diagnostic Logging Properties** wizard page, click the Exchange service for which you want to change the logging level.
4. Select the logging level, and then click **Configure**.

   Note:

   You can return to the default logging levels by selecting **Reset all services to default logging levels** and then clicking **Configure**.

5. On the **Completion** page, confirm whether the process completed successfully. A status of **Completed** indicates that the wizard completed the task successfully. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the Manage Diagnostic Logging Level wizard.

Use the Shell to enable diagnostic logging on a Unified Messaging server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Shell infrastructure permissions" section in the Exchange and Shell Infrastructure Permissions topic.

This example enables diagnostic logging for the **UMCore** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMCore" -level <Lowest
```

This example enables diagnostic logging for the **UMWorkerProcess** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMWorkerProcess" -leve
```

This example enables diagnostic logging for the **UMManagement** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMManagement" -level <
```

This example enables diagnostic logging for the **UMService** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMService" -level <Low
```

This example enables diagnostic logging for the **UMClientAccess** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMClientAccess" -level
```

This example enables diagnostic logging for the **UMCallData** DWORD value.

```
Set-EventlogLevel "MyUMServer\MSExchange Unified Messaging\UMCallData" -level <Lo
```

This example lets you see the current logging level for a Unified Messaging server.

```
Get-EventlogLevel "MyUMServer\MSExchange Unified Messaging"
```

For more information about syntax and parameters, see Set-EventLogLevel.

Use Registry Editor to enable diagnostic logging on a Unified Messaging server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. Start Registry Editor (regedit).
2. Locate the following registry key: **HKeyLocalMachine\System \CurrentControlSet\services\MSExchange Unified Messaging\Diagnostics**
3. In the details pane, double-click the appropriate registry value, and then use the following values to configure the appropriate logging level:

Logging level	Value
Expert	7
High	5
Medium	3
Low	1
Lowest	0

Other Tasks

After you enable diagnostic logging on a Unified Messaging server, you may also want to:

- Enable Tracing for Unified Messaging
- Testing Unified Messaging Server Functionality

1.9.4.3 Testing Unified Messaging Server Functionality

Testing Unified Messaging Server Functionality

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

After you install the Unified Messaging server role on a computer running Microsoft Exchange Server 2010 and enable and configure Unified Messaging, you can use multiple diagnostic tests and a software-based telephone application to test telephony connectivity and the operation of the Unified Messaging server. This topic gives you information about the diagnostic tests for testing a Unified Messaging server.

Test-UMConnectivity

There are three diagnostic tests that can be used to test the functionality of an Exchange 2010 Unified Messaging system and a Unified Messaging server: Local, Local with a TUILogon, and Remote. The **Test-UMConnectivity** cmdlet can be used to check connectivity to Unified Messaging servers in several ways, depending on the parameters used with the cmdlet. For testing Unified Messaging functionality, you can use these tests:

- **Local** The **Test-UMConnectivity** cmdlet verifies Voice over IP (VoIP) communication with the Unified Messaging server running on the same local computer.
- **Local with TUILogon** The **Test-UMConnectivity** cmdlet tries to establish VoIP communication with the Unified Messaging server running on the same computer. If it connects, it tries to sign in to one or more UM-enabled mailboxes by sending the extension number and PIN of the mailbox. If the *–TUILogon* parameter is supplied, the following parameter values must also be supplied for the test to complete successfully. You must supply the following parameters with the appropriate information for the test mailbox:
  - *–Phone* This parameter must contain the extension number for the test mailbox.
  - *–PIN* This parameter must contain the PIN of the UM-enabled mailbox.
  - *–UMDialPlan* This parameter must contain the dial plan associated with the test mailbox.

  When you use this diagnostic test, you must create a test mailbox using the New-TestCasConnectivity.ps1 script located in the %ExchangeRoot%\Scripts folder. Mailboxes created using this script can also be used for other kinds of connectivity testing, for example, with Microsoft Exchange ActiveSync. When you create the test mailbox, you have the option to also enable the test mailbox for Unified Messaging by specifying the *-UMDialPlan* and *-UMExtension* parameters. If you created the test mailbox but didn't enable it for Unified Messaging, you can use the **Enable-UMMailbox** cmdlet or the Exchange Management Console to enable the test mailbox.
  If the *–TUILogonAll* parameter is supplied with the **Test-UMConnectivity** cmdlet, the **Test-UMConnectivity** cmdlet will try to log on to each Client Access server connectivity test mailbox created using the New-TestCasConnectivityUser.ps1 script in the current Active Directory site.
- **Remote** The **Test-UMConnectivity** cmdlet tries to connect to a remote Unified Messaging server by placing a call through an IP gateway. After it connects, it performs connectivity checks on the remote Unified Messaging server and the media paths.

Note:

If you receive the following message, you should restart the Microsoft

Exchange Unified Messaging service because it has stopped or is not responding: "The Test-UMConnectivity task encountered an error while trying to make a call. Details: Unable to establish a connection."

1.9.4.3.1 Test Unified Messaging Server Operation

Test Unified Messaging Server Operation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Shell to test the operation of a computer running Microsoft Exchange Server 2010 that has the Unified Messaging (UM) server role installed. When you perform the following procedure, the Unified Messaging server initiates a diagnostic Session Initiation Protocol (SIP) call, and then returns a health state variable of the Unified Messaging server.

This diagnostic test can be run only on a local Unified Messaging server, and you can't test the operation of the Unified Messaging server using the EMC.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to test the operation of the Unified Messaging server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example performs connectivity and operational tests on the local Unified Messaging server, and then displays the Voice over IP (VoIP) connectivity information.

```
Test-UMConnectivity
```

This example tests the ability for a local UM server to listen for incoming unencrypted SIP requests on TCP port 5060.

```
Test-UMConnectivity -ListenPort 5060
```

This example tests the ability for a local UM server to listen for incoming encrypted SIP requests on TCP port 5061.

```
Test-UMConnectivity -ListenPort 5061
```

Note:
Use mode 1 when the -UMIPGateway parameter isn't specified.

Note:
You can set the -Timeout parameter with a value of less than 5 seconds. However, we recommend that you always configure this parameter with a value of 5 seconds or more.

For more information about syntax and parameters, see Test-UMConnectivity.

Other Tasks

After you test the operation of the Unified Messaging server and telephony components, you may also want to:

- Testing Unified Messaging Server Functionality
- Test Unified Messaging Server Operation
- Connect a Unified Messaging Server to a Supported IP Gateway

1.9.4.3.2 Test Unified Messaging Server Connectivity to IP Gateways and PBXs

Test Unified Messaging Server Connectivity to IP Gateways and PBXs

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can test the operation of a Microsoft Exchange Server 2010 Unified Messaging (UM) server and related connected telephony equipment. When you perform the following procedure, the Unified Messaging server tests the full end-to-end operation of the UM system. This includes the telephony components connected to the Unified Messaging server, including IP gateways, Private Branch eXchanges (PBXs), and cabling.

This diagnostic test can be run only on a local Unified Messaging server, and you can't test the operation of the Unified Messaging server using the EMC.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Prerequisites

- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM mailbox policy has been created. For detailed steps, see Create a UM Mailbox Policy.

Use the Shell to test the operation of the

Unified Messaging server and telephony components

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

This example tests the ability of the UM IP gateway to listen on TCP port 5060 for incoming SIP requests.

```
Test-UMConnectivity -ListenPort 5060 -UMIPGateway MyIPGateway
```

This example tests the ability of the local Unified Messaging server to use an unsecured TCP connection instead of a secured mutual TLS connection to place a call through a UM IP gateway named MyUMIPGateway by using the telephone number 56780.

```
Test-UMConnectivity -UMIPGateway MyUMIPGateway -Phone 56780 -Secured $false
```

This example tests the subscriber access number on a dial plan by using a SIP URI. This example can be used in an environment that includes Microsoft Office Communications Server 2007.

```
Test-UMConnectivity -UMIPGateway OCSGateway1 -Phone "sip:SIPdialplan.contoso.com@
```

Note:
You can set the -Timeout parameter with a value of less than 5 seconds. However, we recommend that you always configure this parameter with a value of 5 seconds or more. Use mode 2 when the UMIPGateway parameter is specified in the command-line syntax.

For more information about syntax and parameters, see Test-UMConnectivity.

Other Tasks

After you test the operation of the Unified Messaging server and telephony components, you may also want to:

- Testing Unified Messaging Server Functionality
- Test Unified Messaging Server Operation
- Connect a Unified Messaging Server to a Supported IP Gateway

1.9.4.4 Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool

Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-10*

Understanding the Exchange 2010 UM Troubleshooting Tool

1.9.4.4.1 Understanding the Exchange 2010 UM Troubleshooting Tool

Understanding the Exchange 2010 UM Troubleshooting Tool

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-22*

The Microsoft Exchange 2010 Unified Messaging Troubleshooting Tool is an Exchange Management Shell cmdlet named **Test-ExchangeUMCallFlow**. You can use this tool to conduct a series of diagnostic tests for Unified Messaging (UM) in your organization. If any of the tests fail, the tool reports the reason for the failure and possible solutions to fix the problem. You can only use the UM Troubleshooting Tool on Exchange 2010 servers that have Exchange Server 2010 Service Pack 1 (SP1) installed.

The UM Troubleshooting Tool can be used to test whether voice mail is functioning correctly in both on-premises and cross-premises deployments. You can use this tool in UM deployments that include Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010, or in UM deployments that include IP gateways or IP Private Branch eXchanges (IP PBXs).

Note:

The UM Troubleshooting Tool is used for testing and troubleshooting. The **Test-UMConnectivity** cmdlet, on the other hand, should be used for monitoring. The **Test-UMConnectivity** cmdlet is used with System Center Operations Manager (SCOM) management packs that are used for monitoring Unified Messaging servers and the telephony components. The **Test-UMConnectivity** cmdlet performs local SIP tests and local logon tests to mailboxes, and can be run as an SCOM task.

To download the UM Troubleshooting Tool, see Unified Messaging Troubleshooting Tool.

Contents

Overview

The UM Troubleshooting Tool simplifies testing and troubleshooting in UM deployments. When the UM Troubleshooting Tool is run, it automatically generates a set of trace files that are stored in the C:\Users\%UserProfile%\AppData\Roaming\Microsoft Exchange 2010 UM Troubleshooting folder. The following trace files are generated by the tool:

- **UMTool_Collaboration** Includes RTC stack traces.
- **UMTool_DiagnosticLog** Lists all the tests that are run and their results.
- **UMTool_S4** Includes the S4: signaling stack traces.
- **UMTool_SIPMessageLogs** Includes the full SIP traces for the test call that's made.

The UM Troubleshooting Tool connects directly to an on-premises Session Border Controller (SBC), if one exists, or connects to an SBC in a datacenter and emulates an incoming call as if the call was coming from a PBX through an IP gateway or an IP PBX. The UM Troubleshooting tool can be used to diagnose:

- Incorrect settings in on-premises or cross-premises UM deployments in which Office Communications Server R2 or Microsoft Lync Server 2010 is deployed.
- Incorrect settings on on-premises or cross-premises telephony equipment that includes IP gateways and PBXs or IP PBXs.
- Issues with Domain Name System (DNS).
- Certificate issues when you're using SIP secured or Secured UM dial plans.
- Signaling and media issues for DTMF (also known as touchtone) and audio.

If the UM Troubleshooting Tool detects a failure in your configuration, the tool reports the reason for the error and the possible solutions for the issues that have been detected. The errors that can be reported when the UM Troubleshooting Tool is used in an on-premises deployment include the following:

- The maximum call limit has been reached.
- The user isn't enabled for Unified Messaging.
- The UM IP gateway, dial plan, or hunt group information can't be located.
- The security type doesn't match the UM dial plan.
- There are no worker processes available to process the call.
- The UM server is disabled.
- The Active Directory forest couldn't be located.
- No disk space is available.
- Invalid SIP headers were used in the request.
- A call was made to an Office Communications Server 2007 R2 server or Lync Server server.
- The UM IP gateway is disabled.
- The URI for the user who is being called isn't valid.

When the UM Troubleshooting Tool is used in a cross-premises deployment, the errors that can be reported include the following:

- The user isn't enabled for Unified Messaging.
- The UM IP gateway is disabled.
- The URI for the user is invalid.
- The security type doesn't match the UM dial plan.
- Invalid SIP headers were used in the request.
- The UM IP gateway, dial plan, or hunt group information can't be located.

The UM Troubleshooting Tool sends a sample wav file for 15 seconds. After the audio file and RTP audio stream is sent and played back, the tool reports general audio quality metrics for diagnosing audio quality issues related to network connectivity, such as jitter and average packet loss. These reports include the media stream quality to and from a UM server and contain the following:

- Network Mean Opinion Score (NMOS)
- Codec
- Latency in milliseconds (ms)
- Jitter in milliseconds (ms)

- % of packet loss
- The NMOS classification and rating that will be used to determine the audio quality will be:
- NMOS less than 2 = Poor
- NMOS greater than 2 but less than 3 = Average
- NMOS greater than 3 but less than 4 = Good
- NMOS greater than 4 but less than 5 = Excellent

The UM Troubleshooting Tool supports testing UM dial plans that use Secured, SIP Secured, and Unsecured calls. If you choose Secured or SIP Secured, the thumbprint of the certificate that's used is checked to determine whether the certificate is expired and the type of certificate that's used for TLS (Transport Layer Security) communications. The certificate is used to correctly identify and ensure the identity of the remote computer. When Secured or SIP Secured mode is selected, the UM Troubleshooting Tool verifies whether the following are true:

- The local certificate was found in the local computer store.
- The certificate being used is trusted.
- The target name specified in the certificate is valid.
- The certificate has expired.
- The remote computer trusts the certificate.
- The certificate has been revoked.
- The certificate doesn't have the required enhanced key usage.

The UM Troubleshooting Tool can be run in either Gateway or SIPClient mode, depending on whether Office Communications Server 2007 R2 or Lync Server 2010 is deployed or whether IP gateways and PBXs or IP PBXs are used with Unified Messaging servers. When either Gateway or SIPClient mode is used, the UM Troubleshooting Tool supports making calls using the following formats. The format that's used depends on the URI type of the UM dial plan:

- Telephone extension 425-555-1010
- E.164 phone numbers +1 (425) 555-1010
- SIP addresses tonysmith@contoso.com

When SIPClient mode is used, the UM Troubleshooting Tool makes a voice memo call. This is a call that doesn't ring a phone or a Unified Communications (UC) endpoint. Instead, it sends the call directly to voice mail. When the UM Troubleshooting Tool is run in SIPClient mode, it will determine:

- Which target user is being called.
- Whether the SIP call was established successfully.

Whether the SIP call was accepted by an Exchange Unified Messaging server.

- Whether the correct DTMF sequence was received.
- Whether the diagnostic .wav file was sent and received by a UM server.
- The metrics that were used when the media or audio quality stream was received.

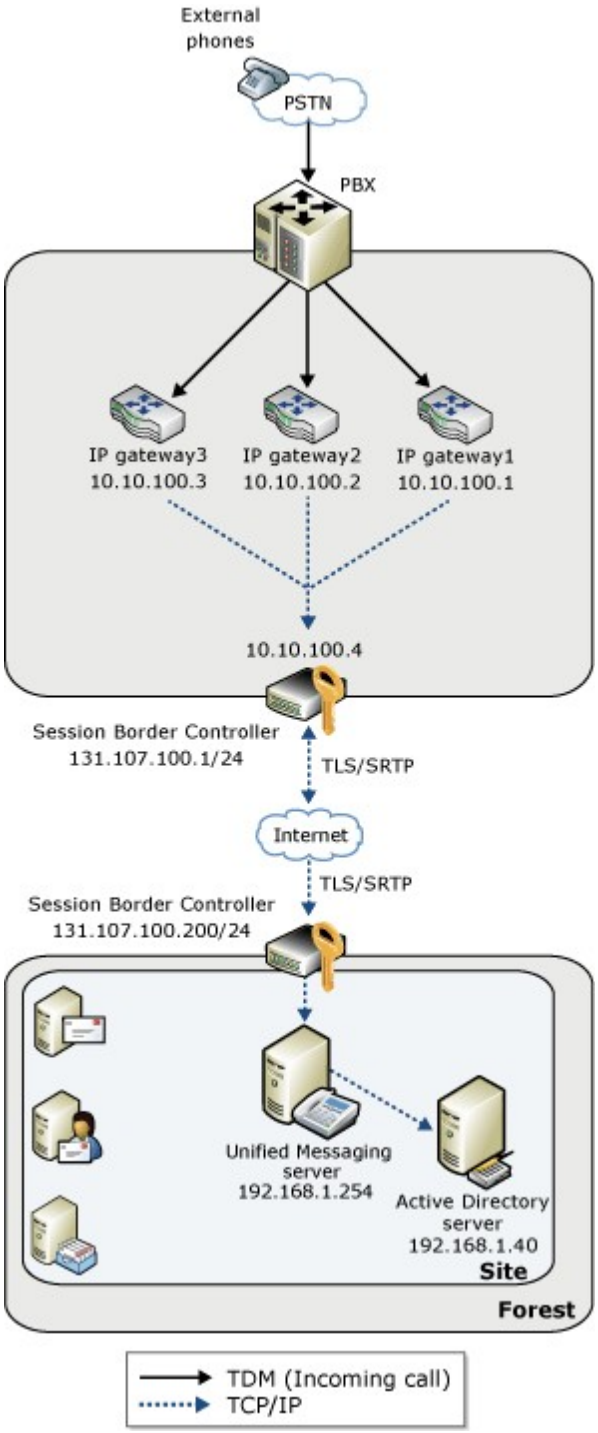
The UM Troubleshooting Tool emulates incoming calls and runs a series of diagnostic tests that help on-premises administrators and tenant administrators test call flow for call answering and identify configuration errors. Although the UM Troubleshooting Tool can be used in call answering scenarios, it can't be used to test the following types of calls:

- Outlook Voice Access calls, including calls that access voice mail, e-mail, calendar, the directory, personal Contacts, or personal options
- UM auto attendants
- Play on Phone
- Call Answering Rules
- Faxing
- Prompt provisioning

Return to top

UM Troubleshooting Architecture

Although the UM Troubleshooting Tool can help you troubleshoot, diagnose, and repair configuration issues in a cross-premises deployments, you can also used it in on-premises Unified Messaging deployments. In cross-premises deployments, the tool also validates on-site SBC configurations. The administrator can test all the Unified Messaging components that are used by Unified Messaging, including the SBCs. The following figure shows an overview of the components that can be tested in a cross premises deployment that includes on-site IP gateways and a local SBC that connects to an off-site SBC.

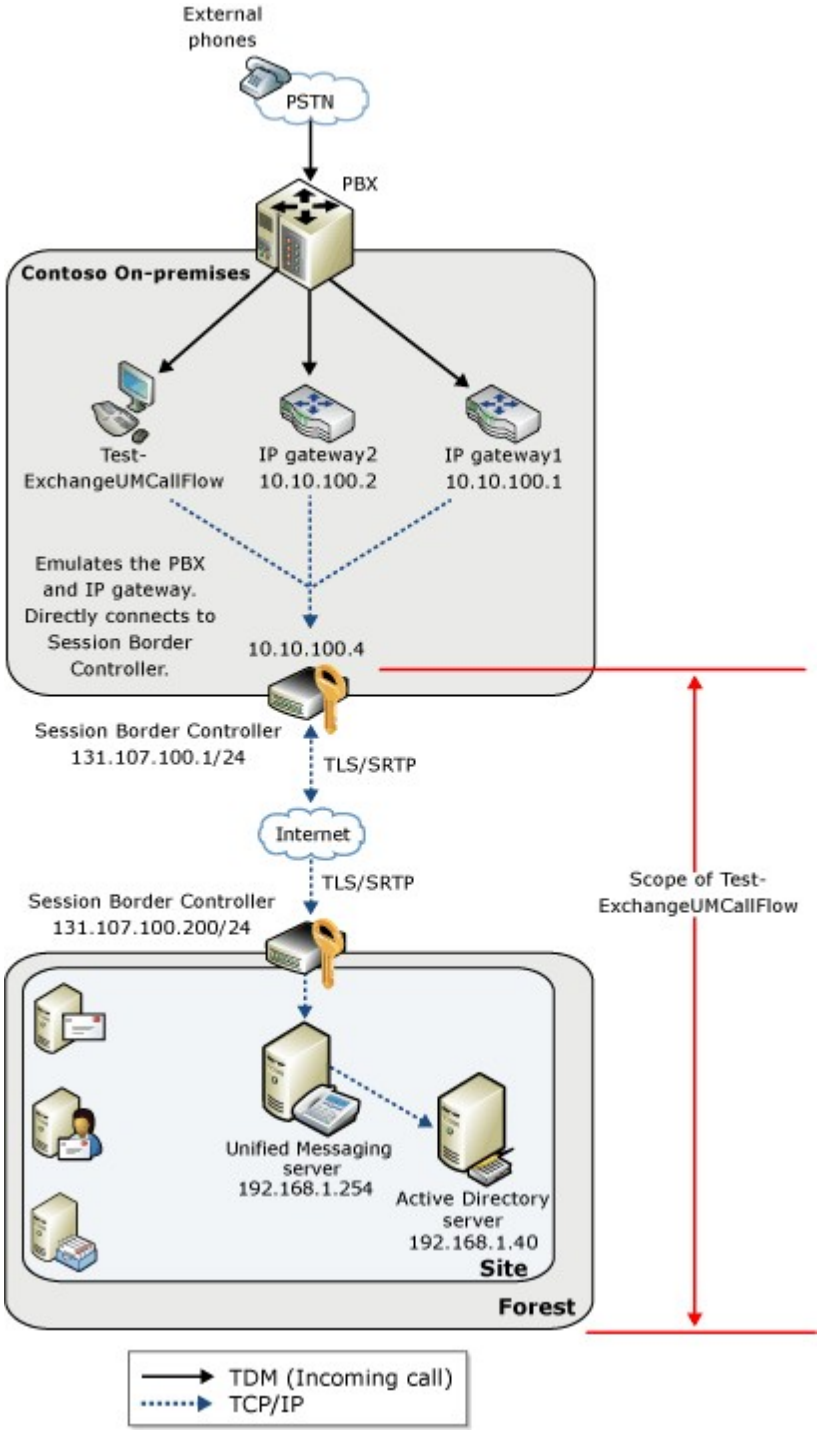


IP Gateway and IP PBX Deployments

In the following example, Gateway mode is used to test call flow in an environment that doesn't include Office Communications Server 2007 R2 or Lync Server 2010. This example tests the telephony equipment, including IP gateways, PBXs and IP PBXs, and the Unified Messaging components. This example sets the Voice over IP (VoIP) security mode to Unsecured, uses the IP address 10.1.1.1 as the next hop, and includes an extension number in the diversion information.

```
Test-ExchangeUMCallFlow -Mode Gateway -VoIPSecurity Unsecured -NextHop 10.1.1.1 -
```

The following figure shows the components that are tested when Gateway mode is used.



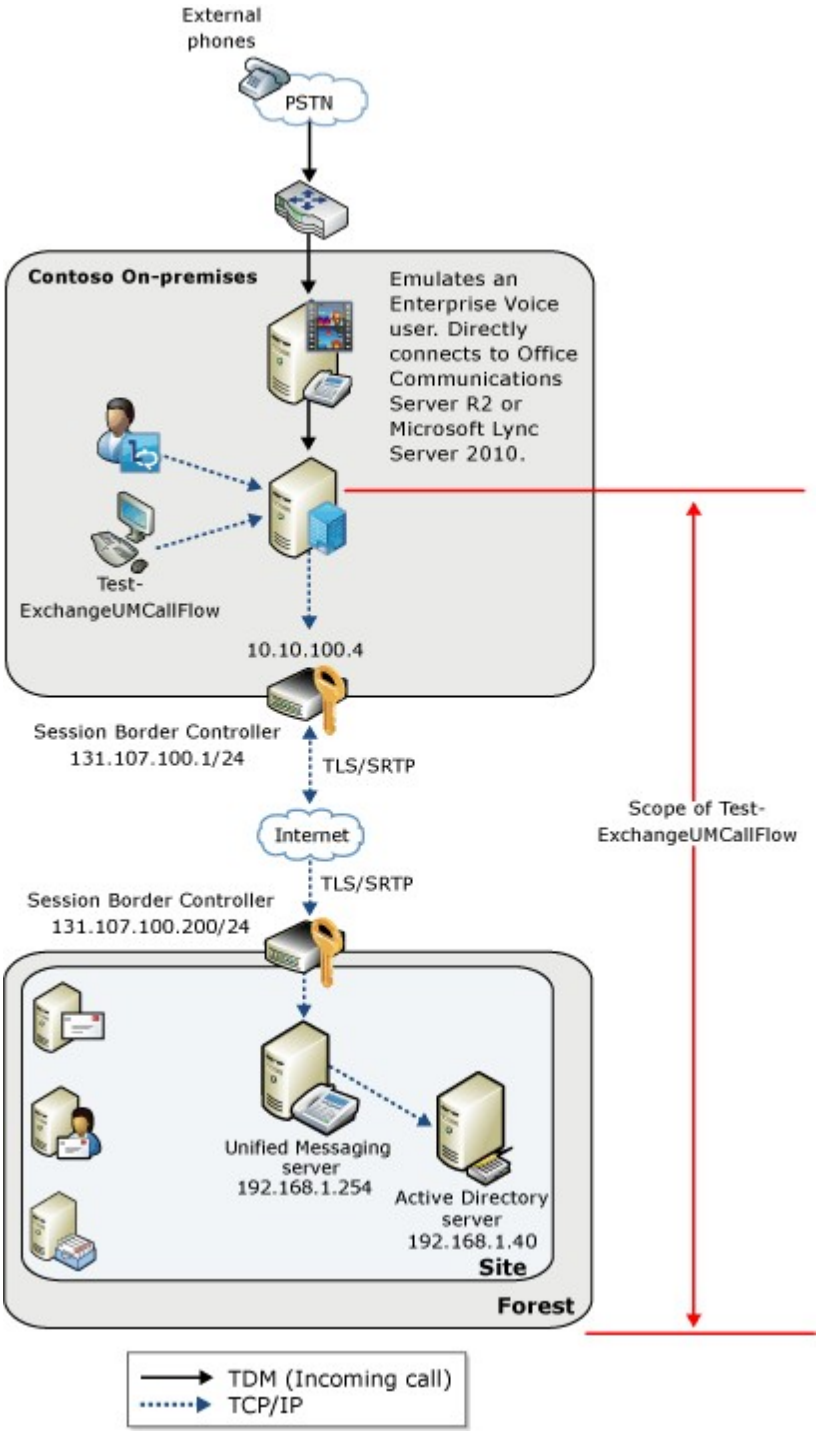
Return to top

Office Communications Server R2 and Microsoft Lync Server 2010 Deployments

The UM Troubleshooting Tool can be used in on-premises or cross-premises deployments that include Office Communications Server 2007 R2 or Microsoft Lync Server 2010 when SIPClient mode is set. The following example uses SIPClient mode and tests the call flow with a secured UM dial plan in an environment that contains Office Communications Server 2007 R2 or Lync Server 2010 servers. By default, when you run the UM Troubleshooting Tool, it uses the credentials of the user who is currently logged on to the computer. When you run the following example, you'll be prompted for the credentials you want to use when you run the UM Troubleshooting Tool. For details, see Set the Credentials to Use with the Exchange 2010 UM Troubleshooting Tool.

```
Test-ExchangeUMCallFlow -Mode SIPClient -VoIPSecurity Secured -CallingParty tony@
```

The following figure shows the components that are tested when SIPClient mode is used.



Installing the UM Troubleshooting Tool

The UM Troubleshooting Tool can be installed on a local Unified Messaging server or on another 64-bit computer running either:

- The Windows 7 or Windows Vista operating systems.
- The Windows Server 2008 or Windows Server 2008 R2 operating systems.

If you're using the UM Troubleshooting Tool on a 64-bit version of Windows 7, Windows

Vista, or the 64-bit edition of Windows Server 2008, the following components must be installed before you can install the UM Troubleshooting Tool:

- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) See Microsoft .NET Framework 3.5 Service Pack 1.

  Note:
  If the tool will be run on a Windows Vista or Windows Server 2008 computer, see Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64.

- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) See Microsoft Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
- Microsoft Unified Communications Managed API 2.0 Core Runtime (UcmaRuntimeWebDownloadX64.msi) See Unified Communications Managed API 2.0, Core Runtime (64-bit).

The UM Troubleshooting Tool (**Test-ExchangeUMCallFlow** cmdlet) isn't included on the Exchange 2010 SP1 DVD or the download that only includes Exchange 2010. However you can download the UM Troubleshooting Tool from the Microsoft Download Center.

For details, see Install the Exchange 2010 UM Troubleshooting Tool.

Return to top

Cmdlet Parameters

The following table includes the parameters you can use with the **Test-ExchangeUMCallFlow** cmdlet and descriptions of those parameters. You can also use the Shell command `Get-help Test-ExchangeUMCallFlow -detailed` to find detailed information about each parameter that can be used with the **Test-ExchangeUMCallFlow** cmdlet, along with usage examples.

Parameters

Parameter	Description
CalledParty	The *CalledParty* parameter specifies the SIP URI of the Office Communications Server 2007 R2 or Lync Server 2010 user who has been enabled for Enterprise Voice. This is the user who the **Test-ExchangeUMCallFlow** cmdlet will make the voice call to, for example: `-CalledParty tonysmith@contoso.com`. Use this parameter if you're running the tool in SIPClient mode.
CallingParty	The *CallingParty* parameter specifies the SIP URI of the Office Communications Server 2007 R2 or Lync Server 2010 user who has been enabled for Enterprise Voice. This is the user who's making the incoming call, for example: `-CallingParty tonysmith@contoso.com`. Use this parameter if you're running the tool in SIPClient mode.
Diversion	The *Diversion* parameter specifies the string that should be sent as diversion information for the incoming call. This can be in the form of a Diversion or History-Info header. The diversion information that is included in the incoming call can be an

	extension number or can include additional diversion information. When you provide diversion information as a History-Info header, verify the following: • There are at least two different entries with different user parts. • The last entry contains pilot number of the user's associated UM dial plan. • The second-to-last entry includes a UM-enabled user's extension number. This entry must also include the appropriate Reason text. This text must be escaped correctly in accordance with standard URL parameter escaping rules.
Mode	The *Mode* parameter specifies whether the IP gateway, IP PBX, or Office Communications Server R2 or Lync Server 2010 mode is to be used. You can specify either Gateway mode when your UM deployment includes IP gateways or IP PBXs or SIPClient mode when your UM deployment includes Office Communications Server 2007 R2 or Lync Server 2010.
NextHop	The *NextHop* parameter specifies the IP address or fully qualified domain name (FQDN) of the next hop and can also include the TCP port of the next hop that the **Test-ExchangeUMCallFlow** cmdlet must connect to while emulating the IP gateway or IP PBX. When you include the TCP port, you must specify either port 5060 for Unsecured mode or port 5061 for Secured or SIP Secured mode. For example: `gateway.contoso.com:5061`.
CertificateThumbprint	The *CertificateThumbprint* parameter specifies the thumbprint of the certificate used for TLS. This is required if either SIP Secured or Secured mode is configured on the UM dial plan. This certificate thumbprint is the certificate that was exported from the IP gateway, IP PBX, or SBC. Also, the computer that has the UM Troubleshooting Tool installed and is being used to test for call flow must trust the certificate of authority for the next hop.
Credential	The *Credential* parameter specifies the credentials that will be used to run the cmdlet.
HuntGroup	The *HuntGroup* parameter specifies the UM hunt group associated with the IP gateway that's being emulated. This is typically an extension number. Use this parameter if you're running the tool in Gateway mode.
VoIPSecurity	The *VoIPSecurity* parameter specifies the security mode when using the cmdlet in Gateway mode. You can use one of the following VoIP security modes: • Secured (TLS/SRTP) • Unsecured (TCP/RTP) (default)

	• SIP Secured (TLS/RTP)

Return to top

1.9.4.4.2 Install the Exchange 2010 UM Troubleshooting Tool

Install the Exchange 2010 UM Troubleshooting Tool

Unified Messaging > Troubleshooting Reference for Unified Messaging Servers > Testing Call Flow with the Exchange 2010 UM Troubleshooting Tool >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Microsoft Exchange 2010 UM Troubleshooting Tool is an Exchange Management Shell cmdlet named **Test-ExchangeUMCallFlow**. You can use the cmdlet to diagnose configuration errors specific to call answering scenarios and to test whether voice mail is functioning correctly in both on-premises and cross-premises Microsoft Exchange Server 2010 Service Pack 1 (SP1) UM deployments. You can use this cmdlet in deployments with Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 or in UM deployments with IP gateways or IP PBXs.

The UM Troubleshooting tool can be installed on a local Unified Messaging server or on another 64-bit computer.

Prerequisites

The UM Troubleshooting tool requires that the following components be installed on a computer running Windows 7, Windows Vista, or the 64-bit edition of Windows Server 2008 before the tool is installed:

- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) See Microsoft .NET Framework 3.5 Service Pack 1.
- If the tool will be run on a Windows Vista or Windows Server 2008 computer See Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64.
- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) See Microsoft Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
- Microsoft Unified Communications Managed API 2.0 Core Runtime (UcmaRuntimeWebDownloadX64.msi) See Unified Communications Managed API 2.0, Core Runtime (64-bit).

Install the UM Troubleshooting Tool

1. Download the Unified Messaging Troubleshooting Tool from the Microsoft Download Center, and then double-click the MicrosoftExchange2010UMTroubleshootingTool.msi installation folder.
2. On the **Welcome to the Microsoft Exchange 2010 UM Troubleshooting Tool Setup Wizard** page, click **Next**.
3. On the **End-User License Agreement** page, review the software license terms, and if you agree, click **I accept the terms in the license agreement** and then click **Next**.
4. On the **Select Installation Folder** page, verify the path to the installation folder and click **Next**.
5. On the **Confirm Installation** page, click **Next** to start installation.

6. On the **Installation Complete** page, click **Close**.

Other Tasks

After you install the UM Troubleshooting Tool, you may also want to review:

- Set the Credentials to Use with the Exchange 2010 UM Troubleshooting Tool
- Run the Exchange 2010 UM Troubleshooting Tool on Windows 7 or Windows Vista

1.9.4.4.3 Set the Credentials to Use with the Exchange 2010 UM Troubleshooting Tool

Set the Credentials to Use with the Exchange 2010 UM Troubleshooting Tool

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Microsoft Exchange 2010 UM Troubleshooting Tool is an Exchange Management Shell cmdlet named **Test-ExchangeUMCallFlow**. You can use the cmdlet to diagnose configuration errors specific to call answering scenarios and to test whether voice mail is functioning correctly in both on-premises and cross-premises Microsoft Exchange Server 2010 Service Pack 1 (SP1) UM deployments. You can use this cmdlet in deployments with Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 or in UM deployments with IP gateways or IP PBXs.

By default, when you're running the UM Troubleshooting Tool, it uses the credentials that are used when you log on to the computer. The credentials used are those that are specified for the calling party. You must set or specify the credentials to be used when you're running the UM Troubleshooting Tool in `SIPClient` mode. However, you don't need to set the credentials when running the UM Troubleshooting Tool in `Gateway` mode.

Prerequisites

- An Exchange 2010 server with the UM server role installed. For detailed steps, see Install the Exchange 2010 Unified Messaging Server Role.
- A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.
- A UM server has been added to a UM dial plan. For detailed steps, see Add a UM Server to a Dial Plan.
- Install the UM Troubleshooting Tool. For detailed steps, see Install the Exchange 2010 UM Troubleshooting Tool.

Important:

If you will be using the UM Troubleshooting Tool in `SIPClient` mode, there are several other Office Communications Server 2007 R2 or Microsoft Lync Server 2010 requirements and prerequisites. For more information, see Checklist: Deploy Office Communications Server 2007 R2 and Exchange 2010 Unified Messaging.

Set the credentials to use with the UM Troubleshooting Tool

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. Open the **Microsoft Exchange 2010 UM Troubleshooting Tool** from the **Start** menu.
2. In the **Microsoft Exchange 2010 UM Troubleshooting Tool** window, at the prompt, type the following and press **Enter**.

```
$cred=Get-Credential
```

3. In the **Windows PowerShell Credential Request** window, type the domain \user name and password and then click **OK**.
4. In the **Microsoft Exchange 2010 UM Troubleshooting Tool** window, specify the necessary cmdlet parameters to test for call flow. For example:

```
Test-ExchangeUMCallFlow -Mode SIPClient -CallingParty tonysmith@contos
```

Other Tasks

After you set the credentials for the UM Troubleshooting Tool, you may also want to:

- Run the Exchange 2010 UM Troubleshooting Tool on Windows 7 or Windows Vista
- Test-UMConnectivity

1.9.4.4.4 Run the Exchange 2010 UM Troubleshooting Tool on Windows 7 or Windows Vista

Run the Exchange 2010 UM Troubleshooting Tool on Windows 7 or Windows Vista

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Microsoft Exchange 2010 UM Troubleshooting Tool is an Exchange Management Shell cmdlet named **Test-ExchangeUMCallFlow**. You can use the cmdlet to diagnose configuration errors specific to call answering scenarios and to test whether voice mail is functioning correctly in both on-premises and cross-premises Microsoft Exchange Server 2010 Service Pack 1 (SP1) UM deployments. You can use this cmdlet in deployments with Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 or in UM deployments with IP gateways or IP PBXs.

Prerequisites

- Make sure your Exchange 2010 organization meets the following requirements:
  - A UM dial plan has been created. For detailed steps, see Create a UM Dial Plan.
  - A UM mailbox policy has been created. For detailed steps, see Create a UM

Mailbox Policy.
- A UM IP gateway has been created. For detailed steps, see Create a UM IP Gateway.
- A UM server has been added to a UM dial plan. For detailed steps, see Add a UM Server to a Dial Plan.

- If you're running the UM Troubleshooting Tool on a local UM server with Exchange 2010 SP1, you may not have to install all the prerequisites listed below. They may have already been installed along with the UM server role. However, if you're installing the UM Troubleshooting Tool on a 64-bit computer other than a server that is running the UM server role, you will need to install the following components:
  - Microsoft .NET Framework 3.5 Service Pack 1 (SP1) See Microsoft .NET Framework 3.5 Service Pack 1.
  - If the tool will be run on a Windows Vista or Windows Server 2008 computer See Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64.
  - Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) See Microsoft Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
  - Microsoft Unified Communications Managed API 2.0 Core Runtime (UcmaRuntimeWebDownloadX64.msi) See Unified Communications Managed API 2.0, Core Runtime (64-bit).
- Download and install the UM Troubleshooting Tool.
  - Download Unified Messaging Troubleshooting Tool from the Microsoft Download Center.
  - Install the tool. For details, see Install the Exchange 2010 UM Troubleshooting Tool.

Important:

If you will be using the UM Troubleshooting Tool in `SIPClient` mode, there are several other Office Communications Server 2007 R2 or Microsoft Lync Server 2010 requirements and prerequisites that must be met. For more information, see Checklist: Deploy Office Communications Server 2007 R2 and Exchange 2010 Unified Messaging.

Run the UM Troubleshooting Tool on Windows 7 or Windows Vista

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM server" entry in the Unified Messaging Permissions topic.

1. Click **Start** > **All Programs** > **Accessories** > **Windows PowerShell**.
2. Right-click **Windows PowerShell**, and from the pop-up menu select **Run as administrator**.
3. At the PowerShell command prompt, go to the folder where the UM Troubleshooting Tool was installed and run the following.

```
C:\Windows\System32\WindowsPowerShell\v1.0\powershell.exe -psconsolefi
```

4. If you're running the UM Troubleshooting Tool on Windows 7, at the PowerShell command prompt, run the following:

```
Set-ExecutionPolicy RemoteSigned
```

5. Open the **Microsoft Exchange 2010 UM Troubleshooting Tool** from the **Start** menu.
6. In the **Microsoft Exchange 2010 UM Troubleshooting Tool** window, at the prompt, type the following and press Enter.

```
$cred=Get-Credential
```

7. In the **Windows PowerShell Credential Request** window, type the domain \user name and password and click **OK**.
8. In the **Microsoft Exchange 2010 UM Troubleshooting Tool** window, specify the necessary cmdlet parameters to test for call flow. For example:

```
Test-ExchangeUMCallFlow -Mode SIPClient -CallingParty tonysmith@contos
```

Other Tasks

After you set the credentials for the UM Troubleshooting Tool, you may also want to:

- Set the Credentials to Use with the Exchange 2010 UM Troubleshooting Tool
- Install the Exchange 2010 UM Troubleshooting Tool
- Test-UMConnectivity

1.9.5 Performance Counter Reference for Unified Messaging Servers

Performance Counter Reference for Unified Messaging Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Ensuring that servers running Microsoft Exchange Server 2010 are operating reliably is a key objective for messaging operations. An important part of Exchange 2010 operations is monitoring the Exchange components to understand the health state of servers and server roles. For more information about Unified Messaging performance counters, see the following topics:

- Unified Messaging Counters
- Performance and Scalability Counters and Thresholds

1.9.6 Error and Event Reference for Unified Messaging Servers

Error and Event Reference for Unified Messaging Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-20*

Microsoft Exchange Server 2010 Unified Messaging (UM) components, features, and services generate errors and events to enable you to effectively troubleshoot and monitor a Unified Messaging server.

Event Viewer maintains logs about program, security, and system events on your computer. You can use Event Viewer to view and manage the event logs, gather information about hardware and software problems, and monitor Microsoft Windows

security events. Although Event Viewer is a Windows operating system tool and not a Microsoft Exchange tool, Event Viewer is useful when you troubleshoot problems with Exchange. This topic describes the basic concepts related to Event Viewer.

This topic also describes the events that Unified Messaging lists in Event Viewer, explains how to use them to monitor Unified Messaging, and describes the error messages that are generated by a Unified Messaging server.

Unified Messaging Errors and Events

Unified Messaging generates errors and events in Event Viewer so that you can troubleshoot and verify the performance of Unified Messaging components, features, and services. Event Viewer tracks error events, warning events, and informational events in order of importance. The logs in Event Viewer provide an audited record of all services and processes in the Windows Server 2008 operating system.

Unified Messaging errors and events are grouped into six categories that are based on core components, processes, and services of Unified Messaging. You can also filter the errors or events that have been generated by a Unified Messaging server by category. The categories for Unified Messaging error and events include the following:

- UMCallData
- UMClientAccess
- UMCore
- UMManagement
- UMService
- UMWorkerProcess

The following is a list of the different types of Unified Messaging errors and events. They are grouped according to the administrative functionality of the errors and events that are generated by a Unified Messaging server.

- Unified Messaging Administrative Errors and Events
- Unified Messaging Auto Attendant Errors and Events
- Unified Messaging Call Answering Errors and Events
- Unified Messaging Call Transfer Errors and Events
- Unified Messaging Outdialing Errors and Events
- Unified Messaging Performance Errors and Events
- Unified Messaging Prompt Publishing Errors and Events
- Unified Messaging Speech Grammar Errors and Events
- Unified Messaging Subscriber Access Errors and Events
- Unified Messaging System Errors and Events
- Unified Messaging Active Directory Errors and Events

1.9.6.1 Unified Messaging Administrative Errors and Events

Unified Messaging Administrative Errors and Events

Exchange Server 2010 > Unified Messaging > Error and Event Reference for Unified Messaging Servers >

Topic Last Modified: *2009-09-23*

Microsoft Exchange Server 2010 Unified Messaging (UM) generates administrative events

in Event Viewer so that you can troubleshoot and verify the performance of UM administrative components, features, and services. Event Viewer tracks the following kinds of events in the following order, based on importance:

1. Error events
2. Warning events
3. Informational events

UM Administrative Errors and Events

The following table provides a list of the UM administrative events that you can use to troubleshoot and monitor Unified Messaging.

Administrative events

Event ID	Category	Event type	Logging	Value or description	Class
1015	UMManagement	Information	LogAlways	User "%1" has been successfully enabled for Unified Messaging.	Administrative
1016	UMManagement	Information	LogAlways	User "%1" has been disabled for Unified Messaging.	Administrative
1017	UMManagement	Information	LogAlways	The Unified Messaging mailbox for UM-enabled user "%1" has been successfully unlocked.	Administrative
1018	UMManagement	Information	LogAlways	The Outlook Voice Access PIN for user "%1" has been changed.	Administrative
1060	UMManagement	Information	LogAlways	A new UM dial plan named "%1" was created.	Administrative
1061	UMManagement	Information	LogAlways	A new UM IP gateway named "%1" with IP address "%2" has been created.	Administrative
1062	UMManagement	Information	LogAlways	A new Unified Messaging hunt group	Administrative

				named "%1" has been created with pilot identifier "%2" and is associated with UM dial plan "%3".	
1063	UMManagement	Information	LogAlways	The dial plan named "%1" has been removed.	Administrative
1064	UMManagement	Information	LogAlways	IP gateway "%1", which has IP address "%2", has been removed.	Administrative
1065	UMManagement	Information	LogAlways	The UM hunt group "%1" with the pilot identifier "%2" that is associated with UM dial plan "%3" has been removed.	Administrative
1066	UMManagement	Information	LogAlways	Unified Messaging server "%1" has been enabled.	Administrative
1067	UMManagement	Information	LogAlways	The UM IP gateway "%1" with IP address "%2" has been enabled.	Administrative
1068	UMManagement	Information	LogAlways	The Unified Messaging server named "%1" has been disabled.	Administrative
1069	UMManagement	Information	LogAlways	The Unified Messaging IP gateway "%1" with the IP address "%2" has been disabled.	Administrative
1070	UMManageme	Information	LogAlways	A new UM	Administrative

	nt			auto attendant named "%1" was created and associated with UM dial plan "%2".	
1071	UMManagement	Information	LogAlways	The UM auto attendant named "%1" has been enabled.	Administrative
1072	UMManagement	Information	LogAlways	The auto attendant named "%1" has been disabled.	Administrative

Unified Messaging Auto Attendant Errors and Events

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-23*

Microsoft Exchange Server 2010 Unified Messaging (UM) generates UM auto attendant events in Event Viewer so that you can troubleshoot and verify the performance of the UM auto attendant components, features, and services. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

UM Auto Attendant Errors and Events

The following table provides a list of the UM auto attendant events that you can use to troubleshoot and monitor Unified Messaging.

Auto attendant events

Event ID	Category	Event type	Logging	Value or description	Class

1128	UMService	Error	LogPeriodic	No operator extension number has been configured for the UM auto attendant named "%1", or for the dial plan to which it belongs. Therefore, incoming calls received by this UM auto attendant cannot be transferred to the operator.	Auto Attendant
1129	UMService	Warning	LogAlways	The Unified Messaging auto attendant "%1" has not been configured with a valid time zone. Incoming calls answered by the UM auto attendant will be answered according to the time zone that has been configured on the Unified Messaging server that answers the call. To resolve this error, configure a valid time zone on the UM auto attendant.	Auto Attendant
1154	UMCore	Warning	LogAlways	An error occurred while adding a custom menu speech grammar entry for "%1" in auto attendant "%	Auto Attendant

				2". Details follow: "%3"	
1156	UMCore	Warning	LogAlways	Auto attendant "%1" is configured to use "%2", a language that is not supported on this Unified Messaging server. The auto attendant will use "%3", which is the default language of the associated dial plan "%4"'.	Auto Attendant
1164	UMCore	Warning	LogAlways	A call to auto attendant "%1" was not handled. "%2"	Auto Attendant
1172	UMCallData	Information	LogAlways	Call data: "%1"	Auto Attendant

Unified Messaging Call Answering Errors and Events

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-23*

Microsoft Exchange Server 2010 Unified Messaging (UM) generates call answering events in Event Viewer so that you can troubleshoot and verify the performance of the call answering components, features, and services. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

Call Answering Errors and Events

The following table provides a list of the call answering events that you can use to troubleshoot and monitor Unified Messaging.

Call answering events

Event ID	Category	Event type	Logging	Value or description	Class
1004	UMCore	Information	LogAlways	A call was received with the following parameters: Calling Party: "%1", Called Party: "%2", Diversion Information: "%3", Call ID "%4".	Call Answering
1006	UMCore	Information	LogAlways	The Unified Messaging server has received a call from "%1", with user extension "%2" and a call ID of "%3".	Call Answering
1021	UMCore	Warning	LogAlways	The Unified Messaging server rejected an incoming call with the ID "%1". Reason: "%2"	Call Answering
1081	UMCore	Warning	LogAlways	The Unified Messaging server failed to receive an incoming call for user "%1" during the call with ID "%2" because a Hub Transport server is currently busy or not available. To correct this error, make sure that there is at least one Hub	Call Answering

				Transport server installed in the same Active Directory site as the Unified Messaging server and that a Hub Transport server is available.	
1082	UMService	Error	LogAlways	The Unified Messaging server was unable to submit messages to a Hub Transport server because there is no Hub Transport server available to process the request with UM header file "%1". Make sure that there is a Hub Transport server located in the same Active Directory site as the UM server. In addition, make sure that the Microsoft Exchange Transport service is started on the Hub Transport server.	Call Answering
1109	UMCore	Warning	LogAlways	The Unified Messaging server has received an inbound call that has an invalid extension "%1" for UM dial plan "%2".	Call Answering

				The call ID is "%3".	
1146	UMCore	Warning	LogAlways	The Unified Messaging server was unable to resolve the caller ID "%1" to a user in Active Directory or personal contact before attempting to submit voice mail to the Hub Transport server. The recipient of the message was "%2". More information: "%3"	Call Answering
1153	UMCore	Information	LogAlways	The Unified Messaging server received an incomplete number of digits for the extension number with ID "%1". The number of digits received was %2. This does not match the number of digits that was configured on dial plan "%3", which is %4. Because the number of digits does not match the number configured on the dial plan, the Unified Messaging server will send this call to the dial	Call Answering

				plan pilot number.	
1169	UMCore	Warning	LogAlways	The user with extension "%1" is not enabled for Unified Messaging.	Call Answering
1170	UMCallData	Information	LogAlways	Call data: %1	Call Answering

1.9.6.9 Unified Messaging Subscriber Access Errors and Events

Unified Messaging Subscriber Access Errors and Events

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-23*

Microsoft Exchange Server 2010 Unified Messaging (UM) generates subscriber access events in Event Viewer so that you can troubleshoot and verify the performance of the subscriber access components and services. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

Subscriber Access Errors and Events

The following table provides a list of the subscriber access events that you can use to troubleshoot and monitor Unified Messaging.

Subscriber access events

Event ID	Category	Event type	Logging	Value or description	Class
1012	UMCore	Warning	LogAlways	User "%1" is locked out of their mailbox because they have entered an incorrect PIN "%2" consecutive times. The PIN must be reset before the user can log on to the mailbox from the telephone again.	Subscriber Access
1013	UMCore	Warning	LogAlways	User "%1" was disconnected by the Unified Messaging server because the user failed to log on "%2" consecutive times. The user did not enter the correct PIN.	Subscriber Access
1019	UMCore	Warning	LogAlways	User "%1" was unable to log on to their mailbox using Outlook Voice Access because the checksum for the user's PIN is not valid. The user will not be able to log on to the system until their PIN is reset.	Subscriber Access
1036	UMCore	Information	LogAlways	The Unified Messaging server successfully authenticated user "%1".	Subscriber Access

				The call ID is "%2".	
1080	UMCore	Warning	LogAlways	The Unified Messaging (UM) server failed to process messages for user "%1" during the call with ID "%2" because the user has exceeded their mailbox quota.	Subscriber Access
1134	UMCore	Warning	LogAlways	The Unified Messaging server detected corrupt user configuration data for user "%1". This data contains information such as whether the user has previously logged on to their mailbox or has set their Out of Office status, and also contains any personalized voice mail greetings the user has recorded. The Unified Messaging server will use default configuration data for the user.	Subscriber Access
1135	UMCore	Error	LogAlways	The Microsoft Exchange Unified Messaging service detected a corrupted PIN	Subscriber Access

				for user "%1". The user's UM configuration data contains information such as the user's current PIN and the number of consecutive times the user has entered an incorrect PIN. The user will not be able to log on to the Unified Messaging system until their PIN is reset.	
1171	UMCallData	Information	LogAlways	Call data: "%1"	Subscriber Access

Unified Messaging System Errors and Events

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-06-20*

Microsoft Exchange Server 2010 Unified Messaging generates system events in Event Viewer so that you can troubleshoot and verify the performance of Unified Messaging system components, features, and services. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

UM System Error and Events

The following table provides a list of Unified Messaging system events that you can use to troubleshoot and monitor Unified Messaging.

Unified Messaging system events

Event ID	Category	Event type	Logging	Value or description	Class
1000	UMWorkerProcess	Information	LogAlways	The Unified Messaging Worker Process was started successfully on port "%1".	System
1001	UMWorkerProcess	Error	LogAlways	The Microsoft Exchange Unified Messaging Worker Process (UMWorkerProcess.exe) was unable to start. More information: %1.	System
1002	UMWorkerProcess	Information	LogAlways	The Unified Messaging Worker Process has been stopped successfully.	System
1003	UMWorkerProcess	Error	LogAlways	An unhandled exception occurred while the UM Worker Process (UMWorkerProcess.exe) was stopping. Exception details follow: %1	System
1007	UMCore	Information	LogAlways	The Unified Messaging server has ended a call with ID "%1" because the user at the far end disconnected.	System
1008	UMCore	Error	LogAlways	The Microsoft Exchange Unified Messaging service failed to initialize because an	System

				exception occurred when it was loading the globcfg.xml configuration file or the finite state machine (FSM) files. To resolve this error, replace the globcfg.xml file or the FSM files with the default files located on the Exchange Server 2010 DVD. More information: "%1".	
1009	UMCore	Information	LogAlways	The telephone user interface is starting activity "%1" for the call with ID "%2".	System
1010	UMCore	Information	LogAlways	The telephone user interface definitions were successfully loaded from the configuration file: "%1"	System
1011	UMCore	Information	LogAlways	The telephone user interface activity "%1" will play the following prompts: "%2"	System
1014	UMCore	Error	LogAlways	The Unified Messaging Worker Process (UMWorkerProcess.exe) encountered an unhandled exception "%1" during an incoming call	System

				with ID "%2". The call was disconnected.	
1035	UMCore	Error	LogAlways	The Unified Messaging server encountered an error when trying to access the mailbox for user "%1". Error: %2 Object: %3	System
1037	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has started successfully.	System
1038	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service was unable to start. More information: "%1"	System
1039	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has been stopped successfully.	System
1040	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service could not be stopped. More information: "%1"	System
1041	UMService	Error	LogAlways	The operating system was unable to create job object "%1" during the initialization of the Microsoft	System

				Exchange Unified Messaging service. Job objects allow multiple processes to be managed as a unit. The Microsoft Exchange Unified Messaging service was stopped. To resolve this error, first try restarting the Unified Messaging server. The Win32 exception error that was returned was: "%2"	
1042	UMService	Error	LogAlways	The operating system was unable to set properties on job object "%1" during the initialization of the Microsoft Exchange Unified Messaging service. A job object allows a group of processes to be managed as a unit. The Microsoft Exchange Unified Messaging service was stopped. To resolve this error, first try restarting the Unified Messaging server. The Win32 exception error that was	System

				returned was: "%2"	
1043	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service was not able to start because the executable file "%1" for the Unified Messaging Worker Process does not exist. To resolve this issue, copy the default file located on the Exchange Server 2010 DVD into the \bin folder in the installation directory.	System
1044	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service failed to create an instance of the Unified Messaging Worker Process. %1	System
1045	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service stopped because the Unified Messaging Worker Process exceeded the configured maximum number of consecutive crashes, %1.	System

				To resolve this error, restart the Microsoft Exchange Unified Messaging service.	
1046	UMService	Information	LogAlways	The Unified Messaging (UM) Worker Process has terminated. The state of the UM Worker Process is "%1".	System
1047	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has requested that a new Unified Messaging Worker Process be created.	System
1048	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging (UM) Worker Process because it was unable to get data from the old UM Worker Process.	System
1049	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process because the	System

				number of incoming calls ("%1") has exceeded the configured maximum, "%2".	
1050	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process because the number of threads ("%1") exceeded the configured maximum, "%2".	System
1051	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process because the working set ("%1 MB") has exceeded the configured maximum: "%2 MB"	System
1052	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process. The previous Worker Process had been running since "%1",	System

				and reached its configured maximum age at "%2".	
1053	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process because the number of health monitoring "heartbeats" missed ("%1") exceeded the configured maximum, "%2".	System
1055	UMService	Information	LogAlways	The Unified Messaging Worker Process was terminated because the configured maximum lifetime was exceeded.	System
1056	UMService	Information	LogAlways	The state of the Unified Messaging Worker Process has changed. Previous state = "%1". Current state = "%2".	System
1057	UMWorkerProcess	Error	LogAlways	An unhandled exception occurred in a Unified Messaging Worker Process: "%1".	System
1058	UMService	Error	LogAlways	The Microsoft Exchange Unified	System

				Messaging service was not able to redirect the call with ID "%1" to an available Unified Messaging Worker Process.	
1059	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has terminated the Unified Messaging Worker Process because a control channel could not be established.	System
1074	UMService	Error	LogAlways	The Unified Messaging server failed to submit the message to the Hub Transport server using header file "%1". The header file was moved to "%2". Make sure that your antivirus software is not modifying the header files in the voice mail folder. Error "%3".	System
1077	UMCore	Information	LogAlways	The Unified Messaging server has received a request to disconnect the user "%1" on the call with	System

				ID "%2".	
1078	UMCore	Warning	LogAlways	The Unified Messaging Worker Process is attempting to recover from an exception "%1" that was encountered during a call with ID "%2".	System
1079	UMCore	Warning	LogAlways	The VoIP platform encountered an exception "%1" during the call with ID "%2". This exception occurred at the Microsoft Exchange Speech Engine VoIP platform during an event-based asynchronous operation submitted by the Unified Messaging server. The Unified Messaging server will attempt to recover from this exception. If this warning occurs frequently, contact Microsoft Product Support.	System
1083	UMClientAccess	Warning	LogAlways	The Unified Messaging Web service was unable to process a "%1" request for user "%2". The error was "%3".	System
1084	UMCore	Information	LogAlways	The call with	System

				ID "%1" ended because the Unified Messaging server disconnected.	
1090	UMService	Information	LogAlways	The IP gateway at %1 responded promptly to a PING request.	System
1091	UMService	Warning	LogAlways	The Unified Messaging server was unable to issue a Session Initiation Protocol (SIP) Option request to the IP gateway or IP PBX named "%1". The operational status of the IP gateway or IP PBX will not be sent to the server. The error received was "%2".	System
1092	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has created a new Unified Messaging Worker Process because the temporary directory size reached "%1" MB, which exceeded the maximum specified size, which is "%2" MB.	System
1103	UMService	Error	LogAlways	XML schema validation failed for file	System

				"%1" at line "%2". The error was "%3". A Unified Messaging configuration data file has been modified and the new changes do not match the expected schema. To resolve this issue, undo any recent changes you have made to the file or replace the file on the Unified Messaging server with the file of the same name located on the Exchange 2010 DVD.	
1104	UMService	Warning	LogAlways	The Microsoft Exchange Unified Messaging service was unable to read the Unified Messaging Worker Process retire time from the configuration data. The Unified Messaging Worker Process retire time is being set to the default value, which is "%1". Reason: "%2"	System
1105	UMWorkerProcess	Warning	LogAlways	The Unified Messaging server could not find a UM IP gateway that allows outgoing calls.	System

1112	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service will attempt to use a certificate with the following details: IssuerName = "%1", SerialNumber = "%2", Thumbprint = "%3", IsSelfSigned = "%4", NotValidAfter = "%5". The path to this certificate is "%6".	System
1113	UMService	Warning	LogPeriodic	The Unified Messaging server failed to exchange the required certificates with a UM IP gateway to enable Transport Layer Security (TLS) for an incoming call. More information: "%1".	System
1114	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service will attempt to start in secured mode.	System
1115	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service will attempt to start in unsecured mode.	System

1116	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service has received notification that a new Transport Layer Security (TLS) certificate must be used. The Microsoft Exchange Unified Messaging service will not process any new calls from an IP gateway until the new TLS certificate can be used.	System
1117	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service was configured to use a new certificate and used the new certificate successfully.	System
1118	UMService	Error	LogAlways	The Microsoft Exchange Unified Messaging service has encountered a problem trying to use the newly assigned certificate for Transport Layer Security (TLS). The Microsoft Exchange Unified Messaging service was stopped. To resolve this issue, replace	System

				the current certificate with another one. The exception error was "% 1".	
1119	UMService	Information	LogAlways	The Microsoft Exchange Unified Messaging service created a new Unified Messaging Worker Process so that a new certificate can be used.	System
1120	UMService	Warning	LogAlways	The certificate that is used to establish secure communication with an IP gateway using Transport Layer Security (TLS) is nearing its expiration date. By default, this event is first logged 30 days before the certificate expires, and then logged one time each day until the certificate is replaced. If the certificate that is stored on the Unified Messaging server is not replaced before it expires, the Microsoft Exchange Unified Messaging service will stop, and the	System

				Unified Messaging server will not be able to process any calls. To resolve this issue, install a new certificate on the Unified Messaging server and the IP gateways that are being used by the Unified Messaging server.	
1124	UMService	Warning	LogAlways	No IP gateways were found for the Microsoft Exchange Unified Messaging service.	System
1125	UMClientAccess	Information	LogAlways	The Microsoft Exchange Unified Messaging service will attempt to use a certificate with the following information: IssuerName = "%1", SerialNumber = "%2", Thumbprint = "%3", IsSelfSigned = "%4" , NotValidAfter = "%5"	System
1126	UMWorkerProcess	Warning	LogPeriodic	The Unified Messaging server failed to exchange the required certificates to enable Transport Layer Security (TLS) with an	System

				IP gateway. More information: "%1".	
1127	UMWorkerProcess	Warning	LogAlways	The Audio Compression Manager failed to convert from the audio format "%1" to audio format "%2": "%3". If this conversion continues to fail, you can either change the audio codec setting on the UM dial plan or change the audio codec setting on the user's UM-enabled mailbox.	System
1133	UMCore	Error	LogAlways	Unified Messaging detected a corrupted custom greeting "%1" for user "%2". The user's custom greeting will be deleted and the Unified Messaging server will use a default greeting until the user records another custom greeting.	System
1138	UMCore	Error	LogAlways	The Microsoft Exchange Unified Messaging service failed to start. The service was	System

				not able to create and register the Simple Mail Transfer Protocol (SMTP) service principal name (SPN) for the Unified Messaging server. The Win32 error code returned was "%1".	
1142	UMCore	Information	LogAlways	"%1" active calls that were associated with remote end point "% 2" were disconnected. An administrator with the appropriate permissions chose to disable all incoming calls immediately on Unified Messaging server "%3".	System
1143	UMCore	Information	LogAlways	"%1" active calls have been disabled on the Unified Messaging server. An administrator with the appropriate permissions chose to disable all incoming calls immediately.	System
1147	UMCore	Warning	LogAlways	The Unified Messaging server was unable to retrieve the IP address for IP gateway "% 1".	System

1148	UMService	Warning	LogAlways	The Unified Messaging server could not obtain a DNS record for the following hosts: "%1". Verify that your UM IP gateway and DNS server have been configured correctly.	System
1149	UMWorkerProcess	Warning	LogAlways	The Unified Messaging server could not locate a DNS record for the following hosts: "%1". To resolve this issue, verify that your UM IP gateways and your DNS server are configured correctly.	System
1151	UMService	Warning	LogPeriodic	The Session Initiation Protocol (SIP) stack that is installed on the Unified Messaging server has encountered an unhandled exception. More information: "%1".	System
1152	UMCore	Warning	LogAlways	The Unified Messaging server has received a SIP header that is not valid from an incoming call with ID "%1". Header details follow: "%2"	System
1159	UMCore	Warning	LogAlways	The call with ID "%1" was	System

				disconnected by the Unified Messaging server because of a system error.	
1165	UMWorkerProcess	Warning	LogAlways	No IP gateways were found for the Microsoft Exchange Unified Messaging service.	System
1166	UMWorkerProcess	Warning	LogAlways	The Unified Messaging server encountered an error while trying to access the Active Directory directory service to determine the UM IP gateways that are associated with this server. More information: "%1"	System
1167	UMService	Warning	LogAlways	The Unified Messaging server encountered an error while trying to access the Active Directory directory service to determine the UM IP gateways that are associated with this server. More information: "%1"	System
1168	UMCallData	Information	LogAlways	Call data: %1	System
1174	UMWorkerProcess	Warning	LogAlways	An error occurred while	System

				the Unified Messaging server was performing the following operation: "%1" for user "%2". "%3"	
1175	UMCore	Warning	LogAlways	The UM IP gateways "%1" and "%2" cannot be configured with the same IP address. Check your UM IP gateway and DNS server configuration.	System
1176	UMCore	Warning	LogAlways	UM dial plan "%2" does not include the following dial groups "%1".	System
1400	UMService	Warning	LogPeriodic	The IP gateway or IP PBX did not respond to a PING request from the Unified Messaging server. The error code that was returned is "%2" and the error text is "%3".	System

Microsoft Exchange Server 2010 Unified Messaging (UM) generates Active Directory errors and events in Event Viewer so that you can troubleshoot and verify the performance when an Exchange 2010 Unified Messaging server accesses the Active Directory directory service. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

Active Directory System Errors and Events

The following table provides a list of Active Directory events that you can use to troubleshoot and monitor Unified Messaging.

Active Directory system events

Event ID	Category	Event type	Logging	Value or description	Class
1020	UMCore	Information	LogAlways	Directory search key "%1" returned the following results: "%2".	Active Directory
1106	UMWorkerProcess	Warning	LogAlways	The Unified Messaging server encountered an error while trying to access Active Directory in the call with ID "%1". "%2"	Active Directory
1107	UMWorkerProcess	Warning	LogAlways	The Unified Messaging server encountered an error during the call with ID "%1" while trying to read from Active Directory. The operation cannot be retried. Additional information: "%2"	Active Directory
1108	UMWorkerProcess	Warning	LogAlways	The Unified Messaging	Active Directory

				server encountered a data error while trying to read information stored in Active Directory during the call with ID: "%1". This event may have been caused because the UM configuration data that is stored in Active Directory is internally inconsistent. Additional information follows: "%2"	
1110	UMCore	Warning	LogAlways	The Unified Messaging server failed to register for directory change notifications on the UM DialPlan container. The Unified Messaging server will retry this operation after "%1" minutes. Additional information: "%2"	Active Directory
1111	UMCore	Warning	LogAlways	The Unified Messaging server failed to register for directory change notifications on the UM IPGateway container. The Unified	Active Directory

				Messaging server will retry this operation after "%1" minutes. Additional information: "%2"	
1121	UMCore	Warning	LogAlways	The Unified Messaging server failed to register for directory change notifications on the Servers container. The Unified Messaging server will retry this operation after "%1" minutes. Additional information: "%2"	Active Directory
1122	UMCore	Warning	LogAlways	The Unified Messaging server failed to register for directory change notifications on the UM AutoAttendant container. The Unified Messaging server will retry this operation after "%1" minutes. Additional information: "%2"	Active Directory
1144	UMCore	Warning	LogAlways	An unhandled exception occurred while an Active Directory configuration change notification	Active Directory

				was being processed. This error may have been caused by network connectivity issues between Active Directory domain controllers and the Unified Messaging server. Additional information: "%1"	
1145	UMCore	Warning	LogAlways	The Unified Messaging server failed to register for directory change notifications on the UM HuntGroup container. The Unified Messaging server will retry this operation after "%1" minutes. Additional information: "%2"	Active Directory
1155	UMCore	Error	LogAlways	The Active Directory directory service failed to initialize. Additional information: "%1"	Active Directory

1.9.6.12 Unified Messaging Fax Answering Errors and Events

Unified Messaging Fax Answering Errors and Events

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-23*

Microsoft Exchange Server 2010 Unified Messaging (UM) generates fax answering events in Event Viewer so that you can troubleshoot and verify the performance of the Unified Messaging fax answering components, features, and services. Event Viewer tracks the following kinds of events in the following order based on importance:

1. Error events
2. Warning events
3. Informational events

Fax Answering Errors and Events

The following table provides a list of the fax answering events that you can use to troubleshoot and monitor Unified Messaging.

Fax answering events

Event ID	Category	Event type	Logging	Value or description	Class
1022	UMCore	Information	LogAlways	The Microsoft Exchange Unified Messaging service has received a fax call with ID "%1".	Fax
1023	UMCore	Information	LogAlways	The fax call with ID "%1" ended for the following reason: "%2"	Fax
1027	UMCore	Information	LogAlways	The Unified Messaging server has successfully received a fax from "%1" for "%2" at extension number "%3". The fax contains %4 pages. The fax call was %5 seconds long. The call was received from IP gateway	Fax

				"%6".	
1028	UMCore	Information	LogAlways	The fax call from "%1" for "%2" at number "%3" was received but no pages were received. The fax call was %4 seconds long. The fax call was received from UM IP gateway "%5".	Fax
1029	UMCore	Information	LogAlways	A fax call from "%1" for "%2" at number "%3" failed to complete. The fax contained %4 pages. The fax call was %5 seconds long. The call was received from UM IP gateway "%6".	Fax
1030	UMCore	Information	LogAlways	The Unified Messaging server has received both fax and audio media from "%1" for "%2" at number "%3". The fax contains %4 pages. The fax call was %5 seconds long. The call came through IP gateway "%6".	Fax
1031	UMCore	Warning	LogAlways	The fax call has exceeded the configured time for a call. The call was made from %1 for %2 at number %3.	Fax

				The fax contains %4 pages. The fax call was %5 seconds long. The call came through gateway %6.	
1032	UMCore	Warning	LogAlways	The UM dial plan that is associated with the Unified Messaging server is not configured to receive fax messages or the maximum number of concurrent fax calls on the Unified Messaging server is set to 0. The fax message that originated from telephone number "%1" and was destined for user "%2" at extension "%3" was terminated. To resolve this issue, use the Exchange Management Console or the Set-UMDialPlan cmdlet to enable the dial plan to receive incoming faxes or increase the maximum number of concurrent fax calls that can be accepted by the Unified Messaging server.	Fax

1033	UMCore	Warning	LogAlways	The Unified Messaging-enabled user "%1" is not configured to receive fax messages. The fax message that originated from phone number "%2", destined for extension "%3", was terminated. To resolve this issue, use the Exchange Management Console or the **Set-UMMailbox** cmdlet to enable the user to receive incoming fax messages.	Fax
1034	UMCore	Warning	LogAlways	The number of fax calls currently connected to the Unified Messaging server has exceeded the maximum number (%1) that is allowed. The fax call that originated from telephone number "%3" for user "%3" at extension "%4" was disconnected. To resolve this warning, increase the maximum number of concurrent fax connections that the	Fax

				Unified Messaging server will accept or install another Unified Messaging server to accept incoming fax calls.	
1150	UMCore	Warning	LogAlways	The Unified Messaging server was unable to create a message for the fax call with ID "%1". The following invalid media details were received in the session description: "%2".	Fax

1.10 High Availability and Site Resilience

High Availability and Site Resilience

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-08*

You can use high availability and site resilience to design, build, and operate a highly available messaging solution based on Microsoft Exchange Server 2010. You can design and deploy a configuration that enables site resilience, and use procedures related to the various backup, restore, and recovery operations supported by Exchange 2010.

Use the following links to access the information you need about high availability, disaster recovery, and site resilience.

Understanding High Availability and Site Resilience

Refer to this section for an overview of the architectural changes and new features in Exchange 2010 that enable high availability and site resilience. Learn about definitions for key terms, details of changes to high availability over previous versions of

Exchange, and key characteristics of the Exchange 2010 solution. Use links to learn about specific features, such as database availability groups (DAGs), mailbox database copies, Active Manager, shadow redundancy, online move mailbox, the third-party replication API, and more. This topic complements the guidance in Understanding Database Availability Groups, Understanding Mailbox Database Copies, and Understanding Active Manager.

Database Availability Group Design Examples

Review design examples for DAGs in a variety of environments:

- A two-member DAG, which is suited for small office and branch office deployments.
- A four-member DAG that provides high availability within a single datacenter by locating all members in the same datacenter.
- A four-member DAG that provides high availability within a single datacenter, and site resilience for that datacenter, by locating two of the members in the primary datacenter and two of the members in a second datacenter.

Planning for High Availability and Site Resilience

Get Microsoft guidance for planning high availability for Exchange 2010. Learn about the general hardware, software, and network requirements for Exchange 2010 high availability, and learn about best practices for planning DAGs and mailbox database copies. Get details about the requirements for site resilience and guidance for planning site resilience.

Deploying High Availability and Site Resilience

Get guidance and use links to detailed instructions for deploying Exchange 2010 high availability and site resilience using DAGs and mailbox database copies. Refer to this section for an overview of the deployment process, and use the links for performing each procedure. Get an example of deployment from start to finish of a four-member DAG extended across two datacenters.

Managing High Availability and Site Resilience

Use links to detailed procedures for managing Exchange 2010 high availability and site resilience. Get details about how to create a DAG, manage DAG membership, create and configure DAG networks, shut down DAG members, create and configure mailbox database copies, manage mailbox database copies, and perform database and server switchovers.

Managing Database Availability Groups

Refer to this section for an overview of the various management tasks associated with DAGs, and use links to detailed procedures for performing those tasks. These tasks include creating DAGs, managing DAG membership, configuring DAG properties, configuring DAG networks, and shutting down DAG members.

Managing Mailbox Database Copies

1.10.1 Understanding High Availability and Site Resilience

Understanding High Availability and Site Resilience

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-24*

Mailbox databases and the data they contain are one of the most critical components (perhaps the most critical component) of any Exchange organization. In Microsoft Exchange Server 2010, you can protect mailbox databases and the data they contain by configuring your mailbox databases for high availability and site resilience. Exchange 2010 reduces the cost and complexity of deploying a highly available and site resilient messaging solution while providing higher levels of end-to-end availability and supporting large mailboxes. Building on the native replication capabilities introduced in Exchange Server 2007, the new high availability architecture in Exchange 2010 provides a simplified, unified framework for high availability and site resilience. Exchange 2010 integrates high availability into the core architecture of Exchange, enabling customers of all sizes and in all segments to economically deploy a messaging continuity service in their organization.

Looking for management tasks related to high availability and site resilience? Check out Managing High Availability and Site Resilience.

Contents

Key Terminology

The following terms apply:

Address Book service
: A service on the Client Access server that provides a directory access endpoint for Microsoft Outlook clients.

Continuous replication - block mode
: A new form of continuous replication in SP1 whereby as each update is written to the active database copy's active log buffer, it's also shipped to a log buffer on each of the passive mailbox copies. When the log buffer is full, each database copy builds, inspects and creates the next log file in the generation sequence.

Continuous replication - file mode
: The name for the original form of continuous replication in the release to manufacturing (RTM) version of Exchange 2010, whereby closed transaction log files are pushed from the active database copy to one or more passive database copies.

Database availability group (DAG)
: A group of up to 16 Exchange 2010 Mailbox servers that hosts a set of replicated databases.

Database mobility
: The ability of a single Exchange 2010 mailbox database to be replicated to and mounted on other Exchange 2010 Mailbox servers.

Datacenter
: An Active Directory site.

Disaster recovery
: Any process used to manually recover from a failure. This can be a failure that affects a single item, or it can be a failure that affects an entire physical location.

Exchange third-party replication API
: An Exchange-provided API that enables use of third-party synchronous replication for a database availability group instead of continuous replication.

High availability
: A solution that provides service availability, data availability, and automatic recovery from failures that affect the service or data (such as a network, storage, or server failure).

Incremental deployment
: The ability to deploy high availability and site resilience after Exchange 2010 is installed.

Lagged mailbox database copy
: A passive mailbox database copy that has a log replay lag time greater than zero.

Mailbox database copy
: A mailbox database (.edb file and logs), which is either active or passive.

Mailbox resiliency

The name of a unified high availability and site resilience solution in Exchange 2010.

RPC Client Access service

A service on the Client Access server that provides a MAPI endpoint for Microsoft Outlook clients.

Site resilience

A manual disaster recovery process used to activate an alternate or standby datacenter when the primary datacenter is no longer able to provide a sufficient level of service to meet the needs of the organization. Also includes the process of re-activating a primary datacenter that has been recovered, restored or recreated. You can configure your messaging solution for high availability and enable site resilience using the built-in features and functionality in Exchange 2010.

Shadow redundancy

A transport server feature that provides redundancy for messages for the entire time they are in transit.

**over* (pronounced "star over")

Short for *switchovers* and *failovers*. A switchover is a manual activation of one or more database copies. A failover is an automatic activation of one or more database copies after a failure.

Return to top

Key Characteristics of the Exchange Server 2010 Solution

Exchange 2007 decreased the costs of high availability and made site resilience more economical by introducing technologies such as cluster continuous replication (CCR) and standby continuous replication (SCR). However, some challenges remained:

- Windows failover clustering could be confusing because of its complexity.
- Achieving a high level of uptime could require a high level of administrator intervention.
- Each type of continuous replication was managed differently and separately.
- Recovering from a failure of a single database on a large Mailbox server could result in a temporary disruption of service to all users on the Mailbox server.
- The transport dumpster feature of the Hub Transport server could only protect messages destined for mailboxes in a CCR environment. If a Hub Transport server fails while processing messages and can't be recovered, it could result in data loss.

Exchange 2010 includes significant core changes that integrate high availability in the architecture, making it less costly and easier to deploy and maintain than previous versions of Exchange. Exchange 2010 includes a new unified platform for both high availability and site resilience.

With the significant core improvements made to Exchange 2010, the recommended maximum mailbox database size when using continuous replication has increased from 200 gigabytes (GB) in Exchange 2007 to 2 terabytes in Exchange 2010. With more companies realizing the greater value in large mailboxes (from 2 GB through 10 GB), significantly larger database sizes can quickly become a reality. Supporting larger databases means moving away from legacy recovery mechanisms, such as backup and restore, and moving to newer, faster forms of protection, such as data replication and server redundancy. Ultimately, the size of your mailbox databases depends on many factors you derive during the Exchange 2010 planning process for. For detailed planning guidance for mailboxes and Mailbox servers, see Mailbox Server Storage Design.

Exchange 2010 combines the key availability and resilience features of CCR and SCR into a single solution that handles both on-site and off-site data replication. Mailbox servers

can be defined as part of a DAG to provide automatic recovery at the mailbox database level instead of at the server level. Other new high availability concepts are introduced in Exchange 2010, such as *database mobility* and *incremental deployment*.

Return to top

Database Mobility

Exchange 2007 introduced many architectural changes designed to make deploying high availability and site resiliency solutions for Exchange faster and simpler. These improvements included an integrated Setup experience, optimized configuration settings, and the ability to manage most aspects of the high availability solution using native Exchange management tools.

However, management of an Exchange 2007 high availability solution required complex clustering concepts, such as the concept of moving network identities and managing cluster resources. In addition, when troubleshooting issues related to a clustered mailbox server, Exchange tools and cluster tools were used to review and correlate logs and events from two different sources: one from Exchange and one from the cluster.

Two other limiting aspects of the Exchange 2007 architecture have been evaluated and revised based on customer feedback:

- Clustered Exchange 2007 servers require dedicated hardware. Only the Mailbox server role could be installed on a node in the cluster. This meant that a minimum of four Exchange servers were required to achieve full redundancy of the primary components of a deployment, for example, the core server roles (Mailbox, Hub Transport, and Client Access).
- In Exchange 2007, failover of a clustered mailbox server occurs at the server level. As a result, if a single database failure occurred, the administrator had to fail over the entire clustered mailbox server to another node in the cluster (which resulted in brief downtime for all users on the server, and not just those users with a mailbox on the affected database), or leave the users on the failed database offline (potentially for hours) while restoring the database from backup.

Exchange 2010 has been engineered with the concept of *database mobility*. Database mobility expands the system's use of continuous replication by replicating a database to multiple, different servers that are grouped together. This model provides better protection of the database and increased availability. In this model, automatic failover protection and manual switchover control is provided at the mailbox database level instead of at the server level.

In the case of failures, other servers that have copies of the database can mount the database. As a result of this and other architectural changes, failover actions now complete much faster than in previous versions of Exchange. For example, failover of a clustered mailbox server in a CCR environment running Exchange 2007 with Service Pack 1 completes in about 2 minutes (assuming an intra-site failure where the IP address of the clustered mailbox server doesn't change). By comparison, failover of a mailbox database in an Exchange 2010 environment completes within 30 seconds (measured from the time when the failure is detected to when a database copy is mounted, assuming the copy is healthy and up to date with log replay). The combination of database-level failovers and significantly faster failover times improves an organization's overall uptime.

Return to top

Incremental Deployment

Exchange 2010 introduces the concept of *incremental deployment*, which enables you to deploy service and data availability for all Mailbox servers and databases after Exchange is installed. Service and data redundancy is achieved by using new features in Exchange 2010 such as DAGs and database copies.

In previous versions of Exchange, service availability for the Mailbox server roles was achieved by deploying Exchange in a Windows failover cluster. To deploy Exchange in a cluster, you had to first build a failover cluster, and then install the Exchange program files. This process created a special Mailbox server called a clustered mailbox server (or Exchange Virtual Server in older versions of Exchange). If you had already installed the Exchange program files on a non-clustered server and you decided you wanted a clustered mailbox server, you had to build a cluster using new hardware, or remove Exchange from the existing server, install failover clustering, and reinstall Exchange.

Return to top

Database Availability Groups

A DAG is the base component of the high availability and site resilience framework built into Exchange 2010. A DAG is a group of up to 16 Mailbox servers that hosts a set of databases and provides automatic database-level recovery from failures that affect individual databases. Any server in a DAG can host a copy of a mailbox database from any other server in the DAG. When a server is added to a DAG, it works with the other servers in the DAG to provide automatic recovery from failures that affect mailbox databases, such as a disk failure or server failure.

Exchange 2007 introduced a built-in data replication technology called continuous replication. Continuous replication, which was available in three forms: local, cluster, and standby, significantly reduced the cost of deploying a highly available Exchange infrastructure, and provided a much improved deployment and management experience over previous versions of Exchange. Even with these cost savings and improvements, however, running a highly available Exchange 2007 infrastructure still required much time and expertise because the integration between Exchange and Windows failover clustering wasn't seamless. In addition, customers wanted an easier way to replicate their e-mail data to a remote location, to protect their Exchange environment against site-level disasters.

Exchange 2010 uses the same continuous replication technology found in Exchange 2007. Exchange 2010 combines on-site data replication (CCR) and off-site data replication (SCR) into a single framework called a *database availability group* (DAG). After servers are added to a DAG, you can add replicated database copies incrementally (up to 16 total), and Exchange 2010 switches between these copies automatically, to maintain availability.

Unlike Exchange 2007, where clustered mailbox servers required dedicated hardware, Mailbox servers in a DAG can host other Exchange roles (Client Access, Hub Transport, and Unified Messaging), providing full redundancy of Exchange services and data with just two servers.

This new high availability architecture also provides simplified recovery from a variety of failures (disk-level, server-level, and datacenter-level), and the architecture can be deployed on a variety of storage types.

For more information about DAGs, see Understanding Database Availability Groups.

Return to top

Mailbox Database Copies

The high availability and site resilience features first introduced in Exchange 2007 are used in Exchange 2010 to create and maintain database copies, so that you can achieve your availability goals in Exchange 2010. Exchange 2010 also introduces the concept of database mobility, which is Exchange-managed database-level failovers.

Database mobility disconnects databases from servers and adds support for up to 16 copies of a single database, and it provides a native experience for adding database copies to a database. In Exchange 2007, a feature called database portability also enabled you to move a mailbox database between servers. A significant distinction between database portability and database mobility, however, is that all copies of a database have the same GUID.

Setting a database copy as the active mailbox database is known as a *switchover*. When a failure affecting a database occurs and a new database becomes the active copy, this process is known as a *failover*. This process also refers to a server failure in which one or more servers bring online the databases previously online on the failed server. When either a switchover or failover occurs, other Exchange 2010 server roles become aware of the switchover almost immediately and redirect client and messaging traffic to the new active database.

For example, if an active database in a DAG fails because of an underlying storage failure, Active Manager will automatically recover by failing over to a database copy on another Mailbox server in the DAG. If the database is outside the automatic mount criteria and can't be automatically mounted, you can manually perform a database failover.

For more information about mailbox database copies, see Understanding Mailbox Database Copies.

Return to top

Active Manager

In Exchange 2007 and previous versions, Exchange used the cluster resource management model to install, implement, and manage the Mailbox server high availability solution. Historically, building a highly available Mailbox server involved first building a Windows failover cluster, and then running Exchange Setup in clustered mode. In this mode, the Exchange cluster resource DLL file, exres.dll, would be registered and allow the creation of a clustered mailbox server (called an Exchange Virtual Server in legacy versions). When deploying legacy shared storage clusters or single copy clusters, additional steps for configuring storage were needed before and after failover cluster formation, and after clustered mailbox server and storage group formation.

Exchange 2010 includes a new component called *Active Manager* that provides functionality that replaces the resource model and failover management features provided by integration with the Cluster service in previous versions of Exchange. For more information about Active Manager, see Understanding Active Manager.

Return to top

Changes to High Availability from Previous Versions of Exchange

There are several changes to the core architecture of Exchange 2010 that have a direct effect on how you configure Exchange for high availability, as well as a direct effect on how you perform site recovery. One significant change is the removal of clustered mailbox servers and the use of the Windows Failover Cluster resource model. Other significant changes include the globalization of databases and enhancements to the built-in

continuous replication technology first introduced in Exchange 2007.

Removal of Clustered Mailbox Servers

In Exchange 2010, Exchange is no longer a clustered application, and the cluster resource model is no longer used for Exchange high availability. Exres.dll and all Exchange cluster resources it provided also no longer exist, including clustered mailbox servers. Instead, Exchange 2010 uses its own internal high availability model. Some components of Windows failover clustering are still used, but they are now integrated into other functionality by Exchange 2010.

Globalization of Databases

In Exchange 2010, a database is associated with a single, dedicated log stream, represented by a series of sequentially-named, 1-megabyte (MB) log files. The concept of storage groups has also been removed from Exchange 2010. As a result of these changes, Exchange databases have a dedicated log stream, and no longer share log streams with other databases.

Unlike in previous versions of Exchange, databases are no longer closely tied to a specific Mailbox server. In addition, databases are no longer identified by the Mailbox servers on which they reside, and server names are no longer part of database identities. As a result of these changes, databases are now global objects in Active Directory and in each Exchange organization. When using the Exchange Management Console, databases are now managed from the Mailbox node under the Organization Configuration node.

Each Mailbox server can host a maximum of 100 databases (total combined number of active and passive databases). The total number of databases equals the combined number of active and passive databases on a server. The recovery database doesn't count against the 100 database limit.

Changes to Continuous Replication in Exchange 2010 RTM

The continuous replication technology introduced in Exchange 2007 is also available in Exchange 2010. However, the feature has evolved considerably to support new high availability features and greater scalability. Some of these architectural changes include:

- Because storage groups are removed in Exchange 2010, continuous replication now operates at the database level. Exchange 2010 still uses an Extensible Storage Engine (ESE) database that produces transaction logs replicated to one or more other locations and replayed into one or more mailbox database copies. Each mailbox database can have as many as 16 copies.
- Log shipping no longer uses Server Message Block (SMB) and Windows file system notifications. Log shipping no longer uses a pull model, where the passive copy pulls a closed log file from the active copy. Instead, the passive copy uses TCP-based notifications to notify the active copy about which log files are required by the passive copy. The active copy then pushes the log files to each configured passive copy through the TCP socket.
- Exchange 2010 continuous replication uses one administrator-defined TCP port for data transfer. In addition, Exchange 2010 includes built-in options for network encryption and compression for the data stream.
- Seeding is no longer restricted to using only the active copy of the database. Passive copies of mailbox databases can now be specified as sources for database copy seeding and reseeding.
- Database copies are for mailbox databases only. For redundancy and high availability of public folder databases, we recommend that you use public folder replication. Unlike CCR, where multiple copies of a public folder database couldn't exist in the same cluster, you can use public folder replication to replicate public folder databases between servers in a DAG.
- In Exchange 2007, the Microsoft Exchange Replication service was responsible for replaying logs into passive database copies. When the passive copy was activated, the database cache that had been built by the Microsoft Exchange Replication service as a result of replay activity would be lost when the

Microsoft Exchange Information Store service would mount the database. This put the database cache in a state known as a *cold state*. The database cache, which is used to cache read/write operations, is small in size (cold) during this period. Therefore, it has a significantly diminished ability to reduce read I/O operations. In Exchange 2010, the passive copy replay functionality previously performed by the Microsoft Exchange Replication service has been moved into the Microsoft Exchange Information Store service. As a result, a warm database cache is present and immediately available for use after a failover or switchover occurs.

Several concepts used in Exchange 2007 continuous replication also remain in Exchange 2010. These include the concepts of failover management, divergence, the use of the automatic database mount dial, and the use of replication and client access (MAPI) networks.

Changes to Continuous Replication in Exchange 2010 SP1

In the RTM version of Exchange 2010 and in all versions of Exchange Server 2007, continuous replication operates by shipping copies of the log files generated by the active database copy to the passive database copies. Beginning with Exchange 2010 SP1, this form of continuous replication is known as *continuous replication - file mode*. SP1 also introduces a new form of continuous replication known as *continuous replication - block mode*. In block mode, as each update is written to the active database copy's active log buffer, it's also shipped to a log buffer on each of the passive mailbox copies. When the log buffer is full, each database copy builds, inspects and creates the next log file in the generation sequence. In the event of a failure affecting the active copy, the passive copies will have been updated with most or all of the latest updates. The active copy doesn't wait for replication to complete in order to preclude replication issues from affecting the client experience.

Block mode dramatically reduces the latency between the time a change is made on the active copy and when the change is replicated to passive copies. In addition to replicating individual log file writes, block mode also changes the activation process for a passive copy. If a copy is in block mode when a failure occurs, the system uses whatever partial log content is available during the activation process. This eliminates the current log file on the active copy from being a single point of failure.

The initial mode of operation is always file mode. Block mode is only active when continuous replication is up-to-date in file mode. The transition into and out of block mode is performed automatically by the log copier. When the passive copy requests the current log file, it indicates that continuous replication is up-to-date (the copy queue length is 0), and the system should automatically switch from file mode to block mode.

You can determine if a passive database copy is in block mode by monitoring the **Continuous replication – block mode Active** performance counter under the **MSExchange Replication** performance object. Each database copy has its own instance of this counter. The value of the counter is set to 1 when the passive copy is in block mode and 0 when the passive copy is in file mode. You can also determine the value of this counter by using the Get-Counter or Get-WMIObject cmdlets, as shown in these examples:

```
Get-Counter -ComputerName <DAGMemberName> -Counter "\MSExchange Replication(*)\Co
Get-WMIObject -ComputerName <DAGMemberName> Win32_PerfRawData_MSExchangeReplicati
```

Changes to Transport Dumpster from Exchange 2007

The Exchange 2010 Hub Transport server role includes a feature called the transport dumpster, which was first introduced in Exchange 2007. The transport dumpster is designed to help protect against data loss by maintaining a queue of all recent e-mail messages sent to users whose mailboxes were protected by CCR or LCR. When a lossy failure occurred in either of these environments, the bulk of the data that would have ordinarily been lost as a result of the failure is automatically recovered by the transport dumpster.

The transport dumpster is used for replicated mailbox databases only. It doesn't protect messages sent to public folders, nor does it protect messages sent to recipients on mailbox databases that aren't replicated. The transport dumpster queue for a specific mailbox database is located on all Hub Transport servers in the Active Directory sites containing the DAG.

In Exchange 2007, messages were retained in the transport dumpster until the administrator-defined time limit or size limit is reached. In Exchange 2010, the transport dumpster now receives feedback from the replication pipeline to determine which messages have been delivered and replicated. As a message goes through Hub Transport servers on its way to a replicated mailbox database in a DAG, a copy is kept in the transport queue (mail.que) until the transaction logs representing the message have been successfully replicated to and inspected by all copies of the mailbox database. After the logs have been replicated to and inspected by all database copies, the messages in those logs are truncated from the transport dumpster. This keeps the transport dumpster queue smaller by maintaining only copies of messages whose transactions logs haven't yet been replicated.

Each DAG's Active Manager tracks the value for the last log inspected time on each passive database copy. The Active Manager client running on the Hub Transport server obtains this information from the DAG's Standby Active Manager (SAM) and converts that information into a time-based watermark. The Hub Transport server then compares the delivery time of messages in the transport dumpster with the watermark. If the delivery time of a message is older than the watermark, then the message is truncated from the transport dumpster.

The transport dumpster has also been enhanced to account for the changes to the Mailbox server role that enable a single mailbox database to move between Active Directory sites. DAGs can be extended to multiple Active Directory sites, and as a result, a single mailbox database in one Active Directory site can fail over to another Active Directory site. When this occurs, any transport dumpster redelivery requests will be sent to both Active Directory sites: the original site and the new site.

Changes to Routing Behavior When Hub Transport and Mailbox are Co-Located in a DAG

When the Hub Transport server is co-located with a Mailbox server that's a member of a DAG, there are changes in routing behavior to ensure that the resiliency features in both server roles will provide the necessary protection for messages sent to and received by users on that server. The Hub Transport server role was modified so that it now attempts to reroute a message for a local Mailbox server to another Hub Transport server in the same site if the Hub Transport server is also a DAG member and it has a copy of the mailbox database mounted locally. This extra hop was added to put the message in the transport dumpster on a different Hub Transport server.

For example, EX1 hosts the Hub Transport server role and Mailbox server role and is a member of a DAG. When a message arrives in transport for EX1 destined for a recipient whose mailbox is also on EX1, transport will reroute the message to another Hub Transport server in the site (for example, EX2), and that server will deliver the message to the mailbox on EX1.

There's a second, similar behavior change related to the Microsoft Exchange Mail Submission service. This service was modified so that it would not submit messages to a local Hub Transport server role when the Mailbox server or Hub Transport server is a member of a DAG. In this scenario, the behavior of transport is to load balance submission requests across other Hub Transport servers in the same Active Directory site, and fall back to a local Hub Transport server if there are no other available Hub Transport servers in the same site.

Return to top

High Availability for Non-Mailbox Server Roles

High availability for the Hub Transport, Edge Transport, Client Access, and Unified Messaging server roles is achieved through a combination of server redundancy, load balancing, and Domain Name System (DNS) round robin, as well as proactive server, service, and infrastructure management. In general, you can achieve high availability for the Client Access, Hub Transport, Edge Transport, and Unified Messaging server roles by using the following strategies and technologies:

- **Edge Transport** You can deploy multiple Edge Transport servers and use multiple DNS MX resource records to load balance activity across those servers. You can also use Network Load Balancing (NLB) to provide load balancing and high availability for Edge Transport servers.
- **Client Access** You can use NLB or a third-party hardware-based network load balancing device for Client Access server high availability.
- **Hub Transport** You can deploy multiple Hub Transport servers for internal transport high availability. Resiliency has been designed into the Hub Transport server role in the following ways:
  - **Hub Transport server to Hub Transport server (intra-organization)** Hub Transport server to Hub Transport server communication inside an organization automatically load balances between available Hub Transport servers in the target Active Directory site.
  - **Mailbox server to Hub Transport server (intra-Active Directory site)** The Microsoft Exchange Mail Submission service on Mailbox servers automatically load balances between all available Hub Transport servers in the same Active Directory site.
  - **Unified Messaging server to Hub Transport server** The Unified Messaging server automatically load balances connections between all available Hub Transport servers in the same Active Directory site.
  - **Edge Transport server to Hub Transport server** The Edge Transport server automatically load balances inbound SMTP traffic to all Hub Transport servers in the Active Directory site to which the Edge Transport server is subscribed.

  For additional redundancy (for example, applications that require an SMTP relay), you can create a DNS record (for example, relay.company.com), assign an IP address, and use a hardware load balancer to redirect that IP address to multiple Hub Transport servers. You can also use NLB for the client connectors on Hub Transport servers. When using a hardware load balancer, you need to confirm that no intra-organization traffic will be crossing the hardware load balancer because intra-organization traffic uses built-in load balancing algorithms (as previously described).
- **Unified Messaging** Unified Messaging deployments can be made more resilient by deploying multiple Unified Messaging servers where two or more are in a single dial plan. The Voice over IP (VoIP) gateways supported by Unified Messaging can be configured to route calls to Unified Messaging servers in a round-robin fashion. In addition, these gateways can retrieve the list of servers for a dial plan from DNS. In either case, the VoIP gateways will present a call to a Unified Messaging server and if the call isn't accepted, the call will be presented to another server, providing redundancy at the time the call is established.

Return to top

Site Resilience

Exchange 2010 includes a unified platform for both high availability and site resilience. By combining the native site resilience support in Exchange 2010 with proper planning, a second datacenter can be rapidly activated to serve a failed datacenter's clients. A datacenter or site failure is managed differently from the types of failures that can cause a server or database failover. In a high availability configuration, automatic recovery is initiated by the system, and the failure typically leaves the messaging system in a fully functional state. By contrast, a datacenter failure is considered to be a disaster recovery event. Recovery must be manually performed and completed for the client service to be restored and for the outage to end. The process you perform is referred to as a *datacenter switchover*. As with many disaster recovery scenarios, prior planning and preparation for a datacenter switchover can simplify the recovery process and reduce the duration of the outage.

For details about planning and deploying site resilience, see Planning for High Availability and Site Resilience, Deploying High Availability and Site Resilience and Datacenter Switchovers.

Return to top

End-to-End Availability

Exchange 2010 also includes many features designed to increase end-to-end availability of the system. These features include:

- Shadow redundancy
- Online move mailbox
- Flexible mailbox protection
- Incremental resync
- Third-party replication API

Shadow Redundancy

In addition to the transport dumpster and routing behavior enhancements described previously, a new Hub Transport server feature named *shadow redundancy* has been added. Shadow redundancy provides redundancy for messages for the entire time they are in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport database is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting successful delivery, the message is resubmitted for delivery to that next hop. For more information about shadow redundancy, see Understanding Shadow Redundancy.

Online Move Mailbox

Exchange 2010 includes a new feature that enables you to move mailboxes asynchronously. In Exchange 2007, when you used the **Move-Mailbox** cmdlet to move a mailbox, the cmdlet logged on to both the source database and the target database and moved the content from one mailbox to the other mailbox. There were several disadvantages to having the cmdlets perform the move operation:

- Mailbox moves typically took hours to complete, and during the move, users weren't able to access their mailbox.
- If the Command Prompt window used to run the **Move-Mailbox** cmdlet was closed, the move was terminated and had to be restarted.
- The computer used to perform the move participated in the data transfer. If an administrator ran the cmdlets from his or her workstation, the mailbox data would flow from the source server to the administrator's workstation and then to the target server.

The **New-MoveRequest** cmdlet in Exchange 2010 can be used to perform asynchronous moves. Unlike in Exchange 2007, the cmdlets don't perform the actual move. The move is performed by the Microsoft Exchange Mailbox Replication service, a new service that runs on a Client Access server. The **New-MoveRequest** cmdlet sends requests to the Microsoft Exchange Mailbox Replication service. For more information about online mailbox moves, see Understanding Move Requests.

Flexible Mailbox Protection

There are several changes to the core architecture of Exchange 2010 that have a direct effect on how you will protect your mailbox databases and the mailboxes they contain.

One significant change is the removal of storage groups. In Exchange 2010, each database is associated with a single log stream, represented by a series of 1 megabyte (MB) log files. Each server can host a maximum of 100 databases.

Another significant change for Exchange 2010 is that databases are no longer closely tied to a specific Mailbox server. Database mobility expands the system's use of continuous replication by replicating a database to multiple, different servers. This provides better protection of the database and increased availability. In the case of failures, the other servers that have copies of the database can mount the database.

The ability to have multiple copies of a database hosted on multiple servers means that if you have a sufficient number of database copies, you can use these copies as your backups. For more information about this strategy, see Understanding Backup, Restore and Disaster Recovery.

Incremental Resync

Exchange 2007 introduced the concepts of lost log resilience and incremental reseed. Lost log resilience is an internal component of ESE that enables you to recover Exchange mailbox databases even if one or more of the most recently generated transaction log files have been lost or damaged. Lost log resilience enables a mailbox database to mount even when recently generated log files are unavailable. Lost log resilience works by delaying writes to the database until the specified number of log generations have been created. Lost log resilience delays recent updates to the database file for a short time. The length of time that writes are delayed depends on how quickly logs are being generated.

Exchange 2007 also introduced the concept of incremental reseed, which provided the ability to correct divergences in the transaction log stream between a source and target storage group, by relying on the delayed replay capabilities of lost log resilience. Incremental reseed didn't provide a means to correct divergences in the passive copy of a database, after divergent logs had been replayed, which forced the need for a complete reseed. Unlike Exchange 2007, there is no amount of log loss that requires a full reseed in Exchange 2010.

In Exchange 2010, *incremental resync* is the new name for the feature that automatically corrects divergences in database copies under the following conditions:

- After an automatic failover for all of the configured copies of a database
- When a new copy is enabled and some database and log files already exist at the copy location
- When replication is resumed following a suspension or restarting of the Microsoft Exchange Replication service

As a result of these changes, lost log resilience is now hard-coded to one log file for all Exchange 2010 mailbox databases.

When divergence between an active database and a copy of that database is detected, incremental resync performs the following tasks:

- Searches historically in the log file stream to locate the point of divergence.

- Locates the changed database pages on the diverged copy.
- Reads the changed pages from the active copy, and then copies the necessary log files from the active copy.
- Applies the database page changes to the diverged copy.
- Runs recovery on the diverged copy and replays the necessary log files into the database copy.

Third-Party Replication API

Exchange 2010 also includes a new third-party replication API that enables organizations to use third-party synchronous replication solutions instead of the built-in continuous replication feature. Microsoft supports third-party solutions that use this API, provided that the solution provides the necessary functionality to replace all native continuous replication functionality that is disabled as a result of using the API. Solutions are supported only when the API is used within a DAG to manage and activate mailbox database copies. Use of the API outside of these boundaries is not supported. In addition, the solution must meet the applicable Windows hardware support requirements (test validation is not required for support).

When deploying a solution that uses the built in third-party replication API, be aware that the solution vendor is responsible for primary support of the solution. Microsoft supports Exchange data for both replicated and non-replicated solutions. Solutions that use data replication must adhere to Microsoft's support policy for data replication, as described in Microsoft Knowledge Base article 895847, Multi-site data replication support for Exchange Server. In addition, solutions that utilize the Windows Failover Cluster resource model must meet Windows cluster supportability requirements as described in Microsoft Knowledge Base article 943984, The Microsoft Support Policy for Windows Server 2008 Failover Clusters.

Microsoft's backup and restore support policy for deployments that use third-party replication API-based solutions is the same as for native continuous replication deployments.

If you are a partner seeking information about the third-party API, contact your Microsoft representative. For information about partner products for Exchange 2010, see Microsoft Exchange Partners.

1.10.1.1 Understanding Database Availability Groups

Understanding Database Availability Groups

Exchange Server 2010 > High Availability and Site Resilience > Understanding High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

A database availability group (DAG) is the base component of the high availability and site resilience framework built into Microsoft Exchange Server 2010. A DAG is a group of up to 16 Mailbox servers that hosts a set of databases and provides automatic database-level recovery from failures that affect individual servers or databases.

A DAG is a boundary for mailbox database replication, database and server switchovers, failovers, and an internal Exchange 2010 component called *Active Manager*. Active Manager, which runs on every server in a DAG, manages switchovers and failovers. For more information about Active Manager, see Understanding Active Manager.

Any server in a DAG can host a copy of a mailbox database from any other server in the DAG. When a server is added to a DAG, it works with the other servers in the DAG to provide automatic recovery from failures that affect mailbox databases, such as a disk failure or server failure.

Contents

Database Availability Group Lifecycle

DAGs leverage a feature of Exchange 2010 known as *incremental deployment*, which is the ability to deploy service and data availability for all Mailbox servers and databases after Exchange is installed. After you deploy Exchange 2010, you can create a DAG, add Mailbox servers to the DAG, and then replicate mailbox databases between the DAG members.

Note:
It is supported to create a DAG that contains a combination of physical Mailbox servers and virtualized Mailbox servers, provided that the servers and solution comply with the Exchange 2010 System Requirements. As with all Exchange high availability configurations, you must ensure that all Mailbox servers in the DAG are sized appropriately to handle the necessary workload during scheduled or unscheduled outages.

A DAG is created by using the New-DatabaseAvailabilityGroup cmdlet. A DAG is initially created as an empty object in Active Directory. This directory object is used to store relevant information about the DAG, such as server membership information. When you add the first server to a DAG, a failover cluster is automatically created for the DAG. This failover cluster is used exclusively by the DAG, and the cluster must be dedicated to the DAG. Use of the cluster for any other purpose isn't supported.

In addition to a failover cluster being created, the infrastructure that monitors the servers for network or server failures is initiated. The failover cluster heartbeat mechanism and cluster database are then used to track and manage information about the DAG that can change quickly, such as database mount status, replication status, and last mounted location.

During creation, the DAG is given a unique name, and either assigned one or more static IP addresses or configured to use Dynamic Host Configuration Protocol (DHCP). You can specify a single IP address or a comma-separated list of IP addresses by using the *DatabaseAvailabilityGroupIPAddresses* parameter.

This example shows a DAG that will have three servers. Two servers (EX1 and EX2) are on the same subnet (10.0.0.0), and the third server (EX3) is on a different subnet (192.168.0.0).

```
New-DatabaseAvailabilityGroup -Name DAG1 -DatabaseAvailabilityGroupIPAddresses 10
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer EX1
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer EX2
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer EX3
```

Note:
Configuring the *DatabaseAvailabilityGroupIPAddresses* parameter with a value of 0.0.0.0

configures the DAG (cluster) to use DHCP for its IP addresses or IP address resources.

The cluster for DAG1 is created when EX1 is added to the DAG. During cluster creation, the **Add-DatabaseAvailabilityGroupServer** cmdlet retrieves the IP addresses configured for the DAG and ignores the ones that don't match any of the subnets found on EX1. In this example, the cluster for DAG1 is created with an IP address of 10.0.0.5, and 192.168.0.5 is ignored.

Then, EX2 is added, and the **Add-DatabaseAvailabilityGroupServer** cmdlet again retrieves the IP addresses configured for the DAG. There are no changes to the cluster's IP addresses because EX2 is on the same subnet as EX1.

Then, EX3 is added, and the **Add-DatabaseAvailabilityGroupServer** cmdlet again retrieves the IP addresses configured for the DAG. Because a subnet matching 192.168.0.5 is present on EX3, the 192.168.0.5 address is added as an IP address resource in the cluster group. In addition, an **OR** dependency for the Network Name resource for each IP address resource is automatically configured. The 192.168.0.5 address will be used by the cluster when the cluster group moves to EX3.

Windows failover clustering registers the IP addresses for the cluster in the Domain Name System (DNS) when the Network Name resource is brought online. In addition, a cluster name object (CNO) is created in Active Directory. The name, IP addresses and CNO for the cluster are used only internally by the system to secure the DAG and for internal communication purposes. Administrators and end users don't need to interface with or connect to the DAG name or IP address for any reason.

In addition to a name and one or more IP addresses, the DAG is also configured to use a witness server and a witness directory. The witness server and witness directory are either automatically specified by the system, or they can be manually specified by the administrator.

By default, a DAG is designed to use the built-in continuous replication feature to replicate mailbox databases among servers in the DAG. If you're using third-party data replication that supports the Third Party Replication API in Exchange 2010, you must create the DAG in third-party replication mode by using the New-DatabaseAvailabilityGroup cmdlet with the *ThirdPartyReplication* parameter. After this mode is enabled, it can't be disabled.

After the DAG is created, Mailbox servers can be added to the DAG. When the first server is added to the DAG, a cluster is formed for use by the DAG. DAGs make limited use of Windows failover clustering technology, such as the cluster heartbeat, cluster networks, and the cluster database (for storing data that changes, such as database state changes from active to passive or vice versa, or from mounted to dismounted and vice versa). As each subsequent server is added to the DAG, it's joined to the underlying cluster, the cluster's quorum model is automatically adjusted by the system, and the server is added to the DAG object in Active Directory.

After Mailbox servers are added to a DAG, you can configure a variety of DAG properties, such as whether to use network encryption or network compression for database replication within the DAG. You can also configure DAG networks and create additional DAG networks.

After you add members to a DAG and configure the DAG, the active mailbox databases on each server can be replicated to the other DAG members. After you create mailbox database copies, you can monitor the health and status of the copies using a variety of built-in monitoring tools. In addition, you can perform database and server switchovers.

For more information about creating DAGs, managing DAG membership, configuring DAG properties, creating and monitoring mailbox database copies, and performing switchovers, see Managing High Availability and Site Resilience.

Database Availability Group Quorum Models

Underneath every DAG is a Windows failover cluster. Failover clusters use the concept of quorum, which uses a consensus of voters to ensure that only one subset of the cluster members (which could mean all members or a majority of members) is functioning at one time. Quorum isn't a new concept for Exchange 2010. Highly available Mailbox servers in previous versions of Exchange also use failover clustering and its concept of quorum. Quorum represents a shared view of members and resources, and the term quorum is also used to describe the physical data that represents the configuration within the cluster that is shared between all cluster members. As a result, all DAGs require their underlying failover cluster to have quorum. If the cluster loses quorum, all DAG operations terminate and all mounted databases hosted in the DAG will dismount. In this event, administrator intervention will be required to correct the quorum problem and restore DAG operations.

Quorum is important to ensure consistency, to act as a tie-breaker to avoid partitioning, and to ensure cluster responsiveness:

- **Ensuring consistency** A primary requirement for a Windows failover cluster is that each of the members always has a view of the cluster that's consistent with the other members. The cluster hive acts as the definitive repository for all configuration information relating to the cluster. If the cluster hive can't be loaded locally on a DAG member, the Cluster service doesn't start, because it isn't able to guarantee that the member meets the requirement of having a view of the cluster that's consistent with the other members.
- **Acting as a tie-breaker** A quorum witness resource is used in DAGs with an even number of members to avoid split brain syndrome scenarios and to make sure that only one collection of the members in the DAG is considered official. When the witness server is needed for quorum, any member of the DAG that can communicate with the witness server can place a Server Message Block (SMB) lock on the witness server's witness.log file. The DAG member that locks the witness server (referred to as the *locking node*) retains an additional vote for quorum purposes. The DAG members in contact with the locking node are in the majority and maintain quorum. Any DAG members that can't contact the locking node are in the minority and therefore lose quorum.
- **Ensuring responsiveness** To ensure responsiveness, the quorum model makes sure that, whenever the cluster is running, enough members of the distributed system are operational and communicative, and at least one replica of the cluster's current state can be guaranteed. No additional time is required to bring members into communication or to determine whether a specific replica is guaranteed.

DAGs with an even number of members use the failover cluster's Node and File Share Majority quorum mode, which employs an external witness server that acts as a tie-breaker. In this quorum mode, each DAG member gets a vote. In addition, the witness server is used to provide one DAG member with a weighted vote (e.g., it gets two votes instead of one). The cluster quorum data is stored by default on the system disk of each member of the DAG, and is kept consistent across those disks. However, a copy of the quorum data isn't stored on the witness server. A file on the witness server is used to keep track of which member has the most updated copy of the data, but the witness server doesn't have a copy of the cluster quorum data. In this mode, a majority of the voters (the DAG members plus the witness server) must be operational and able to communicate with each other to maintain quorum. If a majority of the voters can't communicate with each other, the DAG's underlying cluster loses quorum, and the DAG will require administrator intervention to become operational again.

DAGs with an odd number of members use the failover cluster's Node Majority quorum mode. In this mode, each member gets a vote, and each member's local system disk is used to store the cluster quorum data. If the configuration of the DAG changes, that change is reflected across the different disks. The change is only considered to have been committed and made persistent if that change is made to the disks on half the members (rounding down) plus one. For example, in a five-member DAG, the change must be made

on two plus one members, or three members total.

Quorum requires a majority of voters to be able to communicate with each other. Consider a DAG that has four members. Because this DAG has an even number of members, an external witness server is used to provide one of the cluster members with a fifth, tie-breaking vote. To maintain a majority of voters (and therefore quorum), at least three voters must be able to communicate with each other. At any time, a maximum of two voters can be offline without disrupting service and data access. If three or more voters are offline, the DAG loses quorum, and service and data access will be disrupted until you resolve the problem.

Return to top

Using a Database Availability Group for High Availability

To illustrate how a DAG can provide high availability for your mailbox databases, consider the following example, which uses a DAG with five members. This DAG is illustrated in the following figure.

In the preceding figure, the green databases are active mailbox database copies and the blue databases are passive mailbox database copies. In this example, the database copies aren't mirrored across each server, but rather spread across multiple servers. This ensures that no two servers in the DAG have the same set of database copies, providing the DAG with greater resilience to failures, including failures that occur while other components are unavailable as a result of regular maintenance.

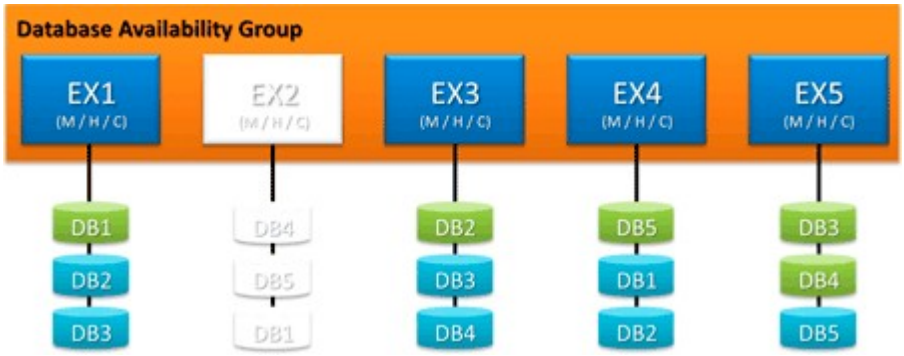
Consider the following scenario, using the preceding example DAG, which illustrates resilience to multiple database and server failures.

Initially, all databases and servers are healthy. You need to install some operating system updates on EX2. You perform a server switchover, which activates the copy of DB4 on another Mailbox server. A server switchover moves all active mailbox database copies from their current server to one or more other Mailbox servers in the DAG in preparation for a scheduled outage for the current server. You can perform a server switchover quickly by running the following command in the Exchange Management Shell.

```
Move-ActiveMailboxDatabase -Server EX2
```

In this example, there's only one active mailbox database on EX2 (DB4), so only one active mailbox database copy is moved. By omitting the *ActivateOnServer* parameter in the preceding command, you chose to have the system select the best possible new active copy, and the system chose the copy on EX5, as shown in the following figure.

DAG with a server offline for maintenance

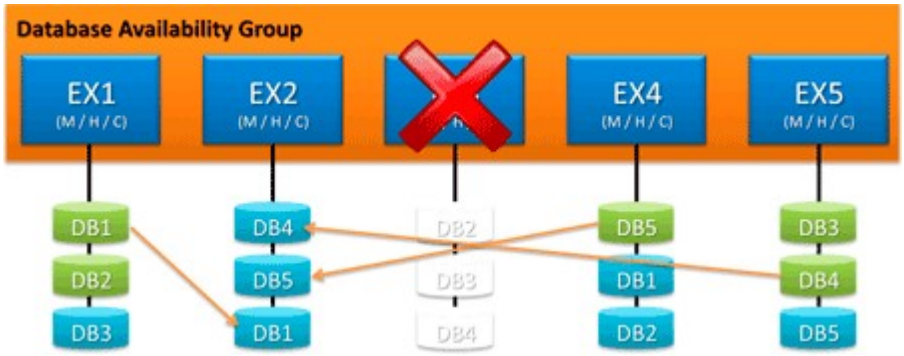


While you perform maintenance on EX2, EX3 experiences a catastrophic hardware failure and goes offline. Prior to going offline, EX3 hosted the active copy of DB2. To recover from the failure, the system automatically activates the copy of DB2 that's hosted on EX1 within 30 seconds. This is illustrated in the following figure.

DAG with a server offline for maintenance and a failed server

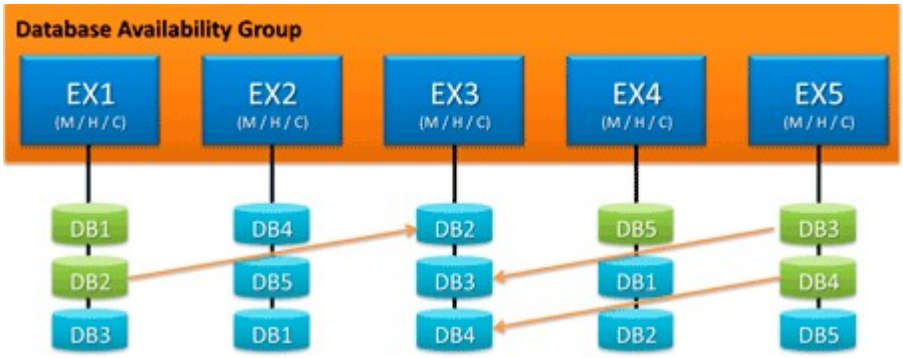
After the scheduled maintenance is completed for EX2, you bring the server online. As soon as EX2 is available, the other members of the DAG are notified, and the copies of DB1, DB4, and DB5 hosted on EX2 are automatically synchronized with the active copy of each database. This is illustrated in the following figure.

DAG with a restored server synchronizing its database copies



After the failed hardware component in EX3 is replaced with a new component, EX3 is brought online. After EX3 is available, the other members of the DAG are notified, and the copies of DB2, DB3, and DB4 hosted on EX3 are automatically synchronized with the active copy of each database. This is illustrated in the following figure.

DAG with a repaired server synchronizing its database copies

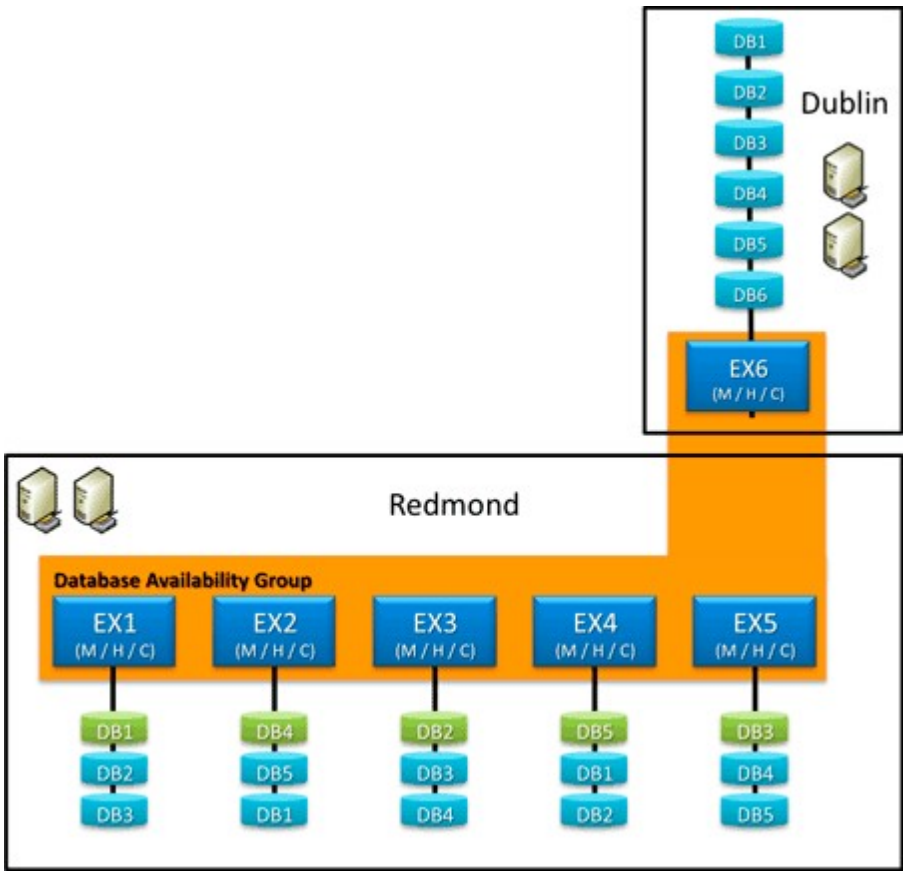


Return to top

Using a Database Availability Group for Site Resilience

In addition to providing high availability within a datacenter, a DAG can also be extended to one or more datacenters in a configuration that provides site resilience for one or multiple datacenters. In the preceding example figures, the DAG is located in a single datacenter and single Active Directory site. Incremental deployment can be used to extend this DAG to a second datacenter (and a second Active Directory site) by deploying a Mailbox server and the necessary supporting resources (one or more Active Directory servers, and one or more Hub Transport and Client Access servers). The Mailbox server is then added to the DAG, as illustrated in the following figure.

DAG extended across two Active Directory sites



In this example, a passive copy of each active database in the Redmond datacenter is configured on EX6 in the Dublin datacenter. However, there are many other examples of DAG configurations that provide site resilience. For example:

- Instead of hosting only passive database copies, EX6 could host all active copies, or it could host a mixture of active and passive copies.
- In addition to EX6, multiple DAG members could be deployed in the Dublin datacenter, providing protection against additional failures. This configuration also provides additional capacity, so that if the Redmond datacenter fails, the Dublin datacenter can support a much larger user population.

Using Multiple Database Availability Groups for Site Resilience

In the preceding example, a single DAG extends across multiple datacenters, providing site resilience for either or both datacenters. When using a single DAG to provide site resilience in an environment where each datacenter to which you extend the DAG has an active user population, there is a single point of failure in the wide area network (WAN) connection. This is because quorum requires a majority of the voters to be active and able to communicate with each other.

In the preceding example, the majority of voters are located in the Redmond datacenter. If the Dublin datacenter hosts active mailbox databases, and it has a local user population, a WAN outage would result in a messaging service outage for the Dublin users. When WAN connectivity breaks, only the DAG members in the Redmond datacenter retain quorum and continue providing messaging service.

To eliminate the WAN as a single point of failure when you need to provide site resilience for multiple datacenters that each have an active user population, you should deploy multiple DAGs, where each DAG has a majority of voters in a separate datacenter. When a WAN outage occurs, replication will be blocked until connectivity is restored. Users will

have messaging service, because each DAG continues to service its local user population.

Return to top

Client Experience When Using Database Availability Groups

DAGs can be used to provide both high availability and site resilience. The client experience when using a DAG depends on the type and version of the client and the protocol used by the client to access mailbox data. For example, if a cross-site database failover occurs, the behavior and reconnection logic used by a POP3 or IMAP4 client is different from the behavior and reconnection logic used by a Microsoft Outlook 2010 client.

The following sections describe the client behavior and logic in various scenarios. The behavior described assumes that:

- The environment contains a single Client Access server array in each Active Directory site, and each site contains at least two Client Access servers.
- An appropriate hardware-based or software-based load balancer is installed and configured in front of the Client Access server array.
- Proper namespace and certificate planning and configuration are complete, including the necessary DNS records.

Microsoft Outlook Behavior and Logic

Generally, all versions of Outlook behave the same for database failovers that occur within a single datacenter and single Active Directory site. Unlike previous versions of Exchange, in Exchange 2010, Outlook no longer connects directly to the Exchange store on the Mailbox server. Instead, Outlook (and any other MAPI client) connects to the RPC Client Access and Address Book services on the Client Access server role, and the user's Outlook is configured to connect to the Client Access server array, which then connects the client to an individual Client Access server. This abstraction of the Outlook connection away from the Mailbox server provides the following benefits:

- When a database failover occurs, Outlook remains connected to the same server in the Client Access server array. When this occurs, the Active Manager client running on the Client Access server learns which DAG member hosts the active database copy from the DAG's Active Manager. Then, the Client Access server connects to that Mailbox server, and Outlook indicates it's connected to the Exchange server.
- If one of the Client Access servers in the Client Access server array becomes unavailable because of a scheduled or unscheduled outage, the remaining Client Access servers in that array handle the client load. Because Outlook is configured to connect to the Client Access server array and not an individual Client Access server, Client Access server array members can individually experience failures or be manually taken offline without affecting the user's Outlook profile. This can happen automatically (for example, automatic array reconfiguration, based on monitoring performed by the load balancer solution in front of the array), or you can perform this manually.

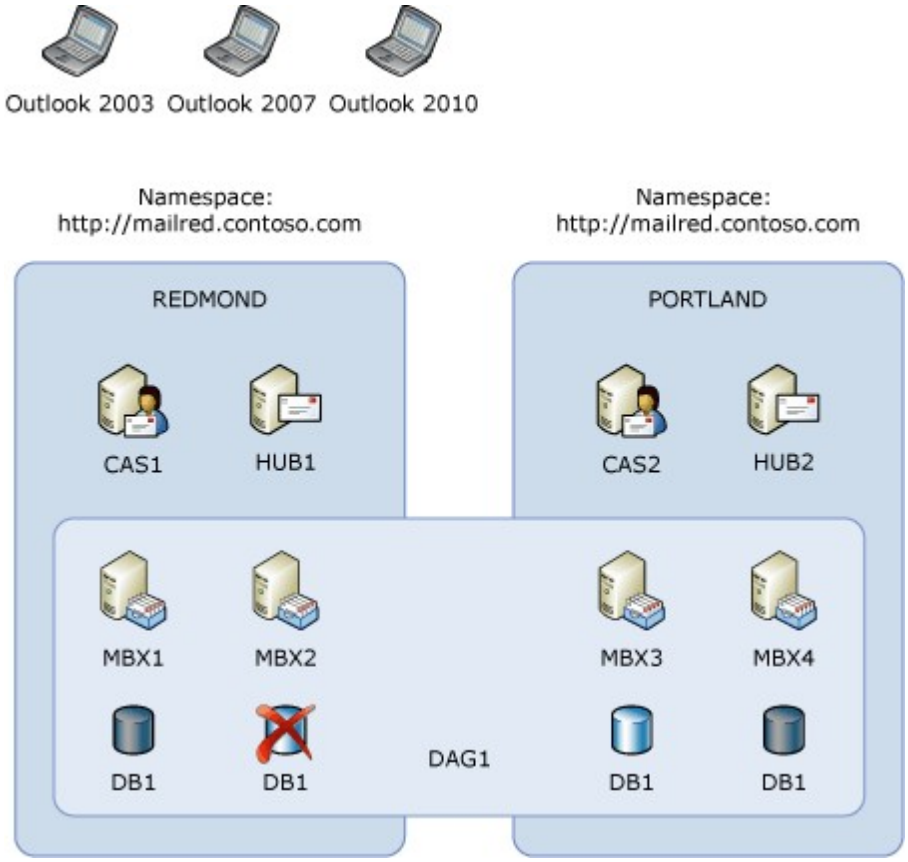
All versions of Outlook also behave the same for datacenter switchovers that occur between two datacenters and two Active Directory sites. Datacenter switchovers involve changing the IP addresses used by client access namespaces (for example, Microsoft Office Outlook Web App, SMTP, POP3, IMAP4, Autodiscover, Exchange Web Services, or RPC Client Access) from IP addresses in the primary datacenter to IP addresses in the secondary datacenter. As a result, the namespace used in the user's Outlook profile doesn't change, and Autodiscover continues to point clients to the same Client Access server array namespace.

The behavior of Outlook after a cross-site database failover is different from its behavior

after a database failover in a single Active Directory site or after a datacenter switchover.

Example Behavior for Outlook Versions

The following examples illustrate the behavior of Outlook 2010, Office Outlook 2007, and Office Outlook 2003 after a cross-site database failover occurs. The topology used in each example is a four-member DAG extended to two Active Directory sites: Redmond and Portland. The user's mailbox is hosted on DB1, which is replicated to each of the servers. In each example, the active copy of DB1 fails over from MBX2 to MBX3.



Each client is configured with CAS1 as its home server, making Redmond the *Outlook profile site*. Because the clients are located in Redmond, the **RPCClientAccessServer** property for DB1 is configured for CAS1, making Redmond the *preferred database site*. Because DB1 failed on MBX2 and has become active on MBX3, Portland is the *mounted database site*.

Example for Outlook 2010 and Outlook 2007

If a Client Access server is available in the Redmond site, Outlook 2010 and Outlook 2007 will continue to connect to the RPC Client Access array in the Redmond site. The Client Access server used by the client will communicate using MAPI RPC with the user's Mailbox server in the Portland site.

If there are no Client Access servers available in the Redmond site, then a datacenter switchover from Redmond to Portland must be performed in order to restore access to service and data. For detailed steps to perform a datacenter switchover, see Perform a Server Switchover.

Example for Outlook 2003

When Outlook 2003 attempts to connect to CAS1, it also receives an *ecWrongServer*

message in response. Unlike Outlook 2010 and Outlook 2007, Outlook 2003 doesn't include the Autodiscover feature, and it must use some other means to update the user's profile. MAPI profile redirection is the mechanism used by Outlook 2003. MAPI profile redirection requires that the original source server be online. If CAS1 is unavailable, and if all other Client Access servers in the array are also unavailable (or if the array contains only CAS1), Outlook 2003 can't perform MAPI redirection or connect to the user's mailbox database without manual intervention.

Outlook Behavior and Logic When Public Folders Are Used

Although public folder databases can be hosted on Mailbox servers that are members of a DAG, public folder databases don't use continuous replication, and they rely on public folder replication for high availability. The behavior for Outlook clients reconnecting to a public folder database after a mailbox database failover depends not only on the nature of the failure, but on your public folder replication configuration settings and the health and currency of your public folder databases. Because continuous replication can't be used for public folder databases, high availability for public folder databases is accomplished by deploying multiple public folder databases and configuring them to replicate with each other. We recommend that you configure more than one replica of each folder.

In any scenario where a user's default public folder database server is unavailable, you must manually reconfigure the default public folder database for the user's mailbox database so that Outlook can access public folder data. For detailed steps about how to change the default public folder database for a mailbox database, see Change the Default Public Folder Database for a Mailbox Database.

Non-Outlook Client Behavior and Logic

Generally, the behavior of clients and protocols other than Outlook and MAPI varies based on the application being used and the failure scenario. Generally, as with Outlook, the typical Exchange applications and clients (for example, Outlook Web App, Microsoft Exchange ActiveSync, POP3, IMAP4, and Exchange Web Services) behave the same for database failovers that occur within a single datacenter and single Active Directory site. Similarly, all these clients and protocols (including SMTP and Windows PowerShell) behave the same as Outlook after a datacenter switchover.

If a cross-site database failover occurs, the behavior varies among these clients and protocols. The following table lists the behavior for these clients.

Cross-site database failover behavior for typical Exchange clients

Client or protocol	Behavior
Outlook Web App	Manual redirection. In this scenario, the client namespace is changing from http://mailred.contoso.com to http://mailpdx.contoso.com. After the user enters logon credentials, the user is redirected to CAS2 in the Portland site through a manual redirection page explaining that the wrong URL was used and that the correct URL is https://mailpdx.contoso.com/owa.
Exchange ActiveSync	Proxy or redirection. In this scenario, the client behavior is determined by the implementation and version of the Exchange ActiveSync protocol on the client device.
POP3 and IMAP4	Proxy. This scenario always involves Client Access server to Client Access server proxying.
Exchange Web Services	Uses Autodiscover to determine new

	connection endpoint.

1.10.1.1.1 Understanding Active Manager

Understanding Active Manager

High Availability and Site Resilience > Understanding High Availability and Site Resilience > Understanding Database Availability Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-03*

Microsoft Exchange Server 2010 includes a new component called *Active Manager* that provides functionality that replaces the resource model and failover management features provided by integration with the Cluster service in previous versions of Exchange. Exchange no longer uses the cluster resource model for high availability. All Exchange cluster resources provided by exres.dll no longer exist, including the construct known as a clustered mailbox server. A Windows Failover Cluster is used by Exchange, but there are no cluster groups for Exchange, and there are no storage resources in the cluster. Thus, if you examine the cluster using cluster management tools, you'll see only the core cluster resources (IP Address and Network Name, and if needed, quorum resource). Cluster nodes and networks will also exist, but those are managed by Exchange and not cluster or cluster tools.

Active Manager runs as a role on all Mailbox servers. On Mailbox servers that are not configured for high availability, there is a single Active Manager role: *Standalone Active Manager*. On servers that are members of a database availability group (DAG), there are two Active Manager roles: *Primary Active Manager* (PAM) and *Standby Active Manager* (SAM). PAM is the Active Manager in a DAG that decides which copies will be active and passive. PAM is responsible for getting topology change notifications and reacting to server failures. The DAG member that holds the PAM role is always the member that currently owns the cluster quorum resource (default cluster group). If the server that owns the cluster quorum resource fails, the PAM role automatically moves to a surviving server that takes ownership of the cluster quorum resource. In addition, if you need to take the server that hosts the cluster quorum resource offline for maintenance or an upgrade, you must first move the PAM to another server in the DAG. The PAM controls all movement of the active designations between a database's copies (only one copy can be active at any specified time, and that copy may be mounted or dismounted). The PAM also performs the functions of the SAM role on the local system (detecting local database and local Information Store failures).

The SAM provides information on which server hosts the active copy of a mailbox database to other components of Exchange that are running an Active Manager client component (for example, RPC Client Access service or Hub Transport server). The SAM detects failures of local databases and the local Information Store. It reacts to failures by asking the PAM to initiate a failover (if the database is replicated). A SAM doesn't determine the target of failover, nor does it update a database's location state in the PAM. It will access the active database copy location state to answer queries for the active copy of the database that it receives.

Note:
Exchange 2010 is not a clustered application. Instead, it uses the cluster library functions implemented in clusapi.dll for cluster, group, cluster network (heartbeating), node management, cluster registry, and a few control code functions. In addition, Active

Manager stores current mailbox database information (for example, active and passive data, and mounted data) in the cluster database. Although the information is stored directly in the cluster database, it isn't accessed directly by any other components.

In Exchange 2010, the Microsoft Exchange Replication service periodically monitors the health of all mounted databases. In addition, it also monitors Extensible Storage Engine (ESE) for any I/O errors or failures. When the service detects a failure, it notifies Active Manager. Active Manager then determines which database copy should be mounted and what it requires to mount that database. In addition, it tracks the active copy of a mailbox database (based on the last mounted copy of the database) and provides the tracking results information to the RPC Client Access component on the Client Access server to which the client is connected.

Active Manager Best Copy Selection

When a failure occurs that affects a replicated mailbox database, Active Manager takes several steps to recover from the failure by selecting the best possible copy of the failed database to activate. The general process occurs in the following order:

1. Active Manager detects the failure.
2. The PAM runs an internal algorithm called best copy selection (BCS).
3. A process called *attempt copy last logs* (ACLL) occurs, which tries to copy any missing log files from the server that hosted the active database copy prior to the failover.
4. Once the ACLL process has completed, the PAM issues a mount request to the Microsoft Exchange Information Store via remote procedure call (RPC). At this point, either:
   4.a. The database mounts and is made available to clients; or
   4.b. The database does not mount, and PAM performs steps 3 and 4 on the next best copy (if one is available).

When searching for the best possible copy, the PAM uses up to ten separate sets of criteria to determine the best copy to activate. After locating the best possible copy, ACLL runs. After the ACLL process has completed, if all missing log files were copied from the previous active copy, the database mounts without any data loss. This is known as a lossless failover. If the ACLL process is unsuccessful, the configured value for *AutoDatabaseMountDial* is consulted. For more information about *AutoDatabaseMountDial*, see Set-MailboxServer. If the number of lost logs is within the configured value for *AutoDatabaseMountDial*, the database is mounted. If the number of lost logs is outside the configured value for *AutoDatabaseMountDial*, the database isn't mounted until either missing log files are recovered or until an administrator explicitly mounts the database and accepts the larger data loss. If the database doesn't mount automatically, the PAM will select the next best copy (if one is available). There are at least three reasons why the initially selected database copy does not mount automatically:

1. The number of lost log files is greater than the configured value for *AutoDatabaseMountDial*.
2. The server on which the mount attempt was made is configured with a soft maximum for the active number of databases, and the maximum number of active database copies has been reached on the server.
3. The database copy is suspended for activation.

Best Copy Selection Process

Active Manager begins the best copy selection process by creating a list of database copies that are potential candidates for activation. Any database copies that are unreachable or are administratively blocked from activation (by using the *DatabaseCopyAutoActivationPolicy* property of the **Set-MailboxServer** cmdlet) are ignored and not used during the selection process. The order of the list depends on the version of Exchange 2010:

- In the release to manufacturing (RTM) version of Exchange 2010, Active Manager sorts the resulting list using the copy queue length as the primary

key. The calculation is based on LastLogInspected (from the copy's point of view), so the list of potential copies is sorted by the highest value for LastLogInspected (which will be the copy with the lowest copy queue length). Then, Active Manager sorts the list a second time, using the value for ActivationPreference as a secondary key. The copy with the lowest ActivationPreference value has the higher priority on the list.

- In Exchange 2010 Service Pack 1 (SP1), the behavior is the same as in the RTM version, except for servers configured with an automatic database mount dial value of *Lossless*, and for target-less switchovers performed by an administrator or administrative script When a Lossless setting is used, Active Manager sorts the resulting list in ascending order by using the value for ActivationPreference as the primary key. In addition, when an administrator performs a lossless server or database switchover without specifying a target, Active Manager also sorts the resulting list in ascending order by using the value for ActivationPreference as the primary key.

Next, Active Manager attempts to locate a mailbox database copy on the list that has a status of Healthy, DisconnectedAndHealthy, DisconnectedAndResynchronizing, or SeedingSource, and then evaluates the activation potential of each of the copies on the list by using an order set of ten criteria. Active Manager determines if any of the candidates for activation meet the first set of criteria:

- It has a content index with a status of Healthy.
- It has a copy queue length less than 10 log files.
- It has a replay queue length of less than 50 log files.

If none of the database copies meet the first set of criteria, Active Manager tries to locate a database copy that meets the second set of criteria:

- It has a content index with a status of Crawling.
- It has a copy queue length less than 10 log files.
- It has a replay queue length of less than 50 log files.

If none of the database copies meet the second set of criteria, Active Manager tries to locate a database copy that meets the third set of criteria:

- It has a content index with a status of Healthy.
- It has a replay queue length of less than 50 log files.

If none of the database copies meet the third set of criteria, Active Manager tries to locate a database copy that meets the fourth set of criteria:

- It has a content index with a status of Crawling.
- It has a replay queue length of less than 50 log files.

If none of the database copies meet the fourth set of criteria, Active Manager tries to locate a database copy that meets the fifth set of criteria:

- It has a replay queue length of less than 50 log files.

If none of the database copies meet the fifth set of criteria, Active Manager tries to locate a database copy that meets the sixth set of criteria:

- It has a content index with a status of Healthy.
- It has a copy queue length less than 10 log files.

If none of the database copies meet the sixth criteria, Active Manager tries to locate a database copy that meets the seventh set of criteria:

- It has a content index with a status of Crawling.
- It has a copy queue length that is less than 10 log files.

If none of the database copies meet the seventh set of criteria, Active Manager tries to locate a database copy that meets the eighth set of criteria:

- It has a content index with a status of Healthy.

If none of the database copies meet all of the eighth set of criteria, Active Manager tries to locate a database copy that meets the ninth set of criteria:

- It has a content index with a status of Crawling.

If none of the database copies meet the ninth set of criteria, Active Manager tries to activate any database copy with a status of Healthy, DisconnectedAndHealthy, DisconnectedAndResynchronizing, or SeedingSource (the tenth set of criteria). If it can't find any database copies that meet the tenth set of criteria, it isn't able to automatically activate a database copy.

Once one or more copies are located that meet one or more sets of criteria, the ACLL process runs to copy any log files from the original source to the potential new active copy. Once the ACLL process has completed, the PAM issues a mount request and either the database mounts and is made available to clients or the database does not mount and the PAM searches for the next best copy (if one is available).

Best Copy Selection Examples

The following section illustrates some examples of Active Manager's best copy selection and activation process.

Example 1: Basic Scenario

In this example, there are four copies of mailbox database DB1. DB1 is currently active on Server1, which experiences a hardware failure. The following table shows the current status of the database copies of DB1 on Server2, Server3 and Server4.

Database Copy	Activation Preference	Copy Queue Length	Replay Queue Length	Content Index State	Database State	Activation Blocked
Server2\DB1	2	4	0	Healthy	Healthy	No
Server3\DB1	3	2	2	Healthy	DisconnectedAndHealthy	No
Server4\DB1	4	10	0	Crawling	Healthy	No

Sorting the available copies based on their copy queue lengths (using Activation Preference if necessary) results in the following ordered list:

- Server3\DB1
- Server2\DB1
- Server4\DB1

Out of this list, only two database copies meet the first set of criteria for activation:

- The copy on Server3, which has a database state of Disconnectedandhealthy, a copy queue length less than 10, a replay queue length less than 50, and a healthy content index.
- The copy on Server2, which has a database state of Healthy, a copy queue length less than 10, a replay queue length less than 50, and a healthy content index.

Of these two, the copy on Server3 has the lowest copy queue length; therefore, Server3 is selected as the copy to attempt to activate since it has the least amount of missing data.

After the copy on Server3 is activated, the Microsoft Exchange Replication service on the Server3 performs the ACLL process and attempts to copy any missing log files from the previous active server (in this case, Server1). When the ACLL process has completed, the PAM is notified of the results of the ACLL process. If all logs are successfully copied, then the database will be marked as the active copy and will be mounted with zero data loss.

If one or more logs are missing, the value for the AutoDatabaseMountDial parameter is consulted. If the data loss is within the configured value, then the database will be marked as the active copy and will be mounted with data loss. The majority of any missing data would then be recovered from the transport dumpster.

If Active Manager does send a mount request to the Information Store and the mount operation is unsuccessful, Active Manager will go back to the above sorted list and attempt to activate the next best copy (in this case, Server2).

Example 2: Two Copies with Same Copy Queue Length

In this example, there are four copies of mailbox database DB2. DB2 is currently active on Server1, which experiences a hardware failure. The following table shows the current status of the database copies of DB2 on Server2, Server3 and Server4.

Database Copy	Activation Preference	Copy Queue Length	Replay Queue Length	Content Index State	Database State	Activation Blocked
Server2\DB2	2	2	0	Healthy	Healthy	No
Server3\DB2	3	2	2	Healthy	DisconnectedAndHealthy	No
Server4\DB2	4	10	0	Crawling	Healthy	No

Sorting the available copies based on their copy queue lengths (using Activation Preference if necessary) results in the following ordered list:

- Server2\DB2
- Server3\DB2
- Server4\DB2

Out of this list, only two database copies meet the first set of criteria for activation:

- The copy on Server2, which has a database state of Healthy, a copy queue length less than 10, a replay queue length less than 50, and a healthy content index.
- The copy on Server3, which has a database state of DisconnectedandHealthy, a copy queue length less than 10, a replay queue length less than 50, and a healthy content index.

Of these two, the copy on Server2 has a copy queue length equal to the copy on Server3, but it also has a lower Activation Preference value; therefore, the copy on Server2 is on the top of the list and is selected as the copy to attempt to activate since it has the least amount of missing data and the lowest Activation Preference value.

Example 3: Copies with Identical Database State and Different Content Index State

In this example, there are four copies of mailbox database DB3. DB3 is currently active on Server1, which experiences a hardware failure. The following table shows the current status of the database copies of DB3 on Server2, Server3 and Server4.

Database Copy	Activation Preference	Copy Queue Length	Replay Queue Length	Content Index State	Database State	Activation Blocked
Server2\DB3	2	0	3	Crawling	Healthy	No
Server3\DB3	3	0	3	Healthy	DisconnectedAndHealthy	No

Server4\DB3	4	0	0	Healthy	Healthy	No

Sorting the available copies based on their copy queue lengths (using Activation Preference if necessary) results in the following ordered list:

- Server2\DB3
- Server3\DB3
- Server4\DB3

All three of the database copies hosted on the above servers meet the criteria for activation. Although Server2 has a lower Activation Preference value, its content index state is Crawling; as a result, when Active Manager checks the list against the first set of criteria (which includes a content index status of Healthy), the database copy on Server3 will be preferred, as it's content index state is Healthy.

Example 4: Effect of AutoDatabaseMountDial on Best Copy Selection

In this example, there are four copies of mailbox database DB4. DB4 is currently active on Server1, which experiences a failure that causes it to reboot. The following table shows the current status of the database copies of DB4 on Server2, Server3 and Server4. The *AutoDatabaseMountDial* parameter for all Mailbox servers in the DAG is configured for Lossless (copy queue length is 0).

Database Copy	Activation Preference	Copy Queue Length	Replay Queue Length	Content Index State	Database State	Activation Blocked
Server2\DB4	2	0	4523	Healthy	Healthy	No
Server3\DB4	3	100	25	Crawling	Healthy	No
Server4\DB4	4	6	62	Healthy	Healthy	No

Because the automatic database mount dial setting is set to Lossless, Active Manager uses Activation Preference instead of copy queue length as the primary sorting key. Sorting the available copies based on their Activation Preference results in the following ordered list:

- Server2\DB4
- Server3\DB4
- Server4\DB4

None of the databases meet the first, second or third set of criteria, but the database copy on Server3 does meet the fourth set of criteria (it has a content index state of Crawling and a replay queue length less than 50). The database copy on Server3 has a copy queue length of 100, but because Server1 has not finished rebooting, the ACLL process is unable to copy these missing logs files to Server3. The ACLL process tells the PAM that the amount of missing data is not within the configured value for the *AutoDatabaseMountDial* parameter, and this causes the PAM to select the next best available copy.

In the above scenario, the database copies on Server2 and Server4 match the sixth set of criteria (they have a healthy database and content index, and a copy queue length less than 10). As it is higher in the sorted listed of available copies, the database copy on Server2 is tried next. The ACLL process runs on Server2, but Server1 is still not communicating on the network, and ACLL is unable to copy any logs. But because the copy queue length is within the configured value for the *AutoDatabaseMountDial* parameter, ACLL sends a success message to the PAM and the PAM issues a database mount request via RPC.

Understanding Datacenter Activation Coordination Mode

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-01*

Datacenter Activation Coordination (DAC) mode is a property setting for a database availability group (DAG). DAC mode is disabled by default and should be enabled for all DAGs with two or more members that use continuous replication. DAC mode shouldn't be enabled for DAGs in third-party replication mode unless specified by the third-party vendor.

If a catastrophic failure occurs that affects the DAG (for example, a complete failure of one of the datacenters), DAC mode is used to control the startup database mount behavior of a DAG. When DAC mode isn't enabled, and a failure occurs that affects multiple servers in the DAG, when a majority of the DAG members are restored after the failure, the DAG will restart and attempt to mount databases. In a multi-datacenter configuration, this behavior could cause *split brain syndrome*, a condition that occurs when all networks fail, and DAG members can't receive heartbeat signals from each other. Split brain syndrome can also occur when network connectivity is severed between the datacenters. Split brain syndrome is prevented by always requiring a majority of the DAG members (and in the case of DAGs with an even number of members, the DAG's witness server) to be available and interacting for the DAG to be operational. When a majority of the members are communicating, the DAG is said to have quorum.

For example, consider a scenario where the first datacenter contains two DAG members and the witness server, and the second datacenter contains two other DAG members. If the first datacenter loses power and you activate the DAG in the second datacenter (for example, by activating the alternate witness server in the second datacenter), if the first datacenter is restored without network connectivity to the second datacenter, the active databases within the DAG may enter a split brain condition.

How DAC Mode Works

DAC mode is designed to prevent split brain from occurring by including a protocol called Datacenter Activation Coordination Protocol (DACP). After a catastrophic failure, when the DAG recovers, it won't automatically mount databases even though the DAG has a quorum. Instead DACP is used to determine the current state of the DAG and whether Active Manager should attempt to mount the databases.

You might think of DAC mode as an application level of quorum for mounting databases. To understand the purpose of DACP and how it works, it's important to understand the primary scenario it's intended to deal with. Consider the two-datacenter scenario. Suppose there is a complete power failure in the primary datacenter. In this event, all of the servers and the WAN are down, so the organization makes the decision to activate the standby datacenter. In almost all such recovery scenarios, when power is restored to the primary datacenter, WAN connectivity is typically not immediately restored. This means that the DAG members in the primary datacenter will power up, but they won’t be able to communicate with the DAG members in the activated standby datacenter. The primary datacenter should always contain the majority of the DAG quorum voters, which means that when power is restored, even in the absence of WAN connectivity to the DAG members in the standby datacenter, the DAG members in the primary datacenter have a majority and therefore have quorum. This is a problem because with quorum, these servers may be able to mount their databases, which in turn would cause divergence from the actual active databases that are now mounted in the activated standby datacenter.

DACP was created to address this issue. Active Manager stores a bit in memory (either a 0 or a 1) that tells the DAG whether it's allowed to mount local databases that are assigned as active on the server. When a DAG is running in DAC mode (which would be any DAG with three or more members), each time Active Manager starts up the bit is set to 0, meaning it isn't allowed to mount databases. Because it's in DAC mode, the server must try to communicate with all other members of the DAG that it knows to get another DAG member to give it an answer as to whether it can mount local databases that are assigned as active to it. The answer comes in the form of the bit setting for other Active Managers in the DAG. If another server responds that its bit is set to 1, it means servers are allowed to mount databases, so the server starting up sets its bit to 1 and mounts its databases.

But when you recover from a primary datacenter power outage where the servers are recovered but WAN connectivity has not been restored, all of the DAG members in the primary datacenter will have a DACP bit value of 0; and therefore none of the servers starting back up in the recovered primary datacenter will mount databases, because none of them can communicate with a DAG member that has a DACP bit value of 1.

DAC Mode for DAGs with Two Members

DAGs with two members have inherent limitations that prevent the DACP bit alone from fully protecting against application-level split brain syndrome. For DAGs with only two members, DAC mode also uses the boot time of the DAG's alternate witness server to determine whether it can mount databases on startup. The boot time of the alternate witness server is compared to the time when the DACP bit was set to 1.

- If the time the DACP bit was set is earlier than the boot time of the alternate witness server, the system assumes that the DAG member and witness server were rebooted at the same time (perhaps because of power loss in the primary datacenter), and the DAG member isn't permitted to mount databases.
- If the time that the DACP bit was set is more recent than the boot time of the alternate witness server, the system assumes that the DAG member was rebooted for some other reason (perhaps a scheduled outage in which maintenance was performed or perhaps a system crash or power loss isolated to the DAG member), and the DAG member is permitted to mount databases.

Important:

Because the alternate witness server's boot time is used to determine whether a DAG member can mount its active databases on startup, you should never restart the alternate witness server and the sole DAG member at the same time. Doing so may leave the DAG member in a state where it cannot mount databases on startup. If this happens, you must run the Restore-DatabaseAvailabilityGroup cmdlet on the DAG. This resets the DACP bit and permits the DAG member to mount databases.

Other Benefits of DAC Mode

In addition to preventing split brain syndrome at the application level, DAC mode also enables the use of the built-in site resilience cmdlets used to perform datacenter switchovers. These include the following:

- Stop-DatabaseAvailabilityGroup
- Restore-DatabaseAvailabilityGroup
- Start-DatabaseAvailabilityGroup

Performing a datacenter switchover for DAGs that are not in DAC mode involves using a combination of Exchange tools and cluster management tools.

For more information about datacenter switchovers, see Datacenter Switchovers.

Enabling DAC Mode

DAC mode can be enabled only by using the Exchange Management Shell. Specifically, you can use the Set-DatabaseAvailabilityGroup cmdlet to enable and disable DAC mode, as illustrated in the following example.

```
Set-DatabaseAvailabilityGroup -Identity DAG2 -DatacenterActivationMode DagOnly
```

In the preceding example, a DAG named DAG2 is enabled for DAC mode.

For more information about enabling DAC mode, see Configure Database Availability Group Properties and Set-DatabaseAvailabilityGroup.

1.10.1.1.3 Database Availability Group Design Examples

Database Availability Group Design Examples

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-10-01*

The ability of a database availability group (DAG) to contain as many as 16 Mailbox servers, combined with the ability to extend a DAG across multiple physical locations and Active Directory sites, provides a large number of architectural design possibilities for DAGs.

You can use design examples for DAGs in a variety of environments:

- Two-member DAG, which is suited for small office and branch office deployments
- Four-member DAG that provides high availability within a single datacenter by locating all members in the same datacenter
- Four-member DAG that provides high availability within a single datacenter, and site resilience for that datacenter, by locating two of the members in the primary datacenter and two of the members in a second datacenter

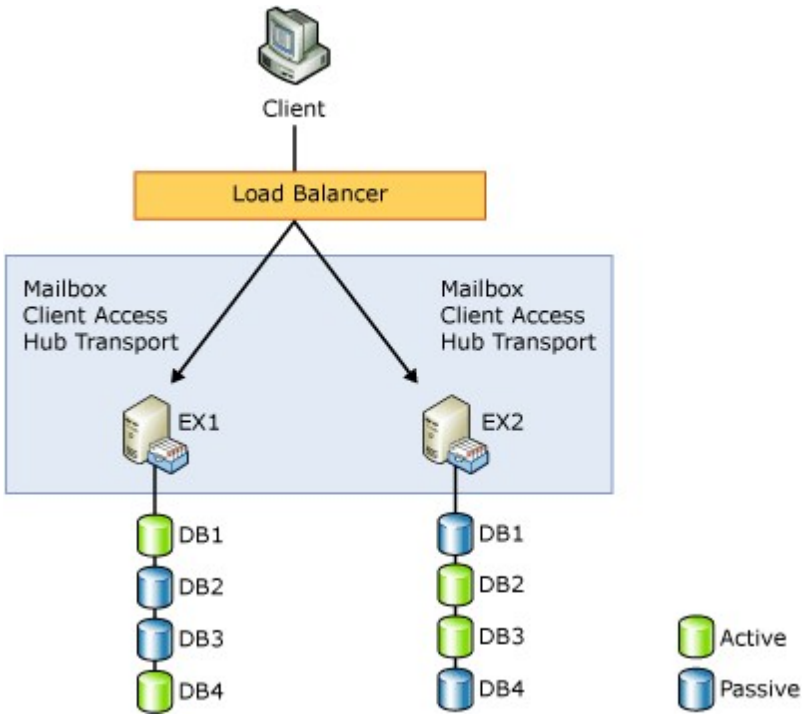
The design you use for your DAGs and the distribution of mailbox database copies will be based on your organization's service level agreements (SLAs) and the recovery time objective and recovery point objective for the mailbox service and data as stated in those SLAs.

Contents

Looking for management tasks related to high availability and site resilience? See Managing High Availability and Site Resilience.

Two-Member DAG in Single Datacenter/ Active Directory Site

A two-member DAG is the smallest possible DAG that can provide high availability. Two-member DAGs are best suited for organizations that require some form of high availability for mailbox services and data, but that don't require site resilience. This configuration works especially well in small office and branch office deployments because it enables redundancy for the Client Access, Mailbox, and Hub Transport server roles using only two Exchange servers. The following figure illustrates this configuration.



There are several aspects worth noting about this configuration:

- In this design, only the Client Access, Mailbox, and Hub Transport server roles are co-located. Although it's supported to co-locate the Unified Messaging server role, we don't recommend that configuration for performance reasons.
- To achieve high availability for Client Access and Hub Transport server roles, some form of load balancing should be used between the clients and those server roles. Because these server roles are co-located with a Mailbox server that's a member of a DAG, Windows Network Load Balancing can't be used (because Network Load Balancing and Windows failover clustering can't be installed on the same server). Instead, a non-Windows Network Load Balancing solution must be used (for example, a hardware load balancer or a third-party software-based load balancer).
- As with all DAGs that contain an even number of members, a two-member DAG requires a witness server to maintain quorum. The witness server (not pictured) is a Windows server that isn't and will never be a member of the DAG. For example, smaller organizations that use this configuration may use a file server or a directory server as the witness server. Quorum is maintained as long as more than half of the quorum voters are available and in communication. A two-member DAG with a witness server provides three quorum voters. (Each DAG member and the witness server can vote whenever

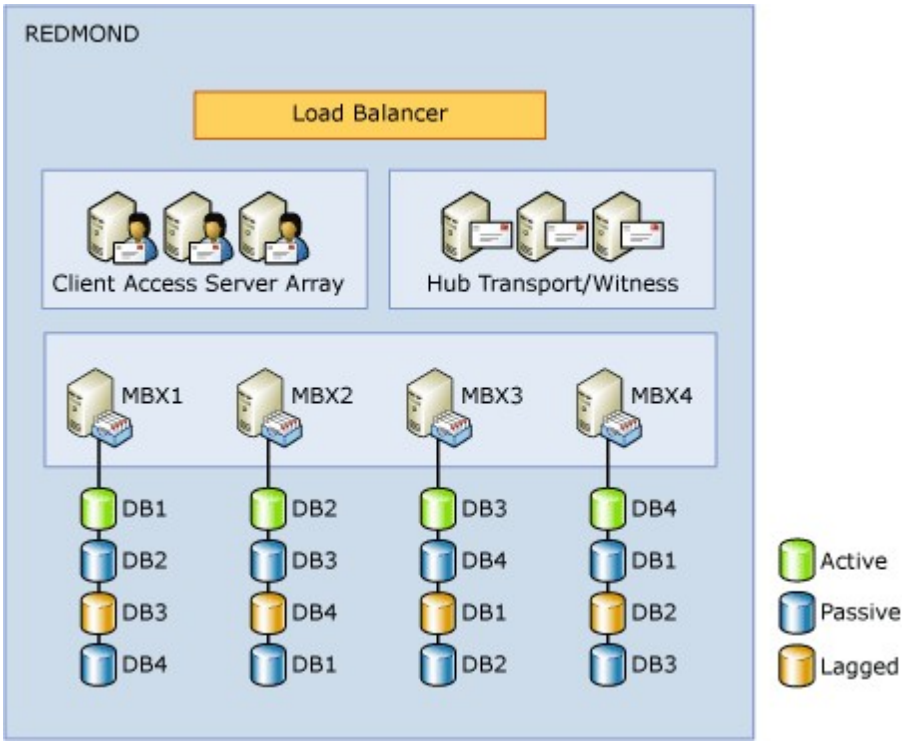
they are available and in communication.) Therefore, a two-member DAG can survive the failure or outage of a single voter (for example, either of the DAG members, or just the witness server) without an interruption in service. However, the loss of two of the voters (for example, a DAG member and the witness server) will result in a loss of quorum, which will result in an interruption in service.

Return to top

Four-Member DAG in Single Datacenter/ Active Directory Site

A four-member DAG in a single datacenter deployment provides greater resilience to failures than a two-member or three-member DAG. Larger DAGs inherently provide greater resilience because they can sustain more failures without an interruption in service. Whereas a two-member or three-member DAG can sustain the loss of only a single voter without losing quorum and compromising service, a four-member DAG, which by definition has five quorum voters, can sustain the loss of two voters without losing quorum and compromising service.

The following figure illustrates a four-member DAG with all members located in a single datacenter.



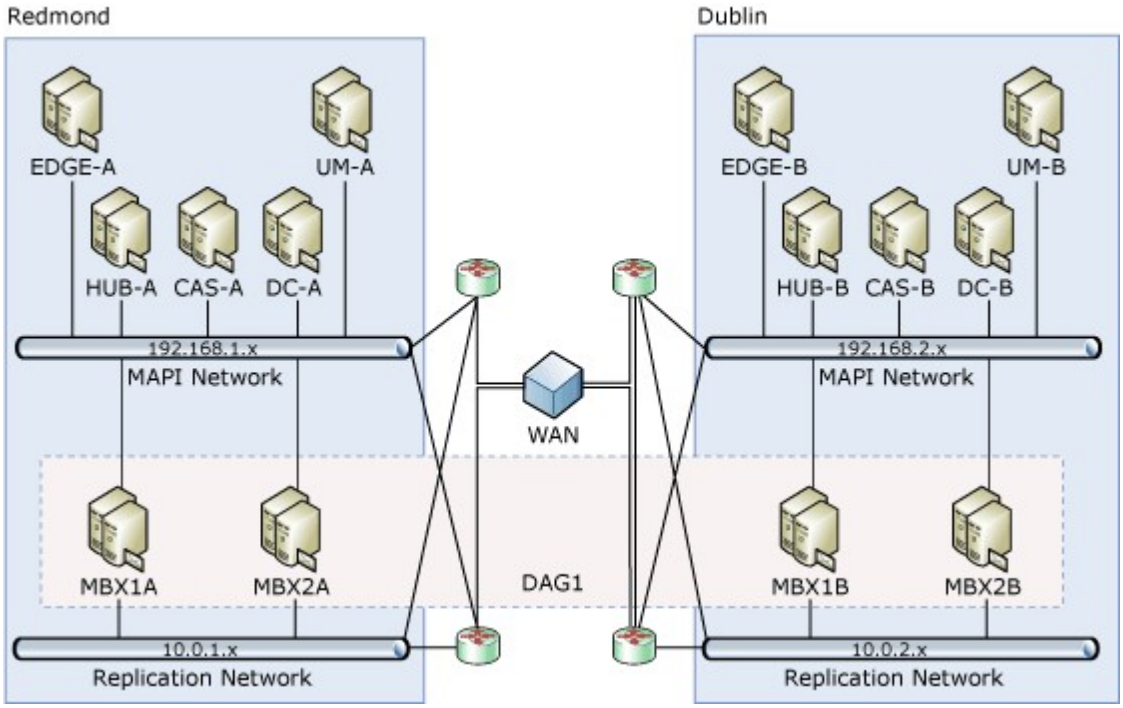
Using a four-member DAG, you can create a maximum of four copies of each database. This is a sufficient number of database copies to enable the use of alternate data protection scenarios, such as flexible mailbox protection. Flexible mailbox protection enables you to combine the Microsoft Exchange Server 2010 high availability and Extensible Storage Engine (ESE) resilience features with other built-in protection features, such as lagged mailbox database copies, retention policies, the Recoverable Items folder, and the hold policy, to create a solution that can reduce the need for other forms of protection, such as using Redundant Array of Independent Disks (RAID) or making data

backups. For more information about flexible mailbox protection, see Understanding Backup, Restore and Disaster Recovery. For more information about using replication for your backups and using just a bunch of disks (JBOD), see Mailbox Server Storage Design.

Return to top

Four-Member DAG in Two Datacenter/ Active Directory Sites

A four-member DAG extended across two datacenters provides both datacenters high availability and site resilience for the mailbox services and data. This configuration is illustrated in the following figure.



There are several aspects worth noting about this configuration:

- The witness server for the DAG should be located in the primary datacenter. Generally, the primary datacenter is the datacenter containing the majority of the user population. Using a witness server in the primary datacenter enables continued functionality for the majority of the user population in the event of a wide area network (WAN) outage. You can use multiple DAGs to eliminate the WAN as a single point of failure and to allow service and data access to remain functional for multiple datacenters in the event of a WAN outage. For more information, see the next example.
- There's no direct routing that allows traffic from the replication network on one DAG member server to the MAPI network on another DAG member server, or the reverse, or between multiple replication networks in the DAG. For example, you would want to block traffic between the MAPI network on each DAG member and the replication networks on each other DAG network. (In the previous figure, the MAPI network on MBX1A shouldn't have any network connectivity with the replication networks on MBX1B or MBX2B.) You can use router access control lists (ACLs) to block this traffic. In addition, if you're using Dynamic Host Configuration Protocol (DHCP) for the replication network, you

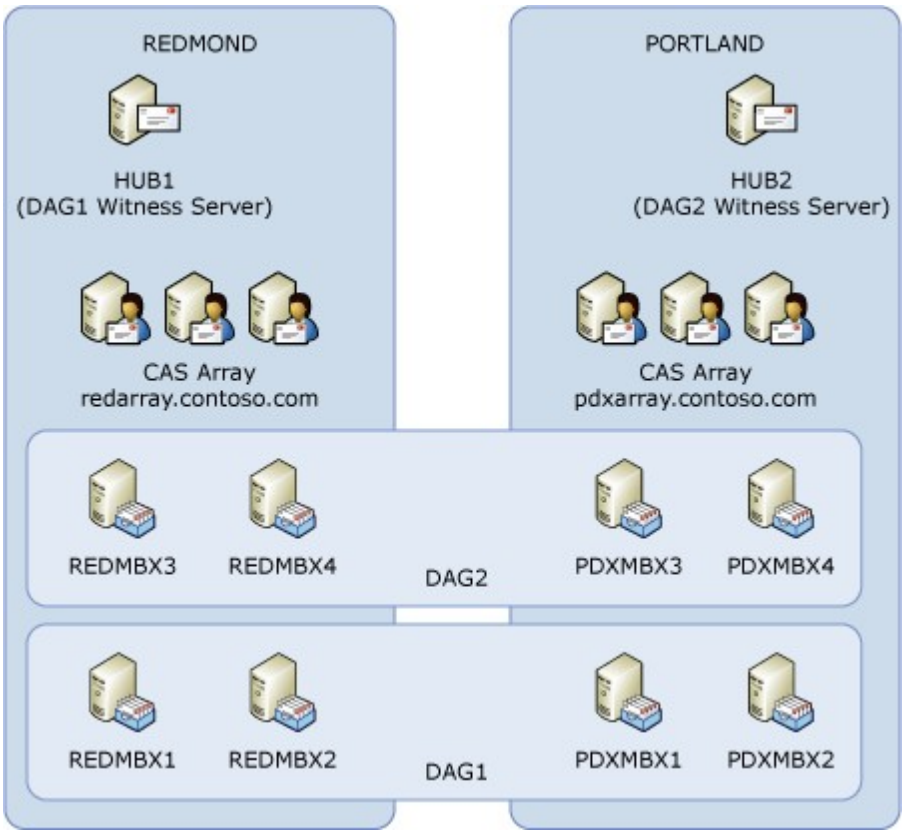
can use DHCP to configure static routes for the DAG members.
- Because this DAG configuration is intended to provide site resilience, the Time to Live (TTL) value for the Exchange client access namespaces (Microsoft Office Outlook Web App, Autodiscover, Microsoft Exchange ActiveSync, Outlook Anywhere, POP3, IMAP4, SMTP, and the RPC Client Access array) should be set to 5 minutes in both the internal and external DNS zones.
- In this example, the Exchange server roles are deployed on dedicated hardware. Because the Client Access and Hub Transport server roles aren't co-located with the Mailbox server in the DAG, Windows Network Load Balancing is used to load balance the Client Access and Hub Transport server roles.

Return to top

Two Four-Member DAGs in Two Datacenter/Active Directory Sites

As illustrated in the previous example, using a single four-member DAG extended across two datacenters can provide high availability and site resilience for the mailbox services and data. However, if a WAN outage occurs, only the primary datacenter retains service because it contains the majority of the voters. The datacenter with the minority of voters loses majority, and the DAG members in that datacenter lose quorum and go offline.

To deploy highly available Mailbox servers in a multiple datacenter environment, where each datacenter is actively serving a local user population, we recommend that you deploy multiple DAGs, where each DAG has a majority of voters in a different datacenter, as illustrated in the following figure.



Because DAG1 and DAG2 contain an even number of members, they use a witness server.

Although multiple DAGs can use the same witness server, multiple witness servers in separate datacenters are used to maintain service to each datacenter's local user population in the event of a WAN outage.

Users located in Portland would have their active mailbox database located on PDXMBX3 and/or PDXMBX4, with passive database copies on REDMBX3 and/or REDMBX4. Similarly, users located in Redmond would have their active mailbox database located on REDMBX1 and/or REDMBX2, with passive database copies on PDXMBX1 and/or PDXMBX2. If all network connectivity is lost between Redmond and Portland, the following occurs:

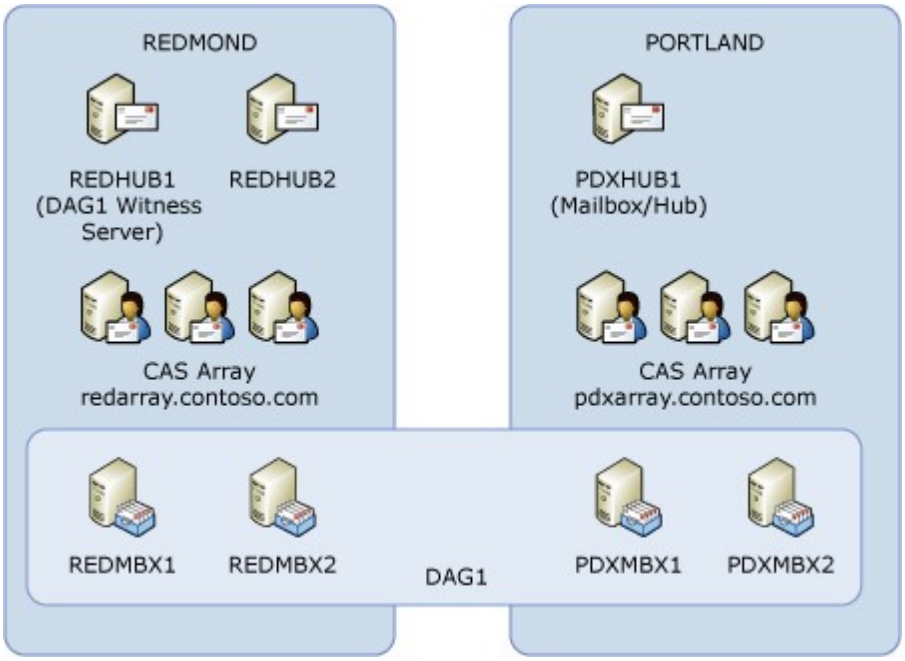
- For DAG1, members REDMBX1 and REDMBX2 would be in the majority and would continue to service users in the Redmond datacenter because they can communicate with the DAG1's witness server, HUB1.
- For DAG2, members PDXMBX3 and PDXMBX4 would be in the majority and would continue to service users in the Portland datacenter because they can communicate with DAG2's witness server, HUB2.

Return to top

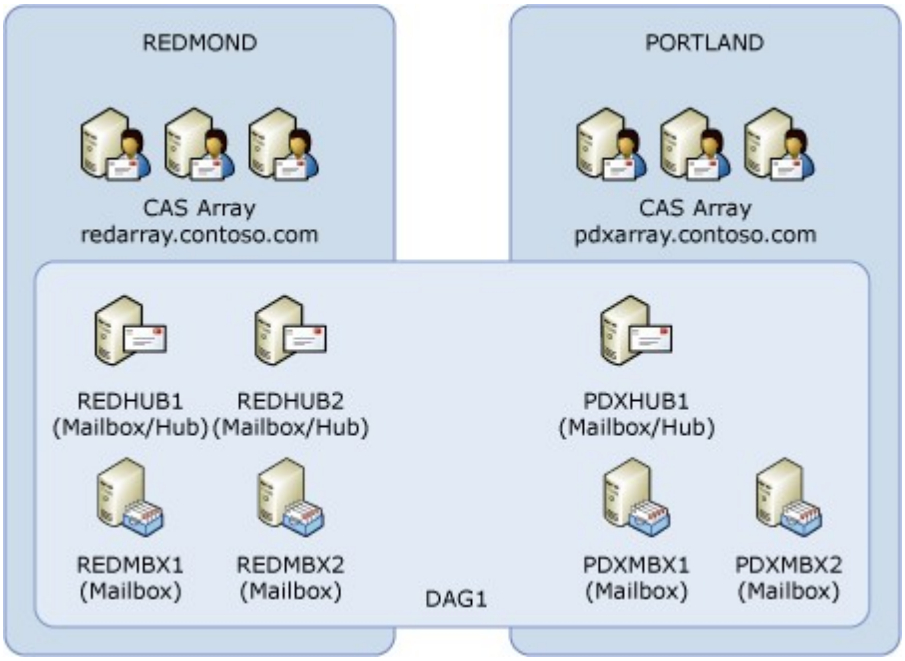
Using Mailbox Servers That Don't Contain Databases in a DAG for Additional Votes

As previously mentioned, larger DAGs inherently provide greater resilience because they can sustain more failures without an interruption in service. One design strategy that can help increase resilience when dealing with DAG member failures is to leverage the existing Hub Transport servers in the DAG's primary datacenter. This strategy involves adding the Mailbox server role (without any databases or database copies) to the Hub Transport server, and then adding that server to the DAG. In this scenario, the Mailbox server role is being used only for voting and quorum purposes. The more voters in a DAG, the more voter failures the DAG can sustain and still maintain quorum.

For example, consider a four-member DAG extended across two datacenters. The primary datacenter contains two DAG members and the witness server, and a second datacenter contains two DAG members. As illustrated in the following figure, there are five quorum voters. Therefore, this DAG can lose two voters and still maintain quorum. If the DAG loses a third voter, it loses quorum and requires manual administrative intervention to restore service.



Using the same servers in this example, you can add the Mailbox server role to the Hub Transport servers REDHUB1, REDHUB2, and PDXHUB1, and then add these servers to DAG1 (assuming these servers are capable of running Windows failover clustering).



At this point, you don't create any production mailbox databases on these servers. You also don't replicate any database copies to these servers. In this configuration, you can delete the default mailbox database and stop the Microsoft Exchange Information Store service (which can also be optionally disabled).

Note:

Although the Microsoft Exchange Information Store service isn't needed for a Mailbox server that doesn't contain a database to participate in quorum voting, the Microsoft

Exchange Replication service must be running for the Mailbox server to participate in quorum and DAG functions.

After the Mailbox servers that don't contain databases are added as members of the DAG, they become participants in quorum for the DAG. In this configuration, DAG1 now has seven quorum voters. As a result, it can lose three servers and still maintain quorum.

Return to top

1.10.1.1.4 Database Copy Layout Design

Database Copy Layout Design

High Availability and Site Resilience > Understanding High Availability and Site Resilience > Understanding Database Availability Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-11*

When designing a highly available solution for Mailbox servers, you need to ensure high availability for a variety of infrastructure components, including:

- Infrastructure services, such as Active Directory and Domain Name System (DNS)
- Database availability group (DAG) member servers
- Individual storage components, such as disks, storage controllers, and storage shelves
- Individual network components, such as routers, switches, and aggregators
- Server and storage racks
- Power buses
- Datacenters

Each of these component areas represents potential points of failure, which are sometimes referred to as *failure domains*. As a result, the availability level of your DAG ultimately depends on how you design the solution to isolate and minimize the negative effects that a failure in one of these domains can have on your DAG environment. To achieve independence between failure domains, each failure domain must have one copy of the database. In addition, because a failure would result in multiple copies being unavailable, no more than one copy is required per failure domain.

For example, consider a scenario in which you have two copies of a database. Each copy is stored on a separate set of disks but both are located within the same storage array. If the storage array fails or becomes unavailable for any reason, both copies would be unavailable. In this example, the failure domain is the storage array. Only a single copy of each mailbox database should reside on the array. Otherwise, if the array fails, multiple (perhaps all) copies of the database will be unavailable.

When planning your mailbox architecture, consider the following additional design points:

- Will you deploy multiple database copies?
- How many database copies will you deploy?
- Will you have a site-resilient architecture?
- What kind of Mailbox server resiliency model will you deploy?
- How many Mailbox servers will you deploy?
- What backup model will you utilize?
- What storage architecture will you utilize?

For detailed information about how to plan for these questions, see Understanding High

Availability Factors.

Contents

Looking for management tasks related to high availability and site resilience? See Managing High Availability and Site Resilience.

Unbalanced Database Copy Layouts

To understand how the database copies should be distributed within a DAG, consider a DAG design that Contoso, Ltd is planning for their highly available Mailbox server solution. Contoso is building a DAG comprised of:

- 4 Mailbox servers
- 20 mailbox databases
- 2 copies of each mailbox database

All servers are deployed in a single datacenter, each server has its own dedicated storage, and each server is deployed in its own server rack.

Contoso requires that two highly available database copies (for example, non-lagged) be available at all times, and that the solution survive two simultaneous DAG member outages without negatively affecting the availability of the databases.

Based on these requirements, the database copy layout used is shown in the following figure.

	Server1	Server2	Server3	Server4
DB1	Active			Passive
DB2	Active			Passive
DB3	Active			Passive
DB4	Active			Passive
DB5	Active			Passive
DB6		Active	Passive	
DB7		Active	Passive	
DB8		Active	Passive	
DB9		Active	Passive	
DB10		Active	Passive	
DB11		Passive	Active	
DB12		Passive	Active	
DB13		Passive	Active	
DB14		Passive	Active	
DB15		Passive	Active	
DB16	Passive			Active
DB17	Passive			Active
DB18	Passive			Active
DB19	Passive			Active
DB20	Passive			Active

Initially, the design looks sound because it spreads the active copies of each database across the four DAG members. However, there are concerns with this design. The layout isn't optimal from a server resource perspective. For example, when a single server fails, it results in an uneven distribution of databases, as shown in the following figure.

	Server1	Server2	Server3	Server4
DB1	Active			
DB2	Active			
DB3	Active			
DB4	Active			
DB5	Active			
DB6		Active	Passive	
DB7		Active	Passive	
DB8		Active	Passive	
DB9		Active	Passive	
DB10		Active	Passive	
DB11		Passive	Active	
DB12		Passive	Active	
DB13		Passive	Active	
DB14		Passive	Active	
DB15		Passive	Active	
DB16	Active			
DB17	Active			
DB18	Active			
DB19	Active			
DB20	Active			

The failure of Server4 results in databases DB16 through DB20 being activated on Server1, instead of being distributed across the remaining three servers. The result is an uneven distribution of activated mailbox databases and an uneven utilization of server resources. Compared to the other two remaining servers (Server2 and Server3), the utilization of Server1 doubled.

Another concern is the DAG doesn't contain enough copies to survive two simultaneous server outages in all cases. Another server failure could result in 50 percent of the databases being unavailable. If Server1 and Server4 fail or become unavailable within

moments of each other, 10 databases would be unavailable, as shown in the following figure.

	Server1	Server2	Server3	Server4
DB1				
DB2				
DB3				
DB4				
DB5				
DB6		Active	Passive	
DB7		Active	Passive	
DB8		Active	Passive	
DB9		Active	Passive	
DB10		Active	Passive	
DB11		Passive	Active	
DB12		Passive	Active	
DB13		Passive	Active	
DB14		Passive	Active	
DB15		Passive	Active	
DB16				
DB17				
DB18				
DB19				
DB20				

This design doesn't meet the core requirement of being able to survive a double server failure. To survive a double server failure and maintain all active databases, a third copy must be deployed, and a new layout must be devised.

Return to top

Designing a Balanced Database Copy Layout

Designing a balanced database copy layout may require you to revisit several design decisions to derive the optimal design. Use the following design principles when planning the database copy layout:

- Make sure that you minimize multiple database copy failures of a mailbox database by isolating each copy from one another and placing them in different failure domains. For example, don't place more than a single database copy of a specific mailbox database within the same server rack or in the same storage array.
- Lay out the database copies in a consistent, distributed fashion to make sure that the active mailbox databases are evenly distributed after a failure. The sum of the activation preferences of each database copy on any specific server must be equal or close to equal. This results in an approximately equal distribution after failure, assuming replication is healthy and up to date.

Building Blocks

To adhere to the previous design principles, we recommend placing the database copies in a particular arrangement that ensures all active copies are symmetrically distributed across as many servers as possible. The arrangement of database copies is based on a *building block* concept.

The first building block (known as the level 1 building block) is based on the number of Mailbox servers that will host active database copies. Assume this number is *N*. *N* defines not only the number of Mailbox servers, but also the number of databases within the building block. One active database copy is distributed on each server, forming a diagonal pattern. As in the previous example, there are 4 Mailbox servers and 20 mailbox databases. The size of the first level 1 building block is 4, as shown in the following figure.

		Server1	Server2	Server3	Server4
Level 1 Building Block Set 1	DB1	Active			
	DB2		Active		
	DB3			Active	
	DB4				Active

The same pattern is repeated for each remaining level 1 building block set. Because there are 20 databases, there are five level 1 building block sets, as shown in the following figure.

	Server1	Server2	Server3	Server4
DB1	Active			
DB2		Active		
DB3			Active	
DB4				Active
DB5	Active			
DB6		Active		
DB7			Active	
DB8				Active
DB9	Active			
DB10		Active		
DB11			Active	
DB12				Active
DB13	Active			
DB14		Active		
DB15			Active	
DB16				Active
DB17	Active			
DB18		Active		
DB19			Active	
DB20				Active

When you add a second database copy, you place it differently for each building block set. Because one server already hosts the active copy, there are $N - 1$ servers available to host the second database copy. As you use each of these $N - 1$ servers once, you have a complete symmetric distribution that forms the new larger building block. Therefore, the new building block (known as the level 2 building block) size becomes $N \times (N - 1)$ databases. This means that the second database copy for the first database is placed on the second server, and each second copy thereafter is deployed in a diagonal pattern within the building block. After the pattern is completed within the first level 1 building block set, the starting position of the second copy for the next block is offset by one so

the second copy starts on the third server.

In the example, the building block size now becomes 4 × (4 – 1) = 4 × 3 = 12, which means that 12 databases make up each level 2 building block set. For the level 1 building block set 1 (DB1 through DB4), the second copy for DB1 is placed on Server2, while for the level 1 building block set 2 (DB5 through DB8), the second copy for DB5 is placed on Server3. The placement of the starting server for each level 1 building block set is offset from the previous level 1 building block set by one server. This layout is continued by placing the second copy of DB9 on Server4. This ensures that a Server1 failure activates second copies across all three remaining servers rather than activating multiple databases on the same server.

			Server1	Server2	Server3	Server4
Level 2 Building Block (4 x 3 = 12) Set 1	Level 1 Building Block Set 1	DB1	Active	Passive		
		DB2		Active		
		DB3			Active	
		DB4				Active
	Level 1 Building Block Set 2	DB5	Active		Passive	
		DB6		Active		
		DB7			Active	
		DB8				Active
	Level 1 Building Block Set 3	DB9	Active			Passive
		DB10		Active		
		DB11			Active	
		DB12				Active

This pattern is repeated for each remaining second building block set. Because there are 20 databases, there are two level 2 building block sets in this example. Note that the second copy for DB13 is placed on Server2.

			Server1	Server2	Server3	Server4
Level 2 Building Block (4 x 3 = 12) Set 2	Level 1 Building Block Set 4	DB13	Active	Passive		
		DB14		Active		
		DB15			Active	
		DB16				Active
	Level 1 Building Block Set 5	DB17	Active		Passive	
		DB18		Active		
		DB19			Active	
		DB20				Active

To understand this logic better, compare database copy placement for DB1, DB5, and DB9. These databases each have an active copy hosted on Server1. If Server1 fails, you want to have second database copies activated on different remaining servers to achieve equal load distribution. You can achieve this by placing a second database copy of DB1 on Server2, a second database copy of DB5 on Server3, and a second database copy of DB9

on Server4. Starting with DB13, you simply repeat the pattern. The remaining database copies are added in a diagonal pattern, as shown in the following figure.

	Server1	Server2	Server3	Server4
DB1	Active	Passive		
DB2		Active	Passive	
DB3			Active	Passive
DB4	Passive			Active
DB5	Active		Passive	
DB6		Active		Passive
DB7	Passive		Active	
DB8		Passive		Active
DB9	Active			Passive
DB10	Passive	Active		
DB11		Passive	Active	
DB12			Passive	Active
DB13	Active	Passive		
DB14		Active	Passive	
DB15			Active	Passive
DB16	Passive			Active
DB17	Active		Passive	
DB18		Active		Passive
DB19	Passive		Active	
DB20		Passive		Active

Note that the second building block (DB13 through DB20) contains only 8 databases, not 12. As a result, this design won't be entirely symmetrical if a single failure occurs. To provide a fully symmetric distribution, plan your architecture so the number of databases is a multiple of the largest building block size. (In this example, optimal numbers are 24, 36, 48, or 60 databases, and so on.)

As you add a third database copy, again you must place it differently for each group of

now $N \times (N - 1)$ databases. Because you now have only $N - 2$ servers available from which to select for the third database copy placement, this generates $N - 2$ variations. The new building block (known as the level 3 building block) becomes $N \times (N - 1) \times (N - 2)$ databases. Therefore, the third database copy for the first database is placed on the third server, and each third copy thereafter is deployed in a diagonal pattern according to the starting position within this new building block. After the pattern is completed within the first level 1 building block set, the starting position is offset by one so that the third copy is placed in the fourth position.

In this example, the building block now becomes $4 \times (4 - 1) \times (4 - 2) = 4 \times 3 \times 2 = 24$, which means that 24 databases make up each level 3 building block set. To produce the symmetric database placement pattern, place the third database copy of DB1 on Server3 (which is the first available server because Server1 hosts the first copy and Server2 hosts the second copy), and offset each additional copy by one until you reach the end of the level 1 building block set 1. For the next building block set, again place the third database copy on the next available server (Server4) and continue in the same manner until you reach DB12, which marks the end of the level 2 building block set 1. For DB13 through DB20, follow the same pattern but offset the third database copy placement by one so it doesn't end up on the same servers as DB1 through DB12.

				Server1	Server2	Server3	Server4
Level 3 Building Block (4x3x2 = 24)	Level 2 Building Block (4x3 = 12) Set 1	Level 1 Building Block Set 1	DB1	Active	Passive1	Passive2	
			DB2		Active	Passive1	Passive2
			DB3	Passive2		Active	Passive1
			DB4	Passive1	Passive2		Active
		Level 1 Building Block Set 2	DB5	Active		Passive1	Passive2
			DB6	Passive2	Active		Passive1
			DB7	Passive1	Passive2	Active	
			DB8		Passive1	Passive2	Active
		Level 1 Building Block Set 3	DB9	Active	Passive2		Passive1
			DB10	Passive1	Active	Passive2	
			DB11		Passive1	Active	Passive2
			DB12	Passive2		Passive1	Active
	Level 2 Building Block (4x3 = 12) Set 2	Level 1 Building Block Set 4	DB13	Active	Passive1		Passive2
			DB14	Passive2	Active	Passive1	
			DB15		Passive2	Active	Passive1
			DB16	Passive1		Passive2	Active
		Level 1 Building Block Set 5	DB17	Active	Passive2	Passive1	
			DB18		Active	Passive2	Passive1
			DB19	Passive1		Active	Passive2
			DB20	Passive2	Passive1		Active

Again, to understand this logic better, compare database copy placement for databases

DB1 through DB13. These databases have the active database copy hosted on Server1, and the second database copy hosted on Server2. If these servers fail, you want to have the third database copies activated on different remaining servers to achieve equal load distribution. You can achieve this by placing the third database copy of DB1 on Server3 and the third database copy of DB13 on Server4. Similar pairs are formed by DB2 and DB14, DB3 and DB15, and so on. Starting with DB25, you simply repeat the pattern (this example doesn't address that many databases).

Note that the third building block (DB1 through DB20) contains only 20 databases, not 24 databases. As a result, this design won't be entirely symmetrical if double failures occur. Again, to provide a fully symmetric distribution, plan your architecture so the number of databases is a multiple of the largest building block size. (In this example, the optimal numbers are 24, 48, or 72 databases, and so on.)

As you add a fourth database copy, again you must place it differently for each group of now $N \times (N - 1) \times (N - 2)$ databases. The new building block becomes $N \times (N - 1) \times (N - 2) \times (N - 3)$ databases. This follows the same logical approach and ensures that the database distribution is even within the new building block in case three servers fail.

The example of four servers leaves only one variation for placing the fourth database copy (only one remaining server is available). Therefore, the building block size actually remains at 24. This is also apparent when using the formula for building block size: $4 \times 3 \times 2 \times (4 - 3) = 4 \times 3 \times 2 \times 1 = 24$.

As you continue to add more database copies, the building block keeps growing such that the general formula for the building block size is $Perm(N,M) = N \times (N - 1) \ldots (N - M + 1) = N!/(N - M)! = C(N,M)$, where N = number of servers and M = number of database copies. This becomes obvious as you realize that complete symmetric distribution of the database copies is achieved by selecting all possible permutations of M database copies across N available servers.

There are several caveats to using this methodology:

- Deploying a number of databases that isn't a multiple of the largest building block size results in a nonsymmetrical distribution of active databases during failure events.
- Deploying architectures to mitigate multiple domain failures may result in a nonsymmetrical distribution of active databases during failure events. This is because failure domain definitions impose restraints on database copy placement, which breaks the symmetry of the pattern.
- Deploying site-resilient solutions that result in out-of-site database *over events may result in a nonsymmetrical distribution of databases activated in the secondary datacenter during primary datacenter server failure events.

Return to top

Active Database Distribution in Example Scenario During Server Failures

Using the previous example, in the event of a single server failure (for example, a failure of Server4), the active mailbox databases are distributed as shown in the following figure. The second copy is activated for DB4, DB8, DB12, DB16, and DB20, denoted as Active in orange.

	Server1	Server2	Server3	Server4
DB1	Active	Passive1	Passive2	
DB2		Active	Passive1	
DB3	Passive2		Active	
DB4	Active	Passive2		
DB5	Active		Passive1	
DB6	Passive2	Active		
DB7	Passive1	Passive2	Active	
DB8		Active	Passive2	
DB9	Active	Passive2		
DB10	Passive2	Active	Passive2	
DB11		Passive2	Active	
DB12	Passive2		Active	
DB13	Active	Passive2		
DB14	Passive2	Active	Passive2	
DB15		Passive2	Active	
DB16	Active		Passive2	
DB17	Active	Passive2	Passive1	
DB18		Active	Passive2	
DB19	Passive2		Active	
DB20	Passive2	Active		
Active Database Count	7	7	6	

If double server failure occurs (the third copy is activated for several databases and denoted as Active in green), the remaining two servers, Server1 and Server3, will have an equal number of activated mailbox databases.

	Server1	Server2	Server3	Server4
DB1	Active		Passive2	
DB2			Active	
DB3	Passive2		Active	
DB4	Active			
DB5	Active		Passive1	
DB6	Active			
DB7	Passive1		Active	
DB8			Active	
DB9	Active			
DB10	Active		Passive2	
DB11			Active	
DB12	Passive2		Active	
DB13	Active			
DB14	Passive2		Active	
DB15			Active	
DB16	Active		Passive2	
DB17	Active		Passive1	
DB18			Active	
DB19	Passive2		Active	
DB20	Active			
Active Database Count	10		10	

However, because the number of databases in this example isn't a multiple of the largest building block size (24 databases), not all double server failure events will result in a symmetrical distribution.

	Server1	Server2	Server3	Server4
DB1		Active	Passive2	
DB2		Active	Passive1	
DB3			Active	
DB4		Active		
DB5			Active	
DB6		Active		
DB7		Passive2	Active	
DB8		Active	Passive2	
DB9		Active		
DB10		Active	Passive2	
DB11		Passive1	Active	
DB12			Active	
DB13		Active		
DB14		Active	Passive1	
DB15		Passive2	Active	
DB16			Active	
DB17		Passive2	Active	
DB18		Active	Passive2	
DB19			Active	
DB20		Active		
Active Database Count		11	9	

Return to top

Design Scenarios

To understand the design principle of the database copy layout, including the associated mathematical formula, consider two other architectural layouts.

Design Scenario: Active/Passive User Distribution Site-Resilient Solution

In this scenario, Contoso decides to deploy the following architecture:

- The DAG is extended across two datacenters, operating in an active/passive user distribution model.
- Each server is deployed in a separate server rack.
- Each server's storage is isolated from the other servers' storage within the datacenter.
- There are four Mailbox servers per datacenter.
- There are a total of 24 mailbox databases.
- The desire is to have four highly available database copies and to survive a double server failure or a single datacenter failure.

In this example, the level 1 building block is 4, the databases are grouped into units of four, and the active copies are distributed across the four servers within the building block.

	Server1	Server2	Server3	Server4	Server5	Server6	Server7	Server8
DB1	COPY							
DB2		COPY						
DB3			COPY					
DB4				COPY				
DB5	COPY							
DB6		COPY						
DB7			COPY					
DB8				COPY				
DB9	COPY							
DB10		COPY						
DB11			COPY					
DB12				COPY				
DB13	COPY							
DB14		COPY						
DB15			COPY					
DB16				COPY				
DB17	COPY							
DB18		COPY						
DB19			COPY					
DB20				COPY				
DB21	COPY							
DB22		COPY						
DB23			COPY					
DB24				COPY				

For each server hosting active copies, the second database copy is distributed as evenly as possible across all remaining member servers, continuing with a diagonal pattern because each copy is isolated from one another. In this example, the level 2 building block becomes 12, which becomes the repeating set every 12 databases.

	Server1	Server2	Server3	Server4		Server5	Server6	Server7	Server8
DB1	COPY	COPY							
DB2		COPY	COPY						
DB3			COPY	COPY					
DB4	COPY			COPY					
DB5	COPY		COPY						
DB6		COPY		COPY					
DB7	COPY		COPY						
DB8		COPY		COPY					
DB9	COPY			COPY					
DB10	COPY	COPY							
DB11		COPY	COPY						
DB12			COPY	COPY					
DB13	COPY	COPY							
DB14		COPY	COPY						
DB15			COPY	COPY					
DB16	COPY			COPY					
DB17	COPY		COPY						
DB18		COPY		COPY					
DB19	COPY		COPY						
DB20		COPY		COPY					
DB21	COPY			COPY					
DB22	COPY	COPY							
DB23		COPY	COPY						
DB24			COPY	COPY					

Because this site resilient solution is for an active/passive user distribution model with an equal number of servers and database copies in both datacenters, the third database copy is placed in a diagonal pattern across Server5 and Server6, using the level 1 building block value of 4. This ensures that Server5 and Server6 mirror the first database copy placement on Server1 through Server4.

	Server1	Server2	Server3	Server4	Server5	Server6	Server7	Server8
DB1	COPY	COPY			COPY			
DB2		COPY	COPY			COPY		
DB3			COPY	COPY			COPY	
DB4	COPY			COPY				COPY
DB5	COPY		COPY		COPY			
DB6		COPY		COPY		COPY		
DB7	COPY		COPY				COPY	
DB8		COPY		COPY				COPY
DB9	COPY			COPY	COPY			
DB10	COPY	COPY				COPY		
DB11		COPY	COPY				COPY	
DB12			COPY	COPY				COPY
DB13	COPY	COPY			COPY			
DB14		COPY	COPY			COPY		
DB15			COPY	COPY			COPY	
DB16	COPY			COPY				COPY
DB17	COPY		COPY		COPY			
DB18		COPY		COPY		COPY		
DB19	COPY		COPY				COPY	
DB20		COPY		COPY				COPY
DB21	COPY			COPY	COPY			
DB22	COPY	COPY				COPY		
DB23		COPY	COPY				COPY	
DB24			COPY	COPY				COPY

Because this site resilient solution is for an active/passive user distribution model with an equal number of servers and database copies in both datacenters, the fourth database copy is placed in a diagonal pattern across Server5 and Server6, using the level 2 building block value of 12. This ensures that Server5 and Server6 mirror the second database copy placement on Server1 through Server4.

	Server1	Server2	Server3	Server4	Server5	Server6	Server7	Server8
DB1	COPY	COPY			COPY	COPY		
DB2		COPY	COPY			COPY	COPY	
DB3			COPY	COPY			COPY	COPY
DB4	COPY			COPY	COPY			COPY
DB5	COPY		COPY		COPY		COPY	
DB6		COPY		COPY		COPY		COPY
DB7	COPY		COPY		COPY		COPY	
DB8		COPY		COPY		COPY		COPY
DB9	COPY			COPY	COPY			COPY
DB10	COPY	COPY			COPY	COPY		
DB11		COPY	COPY			COPY	COPY	
DB12			COPY	COPY			COPY	COPY
DB13	COPY	COPY			COPY	COPY		
DB14		COPY	COPY			COPY	COPY	
DB15			COPY	COPY			COPY	COPY
DB16	COPY			COPY	COPY			COPY
DB17	COPY		COPY		COPY		COPY	
DB18		COPY		COPY		COPY		COPY
DB19	COPY		COPY		COPY		COPY	
DB20		COPY		COPY		COPY		COPY
DB21	COPY			COPY	COPY			COPY
DB22	COPY	COPY			COPY	COPY		
DB23		COPY	COPY			COPY	COPY	
DB24			COPY	COPY			COPY	COPY

If a single server failure occurs, the remaining three servers in the primary datacenter will have an equal number of activated mailbox databases (8 per server).

	Server1	Server2	Server3	Server4		Server5	Server6	Server7	Server8
DB1		COPY				COPY	COPY		
DB2		COPY	COPY				COPY	COPY	
DB3			COPY	COPY				COPY	COPY
DB4				COPY		COPY			COPY
DB5			COPY			COPY		COPY	
DB6		COPY		COPY			COPY		COPY
DB7			COPY			COPY		COPY	
DB8		COPY		COPY			COPY		COPY
DB9				COPY		COPY			COPY
DB10		COPY				COPY	COPY		
DB11		COPY	COPY				COPY	COPY	
DB12			COPY	COPY				COPY	COPY
DB13		COPY				COPY	COPY		
DB14		COPY	COPY				COPY	COPY	
DB15			COPY	COPY				COPY	COPY
DB16				COPY		COPY			COPY
DB17			COPY			COPY		COPY	
DB18		COPY		COPY			COPY		COPY
DB19			COPY			COPY		COPY	
DB20		COPY		COPY			COPY		COPY
DB21				COPY		COPY			COPY
DB22		COPY				COPY	COPY		
DB23		COPY	COPY				COPY	COPY	
DB24			COPY	COPY				COPY	COPY
Active Database Count		8	8	8					

If two simultaneous server failures occur, the remaining two servers in the primary datacenter will have an equal number of activated mailbox databases (10 per server), while 4 databases will be activated in the secondary datacenter.

	Server1	Server2	Server3	Server4		Server5	Server6	Server7	Server8
DB1		COPY				COPY	COPY		
DB2		COPY					COPY	COPY

DB23		COPY					COPY	COPY	
DB24				COPY				COPY	COPY
Active Database Count		10		10		2		2	

Design Scenario: Multiple Failure Domains

In this example, Wingtip Toys decides to deploy the following architecture:

- All servers are deployed in a single datacenter.
- Servers are grouped in units of two.
- Each of the two servers is placed in the same rack with its storage.
- There are a total of 3 racks and 6 servers.
- There are a total of 18 mailbox databases.
- The desire is to have three highly available database copies and to survive two member server failures or one rack failure.

In this example, the level 1 building block is 6, so the databases are grouped into units of 6, and the active copies are distributed across the six servers within the building block.

	Server1	Server2	Server3	Server4	Server5	Server6
DB1	COPY1					
DB2		COPY1				
DB3			COPY1			
DB4				COPY1		
DB5					COPY1	
DB6						COPY1
DB7	COPY1					
DB8		COPY1				
DB9			COPY1			
DB10				COPY1		
DB11					COPY1	
DB12						COPY1
DB13	COPY1					
DB14		COPY1				
DB15			COPY1			
DB16				COPY1		
DB17					COPY1	
DB18						COPY1
DB19	COPY1					
DB20		COPY1				
DB21			COPY1			
DB22				COPY1		
DB23					COPY1	
DB24						COPY1
DB25	COPY1					
DB26		COPY1				
DB27			COPY1			
DB28				COPY1		
DB29					COPY1	
DB30						COPY1
DB31	COPY1					
DB32		COPY1				
DB33			COPY1			
DB34				COPY1		
DB35					COPY1	

For each server hosting active copies, the second database copy is spread as evenly as possible across all remaining member servers, while also ensuring that two copies of the same database aren't placed in the same server rack. In this example, instead of the level 2 building block formula of $N \times (N - 1)$, the formula of $N \times (N - 2)$ is used to ensure two copies of the same database aren't placed in the same rack. This means that the level 2 building block is $6 \times 4 = 24$.

	Server1	Server2	Server3	Server4	Server5	Server6
DB1	COPY1		COPY2			
DB2		COPY1		COPY2		
DB3			COPY1		COPY2	
DB4				COPY1		COPY2
DB5	COPY2				COPY1	
DB6		COPY2				COPY1
DB7	COPY1			COPY2		
DB8		COPY1			COPY2	
DB9			COPY1			COPY2
DB10	COPY2			COPY1		
DB11		COPY2			COPY1	
DB12			COPY2			COPY1
DB13	COPY1				COPY2	
DB14		COPY1				COPY2
DB15	COPY2		COPY1			
DB16		COPY2		COPY1		
DB17			COPY2		COPY1	
DB18				COPY2		COPY1
DB19	COPY1					COPY2
DB20		COPY1	COPY2			
DB21		COPY2	COPY1			
DB22				COPY1	COPY2	
DB23				COPY2	COPY1	
DB24	COPY2					COPY1
DB25	COPY1		COPY2			
DB26		COPY1		COPY2		
DB27			COPY1		COPY2	
DB28				COPY1		COPY2
DB29	COPY2				COPY1	
DB30		COPY2				COPY1
DB31	COPY1			COPY2		
DB32		COPY1			COPY2	
DB33			COPY1			COPY2
DB34	COPY2			COPY1		
DB35		COPY2			COPY1	
DB36			COPY2			COPY1
DB37	COPY1				COPY2	

The third database copy is placed in a diagonal pattern across the servers, again ensuring that multiple copies of the same database aren't placed in the same server rack. In this example, instead of the level 3 building block formula $N \times (N - 2)$, the formula of $N \times (N - 2) \times (N - 4)$ is used to ensure two copies of the same database aren't placed in the same rack. This means that the level 3 building block is $6 \times 4 \times 2 = 48$.

DB32		COPY1		COPY3	COPY2	
DB33		COPY3	COPY1			COPY2
DB34	COPY2			COPY1		COPY3
DB35		COPY2	COPY3		COPY1	

If a single server failure occurs, the remaining five servers in the primary datacenter will have a near equal number of activated mailbox databases. Four servers will have 10 activated databases per server, while one server (the rack partner) will have 8 activated databases.

	Server1	Server2	Server3	Server4	Server5	Server6

1.10.1.2 Understanding Mailbox Database Copies

Understanding Mailbox Database Copies

Exchange Server 2010 > High Availability and Site Resilience > Understanding High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-24*

Microsoft Exchange Server 2010 introduces the concept of database mobility, which is Exchange-managed database-level failovers. An enhanced version of the continuous replication feature first introduced in Exchange Server 2007 is used in Exchange 2010 to create and maintain database copies.

Database mobility disconnects databases from servers, adds support for up to 16 copies of a single database, and provides a native experience for adding database copies to a database. In Exchange 2007, a feature called database portability also enabled you to move a mailbox database between servers. A significant distinction between database portability and database mobility, however, is that with database mobility, all copies of a database have the same GUID.

Because clustered mailbox servers and storage groups have been removed from Exchange 2010, continuous replication now operates at the database level. In Exchange 2010, transaction logs are replicated to one or more Mailbox servers and replayed into a copy of a mailbox database that's stored on those servers. A failover or switchover can occur at either the database level or at the server level.

Key Characteristics

The key characteristics of mailbox database copies are:

- Database copies are for mailbox databases only. For redundancy and high availability for public folder databases, we recommend that you use public folder replication.
- Up to 16 copies of an Exchange 2010 mailbox database can be created on multiple Mailbox servers, provided the servers are grouped into a database availability group (DAG), which is a boundary for continuous replication. Exchange 2010 mailbox databases can be replicated only to other Exchange 2010 Mailbox servers within a DAG. You can't replicate a database outside of a DAG, nor can you replicate an Exchange 2010 mailbox database to a server running Exchange 2007. For detailed information about DAGs, see Understanding Database Availability Groups.
- All Mailbox servers in a DAG must be in the same Active Directory domain.
- Like standby continuous replication (SCR), all mailbox database copies support the concepts of replay lag time and truncation lag time. Note however, careful planning must be performed before enabling these features.
- All database copies can be backed up using an Exchange-aware, Volume Shadow Copy Service (VSS)-based backup application. However, the built-in support for Windows Server Backup is for active copies only. You can't use Windows Server Backup to back up passive copies.
- Database copies can be created only on Mailbox servers that don't host the active (mounted and in-use) copy of a database. You can't create two copies of the same database on the same server.

- All copies of a database use the same path on each server containing a copy. The database and log file paths for a database copy on each Mailbox server must not conflict with any other database paths.
- Database copies can be created in the same or different Active Directory sites, and on the same or different network subnets.
- Database copies aren't supported between Mailbox servers with round trip network latency greater than 500 milliseconds (ms).

Mailbox Database Copies

You can create a mailbox database copy at any time. Mailbox database copies can be distributed across Mailbox servers in a flexible and granular way. You can replicate one, some, or all mailbox databases on a server in a variety of ways.

You can create a mailbox database copy using the Add Mailbox Database Copy wizard in the Exchange Management Console or by using the **Add-MailboxDatabaseCopy** cmdlet in the Exchange Management Shell.

When creating a mailbox database copy, specify the following parameters:

- *Identity* This parameter specifies the name of the database being copied. Database names must be unique within the Exchange organization.
- *MaliboxServer* This parameter specifies the name of the Mailbox server that will host the database copy. This server must be a member of the same DAG and must not already host a copy of the database.

Optionally, you can also specify:

- *ActivationPreference* This parameter specifies the activation preference number, which is used as part of Active Manager's best copy selection process. It's also used to redistribute active mailbox databases throughout the DAG when using the RedistributeActiveDatabases.ps1 script. The value for the activation preference is a number equal to or greater than one, where one is at the top of the preference order. The position number cannot be larger than the number of mailbox database copies.
- *ReplayLagTime* This parameter specifies the amount of time that the Microsoft Exchange Replication service should wait before replaying log files that are copied to the database copy. The format for this parameter is (Days.Hours:Minutes:Seconds). The default setting for this value is 0 seconds. The maximum allowable setting for this value is 14 days. The minimum allowable setting is 0 seconds. Setting the value for replay lag time to 0 turns off log replay delay.
- *TruncationLagTime* This parameter specifies the amount of time that the Microsoft Exchange Replication service should wait before truncating log files that have replayed into a copy of the database. The time period begins after the log has been successfully replayed into the copy of the database. The format for this parameter is (Days.Hours:Minutes:Seconds). The default setting for this value is 0 seconds. The maximum allowable setting for this value is 14 days. The minimum allowable setting is 0 seconds. Setting the value for truncation lag time to 0 turns off log truncation delay.
- *SeedingPostponed* This parameter specifies that the task shouldn't automatically seed the database copy on the specified Mailbox server. This option is typically used when you intend to seed a new mailbox database copy by using an existing passive copy of the database (for example, adding a second copy of a specific database to a remote location). When you use this parameter, you must manually seed the database copy using the Update-MailboxDatabaseCopy cmdlet.

For more information about creating, using, and managing mailbox database copies, see Managing Mailbox Database Copies.

1.10.2 Planning for High Availability and Site Resilience

Planning for High Availability and Site Resilience

Exchange Server 2010 > High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

Microsoft Exchange Server 2010 includes a new unified framework for mailbox resiliency that includes new features such as the database availability group (DAG) and mailbox database copies. Although deploying these new features is a quick and simple process, careful planning must be performed beforehand to ensure that any high availability and site resilient solution using these features meets your expectations and your business requirements.

During the planning phase, the system architects, administrators, and other key stakeholders should identify the requirements for the deployment; in particular the requirements for high availability and site resilience. There are general requirements that must be met for deploying these features, as well as hardware, software, and networking requirements that must also be met. For guidance on the storage requirements for DAGs, see Mailbox Server Storage Design.

Contents

General Requirements

Before deploying a DAG and creating mailbox database copies, make sure that the following system-wide recommendations are met:

- Domain Name System (DNS) must be running. Ideally, the DNS server should accept dynamic updates. If the DNS server doesn't accept dynamic updates, you must create a DNS host (A) record for each Exchange server. Otherwise, Exchange won't function properly.
- Each Mailbox server in a DAG must be a member server in the same domain.
- It isn't supported to add an Exchange 2010 Mailbox server that's also a directory server to a DAG.
- The name that you assign to the DAG must be a valid, available, and unique computer name of 15 characters or less.

Hardware Requirements

Generally, there are no special hardware requirements that are specific to DAGs or mailbox database copies. The servers used must meet all of the requirements set forth in the topics for Exchange 2010 Prerequisites and Exchange 2010 System Requirements. For hardware planning information, see the following topics:

- Understanding Processor Configurations and Exchange Performance
- Understanding Memory Configurations and Exchange Performance
- Mailbox Server Storage Design
- Understanding Server Role Ratios and Exchange Performance

Storage Requirements

Generally, there are no special storage requirements that are specific to DAGs or mailbox database copies. DAGs don't require or use cluster-managed shared storage. Cluster-managed shared storage is supported for use in a DAG only when the DAG is configured to use a solution that leverages the Third Party Replication API built into Exchange 2010. For storage planning information, see Mailbox Server Storage Design.

Software Requirements

DAGs are available in both Exchange 2010 Standard Edition and Exchange 2010 Enterprise Edition. In addition, a DAG can contain a mix of servers running Exchange 2010 Standard Edition and Exchange 2010 Enterprise Edition.

Each member of the DAG must also be running the same operating system. Exchange 2010 is supported on both the Windows Server 2008 and Windows Server 2008 R2 operating systems. All members of a DAG must run either Windows Server 2008 or Windows Server 2008 R2. They can't contain a combination of both Windows Server 2008 and Windows Server 2008 R2.

In addition to meeting the prerequisites for installing Exchange 2010, there are operating system requirements that must be met. DAGs use Windows Failover Clustering technology, and as a result, they require the Enterprise version of Windows.

Network Requirements

There are specific networking requirements that must be met for each DAG and for each DAG member. DAG networks are similar to the public, mixed, and private networks used in previous versions of Exchange. However, unlike previous versions, using a single network in each DAG member is a supported configuration. In addition, the terminology has changed somewhat. Instead of public, private or mixed networks, each DAG has a single *MAPI network*, which is used by other servers (e.g., other Exchange 2010 servers, directory servers, etc.) to communicate with the DAG member, and zero or more *Replication networks*, which are networks that are dedicated to log shipping and seeding.

Although a single network is supported, we recommend that each DAG have at least two networks: a single MAPI network and a single Replication network. This provides redundancy for the network and the network path, and enables the system to distinguish between a server failure and a network failure. Using a single network adapter prevents the system from distinguishing between these two types of failures.

Note:

The product documentation in this content area is written with the assumption that each DAG member contains at least two network adapters, that each DAG is configured with a MAPI network and at least one Replication network, and that the system is able to distinguish between a network failure and a server failure.

Consider the following when designing the network infrastructure for your DAG:

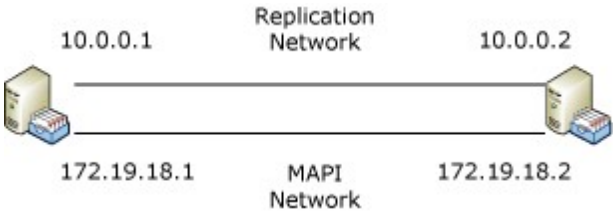
- Each member of the DAG must have at least one network adapter that is able to communicate with all other DAG members. If you are using a single network path, we recommend that you use gigabit Ethernet. When using a single network adapter in each DAG member, the DAG network does need to be enabled for replication and should be configured as a MAPI network. Because there are no other networks, the system will use the MAPI network as a Replication network, as well. In addition, when using a single network adapter in each DAG member, we recommend that you design the overall solution with the single network adapter and path in mind.
- Using two network adapters in each DAG member provides you with one MAPI network and one Replication network, and the following recovery behaviors:
  - In the event of a failure affecting the MAPI network, a server failover will occur (assuming there are healthy mailbox database copies that can be activated).
  - In the event of a failure affecting the Replication network, if the MAPI network is unaffected by the failure, log shipping and seeding operations will revert to use the MAPI network, even if the MAPI network has it's *ReplicationEnabled* property set to False. When the failed Replication network is restored to health and ready to resume log shipping and seeding operations, you must manually switch over to the Replication network. To change replication from the MAPI network to a restored Replication network, you can either suspend and resume continuous replication by using the Suspend-MailboxDatabaseCopy and Resume-MailboxDatabaseCopy cmdlets, or restart the Microsoft Exchange Replication service. We recommend using the suspend and resume operations to avoid the brief outage caused by restarting the Microsoft Exchange Replication service.
- Each DAG member must have the same number of networks. For example, if you plan on using a single network adapter in one DAG member, then all members of the DAG must also use a single network adapter.
- Each DAG must have no more than one MAPI network. The MAPI network must provide connectivity to other Exchange servers and other services, such as Active Directory and DNS.
- Additional Replication networks can be added, as needed. You can also prevent an individual network adapter from being a single point of failure by using network adapter teaming or similar technology. However, even when using teaming, this does not prevent the network itself from being a single point of failure.
- Each network in each DAG member server must be on its own network subnet. Each server in the DAG can be on a different subnet, but the MAPI and Replication networks must be routable and provide connectivity, such that:
  - Each network in each DAG member server is on its own network subnet that's separate from the subnet used by each other network in the server.
  - Each DAG member server's MAPI network can communicate with each other DAG member's MAPI network.
  - Each DAG member server's Replication network can communicate with each other DAG member's Replication network.
  - There is no direct routing that allows heartbeat traffic from the Replication network on one DAG member server to the MAPI network on another DAG member server, or vice versa, or between multiple Replication networks in the DAG.
- Regardless of their geographic location relative to other DAG members, each member of the DAG must have round trip network latency no greater than 500 milliseconds (ms) between each other member. As the round trip latency between two mailbox servers hosting copies of a database increases, the potential for replication being not up-to-date also increases. Regardless of the latency of the solution, customers should validate that the network(s) between all DAG members is capable of satisfying the data protection and availability goals of the deployment. Configurations with higher latency values may require special tuning of DAG, replication and network parameters, such as increasing the number of databases or decreasing the number of mailboxes

per database, to achieve the desired goals.
- Round trip latency requirements may not be the most stringent network bandwidth and latency requirement for a multi-datacenter configuration. You must evaluate the total network load, which includes client access, Active Directory, transport, continuous replication, and other application traffic, to determine the necessary network requirements for your environment.
- DAG networks support Internet Protocol Version 4 (IPv4) and IPv6. IPv6 is supported only when IPv4 is also used; a pure IPv6 environment isn't supported. Using IPv6 addresses and IP address ranges is supported only when both IPv6 and IPv4 are enabled on that computer, and the network supports both IP address versions. If Exchange 2010 is deployed in this configuration, all server roles can send data to and receive data from devices, servers, and clients that use IPv6 addresses.
- Automatic Private IP Addressing (APIPA) is a feature of Microsoft Windows that automatically assigns IP addresses when no Dynamic Host Configuration Protocol (DHCP) server is available on the network. APIPA addresses (including manually assigned addresses from the APIPA address range) aren't supported for use by DAGs or by Exchange 2010.

DAG Name and IP Address Requirements

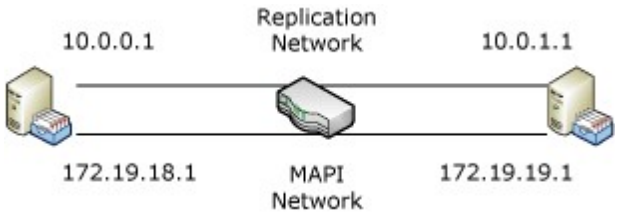
During creation, each DAG is given a unique name, and either assigned one or more static IP addresses, or configured to use DHCP. Regardless of whether you use static or dynamically-assigned addresses, any IP address assigned to the DAG must be on the MAPI network.

Each DAG requires a minimum of one IP address on the MAPI network. A DAG requires additional IP addresses when the MAPI network is extended across multiple subnets. The following figure illustrates a DAG where all nodes in the DAG have the MAPI network on the same subnet.



In this example, the MAPI network in each DAG member is on the 172.19.18.*x* subnet. As a result, the DAG requires a single IP address on that subnet.

The next figure illustrates a DAG that has a MAPI network which extends across two subnets: 172.19.18.*x* and 172.19.19.*x*.



In this example, the MAPI network in each DAG member is on a separate subnet. As a result, the DAG requires two IP addresses, one for each subnet on the MAPI network.

Each time the DAG's MAPI network is extended across an additional subnet, an additional IP address for that subnet must be configured for the DAG. Each IP address that's configured for the DAG is assigned to and used by the DAG's underlying failover cluster. The name of the DAG is also used as the name for the underlying failover cluster.

At any specific time, the cluster for the DAG will use only one of the assigned IP addresses. Windows Failover Clustering registers this IP address in DNS when the cluster IP address and Network Name resources are brought online. In addition to using an IP address and network name, a cluster name object (CNO) is created in Active Directory. The name, IP address and CNO for the cluster are used internally by the system to secure the DAG and for internal communication purposes. Administrators and end-users don't need to interface with or connect to the DAG name or IP address.

Note:

Although the cluster's IP address and network name are used internally by the system, there is no hard dependency in Exchange 2010 that these resources be available. Even if the underlying cluster's IP Address and Network Name resources are offline, internal communication still occurs within the DAG by using the DAG member's server names. However, we recommend that you periodically monitor the availability of these resources to ensure that they aren't offline for more than 30 days. If the underlying cluster is offline for more than 30 days, the cluster CNO account may be invalidated by the garbage collection mechanism in Active Directory.

Network Adapter Configuration for DAGs

Each network adapter must be configured properly based on its intended use. A network adapter that's used for a MAPI network is configured differently from a network adapter that's used for a Replication network. In addition to configuring each network adapter correctly, you must also configure the network connection order in Windows so that the MAPI network is at the top of the connection order. For detailed steps about how to modify the network connection order, see Modify the Protocol Bindings Order.

MAPI Network Adapter Configuration

A network adapter intended for use by a MAPI network should be configured as described in the following table.

Networking Features	Setting
Client for Microsoft Networks	Enabled
QoS Packet Scheduler	Optionally enable
File and Printer Sharing for Microsoft Networks	Enable
Internet Protocol Version 6 (TCP/IP v6)	Optionally enable
Internet Protocol Version 4 (TCP/IP v4)	Enabled
Link-Layer Topology Discovery Mapper I/O Driver	Enabled
Link-Layer Topology Discovery Responder	Enabled

The TCP/IP v4 properties for a MAPI network adapter are configured as follows:

- The IP address for a DAG member's MAPI network can be manually assigned or configured to use DHCP. If DHCP is used, we recommend using persistent reservations for server's IP address.
- The MAPI network typically uses a default gateway, although one isn't required.
- At least one DNS server address must be configured. Using multiple DNS servers is recommended for redundancy.
- The **Register this connection's addresses in DNS** checkbox should be checked.

Replication Network Adapter Configuration

A network adapter intended for use by a Replication network should be configured as

described in the following table.

Networking Features	Setting
Client for Microsoft Networks	Disabled
QoS Packet Scheduler	Optionally enable
File and Printer Sharing for Microsoft Networks	Disabled
Internet Protocol Version 6 (TCP/IP v6)	Optionally enable
Internet Protocol Version 4 (TCP/IP v4)	Enabled
Link-Layer Topology Discovery Mapper I/O Driver	Enabled
Link-Layer Topology Discovery Responder	Enabled

The TCP/IP v4 properties for a Replication network adapter are configured as follows:

- The IP address for a DAG member's Replication network can be manually assigned or configured to use DHCP. If DHCP is used, we recommend using persistent reservations for server's IP address.
- Replication networks typically do not have default gateways, and if the MAPI network has a default gateway, then no other networks should have default gateways. Routing of network traffic on a Replication network can be configured by using persistent, static routes to the corresponding network on other DAG members using gateway addresses that have the ability to route between the Replication networks. All other traffic not matching this route will be handled by the default gateway that's configured on the adapter for the MAPI network.
- DNS server addresses should not be configured.
- The **Register this connection's addresses in DNS** checkbox should not be checked.

Return to top

Witness Server Requirements

A *witness server* is a server outside of a DAG that's used to achieve and maintain quorum when the DAG has an even number of members. DAGs with an odd number of members do not use a witness server. All DAGs with an even number of members will use a witness server. The witness server can be any computer running Windows Server. There is no requirement that the version of the Windows Server operating system of the witness server match the operating system used by the DAG members.

Quorum is maintained at the cluster level, underneath the DAG. A DAG has quorum when the majority of its members are online and can communicate with the other online members of the DAG. This notion of quorum is one aspect of the concept of quorum in Windows failover clustering. A related and necessary aspect to quorum in failover clusters is the *quorum resource*. The quorum resource is a resource inside a failover cluster that provides a means for arbitration leading to cluster state and membership decisions. The quorum resource also provides persistent storage for storing configuration information. A companion to the quorum resource is the *quorum log*, which is a configuration database for the cluster. The quorum log contains information such as which servers are members of the cluster, what resources are installed in the cluster, and the state of those resources (for example, online or offline).

It is critical that each DAG member have a consistent view of how the DAG's underlying

cluster is configured. The quorum acts as the definitive repository for all configuration information relating to the cluster. The quorum is also used as a tie-breaker to avoid "split-brain" syndrome. Split brain syndrome is a condition that occurs when DAG members cannot communicate with each other but are up and running. Split brain syndrome is prevented by always requiring a majority of the DAG members (and in the case of DAGs with an even number of member, the DAG witness server) to be available and interacting for the DAG to be operational.

Planning for Site Resilience

Every day, more and more businesses recognize that access to a reliable and available messaging system is fundamental to their success. For many organizations, the messaging system is part of the business continuity plans, and their messaging service deployment is designed with site resilience in mind. Fundamentally, many site resilient solutions involve the deployment of hardware in a second datacenter.

Ultimately, the overall design of a DAG, including the number of DAG members and the number of mailbox database copies, will depend on each organization's recovery service level agreements (SLAs) that cover various failure scenarios. During the planning stage, the solution's architects and administrators identify the requirements for the deployment, including in particular the requirements for site resilience. They identify the location(s) to be used and the required recovery SLA targets. The SLA will identify two specific elements that should be the basis for the design of a solution that provides high availability and site resilience: the Recovery Time Objective (RTO) and the Recovery Point Objective (RPO). Both of these values are measured in minutes. The RTO is how long it takes to restore service. The RPO refers to how current the data is after the recovery operation has completed. An SLA may also be defined for restoring the primary datacenter to full service after its problems are corrected.

The solution's architects and administrators will also identify which set of users require site resilience protection, and determine if the multi-site solution will be active/passive or active/active configuration. In an active/passive configuration, no users are normally hosted in the standby datacenter. In an active/active configuration, users are hosted in both locations, and some percentage of the total number of databases within the solution has a preferred active location in a second datacenter. When service for the users of one datacenter fails, those users are activated in the other datacenter.

Constructing the appropriate SLAs often requires answering the following basic questions:

- What level of service is required after the primary datacenter fails?
- Do users need their data or just messaging services?
- How rapidly is data required?
- How many users must be supported?
- How will users access their data?
- What is the standby datacenter activation service level agreement (SLA)?
- How is service moved back to the primary datacenter?
- Are the resources dedicated to the site resilience solution?

By answering these questions, you begin to shape a site resilient design for your messaging solution. A core requirement of recovery from site failure is to create a solution that gets the necessary data to the backup datacenter that hosts the backup messaging service.

Namespace Planning

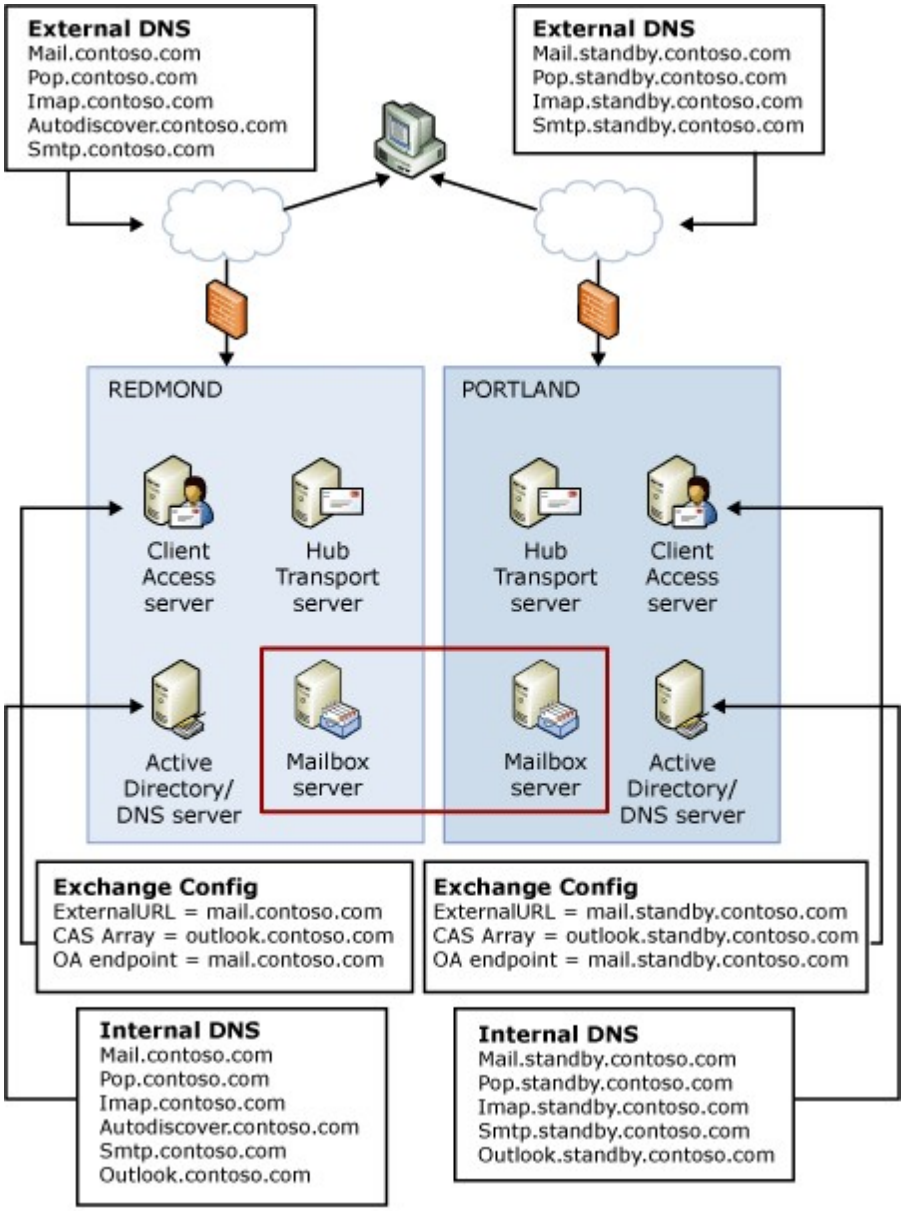
Exchange 2010 changes the way in which you plan your namespace design when deploying a site resilient configuration. Proper namespace planning is essential in order for datacenter switchovers to be successful. From a namespace perspective, each datacenter used in a site resilience configuration is considered to be active. As a result,

each datacenter will require its own unique namespace for the various Exchange 2010 services in that site, including namespaces for Outlook Web App, Outlook Anywhere, Exchange ActiveSync, Exchange Web Services, RPC Client Access, Post Office Protocol version 3 (POP3), Internet Message Access Protocol version 4 (IMAP4), and Simple Mail Transfer Protocol (SMTP). In addition, one of the datacenters also hosts the namespace for Autodiscover. This design also enables you to perform a single database switchover from the primary datacenter to a second datacenter to validate the configuration of the second data as part of validation of and practice for a datacenter switchover.

As a best practice, we recommend that you use *split DNS* for the Exchange hostnames that are used by clients. Split DNS refers to a DNS server configuration in which internal DNS servers return an internal IP address for a hostname and external (Internet-facing) DNS servers return a public IP address for the same hostname. Because using split DNS uses the same hostnames internally and externally, this strategy enables you to minimize the number of hostnames you'll need.

The following figure illustrates namespace planning for a site resilient configuration.

Namespaces for site resilient DAG deployment



As shown above, each datacenter uses a separate and unique namespace and each contains DNS servers in a split DNS configuration for those namespaces. The Redmond datacenter, which is considered the primary datacenter, is configured with a namespace of *protocol*.contoso.com. The Portland datacenter is configured with a namespace of *protocol*.standby.contoso.com. Namespaces can include designations of standby, as in the example figure, they can be based on region (e.g., *protocol*.portland.contoso.com), or they can be based on other naming conventions that suit your organization's needs. The key requirement is that, regardless of the naming convention you use, each datacenter should have its own unique namespace.

FailbackURL Configuration

Some Web browsers, including Microsoft Internet Explorer, maintain a DNS name cache during each browser session that is separate from the DNS cache provided by the operating system. During failback to the primary datacenter after a datacenter switchover has occurred, the Web browser's use of this separate cache can result in logon loops for Outlook Web App users wherein users are redirected to the same URL in a repeating

loop.

During the failback process, the IP address for the Outlook Web App namespace is changed in DNS from an endpoint in the standby datacenter back to its original endpoint in the primary datacenter. After the TTL for the DNS record has expired and even after the operating system's DNS cache is cleared, Web browsers that maintain their own separate name cache may continue to connect to the endpoint in the standby datacenter, even though the namespace is hosted in the primary datacenter.

Typically, closing the Web browser is sufficient to clear its separate name cache and prevent the logon loops. However, to mitigate this issue for all Web browsers and Outlook Web App users, you can configure the *FailbackURL* property of your Outlook Web App virtual directory. The *FailbackUrl* parameter specifies the host name that Outlook Web App uses to connect to the Client Access server after failback to a primary site. This namespace requires a separate DNS entry pointing to the original Client Access server's IP address. The value of the *FailbackUrl* parameter must be different from the value of the *ExternalUrl* parameter for the Outlook Web App virtual directory. When an Outlook Web App user provides their credentials, the Client Access server will detect if the redirection URL is the same URL the user is visiting. If the URLs are the same, the Client Access server will check to see if the *FailbackUrl* parameter is configured:

- If the *FailbackUrl* parameter is configured, it will redirect the user to that URL where they should be able to access Outlook Web App.
- If the *FailbackUrl* parameter is not configured, the user will receive an error message that indicates that a server configuration change is temporarily preventing access to their mailbox. The message instructs the user to close all browser windows (thereby clearing the browser's name cache) and try again in a few minutes.

Certificate Planning

There are no unique or special design considerations for certificates when deploying a DAG in a single datacenter. However, when extending a DAG across multiple datacenters in a site resilient configuration, there are some specific considerations with respect to certificates. Generally, your certificate design will depend on the clients in use, as well as the certificate requirements by other applications that use certificates. But there are some specific recommendations and best practices you should follow with respect to the type and number of certificates.

As a best practice, you should minimize the number of certificates you use for your Client Access servers, reverse proxy servers, and transport servers (Edge and Hub). We recommend using a single certificate for all of these service endpoints in each datacenter. This approach minimizes the number of certificates that are needed, which reduces both cost and complexity for the solution.

For Outlook Anywhere clients, we recommend that you use a single Subject Alternative Name (SAN) certificate for each datacenter, and include multiple host names in the certificate. To ensure Outlook Anywhere connectivity after a database, server or datacenter switchover, you must use the same Certificate Principal Name on each certificate, and configure the Outlook Provider Configuration object Active Directory with the same Principal Name in Microsoft-Standard Form (msstd). For example, if you use a Certificate Principal Name of mail.contoso.com, you would configure the attribute as follows:

```
Set-OutlookProvider EXPR -CertPrincipalName "msstd:mail.contoso.com"
```

Some applications that integrate with Exchange have specific certificates requirements that may require using additional certificates. Exchange 2010 can co-exist with Office Communications Server (OCS). OCS requires certificates with 1024-bit or greater certificates that use the OCS server name for the Certificate Principal Name. Because using an OCS server name for the Certificate Principal Name would prevent Outlook Anywhere from working properly, you would need to use an additional and separate

certificate for the OCS environment.

For more information about using SAN certificates for Exchange 2010 client access, see Configure SSL Certificates to Use Multiple Client Access Server Host Names.

Network Planning

In addition to the specific networking requirements that must be met for each DAG, as well as for each server that's a member of a DAG, there are some requirements and recommendations that are specific to site resilience configurations. As with all DAGs, whether the DAG members are deployed in a single site or in multiple sites, the round-trip return network latency between DAG members DAG must be no greater than 500 milliseconds (ms). In addition, there are specific configuration settings that are recommended for DAGs that are extended across multiple sites:

- **MAPI networks should be isolated from Replication networks** Windows network policies, Windows firewall policies or router access control lists (ACLs) should be used to block traffic between the MAPI network and the Replication network(s). This configuration is necessary to prevent network heartbeat cross-talk.
- **Client-facing DNS records should have a Time to Live (TTL) of 5 minutes** The amount of downtime that clients experience is dependent not just on how quickly a switchover can occur, but also on how quickly DNS replication occurs and how quickly the clients query for updated DNS information. DNS records for all Exchange client services, including Outlook Web App, Exchange ActiveSync, Exchange Web services, Outlook Anywhere, SMTP, POP3, IMAP4, and RPC Client Access in both the internal and external DNS servers should be set with a TTL of 5 minutes.
- **Use static routes to configure connectivity across Replication networks** To provide network connectivity between each of the Replication network adapters, use persistent static routes. This is a quick and one-time configuration that is performed on each DAG member when using static IP addresses. If you are using DHCP to obtain IP addresses for your Replication networks, you can also use it to assign static routes for the Replication, thereby simplifying the configuration process.

General Site Resilience Planning

In addition to the requirements listed above for high availability, there are other recommendations for deploying Exchange 2010 in a site resilient configuration (e.g., extending a DAG across multiple datacenters). What you do during the planning phase will directly affect the success of your site resilience solution. For example, poor namespace design can cause difficulties with certificates, and an incorrect certificate configuration can prevent users from accessing services.

In order to minimize the time it takes to activate a second datacenter, and allow the second datacenter to host the service endpoints of a failed datacenter, the appropriate planning must be completed. For example:

- The Service Level Agreement (SLA) goals for the site resilience solution must be well understood and documented.
- The servers in the second datacenter must have sufficient capacity to host the combined user population of both datacenters.
- The second datacenter must have all services enabled that are provided in primary datacenter (unless the service isn't included as part of the site resilience SLA). This includes Active Directory, networking infrastructure (DNS, TCP/IP, etc.), telephony services (if Unified Messaging is in use), and site infrastructure (power, cooling, etc.).
- In order for some services to be able to service users from the failed datacenter, they must have the proper server certificates configured. Some services do not allow instancing (for example, POP3 and IMAP4) and only allow the use of a single certificate. In these cases, either the certificate must be a subject alternative name (SAN) certificate that includes multiple names, or the

multiple names must be similar enough so that a wildcard certificate can be used (assuming the security policies of the organization allows the use of wildcard certificates).

- The necessary services must be defined in the second datacenter. For example, if first datacenter has three different SMTP URLs on different transport servers, then the appropriate configuration must be defined in the second datacenter to enable at least one (if not all three) transport server(s) to host the workload.
- The necessary network configuration must be in place to support the datacenter switchover. This might mean making sure that load balancing configurations are in place, that global DNS is configured, and that the Internet connection is enabled with the appropriate routing configured.
- The strategy for the enabling the DNS changes necessary for a datacenter switchover must be understood. The specific DNS changes, including their Time to Live (TTL) settings, must be defined and documented to support the SLA(s) in effect.
- A strategy for testing the solution must also be established and factored into the SLA. Periodic validation of the deployment is the only way to guarantee that the quality and viability of the deployment does not degrade over time. After the deployment is validated, we recommend that the part of the configuration that directly affects the success of the solution be explicitly documented. In addition, we recommend that you enhance your change management processes around those segments of the deployment.

Return to top

Planning for Datacenter Switchovers

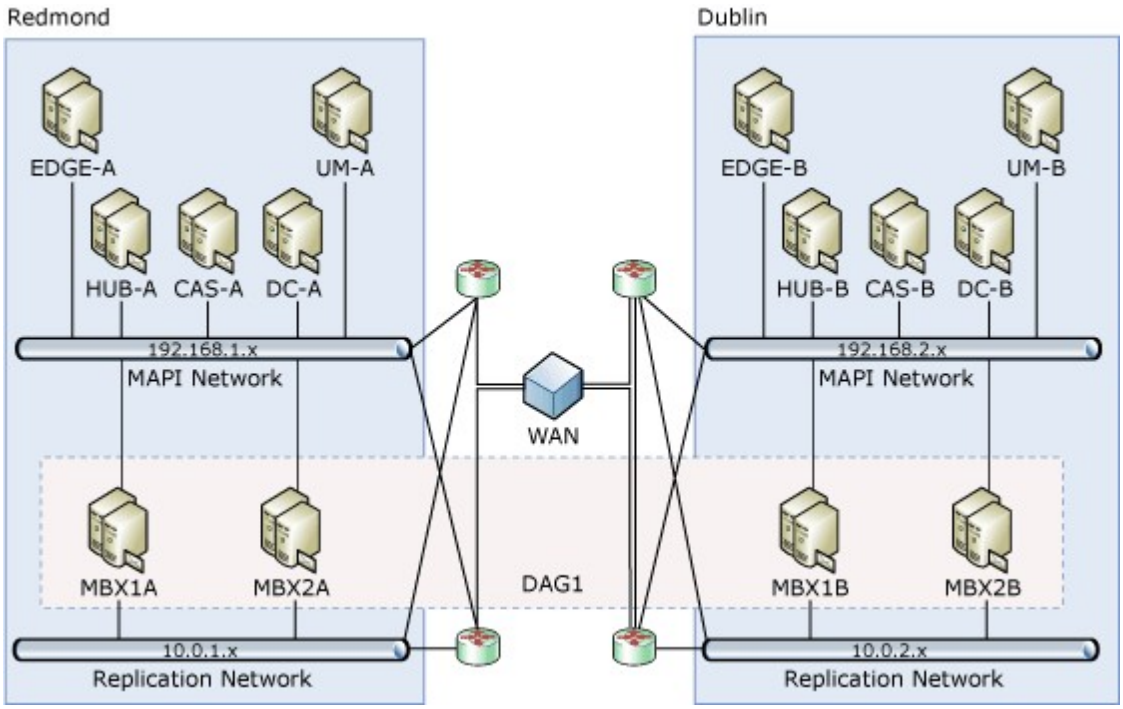
The proper planning and preparation involves not only the deployment of the second datacenter resources, such as live Client Access and Hub Transport servers, but also pre-configuration of those resources to minimize the changes required as part of a datacenter switchover operation.

Note:

Client Access and Hub Transport services are required in the second datacenter even when automatic activation of the mailbox databases in the second datacenter is blocked. These services are necessary in order to perform database switchovers, as well as to perform testing and validation of the services and data in the second datacenter.

To better understand the how a datacenter switchover process works, it's helpful to understand the basic operation of an Exchange 2010 datacenter switchover.

As illustrated in the following figure, a site resilient deployment consists of a DAG that has members in both datacenters.



When a DAG is extended across multiple datacenters, it should be designed so that either the majority of the DAG members are located in the primary datacenter or, when each datacenter has the same number of members, the primary datacenter hosts the witness server. This design guarantees that service will provided in the primary datacenter even if network connectivity between the two datacenters fails. It also means that when the primary datacenter fails, however, quorum will be lost for the members in the second datacenter.

Partial datacenter failures are also possible and will happen. The presumption is that if enough functionality is lost in the primary datacenter to preclude effective service and management then a datacenter switchover should be performed to activate the second datacenter. The activation process involves the administrator configuring the surviving servers of partially operational state to cease service. Activation can then proceed in the second datacenter. This is done to preclude both sets of services to try and operate at the same time.

As a result of the loss of the quorum, the DAG members in the second datacenter cannot automatically come online. Thus, activating the mailbox servers in the second datacenter also requires a step where the DAG member servers are forced to create quorum, at which point the servers in the failed datacenter are internally (but only temporarily) removed from the DAG. This provides a partial-service solution that's stable and able to experience some level of additional failures and still continue to function.

Note:

One prerequisite of being able to experience additional failures is that the DAG has at least four members and the four members are spread between two Active Directory sites (e.g., at least two members in each datacenter).

This is the basic process used to re-establish Mailbox role functionality in the second datacenter. The activation of the other roles in the second datacenter does not involve explicit actions on the impacted servers in the second datacenter. Instead, servers in the second datacenter become the service endpoints for those services normally hosted by the primary datacenter. For example, a user normally hosted in the primary datacenter might use https://mail.contoso.com/owa to connect to Outlook Web App. After the

datacenter failure, these service endpoints are moved to endpoints in the second datacenter as part of the switchover operation. During the switchover operation, the service endpoints for the primary datacenter are re-targeted at alternate IP addresses for the same services in the second datacenter. This minimizes the amount of changes that must be made to configuration information stored in Active Directory during the switchover process. Generally, there are two ways to complete this step:

- Update DNS records; or
- Reconfigure DNS and load balancer(s) to enable and disable alternate IP addresses, thus moving services between datacenters.

A strategy for testing the solution must be established. It must be factored into the SLA. Periodic validation of the deployment is the only way to guarantee the deployment does not degrade over time.

Careful completion of these planning steps will directly impact the success of a datacenter switchover. For example, poor namespace design can cause difficulties with certificates, and an incorrect certificate configuration can preclude users from being able to access services.

After the deployment is validated, we recommend that all parts of the configuration that directly affect the success of a datacenter switchover be explicitly documented. In addition, it might be prudent to enhance the change management processes around those segments of the deployment.

For more information about datacenter switchovers, including activating a secondary datacenter, and re-activating a failed (primary) datacenter, see Datacenter Switchovers.

1.10.3 Deploying High Availability and Site Resilience

Deploying High Availability and Site Resilience

Exchange Server 2010 > High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

To create a highly available Mailbox server in previous versions of Exchange, you would install Exchange on a server that was configured as a member of a Microsoft Windows failover cluster. If you wanted a highly available Mailbox server, you had to build and configure the cluster prior to running Exchange Setup. The Exchange Setup program (and other Exchange components, such as the Exchange store and the Microsoft Exchange System Attendant service) was cluster-aware, and therefore behaved differently from when it was run on a stand-alone server. If Exchange was already installed on a stand-alone Windows server, you couldn't configure that server for high availability without first removing Exchange, building a cluster, and then reinstalling Exchange using the cluster-aware version of Setup.

Microsoft Exchange Server 2010 uses the concept known as *incremental deployment* for both high availability and site resilience. Unlike previous versions, Exchange 2010 no longer uses the cluster resource model for high availability. As a result of this architectural change, there is no longer a cluster-aware version of Setup, and you no longer configure high availability during Setup. Instead, you simply install all Exchange 2010 servers as standalone servers, and then incrementally configure mailbox servers and mailbox databases for high availability and site resilience as needed.

Overview of the Deployment Process

While the actual steps used by each organization may vary slightly, the overall process for deploying Exchange 2010 in a highly available or site resilient configuration is generally the same. After performing the necessary planning and design tasks for building and deploying a database availability group (DAG) and creating mailbox database copies, you would:

1. Create a DAG. For detailed steps, see Create a Database Availability Group.
2. If necessary, pre-stage the cluster name object (CNO). Pre-staging the CNO is required when deploying a DAG with Mailbox servers running Windows Server 2012. Pre-staging is also required in environments where computer account creation is restricted or where computer accounts are created in a container other than the default computers container. For detailed steps, see Pre-stage the Cluster Name Object for a Database Availability Group.
3. Add two or more Mailbox servers to the DAG. For detailed steps, see Manage Database Availability Group Membership.
4. Configure the DAG properties as needed:
   4.a. Optionally configure DAG encryption and compression, replication port, DAG IP addresses, and other DAG properties. For detailed steps, see Configure Database Availability Group Properties.
   4.b. If the DAG contains three or more Mailbox servers that are deployed in multiple Active Directory sites, Datacenter Activation Coordination (DAC) mode should be enabled. For more information, see Understanding Datacenter Activation Coordination Mode.
   4.c. For detailed steps about how to create a DAG network, see Create a Database Availability Group Network. To manage a DAG network, see Configure Database Availability Group Network Properties.
5. Add mailbox database copies across Mailbox servers in the DAG. For detailed steps, see Add a Mailbox Database Copy.

Example Deployment: Four Member DAG in Two Datacenters

This example details how an organization, Contoso, Ltd., is configuring and deploying a four-member DAG that will be extended across two physical locations: a primary datacenter referred to as Active Directory SITEA and a second datacenter referred to as Active Directory SITEB. SITEA is located in Redmond, Washington, and SITEB is located in Dublin, Ireland.

Base Infrastructure

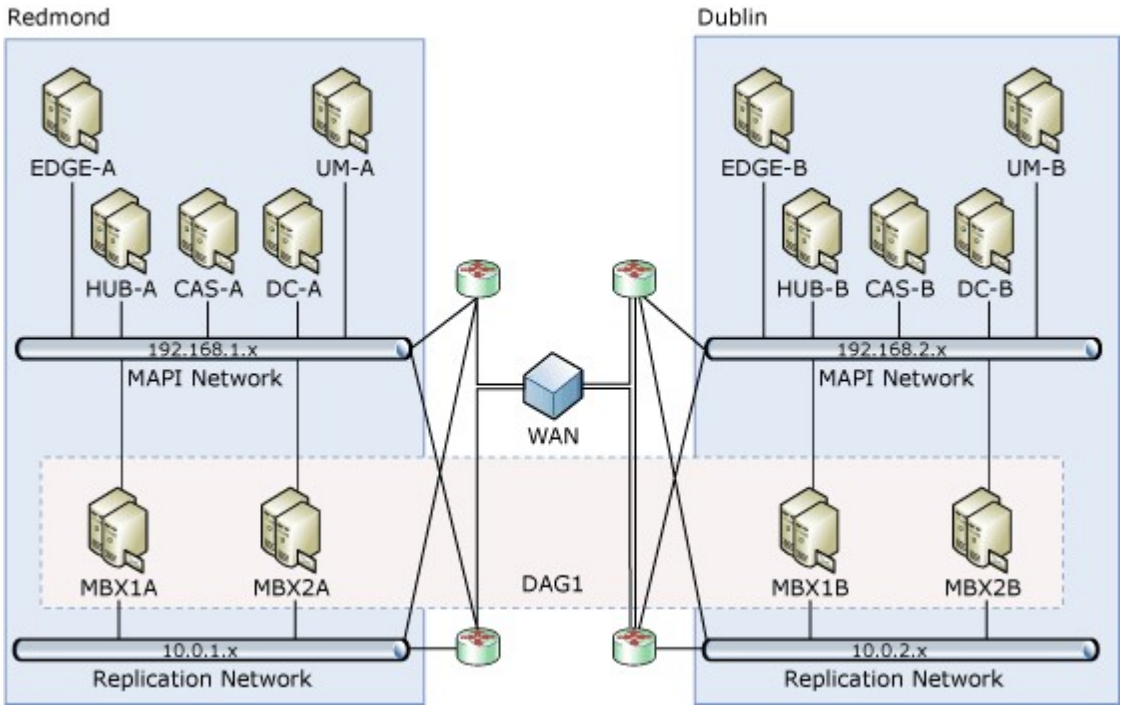
Each location contains the infrastructure elements that are necessary to operate a messaging infrastructure based on Exchange 2010, namely:

- Directory services (either Active Directory or Active Directory Domain Services (AD DS))
- Domain Name System (DNS) name resolution
- One or more Exchange 2010 Client Access servers
- One or more Exchange 2010 Hub Transport servers
- One or more Exchange 2010 Mailbox servers

Note:

The Client Access, Hub Transport, and Mailbox server roles can be co-located on a single computer. In this example deployment, the server roles are installed on separate computers.

The following figure illustrates the Contoso configuration.



Except for the Mailbox servers, all of the servers in the Contoso environment are running the Windows Server 2008 R2 Standard operating system. The Mailbox servers, which were planned with DAGs in mind, are running Windows Server 2008 R2 Enterprise.

In addition to the preceding infrastructure components, each location contains other messaging elements, such as Edge Transport servers and Unified Messaging servers.

Network Configuration

As illustrated in the previous figure, the solution involves the use of multiple subnets and multiple networks. Each Mailbox server in the DAG has two network adapters on separate subnets. In each Mailbox server, one network adapter will be used for the MAPI network (192.168.*x*.*x*) and one network adapter will be used for the Replication network (10.0.*x*.*x*). Only the MAPI network provides connectivity to Active Directory, DNS services, other Exchange servers and clients. The adapter used for the Replication network in each member provides connectivity only to the Replication network adapters in the other members of the DAG.

The settings for each network adapter in each node are detailed in the following table.

Name	IPv4 address	Subnet mask	Default gateway
MBX1A (MAPI)	192.168.1.4	255.255.255.0	192.168.1.1
MBX2A (MAPI)	192.168.1.5	255.255.255.0	192.168.1.1
MBX1B (MAPI)	192.168.2.4	255.255.255.0	192.168.2.1
MBX2B (MAPI)	192.168.2.5	255.255.255.0	192.168.2.1
MBX1A (Replication)	10.0.1.4	255.255.0.0	None
MBX2A (Replication)	10.0.1.5	255.255.0.0	None
MBX1B (Replication)	10.0.2.4	255.255.0.0	None
MBX2B (Replication)	10.0.2.5	255.255.0.0	None

As shown in the preceding table, adapters used for Replication networks don't use default gateways. To provide network connectivity between each of the Replication network adapters, Contoso uses persistent static routes, which they configure by using Netsh.exe tool. Netsh.exe is a tool you can use to configure and monitor Windows-based computers at a command prompt. With the Netsh.exe tool, you can direct the context commands you enter to the appropriate helper, and the helper then carries out the command. A helper is a dynamic-link library file (.dll) that extends the functionality of the Netsh.exe tool by providing configuration, monitoring, and support for one or more services, utilities, or protocols.

To configure routing for the Replication network adapters on MBX1A and MBX2A, the following command was run on each server.

```
netsh interface ipv4 add route 10.0.2.0/24 <NetworkName> 10.0.1.254
```

To configure routing for the Replication network adapters on MBX1B and MBX2B, the following command was run on each server.

```
netsh interface ipv4 add route 10.0.1.0/24 <NetworkName> 10.0.2.254
```

The following additional network settings have also been configured:

- The **Register this connection's addresses in DNS** check box is selected for each DAG member's MAPI network adapter, and cleared for each Replication network adapter.
- At least one DNS server address is configured for each DAG member's MAPI network adapter, and none are configured for the Replication network adapters. For redundancy, Contoso is using multiple DNS server addresses for their MAPI network adapters.
- Contoso doesn't use IPv6, and they disabled the protocol on their servers.
- Contoso doesn't use the Windows Firewall and have turned it off on their servers.

After the network adapters have been configured, Contoso is ready to create a DAG and add the Mailbox servers to the DAG.

Database Availability Group Creation and Configuration

The administrator has decided to create a Windows PowerShell command-line interface script that performs several tasks:

- It uses the New-DatabaseAvailabilityGroup cmdlet to create the DAG. Because SITEA is considered to be the primary datacenter, Contoso has chosen to use a witness server in the same datacenter, namely, HUB-A.
- It uses the Set-DatabaseAvailabilityGroup cmdlet to preconfigure an alternate witness server and alternate witness directory in case a site switchover is ever necessary.
- It uses the Add-DatabaseAvailabilityGroupServer cmdlet to add each of the four Mailbox servers to the DAG.
- It uses the Set-DatabaseAvailabilityGroup cmdlet to configure the DAG for DAC mode. For more information about DAC mode, see Understanding Datacenter Activation Coordination Mode.

The following are the commands used in the script:

```
New-DatabaseAvailabilityGroup -Name DAG1 -WitnessServer HUB-A -WitnessDirectory C
```

The preceding command creates a DAG named DAG1, configures Hub-A to act as the witness server, configures a specific witness directory (C:\DAGWitness \DAG1.contoso.com), and configures two IP addresses for the DAG (one for each subnet on the MAPI network).

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -AlternateWitnessDirectory C:\DAGWit
```

The preceding command configures DAG1 to use an alternate witness server of Hub-B and an alternate witness directory on Hub-B that uses the same path that was configured on Hub-A.

Note:

Using the same path isn't required; Contoso has chosen to do this to standardize their configuration.

```
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX1A
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX1B
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX2A
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX2B
```

The preceding commands add each of the Mailbox servers, one at a time, to the DAG. The commands also install the Windows Failover Clustering component on each Mailbox server (if it isn't already installed), create a failover cluster, and join each Mailbox server to the newly created cluster.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -DatacenterActivationMode DagOnly
```

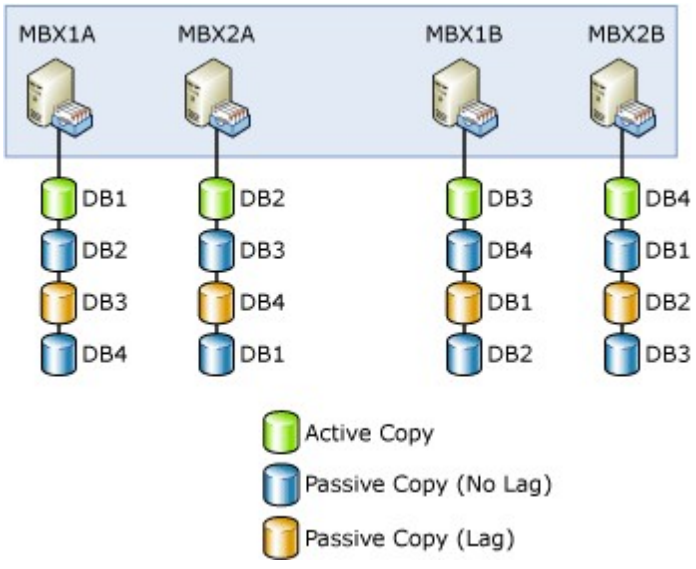
The preceding command enables DAC mode for the DAG.

Mailbox Databases and Mailbox Database Copies

After creating the DAG and adding the Mailbox servers to the DAG, Contoso prepares to create mailbox databases and mailbox database copies. To meet their criteria for failure resistance, Contoso is planning to configure each mailbox database with three non-lagged database copies, and one lagged database copy. The lagged copy will have a configured log replay delay of three days.

This configuration provides a total of four copies for each database (one active, two non-lagged passives, and a lagged passive). Contoso plans on having four active databases per server. With four active databases per server, and three passive copies of each database, the Contoso solution contains 16 total database copies.

As shown in the following figure, Contoso is taking a balanced approach to their database layout.



Each Mailbox server hosts an active mailbox database copy, two non-lagged passive database copies, and one lagged passive database copy. The lagged copy of each active mailbox database is hosted on a Mailbox server in the other site.

To create this configuration, the administrator runs several commands.

On MBX1A, run the following commands.

```
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX2A
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX2B
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX1B -ReplayLagTime 3.00:00
Suspend-MailboxDatabaseCopy -Identity DB1\MBX1B -SuspendComment "Seed from MBX2B"
Update-MailboxDatabaseCopy -Identity DB1\MBX1B -SourceServer MBX2B
Suspend-MailboxDatabaseCopy -Identity DB1\MBX1B -ActivationOnly
```

On MBX2A, run the following commands.

```
Add-MailboxDatabaseCopy -Identity DB2 -MailboxServer MBX1A
Add-MailboxDatabaseCopy -Identity DB2 -MailboxServer MBX1B
Add-MailboxDatabaseCopy -Identity DB2 -MailboxServer MBX2B -ReplayLagTime 3.00:00
Suspend-MailboxDatabaseCopy -Identity DB2\MBX2B -SuspendComment "Seed from MBX1B"
Update-MailboxDatabaseCopy -Identity DB2\MBX2B -SourceServer MBX1B
Suspend-MailboxDatabaseCopy -Identity DB2\MBX2B -ActivationOnly
```

On MBX1B, run the following commands.

```
Add-MailboxDatabaseCopy -Identity DB3 -MailboxServer MBX2B
Add-MailboxDatabaseCopy -Identity DB3 -MailboxServer MBX2A
Add-MailboxDatabaseCopy -Identity DB3 -MailboxServer MBX1A -ReplayLagTime 3.00:00
Suspend-MailboxDatabaseCopy -Identity DB3\MBX1A -SuspendComment "Seed from MBX2A"
Update-MailboxDatabaseCopy -Identity DB3\MBX1A -SourceServer MBX2A
Suspend-MailboxDatabaseCopy -Identity DB3\MBX1A -ActivationOnly
```

On MBX2B, run the following commands.

```
Add-MailboxDatabaseCopy -Identity DB4 -MailboxServer MBX1B
Add-MailboxDatabaseCopy -Identity DB4 -MailboxServer MBX1A
Add-MailboxDatabaseCopy -Identity DB4 -MailboxServer MBX2A -ReplayLagTime 3.00:00
Suspend-MailboxDatabaseCopy -Identity DB4\MBX2A -SuspendComment "Seed from MBX1A"
Update-MailboxDatabaseCopy -Identity DB4\MBX2A -SourceServer MBX1A
Suspend-MailboxDatabaseCopy -Identity DB4\MBX2A -ActivationOnly
```

In the preceding examples for the **Add-MailboxDatabaseCopy** cmdlet, the *ActivationPreference* parameter wasn't specified. The task automatically increments the activation preference number with each copy that's added. The original database always has a preference number of 1. The first copy added with the **Add-MailboxDatabaseCopy** cmdlet is automatically assigned a preference number of 2. Assuming no copies are removed, the next copy added is automatically assigned a preference number of 3, and so forth. Thus, in the preceding examples, the passive copy in the same datacenter as the active copy has an activation preference number of 2; the non-lagged passive copy in the remote datacenter has an activation preference number of 3, and the lagged passive copy in the remote datacenter has an activation preference number of 4.

Although there are two copies of each active database across the WAN in the other location, seeding over the WAN was only performed once. This is because Contoso is leveraging the Exchange 2010 ability to use a passive copy of a database as the source for seeding. Using the Add-MailboxDatabaseCopy cmdlet with the *SeedingPostponed* parameter prevents the task from automatically seeding the new database copy being created. Then, the administrator can suspend the un-seeded copy, and by using the Update-MailboxDatabaseCopy cmdlet with the *SourceServer* parameter, the administrator can specify the local copy of the database as the source of the seeding operation. As a result, seeding of the second database copy added to each location happens locally and not over the WAN.

Note:

In the preceding example, the non-lagged database copy is seeded over the WAN, and that copy is then used to seed the lagged copy of the database that's in the same datacenter as the non-lagged copy.

Contoso has configured one of the passive copies of each mailbox database as a lagged database copy to provide protection against the extremely rare but catastrophic case of database logical corruption. As a result, the administrator is configuring the lagged copies as blocked for activation by using the Suspend-MailboxDatabaseCopy cmdlet with the *ActivationOnly* parameter. This ensures that the lagged database copies won't be activated if a database or server failover occurs.

Validating the Solution

After the solution has been deployed and configured, the administrator performs several tasks that validate the solution's readiness prior to moving production mailboxes to the databases in the DAG. The solution should be tested and inspected using several methods, including failure simulations. To validate the solution, the administrator performs several tasks.

To verify the overall health of the DAG, the administrator runs the Test-ReplicationHealth cmdlet. This cmdlet checks several aspects of the replication and replay status to provide information about each Mailbox server and database copy in the DAG.

To verify replication and replay activity, the administrator runs the Get-MailboxDatabaseCopyStatus cmdlet. This cmdlet can provide real-time status information about a specific mailbox database copy or for all mailbox database copies on a specific server. For more information about monitoring the health and status of replicated databases in a DAG, see Monitoring High Availability and Site Resilience.

To verify switchovers work as expected, the administrator uses the Move-ActiveMailboxDatabase cmdlet to perform a series of database switchovers and server switchovers. When these tasks have completed successfully, the administrator uses the same cmdlet to move the active database copies back to their original locations.

To verify the expected behaviors in various failure scenarios, the administrator performs several tasks that either simulate failures or actually cause failures to occur. For example, the administrator might:

- Unplug the power cord on MBX1A, thereby triggering a server failover. The administrator then verifies that DB1 becomes active on another server (preferably MBX2A, based on the activation preference values).
- Unplug the network cable for the MAPI network adapter on MBX2A, thereby triggering a server failover. The administrator then verifies that DB2 becomes active on another server (preferably MBX1A, based on the activation preference values).
- Take the disk used by the active copy of DB3 offline, thereby triggering a database failover. The administrator then verifies that DB3 becomes active on another server (preferably MBX2B, based on activation preference values).

There may be other failure scenarios that are tested by an organization, based on the business needs. After simulating a single failure (such as pulling the power plug), and verifying the solution's recovery behavior, the administrator may revert the solution back to its original configuration. In some cases, the solution may be tested for multiple concurrent failures. Ultimately, your solution test plan will dictate whether the solution is reverted back to its original configuration after each failure simulation has been completed.

In addition, an administrator may decide to disconnect the network connection between the two datacenters, thereby simulating a site failure. Performing a datacenter switchover is a much more involved and coordinated process; however, it's a recommended process if the solution being deployed is intended to provide site resilience for the messaging services and data. For details on datacenter switchovers, see Datacenter Switchovers.

Transitioning to Operations

After the solution has been deployed, it can be extended further using incremental

deployment. At this point, management of the solution would also transition to operation processes, in which the following tasks would be performed:

- Monitor the health and status of DAGs and mailbox database copies. For more information, see Monitoring High Availability and Site Resilience.
- Perform database and server switchovers as needed. For detailed steps to perform a database switchover, see Move the Active Mailbox Database. For detailed steps to perform a server switchover, see Perform a Server Switchover. If necessary, initiate a datacenter switchover. For more information about datacenter switchovers, see Datacenter Switchovers.

For more information about managing the solution, see Managing High Availability and Site Resilience.

1.10.4 Managing High Availability and Site Resilience

Managing High Availability and Site Resilience

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-06*

After you build, validate, and deploy a Microsoft Exchange Server 2010 high availability or site resilience solution, the solution transitions from the deployment phase to the operational phase of the overall solution lifecycle. The operational phase consists of several tasks, and all tasks are related to one of the following areas: database availability groups (DAGs), mailbox database copies, performing proactive monitoring, and managing switchovers and failovers.

Management of an Exchange 2010 high availability or site resilience solution is performed differently from previous versions of Exchange. Several architectural and design changes have been made in Exchange 2010 that eliminate the need to perform tasks required in previous versions of Exchange, and that provide you with greater granularity and control over the solution. For example:

- Exchange 2010 doesn't use the concept of a clustered mailbox server (referred to as an Exchange Virtual Server in Exchange Server 2003 and earlier). As a result, Exchange is no longer a clustered application, and Exchange server identities no longer move between clustered servers.
- Exchange 2010 doesn't use the concept of storage groups. As a result, databases are uncoupled from servers and are now managed globally, databases no longer share log streams, and continuous replication (including switchovers and failovers) operates at the database level.
- Exchange 2010 doesn't use the concepts of public and private networks. These concepts are replaced with the concepts of MAPI networks and replication networks. Each DAG should contain one MAPI network and one or more replication networks.

Contents

Database Availability Group Management

The operational management tasks associated with DAGs include:

- **Creating one or more DAGs** Creating a DAG is typically a one-time procedure performed during the deployment phase of the solution lifecycle. However, there may be reasons for creating DAGs that occur during the operational phase. For example:
  - The DAG is configured for third-party replication mode, and you want to revert to using continuous replication. You can't convert a DAG back to continuous replication; you need to create a DAG.
  - You have servers in multiple domains. All members of the same DAG must also be members of the same domain.
- **Managing DAG membership** Managing DAG members is an infrequent task typically performed during the deployment phase of the solution lifecycle. However, because of the flexibility provided by incremental deployment, managing DAG membership may also be performed throughout the solution lifecycle.
- **Configuring DAG properties** Each DAG has various properties that can be configured as needed. These properties include:
  - **Witness server and witness directory** The witness server is a server outside the DAG that acts as a quorum voter when the DAG contains an even number of members. The witness directory is a directory created and shared on the witness server for use by the system in maintaining a quorum.
  - **IP addresses** Each DAG will have one or more IPv4 addresses, and optionally, one or more IPv6 addresses. The IP addresses assigned to the DAG are used by the DAG's underlying cluster. The number of IPv4 addresses assigned to the DAG equals the number of subnets that comprise the MAPI network used by the DAG. You can configure the DAG to use static IP addresses or to obtain addresses automatically by using Dynamic Host Configuration Protocol (DHCP).
  - **Database activation coordination mode** Database activation coordination mode is a property setting on a DAG that's designed for DAGs with three or more members that have been deployed to multiple sites. Database activation coordination mode is used to handle conditions that would otherwise lead to a split-brain syndrome within the DAG, such as a site failure. For more information about database activation coordination mode, see Understanding Datacenter Activation Coordination Mode.
  - **Alternate witness server and alternate witness directory** The alternate witness server and alternate witness directory are values that you can preconfigure as part of the planning process for DAGs configured for site resilience.
  - **Replication port** By default, all DAGs use TCP port 64327 for continuous replication. You can modify the DAG to use a different TCP port for replication by using the *ReplicationPort* parameter of the Set-DatabaseAvailabilityGroup cmdlet.
  - **Network discovery** You can force the DAG to rediscover networks and network interfaces. This operation is used when you add or remove networks or change DAG network subnets. Rediscovery of all DAG networks can be forced by using the *DiscoverNetworks* parameter of the Set-DatabaseAvailabilityGroup cmdlet.
  - **Network compression** By default, DAGs use compression only between DAG networks on different subnets. You can enable compression for all DAG networks or for seeding operations only, or you can disable compression for all DAG networks.
  - **Network encryption** By default, DAGs use encryption only between DAG networks on different subnets. You can enable encryption for all DAG

networks or for seeding operations only, or you can disable encryption for all DAG networks.

- **Managing DAG networks** Although using a single network interface card (NIC) is supported, we recommend that each DAG member have at least two NICs. One NIC is used for the MAPI network, and one NIC is used for the replication network. Additional NICs can be added to create additional replication networks, for use as dedicated backup networks, or for use by the system as Internet SCSI (iSCSI) storage. DAG network management involves designating a network as a MAPI network or as a replication network, and configuring network subnets.
- **Shutting down DAG members** The Exchange 2010 high availability solution is integrated with the Windows shutdown process. If an administrator or application initiates a shutdown of a Windows server in a DAG that has a mounted database that's replicated to one or more DAG members, the system will try to activate another copy of the mounted databases prior to allowing the shutdown process to complete. However, this new behavior doesn't guarantee that all of the databases on the server being shut down will experience a loss-less activation. As a result, it's a best practice to perform a server switchover prior to shutting down a server that's a member of a DAG.

For detailed steps to create a DAG, see Create a Database Availability Group. For detailed steps to configure DAGs and DAG properties, see Configure Database Availability Group Properties. For more information about each of the preceding management tasks, and about managing DAGs in general, see Managing Database Availability Groups.

Return to top

Mailbox Database Copy Management

The operational management tasks associated with mailbox database copies include:

- **Adding mailbox database copies** When you add a copy of a mailbox database, continuous replication is automatically enabled between the existing database and the database copy.
- **Configuring mailbox database copy properties** You can configure a variety of properties, such as the database activation policy, the amount of time, if any, for replay lag and truncation lag, and the activation preference for the database copy.
- **Suspending or resuming a mailbox database copy** You can suspend a mailbox database copy in preparation for seeding, or for other forms of maintenance. You can also suspend a mailbox database copy for activation only. This configuration prevents the system from automatically activating the copy as a result of a failure, but it still allows the system to keep the database copy up to date with log shipping and replay.
- **Updating a mailbox database copy** Updating, also known as *seeding*, is the process in which a copy of a mailbox database is added to another Mailbox server. This becomes the baseline database for the copy. After the initial first seed of the baseline database copy, only in rare circumstances will the database need to be seeded again.
- **Activating a mailbox database copy** Activating is the process of designating a specific passive copy as the new active copy of a mailbox database. This process is referred to as a *switchover*. For more information, see "Switchovers and Failovers" later in this topic.
- **Removing a mailbox database copy** You can remove a mailbox database copy at any time. Occasionally, it may be necessary to remove a mailbox database copy. For example, you can't remove a Mailbox server from a DAG until all mailbox database copies are removed from the server. In addition, you must remove all copies of a mailbox database before you can change the path for a mailbox database.

For detailed steps to add a mailbox database copy, see Add a Mailbox Database Copy. For detailed steps to configure mailbox database copies, see Configure Mailbox Database Copy Properties. For more information about each of the preceding management tasks, and about managing mailbox database copies in general, see Managing Mailbox Database Copies. For detailed steps to remove a mailbox database copy, see Remove a Mailbox Database Copy.

Return to top

Proactive Monitoring

Making sure that your servers are operating reliably and that your database copies are healthy are key objectives for daily messaging operations. Exchange 2010 includes a number of features that can be used to perform a variety of health monitoring tasks for DAGs and mailbox database copies, including:

- Get-MailboxDatabaseCopyStatus
- Test-ReplicationHealth
- Crimson channel event logging

In addition to monitoring the health and status, it is also critical to monitor for situations that can compromise availability. For example, we recommend that you monitor the redundancy of your replicated databases. It is critical to avoid situations where you are down to a single copy of a database. This scenario should be treated with the highest priority and resolved as soon as possible.

For more detailed information about monitoring the health and status of DAGs and mailbox database copies, see Monitoring High Availability and Site Resilience.

Return to top

Switchovers and Failovers

A *switchover* is a manual process in which an administrator manually activates one or more mailbox database copies. Switchovers, which can occur at the database or server level, are typically performed as part of preparation for maintenance activities. Switchover management involves performing database or server switchovers as needed. For example, if you need to perform maintenance on a Mailbox server in a DAG, you would first perform a server switchover so that the server didn't host any active mailbox database copies. For detailed steps to perform a database switchover, see Move the Active Mailbox Database. For detailed steps to perform a server switchover, see Perform a Server Switchover. Switchovers can also be performed at the datacenter level. For more information about datacenter switchovers, see Datacenter Switchovers.

A *failover* is the automatic activation by the system of one or more database copies in reaction to a failure. For example, the loss of a disk drive will trigger a database failover. The loss of the MAPI network or a power failure will trigger a server failover.

For more information about switchovers and failovers, see Switchovers and Failovers.

Return to top

1.10.4.1 Managing Database Availability Groups

Managing Database Availability Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

A database availability group (DAG) is a set of up to 16 Microsoft Exchange Server 2010 Mailbox servers that provides automatic, database-level recovery from a database, server, or network failure. DAGs use continuous replication and a subset of Windows failover clustering technologies to provide high availability and site resilience. Mailbox servers in a DAG monitor each other for failures. When a Mailbox server is added to a DAG, it works with the other servers in the DAG to provide automatic, database-level recovery from database failures.

When you create a DAG, it's initially empty, and a directory object is created in Active Directory that represents the DAG. The directory object is used to store relevant information about the DAG, such as server membership information. When you add the first server to a DAG, a failover cluster is automatically created for the DAG. In addition, the infrastructure that monitors the servers for network or server failures is initiated. The failover cluster heartbeat mechanism and cluster database are then used to track and manage information about the DAG that can change quickly, such as database mount status, replication status, and last mounted location.

Contents

Creating DAGs

A DAG can be created using the New Database Availability Group wizard in the Exchange Management Console (EMC), or by running the **New-DatabaseAvailabilityGroup** cmdlet in the Exchange Management Shell. When creating a DAG, you provide a name for the DAG, and optional witness server and witness directory settings. In addition, one or more IP addresses are assigned to the DAG, either by using static IP addresses or by allowing the DAG to be automatically assigned the necessary IP addresses using Dynamic Host Configuration Protocol (DHCP). You can manually assign IP addresses to the DAG by using the *DatabaseAvailabilityGroupIpAddresses* parameter. If you omit this parameter, the DAG attempts to obtain an IP address by using a DHCP server on your network.

For detailed steps about how to create a DAG, see Create a Database Availability Group.

When you create a DAG, an empty object representing the DAG with the name you specified and an object class of **msExchMDBAvailabilityGroup** is created in Active Directory.

DAGs use a subset of Windows failover clustering technologies, such as the cluster heartbeat, cluster networks, and cluster database (for storing data that changes or can change quickly, such as database state changes from active to passive or the reverse, or from mounted to dismounted or the reverse). Because DAGs rely on Windows failover clustering, they can only be created on Exchange 2010 Mailbox servers running the Windows Server 2008 Enterprise operating system or Windows Server 2008 R2 Enterprise operating system.

Note:

The failover cluster created and used by the DAG must be dedicated to the DAG. The cluster can't be used for any other high availability solution or for any other purpose. For example, the failover cluster can't be used to cluster other applications or services. Using a DAG's underlying failover cluster for purposes other than the DAG isn't supported.

DAG Witness Server and Witness Directory

When creating a DAG, you need to specify a name for the DAG no longer than 15 characters that's unique within the Active Directory forest. In addition, each DAG is configured with a witness server and witness directory. The witness server and its directory are used only for quorum purposes where there's an even number of members in the DAG. You don't need to create the witness directory in advance. Exchange automatically creates and secures the directory for you on the witness server. The directory shouldn't be used for any purpose other than for the DAG witness server.

The requirements for the witness server are as follows:

- The witness server can't be a member of the DAG.
- The witness server must be in the same Active Directory forest as the DAG.
- The witness server must be running Windows Server 2008 R2, Windows Server 2008, Windows Server 2003 R2, or Windows Server 2003.
- A single server can serve as a witness for multiple DAGs. However, each DAG requires its own witness directory.

We recommend that you use an Exchange 2010 Hub Transport server in the Active Directory site containing the DAG. This allows the witness server and directory to remain under the control of an Exchange administrator. Regardless of what server is used as the witness server, if the Windows Firewall is enabled on the intended witness server, you must enable the Windows Firewall exception for File and Printer Sharing.

Important:

If the witness server you specify isn't an Exchange 2010 server, you must add the Exchange Trusted Subsystem universal security group (USG) to the local Administrators group on the witness server prior to creating the DAG. These security permissions are necessary to ensure that Exchange can create a directory and share on the witness server as needed.

Neither the witness server nor the witness directory needs to be fault tolerant or use any form of redundancy or high availability. There's no need to use a clustered file server for the witness server or employ any other form of resiliency for the witness server. There are several reasons for this. With larger DAGs (for example, six members or more), several failures are required before the witness server is needed. Because a six-member DAG can tolerate as many as two voter failures without losing quorum, it would take as many as three voters failing before the witness server would be needed to maintain a quorum. Also, if there's a failure that affects your current witness server (for example, you lose the witness server because of a hardware failure), you can use the Set-DatabaseAvailabilityGroup cmdlet to configure a new witness server and witness directory

(provided you have a quorum).

Note:

You can also use the **Set-DatabaseAvailabilityGroup** cmdlet to configure the witness server and witness directory in the original location if the witness server lost its storage or if someone changed the witness directory or share permissions.

As a best practice, in an environment where a DAG is extended across multiple datacenters (and Active Directory sites) and configured for site resilience, we recommend that you use a witness server in your primary data center (the data center containing the majority of your user population). If each data center has a similar number of users, the data center you choose to host the witness server is considered to be the primary datacenter from the solution's perspective. If the witness server is in the datacenter with the majority of the client population, the majority of clients retain access after a failure.

If the datacenter is remote to large user populations, this may affect your decision. You would then need to determine if there's a requirement for the primary datacenter to remain healthy and active if there's a loss of wide are network (WAN) connectivity to the other two datacenters. In that event, the witness server should also be in the primary datacenter.

Although it's supported to use a witness server in a third datacenter, we don't recommend this scenario. From an Exchange perspective, this configuration doesn't provide you with greater availability. It's important that you examine the critical path factors if you use a witness server in a third datacenter. For example, if the WAN connection between the primary datacenter and the second and third datacenter fails, the solution in the primary datacenter becomes unavailable.

Specifying a Witness Server and Witness Directory During DAG Creation

When creating a DAG, you must provide a name for the DAG. You can optionally also specify a witness server and witness directory. If you specify a witness server, we recommend that you use a Hub Transport server, because this allows an Exchange administrator to be aware of the availability of the witness server.

When creating a DAG, the following combinations of options and behaviors are available:

- You can specify only a name for the DAG, and leave the **Witness server** and **Witness directory** fields blank. In this scenario, the wizard searches for a Hub Transport server that doesn't have the Mailbox server role installed, and it automatically creates the default directory (%SystemDrive% :\DAGFileShareWitnesses\<*DAGFQDN*>) and default share (<*DAGFQDN*>) on that server and uses that Hub Transport server as the witness server. For example, consider a witness server named EXMBX3 on which the operating system has been installed onto drive C. A DAG named DAG1 in a domain named contoso.com would use a default witness directory of C:\DAGFileShareWitnesses\DAG1.contoso.com, which would be shared as \ \EXMBX3\DAG1.contoso.com.
- You can specify a name for the DAG, the witness server that you want to use, and the directory you want created and shared on the witness server.
- You can specify a name for the DAG and the witness server that you want to use, and leave the **Witness directory** field blank. In this scenario, the wizard creates the default directory on the specified witness server.
- You can specify a name for the DAG, leave the **Witness server** field blank, and specify the directory you want created and shared on the witness server. In this scenario, the wizard searches for a Hub Transport server that doesn't have the Mailbox server role installed, and it automatically creates the specified DAG on that server, shares the directory, and uses that Hub Transport server as the witness server.

When a DAG is formed, it initially uses the Node Majority quorum model. When the second

Mailbox server is added to the DAG, the quorum is automatically changed to a Node and File Share Majority quorum model. When this change occurs, the DAG begins using the witness server for maintaining a quorum. If the witness directory doesn't exist, Exchange automatically creates it, shares it, and provisions the share with full control permissions for the cluster name object (CNO) computer account for the DAG.

Note:

Using a file share that is part of a Distributed File System (DFS) namespace is not supported.

If Windows Firewall is enabled on the witness server before the DAG is created, it may block the creation of the DAG. Exchange uses Windows Management Instrumentation (WMI) to create the directory and file share on the witness server. If Windows Firewall is enabled on the witness server and there are no firewall exceptions configured for WMI, the **New-DatabaseAvailabilityGroup** cmdlet fails with an error. If you specify a witness server, but not a witness directory, you receive the following error message.

```
The task was unable to create the default witness directory on server <Server Name>.
Please manually specify a witness directory.
```

If you specify a witness server and witness directory, you receive the following warning message.

```
Unable to access file shares on witness server 'ServerName'. Until this problem is
corrected, the database availability group may be more vulnerable to failures. You can
use the Set-DatabaseAvailabilityGroup cmdlet to try the operation again. Error: The
network path was not found.
```

If Windows Firewall is enabled on the witness server after the DAG is created but before servers are added, it may block the addition or removal of DAG members. If Windows Firewall is enabled on the witness server and there are no firewall exceptions configured for WMI, the **Add-DatabaseAvailabilityGroupServer** cmdlet displays the following warning message.

```
Failed to create file share witness directory 'C:\DAGFileShareWitnesses\DAG_FQDN' on
witness server 'ServerName'. Until this problem is corrected, the database availability
group may be more vulnerable to failures. You can use the Set-DatabaseAvailabilityGroup
cmdlet to try the operation again. Error: WMI exception occurred on server 'ServerName':
The RPC server is unavailable. (Exception from HRESULT: 0x800706BA)
```

To resolve the preceding error and warnings, do one of the following:

- Manually create the witness directory and share on the witness server, and assign the CNO for the DAG full control for the directory and share.
- Enable the WMI exception in Windows Firewall.
- Disable Windows Firewall.

Return to top

DAG Membership

After a DAG has been created, you can add servers to or remove servers from the DAG using the Manage Database Availability Group wizard in the EMC, or using the **Add-DatabaseAvailabilityGroupServer** or **Remove-DatabaseAvailabilityGroupServer** cmdlets in the Shell. For detailed steps about how to manage DAG membership, see Manage Database Availability Group Membership.

Note:

Each Mailbox server that's a member of a DAG is also a node in the underlying cluster used by the DAG. As a result, at any one time, a Mailbox server can be a member of only one DAG.

If the Mailbox server being added to a DAG doesn't have the failover clustering component installed, the method used to add the server (for example, the **Add-DatabaseAvailabilityGroupServer** cmdlet or the Manage Database Availability Group wizard) installs the failover clustering feature.

When the first Mailbox server is added to a DAG, the following occurs:

- The Windows failover clustering component is installed, if it isn't already installed.
- A failover cluster is created using the name of the DAG. This failover cluster is used exclusively by the DAG, and the cluster must be dedicated to the DAG. Use of the cluster for any other purpose isn't supported.
- A CNO is created in the default computers container.
- The name and IP address of the DAG is registered as a Host (A) record in Domain Name System (DNS).
- The server is added to the DAG object in Active Directory.
- The cluster database is updated with information on the databases mounted on the added server.

In a large or multiple site environment, especially those in which the DAG is extended to multiple Active Directory sites, you must wait for Active Directory replication of the DAG object containing the first DAG member to complete. If this Active Directory object isn't replicated throughout your environment, adding the second server may cause a new cluster (and new CNO) to be created for the DAG. This is because the DAG object appears empty from the perspective of the second member being added, thereby causing the **Add-DatabaseAvailabilityGroupServer** cmdlet to create a cluster and CNO for the DAG, even though these objects already exist. To verify that the DAG object containing the first DAG server has been replicated, use the **Get-DatabaseAvailabilityGroup** cmdlet on the second server being added to verify that the first server you added is listed as a member of the DAG.

When the second and subsequent servers are added to the DAG, the following occurs:

- The server is joined to the Windows failover cluster for the DAG.
- The quorum model is automatically adjusted:
  - A Node Majority quorum model is used for DAGs with an odd number of members.
  - A Node and File Share Majority quorum model is used for DAGs with an even number of members.
- The witness directory and share are automatically created by Exchange when needed.
- The server is added to the DAG object in Active Directory.
- The cluster database is updated with information about mounted databases.

Note:

The quorum model change should happen automatically. However, if the quorum model doesn't automatically change to the proper model, you can run the **Set-DatabaseAvailabilityGroup** cmdlet with only the *Identity* parameter to correct the quorum settings for the DAG.

Pre-Staging the Cluster Name Object for a DAG

The CNO is a computer account created in Active Directory and associated with the cluster's Name resource. The cluster's Name resource is tied to the CNO, which is a Kerberos-enabled object that acts as the cluster's identity and provides the cluster's security context. In Exchange 2007, this Kerberos-enabled machine account was created in the domain using the security context of the user performing the tasks. This required the user's account to have permissions to create and enable machine accounts in the

domain or that the computer account was properly pre-staged and provisioned.

The formation of the DAG's underlying cluster and the CNO for that cluster is performed when the first member is added to the DAG. When the first server is added to the DAG, Powershell contacts the Microsoft Exchange Replication service on the Mailbox server being added. The Microsoft Exchange Replication service installs the failover clustering feature (if it isn't already installed) and begins the cluster creation process. The Microsoft Exchange Replication service runs under the LOCAL SYSTEM security context, and it's under this context in which cluster creation is performed.

Warning:
If your DAG members are running Windows Server 2012, you must pre-stage the CNO prior to adding the first server to the DAG.

In environments where computer account creation is restricted, or where computer accounts are created in a container other than the default computers container, you can pre-stage and provision the CNO. You create and disable a computer account for the CNO, and then either:

- Assign full control of the computer account to the computer account of the first Mailbox server you're adding to the DAG.
- Assign full control of the computer account to the Exchange Trusted Subsystem USG.

Assigning full control of the computer account to the computer account of the first Mailbox server you're adding to the DAG ensures that the LOCAL SYSTEM security context will be able to manage the pre-staged computer account. Assigning full control of the computer account to the Exchange Trusted Subsystem USG can be used instead because the Exchange Trusted Subsystem USG contains the machine accounts of all Exchange servers in the domain.

For detailed steps about how to pre-stage and provision the CNO for a DAG, see Pre-stage the Cluster Name Object for a Database Availability Group.

Removing Servers from a DAG

Mailbox servers can be removed from a DAG by using the Manage Database Availability Group wizard in the EMC or the **Remove-DatabaseAvailabilityGroupServer** cmdlet in the Shell. Before a Mailbox server can be removed from a DAG, all replicated mailbox databases must first be removed from the server. If you attempt to remove a Mailbox server with replicated mailbox databases from a DAG, the task fails.

There are scenarios in which you must remove a Mailbox server from a DAG before performing certain operations. These scenarios include:

- **Performing a server recovery operation** If a Mailbox server that's a member of a DAG is lost, or otherwise fails and is unrecoverable and needs replacement, you can perform a server recovery operation using the **Setup /m:RecoverServer** switch. However, before you can perform the recovery operation, you must first remove the server from the DAG using the Remove-DatabaseAvailabilityGroupServer cmdlet with the *ConfigurationOnly* parameter.
- **Removing the database availability** There may be situations in which you need to remove a DAG (for example, when disabling third-party replication mode). If you need to remove a DAG, you must first remove all servers from the DAG. If you attempt to remove a DAG that contains one or more members, the task fails.

Return to top

Configuring DAG Properties

After servers have been added to the DAG, you can use the EMC or the Shell to configure

the properties of a DAG, including the witness server and witness directory used by the DAG, and the IP addresses assigned to the DAG.

Configurable properties include:

- **Witness server** The name of the server that you want to host the file share for the file share witness. We recommend that you specify a Hub Transport server outside the DAG as the witness server. This enables the system to automatically configure, secure, and use the share, as needed.
- **Witness directory** The name of a directory that will be used to store file share witness data. This directory will automatically be created by the system on the specified witness server.
- **Database availability group IP addresses** One or more IP addresses assigned to the DAG. These addresses can be configured using manually assigned static IP addresses, or they can be automatically assigned to the DAG using a DHCP server in your organization.

The Shell enables you to configure DAG properties that aren't available in the EMC, such as DAG IP addresses, network encryption and compression settings, network discovery, the TCP port used for replication, and alternate witness server and witness directory settings, and to enable Datacenter Activation Coordination mode.

For detailed steps about how to configure DAG properties, see Configure Database Availability Group Properties.

DAG Network Encryption

DAGs support the use of encryption by leveraging the encryption capabilities of the Windows Server operating system. DAGs use Kerberos authentication between Exchange servers. Microsoft Kerberos security support provider (SSP) EncryptMessage and DecryptMessage APIs handle encryption of DAG network traffic. Microsoft Kerberos SSP supports multiple encryption algorithms. (For the complete list, see section 3.1.5.2, "Encryption Types" of Kerberos Protocol Extensions). The Kerberos authentication handshake selects the strongest encryption protocol supported in the list: typically Advanced Encryption Standard (AES) 256-bit, potentially with a SHA Hash-based Message Authentication Code (HMAC) to maintain integrity of the data. For details, see HMAC.

Network encryption is a property of the DAG and not a DAG network. You can configure DAG network encryption using the **Set-DatabaseAvailabilityGroup** cmdlet in the Shell. The possible encryption settings for DAG network communications are shown in the following table.

DAG network communication encryption settings

Setting	Description
Disabled	Network encryption isn't used.
Enabled	Network encryption is used on all DAG networks for replication and seeding.
InterSubnetOnly	Network encryption is used on DAG networks when replicating across different subnets. This is the default setting.
SeedOnly	Network encryption is used on all DAG networks for seeding only.

DAG Network Compression

DAGs support built-in compression. When compression is enabled, DAG network communication uses XPRESS, which is the Microsoft implementation of the LZ77 algorithm. For details, see An Explanation of the Deflate Algorithm and section 3.1.7.2 "Compression Algorithm" of Wire Format Protocol Specification. This is the same type of compression

used in many Microsoft protocols, in particular, MAPI RPC compression between Microsoft Outlook and Exchange.

As with network encryption, network compression is also a property of the DAG and not a DAG network. You configure DAG network compression by using the Set-DatabaseAvailabilityGroup cmdlet in the Shell. The possible compression settings for DAG network communications are shown in the following table.

DAG network communication compression settings

Setting	Description
Disabled	Network compression isn't used.
Enabled	Network compression is used on all DAG networks for replication and seeding.
InterSubnetOnly	Network compression is used on DAG networks when replicating across different subnets. This is the default setting.
SeedOnly	Network compression is used on all DAG networks for seeding only.

Return to top

DAG Networks

A DAG network is a collection of one or more subnets used for either replication traffic or MAPI traffic. Each DAG contains a maximum of one MAPI network and zero or more replication networks. In a single network adapter configuration, the network is used for both MAPI and replication traffic. Although a single network adapter and path is supported, we recommend that each DAG have a minimum of two DAG networks. In a two-network configuration, one network is typically dedicated for replication traffic, and the other network is used primarily for MAPI traffic. You can also add network adapters to each DAG member and configure additional DAG networks as replication networks.

Note:
When using multiple replication networks, there's no way to specify an order of precedence for network use. Exchange randomly selects a replication network from the group of replication networks to use for log shipping.

You can use the New Database Availability Group Network wizard in the EMC or the **New-DatabaseAvailabilityGroupNetwork** cmdlet in the Shell to create a DAG network. For detailed steps about how to create a DAG network, see Create a Database Availability Group Network.

You can use the DAG network's **Properties** dialog box in the EMC or the **Set-DatabaseAvailabilityGroupNetwork** cmdlet in the Shell to configure DAG network properties. For detailed steps about how to configure DAG network properties, see Configure Database Availability Group Network Properties. Each DAG network has required and optional parameters to configure:

- **Network name** A unique name for the DAG network of up to 128 characters.
- **Network description** An optional description for the DAG network of up to 256 characters.
- **Network subnets** One or more subnets entered using a format of *IPAddress/Bitmask* (for example, 192.168.1.0/24 for Internet Protocol version 4 (IPv4) subnets; 2001:DB8:0:C000::/64 for Internet Protocol version 6 (IPv6) subnets).
- **Enable replication** In the EMC, select the check box to dedicate the DAG

network to replication traffic, and block MAPI traffic. Clear the check box to prevent replication from using the DAG network, and to enable MAPI traffic. In the Shell, use the *ReplicationEnabled* parameter in the Set-DatabaseAvailabilityGroupNetwork cmdlet to enable and disable replication.

Note:

Disabling replication for the MAPI network doesn't guarantee that the system won't use the MAPI network for replication. When all configured replication networks are offline, failed, or otherwise unavailable, and only the MAPI network remains (which is configured as disabled for replication), the system uses the MAPI network for replication.

The initial DAG networks (for example, DAGNetwork01 and DAGNetwork02) created by the system are based on the subnets enumerated by the Cluster service. Each DAG member must have the same number of network adapters, and each network adapter must have an IPv4 address (and optionally, an IPv6 address as well) on a unique subnet. Multiple DAG members can have IPv4 addresses on the same subnet, but each network adapter and IP address pair in a specific DAG member must be on a unique subnet. In addition, only the adapter used for the MAPI network should be configured with a default gateway. Replication networks shouldn't be configured with a default gateway.

For example, consider DAG1, a two-member DAG where each member has two network adapters (one dedicated for the MAPI network and the other for a replication network). Example IP address configuration settings are shown in the following table.

Example network adapter settings

Server-network adapter	IP address/subnet mask	Default gateway
EX1-MAPI	192.168.1.15/24	192.168.1.1
EX1-Replication	10.0.0.15/24	Not applicable
EX2-MAPI	192.168.1.16	192.168.1.1
EX2-Replication	10.0.0.16	Not applicable

In the following configuration, there are two subnets configured in the DAG: 192.168.1.0 and 10.0.0.0. When EX1 and EX2 are added to the DAG, two subnets will be enumerated and two DAG networks will be created: DAGNetwork01 (192.168.1.0) and DAGNetwork02 (10.0.0.0). These networks will be configured as shown in the following table.

Enumerated DAG network settings for a single-subnet DAG

Name	Subnets	Interfaces	MAPI access enabled	Replication enabled
DAGNetwork01	192.168.1.0/24	EX1 (192.168.1.15) EX2 (192.168.1.16)	True	True
DAGNetwork02	10.0.0.0/24	EX1 (10.0.0.15) EX2 (10.0.0.16)	False	True

To complete the configuration of DAGNetwork02 as the dedicated replication network, disable replication for DAGNetwork01 by running the following command.

```
Set-DatabaseAvailabilityGroupNetwork -Identity DAG1\DAGNetwork01 -ReplicationEnab
```

After replication is disabled for DAGNetwork01, the Microsoft Exchange Replication service

uses DAGNetwork02 for continuous replication. If DAGNetwork02 experiences a failure, the Microsoft Exchange Replication service reverts to using DAGNetwork01 for continuous replication. This is done intentionally by the system to maintain high availability.

DAG Networks and Multiple Subnet Deployments

In the preceding example, even though there are two different subnets in use by the DAG (192.168.1.0 and 10.0.0.0), the DAG is considered a single-subnet DAG because each member uses the same subnet to form the MAPI network. When DAG members use different subnets for the MAPI network, the DAG is referred to as a *multi-subnet DAG*. In a multi-subnet DAG, additional configuration of the DAG networks must be performed to associate the proper subnets with each DAG network.

For example, consider DAG2, a two-member DAG where each member has two network adapters (one dedicated for the MAPI network and the other for a replication network), and each DAG member is located in a separate Active Directory site, with its MAPI network on a different subnet. Example IP address configuration settings are shown in the following table.

Example network adapter settings for a multi-subnet DAG

Server-network adapter	IP address/subnet mask	Default gateway
EX1-MAPI	192.168.0.15/24	192.168.0.1
EX1-Replication	10.0.0.15/24	Not applicable
EX2-MAPI	192.168.1.15	192.168.1.1
EX2-Replication	10.0.1.15	Not applicable

In the following configuration, there are four subnets configured in the DAG: 192.168.0.0, 192.168.1.0, 10.0.0.0, and 10.0.1.0. When EX1 and EX2 are added to the DAG, four subnets will be enumerated and two DAG networks will be created: DAGNetwork01 (192.168.0.0), DAGNetwork02 (10.0.0.0), DAGNetwork03 (192.168.1.0), and DAGNetwork04 (10.0.1.0). These networks will be configured as shown in the following table.

Enumerated DAG network settings for a multi-subnet DAG

Name	Subnets	Interfaces	MAPI access enabled	Replication enabled
DAGNetwork01	192.168.0.0/24	EX1 (192.168.0.15)	True	True
DAGNetwork02	10.0.0.0/24	EX1 (10.0.0.15)	False	True
DAGNetwork03	192.168.1.0/24	EX2 (192.168.1.15)	True	True
DAGNetwork04	10.0.1.0/24	EX2 (10.0.1.15)	False	True

To complete the necessary configuration, DAGNetwork03 and DAGNetwork04 should be collapsed into DAGNetwork01 and DAGNetwork02, respectively. This involves adding the subnet currently associated with DAGNetwork03 to DAGNetwork01, and adding the subnet currently associated with DAGNetwork04 to DAGNetwork02. This will remove the subnet associations from DAGNetwork03 and DAGNetwork04, leaving them as empty DAG networks that can then be removed. To collapse the subnets into two DAG networks and disable replication on the MAPI network, run the following commands.

```
Set-DatabaseAvailabilityGroupNetwork -Identity DAG2\DAGNetwork01 -Subnets 192.168
Set-DatabaseAvailabilityGroupNetwork -Identity DAG2\DAGNetwork02 -Subnets 10.0.0.
```

```
Remove-DatabaseAvailabilityGroupNetwork -Identity DAG2\DAGNetwork03
Remove-DatabaseAvailabilityGroupNetwork -Identity DAG2\DAGNetwork04
```

DAG Networks and iSCSI Networks

By default, DAGs perform discovery of all networks detected and configured for use by the underlying cluster. This includes any Internet SCSI (iSCSI) networks in use as a result of using iSCSI storage for one or more DAG members. As a best practice, iSCSI storage should use dedicated networks and network adapters. These networks shouldn't be managed by the DAG or its cluster, or used as DAG networks (MAPI or replication). Instead, these networks should be manually disabled from use by the DAG, so they can be dedicated to iSCSI storage traffic. To disable iSCSI networks from being detected and used as DAG networks, configure the DAG to ignore any currently detected iSCSI networks using the Set-DatabaseAvailabilityGroupNetwork cmdlet, as shown in this example:

```
Set-DatabaseAvailabilityGroupNetwork -Identity DAG2\DAGNetwork02 -ReplicationEnab
```

This command will also disable the network for use by the cluster. Although the iSCSI networks will continue to appear as DAG networks, they will not be used for MAPI or replication traffic after running the above command.

Return to top

Configuring DAG Members

Mailbox servers that are members of a DAG have some properties specific to high availability that should be configured as described in the following sections:

- Automatic Database Mount Dial
- Database Copy Automatic Activation Policy
- Maximum Active Databases

Automatic Database Mount Dial

The *AutoDatabaseMountDial* parameter specifies the automatic database mount behavior after a database failover. You can use the Set-MailboxServer cmdlet to configure the *AutoDatabaseMountDial* parameter with any of the following values:

- `BestAvailability` If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to 12. The copy queue length is the number of logs recognized by the passive copy that needs to be replicated. If the copy queue length is more than 12, the database doesn't automatically mount. When the copy queue length is less than or equal to 12, Exchange attempts to replicate the remaining logs to the passive copy and mounts the database.
- `GoodAvailability` If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to six. The copy queue length is the number of logs recognized by the passive copy that needs to be replicated. If the copy queue length is more than six, the database doesn't automatically mount. When the copy queue length is less than or equal to six, Exchange attempts to replicate the remaining logs to the passive copy and mounts the database.
- `Lossless` If you specify this value, the database doesn't automatically mount until all logs generated on the active copy have been copied to the passive copy. This setting also causes the Active Manager best copy selection algorithm to sort potential candidates for activation based on the database copy's activation preference value and not its copy queue length.

The default value is `GoodAvailability`. If you specify either `BestAvailability` or `GoodAvailability`, and all the logs from the active copy can't be copied to the passive copy being activated, you may lose some mailbox data. However, the transport dumpster feature (which is enabled by default) helps protect against most data loss by resubmitting messages that are in the transport dumpster queue.

In addition to the preceding values, you can also configure the *AutoDatabaseMountDial* parameter with a custom value by using ADSI Edit or Ldp.exe to modify the attribute directly in Active Directory. The *AutoDatabaseMountDial* parameter is represented by the **msExchDataLossForAutoDatabaseMount** attribute of the Mailbox server object. The whole number numeric value for this attribute represents the maximum number of transaction log files you are willing to lose to mount a database without human intervention. If you configure the *AutoDatabaseMountDial* parameter with a custom value greater than 12, we recommend that you also increase the size of the transport dumpster to enable increased protection against a greater number of lost logs.

Example: Configuring Automatic Database Mount Dial

The following example configures a Mailbox server with an *AutoDatabaseMountDial* setting of `GoodAvailability`.

```
Set-MailboxServer -Identity EX1 -AutoDatabaseMountDial GoodAvailability
```

Database Copy Automatic Activation Policy

The *DatabaseCopyAutoActivationPolicy* parameter specifies the type of automatic activation available for mailbox database copies on the selected Mailbox servers. You can use the Set-MailboxServer cmdlet to configure the *DatabaseCopyAutoActivationPolicy* parameter with any of the following values:

- `Blocked` If you specify this value, databases can't be automatically activated on the selected Mailbox servers.
- `IntrasiteOnly` If you specify this value, the database copy is allowed to be activated on servers in the same Active Directory site. This prevents cross-site failover or activation. This property is for incoming mailbox database copies (for example, a passive copy being made an active copy). Databases can't be activated on this Mailbox server for database copies that are active in another Active Directory site.
- `Unrestricted` If you specify this value, there are no special restrictions on activating mailbox database copies on the selected Mailbox servers.

Example: Configuring Database Copy Automatic Activation Policy

The following example configures a Mailbox server with a *DatabaseCopyAutoActivationPolicy* setting of `Blocked`.

```
Set-MailboxServer -Identity EX1 -DatabaseCopyAutoActivationPolicy Blocked
```

Maximum Active Databases

The *MaximumActiveDatabases* parameter (also used with the Set-MailboxServer cmdlet) specifies the number of databases that can be mounted on a Mailbox server. You can configure Mailbox servers to meet your deployment requirements by ensuring that an individual Mailbox server doesn't become overloaded.

The *MaximumActiveDatabases* parameter is configured with a whole number numeric value. When the maximum number is reached, the database copies on the server won't be activated if a failover or switchover occurs. If the copies are already active on a server, the server won't allow databases to be mounted.

Example: Configuring Maximum Active Databases

The following example configures a Mailbox server to support a maximum of 20 active databases.

```
Set-MailboxServer -Identity EX1 -MaximumActiveDatabases 20
```

Return to top

Performing Maintenance on DAG Members

Before performing any type of software or hardware maintenance on a DAG member, you

should first remove the DAG member from service by using the StartDagServerMaintenance.ps1 script. This script moves all the active databases off the server and blocks active databases from moving to that server. The script also ensures that all critical DAG support functionality that may be on the server (for example, the Primary Active Manager (PAM) role) is moved to another server and blocked from moving back to the server. Specifically, the StartDagServerMaintenance.ps1 script performs the following tasks:

- Runs Suspend-MailboxDatabaseCopy with the *ActivationOnly* parameter to suspend each database copy hosted on the DAG member for activation.
- Pauses the node in the cluster, which prevents the node from being and becoming the PAM.
- Sets the value of the *DatabaseCopyAutoActivationPolicy* parameter on the DAG member to `Blocked`.
- Moves all active databases currently hosted on the DAG member to other DAG members.
- If the DAG member currently owns the default cluster group, the script moves the default cluster group (and therefore the PAM role) to another DAG member.

If any of the preceding tasks fails, all operations, except for successful database moves, are undone.

After the maintenance is complete and the DAG member is ready to return to service, you can use the StopDagServerMaintenance.ps1 script to take the DAG member out of maintenance mode and put it back into production. Specifically, the StopDagServerMaintenance.ps1 script performs the following tasks:

- Runs the Resume-MailboxDatabaseCopy cmdlet for each database copy hosted on the DAG member.
- Resumes the node in the cluster, which enables full cluster functionality for the DAG member.
- Sets the value of the *DatabaseCopyAutoActivationPolicy* parameter on the DAG member to `Unrestricted`.

Both scripts accept the *-ServerName* parameter (which can be either the host name or the fully qualified domain name (FQDN) of the DAG member) and the *-WhatIf* parameter. Both scripts can be run locally or remotely. The server on which the scripts are executed must have the Windows Failover Cluster Management tools installed (RSAT-Clustering).

Return to top

Shutting Down DAG Members

The Exchange 2010 high availability solution is integrated with the Windows shutdown process. If an administrator or application initiates a shutdown of a Windows server in a DAG that has a mounted database that's replicated to one or more DAG members, the system attempts to activate another copy of the mounted database prior to allowing the shutdown process to complete.

However, this new behavior doesn't guarantee that all of the databases on the server being shut down will experience a `lossless` activation. As a result, it's a best practice to perform a server switchover prior to shutting down a server that's a member of a DAG. For detailed steps about how to perform a server switchover, see Perform a Server Switchover.

Return to top

Installing Update Rollups on DAG Members

Installing Microsoft Exchange Server 2010 update rollups on a server that is a member of a database availability group (DAG) is a relatively straightforward process. When you install an update rollup on a server that's a member of a DAG, several services are stopped during the installation, including all Exchange services and the Cluster service. The general process for applying update rollups to a DAG member is as follows:

1. Use the StartDagServerMaintenance.ps1 script to put the DAG member in maintenance mode.
2. Install the update rollup.
3. Use the StopDagServerMaintenance.ps1 script to take the DAG member out of maintenance mode and put it back into production.
4. Use the RedistributeActiveDatabases.ps1 script to rebalance the active database copies across the DAG.

You can download the latest update rollup for Exchange 2010 from the Microsoft Download Center. For detailed steps about how to install an update rollup on a DAG member, see Installing Update Rollups on Database Availability Group Members.

1.10.4.1.1 Pre-stage the Cluster Name Object for a Database Availability Group

Pre-stage the Cluster Name Object for a Database Availability Group

High Availability and Site Resilience > Managing High Availability and Site Resilience > Managing Database Availability Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

In environments where computer account creation is restricted or where computer accounts are created in a container other than the default computers container, you can pre-stage the cluster name object (CNO) and then provision the CNO by assigning permissions to it. In addition, when deploying a database availability group (DAG) using Mailbox servers that are running Windows Server 2012, you must pre-stage and provision the CNO. Pre-staging the CNO is required for Windows Server 2012 DAG members due to permissions changes in Windows Server 2012 for computer objects. You create and disable a computer account for the CNO and then either:

- Assign full control of the computer account to the computer account of the first mailbox server you're adding to the DAG.
- Assign full control of the computer account to the Exchange Trusted Subsystem universal security group (USG).

After completing the following steps, allow time for Active Directory replication to occur. After the object is replicated, you can add the first member to the DAG.

Pre-stage the CNO

1. Open Active Directory Users and Computers.
2. Expand the forest node.
3. Right-click the organizational unit (OU) in which you want to create the new

account, select **New** and then select **Computer**.
4. In **New Object - Computer**, type the computer account name for the CNO in the **Computer name** box. This is the name that you'll use for the DAG itself. Click **OK** to create the account.
5. Right-click the new computer account, and then click **Disable Account**. Click **Yes** to confirm the disable action, and then click **OK**.

Assign permissions to the CNO

1. Open Active Directory Users and Computers.
2. If Advanced Features aren't enabled, turn them on by clicking **View**, and then clicking **Advanced Features**.
3. Right-click the new computer account, and then click **Properties**.
4. In **<Computer Name> Properties**, on the **Security** tab, click **Add** to add either the computer account for the first node to be added to the DAG or to add the Exchange Trusted Subsystem USG:
   - To add the Exchange Trusted Subsystem, type **Exchange Trusted Subsystem** in the **Enter the object names to select** field. Click **OK** to add the USG. Then select the Exchange Trusted Subsystem USG and in **Permissions for Exchange Trusted Subsystem field**, select **Full Control** in the **Allow** column. Click **OK** to save the permission settings.
   - To add the computer account for the first node to be added to the DAG, click **Object Types**. In the **Object Types** dialog box, clear the **Built-in security principals**, **Groups**, and **Users** check boxes. Select the **Computers** check box. Click **OK**. In the **Enter the object names to select** field, type the name of the first Mailbox server to be added to the DAG, and then click **OK**. Then, select the first node's computer account, and in the **Permissions for <NodeName>** field, select **Full Control** in the **Allow** column. Click **OK** to save the permission settings.

1.10.4.1.2 Create a Database Availability Group

Create a Database Availability Group

High Availability and Site Resilience > Managing High Availability and Site Resilience > Managing Database Availability Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

A database availability group (DAG) is a set of up to 16 Microsoft Exchange Server 2010 Mailbox servers that provide automatic database-level recovery from a database, server, or network failure. Mailbox servers in a DAG monitor each other for failures. When a Mailbox server is added to a DAG, it works with the other servers in the DAG to provide automatic, database-level recovery from database, server, and network failures.

When creating a DAG, you provide a unique name for the DAG of up to 15 characters. In addition to providing a name for the DAG, you must also assign one or more IP addresses (either IPv4 or both IPv4 and IPv6) to the DAG. The IP addresses you assign must be on the subnet intended for the MAPI network and must be available for use. You can assign static IP addresses to the DAG by using the *DatabaseAvailabilityGroupIpAddresses* parameter. If you use the Exchange Management Console (EMC) to create the DAG, or if you use the **New-DatabaseAvailabilityGroup** cmdlet without the *DatabaseAvailabilityGroupIpAddresses* parameter, the task will configure the DAG to use Dynamic Host Configuration Protocol (DHCP) to obtain the necessary IPv4 addresses. If

you don't want the DAG to use DHCP, you can use the **Set-DatabaseAvailabilityGroup** cmdlet to configure one or more IP addresses for the DAG after it has been created. If your system is configured to use IPv6, the task will also attempt to automatically assign the DAG one or more IPv6 addresses.

Optionally, you can also specify a witness server and witness directory. If you do specify a witness server, we recommend that you use a Hub Transport server. This allows an Exchange administrator to be aware of the availability of the witness.

The following combinations of options and behaviors are available:

- You can specify only a name for the DAG and leave the **Witness Server** and **Witness Directory** check boxes cleared. In this scenario, the wizard will search for a Hub Transport server that doesn't have the Mailbox server role installed. It will automatically create the default directory and share on that Hub Transport server and use that server as the witness server.
- You can specify a name for the DAG, the witness server that you want to use, and the directory you want created and shared on the witness server.
- You can specify a name for the DAG and the witness server that you want to use, and leave the **Witness Directory** check box cleared. In this scenario, the wizard will create the default directory on the specified witness server.
- You can specify a name for the DAG, leave the **Witness Server** check box cleared, and specify the directory you want created and shared on the witness server. In this scenario, the wizard will search for a Hub Transport server that doesn't have the Mailbox server role installed, and it will automatically create the specified directory on that server, share the directory, and use that Hub Transport server as the witness server.

Important:

If the witness server you specify isn't an Exchange 2010 server, you must add the Exchange Trusted Subsystem universal security group to the local Administrators group on the witness server. These security permissions are necessary to ensure that Exchange can create a directory and share on the witness server as needed. If the proper permissions aren't configured, the following error is returned:
Error: An error occurred during discovery of the database availability group topology. Error: An error occurred while attempting a cluster operation. Error: Cluster API "AddClusterNode() (MaxPercentage=12) failed with 0x80070005. Error: Access is denied."

When creating a DAG with Mailbox servers running Windows Server 2012, you must pre-stage the cluster name object (CNO) before adding members to the DAG. For detailed steps, see Pre-stage the Cluster Name Object for a Database Availability Group.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

What Do You Want to Do?

- Use the EMC to create a database availability group
- Use the Shell to create a database availability group

Use the EMC to create a database availability group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability groups" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Database Availability Group**.

3. On the **New Database Availability Group** page, provide the following information for the new DAG:
   - **Database availability group name** Use this box to type a valid and unique name for the DAG of up to 15 characters. The name is equivalent to a computer name, and a corresponding Cluster Name Object (CNO) will be created in Active Directory with the name of the DAG. The name of the DAG isn't used by end users or administrators. It is used only by the system for internal communication and to secure the DAG.
   - **Witness Server** Select this check box and use the corresponding text box to specify a witness server for the DAG. If you don't select this check box, the system will attempt to automatically select a Hub Transport server that doesn't have the Mailbox server role installed to be used as the witness server.

     Note:
     If you specify a witness server, you must use either a host name or a fully-qualified domain name (FQDN). Using an IP address or a wildcard name isn't supported. In addition, the witness server cannot be a member of the DAG.
   - **Witness Directory** Select this check box and use the corresponding text box to type the path to a directory that will be used to store witness data. If the directory doesn't exist, the system will create it for you on the witness server. If you don't select this check box, the default directory will be created on the witness server.
4. Click **New** to create the database availability group.
5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to close the wizard.

After you create a DAG, it will be configured to use DHCP. If you don't want the DAG to use DHCP, you can use the **Set-DatabaseAvailabilityGroup** cmdlet to configure one or more IP addresses for the DAG.

Use the Shell to create a database availability group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability groups" entry in the High Availability Permissions topic.

This example creates a DAG named DAG1 that is configured to use the witness server EXHUB1 and the local directory C:\DAG1. DAG1 is also configured to use DHCP for the DAG's IP addresses.

```
New-DatabaseAvailabilityGroup -Name DAG1 -WitnessServer EXHUB1 -WitnessDirectory
```

This example creates a DAG named DAG2. The system will automatically select a Hub Transport server that doesn't have the Mailbox server role installed in the same site as the DAG to use as the witness server. DAG2 is assigned a single static IP address because all members are on the same subnet.

```
New-DatabaseAvailabilityGroup -Name DAG2 -DatabaseAvailabilityGroupIPAddresses 10
```

This example creates a DAG named DAG3. DAG3 is configured to use the witness server EXHUB2 and the local directory C:\DAG3. DAG3 is assigned multiple static IP addresses because its members are or will be on different subnets.

```
New-DatabaseAvailabilityGroup -Name DAG3 -WitnessServer EXHUB2 -WitnessDirectory
```

This example creates a w DAG named DAG4 that is configured to use DHCP. In addition, the witness server will be automatically selected by the system and the default witness directory will be created.

```
New-DatabaseAvailabilityGroup -Name DAG4
```

1.10.4.1.3 Configure Database Availability Group Properties

Configure Database Availability Group Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-23*

You can use the Exchange Management Console (EMC) or the Exchange Management Shell to configure the properties of a database availability group (DAG), including the *witness* server and directory used by the DAG. The Shell enables you to configure DAG properties that are not available in EMC, network discovery and settings, the TCP port used for replication, and datacenter activation coordination (DAC) mode.

DAG property values are stored in both Active Directory and the cluster database. However, some properties are stored on in the cluster database. As a result, the underlying cluster for the DAG must be up and running and have quorum in order to set the properties for:

- ReplicationPort
- NetworkCompression
- NetworkEncryption
- DiscoverNetworks

What Do You Want to Do?

- Use the EMC to configure database availability group properties

Use the EMC to configure database availability group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the" Database availability group" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Availability Group** tab, right-click the DAG you want to configure, and then click **Properties**.
3. Use the **General** tab to view DAG membership, configure the DAG's witness server, and to configure network encryption and compression for the DAG networks.
   - **Modified** This read-only field displays the date and time at which the DAG's properties were last changed.
   - **Member servers** This read-only field displays the Mailbox servers that are members of the DAG.
   - **Witness Server** This box displays the host name or fully-qualified domain name (FQDN) of a server that's external to the DAG that is used when the DAG contains an even number of members.
   - **Witness Directory** This box displays the full name and path of the directory used to store the witness.log file on the witness server.
   - **Alternate Witness Server** This box displays the host name or FQDN of a server that's external to the DAG and is used as a replacement for the witness server during a datacenter switchover process.
   - **Alternate Witness Directory** This box displays the name of the directory used to store the witness.log file on the alternate witness server.
4. Use the **IP Addresses** tab to view and modify the IP addresses assigned to the DAG.
   - **Add** Click this button to add a static IPv4 address to the DAG.
   - **Edit** Select an existing IPv4 address and then click this button to modify it.
   -  Select one or more existing IPv4 addresses and then click this button to remove them from them DAG.
5. Use the **Operational Servers** tab to view the list of DAG members that are currently operational.

Use the Shell to configure database availability group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability group" entry in the High Availability Permissions topic.

This example sets the witness directory to C:\DAG1DIR for a DAG named DAG1.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -WitnessDirectory C:\DAG1DIR
```

This example pre-configures an alternate witness server of EXHUB3 and an alternate witness directory of C:\DAGFileShareWitnesses\DAG1.contoso.com for a DAG named DAG1.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -AlternateWitnessDirectory C:\DAGFil
```

This example configures a DAG named DAG1 to use DHCP to obtain an IP address.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -DatabaseAvailabilityGroupIPAddresse
```

This example configures a DAG named DAG1 to use a static IP address of 10.0.0.8.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -DatabaseAvailabilityGroupIPAddresse
```

This example configures a multi-subnet DAG named DAG1 with multiple static IP addresses.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -DatabaseAvailabilityGroupIPAddresse
```

This example configures a DAG named DAG1 for datacenter activation mode.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -DatacenterActivationMode DagOnly
```

This example configures the replication port for a DAG named DAG1 to be 63132.

```
Set-DatabaseAvailabilityGroup -Identity DAG1 -ReplicationPort 63132
```

Note:
After changing the default replication port for a DAG, you must manually modify the Windows Firewall exceptions on each member of the DAG to allow communication to occur over the specified port.

1.10.4.1.4 Manage Database Availability Group Membership

Manage Database Availability Group Membership

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-09*

When you add a server to a database availability group (DAG), it works with the other servers in the DAG to provide automatic, database-level recovery from database, server, or network failures. When you remove a server from a DAG, it is no longer automatically protected from failures.

DAGs use Windows Failover Clustering (WFC) technologies. Each Mailbox server that is a member of a DAG is also a node in the underlying cluster that is used by the DAG. As a

result, at any given time, a Mailbox server can be a member of only one DAG.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

Prerequisites

- A DAG has been created. For detailed steps, see Create a Database Availability Group.
- Because DAGs use WFC technology, all servers added to a DAG must be running either Windows Server 2008 Service Pack 2 (SP2) Enterprise Edition or Windows Server 2008 R2 Enterprise Edition.
- All servers in a DAG must be running the same operating system. You can't have DAG members that are running Windows Server 2008 SP2 and others that are running Windows Server 2008 R2.
- If you're adding Mailbox servers running Windows Server 2012, you must pre-stage the cluster name object (CNO) for the DAG. For detailed steps, see Pre-stage the Cluster Name Object for a Database Availability Group.
- You must remove all replicated database copies from the server before you can remove it from a DAG.

What Do You Want to Do?

- Use the EMC to manage database availability group membership
- Use the Shell to manage database availability group membership

Use the EMC to manage database availability group membership

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability groups" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Availability Group** tab, right-click the DAG you want to manage, and then click **Manage Database Availability Group Membership**.
3. On the **Manage Database Availability Group Membership** page, you can perform the following tasks.
   - To add a local server to the DAG, click **Add** and then use the **Select Mailbox Server** dialog box to select the server you want.
   - To remove a local server from the DAG, select a server from the list of members, and the click  .
4. Click **Manage** to perform the configured management action (adding or removing a server).
5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to manage database

availability group membership

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability groups" entry in the High Availability Permissions topic.

This example adds a Mailbox server named MBX1 to a DAG named DAG1.

```
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX1
```

This example removes a Mailbox server named MBX1 from a DAG named DAG1. Before running this command, make sure that no replicated databases exist on the Mailbox server.

```
Remove-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX1
```

This example removes the configuration settings for Mailbox server named MBX4 from a DAG named DAG2. MBX4 is expected to be offline for an extended period, so its configuration is being removed from the DAG while it is offline in order to establish quorum with the remaining online DAG members.

```
Remove-DatabaseAvailabilityGroupServer -Identity DAG2 -MailboxServer MBX4 -Config
```

Add-DatabaseAvailabilityGroupServer

Remove-DatabaseAvailabilityGroupServer

1.10.4.1.5 Recover a Database Availability Group Member Server

Recover a Database Availability Group Member Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-06-08*

If a Mailbox server that's a member of a database availability group (DAG) is lost or otherwise fails and is unrecoverable and needs replacement, you can perform a server recovery operation. Microsoft Exchange Server 2010 Setup includes the switch **/m:RecoverServer** that can be used to perform the server recovery operation. Running Setup with the **/m:RecoverServer** switch causes Setup to read the server's configuration information from Active Directory for a server with the same name as the server from which you're running Setup. After the server's configuration information is gathered from Active Directory, the original Exchange files and services are then installed on the server, and the roles and settings that were stored in Active Directory are then applied to the server.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

Note:

If Exchange is installed in a location other than the default location, you must use the **/TargetDir** Setup switch to specify the location of the Exchange program files. If you don't

use the **/TargetDir** switch, the Exchange program files will be installed in the default location (%programfiles%\Microsoft\Exchange Server\V14).
To determine the install location, follow these steps:

1. Open ADSIEDIT.MSC or LDP.EXE.
2. Navigate to the following location:
   CN=ExServerName,CN=Servers,CN=First Administrative Group,CN=Administrative Groups,CN=ExOrg Name,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=DomainName,CN=Com
3. Right-click the Exchange server object, and then click **Properties**.
4. Locate the **msExchInstallPath** attribute. This attribute stores the current installation path.

Use Setup /m:RecoverServer to recover a server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

1. Retrieve any replay lag or truncation lag settings for any mailbox database copies that exist on the server being recovered by using the Get-MailboxDatabase cmdlet.

```
Get-MailboxDatabase DB1 | Format-List *lag*
```

2. Remove any mailbox database copies that exist on the server being recovered by using the Remove-MailboxDatabaseCopy cmdlet.

```
Remove-MailboxDatabaseCopy DB1\MBX1
```

3. Remove the failed server's configuration from the DAG by using the Remove-DatabaseAvailabilityGroupServer cmdlet.

```
Remove-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer M
```

Note:
If the DAG member being removed is offline and cannot be brought online, you must add the *ConfigurationOnly* parameter to the above command.

1. Reset the server's computer account in Active Directory. For detailed steps, see Reset a Computer Account.
2. Open a Command Prompt window. Using the original Setup media, run the following command.

```
Setup /m:RecoverServer
```

3. When the Setup recovery process is complete, add the recovered server to the DAG by using the Add-DatabaseAvailabilityGroupServer cmdlet.

```
Add-DatabaseAvailabilityGroupServer -Identity DAG1 -MailboxServer MBX1
```

4. After the server has been added back to the DAG, you can reconfigure mailbox database copies by using the Add-MailboxDatabaseCopy cmdlet. If any of the database copies being added previously had replay lag or truncation lag times greater than 0, you can use the *ReplayLagTime* and *TruncationLagTime* parameters of the Add-MailboxDatabaseCopy cmdlet to reconfigure those settings.

```
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX1
Add-MailboxDatabaseCopy -Identity DB2 -MailboxServer MBX1 -ReplayLagTi
Add-MailboxDatabaseCopy -Identity DB3 -MailboxServer MBX1 -ReplayLagTi
```

Create a Database Availability Group Network

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can create multiple networks in a database availability group (DAG) and dedicate them for client access or for replication purposes.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

What Do You Want to Do?

- Use the EMC to create a database availability group network
- Use the Shell to create a database availability group network

Use the EMC to create a database availability group network

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability group" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Availability Group** tab.
3. Right-click the DAG for which you want to create the new network, and then click **New Database Availability Group Network**. You can also select the DAG and then click **New Database Availability Group Network** in the action pane.
4. On the **New Database Availability Group Network** page, provide the following configuration information for the new DAG network.
   - **Network name** Provide a unique name for the DAG network (a name that doesn't conflict with the name of any other DAG network). The limit is 128 characters.
   - **Network description** Provide an optional description for the DAG network. The limit is 256 characters.
   - **Database Availability Group network subnets** Click **Add** to add each network subnet to the DAG network. Subnets should be entered using a format of IP address/bitmask (for example, 192.168.1.0/24 for IPv4 subnets; 2001:DB8:0:C000::/54 for IPv6 subnets). If you add a subnet that's currently associated with another DAG network, the subnet will be removed from the other DAG network and associated with the network being created.
   - **Enable replication** Select this check box to enable the DAG network for use by replication. When a DAG network is enabled for replication, MAPI traffic is restricted on that network. Clear this check box to prevent replication from using the DAG network and to enable MAPI traffic on that network.
5. Click **New** to create the DAG network.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task

successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

7. Click **Finish** to close the wizard.

Use the Shell to create a database availability group network

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability group" entry in the High Availability Permissions topic.

In this example, the network DagNet1 is being created with a subnet of 10.0.0.0 and a bitmask of 8 in a DAG named DAG1. Replication is enabled for the network, and an optional description of the network is also being added.

```
New-DatabaseAvailabilityGroupNetwork -DatabaseAvailabilityGroup DAG1 -Name DagNet
```

For More Information

Set-DatabaseAvailabilityGroupNetwork

Get-DatabaseAvailabilityGroupNetwork

New-DatabaseAvailabilityGroupNetwork

Remove-DatabaseAvailabilityGroupNetwork

1.10.4.1.7 Configure Database Availability Group Network Properties

Configure Database Availability Group Network Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Each database availability group (DAG) network has several properties that you can configure, including the name of the DAG network, a description field for the DAG network, a list of subnets that are used by the DAG network, and whether or not the DAG network is enabled for replication.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

What Do You Want to Do?

- Use the EMC to configure database availability group network properties
- Use the Shell to configure database availability group network properties

Use the EMC to configure database

availability group network properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the" database availability group" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Availability Group** tab, select the DAG you want.
3. In the work pane, on the **Networks** tab, right-click the DAG network you want, and then click **Properties**.
4. Use the **General** tab to configure DAG network properties.
   - The top field contains the name of the DAG network. Each DAG network name must be unique and can't contain more than 128 characters.
   - **Description of this network** Use this box to provide an optional description of up to 256 characters for the DAG network.
   - **Edit subnets for this network** Each DAG network must contain at least one subnet. Subnets using should be added using a format of IPAddress/Bitmask (for example, 192.168.1.0/24 for IPv4 subnets; 2001:DB8:0:C000::/54 for IPv6 subnets).
   - **Enable replication** Leave this check box checked to enable replication traffic on the DAG network. When a DAG network is enabled for replication, MAPI traffic is restricted on that network. Clear this check box to prevent the DAG network from being used for replication (provided one or more replication networks are available) and to enable MAPI traffic on that network.

Use the Shell to configure database availability group network properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the" database availability group" entry in the High Availability Permissions topic.

In this example, a DAG network in a DAG named DAG1 is being renamed from its default network of DAGNetwork01 to a new name of CRNET1.

```
Set-DatabaseAvailabilityGroupNetwork -Name DAGNET1 -Identity DAG1\DAGNetwork01
```

In this example, a subnet of 10.0.0.0 and subnet mask of 255.0.0.0 is being added to a DAG network named DAGNET1 in a DAG named DAG1.

```
Set-DatabaseAvailabilityGroupNetwork -Subnets 10.0.0.0/8 -Identity DAG1\DAGNET1
```

For More Information

Set-DatabaseAvailabilityGroupNetwork

Get-DatabaseAvailabilityGroupNetwork

Remove-DatabaseAvailabilityGroupNetwork

1.10.4.1.8 Remove a Database Availability Group

Remove a Database Availability Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Before you can remove a database availability group (DAG), the DAG must be empty. If the DAG you want to remove contains any Mailbox servers, you must first remove the servers from the DAG. For detailed steps about how to remove a Mailbox server from a DAG, see Manage Database Availability Group Membership.

Looking for other management tasks related to DAGs? Check out Managing Database Availability Groups.

Use the EMC to remove a database availability group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Database availability groups" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Availability Group** tab, right-click the DAG you want to remove, and then click **Remove**.
3. Click **Yes** to confirm the action and remove the DAG.

Use the Shell to remove a database availability group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Database availability groups" entry in the High Availability Permissions topic.

This example removes a DAG named DAG1.

```
Remove-DatabaseAvailabilityGroup -Identity DAG1 -Confirm:$False
```

1.10.4.2 Managing Mailbox Database Copies

Managing Mailbox Database Copies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-03*

Database mobility is a new architecture in Microsoft Exchange Server 2010 that removes the concept of storage groups and uncouples the Exchange 2010 mailbox database from Mailbox servers. Because storage groups have been removed from Exchange 2010, continuous replication now operates at the database level. In Exchange 2010, transaction

logs are replicated to one or more Mailbox servers in a database availability group (DAG), and replayed into one or more copies of a mailbox database stored on those servers. Several concepts used in Exchange Server 2007 continuous replication remain in Exchange 2010. These include the concepts of divergence, the use of the automatic database mount dial, and the use of public and private networks.

Managing Database Copies

After multiple copies of a database are created, you can use the Exchange Management Console (EMC) and the Exchange Management Shell to monitor the health and status of each copy and to perform other management tasks associated with database copies. Some of the management tasks you may need to perform include suspending or resuming a database copy, seeding a database copy, monitoring database copies, configuring database copy settings, and removing a database copy.

Suspending and Resuming Database Copies

For a variety of reasons, such as performing planned maintenance, it may be necessary to suspend and resume continuous replication activity for a database copy. In addition, some administrative tasks, such as seeding, require you to first suspend a database copy. We also recommend that all replication activity be suspended when the path for the database or its log files is being changed. You can suspend and resume database copy activity by using the EMC, or by running the **Suspend-MailboxDatabaseCopy** and **Resume-MailboxDatabaseCopy** cmdlets in the Shell. For detailed steps to suspend or resume continuous replication activity for a database copy, see Suspend or Resume a Mailbox Database Copy.

Log truncation doesn't occur on the active mailbox database copy when one or more passive copies are suspended. If your planned maintenance activities are going to take an extended period of time (for example, several days), you may have considerable log file buildup. To prevent the log drive from filling up with transaction logs, you can remove the affected passive database copy instead of suspending it. When the planned maintenance is completed, you can re-add the passive database copy.

Seeding a Database Copy

Seeding, also known as *updating*, is the process in which a database, either a blank database or a copy of the production database, is added to the target copy location on another Mailbox server in the same DAG as the active database. This becomes the baseline database for the copy maintained by that server.

Depending on the situation, seeding can be an automatic process or a manual process that you initiate. When a database copy is added, the copy will be automatically seeded, provided that the target server and its storage are properly configured. If you want to manually seed a database copy and don't want automatic seeding to occur when creating the copy, you can use the *SeedingPostponed* parameter when running the Add-MailboxDatabaseCopy cmdlet.

Database copies rarely need to be reseeded after the initial seeding has occurred. But if reseeding is necessary, or if you want to manually seed a database copy instead of having the system automatically seed the copy, these tasks can be performed by using the Update Database Copy wizard in the EMC or by using the Update-MailboxDatabaseCopy cmdlet in the Shell. Before seeding a database copy, you must first suspend the mailbox database copy. For detailed steps to seed a database copy, see Update a Mailbox Database Copy.

After a manual seed operation has completed, replication for the seeded mailbox database copy is automatically resumed. If you don't want replication to automatically resume, you can use the *ManualResume* parameter when running the Update-MailboxDatabaseCopy cmdlet.

Choosing What to Seed

When performing a seed operation, you can choose to seed the mailbox database copy, the content index catalog for the mailbox database copy, or both the database copy and the content index catalog copy. The default behavior of the Update Database Copy wizard and the Update-MailboxDatabaseCopy cmdlet is to seed both the mailbox database copy and the content index catalog copy. To seed just the mailbox database copy without seeding the content index catalog, use the *DatabaseOnly* parameter when running the Update-MailboxDatabaseCopy cmdlet. To seed just the content index catalog copy, use the *CatalogOnly* parameter when running the Update-MailboxDatabaseCopy cmdlet.

Selecting the Seeding Source

In Exchange 2007, continuous replication could only seed a database copy by copying the active copy of the database. In Exchange 2010, any healthy database copy can be used as the seeding source for an additional copy of that database. This is particularly useful when you have a DAG that has been extended across multiple physical locations. For example, consider a four-member DAG deployment, where two members (MBX1 and MBX2) are located in Portland, Oregon and two members (MBX3 and MBX4) are located in New York, New York. A mailbox database named DB1 is active on MBX1 and there are passive copies of DB1 on MBX2 and MBX3. When adding a copy of DB1 to MBX4, you have the option of using the copy on MBX3 as the source for seeding, and in doing so, you avoid seeding over the wide area network (WAN) link between Portland and New York.

To use a specific copy as a source for seeding when adding a new database copy, you would do the following:

- Use the *SeedingPostponed* parameter when running the Add-MailboxDatabaseCopy cmdlet to add the database copy. If the *SeedingPostponed* parameter isn't used, the database copy will be explicitly seeded using the active copy of the database as the source.
- Use the *SourceServer* parameter when running the Update-MailboxDatabaseCopy cmdlet and specify the desired source server for seeding. In the preceding example, you would specify MBX3 as the source server. If the *SourceServer* parameter isn't used, the database copy will be explicitly seeded using the active copy of the database as the source.

Seeding and Networks

In addition to selecting a specific source server for seeding a mailbox database copy, you can also specify which DAG networks to use, and optionally override the DAG network's compression and encryption settings during the seed operation.

To specify the networks you want to use for seeding, use the *Network* parameter when running the Update-MailboxDatabaseCopy cmdlet and specify the DAG networks that you want to use. If you don't use the *Network* parameter, the system uses the following default behavior for selecting a network to use for the seeding operation:

- If the source server and target server are on the same subnet and a replication network has been configured that includes the subnet, the replication network will be used.
- If the source server and target server are on different subnets, even if a replication network that contains those subnets has been configured, the client (MAPI) network will be used for seeding.
- If the source server and target server are in different datacenters, the client (MAPI) network will be used for seeding.

At the DAG level, DAG networks are configured for encryption and compression. The default settings are to use encryption and compression only for communications on different subnets. If the source and target are on different subnets and the DAG is configured with the default values for *NetworkCompression* and *NetworkEncryption*, you can override these values by using the *NetworkCompressionOverride* and *NetworkEncryptionOverride* parameters, respectively, when running the Update-

MailboxDatabaseCopy cmdlet.

Seeding Process

When you initiate a seeding process by using the Add-MailboxDatabaseCopy or Update-MailboxDatabaseCopy cmdlets, the following tasks are performed:

1. Database properties from Active Directory are read to validate the specified database and servers, and to verify that the source and target servers are running Exchange 2010, they are both members of the same DAG, and that the specified database isn't a recovery database. The database file paths are also read.
2. Preparations occur for reseed checks from the Microsoft Exchange Replication service on the target server.
3. The Microsoft Exchange Replication service on the target server checks for the presence of database and transaction log files in the file directories read by the Active Directory checks in step 1.
4. The Microsoft Exchange Replication service returns the status information from the target server to the administrative interface from where the cmdlet was run.
5. If all preliminary checks have passed, you are prompted to confirm the operation before continuing. If you confirm the operation, the process continues. If an error is encountered during the preliminary checks, the error is reported and the operation fails.
6. The seed operation is started from the Microsoft Exchange Replication service on the target server.
7. The Microsoft Exchange Replication service suspends database replication for the active database copy.
8. The state information for the database is updated by the Microsoft Exchange Replication service to reflect a status of Seeding.
9. If the target server doesn't already have the directories for the target database and log files, they are created.
10. A request to seed the database is passed from the Microsoft Exchange Replication service on the target server to the Microsoft Exchange Replication service on the source server using TCP. This request and the subsequent communications for seeding the database occur on a DAG network that has been configured as a replication network.
11. The Microsoft Exchange Replication service on the source server initiates an Extensible Storage Engine (ESE) streaming backup via the Microsoft Exchange Information Store service interface.
12. The Microsoft Exchange Information Store service streams the database data to the Microsoft Exchange Replication service.
13. The database data is moved from the source server's Microsoft Exchange Replication service to the target server's Microsoft Exchange Replication service.
14. The Microsoft Exchange Replication service on the target server writes the database copy to a temporary directory located in the main database directory called **temp-seeding**.
15. The streaming backup operation on the source server ends when the end of the database is reached.
16. The write operation on the target server completes and the database is moved from the temp-seeding directory to the final location. The temp-seeding directory is deleted.
17. On the target server, the Microsoft Exchange Replication service proxies a request to the Microsoft Exchange Search service to mount the content index catalog for the database copy, if it exists. If there are existing out-of-date catalog files from a previous instance of the database copy, the mount operation fails, which triggers the need to replicate the catalog from the source server. Likewise, if the catalog doesn't exist, and it doesn't on a new instance of the database copy on the target server, a copy of the catalog is required. The Microsoft Exchange Replication service directs the Microsoft Exchange Search service to suspend indexing for the database copy while a

new catalog is copied from the source.
18. The Microsoft Exchange Replication service on the target server sends a seed catalog request to the Microsoft Exchange Replication service on the source server.
19. On the source server, the Microsoft Exchange Replication service requests the directory information from the Microsoft Exchange Search service and requests that indexing be suspended.
20. The Microsoft Exchange Search service on the source server returns the search catalog directory information to the Microsoft Exchange Replication service.
21. The Microsoft Exchange Replication service on the source server reads the catalog files from the directory.
22. The Microsoft Exchange Replication service on the source server moves the catalog data to the Microsoft Exchange Replication service on the target server using a connection across the replication network. After the read is complete, the Microsoft Exchange Replication service sends a request to the Microsoft Exchange Search service to resume indexing of the source database.
23. If there are any existing catalog files on the target server in the directory, the Microsoft Exchange Replication service on the target server deletes them.
24. The Microsoft Exchange Replication service on the target server writes the catalog data to a temporary directory called **CiSeed.Temp** until the data is completely transferred.
25. The Microsoft Exchange Replication service moves the complete catalog data to the final location.
26. The Microsoft Exchange Replication service on the target server resumes search indexing on the target database.
27. The Microsoft Exchange Replication service on the target server returns a completion status.
28. The final result of the operation is passed to the administrative interface from which the cmdlet was called.

Configuring Database Copies

After a database copy is created, you can view and modify its configuration settings when needed. You can view some configuration information by examining the **Properties** page for a database copy in the EMC. You can also use the Get-MailboxDatabase and Set-MailboxDatabaseCopy cmdlets in the Shell to view and configure database copy settings, such as replay lag time, truncation lag time, and activation preference order. For detailed steps to view and configure database copy settings, see Configure Mailbox Database Copy Properties.

Using Replay Lag and Truncation Lag Options

Mailbox database copies support the use of a *replay lag time* and a *truncation lag time*, both of which are configured in minutes. Setting a replay lag time enables you to take a database copy back to a specific point in time. Setting a truncation lag time enables you to use the logs on a passive database copy to recover from the loss of log files on the active database copy. Because both of these features result in the temporary build-up of log files, using either of them will affect your storage design.

Replay Lag Time

Replay lag time is a property of a mailbox database copy that specifies the amount of time, in minutes, to delay log replay for the database copy. The replay lag timer starts when a log file has been replicated to the passive copy and has successfully passed inspection. By delaying the replay of logs to the database copy, you have the capability to recover the database to a specific point in time in the past. A mailbox database copy configured with a replay lag time greater than 0 is referred to as a *lagged mailbox database copy*, or simply, a *lagged copy*.

A strategy that uses database copies and the litigation hold features in Exchange 2010 can provide protection against a range of failures that would ordinarily cause data loss.

However, these features can't provide protection against data loss in the event of logical corruption, which although rare, can cause data loss. Lagged copies are designed to prevent loss of data in the case of logical corruption. Generally, there are two types of logical corruption:

- **Database logical corruption** The database pages checksum matches, but the data on the pages is wrong logically. This can occur when ESE attempts to write a database page and even though the operating system returns a success message, the data is either never written to the disk or it's written to the wrong place. This is referred to as a *lost flush*. To prevent lost flushes from losing data, ESE includes a lost flush detection mechanism in the database along with a page patching feature (single page restore).
- **Store logical corruption** Data is added, deleted, or manipulated in a way that the user doesn't expect. These cases are generally caused by third-party applications. It is generally only corruption in the sense that the user views it as corruption. The Exchange store considers the transaction that produced the logical corruption to be a series of valid MAPI operations. The litigation hold feature in Exchange 2010 provides protection from store logical corruption (because it prevents content from being permanently deleted by a user or application). However, there may be scenarios where a user mailbox becomes so corrupted that it would be easier to restore the database to a point in time prior to the corruption, and then export the user mailbox to retrieve uncorrupted data.

The combination of database copies, hold policy, and ESE single page restore leaves only the rare but catastrophic store logical corruption case. Your decision on whether to use a database copy with a replay lag (a lagged copy) will depend on which third-party applications you use and your organization's history with store logical corruption.

If you choose to use lagged copies, be aware of the following implications for their use:

- Unlike standby continuous replication (SCR) in Exchange 2007, which had a hard-coded replay lag of 50 log files, there's no hard-coded number of lagged log files. Instead, the replay lag time is an administrator-configured value, and by default, it's disabled.
- The replay lag time setting has a default setting of 0 days, and a maximum setting of 14 days.
- Lagged copies aren't considered highly available copies. Instead, they are designed for disaster recovery purposes, to protect against store logical corruption.
- The greater the replay lag time, the longer the database recovery process. Depending on the number of log files that need to replayed during recovery, and the speed at which your hardware can replay them, it may take several hours or more to recover a database.
- We recommend that you determine whether lagged copies are critical for your overall disaster recovery strategy. If using them is critical to your strategy, we recommend using multiple lagged copies, or using a redundant array of independent disks (RAID) to protect a single lagged copy, if you don't have multiple lagged copies. If you lose a disk or if corruption occurs, you don't lose your lagged point in time.
- Lagged copies aren't patchable with the ESE single page restore feature. If a lagged copy encounters database page corruption (for example, a -1018 error), it will have to be reseeded (which will lose the lagged aspect of the copy).

Activating and recovering a lagged mailbox database copy is an easy process if you want the database to replay all log files and make the database copy current. If you want to replay log files up to a specific point in time, it's a more difficult operation because you manually manipulate log files and run the Eseutil tool.

For detailed steps to activate a lagged mailbox database copy, see Activate a Lagged Mailbox Database Copy.

Truncation Lag Time

Truncation lag time is a property of a mailbox database copy that specifies the amount of time, in minutes, to delay log deletion for the database copy after the log file has been replayed into the database copy. The truncation lag timer starts when a log file has been replicated to the passive copy, and successfully passed inspection, and has been successfully replayed into the copy of the database. By delaying the truncation of log files from the database copy, you have the capability to recover from failures that affect the log files for the active copy of the database.

Database Copies and Log Truncation

Log truncation works the same in Exchange 2010 as it did in Exchange 2007. Truncation behavior is determined by the replay lag time and truncation lag time settings for the copy.

The following criteria must be met for a database copy's log file to be truncated when lag settings are left at their default values of 0 (disabled):

- The log file must have been successfully backed up, or circular logging must be enabled.
- The log file must be below the checkpoint (the minimum log file required for recovery) for the database.
- All other lagged copies must have inspected the log file.
- All other copies (not lagged copies) must have replayed the log file.

The following criteria must be met for truncation to occur for a lagged database copy:

- The log file must be below the checkpoint for the database.
- The log file must be older than ReplayLagTime + TruncationLagTime.
- The log file must have been truncated on the active copy.

Database Activation Policy

There are scenarios in which you may want to create a mailbox database copy and prevent the system from automatically activating that copy in the event of a failure. For example:

- If you deploy one or more mailbox database copies to a second or standby data center.
- If you configure a database copy as a lagged copy for recovery purposes.
- If you are performing maintenance or an upgrade of a server.

In each of the preceding scenarios, you have database copies that you don't want the system to activate automatically. To prevent the system from automatically activating a mailbox database copy, you can configure the copy to be blocked (suspended) for activation. This allows the system to maintain the currency of the database through log shipping and replay, but prevents the system from automatically activating and using the copy. Copies blocked for activation must be manually activated by an administrator. You can configure the database activation policy by using the Set-MailboxServer cmdlet to set the *DatabaseCopyAutoActivationPolicy* parameter to Blocked.

For more information about configuring database activation policy, see Configure Activation Policy for a Mailbox Database Copy.

Effect of Mailbox Moves on Continuous Replication

On a very busy mailbox database with a high log generation rate, there is a greater chance for data loss if replication to the passive database copies can’t keep up with log generation. One scenario that can introduce a high log generation rate is mailbox moves. Exchange 2010 includes a Data Guarantee API that is used by services such as the Mailbox Replication Service (MRS) to check the health of the database copy architecture based on the value of the *DataMoveReplicationConstraint* parameter that was set by the

system or an administrator. Specifically, the Data Guarantee API can be used to:

- **Check replication health** Confirms that the prerequisite number of database copies is available.
- **Check replication flush** Confirms that the required log files have been replayed against the prerequisite number of database copies.

When executed, the API returns the following status information to the calling application:

- **Retry** Signifies that there are transient errors that prevent a condition from being checked against the database.
- **Satisfied** Signifies that the database meets the required conditions or the database isn't replicated.
- **NotSatisfied** Signifies that the database doesn't meet the required conditions. In addition, information is provided to the calling application as to why the **NotSatisfied** response was returned.

The value of the *DataMoveReplicationConstraint* parameter for the mailbox database determines how many database copies should be evaluated as part of the request. The *DataMoveReplicationConstraint* parameter has the following possible values:

- `None` When you create a mailbox database, this value is set by default. When this value is set, the Data Guarantee API conditions are ignored. This setting should be used only for mailbox databases that aren't replicated.
- `SecondCopy` This is the default value when you add the second copy of a mailbox database. When this value is set, at least one passive database copy must meet the Data Guarantee API conditions.
- `SecondDatacenter` When this value is set, at least one passive database copy in another Active Directory site must meet the Data Guarantee API conditions.
- `AllDatacenters` When this value is set, at least one passive database copy in each Active Directory site must meet the Data Guarantee API conditions.
  `AllCopies` When this value is set, all copies of the mailbox database must meet the Data Guarantee API conditions.

Check Replication Health

When the Data Guarantee API is executed to evaluate the health of the database copy infrastructure, several items are evaluated.

If the *DataMoveReplicationConstraint* parameter is set to...	**Then, for a given database...**	**Conditions**
`SecondCopy`	At least one passive database copy for a replicated database must meet the conditions in the next column.	The passive database copy must: • Be healthy. • Have a replay queue within 10 minutes of the replay lag time. • Have a copy queue length less than 10 logs. • Have an average copy queue length less than 10 logs. The average copy queue length is computed based on the number of times the application has queried the database status.
`SecondDatacenter`	At least one passive database copy in another Active Directory	

	site must meet the conditions in the next column.	
AllDatacenters	The active copy must be mounted, and a passive copy in each Active Directory site must meet the conditions in the next column.	
AllCopies	The active copy must be mounted, and all passive database copies must meet the conditions in the next column.	

Check Replication Flush

The Data Guarantee API can also be used to validate that a prerequisite number of database copies have replayed the required transaction logs. This is verified by comparing the last log replayed timestamp with that of the calling service's commit timestamp (in most cases, this is the timestamp of the last log file that contains required data) plus an additional five seconds (to deal with system time clock skews or drift). If the replay timestamp is greater than the commit timestamp, then the *DataMoveReplicationConstraint* parameter is satisfied. If the replay timestamp is less than the commit timestamp, then the *DataMoveReplicationConstraint* isn't satisfied.

Before moving large numbers of mailboxes to or from replication databases within a DAG, we recommend that you configure the *DataMoveReplicationConstraint* parameter on each mailbox database according to the following:

If you are deploying...	Set DataMoveReplicationConstraint to...
Mailbox databases that do not have any database copies	None
A DAG within a single Active Directory site	SecondCopy
A DAG in multiple datacenters using a stretched Active Directory site	SecondCopy
A DAG that spans two Active Directory sites, and you will have highly available database copies in each site	SecondDatacenter
A DAG that spans two Active Directory sites, and you will have only lagged database copies in the second site SecondCopy	SecondCopy This is because the Data Guarantee API will not guarantee data being committed until the log file is replayed into the database copy and due to the nature of the database copy being lagged this constraint will fail the move request, unless the lagged database copy ReplayLagTime value is less than 30 minutes.
A DAG that spans three or more Active Directory sites, and each site will contain highly available database copies	AllDatacenters

Balancing Database Copies

Due to the inherent nature of DAGs, as the result of database switchovers and failovers, active mailbox database copies will change hosts several times throughout a DAG's lifetime. As a result, DAGs can become unbalanced in terms of active mailbox database copy distribution. The following table shows an example of a DAG that has four databases with four copies of each database (for a total of 16 databases on each server) with an uneven distribution of active database copies.

DAG with unbalanced active copy distribution

Server	Number of active database	Number of passive databases	Number of mounted databases	Number of dismounted databases	Preference count list
EX1	5	11	5	0	4, 4, 3, 5
EX2	1	15	1	0	1, 8, 6, 1
EX3	12	4	12	0	13, 2, 1, 0
EX4	1	15	1	0	1, 1, 5, 9

In the preceding example, there are four copies of each database, and therefore, only four possible values for activation preference (1, 2, 3, or 4). The **Preference count list** column shows the count of the number of databases with each of these values. For example, on EX3, there are 13 database copies with an activation preference of 1, two copies with an activation preference of 2, one copy with an activation preference of 3, and no copies with an activation preference of 4.

As you can see, this DAG is not balanced in terms of the number of active databases hosted by each DAG member, the number of passive databases hosted by each DAG member, or the activation preference count of the hosted databases.

You can use the RedistributeActiveDatabases.ps1 script to balance the active mailbox databases copies across a DAG. This script moves databases between their copies in an attempt to have an equal number of mounted databases on each server in DAG. If required, the script also attempts to balance active databases across sites.

The script provides two options for balancing active database copies within a DAG:

- **BalanceDbsByActivationPreference** When this option is specified, the script attempts to move databases to their most preferred copy (based on Activation Preference) without regard to Active Directory site.
- **BalanceDbsBySiteAndActivationPreference** When this option is specified, the script attempts to move active databases to their most preferred copy, while also trying to balance active databases within each Active Directory site.

After running the script with the first option, the preceding unbalanced DAG becomes balanced, as shown in the following table.

DAG with balanced active copy distribution

Server	Number of active database	Number of passive databases	Number of mounted databases	Number of dismounted databases	Preference count list
EX1	4	12	4	0	4, 4, 4, 4
EX2	4	12	4	0	4, 4, 4, 4
EX3	4	12	4	0	4, 4, 4, 4
EX4	4	12	4	0	4, 4, 4, 4

As shown in the preceding table, this DAG is now balanced in terms of number of active and passive databases on each server and activation preference across the servers.

The following table lists the available parameters for the RedistributeActiveDatabases.ps1 script.

RedistributeActiveDatabases.ps1 script parameters

Parameter	Description
DagName	Specifies the name of the DAG you want to rebalance. If this parameter is omitted, the DAG of which the local server is a member is used.
BalanceDbsByActivationPreference	Specifies that the script should move databases to their most preferred copy without regard to Active Directory site.
BalanceDbsBySiteAndActivationPreference	Specifies that the script should attempt to move active databases to their most preferred copy, while also trying to balance active databases within each Active Directory site.
ShowFinalDatabaseDistribution	Specifies that a report of current database distribution be displayed after redistribution is complete.
AllowedDeviationFromMeanPercentage	Specifies the allowed variation of active databases across sites, expressed as a percentage. The default is 20%. For example, if there were 99 databases distributed between three sites, the ideal distribution would be 33 databases in each site. If the allowed deviation is 20%, the script attempts to balance the databases so that each site has no more than 10% more or less than this number. 10% of 33 is 3.3, which is rounded up to 4. Therefore, the script attempts to have between 29 and 37 databases in each site.
ShowDatabaseCurrentActives	Specifies that the script produce a report for each database detailing how the database was moved and whether it is now active on its most-preferred copy.
ShowDatabaseDistributionByServer	Specifies that the script produce a report for each server showing its database distribution.
RunOnlyOnPAM	Specifies that the script run only on the DAG member that currently has the PAM role. The script verifies it is being run from the PAM. If it is not being run from the PAM, the script exits.
LogEvents	Specifies that the script logs an event (MsExchangeRepl event 4115) containing a summary of the actions.

IncludeNonReplicatedDatabases	Specifies that the script should include non-replicated databases (databases without copies) when determining how to redistribute the active databases. Although non-replicated databases can't be moved, they may affect the distribution of the replicated databases.
Confirm	The Confirm switch can be used to suppress the confirmation prompt that appears by default when this script is run. To suppress the confirmation prompt, use the syntax -Confirm:$False. You must include a colon (:) in the syntax.

RedistributeActiveDatabases.ps1 Examples

This example shows the current database distribution for a DAG, including preference count list.

```
RedistributeActiveDatabases.ps1 -DagName DAG1 -ShowDatabaseDistributionByServer |
```

This example redistributes and balances the active mailbox database copies in a DAG using activation preference without prompting for input.

```
RedistributeActiveDatabases.ps1 -DagName DAG1 -BalanceDbsByActivationPreference -
```

This example redistributes and balances the active mailbox database copies in a DAG using activation preference, and produces a summary of the distribution.

```
RedistributeActiveDatabases.ps1 -DagName DAG1 -BalanceDbsByActivationPreference -
```

Monitoring Database Copies

A database copy is your first defense if a failure occurs that affects the active copy of a database. It is therefore critical to monitor the health and status of database copies to ensure that they will be available when needed. You can view some health and status information by examining the **Properties** page for a database copy in the EMC. You can also use the **Get-MailboxDatabaseCopyStatus** cmdlet in the Shell to view a variety of status information for a database copy.

For more information about monitoring database copies, see Monitoring High Availability and Site Resilience.

Removing a Database Copy

A database copy can be removed at any time by using the EMC or by using the **Remove-MailboxDatabaseCopy** cmdlet in the Shell. After removing a database copy, you must manually delete any database and transaction log files from the server from which the database copy is being removed. For detailed steps to remove a database copy, see Remove a Mailbox Database Copy.

Database Switchovers

The Mailbox server that hosts the active copy of a database is referred to as the *mailbox database master*. The process of activating a passive database copy changes the mailbox database master for the database and turns the passive copy into the new active copy. This process is called a database *switchover*. In a database switchover, the active copy of a database is dismounted on one Mailbox server and a passive copy of that database is mounted as the new active mailbox database on another Mailbox server. When performing a switchover, you can optionally override the database mount dial setting on the new mailbox database master.

You can quickly identify which Mailbox server is the current mailbox database master by reviewing the **Copy Status** column under the **Database Copies** tab in the EMC. Only the active copy will have a status of **Mounted**. All other database copies will display the current status of replication for the database copy. You can perform a switchover by using the Move Mailbox Database Master wizard in the EMC, or by using the **Move-ActiveMailboxDatabase** cmdlet in the Shell.

There are several internal checks that will be performed before activating a passive copy:

- The status of the database copy is checked. If the database copy is in a failed state, the switchover is blocked. You can override this behavior and bypass the health check by using the *SkipHealthChecks* parameter of the **Move-ActiveMailboxDatabase** cmdlet. This parameter allows you to move the active copy to a database copy in a failed state.
- The active database copy is checked to see if it is currently a seeding source for any passive copies of the database. If the active copy is currently being used as a source for seeding, the switchover is blocked. You can override this behavior and bypass the seeding source check by using the *SkipActiveCopyChecks* parameter of the **Move-ActiveMailboxDatabase** cmdlet. This parameter allows you to move an active copy that is being used as a seeding source. Using this parameter will cause the seeding operation to be cancelled and considered failed.
- The copy queue and replay queue lengths for the database copy are checked to ensure their values are within the configured criteria. Also, the database copy is verified to ensure that it isn't currently in use as a source for seeding. If the values for the queue lengths are outside the configured criteria, or if the database is currently used as a source for seeding, the switchover is blocked. You can override this behavior and bypass these checks by using the *SkipLagChecks* parameter of the **Move-ActiveMailboxDatabase** cmdlet. This parameter allows a copy to be activated that has replay and copy queues outside of the configured criteria.
- The state of the search catalog (content index) for the database copy is checked. If the search catalog isn't up to date, is in an unhealthy state, or is corrupt, the switchover is blocked. You can override this behavior and bypass the search catalog check by using the *SkipClientExperienceChecks* parameter of the **Move-ActiveMailboxDatabase** cmdlet. This parameter causes this search to skip the catalog health check. If the search catalog for the database copy you are activating is in an unhealthy or unusable state and you use this parameter to skip the catalog health check and activate the database copy, you will need to either crawl or seed the search catalog again.

When performing a database switchover, you also have the option of overriding the mount dial settings configured for the server that hosts the passive database copy being activated. Using the *MountDialOverride* parameter of the **Move-ActiveMailboxDatabase** cmdlet instructs the target server to override its own mount dial settings and use those specified by the *MountDialOverride* parameter.

For detailed steps to perform a switchover of a database copy, see Move the Active Mailbox Database. For more information about database switchovers, see Switchovers and Failovers.

1.10.4.2.1 Add a Mailbox Database Copy

Add a Mailbox Database Copy

High Availability and Site Resilience > Managing High Availability and Site Resilience > Managing Mailbox Database Copies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-10*

When you add a copy of a mailbox database, continuous replication is automatically enabled between the existing database and the database copy. Database copies are automatically assigned an identity in the format of *<DatabaseName>* *<HostMailboxServerName>*. For example, a copy of a database named DB1 that's hosted on a server named MBX3 would be named DB1\MBX3.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Prerequisites

- The active copy of the mailbox database must be mounted.
- The specified database must be a mailbox database. You can't use continuous replication for public folder databases. For public folder database availability, we recommend deploying multiple public folder databases and using public folder replication. For more information, see Understanding Public Folder Replication.
- The specified Mailbox server must not already host a copy of the specified mailbox database.
- The path for the specified mailbox database and its log files must be available on the specified Mailbox server.
- The server hosting the specified database and the server that will host the database copy must both be in the same database availability group (DAG). The DAG must also have quorum and be healthy.
- If you're adding the second copy of a database (for example, creating the first passive copy of the database), circular logging must not be enabled for the specified mailbox database. If circular logging is enabled, you must first disable it. After the mailbox database copy has been added, circular logging can be enabled. After circular logging is enabled for a replicated mailbox database, continuous replication circular logging (CRCL) is used instead of JET circular logging. If you're adding the third or subsequent copy of a database, CRCL can remain enabled. For information about how to enable and disable circular logging, see Configure Mailbox Database Properties.

What Do You Want to Do?

- Use the EMC to add a mailbox database copy
- Use the Shell to add a mailbox database copy

Use the EMC to add a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copy" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, right-click the mailbox database that you want to copy, and then click **Add Mailbox Database Copy**.
3. On the **Add Mailbox Database Copy** page, complete the following fields.
   - **Mailbox database name** This read-only box displays the name of the database for which you are going to make a copy.

- **Server name** Click **Browse** to open the **Select Mailbox Server** dialog box. Use this dialog box to select the Mailbox server that will host the copy of the mailbox database, and then click **OK**.

  Note:
  The **Select Mailbox Server** dialog displays all Mailbox servers. You must select a Mailbox server that it is in the same DAG as the Mailbox server hosting the active copy.

- **Activation preference number** Use this box to specify the activation preference number for the database copy. The activation preference number is used as part of Active Manager's best copy selection process and to redistribute active mailbox databases throughout the DAG when using the RedistributeActiveDatabases.ps1 script. The value for the activation preference is a number equal to or greater than 1, where 1 is at the top of the preference order. The position number cannot be larger than the number of copies of the mailbox database.

4. Click **Add** to add the copy of the mailbox database.

5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to close the wizard.

Use the Shell to add a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copy" entry in the High Availability Permissions topic.

In this example, a copy of mailbox database DB1 is being added to a Mailbox server named MBX3. Replay lag time and truncation lag time are left at the default values of zero, and the activation preference is configured with a value of 2.

```
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX3 -ActivationPreference 2
```

In this example, a copy of mailbox database DB2 is being added to a Mailbox server named MBX4. Replay lag time and truncation lag time are left at the default values of zero, and the activation preference is configured with a value of 5. In addition, seeding is being postponed for this copy so that it can be seeded using a local source server instead of the current active database copy, which is geographically distant from MBX4.

```
Add-MailboxDatabaseCopy -Identity DB2 -MailboxServer MBX4 -ActivationPreference 5
```

In this example, a copy of mailbox database DB3 is being added to a Mailbox server named MBX5. Replay lag time is set to 3 days, and truncation lag time is left at the default value of zero, and the activation preference is configured with a value of 4.

```
Add-MailboxDatabaseCopy -Identity DB3 -MailboxServer MBX5 -ReplayLagTime 3.00:00:
```

Managing Mailbox Database Copies

1.10.4.2.2 Configure Mailbox Database Copy Properties

Configure Mailbox Database Copy Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Each mailbox database copy has its own properties that you can configure. These include the amount of time, if any, for replay lag and truncation lag, and the activation preference number. For more information about replay lag, truncation lag and the activation preference number, see Managing Mailbox Database Copies.

What Do You Want to Do?

Use the EMC to configure mailbox database copy properties

Use the Shell to configure mailbox database copy properties

Use the EMC to configure mailbox database copy properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the database with the copy whose status you want to check.
3. In the work pane, on the **Database Copies** tab, right-click the database copy whose status you want to view, and then click **Properties**.
4. Use the **General** tab to view status about the mailbox database copy, and to configure for replay lag and truncation lag, and the activation preference number.
   - **Database** This is a read-only field that displays the name of the selected database.
   - **Mailbox server** This is a read-only field that displays the name of the mailbox server that currently hosts the active copy of the mailbox database.
   - **Status** This is a read-only field that displays the current status of the selected database or database copy.
   - **Copy queue length (logs)** Indicates the number of log files waiting to be copied and inspected.
   - **Replay queue length (logs)** Indicates the number of log files waiting to be replayed into this copy of the database.
   - **Activation preference number** The activation preference number is used as part of Active Manager's best copy selection process and to redistribute active mailbox databases throughout the DAG when using the RedistributeActiveDatabases.ps1 script. The value for activation preference

is a number equal to or greater than 1, where 1 is at the top of the preference order. The number cannot be larger than the number of database copies of the mailbox database.

5. Use the **Status** tab to view additional details about the health and status of replication for the database copy.
   - **Seeding** Indicates whether a seeding operation is currently in progress.
   - **Messages** If any failures have occurred, the **View** button is made available. Click this button to view messages about conditions that triggered the failure.
   - **Latest available log time** The time associated with the latest available log generated by the active database copy. This log is available to be copied.
   - **Last inspected log time** The modification time of the last log that was successfully validated by the Mailbox server hosting the database copy.
   - **Last copied log time** The modification time of the last log that was successfully copied.
   - **Last replayed log time** The modification time of the last log that was successfully replayed by the Mailbox server hosting the database copy.

Use the Shell to configure mailbox database copy properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

This example configures a mailbox database copy with an activation preference number of 3.

```
Set-MailboxDatabaseCopy -Identity DB3\EX3 -ActivationPreference 3
```

This example configures a copy of a database named DB1 that is hosted on Server1 with a replay lag time and truncation lag time of 1 day, and an activation preference number of 2.

```
Set-MailboxDatabaseCopy -Identity DB1\Server1 -ReplayLagTime 1.0:0:0 -TruncationL
```

This example returns information about the health and status of replication for a database named DB3 on a server named EX3. This provides the same information as the **General** tab on the **Mailbox Database Properties** page, except it does not display the activation preference number.

```
Get-MailboxDatabaseCopyStatus DB3\EX3
```

This example returns information about the health and status of replication for a database named DB7 on a server named EX5.

```
Get-MailboxDatabaseCopyStatus DB7\EX5 | Format-List
```

This example returns status and Hub Transport shadow redundancy information for a database named DB2. The status results are displayed in a list format.

```
Get-MailboxDatabaseCopyStatus -Identity DB2 -DumpsterStatistics | Format-List
```

This example returns the status and Hub Transport shadow redundancy information for all database copies on a Mailbox server named MBX2. The status results are also displayed in a list format.

```
Get-MailboxDatabaseCopyStatus -Server MBX2 -DumpsterStatistics | Format-List
```

Set-MailboxDatabaseCopy

Get-MailboxDatabaseCopyStatus

Get-MailboxDatabase

1.10.4.2.3 Move the Mailbox Database Path for a Mailbox Database Copy

Move the Mailbox Database Path for a Mailbox Database Copy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

After a mailbox database is created, you can move it to another volume, folder, location, or path by using either the EMC or the Shell. For step-by-step instructions about how to move a mailbox database path, see Move the Database Path. That topic provides information about how to move a non-replicated mailbox database to another path.

If the mailbox database being moved is replicated to one or more mailbox database copies, you must follow the procedure in this topic to move the mailbox database path. All copies of a mailbox database must be located in the same path on each server that hosts a copy. For example, if database DB1 is located at C:\mountpoints\DB1 on server EX1, copies of DB1 on servers EX2, EX3, and so on, must also be located at C:\mountpoints\DB1.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Prerequisites

- To perform the move operation, the database must be temporarily dismounted, making it inaccessible to all users. If the database is currently dismounted, it isn't remounted upon completion.
- To perform the move operation, replication for the database must be disabled for all copies. It's not enough to suspend replication; you must disable it by using the Remove-MailboxDatabaseCopy cmdlet to remove the database copies.

Use the Shell to move a replicated mailbox database to a new path

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

Note:

You can't use the EMC to move a replicated mailbox database to a new path.

1. Note any replay lag or truncation lag settings for all copies of the mailbox database being moved. You can obtain this information by using the Get-

MailboxDatabase cmdlet, as shown in this example.

```
Get-MailboxDatabase DB1 | fl *lag*
```

2. If circular logging is enabled for the database, it must be disabled before proceeding. You can disable circular logging for a mailbox database by using the Set-MailboxDatabase cmdlet, as shown in this example.

```
Set-MailboxDatabase DB1 -CircularLoggingEnabled $false
```

3. Remove all mailbox database copies for the database being moved. For detailed steps, see Remove a Mailbox Database Copy. After all copies are removed, preserve the database and transaction log files from each server from which the database copy is being removed by moving them to another location. These files are being be preserved so the database copies to not require re-seeding after they have been re-added.
4. Move the mailbox database path to the new location. For detailed steps, see Move the Database Path.

Important:

During the move operation, the database being moved must be dismounted. Until the move is complete, this process will cause an interruption in service and an outage for all users with mailboxes on the database being moved. After the move operation completes, the database is automatically mounted.

5. Create the necessary folder structure on each Mailbox server that previously contained a passive copy of the moved mailbox database. For example, if you moved the database to C:\mountpoints\DB1, you must create this same path on each Mailbox server that will host a mailbox database copy.
6. After creating the folder structure, move the passive copy of the mailbox database and its log stream to the new location. These are the files that were left from and preserved after Step 3. Repeat this process for each database copy that was removed in Step 3.
7. Add all of the database copies that were removed in Step 3. For detailed steps, see Add a Mailbox Database Copy.
8. On each server that contains a copy of the mailbox database being moved, run the following commands to stop and restart the content index services.

```
Net stop msftesql-Exchange
Net start MSExchangeSearch
```

9. Optionally, enable circular logging by using the Set-MailboxDatabase cmdlet, as shown in this example.

```
Set-MailboxDatabase DB1 -CircularLoggingEnabled $true
```

10. Reconfigure any previously set values for replay lag time and truncation lag time by using the Set-MailboxDatabaseCopy cmdlet, as shown in this example.

```
Set-MailboxDatabaseCopy DB1\MBX2 -ReplayLagTime 00:15:00
```

11. As each copy is added, we recommend that you verify the health and status of the copy prior to adding the next copy. You can verify the health and status by:
    - 11.a. Examining the event log for any error or warning events related to the database or the database copy.
    - 11.b. Using the Get-MailboxDatabaseCopyStatus cmdlet to check the health and status of continuous replication for the database copy.
    - 11.c. Using the Test-ReplicationHealth cmdlet to verify the health and status of the database availability group and continuous replication.

For detailed syntax and parameter information, see the following topics:

- Get-MailboxDatabase
- Set-MailboxDatabase
- Set-MailboxDatabaseCopy
- Get-MailboxDatabaseCopyStatus
- Test-ReplicationHealth

1.10.4.2.4 Configure Activation Policy for a Mailbox Database Copy

Configure Activation Policy for a Mailbox Database Copy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Activation is the process of changing a mailbox database copy from a *passive copy* to an *active copy*. Activation occurs automatically as part of a database or server failover operation, and it can be performed manually as part of a database or server switchover operation. Blocking a database for activation prevents it from becoming the active copy during a database or server failover.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Use the Shell to suspend or resume a database for activation

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

Note:

You can't use the EMC to suspend or resume a database for activation.

This example blocks the copy of the database DB1 on the server MBX2 for activation.

```
Suspend-MailboxDatabaseCopy -Identity DB1\MBX2 -ActivationOnly
```

This example resumes the copy of the database DB1 on the server MBX2 for activation.

```
Resume-MailboxDatabaseCopy -Identity DB1\MBX2
```

For detailed syntax and parameter information, see Suspend-MailboxDatabaseCopy or Resume-MailboxDatabaseCopy.

1.10.4.2.5 Suspend or Resume a Mailbox Database Copy

Suspend or Resume a Mailbox Database Copy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

These procedures show you how to suspend and resume continuous replication activity for a *mailbox database copy*. You may need to suspend continuous replication for a database copy for a variety of reasons, such as maintenance on the disk that contains a database copy.

Note:
After a database copy has been resumed, the Summary Copy Status for the database copy will display a status of Initializing until a log file has been generated by the active copy of the database.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Use the EMC to suspend a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the database whose copy you want to suspend.
3. In the work pane, on the **Database Copies** tab, right-click the database for which you want to suspend continuous replication, and then click **Suspend Database Copy**.
4. Add an optional comment of up to 430 characters in the **Comment** field.
5. Click **Yes** to suspend continuous replication.

Use the EMC to resume a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the database whose copy you want to resume.
3. In the work pane, on the **Database Copies** tab, right-click the database for which you want to resume continuous replication, and then click **Resume Database Copy**.
4. Optionally review any comments in the read-only **Comment** field.
5. Click **Yes** to resume continuous replication.

Use the Shell to suspend a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

This example suspends continuous replication for a copy of a database named DB1 that is hosted on a server named MBX3. An optional comment has also been specified.

```
Suspend-MailboxDatabaseCopy -Identity DB1\MBX3 -SuspendComment "Maintenance on EX
```

Use the Shell to resume a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

This example resumes a copy of a database named DB1 on a server named MBX3.

```
Resume-MailboxDatabaseCopy -Identity DB1\MBX3
```

This example resumes a copy of a database named DB1 on a server named EX1 for replication only.

```
Resume-MailboxDatabaseCopy -Identity DB1\EX1 -ReplicationOnly
```

1.10.4.2.6 Update a Mailbox Database Copy

Update a Mailbox Database Copy

High Availability and Site Resilience > Managing High Availability and Site Resilience > Managing Mailbox Database Copies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Updating, also known as *seeding*, is the process in which a copy of a mailbox database is added to another Mailbox server. This becomes the baseline database for the copy. Seeding is required under the following conditions:

- When a new passive copy of a database is created. Seeding can be postponed for a new mailbox database copy, but eventually, each passive database copy must be seeded in order to function as a redundant database copy.
- After a failover occurs in which data is lost as a result of the passive database copy having become diverged and unrecoverable.
- When the system has detected a corrupted log file that cannot be replayed into the passive copy of the database.
- After an offline defragmentation of any copy of the database occurs.
- After the log generation sequence for the database has been reset back to 1.

You can perform seeding by using the following methods:

- **Automatic seeding** An automatic seed produces a copy of the active database on the target mailbox server. Automatic seeding only occurs during the creation of a new database.
- **Seeding using the Update-MailboxDatabaseCopy cmdlet** You can use the Update-MailboxDatabaseCopy cmdlet in the Exchange Management Shell to seed a database copy at any time.
- **Seeding using the Update Database Copy wizard** You can use the **Update Database Copy** wizard in the Exchange Management Console (EMC) to seed a database copy at any time.
- **Manually copying the offline database** You can dismount the active copy of the database and copy the database file to the same location on another mailbox server in the same database availability group. If you use this method, there will be an interruption in service because the procedure requires you to dismount the database.

Updating a database copy can take a very long time, especially if the database being copied is very large, or if there is high network latency or low network bandwidth. Once the seeding process has started, don't close the EMC or the Shell until the process has completed. If you do, the seeding operation will be terminated.

A database copy can be seeded using either the active copy or an up-to-date passive copy as the source for the seed. When seeding from a passive copy, be aware that the seed operation will terminate with a network communication error under the following circumstances:

- If the status of the seeding source copy changes to Failed or FailedAndSuspended.
- If the database fails over to another copy.

Multiple database copies can be seeded simultaneously. However, when seeding multiple copies simultaneously, you must seed only the database file, and omit the content index catalog. You can do this by using the *DatabaseOnly* parameter with the Update-MailboxDatabaseCopy cmdlet.

Note:

If you do not use the *DatabaseOnly* parameter when seeding multiple targets from the same source, the task will fail with SeedInProgressException error FE1C6491.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Prerequisites

- The mailbox database copy must be suspended. For detailed steps, see Suspend or Resume a Mailbox Database Copy.
- The Remote Registry service must be running on the server hosting the passive database copy you're updating.

What Do You Want to Do?

- Use the EMC to update a mailbox database copy
- Use the Shell to update a mailbox database copy
- Manually copy an offline database

Use the EMC to update a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab.
3. In the work pane, on the **Database Copies** tab, right-click the database copy you want to update, and then select **Update Database Copy**.
4. On the **Update Database Copy** page, configure the available options for updating a database copy:
   - By default, the active copy of the database is used as the source database for seeding. If you prefer to use a passive copy of the database for seeding, check the Select a source server for seeding checkbox, and then click **Browse** to select the server containing the passive copy you want to use for the source.

- Configure the task's behavior if files exist in the path of the database copy being seeded. If any existing files are in the database path, you can either select **Delete them and continue to update process** to remove all existing files and proceed with the seeding operation, or you can select **Cancel the update process** to terminate the task.
- By default, once seeding has completed, continuous replication will automatically resume for the database. If you don't want replication to automatically resume, select **Leave the database copy suspended. I will manually resume replication later**.
- Optionally specify a DAG network to be used for seeding. Click **Browse** to select the DAG network you want to use.

5. Once you have configured the available options, click **Update** to update the database copy.

6. On the **Completion** page, the **Summary** states whether the operation was successful. The summary also displays the Shell command that was used to perform this procedure.
7. Click **Finish** to exit the wizard.

Use the Shell to update a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

This example shows how to seed a copy of a database named DB1 on MBX1.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1
```

This example shows how to seed a copy of a database named DB1 on MBX1 using MBX2 as the source Mailbox server for the seed.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1 -SourceServer MBX2
```

This example shows how to seed a copy of a database named DB1 on MBX1 without seeding the content index catalog.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1 -DatabaseOnly
```

This example shows how to seed the content index catalog for the copy of a database named DB1 on MBX1 without seeding the database file.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1 -CatalogOnly
```

Manually copy an offline database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

1. If circular logging is enabled for the database, it must be disabled before proceeding. You can disable circular logging for a mailbox database by using the Set-MailboxDatabase cmdlet, as shown in this example.

   ```
   Set-MailboxDatabase DB1 -CircularLoggingEnabled $false
   ```

2. Dismount the database. You can use the Dismount-Database cmdlet, as shown in this example.

   ```
   Dismount-Database DB1 -Confirm $false
   ```

3. Manually copy the database files (the database file and all log files) to a

second location, such as an external disk drive or a network share.

4. Mount the database. You can use the Mount-Database cmdlet, as shown in this example.

```
Mount-Database DB1
```

5. On the server that will host the copy, copy the database files from the external drive or network share to the same path as the active database copy. For example, if the active copy database path is D:\DB1\DB1.edb and log file path is D:\DB1, then you would copy the database files to D:\DB1 on the server that will host the copy.
6. Add the mailbox database copy by using the Add-MailboxDatabaseCopy cmdlet with the *SeedingPostponed* parameter, as shown in this example.

```
Add-MailboxDatabaseCopy -Identity DB1 -MailboxServer MBX3 -SeedingPost
```

7. If circular logging is enabled for the database, enable it again by using the Set-MailboxDatabase cmdlet, as shown in this example.

```
Set-MailboxDatabase DB1 -CircularLoggingEnabled $true
```

1.10.4.2.7 Remove a Mailbox Database Copy

Remove a Mailbox Database Copy

High Availability and Site Resilience > Managing High Availability and Site Resilience > Managing Mailbox Database Copies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

These procedures show you how to remove a copy of a mailbox database. You cannot use these procedures to remove the last copy of a mailbox database. For detailed steps about how to remove the last copy of a mailbox database, see Remove a Mailbox Database or Remove-MailboxDatabase. Mailbox database copies can only be removed from a healthy database availability group (DAG). If the DAG isn't healthy (for example, the DAG's underlying cluster is down because quorum was lost), you won't be able to remove any mailbox database copies.

In addition, if you're removing the last passive copy of the database, continuous replication circular logging (CRCL) must not be enabled for the specified mailbox database. If CRCL is enabled, you must first disable it. After the mailbox database copy has been removed, circular logging can be enabled. Once enabled for a non-replicated mailbox database, JET circular logging is used instead of CRCL. If you aren't removing the last passive copy of a database, CRCL can remain enabled.

After removing a database copy, you must manually delete any database and transaction log files from the server from which the database copy is being removed.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Use the EMC to remove a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the mailbox database whose copy you want to remove.
3. In the work pane, on the **Database Copies** tab, right-click the database copy that you want to remove, and then click **Remove**.
4. Click **Yes** to remove the database copy.

Use the Shell to remove a mailbox database copy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "mailbox database copies" entry in the High Availability Permissions topic.

This example removes a copy of a mailbox database named DB1 from a Mailbox server named MBX3.

```
Remove-MailboxDatabaseCopy -Identity DB1\MBX3 -Confirm:$False
```

1.10.4.2.8 Move the Active Mailbox Database

Move the Active Mailbox Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Moving the active mailbox database is the process of designating a specific passive copy as the new active copy of a mailbox database. This process is referred to as a *database switchover*. A database switchover involves dismounting the current active database and mounting the database copy on the specified server as the new active mailbox database copy. The database copy that will become the active mailbox database must be healthy and current.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

What Do You Want to Do?

- Use the EMC to move the active mailbox database
- Use the Shell to move the active mailbox database

Use the EMC to move the active mailbox database

There are two ways you can use the EMC to move the active mailbox database. You can use the Move Active Mailbox Database wizard or you can use the Activate Database Copy option in the work pane.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability

Permissions topic.

Use the Move Active Mailbox Database wizard

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab, and then right-click the mailbox database whose copy you want to activate.
3. In the action pane, click **Move Active Mailbox Database**.
4. On the **Move Active Mailbox Database** page, click **Browse** to select the server you want to host the active copy of the database.
5. Select the desired setting for the automatic database mount dial setting on the server that you specified in the previous step.
6. In the **Override automatic database mount dial setting on the target mailbox server** list, optionally override the database mount dial settings on target master by selecting a value other than **None**. Possible values are:
   - **Lossless** If you specify this value, the database doesn't automatically mount until all logs that were generated on the active copy have been copied to the passive copy.
   - **Good Availability** If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to 6. If the copy queue length is greater than 6, the database doesn't automatically mount. When the copy queue length is less than or equal to 6, Exchange attempts to replicate the remaining logs to the passive copy and then mounts the database.
   - **Best Effort** If you specify this value, the database automatically mounts regardless of the size of the copy queue length. We recommend using caution when using this setting. Because the database will mount with any amount of log loss, using this value could result in a large amount of data loss.
   - **Best Availability** If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to 12. The copy queue length is the number of logs recognized by the passive copy that needs to be replicated. If the copy queue length is more than 12, the database doesn't automatically mount. When the copy queue length is less than or equal to 12, Exchange attempts to replicate the remaining logs to the passive copy and then mounts the database.
7. Click **Move** to move the active copy of the selected database to the specified server.
8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the work pane

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab, and then click the mailbox database whose copy you want to activate
3. In the **Database Copies** work pane, right-click the passive mailbox database copy that you want to activate, and then click **Activate Database Copy**.
4. In **Activate Database Copy**, you can use the **Override mount dial** list to optionally override the database mount dial settings on target master by selecting a value other than **None**. Possible values are:
   - **Lossless** If you specify this value, the database doesn't automatically mount until all logs that were generated on the active copy have been copied to the passive copy.

- **Good Availability** If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to 6. If the copy queue length is greater than 6, the database doesn't automatically mount. When the copy queue length is less than or equal to 6, Exchange attempts to replicate the remaining logs to the passive copy and then mounts the database.
- **Best Effort** If you specify this value, the database automatically mounts regardless of the size of the copy queue length. Because the database will mount with any amount of log loss, using this value could result in a large amount of data loss.
- **Best Availability** If you specify this value, the database automatically mounts immediately after a failover if the copy queue length is less than or equal to 12. The copy queue length is the number of logs recognized by the passive copy that needs to be replicated. If the copy queue length is more than 12, the database doesn't automatically mount. When the copy queue length is less than or equal to 12, Exchange attempts to replicate the remaining logs to the passive copy and then mounts the database.

5. Click **OK** to activate the passive copy. This action dismounts the current active mailbox database and makes the selected passive copy the new active mailbox database.

Use the Shell to Move the Active Mailbox Database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

In this example, a copy of the database DB4 hosted on MBX3 is activated and mounted as the new active mailbox database. This command makes DB4 the new active mailbox database and it doesn't override the database mount dial settings on MBX3.

```
Move-ActiveMailboxDatabase DB4 -ActivateOnServer MBX3 -MountDialOverride:None
```

This example performs a switchover of the database DB2 to the Mailbox server MBX1. When the command completes, MBX1 hosts the active copy of DB2. Because the *MountDialOverride* parameter is set to None, MBX1 mounts the database using its own defined database auto mount dial settings.

```
Move-ActiveMailboxDatabase DB2 -ActivateOnServer MBX1 -MountDialOverride:None
```

This example performs a switchover of the database DB1 to the Mailbox server MBX3. When the command completes, MBX3 hosts the active copy of DB1. Because the *MountDialOverride* parameter is specified with a value of Good Availability, MBX3 mounts the database using a database auto mount dial setting of *GoodAvailability*.

```
Move-ActiveMailboxDatabase DB1 -ActivateOnServer MBX3 -MountDialOverride:GoodAvai
```

This example performs a switchover of the database DB3 to the Mailbox server MBX4. When the command completes, MBX4 hosts the active copy of DB3. Because the *MountDialOverride* parameter isn't specified, MBX4 mounts the database using a database auto mount dial setting of *Lossless*.

```
Move-ActiveMailboxDatabase DB3 -ActivateOnServer MBX4
```

This example performs a server switchover for the Mailbox server MBX1. All active mailbox database copies on MBX1 will be activated on one or more other Mailbox servers with healthy copies of the active databases on MBX1.

```
Move-ActiveMailboxDatabase -Server MBX1
```

This example performs a switchover of the database DB4 to the Mailbox server MBX5. In this example, the database copy on MBX5 has a replay queue greater than 6. As a result, the *SkipLagChecks* parameter must be specified to activate the database copy on MBX5.

```
Move-ActiveMailboxDatabase DB4 MBX5 -SkipLagChecks
```

This example performs a switchover of the database DB5 to the Mailbox server MBX6. In this example, the database copy on MBX6 has a *ContentIndexState* of Failed. As a result, the *SkipClientExperienceChecks* parameter must be specified to activate the database copy on MBX6.

```
Move-ActiveMailboxDatabase DB5 MBX6 -SkipClientExperienceChecks
```

For More Information

Understanding Mailbox Database Copies

Configure Mailbox Database Copy Properties

1.10.4.2.9 Activate a Lagged Mailbox Database Copy

Activate a Lagged Mailbox Database Copy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A lagged mailbox database copy is a mailbox database copy configured with a replay lag time value greater than 0. Activating and recovering a lagged mailbox database copy is a simple process if you want the database to replay all log files and make the database copy current. If you want to replay log files up to a specific point in time, it's a more difficult operation because you have to manually manipulate log files and run Eseutil.

Looking for other management tasks related to mailbox database copies? Check out Managing Mailbox Database Copies.

Note:

The amount of time it takes to activate a lagged mailbox database copy directly depends on how many log files need to be replayed and how fast the hardware can replay them. At a minimum, you should see a log replay rate of two logs per second per database.

Prerequisites

- The mailbox database copy being activated must be configured with a replay lag time greater than 0.
- The mailbox database copy being activated must have all log files to the point in time to which you want to recover it. Keep in mind that database transactions can span multiple log files when determining the point in time to which you want to recover.

Use the Shell to activate a lagged mailbox

database copy to a specific point in time

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

Note:
You can't use the Exchange Management Console (EMC) to activate a lagged mailbox database copy to a specific point in time.

1. Suspend replication for the lagged copy being activated by using the Suspend-MailboxDatabaseCopy cmdlet, as shown in this example.

```
Suspend-MailboxDatabaseCopy DB1\EX3 -SuspendComment "Activate lagged c
```

2. Optionally (to preserve a lagged copy), take a file system-based (non-Exchange aware) Volume Shadow Copy Service (VSS) snapshot of the volumes containing the database copy and its log files. You can use the vssadmin.exe tool that's included in Windows to take a VSS snapshot, as shown in this example.

```
vssadmin create shadow /For=C:\mountpoints\db01
vssadmin create shadow /For=C:\mountpoints\db01_logs
```

Note:
At this point, you have shadow copies outstanding for the database and log volumes. Continuing to perform this procedure on the existing volume would incur a copy on write performance penalty. If this isn't desirable, you can copy the database and log files to another volume to perform the recovery.

3. Determine which log files are required to replay into the database to meet your point-in-time requirement for this recovery (based on log file date and time, as shown in Windows Explorer). All logs created after this point should be moved to a different directory, until the recovery process is completed, and the logs are no longer needed.
4. Delete the checkpoint (.chk) file for the database.
5. Use Eseutil to perform the recovery operation, as shown in this example.

```
Eseutil.exe /r eXX /a
```

Note:
In the preceding example, *eXX* is the log generation prefix for the database (for example, E00, E01, E02, and so on).

Important:
This step may take a considerable amount of time, depending on several factors, such as the length of the replay lag time, the number of log files generated during that period, and the speed at which your hardware can replay those logs into the database being recovered.

6. After log replay is finished, the database is in a clean shutdown state and can be copied and used for recovery purposes.
7. After the recovery process is complete, resume replication for the database that was used as part of the recovery process, as shown in this example.

```
Resume-MailboxDatabaseCopy DB1\EX3
```

For detailed syntax and parameter information, see Suspend-MailboxDatabaseCopy or Resume-MailboxDatabaseCopy.

Use the Shell to activate a lagged mailbox

database copy by replaying all uncommitted log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database copies" entry in the High Availability Permissions topic.

1. Optionally (to preserve a lagged copy), take a file system-based (non-Exchange aware) Volume Shadow Copy Service (VSS) snapshot of the volumes containing the database copy and its log files.
   1.a. Suspend replication for the lagged copy being activated by using the Suspend-MailboxDatabaseCopy cmdlet, as shown in this example.

```
Suspend-MailboxDatabaseCopy DB1\EX3 -SuspendComment "Activa
```

   1.b. You can use the vssadmin.exe tool that's included in Windows to take a VSS snapshot, as shown in this example.

```
vssadmin create shadow /For=C:\mountpoints\db01
vssadmin create shadow /For=C:\mountpoints\db01_logs
```

   Note:
   At this point, you have shadow copies outstanding for the database and log volumes. Continuing to perform this procedure on the existing volume would incur a copy on write performance penalty. If this isn't desirable, you can copy the database and log files to another volume to perform the recovery.

2. Activate the lagged mailbox database copy using the Move-ActiveMailboxDatabase cmdlet with the *SkipLagChecks* parameter, as shown in this example:

```
Move-ActiveMailboxDatabase DB1 -ActivateOnServer EX3 -SkipLagChecks
```

1.10.4.3 Monitoring High Availability and Site Resilience

Monitoring High Availability and Site Resilience

Exchange Server 2010 > High Availability and Site Resilience > Managing High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-20*

Making sure that your servers are operating reliably and that your database copies are healthy are key objectives for daily messaging operations. To help ensure the availability and reliability of your Microsoft Exchange Server 2010 organization, you must actively monitor the hardware, the Windows operating system, and Exchange 2010 services. Proactive monitoring combined with preventive maintenance can help you identify potential errors before a serious problem interferes with the operation of your Exchange organization.

Monitoring your Exchange organization involves regular checking for problems with services or data. Monitoring typically also includes a notification system that sends alerts

when problems occur. Windows Server 2008 and Exchange 2010 include several tools and services to help make sure that your Exchange organization is running smoothly. The key advantages to daily monitoring are as follows:

- Meeting the requirements of your service level agreements (SLAs)
- Ensuring the successful completion of specific administrative tasks, such as daily backup operations
- Detecting and addressing issues, such as issues that may affect messaging service or data availability

Within an Exchange 2010 organization, the procedures, roles, and responsibilities involved in operations should be formalized. It's important to understand the connection between sound operational practices and procedures and a healthy infrastructure. Well-documented, thorough operational processes and procedures help make sure that all components in an organization's environment on which Exchange relies are managed efficiently and effectively.

Exchange 2010 includes several built-in tools, scripts and features that can be used as part of regular proactive monitoring when Exchange is configured for high availability or site resilience. The primary monitoring cmdlets for high availability and site resilience are Get-MailboxDatabaseCopyStatus and Test-ReplicationHealth. In addition to providing cmdlets that can perform monitoring functions and report status, Exchange 2010 also features a new event log stream that leverages the crimson channel capabilities in Windows Server, as well as built-in scripts that can collect and analyze data from these event channels.

You can use the details in this topic for monitoring the health and status of mailbox database copies for database availability groups (DAGs).

Contents

Get-MailboxDatabaseCopyStatus Cmdlet

You can use the Get-MailboxDatabaseCopyStatus cmdlet to view status information about mailbox database copies. This cmdlet enables you to view information about all copies of a particular database, information about a specific copy of a database on a specific server, or information about all database copies on a server. The following table describes possible values for the copy status of a mailbox database copy.

Database copy status

Database copy status	Description
Failed	The mailbox database copy is in a Failed state because it isn't suspended, and it isn't able to copy or replay log files. While in a Failed state and not suspended, the system will periodically check whether the problem

	that caused the copy status to change to Failed has been resolved. After the system has detected that the problem is resolved, and barring no other issues, the copy status will automatically change to Healthy.
Seeding	The mailbox database copy is being seeded, the content index for the mailbox database copy is being seeded, or both are being seeded. Upon successful completion of seeding, the copy status should change to Initializing.
SeedingSource	The mailbox database copy is being used as a source for a database copy seeding operation.
Suspended	The mailbox database copy is in a Suspended state as a result of an administrator manually suspending the database copy by running the **Suspend-MailboxDatabaseCopy** cmdlet.
Healthy	The mailbox database copy is successfully copying and replaying log files, or it has successfully copied and replayed all available log files.
ServiceDown	The Microsoft Exchange Replication service isn't available or running on the server that hosts the mailbox database copy.
Initializing	The mailbox database copy will be in an Initializing state when a database copy has been created, when the Microsoft Exchange Replication service is starting or has just been started, and during transitions from Suspended, ServiceDown, Failed, Seeding, SinglePageRestore, LostWrite, or Disconnected to another state. While in this state, the system is verifying that the database and log stream are in a consistent state. In most cases, the copy status will remain in the Initializing state for about 15 seconds, but in all cases, it should generally not be in this state for longer than 30 seconds.
Resynchronizing	The mailbox database copy and its log files are being compared with the active copy of the database to check for any divergence between the two copies. The copy status will remain in this state until any divergence is detected and resolved.
Mounted	The active copy is online and accepting client connections. Only the active copy of the mailbox database copy can have a copy status of Mounted.
Dismounted	The active copy is offline and not accepting

	client connections. Only the active copy of the mailbox database copy can have a copy status of Dismounted.
Mounting	The active copy is coming online and not yet accepting client connections. Only the active copy of the mailbox database copy can have a copy status of Mounting.
Dismounting	The active copy is going offline and terminating client connections. Only the active copy of the mailbox database copy can have a copy status of Dismounting.
DisconnectedAndHealthy	The mailbox database copy is no longer connected to the active database copy, and it was in the Healthy state when the loss of connection occurred. This state represents the database copy with respect to connectivity to its source database copy. It may be reported during DAG network failures between the source copy and the target database copy.
DisconnectedAndResynchronizing	The mailbox database copy is no longer connected to the active database copy, and it was in the Resynchronizing state when the loss of connection occurred. This state represents the database copy with respect to connectivity to its source database copy. It may be reported during DAG network failures between the source copy and the target database copy.
FailedAndSuspended	The Failed and Suspended states have been set simultaneously by the system because a failure was detected, and because resolution of the failure explicitly requires administrator intervention. An example is if the system detects unrecoverable divergence between the active mailbox database and a database copy. Unlike the Failed state, the system won't periodically check whether the problem has been resolved, and automatically recover. Instead, an administrator must intervene to resolve the underlying cause of the failure before the database copy can be transitioned to a healthy state.
SinglePageRestore	This state indicates that a single page restore operation is occurring on the mailbox database copy.

The **Get-MailboxDatabaseCopyStatus** cmdlet also includes a parameter called *ConnectionStatus*, which returns details about the in-use replication networks. If you use this parameter, two additional output fields, *IncomingLogCopyingNetwork* and *SeedingNetwork*, will be populated in the task's output.

Get-MailboxDatabaseCopyStatus Examples

The following examples use the **Get-MailboxDatabaseCopyStatus** cmdlet. Each example pipes the results to the **Format-List** cmdlet to display the output in list format.

This example returns status information for all copies of the database DB2.

```
Get-MailboxDatabaseCopyStatus -Identity DB2 | Format-List
```

This example returns the status for all database copies on the Mailbox server MBX2.

```
Get-MailboxDatabaseCopyStatus -Server MBX2 | Format-List
```

This example returns the status for all database copies on the local Mailbox server.

```
Get-MailboxDatabaseCopyStatus -Local | Format-List
```

This example returns status, log shipping, and seeding network information for the database DB3 on the Mailbox server MBX1.

```
Get-MailboxDatabaseCopyStatus -Identity DB3\MBX1 -ConnectionStatus | Format-List
```

For more information about using the **Get-MailboxDatabaseCopyStatus** cmdlet, see Get-MailboxDatabaseCopyStatus.

Return to top

Test-ReplicationHealth Cmdlet

You can use the Test-ReplicationHealth cmdlet to view continuous replication status information about mailbox database copies. This cmdlet can be used to check all aspects of the replication and replay status to provide a complete overview of a specific Mailbox server in a DAG.

The **Test-ReplicationHealth** cmdlet is designed for the proactive monitoring of continuous replication and the continuous replication pipeline, the availability of Active Manager, and the health and status of the underlying cluster service, quorum, and network components. It can be run locally on or remotely against any Mailbox server in a DAG. The **Test-ReplicationHealth** cmdlet performs the tests listed in the following table.

Test-ReplicationHealth cmdlet tests

Test name	Description
ClusterService	Verifies that the Cluster service is running and reachable on the specified DAG member, or if no DAG member is specified, on the local server.
ReplayService	Verifies that the Microsoft Exchange Replication service is running and reachable on the specified DAG member, or if no DAG member is specified, on the local server.
ActiveManager	Verifies that the instance of Active Manager running on the specified DAG member (or if no DAG member is specified, the local server) is in a valid role (primary, secondary,

	or stand-alone).
TasksRpcListener	Verifies that the tasks remote procedure call (RPC) server is running and reachable on the specified DAG member, or if no DAG member is specified, on the local server.
TcpListener	Verifies that the TCP log copy listener is running and reachable on the specified DAG member, or if no DAG member is specified, on the local server.
DagMembersUp	Verifies that all DAG members are available, running, and reachable.
ClusterNetwork	Verifies that all cluster-managed networks on the specified DAG member (or if no DAG member is specified, the local server) are available.
QuorumGroup	Verifies that the default cluster group (quorum group) is in a healthy and online state.
FileShareQuorum	Verifies that the witness server and witness directory and share configured for the DAG are reachable.
DBCopySuspended	Checks whether any mailbox database copies are in a state of Suspended on the specified DAG member, or if no DAG member is specified, on the local server.
DBCopyFailed	Checks whether any mailbox database copies are in a state of Failed on the specified DAG member, or if no DAG member is specified, on the local server.
DBInitializing	Checks whether any mailbox database copies are in a state of Initializing on the specified DAG member, or if no DAG member is specified, on the local server.
DBDisconnected	Checks whether any mailbox database copies are in a state of Disconnected on the specified DAG member, or if no DAG member is specified, on the local server.
DBLogCopyKeepingUp	Verifies that log copying and inspection by the passive copies of databases on the specified DAG member (or if no DAG member is specified, on the local server) are able to keep up with log generation activity on the active copy.
DBLogReplayKeepingUp	Verifies that replay activity for the passive copies of databases on the specified DAG member (or if no DAG member is specified, on the local server) is able to keep up with log copying and inspection activity.

Test-ReplicationHealth Example

This example uses the **Test-ReplicationHealth** cmdlet to test the health of replication for the Mailbox server MBX1.

```
Test-ReplicationHealth -Identity MBX1
```

Return to top

Crimson Channel Event Logging

Windows Server 2008 includes two categories of event logs: Windows logs, and Applications and Services logs. The Windows logs category includes the event logs available in previous versions of Windows: Application, Security, and System event logs. It also includes two new logs: the Setup log and the ForwardedEvents log. Windows logs are intended to store events from legacy applications and events that apply to the entire system.

Applications and Services logs are a new category of event logs. These logs store events from a single application or component rather than events that might have system-wide impact. This new category of event logs is referred to as an application's crimson channel.

The Applications and Services logs category includes four subtypes: Admin, Operational, Analytic, and Debug logs. Events in Admin logs are of particular interest if you use event log records to troubleshoot problems. Events in the Admin log should provide you with guidance about how to respond to the events. Events in the Operational log are also useful, but may require more interpretation. Admin and Debug logs aren't as user friendly. Analytic logs (which by default are hidden and disabled) store events that trace an issue, and often a high volume of events are logged. Debug logs are used by developers when debugging applications.

Exchange 2010 logs events to crimson channels in the Applications and Services logs area. You can view these channels by performing these steps:

1. Open Event Viewer.
2. In the console tree, navigate to **Applications and Services Logs** > **Microsoft** > **Exchange**.
3. Under **Exchange**, select a crimson channel: **HighAvailability** or **MailboxDatabaseFailureItems**.

The HighAvailability channel contains events related to startup and shutdown of the Microsoft Exchange Replication service, and the various components that run within the Microsoft Exchange Replication service, such as Active Manager, the third-party synchronous replication API, the tasks RPC server, TCP listener, and Volume Shadow Copy Service (VSS) writer. The HighAvailability channel is also used by Active Manager to log events related to Active Manager role monitoring and database action events, such as a database mount operation and log truncation, and to record events related to the DAG's underlying cluster.

The MailboxDatabaseFailureItems channel is used to log events associated with any failures that affect a replicated mailbox database.

Return to top

CollectOverMetrics.ps1 Script

Exchange 2010 includes a script called CollectOverMetrics.ps1, which can be found in the Scripts folder. CollectOverMetrics.ps1 reads DAG member event logs to gather information about database operations (such as database mounts, moves, and failovers) over a specific time period. For each operation, the script records the following information:

- Identity of the database

- Time at which the operation began and ended
- Servers on which the database was mounted at the start and finish of the operation
- Reason for the operation
- If the operation was successful, including the error details if the operation failed

The script writes this information to .csv files with one operation per row. It writes a separate .csv file for each DAG.

The script supports parameters that allow you to customize the script's behavior and output. For example, the results can be restricted to a specified subset by using the *Database* or *ReportFilter* parameters. Only the operations that match these filters will be included in the summary HTML report. The available parameters are listed in the following table.

CollectOverMetrics.ps1 script parameters

Parameter	Description
DatabaseAvailabilityGroup	Specifies the name of the DAG from which you want to collect metrics. If this parameter is omitted, the DAG of which the local server is a member will be used. Wildcard characters can be used to collect information from and report on multiple DAGs.
Database	Provides a list of databases for which the report needs to be generated. Wildcard characters are supported, for example, –Database:"DB1","DB2" or –Database:"DB*".
StartTime	Specifies the duration of the time period to report on. The script gathers only the events logged during this period. As a result, the script may capture partial operation records (for example, only the end of an operation at the start of the period or vice-versa). If neither *StartTime* nor *EndTime* is specified, the script defaults to the past 24 hours. If only one parameter is specified, the period will be 24 hours, either beginning or ending at the specified time.
EndTime	Specifies the duration of the time period to report on. The script gathers only the events logged during this period. As a result, the script may capture partial operation records (for example, only the end of an operation at the start of the period or vice-versa). If neither *StartTime* nor *EndTime* is specified, the script defaults to the past 24 hours If only one parameter is specified, the period will be 24 hours, either beginning or ending at the specified time.
ReportPath	Specifies the folder used to store the results of event processing. If this parameter is omitted, the Scripts folder will be used. When specified, the script takes a list of .csv

	files generated by the script and uses them as the source data to generate a summary HTML report. The report is the same one that is generated with the -GenerateHtmlReport option. The files can be generated across multiple database availability groups at many different times, or even with overlapping times, and the script will merge all of their data together.
GenerateHtmlReport	Specifies that the script gather all the information it has recorded, group the data by the operation type, and then generate an HTML file that includes statistics for each of these groups. The report includes the total number of operations in each group, the number of operations that failed, and statistics for the time taken within each group. The report also contains a breakdown of the types of errors that resulted in failed operations.
ShowHtmlReport	Specifies that the HTML-generated report should be displayed in a Web browser after its generated.
SummariseCSVFiles	Specifies that the script read the data from existing .csv files that were previously generated by the script. This data is then used to generate a summary report similar to the report generated by the *GenerateHtmlReport* parameter.
ActionType	Specifies the type of operational actions the script should collect. The values for this parameter are `Move`, `Mount`, `Dismount`, and `Remount`. The `Move` value refers to any time that the database changes its active server, whether by controlled moves or by failovers. The `Mount`, `Dismount`, and `Remount` values refer to times that the database changes its mounted status without moving to another computer.
ActionTrigger	Specifies which administrative operations should be collected by the script. The values for this parameter are `Admin` or `Automatic`. Automatic actions are those performed automatically by the system (for example, a failover when a server goes offline). Admin actions are any actions that were performed by an administrator using either the Exchange Management Shell or the Exchange Management Console.
RawOutput	Specifies that the script writes the results that would have been written to .csv files directly to the output stream, as would happen with write-output. This information can then be piped to other commands.

IncludedExtendedEvents	Specifies that the script collects the events that provide diagnostic details of times spent mounting databases. This can be a very time-consuming stage if the Application event log on the servers is very large.
MergeCSVFiles	Specifies that the script takes all the .csv files containing data about each operation and merges them into a single .csv file.
ReportFilter	Specifies that a filter should be applied to the operations using the fields as they appear in the .csv files. This parameter uses the same format as a `Where` operation, with each element set to `$_` and returning a Boolean value. For example: `{$_DatabaseName -notlike "Mailbox Database*"}` can be used to exclude the default databases from the report.

CollectOverMetrics.ps1 Examples

The following example collects metrics for all databases that match DB* (which includes a wildcard character) in a DAG named DAG1. After the metrics are collected, an HTML report is generated and displayed.

```
CollectOverMetrics.ps1 -DatabaseAvailabilityGroup DAG1 -Database:"DB*" -GenerateH
```

The following examples demonstrate ways that the summary HTML report may be filtered. The first uses the *Database* parameter, which takes a list of database names. The summary report then contains data only about those databases. The next two examples use the *ReportFilter* option. The last example filters out all the default databases.

```
CollectOverMetrics -SummariseCsvFiles (dir *.csv) -Database MailboxDatabase123,Ma
CollectOverMetrics -SummariseCsvFiles (dir *.csv) -ReportFilter { $_.DatabaseName
CollectOverMetrics -SummariseCsvFiles (dir *.csv) -ReportFilter { ($_.ActiveOnSta
```

Return to top

CollectReplicationMetrics.ps1 Script

CollectReplicationMetrics.ps1 is another health metric script included in Exchange 2010. This script provides an active form of monitoring because it collects metrics in real time, while the script is running. CollectReplicationMetrics.ps1 collects data from performance counters related to database replication. The script gathers counter data from multiple Mailbox servers, writes each server's data to a .csv file, and can then report various statistics across all of this data (for example, the amount of time each copy was failed or suspended, the average copy or replay queue length, or the amount of time that copies were outside of their failover criteria).

You can either specify the servers individually, or you can specify entire DAGs. You can either run the script can to first collect the data and then generate the report, or you can run it just gather the data or to only report on data that's already been collected. You can specify the frequency at which data should be sampled and the total duration to gather data.

The data collected from each server is written to a file named **CounterData.<ServerName>.<TimeStamp>.csv**. The summary report will be written to a file named **HaReplPerfReport.<DAGName>.<TimeStamp>.csv**, or **HaReplPerfReport.<TimeStamp>.csv** if you didn't run the script was with the *DagName* parameter.

The script starts PowerShell jobs to collect the data from each server. These jobs run for the full period in which data is being collected. If you specify a large number of servers, this process can use a considerable amount of memory. The final stage of the process, when data is processed into a summary report, can also be quite time consuming for large amounts of data. It's possible to run the collection stage on one computer, and then copy the data elsewhere for processing.

The CollectReplicationMetrics.ps1 script supports parameters that allow you to customize the script's behavior and output. The available parameters are listed in the following table.

CollectReplicationMetrics.ps1 script parameters

Parameter	Description
DagName	Specifies the name of the DAG from which you want to collect metrics. If this parameter is omitted, the DAG of which the local server is a member will be used.
DatabaseNames	Provides a list of databases for which the report needs to be generated. Wildcards characters are supported for use, for example, –`DatabaseNames:"DB1","DB2"` or –`DatabaseNames:"DB*"`.
ReportPath	Specifies the folder used to store the results of event processing. If this parameter is omitted, the Scripts folder will be used.
Duration	Specifies the amount of time the collection process should run. Typical values would be one to three hours. Longer durations should be used only with long intervals between each sample or as a series of shorter jobs run by scheduled tasks.
Frequency	Specifies the frequency at which data metrics are collected. Typical values would be 30 seconds, one minute, or five minutes. Under normal circumstances, intervals that are shorter than these won't show significant changes between each sample.
Servers	Specifies the identity of the servers from which to collect statistics. You can specify any value, including wildcard characters or GUIDs.
SummariseFiles	Specifies a list of .csv files to generate a summary report. These files are the files named **CounterData.<CounterData>*** and are generated by the CollectReplicationMetrics.ps1 script.
Mode	Specifies the processing stages that the script executes. You can use the following values: • `CollectAndReport` This is the default value. This value signifies that the script should both collect the data from the servers and then process them to produce the summary report. • `CollectOnly` This value signifies that the script should just collect the data and not produce the report.

	• `ProcessOnly` This value signifies that the script should import data from a set of .csv files and process them to produce the summary report. The *SummariseFiles* parameter is used to provide the script with the list of files to process.
MoveFilestoArchive	Specifies that the script should move the files to a compressed folder after processing.
LoadExchangeSnapin	Specifies that the script should load the Exchange Shell commands. This parameter is useful when the script needs to run from outside the Exchange Management Shell, such as in a scheduled task.

CollectReplicationMetrics.ps1 Example

The following example gathers one hour's worth of data from all the servers in the DAG "DAG1", sampled at one minute intervals, and then generates a summary report. In addition, the *ReportPath* parameter is used, which causes the script to place all the files in the current directory.

```
CollectReplicationMetrics.ps1 -DagName DAG1 -Duration "01:00:00" -Frequency "00:0
```

The following example reads the data from all the files matching "CounterData*" and then generates a summary report.

```
CollectReplicationMetrics.ps1 -SummariseFiles (dir CounterData*) -Mode ProcessOnl
```

Return to top

CheckDatabaseRedundancy.ps1 Script

As its name implies, the purpose of the CheckDatabaseRedundancy.ps1 script is to monitor the redundancy of replicated mailbox databases by validating that there is at least two configured and healthy and current copies, and to alert you when only a single healthy copy of a replicated database exists. In this case, both active and passive copies are counted when determining redundancy.

When the Mailbox server role is installed, the CheckDatabaseRedundancy.ps1 script is automatically configured by Exchange to run as a scheduled task named **Database One Copy Alert**. By default, the Database One Copy Alert scheduled task is configured to run every 60 minutes. You can modify this behavior and the scheduled task settings using the Windows Task Scheduler. The script is designed to first check for DAG membership, so if the Mailbox server is not a member of a DAG, the script exits out right away.

The script can also be run interactively from the scripts folder. When running the script interactively, you must specify either a database name or a DAG member name. To specify a database, you use the *MailboxDatabaseName* parameter and to specify a DAG member, you use the *MailboxServerName* parameter. When run interactively in the console, the script performs the redundancy check only once, and outputs the CurrentState (red or green) on the screen.

Like other scripts and cmdlets, CheckDatabaseRedundancy.ps1 can also be run in monitoring mode and generate events by adding the *MonitoringContext* parameter. The scheduled task created by Exchange runs the script in monitoring mode. This mode also enables the script to be invoked by a monitoring solution, such as Microsoft System Center Operations Manager (SCOM). In monitoring mode, the script generates red alert and green alert events into the local server's Application event log. A red alert event (event ID 4113) is generated only if the database has been "red" for 20 minutes more (in

duration, not consecutive) in the hour-long run of the script, and a green alert event (event ID 4114) when the database has been "green" for 10 consecutive minutes. By default, once a red alert event is generated, it will continue to be reported every 15 minutes.

In addition, the script has some other useful options. For example, you can add the *ShowDetailedErrors* parameter to get greater detail about any errors that occur, and you can add the *Verbose* parameter for additional troubleshooting information. The script also includes a *SendSummaryMailTos* parameter which can be used to send a summary report by email to a list of specified email addresses when the script has finished running. This enables administrators to quickly look at hourly reports to see if any redundancy issues have occurred. If you do use the email functionality, you'll need to include the *SummaryMailFrom* parameter whenever you use the *SendSummaryMailTos* parameter.

Microsoft recommends running this script regularly, as part of your normal monitoring operations, using either the automated scheduled task, or a monitoring system such as SCOM. To ensure you don't have lengthy periods in which database redundancy is compromised, run the script every 60 minutes. The script includes a parameter called *TerminateAfterDurationSecs*, which when set to -1 or 0 when executing the script, can be used to run the script for an infinite amount of time.

If you're not running a monitoring solution such as SCOM, we recommend you allow the automatically created scheduled task to automate and schedule script execution.

There are known issues in the Windows Server 2008 SP2 Task Scheduler that may cause Task Scheduler to crash when you have scheduled a long-running task. These issues do not exist in Windows Server 2008 R2; so if possible, run the script from Windows Server 2008 R2. If you can't run the script from Windows Server 2008 R2, and you're running it from Windows Server 2008 SP2, we recommend two modifications. First, instead of running the script with its built-in transient suppression of 60 minutes, run the script every 5 minutes by using the following parameters:

```
CheckDatabaseRedundancy.ps1 -MonitoringContext -SleepDurationBetweenIterationsSec
```

Second, if possible, use SCOM to define the transient suppression behavior (e.g., if 3 red alert events are logged within a 20 minute period, generate an alert; and if a green alert event is logged, change the CurrentState to green).

If the Database One Copy Alert scheduled task is altered or removed, you can delete and re-schedule by running the following command:

```
schtasks /create /TN "Check Database Redundancy" /TR "Powershell.exe -NonInteract
```

Replace the parameters in the above script with the script parameters you want to use. Additional parameters for the script are also described in the script.

When using the schtasks command line tool to create a scheduled task, the /TR option is limited to 261 characters. The above example exceeds that limit. If the parameters and paths you use cause the /TR option to exceed 261 characters then you must manually create the scheduled task using the Task Scheduler applet on the Administrative Tools menu. Alternatively, you can copy and paste the following XML into Notepad, edit it appropriately, save it as an XML file and import it using the Task Scheduler applet.

```
<?xml version="1.0" encoding="UTF-16"?>
<Task version="1.2" xmlns="http://schemas.microsoft.com/windows/2004/02/mit/task"
  <RegistrationInfo>
    <Date>2010-05-11T15:55:47</Date>
    <Author>administrator</Author>
  </RegistrationInfo>
  <Triggers>
    <TimeTrigger>
```

```
      <Repetition>
        <Interval>PT1H</Interval>
        <StopAtDurationEnd>false</StopAtDurationEnd>
      </Repetition>
      <StartBoundary>2010-05-11T15:55:00</StartBoundary>

1.10.4.4 Switchovers and Failovers

Switchovers and Failovers

Exchange Server 2010 > High Availability and Site Resilience > Managing High Availability and Site Resilience >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-28*

Switchovers and failovers are the two forms of outages in Microsoft Exchange Server 2010. A *switchover* is a scheduled outage of a database or server that's explicitly initiated by an administrator, typically in preparation for performing a maintenance operation. Switchovers involve an administrator moving the active mailbox database copy to another server in the database availability group (DAG).

A *failover* refers to unexpected events that result in the unavailability of services, data, or both. A failover involves the system automatically recovering from the failure by activating

a passive mailbox database copy to make it the active mailbox database copy.

The high availability platform in Exchange 2010 is designed to handle both switchovers and failovers.

Looking for management tasks related to high availability and site resilience? See Managing High Availability and Site Resilience.

Switchovers

There are three types of switchovers in Exchange 2010:

- Database switchovers
- Server switchovers
- Datacenter switchovers

Database Switchovers

A *database switchover* is the process by which an individual active database is switched over to another database copy (a passive copy), and that database copy is made the new active database copy. Database switchovers can happen both within and across datacenters. A database switchover can be performed by using the Exchange Management Console (EMC) or the Exchange Management Shell. Regardless of which interface is used, the switchover process is the same:

1. The administrator initiates a database switchover to move the current active mailbox database copy to another server. The switchover can be initiated by using the Move-ActiveMailboxDatabase cmdlet or by using the Activate a Database Copy wizard.
2. The client used for the task makes an RPC call to the Microsoft Exchange Replication service on a DAG member.
3. If the DAG member doesn't hold the Primary Active Manager (PAM) role, the DAG member refers the task to the PAM.
4. The task makes an RPC call to the Microsoft Exchange Replication service on the PAM.
5. The PAM reads and updates the database location information that's stored in the cluster database for the DAG.
6. The PAM contacts the Microsoft Exchange Replication service on the DAG member whose passive copy is being activated as the new active mailbox database copy.
7. The Microsoft Exchange Replication service on the target server queries the Microsoft Exchange Replication services on all other DAG members to determine the best log source for the database copy.
8. The database is dismounted from the current server and the Microsoft Exchange Replication service on the target server copies the remaining logs to the target server.
9. The Microsoft Exchange Replication service on the target server requests a database mount.
10. The Microsoft Exchange Information Store service on the target server replays the log files and mounts the database.
11. Any error codes are returned to the Microsoft Exchange Replication service on the target server.
12. The PAM updates the database copy state information in the cluster database for the DAG.
13. Any error codes are returned by the Microsoft Exchange Replication service on the target server to the Microsoft Exchange Replication service on the PAM.
14. The Microsoft Exchange Replication service on the PAM returns any errors to the administrative interface where the task was called.
15. Remote PowerShell returns the results of the operation to the calling administrative interface.

For detailed steps about how to perform a database switchover, see Move the Active Mailbox Database.

Server Switchovers

A server switchover is the process by which all active databases on a DAG member are activated on one or more other DAG members. Like database switchovers, a server switchover can occur both within a datacenter and across datacenters, and it can be initiated by using both the EMC and the Shell. Regardless of which interface is used, the switchover process is the same:

1. The administrator initiates a server switchover to move all current active mailbox database copies to one or more other servers. The switchover can be initiated by using the Move-ActiveMailboxDatabase cmdlet, or by using the Switchover Server UI.
2. The task performs the same steps described earlier in this topic for database switchovers (Steps 2 through 4) for each of the active databases on the current server.
3. The PAM reads and updates the database location information that's stored in the cluster database for the DAG.
4. The PAM contacts the Microsoft Exchange Replication service on each DAG member that has a passive copy being activated.
5. The Microsoft Exchange Replication service on the target servers query the Microsoft Exchange Replication services on all other DAG members to determine the best log source for the database copy.
6. The database is dismounted from the current server and the Microsoft Exchange Replication service on each target server copies the remaining logs.
7. The Microsoft Exchange Replication service on each target server requests a database mount.
8. The Microsoft Exchange Information Store service on each target server replays the log files and mounts the database.
9. Any error codes are returned to the Microsoft Exchange Replication service on the target server.
10. The PAM updates the database copy state information in the cluster database for the DAG.
11. Any error codes are returned by the Microsoft Exchange Replication service on the target server to the Microsoft Exchange Replication service on the PAM.
12. The Microsoft Exchange Replication service on the PAM returns any errors to the administrative interface where the task was called.
13. Remote PowerShell returns the results of the operation to the calling administrative interface.

For detailed steps about how to perform a server switchover, see Perform a Server Switchover.

Datacenter Switchovers

A datacenter or site failure is managed differently from the types of failures that can cause a server or database failover. In a high availability configuration, automatic recovery is initiated by the system, and the failure typically leaves the messaging system in a fully functional state. By contrast, a datacenter failure is considered to be a disaster recovery event, and as such, recovery must be manually performed and completed for the client service to be restored and for the outage to end. The process you perform is called a *datacenter switchover*. As with many disaster recovery scenarios, prior planning and preparation for a datacenter switchover can simplify your recovery process and reduce the duration of your outage.

For more information about datacenter switchovers, including detailed steps for performing a datacenter switchover, see Datacenter Switchovers.

Failovers

A failover is an automatic activation process that can occur at either the database or server level. Failovers occur in response to a failure that affects an individual database (for example, an isolated storage loss) or an entire server (for example, a motherboard failure or a loss of power).

DAGs and mailbox database copies provide full redundancy (and therefore rapid recovery) of both the data and the services that provide access to the data. The following table lists the expected recovery actions for a variety of failures. Some failures require the administrator to initiate the recovery, and other failures are automatically handled by the system.

Description	Automatic activation	Automatic repair action	State during repair: Active	State during repair: Passive	Repair actions	Comments
Extensible Storage Engine (ESE) soft database failure: The drives storing the database are returning errors on some reads (for example, a -1018 error).	Possible short outage. Possible automatic failover.	Automatic patching of bad page.	Manual switchover, automatic failover, or online repair.	Failed	RAID rebuild, database and database copy repair, restore and run recovery then page patching, or page patching from copy.	There may be other soft database failure codes. Doesn't include NTFS file system block failures. If failover or switchover is performed, host server is updated.
ESE "*semi-soft*" database failure: The drives storing the database are returning errors on some writes.	Short outage during automatic failover.	Automatic volume/ disk rebuilt after possible drive replacement.	Dismounted if can't be recovered.	Failed	RAID rebuild may solve the problem. Copy and repair, restore and run recovery, or volume/ disk rebuilt after possible replacement.	An ESE semi-soft write error means some writes are successful. Doesn't include an NTFS block failure.

ESE "semi-soft" log failure: The drives storing the log data are returning non-recovered errors on some reads or writes.	Short outage during automatic failover.	Automatic volume/ disk rebuilt after possible drive replacement.	Dismounted if can't be recovered.	Failed	RAID rebuild may solve the problem. Copy and repair, restore and run recovery, or volume/ disk rebuilt after possible replacement.	An ESE semi-soft read/write error means some reads/ writes are successful. If the database fails, automated recovery will occur before log data recovery processing starts.
ESE software error or resource exhaustion: An error where ESE terminates instance (for example, Event ID 1022, checkpoint depth too deep).	Short outage during automatic failover.	None.	Dismounted if can't be recovered.	Failed	Fix underlying resource issue.	This failure could be the surfaced error of other cases.
NTFS block failures: The drives storing the database or logs experiences a read or write error to an NTFS control structure.	Short outage during automatic failover.	Volume completely rebuilt after possible drive replacement.	Dismounted if can't be recovered.	Failed	RAID rebuild may solve the problem. NTFS utilities may solve the NTFS problems. Exchange recovery may be required.	This is more likely to occur when RAID isn't in use. If this impacts the active log volume, some recent log files will be lost. Doesn't include errors automatically corrected by NTFS or its underlying software or hardware

						stack.
Database or log drive failure: A drive storing the database or logs has completely failed and is inaccessible.	Short outage during automatic failover.	Drive reformatted or replaced, followed by complete volume rebuild.	Dismounted if can't be recovered.	Failed	Drive replacement followed by possible RAID rebuild. Drive replacement followed by complete volume rebuild. Complete volume rebuild.	Not applicable.
Database or log volume failure: The volume fails due to NTFS or lower level volume issues.	Short outage during automatic failover.	Drive reformatted or replaced.	Dismounted if can't be recovered.	Failed	Drive replacement followed by possible RAID rebuild. Drive replacement followed by complete volume rebuild. Complete volume rebuild.	Not applicable.
Database or log volume out of space: The NTFS file system with the database or log files is out of space.	Automatic failover if other copy isn't in similar state.	None.	Dismounted.	Failed	Run full or incremental backups, manually delete logs, let time pass, resume database copy, or repair failed	Not applicable.

					database copy.	
Administrator dismounts the wrong database.	If automatic failover isn't blocked by the administrator, there will be a short outage. If automatic failover is prevented, there will be an outage until the database is mounted.	None.	Dismounted.	Not applicable	Administrator corrects the error.	Not applicable.
Administrator suspends the wrong database copy.	Depending on configuration and impacted copy, auto recovery may be prevented.	None.	Not applicable.	Suspended	Administrator corrects the error.	Not applicable.
Administrator dismounts a database for storage, NTFS, or volume maintenance.	If automatic failover isn't blocked by the administrator, there will be a short outage. If automatic failover is blocked, there will be an outage until the administrator	None.	Dismounted.	Not applicable	Administrator completes the task.	Not applicable.

	completes the task.					
Administrator suspends a database copy for storage, NTFS, or volume maintenance.	Depending on configuration and impacted copy, auto recovery may be prevented.	None.	Not applicable.	Suspended	Administrator completes the actions.	Not applicable.
Administrator dismounts a database for offline database maintenance.	Outage until repaired.	None.	Dismounted.	Suspended	Administrator completes the actions.	Active and passive database copies are diverged. Administrator must suspend copies.
Storage area network (SAN), disk, or storage controller failure.	Short outage during automatic failover.	None.	Dismounted.	Any	Repair hardware.	A passive database copy will be in the state that existed at the time when the system failed.
Server hardware maintenance.	Short outage during automatic failover (unless blocked by an administrator).	None.	Dismounted.	Any	Complete actions.	A passive database copy will be in the state that existed at the time when the system was shut down.
Server software maintenance.	Short outage during automatic failover (unless blocked by an administrator).	None.	Dismounted.	Any	Complete actions.	A passive database copy will be in the state that existed at the time when the system was shut down.

Microsoft Exchange Information Store service is stopped or paused by an administrator.	None.	None.	Dismounted.	Any	Restart the Microsoft Exchange Information Store service.	A passive database copy will be in the state that existed at the time when the service was stopped.
Microsoft Exchange Information Store service fails; operating system is still running.	Short outage during automatic failover.	Service Control Manager restarts the Microsoft Exchange Information Store service.	Dismounted.	Any	Manually or automatically restart the Microsoft Exchange Information Store service.	A passive database copy will be in the state that existed when the Microsoft Exchange Information Store service failed.
Partial Microsoft Exchange Information Store service failure; some part of the Exchange store stops functioning, but it's not identified as completely failed.	Possible short outage during automatic failover.	None.	Mounted and partially functional.	Any, but may be only partially functional	Restart server, operating system, or Microsoft Exchange Information Store service.	Not applicable.
Server failure: The server fails for one of the following reasons: • Complete power failure • Unrecovered failure of the processor chip, motherboard, or backplane • Operating system stop error • Operating system stops responding • Complete communication failure	Short outage during automatic failover.	Restart computer.	Dismounted.	Any	Restore power, change operating system settings, change hardware settings, replace hardware, restart operating system, service operating system, service hardware, or repair communication problems.	Not applicable.

DAG experiences a quorum failure.	Outage until repaired.	None.	Dismounted.	Any	Repair failed quorum, assign new quorum, or restore the network that's causing quorum failure.	A passive database copy will be in the state that existed at the time when the system failed.
MAPI network communication failure: The server is no longer available on the MAPI network.	Short outage during automatic failover; must be lossless.	None. Communication continues to be attempted.	Dismounted.	Any	Fix communication problem by correcting hardware or software issues.	Not applicable.
Replication network communication failure: The server can't receive heartbeats, log copies, or seed through the failed replication network.	Possible short copying or seeding outage while the workload is switched to other network.	None. Communication continues to be attempted.	None.	Any	Fix communication problem by correcting hardware or software issues.	Resiliency impacted by failure.
Multiple network communication failure: The server can't receive heartbeats, log copies, or seed through multiple networks.	Short outage during automatic failover; must be lossless.	None. Communication continues to be attempted.	Dismounted.	Any	Fix communication problem by correcting hardware or software issues.	At least one network is still functional.
Partial failure of one or more networks: Networks experience high error rates.	Failure not detected; no action.	None.	Mounted, but possible performance issues.	Any	Fix communication problem by correcting hardware or software issues.	Network experiences higher than normal error rates.
Undetected operating	None.	None.	Any.	Any	Restart or	Hang isn't detected

system hang: Operating system stops responding but it's not detected by monitoring or clustering.					terminate the resources that aren't responding.	so no action is taken. Some functionality may be operational.
Operating system drive experiences a failure.	Short outage during automatic failover.	None.	Dismounted.	Any	Replace drive and rebuild server or rebuild volume by using RAID.	Not applicable.
Operating system drive out of space.	Short outage during automatic failover.	None.	Dismounted.	Any	Manually free space on the volume.	Not applicable.
Drive containing Exchange binaries experiences a volume or drive failure.	Short outage during automatic failover.	None.	Dismounted.	Any	Replace drive and reinstall application or rebuild volume by using RAID.	Not applicable.
Drive containing the Exchange binaries is out of space.	Short outage during automatic failover.	None.	Dismounted.	Any	Manually free space on the volume.	Not applicable.
Invalid new log detected: The log sequence is disrupted by an existing file.	Short outage during automatic failover; assume other copies don't have the same problem.	None.	Dismounted.	Failed	Remove disruptive logs after determining source.	The disruptive logs shouldn't replicate.
Continuous replication detects invalid log: Replay detects an inappropriate log during copy or replay.	Not applicable.	Discard log.	Not applicable.	Failed	Discard invalid log; move impacting log stream.	Not applicable.

Database Failovers

A database failover occurs when a database copy that was active is no longer able to remain active. The following occurs as part of a database failover:

1. The database failure is detected by the Microsoft Exchange Information Store service.
2. The Microsoft Exchange Information Store service writes failure events to the crimson channel event log.
3. The Active Manager on the server that contains the failed database detects the failure events.
4. The Active Manager requests the database copy status from the other servers that hold a copy of the database.
5. The other servers return the requested database copy status to the requesting Active Manager.
6. The PAM initiates a move of the active database to another server in the DAG using a best copy selection algorithm.
7. The PAM updates the database mount location in the cluster database to refer to the selected server.
8. The PAM sends a request to the Active Manager on the selected server to become the database master.
9. The Active Manager on the selected server requests that the Microsoft Exchange Replication service attempt to copy the last logs from the previous server and set the mountable flag for the database.
10. The Microsoft Exchange Replication service copies the logs from the server that previously had the active copy of the database.
11. The Active Manager reads the maximum log generation number from the cluster database.
12. The Microsoft Exchange Information Store service mounts the new active database copy.

Server Failovers

A server failover occurs when the DAG member is no longer able to service the MAPI network, or when the Cluster service on a DAG member is no longer able to contact the remaining DAG members. The following occurs as part of a server failover:

1. The Cluster service on the PAM sends a notification to the PAM for one of two conditions:
   1.a. **Node Down** The server is reachable but is unable to participate in DAG operations.
   1.b. **MAPI Network Down** The server can't be contacted over the MAPI network and therefore can't participate in DAG operations.
2. If the server is reachable, the PAM contacts the Active Manager on the affected server and requests that all databases be immediately dismounted.
3. For each affected database copy:
   3.a. The PAM requests the database copy status from all servers in the DAG.
   3.b. The PAM receives a response from all reachable and active DAG members.
   3.c. The PAM tries to determine the best log source among all responding servers by querying the most recent log generation number from each of the responders.
   3.d. Each of the servers responds with the log generation number.
4. The PAM retrieves the current search index catalog status from the cluster database.
5. Based on the log generation number and catalog health of each database copy, the PAM selects the best copies to activate.
6. The PAM updates the mounted location of the database in the cluster database.
7. The PAM initiates database failover by communicating with the Active Manager on one or more other servers.
8. The Active Manager on the selected servers requests that the Microsoft Exchange Replication service attempt to copy the last logs from the previous server and set the mountable flag.
9. When the database is mountable, the Active Manager on the servers mounts the databases.

For more information about Active Manager's best copy selection process, see Understanding Active Manager.

1.10.4.4.1 Datacenter Switchovers

Datacenter Switchovers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-14*

By combining the native site resilience capabilities in Microsoft Exchange Server 2010 Service Pack 1 (SP1) with proper planning, a second datacenter can be rapidly activated to serve the failed datacenter's clients. A datacenter or site failure is managed differently from the types of failures that can cause a server or database failover. In a high availability configuration, automatic recovery is initiated by the system, and the failure typically leaves the messaging system in a fully functional state. By contrast, a datacenter failure is considered to be a disaster recovery event, and recovery must be manually performed and completed for the client service to be restored, and for the outage to end. The process you perform is referred to as a *datacenter switchover*. As with many disaster recovery scenarios, prior planning and preparation for a datacenter switchover can simplify the recovery process and reduce the duration of the outage.

There are four basic steps that you complete to perform a datacenter switchover, after making the initial decision to activate the second datacenter:

1. **Terminate a partially running datacenter** This step involves terminating Mailbox and Unified Messaging services in the primary datacenter, if any services are still running. This is particularly important for the Mailbox server role because it uses an active/passive high availability model. If services in a partially failed datacenter aren't stopped, it's possible for problems from the partially failed datacenter to negatively affect the services during a switchover back to the primary datacenter.

   Important:

   If network or Active Directory infrastructure reliability has been compromised as a result of the primary datacenter failure, we recommend that all messaging services be off until these dependencies are restored to healthy service.

2. **Validate and confirm the prerequisites for the second datacenter** This step can be performed in parallel with step 1 because validation of the health of the infrastructure dependences in the second datacenter is largely independent of the first datacenter services. Each organization typically requires its own method for performing this step. For example, you may decide to complete this step by reviewing health information collected and filtered by an infrastructure monitoring application, or by using a tool that's unique to your organization's infrastructure. This is a critical step, because activating the second datacenter when its infrastructure is unhealthy and unstable is likely to yield poor results.
3. **Activate the Mailbox servers** This step begins the process of activating the second datacenter. This step can be performed in parallel with step 4 because the Microsoft Exchange services can handle database outages and recover. Activating the Mailbox servers involves a process of marking the failed servers from the primary datacenter as unavailable followed by activation of the servers in the second datacenter. The activation process for

Mailbox servers depends on whether the DAG is in database activation coordination (DAC) mode. For more information about database activation coordination mode, see Understanding Datacenter Activation Coordination Mode.
If the DAG is in DAC mode, you can use the Exchange site resilience cmdlets to terminate a partially failed datacenter (if necessary) and activate the Mailbox servers. For example, in DAC mode, this step is performed by using the Stop-DatabaseAvailabilityGroup cmdlet. In some cases, the servers must be marked as unavailable twice (once in each datacenter). Next, the Restore-DatabaseAvailabilityGroup cmdlet is run to restore the remaining members of the database availability group (DAG) in the second datacenter by reducing the DAG members to those that are still operational, thereby reestablishing quorum. If the DAG isn't in DAC mode, you must use the Windows Failover Cluster tools to activate the Mailbox servers. After either process is complete, the database copies that were previously passive in the second datacenter can become active and be mounted. At this point, Mailbox server recovery is complete.

4. **Activate the other server roles** This involves using the URL mapping information and the Domain Name System (DNS) change methodology to perform all required DNS updates. The mapping information describes what DNS changes to perform. The amount of time required to complete the update depends on the methodology used and the Time to Live (TTL) settings on the DNS record (and whether the deployment's infrastructure honors the TTL).

Users should start to have access to messaging services sometime after steps 3 and 4 are completed. Steps 3 and 4 are described in greater detail later in this topic.

Looking for management tasks related to high availability and site resilience? See Managing High Availability and Site Resilience.

Contents

Terminating a Partially Failed Datacenter

If any DAG members in the failed datacenter are still running, they should be terminated.

When the DAG is in DAC mode, the specific actions to terminate any surviving DAG members in the primary datacenter are as follows:

1. The DAG members in the primary datacenter must be marked as stopped in the primary datacenter. *Stopped* is a state of Active Manager that prevents databases from mounting, and Active Manager on each server in the failed datacenter is put into this state by using the Stop-DatabaseAvailabilityGroup cmdlet. The *ActiveDirectorySite* parameter of this cmdlet can be used to mark all of the servers in the primary datacenter as stopped with a single command. This step may not be possible depending on the failure. This step should be taken if the state of the datacenter permits it. The **Stop-DatabaseAvailabilityGroup** cmdlet should be run against all servers in the primary datacenter. If the Mailbox server is unavailable but Active Directory is

operating in the primary datacenter, the **Stop-DatabaseAvailabilityGroup** command with the *ConfigurationOnly* parameter must be run against all servers in this state in the primary datacenter, or the Mailbox server must be turned off. Failure to either turn off the Mailbox servers in the failed datacenter or to successfully perform the **Stop-DatabaseAvailabilityGroup** command against the servers will create the potential for split-brain syndrome to occur across the two datacenters. You may need to individually turn off computers through power management devices to satisfy this requirement.

2. The second datacenter must now be updated to represent which primary datacenter servers are stopped. This is done by running the same **Stop-DatabaseAvailabilityGroup** command with the *ConfigurationOnly* parameter using the same *ActiveDirectorySite* parameter and specifying the name of the Active Directory site in the failed primary datacenter. The purpose of this step is to inform the servers in the second datacenter about which mailbox servers are available to use when restoring service.

When the DAG isn't in DAC mode, the specific actions to terminate any surviving DAG members in the primary datacenter are as follows:

1. The DAG members in the primary datacenter must be forcibly evicted from the DAG's underlying cluster by running the following commands on each member:

```
net stop clussvc
cluster <DAGName> node <DAGMemberName> /forcecleanup
```

2. The DAG members in the second datacenter must now be restarted and then used to complete the eviction process from the second datacenter. Stop the Cluster service on each DAG member in the second datacenter by running the following command on each member:

```
net stop clussvc
```

3. On a DAG member in the second datacenter, force a quorum start of the Cluster service by running the following command:

```
net start clussvc /forcequorum
```

4. Open the Failover Cluster Management tool and connect to the DAG's underlying cluster. Expand the cluster, and then expand **Nodes**. Right-click each node in the primary datacenter, select **More Actions**, and then select **Evict**. When you're done evicting the DAG members in the primary datacenter, close the Failover Cluster Management tool.

If any Unified Messaging servers are in use in the failed datacenter, they must be disabled to prevent call routing to the failed datacenter. You can disable a Unified Messaging server by using the Disable-UMServer cmdlet (for example, `Disable-UMServer UM01`). Alternatively, if you are using a Voice over IP (VoIP) gateway, you can also remove the Unified Messaging server entries from the VoIP gateway, or change the DNS records for the failed servers to point to the IP address of the Unified Messaging servers in the second datacenter if your VoIP gateway is configured to route calls using DNS.

Return to top

Activating Mailbox Servers

The steps needed to activate Mailbox servers during a datacenter switchover also depend on whether the DAG is in DAC mode. Before activating the DAG members in the second datacenter, we recommend that you validate that the infrastructure services in the second datacenter are ready for messaging service activation.

When the DAG is in DAC mode, the steps to complete activation of the mailbox servers in

the second datacenter are as follows:

1. The Cluster service must be stopped on each DAG member in the second datacenter. You can use the **Stop-Service** cmdlet to stop the service (for example, `Stop-Service ClusSvc`), or use `net stop clussvc` from an elevated command prompt.
2. The Mailbox servers in the standby datacenter are then activated by using the Restore-DatabaseAvailabilityGroup cmdlet. The Active Directory site of the standby datacenter is passed to the **Restore-DatabaseAvailabilityGroup** cmdlet to identify which servers to use to restore service and to configure the DAG to use an alternate witness server. If the alternate witness server wasn't previously configured, you can configure it by using the *AlternateWitnessServer* and *AlternateWitnessDirectory* parameters of the Restore-DatabaseAvailabilityGroup cmdlet. If this command succeeds, the quorum criteria are shrunk to the servers in the standby datacenter. If the number of servers in that datacenter is an even number, the DAG will switch to using the alternate witness server as identified by the setting on the DAG object.
3. The databases can now be activated. Depending on the specific configuration used by the organization, this may not be automatic. If the servers in the standby datacenter have an activation blocked setting, the system won't do an automatic failover from the primary datacenter to the standby datacenter of any database. If no failover restrictions are present for any of the database copies in the standby datacenter, the system will activate copies in the second datacenter assuming they are healthy. If databases are configured with an activation blocked setting that requires explicit manual action, there are two choices for action:
   3.a. Clear the setting that blocks activation. This will make the system return to its default behavior, which is to activate any available copy.
   3.b. Leave the setting unchanged and use the Move-ActiveMailboxDatabase cmdlet to complete the database activation in the second datacenter. To complete this step using the **Move-ActiveMailboxDatabase** cmdlet when activation blocked is set, you must explicitly identify the target of the move.
4. The last step is to review all error and warning messages from the tasks. Any indicated warnings should be followed up and corrected. The task design model for these commands is to only fail if they can't achieve the fundamental goal of their design. For example, the **Restore-DatabaseAvailabilityGroup** cmdlet will fail if it can't shrink the quorum of the DAG to allow a server in the second datacenter to be restarted for servicing without causing a quorum outage. However, each task's output is also used to identify the issues that require administrator follow-up. You're strongly encouraged to save all task output and review it for follow-up actions.

When the DAG isn't in DAC mode, the steps to complete activation of the mailbox servers in the second datacenter are as follows:

1. The quorum must be modified based on the number of DAG members in the second datacenter.
   1.a. If there's an odd number of DAG members, change the DAG quorum model from a Node a File Share Majority to a Node Majority quorum by running the following command:

```
cluster <DAGName> /quorum /nodemajority
```

   1.b. If there's an even number of DAG members, reconfigure the witness server and directory by running the following command in the Exchange Management Shell:

```
Set-DatabaseAvailabilityGroup <DAGName> -WitnessServer <Ser
```

2. Start the Cluster service on any remaining DAG members in the second

datacenter by running the following command:

```
net start clussvc
```

3. Perform server switchovers to activate the mailbox databases in the DAG by running the following command for each DAG member:

```
Move-ActiveMailboxDatabase -Server <DAGMemberinPrimarySite> -ActivateO
```

4. Mount the mailbox databases on each DAG member in the second site by running the following command:

```
Get-MailboxDatabase <DAGMemberinSecondSite> | Mount-Database
```

5. Because public folder databases don't use continuous replication and instead rely on public folder replication for high availability, the behavior for Outlook clients reconnecting to a public folder database after a datacenter switchover depends on a site-resilient public folder architecture and the health and currency of your public folder databases. To re-establish public folder connectivity for Outlook clients, simply change the default public folder for the mailbox database to point to a public folder database in the second site. For detailed steps about how to change the default public folder database for a mailbox database, see Change the Default Public Folder Database for a Mailbox Database.

Return to top

Activating Other Server Roles

The steps necessary to activate non-Mailbox server roles depend on the specific server and its configuration. The activation process for each of the server roles is described in the following sections.

Activating Client Access Servers

Clients connect to service endpoints (for example Outlook Web App, Autodiscover, Exchange ActiveSync, Outlook Anywhere, POP3, IMAP4, and the RPC Client Access array) to access Exchange services and data. Therefore, activating Client Access servers involves changing the mapping of the DNS records for these service endpoints from IP addresses in the primary datacenter to the IP addresses in the second datacenter that are configured as the new service endpoints. Depending on your DNS configuration, the DNS records that need to be modified may or may not be in the same DNS zone.

Clients will then automatically connect to the new service endpoints in one of two ways:

- Clients will continue to try to connect, and should automatically connect after the TTL has expired for the original DNS entry, and after the entry is expired from the client's DNS cache. Users can also run the `ipconfig /flushdns` command from a command prompt to manually clear their DNS cache.
- Clients starting or restarting will perform a DNS lookup on startup and will get the new IP address for the service endpoint, which will be a Client Access server or array in the second datacenter.

Assuming that all appropriate configuration changes have been completed to define and configure the services in the second datacenter to function as they were in the primary datacenter, and assuming that the established DNS configuration is correct, no further changes should be needed to activate Client Access servers.

Activating Hub Transport Servers

Clients and other servers that submit messages to Hub Transport servers typically identify those servers using DNS. Activating Hub Transport servers involves changing DNS records to point to the IP addresses of the Hub Transport servers in the second datacenter. Clients and sending servers will then automatically connect to the Hub Transport servers in the second datacenter in one of two ways:

- Clients will continue to try to connect, and should automatically connect after

the TTL has expired for the original DNS entry, and after the entry is expired from the client's DNS cache. Users can also run the `ipconfig /flushdns` command from a command prompt to manually clear their DNS cache.
- Clients starting or restarting will perform a DNS lookup on startup and will get the new IP address for the SMTP endpoint, which will be a Hub Transport server in the second datacenter.

Assuming that all appropriate configuration changes have been completed to define and configure the services in the second datacenter to function as they were in the primary datacenter, and assuming that the established DNS configuration is correct, no further changes should be needed to activate Hub Transport servers.

Activating Unified Messaging Servers

Unified Messaging (UM) servers connect to an organization's PBX system and phone lines. The logical connection between the PBX system and the Unified Messaging server is provided by an IP gateway. IP gateways include high availability functionality and are able to switch between multiple Unified Messaging servers when a failure is detected.

If there are Unified Messaging servers in the second datacenter that were in a disabled state because they are dedicated to the site resilience solution, they can be enabled by using the Enable-UMServer cmdlet (for example, `Enable-UMServer UM04`).

Assuming the IP gateways are associated with Unified Messaging servers by using DNS servers, activating Unified Messaging servers therefore involves changing DNS records to point to the new IP addresses that will be configured for the Unified Messaging servers in the second datacenter. After the TTL and DNS cache entries have expired, clients and IP gateways won't be able to connect to the Microsoft Exchange Unified Messaging service. Assuming that all appropriate configuration changes have been completed to define and configure the services in the second datacenter to function as they were in the primary datacenter, and assuming that the established DNS configuration is correct, no further changes should be needed to activate Unified Messaging servers.

If the IP gateway in use doesn't support the use of DNS names to resolve the Unified Messaging servers, additional configuration steps will be necessary to manually point the IP gateway to the IP addresses of the Unified Messaging servers in the second datacenter.

Activating Edge Transport Servers

The steps to activate the Edge Transport server role will vary, depending on the specific configuration. Edge Transport servers in two datacenters can be configured in either an active/passive or an active/active configuration. In an active/passive configuration, the Edge Transport server in the second datacenter is idle until the second datacenter is activated. In an active/active configuration, Edge Transport servers in both datacenters are delivering mail at all times.

In an active/active configuration, no steps are necessary to activate the second datacenter's Edge Transport servers because they are already running. In an active/passive configuration, the DNS MX resource record for each SMTP domain needs to be updated as part of the switchover from the primary datacenter to the standby datacenter. Although the active/active configuration provides a simple datacenter switchover solution, it has the drawback of requiring careful load monitoring to make sure that after the datacenter switchover, the Edge Transport servers in the second datacenter can provide sufficient capacity to support the increased load now flowing through it, as a result of the Edge Transport servers in the primary datacenter being unavailable.

Even with an active/active configuration, it may be appropriate to update the MX resource records for your Edge Transport servers during a datacenter switchover. Allowing the MX resource record for the failed datacenter to continue to point at the failed datacenter means that when the datacenter starts recovering, it could start experiencing connection attempts to its Edge Transport servers. This could happen while the Edge Transport

services are in an unstable state (for example, because dependent services in the datacenter are being restored).

Assuming the DNS records are under the control of the organization, activating Edge Transport servers involves updating the MX resource record for each SMTP domain hosted by the server.

Note:
If the MX resource record used by your organization isn't hosted by a DNS server under your organization's control, you might consider referencing a CNAME record in the MX resource record and using a CNAME record under the organization's control that can then be updated.

DNS updates enable incoming traffic, and outgoing traffic is handled by the activation of the mailbox databases in a site that has functioning Edge Transport servers:

- When incoming SMTP connections are initiated using the updated name resolution information, SMTP clients will connect to the Edge Transport servers in the second datacenter. Traffic will be appropriately routed by the Edge Transport server, and no further changes are required.
- When outgoing SMTP connections are initiated, they will try the locally available Edge Transport server, and those messages will be queued or immediately sent based on the status of the receiving server.

Return to top

Restoring Service to the Primary Datacenter

Generally, datacenter failures are either temporary or permanent. With a permanent failure, such as an event that has caused the permanent destruction of a primary datacenter, there's no expectation that the primary datacenter will be activated. However, with a temporary failure (for example, an extended power loss or extensive but repairable damage), there's an expectation that the primary datacenter will eventually be restored to full service.

The process of restoring service to a previously failed datacenter is referred to as a *switchback*. The steps used to perform a datacenter switchback are similar to the steps used to perform a datacenter switchover. A significant distinction is that datacenter switchbacks are scheduled, and the duration of the outage is often much shorter.

It's important that switchback not be performed until the infrastructure dependencies for Exchange have been reactivated, are functioning and stable, and have been validated. If these dependencies aren't available or healthy, it's likely that the switchback process will cause a longer than necessary outage, and it's possible the process could fail altogether.

Mailbox Server Role Switchback

The Mailbox server role should be the first role that's switched back to the primary datacenter. The following steps detail the Mailbox server role switchback process:

1. As part of the datacenter switchover process, the Mailbox servers in the primary datacenter were put into a stopped state. When the environment (such as primary datacenter, Exchange dependencies, and wide area network (WAN) connectivity) is ready, the first step is to put the Mailbox servers in the restored primary datacenter into a started state and incorporate them into the DAG. The way in which this is done depends on whether the DAG is in DAC mode.
   1.a. If the DAG is in DAC mode, you can reincorporate the DAG members in the primary site by using the Start-DatabaseAvailabilityGroup cmdlet. Then, to

make sure that the proper quorum model is being used by the DAG, run the Set-DatabaseAvailabilityGroup cmdlet against the DAG without specifying any parameters.

1.b.If the DAG isn't in DAC mode, you can reincorporate the DAG members by using the Add-DatabaseAvailabilityGroupServer cmdlet.

2. After the Mailbox servers in the primary datacenter have been incorporated into the DAG, they will need some time to synchronize their database copies. Depending on the nature of the failure, the length of the outage, and actions taken by an administrator during the outage, this may require reseeding the database copies. For example, if during the outage, you remove the database copies from the failed primary datacenter to allow log file truncation to occur for the surviving active copies in the second datacenter, reseeding will be required. Each database can individually proceed from this point forward. After a replicated database copy in the primary datacenter is healthy, it can proceed to the next step.

Note:

This process doesn't require that all databases be moved at the same time. You are encouraged to move the majority of your organization's databases at one time, but some databases many linger in the second datacenter if there are issues associated with the database copies in the primary datacenter.

3. After a majority of the databases are in a healthy state in the primary datacenter, the switchback outage can be scheduled. When the scheduled time arrives, the following steps must be taken:

3.a.During the datacenter switchover process, the DAG was configured to use an alternate witness server. The DAG must be reconfigured to use a witness server in the primary datacenter. If you are using the same witness server and witness directory that was used prior to the primary datacenter outage, you can run the `Set-DatabaseAvailabilityGroup -Identity DAGName` command. If you plan on using a witness server or witness directory that is different from the original witness server and directory, use the Set-DatabaseAvailabilityGroup command to configure the witness server and witness directory parameters with the appropriate values.

3.b.The databases being reactivated in the primary datacenter should be dismounted in the second datacenter. You can use the Dismount-Database cmdlet to dismount the databases.

3.c.After the databases have been dismounted, the Client Access server URLs should be moved from the second datacenter to the primary datacenter. This is accomplished by changing the DNS record for the URLs to point to the Client Access server or array in the primary datacenter. This will result in the system acting as though a database failover has occurred for each database being moved.

Important:

Don't proceed to the next step until the Client Access server URLs have been moved and the DNS TTL and cache entries have expired. Activating the databases in the primary datacenter prior to moving the Client Access server URLs to the primary datacenter will result in an invalid configuration (for example, a mounted database that has no Client Access servers in its Active Directory site).

3.d.Because each database in the primary datacenter is in a healthy state, it can be activated in the primary datacenter by performing database switchovers. This is accomplished by using the Move-ActiveMailboxDatabase cmdlet for each database that will be activated.

3.e.After each database is moved to the primary datacenter, it can be mounted by using the Mount-Database cmdlet.

After one or more databases are active and mounted in the primary datacenter, switchback procedures for the other server roles can be performed.

Other Server Role Switchback

As part of the switchover process, the internal and external DNS records used by clients, other servers, and IP gateways to resolve the service endpoints for Client Access, Hub Transport, Edge Transport, and Unified Messaging servers were modified to point to the corresponding endpoints in the second datacenter. The switchback process for the other server roles involves modifying those records to point to the restored service endpoints in the primary datacenter.

As with the DNS changes that were made during the switchover to the second datacenter, clients, servers, and IP gateways will continue to try to connect, and should automatically connect after the TTL has expired for the original DNS entry, and after the entry is expired from their DNS cache.

Reestablishing Site Resilience

After switchback to the primary datacenter is completed successfully, you can reestablish site resilience for the primary datacenter by verifying the health and status of each mailbox database copy in the second datacenter. In addition, if any database copies in the second datacenter were originally blocked for activation, you can reconfigure those settings at this time.

Return to top

1.10.4.4.2 Perform a Server Switchover

Perform a Server Switchover

High Availability and Site Resilience > Managing High Availability and Site Resilience > Switchovers and Failovers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A server switchover is a task that you perform to move all active mailbox database copies from their current Mailbox server to one or more other Mailbox servers in a database availability group (DAG). This task is performed as part of preparation for a scheduled outage for the current Mailbox server.

Use the EMC to perform a server switchover

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Mailbox**.
2. In the result pane, select the Mailbox server you want.
3. In the action pane, select **Switchover Server**.
4. In the **Switchover server database copies** dialog box, do one of the following:
   4.a. Accept the default setting of **Automatically choose a target server** (in which case, the system automatically selects the best Mailbox server for

each database being switched over), and then click **OK**.

4.b.Click **Use the specified server as the target for switchover**, click **Browse** to select a Mailbox server, and then click **OK**.

Use the Shell to perform a server switchover

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the"Mailbox database copies" entry in the High Availability Permissions topic.

This example performs a server switchover for the server MBX1. The system automatically selects the best Mailbox server for each active database on MBX1.

```
Move-ActiveMailboxDatabase -Server MBX1
```

This example performs a server switchover of the Mailbox server MBX4. When the command completes, MBX5 hosts the active copy of the databases that were previously active on MBX4. Because the *MountDialOverride* parameter isn't specified, MBX5 mounts the databases using a database auto mount dial setting of *Lossless*.

```
Move-ActiveMailboxDatabase -Server MBX4 -ActivateOnServer MBX5
```

For detailed syntax and parameter information, see Move-ActiveMailboxDatabase.

1.10.4.5 Installing Update Rollups on Database Availability Group Members

Installing Update Rollups on Database Availability Group Members

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-14*

It's relatively straightforward to install Microsoft Exchange Server 2010 update rollups on a server that's a member of a database availability group (DAG).

Microsoft Update offers released update rollups to Mailbox servers that are part of DAG. However, we recommend that you download the update rollups from the Microsoft Download Center and then install them manually. When you install an update rollup on a server that's a DAG member, several services will be stopped during the installation, including all Exchange services and the Windows Cluster service.

The general process for installing update rollups on a DAG member is as follows:

- Run the StartDagServerMaintenance.ps1 script to put the DAG member into maintenance mode and prepare it for the update rollup installation.
- Install the update rollup.
- Run the StopDagServerMaintenance.ps1 script to take the DAG member out of maintenance mode and put it back into production.
- Optionally rebalance the DAG by using the RedistributeActiveDatabases.ps1 script.

This process can also be used to install operating system updates from Microsoft Update, as well.

You can download the latest update rollup for Exchange 2010 from the Microsoft Download Center.

Install a Update Rollup on a Database Availability Group Member

To update all DAG members, perform the following procedures on each DAG member, one at a time.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database availability groups" entry in the High Availability Permissions topic.

Run the StartDagServerMaintenance.ps1 script on the server being updated

Run the following command in the Exchange Management Shell from the Scripts directory:

```
.\StartDagServerMaintenance.ps1 <ServerName>
```

For more information about the StartDagServerMaintenance.ps1 script, see Managing Database Availability Groups.

Install the update rollup

1. Close all Exchange management tools.
2. Right-click the Exchange update rollup file (.msp file) you downloaded, and then select **Apply**.
3. On the **Welcome** page, click **Next**.
4. On the **License Terms** page, review the license terms, select **I accept the License Terms**, and then click **Next**.
5. On the **Completion** page, click **Finish**.

Run the StopDagServerMaintenance.ps1 script

Run the following command in the Shell from the Scripts directory:

```
.\StopDagServerMaintenance.ps1  <ServerName>
```

For more information about the StopDagServerMaintenance.ps1 script, see Managing Database Availability Groups.

Re-balance the DAG, as needed

Run the following command in the Shell from the Scripts directory to optionally balance the DAG by Activation Preference and to produce a report when balancing is complete:

```
.\ RedistributeActiveDatabases.ps1 -DagName <DAGName>
-BalanceDbsByActivationPreference -ShowFinalDatabaseDistribution
```

For more information about the RedistributeActiveDatabases.ps1 script, see Managing Database Availability Groups.

1.10.5 Understanding Backup, Restore and Disaster Recovery

Understanding Backup, Restore and Disaster Recovery

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-01*

Microsoft Exchange Server 2010 features a new, unified platform for high availability and site resilience that makes deploying redundant, highly available mailbox databases quicker and easier. But even the most extreme forms of redundancy and fault tolerance can't protect you against every possible failure or disaster. Ensuring there's sufficient protection for the critical data in your Exchange organization is a necessary operational task for all organizations.

As part of your data protection planning, it's important that you understand the ways in which data can be protected, and to determine of those ways, which best suits your organization's needs. Data protection planning is a complex process that relies on many decisions that you make during the planning phase of your deployment.

Contents

Supported Backup Technologies

Microsoft Exchange Server 2007 and Exchange Server 2003 include two different options for data backup and recovery: Extensible Storage Engine (ESE) streaming backup APIs and support for the Volume Shadow Copy Service (VSS) backup APIs. Exchange 2010 no longer supports the ESE streaming APIs for backup and restore of program files or data. Instead, Exchange 2010 supports only VSS-based backups.

Exchange 2010 includes a plug-in for Windows Server Backup that enables you to make VSS-based backups of Exchange data. You can use Windows Server Backup to back up and restore your Exchange databases. To back up and restore Exchange 2010, you must use an Exchange-aware application that supports the VSS writer for Exchange 2010, such as Windows Server Backup (with the VSS plug-in), Microsoft System Center Data Protection Manager, or a third-party Exchange-aware VSS-based application. Be aware of these limitations when using VSS for backup and restore of Exchange data:

- The VSS plug-in that ships with Exchange 2010 can be used to back up volumes containing active mailbox database copies or standalone (non-replicated) mailbox databases only. It can't be used to back up volumes containing passive mailbox database copies. To back up passive mailbox database copies, you need either Microsoft System Center Data Protection Manager or a third-party Exchange-aware VSS-based application.
- Passive mailbox database copies are backed up using a separate VSS writer in

the Microsoft Exchange Replication service. The Microsoft Exchange Replication service VSS Writer doesn't support restores. Although you can back up a passive mailbox database copy using Microsoft System Center Data Protection Manager or a third-party Exchange-aware VSS-based application, you can't perform a VSS restore directly to a passive mailbox database copy. However, you can perform a VSS restore to an alternate location, suspend replication to the passive copy, and then copy the database and log files from the alternate location to the location of the passive database copy in the file system.

For detailed steps to back up and restore Exchange data using Windows Server Backup, see Using Windows Server Backup to Back Up and Restore Exchange Data.

Return to top

Server Recovery

Almost all of the configuration settings for Mailbox, Client Access, Hub Transport, and Unified Messaging server roles are stored in Active Directory. As with previous versions of Exchange, Exchange 2010 includes a Setup parameter for recovering lost servers. This parameter, */m:RecoverServer*, is used to rebuild and re-create a lost server by using the settings and configuration information stored in Active Directory.

For detailed steps to perform a server recovery of a lost Exchange 2010 server, see Recover an Exchange Server. For detailed steps to recover a lost server that's a member of a database availability group, see Recover a Database Availability Group Member Server.

Return to top

Recovery Database

A recovery database is an Exchange 2010 feature that replaces the recovery storage group (RSG) found in previous versions of Exchange. A recovery database is a special kind of mailbox database that allows you to mount a restored mailbox database and extract data from the restored database as part of a recovery operation. You can use the Restore-Mailbox cmdlet to extract data from a recovery database. After extraction, the data can be exported to a folder or merged into an existing mailbox. Recovery databases enable you to recover data from a backup or copy of a database without disturbing user access to current data.

Before you can use a recovery database, there are certain requirements that must be met. A recovery database can be used for Exchange 2010 mailbox databases only. Mailbox databases from previous versions of Exchange aren't supported. In addition, the target mailbox used for data merges and extraction must be in the same Active Directory forest as the database mounted in the recovery database.

For more information, see Recovery Databases. For detailed steps to create a recovery database, see Create a Recovery Database. For detailed steps to use a recovery database, see Restore Data Using a Recovery Database.

Return to top

Database Portability

Database portability is a feature that enables an Exchange 2010 mailbox database to be moved to and mounted on any other Exchange 2010 Mailbox server in the same organization. By using database portability, reliability is improved by removing several

error-prone, manual steps from the recovery processes. In addition, database portability reduces the overall recovery times for various failure scenarios.

For more information, see Database Portability. For detailed steps to use database portability, see Move a Mailbox Database Using Database Portability.

Return to top

Dial Tone Portability

Dial tone portability is a feature that provides a limited business continuity solution for failures that affect a mailbox database, a server, or an entire site. Dial tone portability enables a user to have a temporary mailbox for sending and receiving e-mail while the original mailbox is being restored or repaired. The temporary mailbox can be on the same Exchange 2010 Mailbox server or on any other Exchange 2010 Mailbox server in your organization. This allows an alternative server to host the mailboxes of users who were previously on a server that's no longer available. Clients that support Autodiscover, such as Microsoft Outlook 2010 or Office Outlook 2007, are automatically redirected to the new server without having to manually update the user's desktop profile. After the user's original mailbox data has been restored, an administrator can merge a user's recovered mailbox and the user's dial tone mailbox into a single, up-to-date mailbox.

The process for using dial tone portability is called a *dial tone recovery*. A dial tone recovery involves creating an empty database on a Mailbox server to replace a failed database. This empty database, referred to as a *dial tone database*, allows users to send and receive e-mail while the failed database is recovered. After the failed database is recovered, the dial done database and the recovered database are swapped, and then the data from the dial tone database is merged into the recovered database.

For more information, see Dial Tone Portability. For detailed steps to perform a dial tone recovery, see Perform a Dial Tone Recovery.

Return to top

Exchange Native Data Protection

Exchange 2010 includes several new features and core changes that, when deployed and configured correctly, can provide native data protection that eliminates the need to make traditional backups of your data. Using the high availability features built into Exchange 2010 to minimize downtime and data loss in the event of a disaster can also reduce the total cost of ownership of the messaging system. By combining these features with other built-in features, such as Legal Hold, organizations can reduce or eliminate their dependency on traditional point-in-time backups and reduce the associated costs.

In addition to determining whether Exchange 2010 enables you to move away from traditional point-in-time backups, we also recommend that you evaluate the cost of your current backup infrastructure. Consider the cost of end-user downtime and data loss when attempting to recover from a disaster using your existing backup infrastructure. Also, include hardware, installation, and license costs, as well as the management cost associated with recovering data and maintaining the backups. Depending on the requirements of your organization, it is quite likely that a pure Exchange 2010 environment with at least three mailbox database copies will provide lower total cost of ownership than one with backups.

Backups are typically used for the following scenarios, and there are Exchange 2010 features to meet each of these needs in an efficient and cost effective manner.

- **Disaster recovery** In the event of a hardware or software failure, multiple database copies in a database availability group (DAG) enable high availability

with fast failover with no data loss. This eliminates the end-user downtime and resulting lost productivity that's a significant cost of recovering from a past point-in-time backup to disk or tape. DAGs can be extended to multiple sites and can provide resilience against datacenter failures.

- **Recovery of accidentally deleted items** Historically, in a situation where a user deleted items that later needed to be recovered, it involved finding the backup media on which the data that needed to be recovered was stored, and then somehow obtaining the desired items and providing them to the user. With the new Recoverable Items Folder in Exchange 2010 and the Hold Policy that can be applied to it, it's possible to retain all deleted and modified data for a specified period of time, so recovery of these items is easier and faster. This reduces the burden on Exchange administrators and the IT help desk by enabling end users to recover accidentally deleted items themselves, thereby reducing the complexity and administrative costs associated with single item recovery. For more information, see Messaging Policy and Compliance, Understanding Recoverable Items, and Understanding Retention Tags and Retention Policies.
- **Long-term data storage** Sometimes, backups also serve an archival purpose, and typically tape is used to preserve point-in-time snapshots of data for extended periods of time as governed by compliance requirements. The new archiving, multiple-mailbox search, and message retention features in Exchange 2010 provide a mechanism to efficiently preserve data in an end-user accessible manner for extended periods of time. This eliminates expensive restores from tape, and increases end-user productivity by enabling rich clients such as Microsoft Outlook and Outlook Web App access to older data. For more information see Understanding Personal Archives, Understanding Multi-Mailbox Search, and Understanding Retention Tags and Retention Policies.
- **Point-in-time database snapshot** If a past point-in-time copy of mailbox data is a requirement for your organization, Exchange provides the ability to create a lagged copy in a DAG environment. This can be useful in the rare event that there's a logical corruption that replicates across the databases in the DAG, resulting in a need to return to a previous point in time. It may also be useful if an administrator accidentally deletes mailboxes or user data. Recovery from a lagged copy can be faster than restoring from a backup because lagged copies don't require a time-consuming copy process from the backup server to the Exchange server. This can significantly lower total cost of ownership by reducing end-user downtime.

Log Truncation without Backups

One of the functions performed at the end of a successful full or incremental backup is the truncation of transaction log files that are no longer needed for database recovery. If backups are not being taken, then log truncation will not occur. To prevent a buildup of log files, you enable circular logging for your replicated databases. When you combine circular logging with continuous replication, you have a new type of circular logging called continuous replication circular logging (CRCL), which is different from ESE circular logging. Whereas ESE circular logging is performed and managed by the Microsoft Exchange Information Store service, CRCL is performed and managed by the Microsoft Exchange Replication Service. When enabled, ESE circular logging does not generate additional log files and instead overwrites the current log file when needed. However, in a continuous replication environment, log files are needed for log shipping and replay. As a result, when you enable CRCL, the current log file is not overwritten and closed log files are generated for the log shipping and replay process.

Specifically, the Microsoft Exchange Replication Service manages CRCL so that log continuity is maintained and logs are not deleted if they are still needed for replication. The Microsoft Exchange Replication Service and the Microsoft Exchange Information Store service communicate by using remote procedure calls (RPCs) regarding which log files can be deleted.

For truncation to occur on highly available (non-lagged) mailbox database copies, the answer must be "Yes" to the following questions:

- Has the log file been backed up, or is CRCL enabled?
- Is the log file below the checkpoint?
- Do the other non-lagged copies of the database agree with deletion?
- Has the log file been inspected by all lagged copies of the database?

For truncation to occur on lagged database copies, the answer must be "Yes" to the following questions:

- Is the log file below the checkpoint?
- Is the log file older than ReplayLagTime + TruncationLagTime?
- Is the log file deleted on the active copy of the database?

For information about how to enable and disable circular logging, see Configure Mailbox Database Properties.

Considerations for Implementing Exchange Native Data Protection

There are technical reasons and several issues that you should consider before using the features built into Exchange 2010 as a replacement for traditional backups. The following list includes some of these considerations, although the list isn't exhaustive. There may also be special considerations or considerations unique to your organization. Consider the following issues:

- How many copies of the database will be deployed? We strongly recommend deploying a minimum of three (non-lagged) copies of a mailbox database before eliminating traditional forms of protection for the database, such as RAID or traditional VSS-based backups.
- Your recovery time objective and recovery point objective goals should be clearly defined, and you should establish that using a combined set of built-in features in lieu of traditional backups enables you to meet these goals.
- You should determine how many copies of each database are needed to cover the various failure scenarios against which your system is designed to protect.
- If you eliminate the use of a DAG or some of its members, does that capture sufficient costs to support a traditional backup solution? If so, does that solution improve your recovery time objective or recovery point objective service level agreements (SLAs)?
- Can you afford to lose a point-in-time copy if the DAG member hosting the copy experiences a failure that affects the copy or the integrity of the copy?
- Exchange 2010 allows you to deploy larger mailboxes, and the recommended maximum mailbox database size has been increased from 200 gigabytes (GB) in Exchange 2007 to 2 terabytes (when two or more highly available mailbox database copies are being used). Based on the larger mailboxes that most organizations are likely to deploy, what will your recovery point objective be if you have to replay a large number of log files when activating a database copy or a lagged database copy?
- How will you detect and prevent logical corruption in an active database copy from replicating to the passive copies of the database? What is your recovery plan for this situation? How frequently has this scenario occurred in the past? If logical corruption occurs frequently in your organization, we recommend that you factor that scenario into your design by using one or more lagged copies, with a sufficient replay lag window to allow you to detect and act on logical corruption when it occurs, but before that corruption is replicated to other database copies.

Return to top

1.10.5.1 Using Windows Server Backup to Back Up and Restore Exchange Data

Using Windows Server Backup to Back Up and Restore Exchange Data

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-01*

Microsoft Exchange Server 2010 includes a plug-in for Windows Server Backup that enables you to create Volume Shadow Copy Service (VSS)-based backups of Exchange data. You can use Windows Server Backup to back up and restore your Exchange databases. A thorough understanding of what needs to be backed up, where to store backups, and how to restore backups is key to being an effective Exchange administrator. For more information about what needs to be backed up in Exchange 2010, see Understanding Backup, Restore and Disaster Recovery.

The new plug-in is delivered in the form of an executable called WSBExchange.exe, which is configured to run as a service named Microsoft Exchange Server Extension for Windows Server Backup (the short name for this service is WSBExchange). The plug-in is automatically installed on all Exchange 2010 Mailbox servers and configured by default for manual startup. The plug-in enables Windows Server Backup to create Exchange-aware VSS backups.

Note:

To use the plug-in, you must have the Windows Server Backup feature installed. However, you shouldn't install the Windows Server Backup command-line tools. These tools require an older version of the Windows PowerShell command-line interface, which isn't compatible with Exchange 2010. When you install Windows Server Backup, the command-line tool WBAdmin.exe is also installed. This command-line tool can be run from the Windows command prompt (cmd.exe).

For detailed steps about how to back up an Exchange server using Windows Server Backup, see Use Windows Server Backup to Perform a Backup of Exchange.

For detailed steps about how to restore data from a backup taken with Windows Server Backup, see Use Windows Server Backup to Restore a Backup of Exchange.

Before using Windows Server Backup to back up Exchange data, we recommend that you familiarize yourself with the following features and options for the plug-in:

- Backups are VSS-based only. You can't create streaming Extensible Storage Engine (ESE) backups using Windows Server Backup with or without the plug-in.
- Backups taken with Windows Server Backup occur at volume level. To back up a database and its log stream, you must back up the entire volume containing the database and logs. You can't back up any data without backing up the entire volume containing the data.
- The backup must be run locally on the server being backed up, and you can't use the plug-in to take remote VSS backups. There is no remote administration of Windows Server Backup or the plug-in. You can, however, use Remote Desktop Services or Terminal Services to remotely manage backups.
- The backup can be created on a local drive or on a remote network share.
- Only full backups can be taken. Log truncation will occur only after a successful completion of a full backup of a volume or folders containing an Exchange database.
- When restoring data, it's possible to restore only Exchange data. This data can be restored to its original location or to an alternate location. If you

restore the data to its original location, Windows Server Backup and the plug-in automatically handle the recovery process, including dismounting any existing databases and replaying logs into the recovered database.
- The restore process doesn't directly support the recovery database (RDB). However, if you restore to an alternate location, you can then manually move the restored data from the alternate location into an RDB, if needed.
- When restoring Exchange data, all backed up databases must be restored together. You can't restore a single database.

Using Windows Server Backup on Database Availability Group Members

If a server hosting the data being backed up is a member of a database availability group (DAG) and hosts both active and passive database copies, you must disable the Microsoft Exchange Replication service VSS writer. If the Microsoft Exchange Replication service VSS writer is enabled, the backup operation will fail.

To disable the Microsoft Exchange Replication service VSS writer, perform the following steps:

1. Log on to the server by using an account that has local administrator access, and then start Registry Editor (regedit).

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

2. Navigate to HKEY_LOCAL_MACHINE\Software\Microsoft\ExchangeServer\v14\Replay\Parameters.
3. Add a new DWORD value named **EnableVSSWriter**, and set its value to **0**.
4. Exit Registry Editor and then restart the Microsoft Exchange Replication service.

Important:

If you later want to use a different a backup solution to back up passive database copies on a server that has the Microsoft Exchange Replication service VSS writer disabled, you need to remove the preceding registry key and then restart the Microsoft Exchange Replication service.

1.10.5.1.1 Use Windows Server Backup to Perform a Backup of Exchange

Use Windows Server Backup to Perform a Backup of Exchange

High Availability and Site Resilience > Understanding Backup, Restore and Disaster Recovery > Using Windows Server Backup to Back Up and Restore Exchange Data >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Microsoft Exchange Server 2010 includes a plug-in for Windows Server Backup that allows you to make Volume Shadow Copy Service (VSS)-based backups of Exchange data. You can use Windows Server Backup to back up and restore your Exchange databases.

During the backup operation, a consistency check of the Exchange data files is run to make sure that the files are in a good state and can be used for recovery. If the consistency check succeeds, Exchange data is available for recovery from that backup. If

the consistency check fails, the Exchange data isn't available for recovery. Windows Server Backup runs the consistency check on the snapshot taken for the backup. As a result, before copying files from the snapshot to backup media, the consistency of the backup is known, and the user is notified of the consistency check results.

Prerequisites

- This procedure can only be performed locally on a computer running Exchange 2010 on the Windows Server 2008 or Windows Server 2008 R2 operating system.
- The Windows Server Backup feature must be installed on the local computer.
- If a server hosting the data being backed up is a member of a database availability group (DAG) and hosts both active and passive database copies, you must disable the Microsoft Exchange Replication service VSS writer. If the Microsoft Exchange Replication service VSS writer is enabled, the backup operation will fail. For detailed steps, see Using Windows Server Backup to Back Up and Restore Exchange Data.

Use Windows Server Backup to perform a backup of Exchange

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

1. Start Windows Server Backup.
2. In the **Actions** pane, click **Backup Once**. The Backup Once wizard appears.
3. On the **Backup options** page, select **Different options**, and then click **Next**.
4. On the **Select backup configuration** page, select the type of backup that you want, and then click **Next**:
   4.a. Select **Full server (recommended)** to back up all volumes on the server.
   4.b. Select **Custom** to specify which volumes should be included in the backup. If you select this option, the **Select backup items** page appears. Select the volumes to be backed up, and then click **Next**.

   Note:
   By default, volumes that contain operating system components or applications are included in the backup and can't be excluded.
5. On the **Specify destination type** page, select the location where you want to store the backup, and then click **Next**. If **Remote shared folder** is selected, the **Specify remote folder** page appears. Specify a UNC path for the backup files, and then do one of the following to configure access control settings:
   5.a. Select **Do not inherit** if you want the backup to be accessible only by a set of specified user credentials, and then click **Next**. Type a user name and password for a user account that has write permissions on the computer that is hosting the remote folder, and then click **OK**.
   5.b. Select **Inherit** if you want the backup to be accessible by everyone who has access to the remote folder, and then click **Next**.
6. On the **Specify advanced options** page, select **VSS full backup**, and then click **Next**.
7. On the **Confirmation** page, review the backup settings, and then click **Backup**.
8. On the **Backup progress** page, you can view the status and progress of the backup operation.
9. Click **Close** when the backup operation has completed.

Use Windows Server Backup to Restore a Backup of Exchange

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-12*

Microsoft Exchange Server 2010 includes a plug-in for Windows Server Backup that enables you to make Volume Shadow Copy Service (VSS)-based backups of Exchange data. You can use Windows Server Backup to back up and restore your Exchange databases.

Prerequisites

- This procedure can only be performed locally on a computer running Exchange 2010 on the Windows Server 2008 or Windows Server 2008 R2 operating system.
- When you restore a database to its original location, the database can remain in a dirty shutdown state and be mountable by the system. When you restore to an alternative location (such as the recovery database), the database must be in a clean shutdown state. You can bring a database into a clean shutdown state by using Exchange Server Database Utilities (Eseutil.exe).

Use Windows Server Backup to restore a backup of Exchange

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

1. Start Windows Server Backup.
2. In the **Actions** pane, click **Recover**. The Recovery wizard appears.
3. On the **Getting Started** page, do either of the following:
   3.a. If the data being recovered was backed up from the server on which Windows Server Backup is running, select **This server (ServerName)**, and then click **Next**.
   3.b. If the data being recovered wasn't from the server on which Windows Server Backup is running, or if the backup being recovered is located on another computer, select **Another server**, and then click **Next**. On the **Specify location type** page, select **Local drives** or **Remote shared folder**, and then click **Next**. If you select **Local drives**, select the drive containing the backup on the **Select backup location** page, and then click **Next**. If you select **Remote shared folder**, enter the UNC path for the backup data on the **Specify remote folder** page, and then click **Next**.
4. On the **Select backup date** page, select the date and time of the backup that you want to recover, and then click **Next**.
5. On the **Select recovery type** page, select **Applications**, and then click **Next**.
6. On the **Select application** page, verify that Exchange is selected in the **Applications** field. Click **View Details** to view the application components of the backups. If the backup that you're recovering is the most recent, the **Do not perform a roll-forward recovery of the application database** check box is displayed. Select this check box if you want to prevent Windows Server Backup from rolling forward the database being recovered. Click **Next**.
7. On the **Specify recovery options** page, select where you want to recover the data, and then click **Next**:
   7.a. Select **Recover to original location** to recover backed up data to its original location. If you use this option, you can't set a single database or

multiple databases; all backed up databases are restored to their original location.

7.b.Select **Recover to another location** to restore databases and files to a specified location. Click **Browse** to specify the alternative location. If you use this option, you can restore databases to a custom location. After being restored, the data files can then be moved to a recovery database, and then manually returned to their original location. When you restore databases to an alternative location, the restored databases are in a dirty shutdown state.

8. On the **Confirmation** page, review the recovery settings, and then click **Recover**.
9. On the **Recovery progress** page, you can view the status and progress of the recovery operation.
10. Click **Close** when the recovery operation has completed.

1.10.5.2 Recover an Exchange Server

Recover an Exchange Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-22*

You can recover a lost server by using the **Setup /m:RecoverServer** switch in Microsoft Exchange Server 2010. Most of the settings for a computer running Exchange 2010 are stored in Active Directory. The */m:RecoverServer* switch rebuilds an Exchange server with the same name by using the settings and other information stored in Active Directory.

Recovering a lost Exchange server is often accomplished by using new hardware. However, you can also use an existing server.

This topic shows you how to recover a lost Exchange 2010 server that isn't a member of a database availability group (DAG). For detailed steps about how to recover a server that was a member of a DAG, see Recover a Database Availability Group Member Server.

Note:

If Exchange is installed in a location other than the default location, you must use the **/TargetDir** switch to specify the location of the Exchange binary files. If you don't use the **/TargetDir** switch, the Exchange files are installed in the default location (%programfiles%\Microsoft\Exchange Server\V14).
To determine the install location, follow these steps:

1. Open ADSIEDIT.MSC or LDP.EXE.
2. Navigate to the following location:
   CN=ExServerName,CN=Servers,CN=First Administrative Group,CN=Administrative Groups,CN=ExOrg Name,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=DomainName,CN=Com
3. Right-click the Exchange server object, and then click **Properties**.
4. Locate the **msExchInstallPath** attribute. This attribute stores the current installation path.

Prerequisites

- The server on which recovery is being performed must be running the same

operating system as the lost server. For example, you can't recover a server that was running Exchange 2010 and Windows Server 2008 on a server running Windows Server 2008 R2, or vice versa.
- The same disk drive letters on the failed server for mounted databases must exist on the server on which you're running recovery.
- The server on which recovery is being performed should have the same performance characteristics and hardware configuration as the lost server.
- The following procedure can be run on an Exchange 2010 server that has the Client Access, Hub Transport, Mailbox, or Unified Messaging server roles installed. You can't use **Setup /m:RecoverServer** to recover an Edge Transport server. For information about preserving Edge Transport server settings and applying saved settings to an Edge Transport server, see Understanding Edge Transport Server Cloned Configuration.

Recover a Lost Exchange Server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange infrastructure permissions" section in the Exchange and Shell Infrastructure Permissions topic.

1. Reset the computer account for the lost server. For detailed steps, see Reset a Computer Account.
2. Install the proper operating system and name the new server with the same name as the lost server. Recovery won't succeed if the server on which recovery is being performed doesn't have the same name as the lost server.
3. Join the server to the same domain as the lost server.
4. Install the necessary prerequisites and operating system components. For details, see Exchange 2010 System Requirements and Exchange 2010 Prerequisites.
5. Log on to the server being recovered and open a command prompt.
6. Navigate to the Exchange 2010 installation files, and run the following command:

```
Setup /m:RecoverServer
```

7. After Setup has completed, but before the recovered server is put into production, reconfigure any custom settings that were previously present on the server.

1.10.5.3 Recovery Databases

Recovery Databases

Exchange Server 2010 > High Availability and Site Resilience > Understanding Backup, Restore and Disaster Recovery >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-03-06*

A recovery database (RDB) is a special kind of mailbox database that allows you to mount a restored mailbox database and extract data from the restored database as part of a recovery operation. You can use the Restore-Mailbox cmdlet to extract data from an RDB. After extraction, the data can be exported to a folder or merged into an existing mailbox. RDBs enable you to recover data from a backup or copy of a database without disturbing user access to current data.

Microsoft Exchange Server 2010 supports the ability to restore data directly to a recovery

database. Mounting the recovered data as a recovery database allows the administrator to restore individual mailboxes or individual items in a mailbox. Restoring to a recovery database can be accomplished in two ways:

- If a recovery database already exists, the application can dismount the database, restore the data onto the recovery database and log files, and then remount the database.
- The database and log files can be restored to any disk location. Exchange analyzes the restored data and replays the transaction logs to bring the databases up to date, and then a recovery database can be configured to point to already recovered database files.

Difference between a Mailbox Database and a Recovery Database

RDBs are different from standard mailbox databases in several respects:

- An RDB is created by using the Exchange Management Shell.
- Mail can't be sent to or from an RDB. All client protocol access to an RDB (including SMTP, POP3, and IMAP4) is blocked. This design prevents using an RDB to insert mail into or remove mail from the messaging system.
- Client MAPI access using Microsoft Office Outlook or Outlook Web App is blocked. MAPI access is supported for an RDB, but only by recovery tools and applications. Both the mailbox GUID and the database GUID must be specified when using MAPI to log into a mailbox in an RDB.
- Mailboxes in an RDB can't be connected to user accounts. To allow a user to access the data in a mailbox in an RDB, the mailbox must be merged into an existing mailbox, or exported to a folder.
- System and mailbox management policies aren't applied. This design prevents items in an RDB from being deleted by the system during the recovery process.
- Online maintenance isn't performed for RDBs.
- Circular logging can't be enabled for RDBs.
- An RDB is used for recovering only mailbox database data. You can't use an RDB to recover public folder data.
- Only one RDB can be mounted at any time on a Mailbox server. The use of an RDB doesn't count against the 100 database limit per Mailbox server.
- You can't create mailbox database copies of an RDB.
- An RDB can be used as a target for restore operations, but not backup operations.
- A recovered database mounted as an RDB isn't tied to the original mailbox in any way.

Using a Recovery Database

Before you can use an RDB, there are certain requirements that must be met. An RDB can be used for Exchange 2010 mailbox databases only. Mailbox databases from previous versions of Exchange aren't supported. In addition, the target mailbox used for data merges and extraction must be in the same Active Directory forest as the database mounted in the RDB.

An RDB can be used to recover data in several situations, such as:

- **Same server dial tone recovery** You can perform a recovery from an RDB after the original database has been restored from backup, as part of a dial tone recovery operation.
- **Alternate server dial tone recovery** You can use an alternate server to host the dial tone database, and then later recover data from an RDB after the original database has been restored from backup.
- **Mailbox recovery** You can recover an individual mailbox from backup when

the deleted mailbox retention period has elapsed. You then extract data from the restored mailbox and copy it to a target folder or merge it with another mailbox.

- **Specific item recovery** You can restore from backup data that has been deleted or purged from a mailbox.

Note:

Folder access control lists (ACLs) aren't preserved when recovering content into an active mailbox. Because the recovery process typically involves recovering mailbox data and merging the content back into the original database, there should be no need to recover or copy ACLs.

An RDB is designed for mailbox database recovery under the following conditions and scenarios:

- The logical information about the original database and the mailboxes in that database remains intact and unchanged in Active Directory.
- You need to recover a single mailbox or a single database. Recovery scenarios include:
  - Recovering or repairing a database while a dial tone database is in use, with the goal of merging the two databases.
  - Recovering a database on a server other than the original server for that database. If needed, you can then merge the recovered data back to the original server.
  - Recovering deleted items that users previously deleted from their mailbox, after the deleted item retention period has expired.

An RDB cannot be used when you have to recover public folder content. In addition, RDBs are generally not designed for scenarios in which you have to restore entire servers, when you have to restore multiple databases, or when you're in an emergency situation that requires changing or rebuilding your Active Directory topology.

For detailed steps about how to create an RDB, see Create a Recovery Database. For detailed steps about how to use an RDB, see Restore Data Using a Recovery Database.

1.10.5.3.1 Create a Recovery Database

Create a Recovery Database

High Availability and Site Resilience > Understanding Backup, Restore and Disaster Recovery > Recovery Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use a recovery database, which is a special kind of mailbox database, to mount a restored mailbox database and extract data from the restored database as part of a recovery operation. After you create a recovery database, you can move a recovered or restored mailbox database into the recovery database, and then use the Restore-Mailbox cmdlet to extract data from the recovered database. After extraction, the data can then be exported to a folder or merged into an existing mailbox. Using recovery databases, you can recover data from a backup or copy of a database without disrupting user access to current data.

Looking for other management tasks related to recovery databases? Check out Recovery Databases.

Use the Shell to create a recovery database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to create a recovery database.

This example creates the recovery database RDB1 on the Mailbox server MBX2.

```
New-MailboxDatabase -Recovery -Name RDB1 -Server MBX2
```

This example creates the recovery database RDB2 on the Mailbox server MBX1 using a custom path for the database file and log folder.

```
New-MailboxDatabase -Recovery -Name RDB2 -Server MBX1 -EdbFilePath "C:\Recovery\R
```

For detailed syntax and parameter information, see New-MailboxDatabase.

Other Tasks

After you create a recovery database, you may also want to restore data using a recovery database. For detailed steps, see Restore Data Using a Recovery Database.

1.10.5.3.2 Restore Data Using a Recovery Database

Restore Data Using a Recovery Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-22*

A recovery database (RDB) is a special kind of mailbox database that allows you to mount a restored mailbox database and extract data from the restored database as part of a recovery operation. After you've created an RDB, you can restore a mailbox database into the RDB by using your backup application (or if you have the database and its log files in the file system, by copying them to the RDB file structure). Then you can use the New-MailboxRestoreRequest cmdlet to extract data from the recovered database. After being extracted, the data can then be exported to a folder or merged into an existing mailbox. RDBs allow you to recover data from a backup or copy of a database without disrupting user access to current data.

Looking for other management tasks related to RDBs? Check out Recovery Databases.

Prerequisites

- An RDB must be created. For detailed steps, see Create a Recovery Database.
- The database and log files containing the recovered data must be restored or copied into the RDB folder structure that was created when the RDB was created.
- The database must be in a clean shutdown state. Because an RDB is an

alternate restore location for all databases, all restored databases will be in a dirty shutdown state. You can use **Eseutil /R** to put the database in a clean shutdown state.

Use the Shell to recover data using a recovery database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to restore data using an RDB.

This example restores the source mailbox that has the MailboxGUID 1d20855f-fd54-4681-98e6-e249f7326ddd on mailbox database DB1 to the target mailbox with the alias Scott.

```
New-MailboxRestoreRequest -SouceDatabase DB1 -SourceStoreMailbox 1d20855f-fd54-46
```

This example restores the content of the source mailbox that has the display name Scott Schnoll on mailbox database DB1 to the archive mailbox for scott@contoso.com.

```
New-MailboxRestoreRequest -SourceDatabase DB1 -SourceStoreMailbox "Scott Schnoll"
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

1.10.5.4 Database Portability

Database Portability

Exchange Server 2010 > High Availability and Site Resilience > Understanding Backup, Restore and Disaster Recovery >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-09*

Database portability is a feature that enables a Microsoft Exchange Server 2010 mailbox database to be moved to or mounted on any other Mailbox server in the same organization. By using database portability, reliability is improved by removing several error-prone, manual steps from the recovery processes. In addition, database portability reduces the overall recovery times for various failure scenarios.

Note:

Database portability is for Exchange 2010 mailbox databases only. Public folder databases aren't portable. This is because replication between public folder databases is controlled by each database being linked to and accessed through a specific server. The preferred way to move public folder data between servers is to use public folder replication to replicate it to a different server. If you instead simply copy a public folder database to a different server, it will no longer replicate with other databases.

Mailbox databases from previous versions of Exchange can't be moved to a Mailbox server running Exchange 2010.

For information about how to perform a database recovery using the database portability feature, see Move a Mailbox Database Using Database Portability.

Move a Mailbox Database Using Database Portability

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use database portability to move a Microsoft Exchange Server 2010 mailbox database between Exchange 2010 Mailbox servers in the same organization. This can help reduce overall recovery times for various failure scenarios. To learn more, see Database Portability.

Note:
Database portability in Exchange 2010 can be used only for Exchange 2010 mailbox databases. It can't be used for public folder databases or mailbox databases from previous versions of Microsoft Exchange.

Use the Shell to move user mailboxes to a recovered or dial tone database using database portability

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to move user mailboxes to a recovered or dial tone database using database portability.

1. Verify that the database is in a Clean Shutdown state. If the database isn't in a Clean Shutdown state, perform a soft recovery.

   Note:
   When you perform a soft recovery, any uncommitted log files are committed to the database. If you don't have all of the required log files, you can't complete the soft recovery process. Proceed to step 2.

   To commit all uncommitted log files to the database, from a command prompt, run the following command.

   ```
   ESEUTIL /R <Enn>
   ```

   Note:
   <*Enn*> specifies the log file prefix for the database into which you intend to replay the log files. The log file prefix specified by <*Enn*> is a required parameter for Eseutil /r.

2. Create a database on the new server, as shown in this example.

   ```
   New-MailboxDatabase -Name DB1 -Server MBX1 -EdbFilePath C:\Databases\D
   ```

   Note:
   To create a database, see Create a Mailbox Database.

3. Set the *This database can be over written by restore* attribute using the following syntax.

   ```
   Set-MailboxDatabase <Database Name> -AllowFileRestore:$true
   ```

4. Move the database files (.edb file, log files, and Exchange Search catalog) to the appropriate location. The database files need to be present and in the

correct location for recovery operations to succeed.

5. Mount the database using the following syntax.

```
Mount-Database <Database Name>
```

6. After the database is mounted, modify the user account settings with the Set-Mailbox cmdlet so that the account points to the mailbox on the new mailbox server. To move all of the users from the old database to the new database, use the following syntax.

```
Get-Mailbox -Database <SourceDatabase> |where {$_.ObjectClass -NotMatc
```

After Active Directory replication is complete, all users can access their mailboxes on the new Exchange server. Clients can connect to the new server as follows:

- Microsoft Outlook 2010, Office Outlook 2007, and Windows Mobile 6.1 and later clients are redirected via the Autodiscover service.
- Outlook Web App users are automatically redirected to the new server.
- Older Outlook clients need to be manually configured to point to the new server, if the server name has changed.

1.10.5.5 Dial Tone Portability

Dial Tone Portability

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-26*

Dial tone portability is a feature of Microsoft Exchange Server 2010 that provides a limited business continuity solution for failures that affect a mailbox database, a server, or an entire site. Dial tone portability enables users to have a temporary mailbox for sending and receiving e-mail while their original mailbox is being restored or repaired. The temporary mailbox can be on the same Exchange 2010 Mailbox server or on any other Exchange 2010 Mailbox server in your organization. This allows an alternative server to host the mailboxes of users who were previously on a server that is no longer available. Clients that support Autodiscover, such as Microsoft Office Outlook 2007, are automatically redirected to the new server without having to manually update the user's desktop profile. After the user's original mailbox data has been restored, an administrator can merge a user's recovered mailbox and the user's dial tone mailbox into a single, up-to-date mailbox.

The process for using dial tone portability is called a *dial tone recovery*. A dial tone recovery involves creating an empty database on a Mailbox server to replace a failed database. This empty database, referred to as a *dial tone database*, allows users to send and receive e-mail messages while the failed database is recovered.

There are three options for performing a dial tone recovery:

- **Dial tone recovery on the server with the failed database** If the server hosting the failed database is still functional, we recommend that you perform a dial tone recovery on that server. This means less downtime because you don't need to move database files between servers. In addition, you won't need to reconfigure messaging profiles for clients that don't support Autodiscover.
- **Dial tone recovery using an alternate server for the dial tone database** If a

server fails and needs to be rebuilt, the most efficient way to give users basic mail functionality is to create a dial tone database on another server, and use database portability to move the users' mailbox configuration to that new server. Because this process involves moving the dial tone database back to the original (recovered) server, this option adds more time to the overall recovery process. In addition, this process is more complex than performing a dial tone recovery on the original server. When performing this process, the server hosting the dial tone database must have sufficient resources to support the added load of the additional users. In addition, if the user's client doesn't support Autodiscover, their messaging profile will need to be reconfigured to point to the dial tone server.

- **Dial tone recovery using and staying on an alternate server for the dial tone database** This is similar to the preceding option, except that you don't revert back to the original server. This option is recommended for situations in which it isn't possible or feasible to recover the failed server. In this scenario, users typically remain on an alternate server after the recovery operation has completed. When performing this process, the server hosting the dial tone database must have sufficient resources to support the added load of the additional users. In addition, if the user's client doesn't support Autodiscover, their messaging profile will need to be reconfigured to point to the dial tone server.

All three options follow the same basic steps:

1. **Create an empty dial tone database to replace the failed database**
   This new database will allow users who had mailboxes on the failed database to send and receive new messages. Dial tone portability allows you to point a user to a different database without moving the mailbox. If you created the dial tone database on a different server than the server that housed the failed database, you need to move the mailbox configuration to that new server.
2. **Restore the old database**
   Use the backup and recovery software you typically use to restore the failed database. If there is no backup of the failed database, recover the failed database using other means if possible. If you're using the same server for dial tone recovery, you need to restore the database to a recovery database (RDB).
3. **Swap the dial tone database with the restored database**
   After the failed database is restored, swap it with the dial tone database. This gives the users the ability to send and receive e-mail and access all the data in the restored database. If users were moved to a dial tone database on another server, you need to move the mailbox configuration back to the original server.
4. **Merge the databases**
   To get the data from the dial tone database into the restored database, you merge the data using the Restore-Mailbox cmdlet.

For detailed steps about how to perform a dial tone recovery, see Perform a Dial Tone Recovery.

1.10.5.5.1 Perform a Dial Tone Recovery

Perform a Dial Tone Recovery

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Using dial tone portability, users can have a temporary mailbox for sending and receiving e-mail while their original mailbox is being restored or repaired. The temporary mailbox can be on the same Exchange 2010 Mailbox server or on any other Exchange 2010 Mailbox server in your organization. The process for using dial tone portability is called a dial tone recovery, which involves creating an empty database on a Mailbox server to replace a failed database. To learn more, see Dial Tone Portability.

Prerequisites

You must have fewer than the maximum number of databases deployed to create a dial tone database. Exchange 2010 Standard Edition supports a maximum of 5 databases per server. Exchange 2010 Enterprise Edition supports a maximum of 100 databases per server.

Use the Shell to perform a dial tone recovery on a single server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox recovery" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to perform a dial tone recovery on a single server.

1. Make sure that any existing files for the database being recovered are preserved in case they're needed later for further recovery operations.
2. Use the New-MailboxDatabase cmdlet to create a dial tone database, as shown in this example.

```
New-MailboxDatabase -Name DTDB1 -EdbFilePath D:\DialTone\DTDB1.EDB
```

3. Use the Set-Mailbox cmdlet to rehome the user mailboxes hosted on the database being recovered, as shown in this example.

```
Get-Mailbox -Database DB1 | Set-Mailbox -Database DTDB1
```

4. Use the Mount-Database cmdlet to mount the database so client computers can access the database and send and receive messages, as shown in this example.

```
Mount-Database -Identity DTDB1
```

5. Create a recovery database (RDB) and restore or copy the database and log files containing the data you want to recover into the RDB. For detailed steps, see Create a Recovery Database.
6. After the data is copied to the RDB, but before mounting the restored database, copy any log files from the failed database to the recovery database log folder so they can be played against the restored database.
7. Mount the RDB, and then use the Dismount-Database cmdlet to dismount it, as shown in this example.

```
Mount-Database -Identity RDB1
Dismount-Database -Identity RDB1
```

8. After the RDB is dismounted, move the current database and log files within the RDB folder to a safe location. This is done in preparation for swapping the recovered database with the dial tone database.
9. Dismount the dial tone database, as shown in this example. Note that your end users will experience an interruption in service when you dismount this database.

```
Dismount-Database -Identity DTDB1
```

10. Move the database and log files from the dial tone database folder into the RDB folder.
11. Move the database and log files from the safe location containing the recovered database into the dial tone database folder, and then mount the database, as shown in this example.

```
Mount-Database -Identity DTDB1
```

This ends the service interruption for your end users. They will be able to access their original production database and send and receive messages.

12. Mount the RDB, as shown in this example.

```
Mount-Database -Identity RDB1
```

13. Use the Get-Mailbox and Restore-Mailbox cmdlets to export the data from the RDB and import it into the recovered database, as shown in this example. This will import all the messages sent and received using the dial tone database into the production database.

```
Get-Mailbox -Database DTDB1 | Restore-Mailbox -RecoveryDatabase RDB1
```

14. After the restore operation is complete, you can dismount and remove the RDB, as shown in this example.

```
Dismount-Database -Identity RDB1
Remove-MailboxDatabase -Identity RDB1
```

For detailed syntax and parameter information, see the following topics:

- New-MailboxDatabase
- Get-Mailbox
- Set-Mailbox
- Mount-Database
- Dismount-Database
- Remove-MailboxDatabase

1.11 Messaging Policy and Compliance

Messaging Policy and Compliance

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-21*

Planning for Compliance

Learn about factors you must consider when planning for compliance.

Create a Message Classification

Message classifications allow your organization to comply with e-mail policies and regulatory responsibilities. When a message is classified, the message contains specific metadata that describes the intended use or audience of the message.

Transport Rules

Transport rules allow you to apply messaging policies to e-mail messages that flow through the transport pipeline on Hub Transport and Edge Transport servers. Transport rules help you to comply with messaging policies, secure messages, and protect messaging systems.

Information Rights Management

Information Rights Management (IRM) allows your organization and your users to apply persistent protection to messages so that access is restricted to authorized users and actions (such as forwarding, copying, and printing message content).

Journaling

Journaling can help your organization respond to legal, regulatory, and organizational compliance requirements by recording inbound and outbound e-mail communications. When planning for messaging retention and compliance, it's important to understand journaling, how it fits in your organization's compliance policies, and how Microsoft Exchange Server 2010 helps you secure journaled messages.

Messaging Records Management

Messaging records management (MRM) makes it easier to retain the messages needed to comply with company policy, government regulations, or legal needs. MRM also helps remove older content that has no legal or business value. This is accomplished through the use of retention policies or managed folders.

Discovery

Discovery consists of Multi-Mailbox Search, a tool that allows authorized discovery managers, legal professionals, and Human Resource professionals to perform mailbox searches across the Exchange 2010 organization for messages matching specified criteria.

Litigation Hold

Litigation hold allows you to preserve messages for an extended period and protect them from permanent deletion. It also maintains the version history for items modified while litigation hold is enabled for a mailbox.

Archiving

Personal archives allow you to gain control of your organization's messaging data by eliminating the need for .pst files. Personal archives also allow users to store their messages in an archive mailbox that's accessible by using Microsoft Outlook 2010 and Microsoft Office Outlook Web App.

Mailbox Audit Logging

Mailbox audit logging allows you to audit mailbox access by mailbox owners, delegates, and administrators. You can also use audit logging to audit actions such as deletions and access to messages and folders.

1.11.1 Planning for Compliance

Planning for Compliance

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-09*

Microsoft Exchange Server 2010 is designed to help users meet compliance requirements. Exchange 2010 offers you several features that help you capture, protect, modify, retain, and discover e-mail messages in a user mailbox as the messages flow in, through, and out of your organization.

The following list provides several examples of the areas where compliance features in Exchange 2010 can help you become compliant or respond to future discovery requirements:

- **Data retention policies** Many organizations are required to keep data for a specific time and then remove that data to protect privacy. To learn more, see Understanding Messaging Records Management.
- **Privacy and confidentiality requirements** Every day organizations transmit sensitive and confidential information through e-mail, both to and from individuals and the organization itself. These organizations have to protect the privacy of individuals and the confidentiality of communications. To learn more, see Understanding Information Rights Management.
- **Ethical walls** Organizations that work with securities and other financial information are frequently required to prohibit communication between specific groups in their own organization. To learn more, see Understanding Ethical Walls.
- **Discovery requests** Organizations are sometimes subject to litigation. As part of this process, litigants can request information from each other. Because most business communication occurs over e-mail, complying with discovery requests requires the ability to search mailbox content, including e-mail messages and attachments. To learn more, see Understanding Multi-Mailbox Search.

Why is Compliance Important?

Every organization should consider compliance. Every day organizations are required to produce evidence for litigation or to provide documentation to regulatory agencies to prove they're complying with regulations.

Organizations that consider compliance when they plan their information technology infrastructures, including their e-mail infrastructures, can supply the required documentation on demand with less effort. They can also comply with other regulatory requirements more easily.

On the other hand, organizations that don't consider compliance up-front may find themselves sorting through millions of e-mail messages manually, wasting time and money. Organizations can also be held legally responsible for not complying with laws or regulatory requirements.

Although your organization may have never been subject to litigation or may not be required to follow regulatory requirements, there's a good chance that you handle private and confidential information that may be regulated by laws or regulations in your country or region. It's important that you understand the laws and regulations that apply to your organization and take proactive steps to make sure that you comply with them.

For a list of some of the laws and regulations that may apply to your organization, see Understanding Journaling.

Discussing Compliance in Your Organization

It's important to understand the requirements and obligations that may apply to your organization. If you haven't discussed compliance in your organization, the deployment of Exchange 2010 can be a catalyst for these conversations. Speak with your organization's management and legal representatives to understand the answers to the following questions:

- Do we handle customer data?
- Do we have established policies that protect customer data?
- Do we transmit confidential organizational information through e-mail?
- Do we control who can view confidential information and where it can be sent?
- Have we established policies and procedures that help us respond to legal

requests for information?
- Are there laws or regulations that prohibit communication between specific groups in our organization?
- Are there laws or regulations that require us to remove data after a specific time?

This list presents some of the questions that many organizations must answer. The list isn't definitive. It provides examples to help you consider some of the issues that may apply to your organization. Your organization may have other issues to consider.

If you already have a solid compliance policy in your organization, talk with your compliance officers and management to help them understand how your organization can use Exchange 2010 as a compliance tool.

1.11.2 Message Classifications

Message Classifications

Learn about message classifications and how they can help you implement your organization's messaging policies.

Managing Message Classifications

Learn about managing message classifications in your Exchange organization.

1.11.2.1 Understanding Message Classifications

Understanding Message Classifications

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-06*

Message classifications are a Microsoft Exchange Server 2010 and Microsoft Office Outlook 2007 feature intended to help organizations comply with their e-mail policies and regulatory responsibilities. When a message is *classified*, the message contains specific metadata that describes the intended use or audience of the message. Outlook 2007 or Microsoft Office Outlook Web App may act on this metadata by displaying a user-friendly description of the classification to senders and receivers of a classified message. In Exchange 2010, the Microsoft Exchange Transport service may act on the metadata if there's a transport rule that meets specific criteria that you have configured.

The following list provides a brief description of some of the message classification fields that you can set:

- **Display name** This property specifies the display name for the message classification instance. The display name appears in the **Permission** menu in Outlook 2007 and Outlook Web App and is used by Outlook and Outlook Web App users to select the appropriate message classification before a message

is sent. The display name is also displayed in the recipient description that appears in the InfoBar in an Outlook message. The parameter name for this property is *DisplayName*.

- **Sender description** This property explains to the sender what the message classification is intended to achieve. The text that you enter for this field is used by Outlook and Outlook Web App users to select the appropriate message classification before a message is sent. The parameter name for this property is *SenderDescription*.
- **Recipient description** This property explains to the recipient what the message classification was intended to achieve. The text that you enter for this field is viewed by Outlook and Outlook Web App users when they receive a message that has this message classification. The parameter name for this property is *RecipientDescription*.
- **Locale** This field specifies a culture code to create a locale-specific version of the message classification. For more information about the locale field, see "Localizing Message Classification Instances for Different Languages and Locales" later in this topic. The parameter name for this property is *Locale*.

After Outlook 2007 is enabled to accept the default message classifications, users can apply message classification to messages that they send. Senders see the sender description in the InfoBar in Outlook 2007. By using the Exchange Management Shell, you can customize the sender description for each message classification and locale.

Note:
Outlook Web App requires no special configuration to display or use message classifications.

Three message classifications are enabled in Exchange 2010 by default:

- **Attachment Removed** This classification notifies recipients when attachments have been removed from the message.
- **Originator Requested Alternate Recipient Mail** This classification notifies recipients that the message has been redirected from delivery to the original addressed recipient.
- **Partner Mail** This classification notifies recipients that the message was encrypted and delivered through a secure connector.

Note:
Users can't add these classifications to messages.

In the initial installation of Exchange 2010, all message classifications are informational only. They aren't associated with any transport rules and only provide additional information about a message to the message recipients. By default, in Exchange 2010, the Microsoft Exchange Transport service doesn't take any special action on the message.

However, you can create transport rules based on message classifications. For example, you can configure a transport rule that checks all incoming messages for a specific message classification and direct that these messages be delivered to a designated recipient. For more information, see Create a Transport Rule.

Message classifications can be logically separated into two classes based on how they are attached to a specific message:

- A message classification can be manually added by the sender of a message before the message is sent.
- A message classification can be added as the result of a rule. For example, when the Attachment Filter agent removes an attachment from a message, the Attachment Removed message classification is attached to the message. When the sender receives the message, Outlook 2007 displays an explanation of why the attachment was removed in the recipient description in the InfoBar. As the Exchange administrator, you can customize the recipient description.

Looking for management tasks related to message classifications? See Managing Message Classifications.

Contents

Localizing Message Classification Instances for Different Languages and Locales

In some scenarios, your business needs may dictate using different languages for message classifications for different groups of users, regions, or locales where your business operates. After you create the default message classification instance, you can create more than one message classification instance for different languages.

You can also use a message classification instance to change the content of the sender description and recipient description to reflect differences in regulatory requirements for different jurisdictions. If a message classification for the locale of the recipient exists in Active Directory, Exchange will attach the localized message classification to the message.

For example, health care-related companies that operate in the United States and in Europe may have to comply with Health Insurance Portability and Accountability Act (HIPAA) regulations in the United States but not in Europe. Therefore, the display of message classifications that are HIPAA-specific should only be enabled for employees operating in the United States. You can set Read permission on classifications so that only appropriate users can view specific message classifications.

Each localized version of a specific message classification is a new message classification instance. The *Locale* parameter defines the locale for a particular message classification instance. The *Locale* parameter takes a data type of **CultureInfo**. When you create a localized version of a message classification, you will reference the default instance of the message classification and create a localized instance of the existing message classification.

For an example of a localized message classification and more information about how to create localized versions of message classifications, see Create Localized Versions of Message Classifications.

Return to top

Precedence and Retention of the Message Classification

By default, a message classification travels with a message for the life of the message until it leaves the organization. Therefore, if a sender sets a message classification on a

specific message, the message will retain the message classification as long as other rules don't remove it.

Each message classification can be assigned a relative priority to other message classifications. This sets the precedence on a specified classification and how it's displayed to the recipient in Outlook. The message classification with the highest precedence is shown first, and subsequent classifications with lesser precedence are displayed in the appropriate order thereafter. You set precedence by using the *DisplayPrecedence* parameter on the **Set-MessageClassification** cmdlet in the Shell.

For each message classification, you can specify whether the message classification is retained when a recipient replies to or forwards the message. You can specify whether a classification is retained by setting the *RetainClassificationEnabled* parameter on the **Set-MessageClassification** cmdlet in the Shell.

For more information, see Set-MessageClassification.

Return to top

Providing Read Access to Message Classifications

When you create a message classification and enable the computer on which Outlook runs, the new message classification will be present in the **Permission** menu of Outlook and Outlook Web App.

You can control read access for the message classifications presented in the **Permission** menu of Outlook 2007 if you configure the message classifications that you export into the Classifications.xml file. For more information about how to create and use the Classifications.xml file, see Deploy Message Classifications for Outlook 2007.

You can control read access for the message classifications presented in the **Permission** menu of Outlook Web App if you configure the Read permission on the message classification object. By default, all message classifications are created with Read permission for any authenticated user when you grant Read permission to authenticated users on the message classification object in Active Directory.

It's important to understand that the Read permission set on the message classification object doesn't control whether the sender can use the message classification. Read permission on the message classification only controls whether the message classification is displayed in the **Permission** menu in Outlook Web App. Outlook 2007 users can send message classifications even if the user doesn't have read access to the message classification. Advanced users can still send classified messages by editing the Classifications.xml file installed on their computer to enable message classifications Outlook 2007.

Return to top

Message Classifications in Transport Rules

After you create a message classification instance, you can associate a transport rule with the message classification. You use the Shell to create a transport rule and add the message classification as a condition. For information about how to use the Shell to create transport rules, see Create a Transport Rule.

Return to top

Managing and Deploying Message Classifications

Before Outlook 2007 users can set and view message classifications, you must deploy the message classification configuration files and create an Outlook registry key on the end-users' computers. The Outlook message classification templates are .xml files that you must generate after you create and configure the message classifications.

You manage all message classifications by using the message classification cmdlets in the Shell. You can bind message classifications to transport rules by using the Shell or the Exchange Management Console (EMC).

For more information, see Deploy Message Classifications for Outlook 2007.

1.11.2.1.1 Understanding Attorney-Client Privileged Communication

Understanding Attorney-Client Privileged Communication

Messaging Policy and Compliance > Message Classifications > Understanding Message Classifications >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-20*

In Microsoft Exchange Server 2010, you can use message classifications and transport rules to comply with your organization's messaging policies. For example, a message classification for attorney-client privileged communication could be used to identify messages that should be considered confidential and that contain privileged information that should only be shared between an attorney and their client. This topic provides an overview about this scenario for an Exchange organization.

For more detailed information about deploying an attorney-client privileged message classification, see Deploy an Attorney-Client Privileged Message Classification. Looking for other management tasks related to message classifications? See Managing Message Classifications.

Contents

Attorney-Client Privileged Communication Concepts

The *attorney-client privilege* is a legal doctrine that is intended to protect the confidentiality of communication between an attorney and his or her client. By assuring confidential communication, lawyers and their clients will feel free to discuss sensitive legal matters thoroughly. Communication that meets the legal tests that define the privilege is

considered confidential. Disclosure of that communication can't be compelled by anyone if the client doesn't want the communication disclosed.

To qualify as an attorney-client privileged communication, in general, communication must meet all the following criteria:

- It must be between an attorney and a client.
- It must be for the purpose of seeking or providing legal advice.
- It must be intended to be confidential. Confidentiality must be strictly maintained.

Note:

The rules related to the doctrine of attorney-client privilege may vary by jurisdiction. The information contained in this topic isn't intended to define the privilege or how to ensure protection. This topic is intended to highlight features that may help you in your attempts to improve protection for attorney-client privileged communication that occurs by e-mail using Exchange 2010. The declaration of attorney-client privilege on a message doesn't guarantee that the contents of the message can't be disclosed.

Enabling Attorney-Client Privileged Communication with Exchange 2010

To use the attorney-client privilege when you communicate with an attorney by using e-mail, you typically must declare that your message is intended to be privileged communication between you and your attorney. You must also take reasonable steps to make sure that only your attorney is addressed on the message. The following are examples of requirements that an organization may apply to messages that it wants to preserve under the attorney-client privilege:

- An attorney should be on the To line of the message.
- No recipients outside the organization should be present on the message.
- The subject or body of the message should contain the text "Attorney Client Privileged" or similar wording that clearly specifies that the message is intended as attorney-client privileged communication.
- The message shouldn't be forwarded except by the attorney or at the direction of the attorney.
- The message should be rights-protected.

In earlier versions of Exchange Server, recipients and senders had to manually apply organizational requirements, such as attorney-client privilege requirements, to their messages. In the following circumstances, recipients and senders might unintentionally omit a step or mistakenly forward a privileged message to an external recipient:

- They didn't fully understand complex policies and related procedures.
- They were unaware of these policies and procedures.

By inadvertently violating organizational or regulatory requirements for attorney-client privileged communications, senders and recipients may unknowingly waive the attorney-client privilege. In Exchange 2010, message classifications and transport rules help reduce the possibility of such user errors by alerting users that special handling requirements may be needed for specific message classifications.

Attorney-Client Privileged Message Classification

A custom attorney-client privileged message classification in an Exchange 2010 organization can help reduce the burden on senders and recipients by helping ensure that their messages meet the attorney-client privilege policy requirements adopted by the organization. This classification can be used to display a user-friendly description of the

attorney-client privileged classification to the senders and recipients of the message. It can also include specific instructions about how the message should be handled to maintain the attorney-client privilege.

In addition to displaying specific instructions to the sender and recipients of the message, Exchange 2010 can also enforce the attorney-client privilege requirements when the message enters the transport pipeline. In a typical scenario, you can use transport rules on the Hub Transport server to identify messages to which the attorney-client privileged message classification has been applied. If the classification has been applied, the transport rules can check whether the message meets the organization's list of attorney-client privilege requirements. If the message doesn't meet the requirements, the message may be returned to the sender.

It's important to remember that applying an attorney-client privileged message classification doesn't prevent the recipient from misusing the message by default. This misuse could be any action taken by the recipient that is prohibited by your organization's classification policy, such as printing, forwarding, or copying the message. To prevent these actions, you should apply Information Rights Management (IRM) protection rules to enforce your organizational compliance requirements.

1.11.2.2 Managing Message Classifications

Managing Message Classifications

Exchange Server 2010 > Messaging Policy and Compliance > Message Classifications >

Deploy an Attorney-Client Privileged Message Classification

1.11.2.2.1 Create a Message Classification

Create a Message Classification

Messaging Policy and Compliance > Message Classifications > Managing Message Classifications >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic provides information about how to create a new message classification. For more information about message classifications, see Understanding Message Classifications.

Looking for other management tasks related to message classifications? Check out Managing Message Classifications.

Caution:
Before you create or modify message classifications in your production environment, we recommend that you use a test environment to understand how message classifications work. Before you modify message classifications, test them in a production environment.

Use the Shell to create a message classification

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message classifications" entry in the Transport Permissions topic.

Note:
You can't use the Exchange Management Console to create a message classification.

To create a new message classification instance, you must use the **New-MessageClassification** cmdlet in the Exchange Management Shell. The **New-MessageClassification** cmdlet requires four parameters to create a new message classification:

- *DisplayName*
- *Locale*
- *Name*
- *SenderDescription*

You should also consider setting a value for the optional *RecipientDescription* parameter so that recipients are provided with a detailed description about the intent of the classification and how they should handle the message.

This example creates a new message classification with only the required classification parameters:

```
New-MessageClassification -Name NewMessageClassification -DisplayName "New Messag
```

This example creates a new message classification that includes the *RecipientDescription* parameter with the required classification parameters:

```
New-MessageClassification -Name NewMessageClassification -DisplayName "New Messag
```

Other Tasks

After creating a new message classification, you may also want to:

Create Localized Versions of Message Classifications

1.11.2.2.2 Create Localized Versions of Message Classifications

Create Localized Versions of Message Classifications

Messaging Policy and Compliance > Message Classifications > Managing Message Classifications >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to create localized versions of message classifications in Microsoft

Exchange Server 2010.

Use the Shell to create localized versions of message classifications

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message classifications" entry in the Transport Permissions topic.

Note:
You can't use the EMC to create localized versions of message classifications.

This example creates a Spanish - Spain ("es-ES") version of an existing message classification.

```
New-MessageClassification Example -Locale es-ES -DisplayName "España Example" -Se
```

For detailed syntax and parameter information, see New-MessageClassification.

1.11.2.2.3 Deploy Message Classifications for Outlook 2007

Deploy Message Classifications for Outlook 2007

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Office Outlook 2007 requires a local file (Classifications.xml) that contains definitions of the message classifications that Microsoft Exchange Server 2010 supports before Outlook users can apply message classifications to their messages. You must also create a registry key that enables message classification and references the Classifications.xml file on the Outlook user's computer.

Looking for other management tasks related to message classifications? Check out Managing Message Classifications.

Use Registry Editor to create a registry key for message classifications on Outlook 2007 clients

The following registry key and related registry settings must be created on all Outlook 2007 computers from which users who have mailboxes hosted on Exchange 2010 send message classifications.

```
[HKEY_CURRENT_USER\Software\Microsoft\Office\12.0\Common\Policy]
"AdminClassificationPath"="c:\\Classifications.xml"
"EnableClassifications"=dword:00000001
"TrustClassifications"=dword:00000001
```

Note:
The `Policy` key isn't present by default and therefore must be created.

Caution:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

The following table provides details about each registry value you need to use.

Registry values

Registry value	Description
AdminClassificationPath	You must change the path to refer to the location where you will copy the Classifications.xml file. Although you can use a network share, we recommend that the path is a location on the local computer for any computer running Outlook in cached mode so that Outlook can read the instructions and enable message composition even when offline.
EnableClassifications	You can enable and disable message classification functionality for the specified user. To enable message classification functionality, set this DWORD value to 00000001. To disable message classification functionality, set this DWORD value to 00000000.
TrustClassifications	You can qualify the assertions made on classified messages when the messages are sent to users who have mailboxes on Exchange Server 2003. You should enable TrustClassifications only for users who have mailboxes on Exchange 2010. To enable TrustClassifications, set this DWORD value to 00000001. Outlook also supports message classifications between users on Exchange 2003. Because Exchange 2003 doesn't support or recognize message classifications, the content and validity of the message classifications can't be guaranteed. Therefore, disabling TrustClassifications prepends the text **The sender claims:** to the message classification to protect users from incorrectly assuming that their organization has processed the classification. To disable TrustClassifications, set this DWORD value to 00000000.

The message classifications in the Classifications.xml file are the only message classifications that will be available to Outlook users when they send messages. However, the message classifications in the Classifications.xml file don't restrict the set of classifications that a user can receive.

For example, a user can receive an e-mail message with a message classification that isn't present in his or her version of the Classifications.xml file. If the user forwards the message classification, the message retains its classification, assuming that the *RetainClassificationEnabled* parameter on the originating message classification instance was set to `$True`, even though the recipient who forwards the message doesn't have the specific message classification in the local Classifications.xml file.

Use a script to create a Classifications.xml file for Outlook 2007 clients

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message classifications" entry in the Transport Permissions topic.

1. Open the Shell and run the following script from the Program Files\Microsoft\Exchange Server\V14\Scripts directory:
   ./Export-OutlookClassification.ps1 > c:\exports\Classifications.xml

   Note:
   This script will export all message classifications into the Classifications.xml file. If you don't want all classifications in the XML file, you must manually remove them by removing the specific <Classification> element from Classification.xml.

2. After you export the appropriate message classifications, you must copy the resulting Classifications.xml file onto the end-users' computers to the *AdminClassificationPath* path that you specified in the registry setting discussed earlier in this topic. You must restart Outlook so that the Classifications.xml file is picked up by Outlook.

Other Tasks

After deploying message classifications to Outlook 2007 clients, you may also want to create a message classification. For detailed steps, see Create a Message Classification.

1.11.2.2.4 Deploy an Attorney-Client Privileged Message Classification

Deploy an Attorney-Client Privileged Message Classification

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, Exchange 2010 includes three default message classifications: Attachment Removed, Originator Requested Alternate Recipient Mail, and Partner Mail. For new Exchange 2010 installations, you'll need to create a new message classification for Attorney-Client Privileged communication.

If your organization is transitioning from Exchange Server 2007, you don't need to create the Attorney-Client Privileged message classification. It's included in the Exchange 2007 default classifications and therefore available to servers that have been upgraded from Exchange 2007 to Exchange 2010. However, this classification must exist in each Active Directory forest for users in that forest to see the classification.

You can review existing message classifications by running the following command in the Exchange Management Shell.

```
Get-MessageClassification | Format-Table
```

For more information about attorney-client privileged communication, see Understanding Attorney-Client Privileged Communication.

Step 1: Create the Attorney-Client Privileged message classification

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message classifications" entry in the Transport Permissions topic.

To create a new message classification instance, you must use the **New-MessageClassification** cmdlet in the Exchange Management Shell.

Run the following command to create the Attorney-Client Privileged message classification:

```
New-MessageClassification -Name AttorneyClientPrivileged -DisplayName "Attorney-C
```

Note:

For more information about creating new message classifications, see Create a Message Classification

Step 2: Deploy the Attorney-Client Privileged message classification to all Outlook 2007 Clients

This step requires that you modify the registry. You must have local administrator permissions on the client you want to update.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Outlook 2007 requires a local file (Classifications.xml) that contains definitions of the message classifications that Exchange 2010 supports before Outlook users can apply message classifications to their messages. The Exchange administrator must also create a new registry key that enables message classifications and references the Classifications.xml file on the Outlook user's computer.

Create the following registry key and related registry settings on all computers from which users who have mailboxes hosted on Exchange 2010 send message classifications.

```
HKEY_CURRENT_USER\Software\Microsoft\Office\12.0\Common\Policy
"AdminClassificationPath"="c:\\Classifications.xml"
"EnableClassifications"=dword:00000001
"TrustClassifications"=dword:00000001
```

Note:

The Policy key is not present by default and therefore must be created. For more detailed information about how to deploy message classifications to clients, see Deploy Message

Classifications for Outlook 2007. Changes to message classifications are immediately available in Outlook Web App.

Step 3: Export message classifications from Exchange 2010 and copy Classifications.xml file to all Outlook 2007 clients

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Message classifications" entry in the Transport Permissions topic.

1. Open the Exchange Management Shell and run the following script from the \Program Files\Microsoft\Exchange Server\V14\Scripts directory.

```
./Export-OutlookClassification.ps1 > c:\exports\Classifications.xml
```

Note:
This script will export all message classifications into Classifications.xml. If you don't want all classifications in the XML file, you must manually remove them by removing the specific <Classification> element from Classifications.xml.

2. Copy the resulting Classifications.xml file onto the end user's computers to the AdminClassificationPath that you specified in the registry setting that was discussed in Step 2 earlier. You must restart Outlook so that the Classifications.xml file is picked up by Outlook.

Note:
Whenever new classifications are added to your Exchange organization, the new classifications should be added to the Classifications.xml file on each client. The Classifications.xml file can be exported from Exchange 2010 and copied to all Outlook clients again, or it can be manually updated for each client computer.

Step 4: Create a Transport Rule that checks messages for the Attorney-Client Privileged classification and enforces the addition of a legal disclaimer

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Transport rules let you apply messaging policies to e-mail messages that flow through the transport pipeline on Hub and Edge Transport servers. For more information about Transport Rules, see the following topics:

- Understanding Transport Rules
- Create a Transport Rule

For this scenario, we will create a new transport rule that appends a legal disclaimer to all messages sent from internal users to external recipients for messages that have the Attorney-Client Privileged classification. (Although we will create this transport rule for the Hub Transport servers in the organization using the Exchange Management Shell, the Exchange Management Console can also be used to create a transport rule.)

Run the following command to create a transport rule that appends a legal disclaimer to all messages that have the Attorney-Client privileged classification:

```
New-TransportRule -Name "Attorney-Client Privilege Disclaimer" -Enabled $true -Fr
```

Note:
The rule parameters and action used here are for illustration only. Review all the available transport rule predicates and actions to determine which ones meet your organization's requirements.

Transport Rules: End-to-End Tasks

Learn how to implement transport rules in specific scenarios.

Using Exchange Hosted Services

Transport messaging policies are enhanced by or are also available as a service from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

1.11.3.1 Understanding Transport Rules

Understanding Transport Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-26*

Many organizations today are required by law, regulatory requirements, or company policies to apply messaging policies that limit the interaction between recipients and senders, both inside and outside the organization. In addition to limiting interactions among individuals, departmental groups inside the organization, and entities outside the organization, some organizations are also subject to the following messaging policy requirements:

- Preventing inappropriate content from entering or leaving the organization
- Filtering confidential organization information
- Tracking or archiving messages that are sent to or received from specific individuals
- Redirecting inbound and outbound messages for inspection before delivery
- Applying disclaimers to messages as they pass through the organization

Transport rules let you apply messaging policies to e-mail messages that flow through the transport pipeline on Hub Transport and Edge Transport servers. These rules allow information technology (IT) administrators to comply with messaging policies, secure messages, protect messaging systems, and prevent information leakage.

In Microsoft Exchange Server 2010, transport rules have been enhanced with additional predicates and actions. Additional functionality has been integrated with transport rules, such as rights protection.

Looking for management tasks related to managing transport rules? See Managing Transport Rules.

Contents

Transport Rule Components

Transport rules consist of the following components:

- **Conditions** Transport rule conditions are used to identify messages to which a transport rule action should be applied. Conditions consist of one or more predicates that specify the parts of a message that should be examined. Some predicates examine message fields or headers, such as To, From, or Cc. Other predicates examine message characteristics such as message subject, body, attachments, message size, and message classification. Most predicates require that you specify a comparison operator, such as equals, doesn't equal, or contains, and a value to match.
  For a complete list of transport rule predicates available to Hub Transport and Edge Transport servers, see Transport Rule Predicates. The list of predicates is also available in the New Transport Rule wizard in the Exchange Management Console (EMC), and can be retrieved by using the Get-TransportRulePredicate cmdlet in the Exchange Management Shell.
- **Exceptions** Exceptions are based on the same predicates used to build transport rule conditions. However, unlike conditions, exceptions identify messages to which transport rule actions shouldn't be applied. Exceptions override conditions and prevent actions from being applied to an e-mail message, even if the message matches all configured conditions.
- **Actions** Actions are applied to messages that match the conditions and don't match any exception defined in the transport rule. Transport rules have many actions available, such as rejecting, deleting, or redirecting messages, adding additional recipients, adding prefixes in the message subject, or inserting disclaimers and personalized signatures in the message body.
  To view a complete list of transport rule actions available on Hub Transport and Edge Transport servers, see Transport Rule Actions. The list of transport rule actions can also be viewed in the New Transport Rule wizard in the EMC, and can be retrieved by using the Get-TransportRuleAction cmdlet in the Shell.

Return to top

Rules Agents

Transport rules are applied on Hub Transport and Edge Transport servers by transport agents. On the Hub Transport server, rules are applied by the Transport Rules agent. On the Edge Transport server, this is the job of the Edge Rules agent. Although similar in functionality, both agents have some differences in the predicates and actions available, the transport event on which each agent fires, and the priority of each agent relative to other transport agents enabled on that transport server.

Transport Rules Agent

The Transport Rules agent processes transport rules on Hub Transport servers. It fires on the **OnRoutedMessage** transport event. All messages in an Exchange 2010 organization are touched by at least one Hub Transport server. This includes:

- Messages to and from users in the same Active Directory site, including users with mailboxes on the same Mailbox server.
- Messages to and from users in different Active Directory sites.
- Messages to and from users in the Exchange organization and external users.

Transport rules configured on Hub Transport servers are stored in Active Directory, making them accessible to all Hub Transport servers in the organization as the configuration is replicated to all domain controllers across the Active Directory forest. This allows Exchange to consistently apply a single set of rules across the entire organization. Each Hub Transport server queries Active Directory to retrieve the organization's current

transport rule configuration and then applies the rules to messages it handles.

Important:
Transport rules are an Exchange feature. They can't prevent users from communicating in other ways, such as networked file shares, newsgroups, and forums, or e-mail services that don't deliver messages to an Exchange organization.

Important:
Replication of transport rules across an organization is dependent on Active Directory replication. Replication time between Active Directory domain controllers varies depending on the number of Active Directory sites in the organization, slow links, and other factors outside the control of Exchange. When deploying transport rules, consider replication delays.

For more information about Active Directory replication, see Active Directory Replication Technologies.

Edge Rules Agent

The Edge Rules agent processes transport rules on Edge Transport servers. It fires on the **EndOfData** transport event. The Edge Transport server, which serves as an e-mail gateway to and from external messaging systems, is the ideal place to apply messaging hygiene and policy to inbound Internet e-mail. Rules applied by the Edge Rules agent can reduce the total number of messages delivered to and processed by Hub Transport servers, and ultimately delivered to recipients. The agent can also help remove any harmful or objectionable message content. The following list provides some examples of how the Edge Rules agent can help you protect your organization.

- **Virus outbreaks** Thousands of new viruses, worms, and other types of malicious code are created each year. There's generally a lag between when such malware is noticed or reported, identified by antivirus software providers, an update created for the antivirus software, and then sent to customers. This causes a gap in protection during which an infected message can enter an organization undetected.
- **Denial of service attacks** Individuals who want to harm organizations may use denial of service (DoS) attacks, which can potentially result in deterioration, unavailability, or an outage of network services such as e-mail.

The Edge Rules agent is designed to help mitigate the impact of each of these risks.

Outbound Internet e-mail can also be subjected to similar policy-based scrutiny, and harmful or objectionable content can be prevented from leaving the organization. Additionally, message content can be checked to prevent sensitive information from being leaked outside the organization.

Transport rules configured on Edge Transport servers are stored in Active Directory Lightweight Directory Services (AD LDS), formerly known as Active Directory Application Mode (ADAM), on each Edge Transport server. Rules configured on one Edge Transport server aren't automatically replicated to other Edge Transport servers in your organization, with or without the use of EdgeSync. Depending on your requirements, you may want to configure each Edge Transport server with identical transport rules, or you may want to configure different transport rules on different Edge Transport servers that address the unique e-mail message traffic patterns of each server. To duplicate rule configuration, you can use the Export-TransportRuleCollection and Import-TransportRuleCollection cmdlets.

1.11.3.2 Understanding How Transport Rules Are Applied

Understanding How Transport Rules Are Applied

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-25*

In Microsoft Exchange Server 2010, transport rules allow you to apply messaging policies to messages in the transport pipeline. Actions such as redirecting a message or adding recipients, rights-protecting messages, and rejecting or silently deleting a message can be taken on messages that match the conditions and none of the exceptions defined in the rule.

Given the scope and potential impact of transport rules on messages, it's important to understand how transport rules work. To learn more about transport rules, see Understanding Transport Rules. For a comprehensive list of transport rule predicates and actions available on the Hub Transport server and Edge Transport server, see Transport Rule Predicates and Transport Rule Actions.

Looking for management tasks related to managing transport rules? Check out Managing Transport Rules.

Contents

Transport Rule Scope

Although the procedures used to create and modify transport rules on each server role are the same, the scope of transport rules on each server role is very different.

Transport rule scope

Transport component	Hub Transport server role	Edge Transport server role
Agent	Transport Rules agent	Edge Rules agent
Transport event	**OnRoutedMessage**	**EndOfData**
Rule storage	Active Directory domain controllers	Active Directory Lightweight Directory Services (AD LDS) (local)
Rule replication	Active Directory replication	No automated replication between Edge Transport servers
Rule scope	Entire Exchange organization	Local to each Edge Transport server
Message types	All messages except system messages	All messages
Lookup distribution group membership	Yes	No
Lookup Active Directory attributes	Yes	No
Inspect or modify Information Rights Management (IRM)-protected message content	Yes (requires transport decryption)	No

Rule Storage and Replication

The transport rules you create on a Hub Transport server are stored in Active Directory and are available after Active Directory replication on all Hub Transport servers in your Exchange 2010 organization. This allows you to apply a consistent set of rules across the entire Exchange organization.

Transport rules created on an Edge Transport server are stored in the local instance of AD LDS. No automated replication of configuration information or transport rules occurs between two Edge Transport servers. You can use distinct sets of transport rules on different Edge Transport servers. For example, if an organization uses a different set of Edge Transport servers for inbound and outbound messages to and from the Internet, different rules can be used on these servers. Rules created on the Edge Transport server apply only to messages that pass through that server. However, if applying the same set of transport rules on all Edge Transport servers is a requirement, you can also clone the Edge Transport server configuration, or export transport rules from one Edge Transport server and import it to other Edge Transport servers. For more details, see Understanding Edge Transport Server Cloned Configuration and Export and Import Transport Rules.

Message Types

On Edge Transport servers, rules apply to all messages. On Hub Transport servers, rules are applied to messages that meet the following criteria:

- **Messages sent by anonymous senders** Transport rules are applied to all messages received from anonymous senders. E-mail received from the Internet falls under this category.
- **Messages sent between authenticated users** Transport rules are applied to the following types of messages sent between authenticated users:
  - **Interpersonal messages** Interpersonal messages that contain a single rich

text format (RTF), HTML, or plain text message body or a multipart or alternative set of message bodies.

- **Encrypted e-mail messages** Messages that are encrypted using S/MIME. Transport rules can access envelope headers contained in encrypted messages and process messages based on predicates that inspect them. Rules with predicates that require inspection of message content, or actions that modify content, can't be processed.
- **Protected messages** Messages that are protected by applying an Active Directory Rights Management Services (AD RMS) rights policy template. With transport decryption enabled, the Transport Rules agent on a Hub Transport server can access the content of protected messages. Messages must be published using an AD RMS cluster in the same Active Directory forest as the Exchange 2010 server. With transport decryption disabled, the agent can't access message content and treats the message as an encrypted message.
- **Clear-signed messages** Messages that have been signed but not encrypted.
- **Unified messaging e-mail messages** Messages that are created or processed by the Unified Messaging server role, such as voice mail, fax, missed call notifications, and messages created or forwarded by using Microsoft Outlook Voice Access.
- **Read reports** Reports that are generated in response to read receipt requests by senders. Read reports have a message class of `IPM.Note*.MdnRead` or `IPM.Note*.MdnNotRead`.

Return to top

Transport Rule Replication

Transport rules configured on Hub Transport servers are applied to all messages handled by the Hub Transport servers in the Exchange 2010 organization. When a transport rule is created or an existing transport rule is modified or deleted on one Hub Transport server, the change is replicated to all Active Directory domain controllers in the organization. All the Hub Transport servers in the organization then read the new configuration from the Active Directory servers and apply the new or modified transport rules. By replicating transport rules across the organization, Exchange 2010 enables you to apply a consistent set of rules across the organization.

Important:

Replication of transport rules across an organization depends on Active Directory replication. Replication time between Active Directory domain controllers varies depending on the number of sites in the organization, slow links, and other factors outside the control of Exchange. When you configure transport rules in your organization, make sure that you consider replication delays. For more information about Active Directory replication, see Active Directory Replication Technologies.

Important:

Each Hub Transport server maintains a recipient cache that's used to look up recipient and distribution list information. The recipient cache reduces the number of requests that each Hub Transport server must make to an Active Directory domain controller. The recipient cache updates every four hours. You can't modify the recipient cache update interval. Therefore, changes to transport rule recipients, such as the addition or removal of distribution list members, may not be applied to transport rules until the recipient cache is updated. To force an immediate update of the recipient cache, you must stop and start the Microsoft Exchange Transport service. You must do this for each Hub Transport server where you want to forcibly update the recipient cache.

Note:

Each time the Hub Transport server retrieves a new transport rule configuration, an event is logged in the Security log in Event Viewer.

Transport rules configured on Edge Transport servers are applied only to the local server on which the transport rule was created. New transport rules and changes to existing transport rules affect only messages that pass through that specific Edge Transport server. If you have more than one Edge Transport server and you want to apply a consistent set of rules across all Edge Transport servers, you must either manually configure each server or export the transport rules from one server and import them into all other Edge Transport servers.

Return to top

Order in Which Transport Rules Are Applied

Transport rules are applied in the following order:

1. **Message scope** The first check performed by rules agents is whether a message falls within the scope of the agent. Transport rules aren't applied to all types of messages.
2. **Priority** For messages that fall within the scope of the rules agent, the agent starts processing rules based on rule priority in ascending order. Rules with lower priority are applied first. Transport rule priority values range from 0 to n–1, where n is the total number of transport rules. Only enabled rules are applied, regardless of priority. You can change the priority of rules using the Exchange Management Console or the Exchange Management Shell.
3. **Conditions** Transport rule conditions are made up of predicates.
4. **Rule with no conditions** A rule with no predicates and no exceptions is applied to all messages.
5. **Rule with multiple predicates** For a rule's action to be applied to a message, it must match all of the predicates selected in the rule. For example, if a rule uses the predicates **from a member of distribution list**, and **when the Subject field contains specific words**, the message must match both predicates. It must be sent by a member of the distribution list specified, and the message subject must contain the word specified.
6. **Predicate with multiple values** If one predicate allows entering multiple values, the message must match any value specified for that predicate. For example, if an e-mail message has the subject **Stock price information**, and the `SubjectContains` condition on a transport rule is configured to match the words **Contoso** and **stock**, the condition is satisfied because the subject contains at least one of the values of the condition.
7. **Exceptions** A rule isn't applied to messages that match any of the exceptions defined in the rule. Note, this is exactly opposite of how the rules agent treats predicates. For example, if the exceptions **except when the message is from people** and **except when the message contains specific words** are selected, the message fails to match the rule condition if the message is sent from any of the specified senders, or if the message contains any of the specified words.
8. **Actions** Messages that match the rules conditions get all actions specified in the rule applied to them. For example, if the actions **prepend the subject with string** and **Blind carbon copy (Bcc) the message to addresses** are selected, both actions are applied to the message. The message will get the specified string prefixed to the message subject, and the recipients specified will be added as Bcc recipients.

Note:

Some actions, such as the **Delete the message without notifying anyone** action, prevent subsequent rules from being applied to a message.

Return to top

Transport Rules and Group Membership

When you define a transport rule using a predicate that expands membership of a distribution group, the resulting list of recipients is cached by the Hub Transport server that applies the rule. This is known as the *Expanded Groups Cache* and is also used by the Journaling agent for evaluating group membership for journal rules. By default, the Expanded Groups Cache stores group membership for four hours. Recipients returned by the recipient filter of a dynamic distribution group are also stored. The Expanded Groups Cache makes repeated round-trips to Active Directory and the resulting network traffic from resolving group memberships unnecessary.

In Exchange 2010, this interval and other parameters related to the Expanded Groups Cache are configurable. You can lower the cache expiration interval, or disable caching altogether, to ensure group memberships are refreshed more frequently. You must plan for the corresponding increase in load on your Active Directory domain controllers for distribution group expansion queries. You can also clear the cache on a Hub Transport server by restarting the Microsoft Exchange Transport service on that server. You must do this on each Hub Transport server where you want to clear the cache. When creating, testing, and troubleshooting transport rules that use predicates based on distribution group membership, you must also consider the impact of Expanded Groups Cache.

Note:

The Expanded Groups Cache isn't used by the categorizer to resolve recipients for message delivery.

Return to top

1.11.3.3 Transport Rule Predicates

Transport Rule Predicates

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-22*

In Microsoft Exchange Server 2010, predicates are used to create conditions and exceptions in a transport rule. Transport rules can be applied to e-mail messages routed through Hub Transport and Edge Transport servers. Some predicates are available on both transport server roles, and some are exclusive to just one transport server role.

Contents

Predicates and Predicate Properties

Transport rule conditions and exceptions consist of one or more predicates. Predicates instruct the Transport Rules agent on a Hub Transport server (or the Edge Rules agent on an Edge Transport server) to examine a specific part of an e-mail message, such as sender, recipients, subject, other message headers, and message body, to determine whether the rule should be applied to that message. As such, predicates act as building blocks for conditions and exceptions.

To determine whether a transport rule should be applied to a message, most predicates have one or more properties for which you must specify a value. The Transport Rules agent inspects message properties for specified values. For example, the **HasClassification** predicate requires that you specify one or more message classifications for the classification property. Some predicates don't have properties. For example, the **HasNoClassification** predicate simply inspects whether a message has a classification, and therefore doesn't require any values.

To assign a value to a predicate, you must determine the predicate property or properties in the case of predicates that require more than one property. In the Exchange Management Console (EMC), you can specify predicate values in the **Edit the rule description by clicking an underlined value** box of the New Transport Rule or Edit Transport Rule wizards. In the Exchange Management Shell the properties are available as parameters of the New-TransportRule and Set-TransportRule cmdlets. Property values are specified after the property name.

Note:

In Exchange 2010, you don't need to instantiate predicates and actions by using the Get-TransportRulePredicate and Get-TransportRuleAction cmdlets. These cmdlets only allow you to list the predicates and actions available for use on the Hub Transport and Edge Transport servers on which the cmdlets are executed. The **New-TransportRule** and **Set-TransportRule** cmdlets have all the predicates and actions available as parameters, allowing you to create or modify a transport rule using a single command.

Because some predicates examine specific fields within an e-mail message (such as the message header fields), you must set two predicate properties. When you use a predicate to inspect message headers, one predicate property specifies the header to examine, such as To, From, Received, or Content-Type. You must also specify a value for the second property. Predicates that require a second property are listed in Table 1 and Table 2, with the second property listed in the **Second predicate property** column.

Return to top

Predicates Available on Hub Transport Servers

Table 1 lists the predicates available on a Hub Transport server, and provides the following information about each predicate:

- The **Predicate** column lists the predicate as it appears in the New Transport Rule and Edit Transport Rule wizards in the EMC.
- The **Predicate name** column lists the predicate name as returned by the Get-TransportRulePredicate cmdlet.
- The **Predicate property** and **Second predicate property** columns list the property types. Most property types accept specific values. Refer to Table 3 to determine valid values for a property type.

Note:

Each predicate listed in Table 1 also has an equivalent exception that can be selected

from the **Exceptions** page of the New Transport Rule and Edit Transport Rule wizards. In the Shell, the predicates that can be used as exceptions start with **ExceptIf**. For example, for the **FromMemberOf** predicate, the parameter that can be used as an exception in transport rule cmdlets is called *ExceptIfFromMemberOf*.
The same predicate object contains the logic for use in a transport rule condition and exception. Therefore, when you use the **Get-TransportRulePredicate** cmdlet to list predicates, exceptions aren't listed as separate predicates.

Table 1 Predicates available on Hub Transport servers

No	Predicate	Predicate name	Predicate property	Second predicate property	Description
1	**from people**	From	Addresses	Not applicable	From matches messages sent by the specified mailboxes, mail-enabled users, or contacts. **Note:** You can't specify a distribution group by using this predicate. If you need to create a rule that takes action on messages sent to a distribution group, use the "when any of the recipients in the To field is people" (AnyOfToHeader) predicate instead. The AnyOfToHeader predicate compares the actual values of the headers in the message. This differs from the SentTo type of predicates that compare the resolved set of recipients, including recipients found from group

					expansions.
2	**from a member of distribution list**	FromMemberOf	Addresses	Not applicable	`FromMemberOf` matches messages where the sender is a member of the specified distribution group.
3	**from users that are inside or outside the organization**	FromScope	FromUserScope	Not applicable	`FromScope` matches messages that are sent by senders within the specified scope.
4	**sent to people**	SentTo	Addresses	Not applicable	`SentTo` matches messages where one of the recipients is the specified mailbox, mail-enabled user, or contact. The specified recipients can be listed in the **To**, **Cc**, or **Bcc** fields. **Note:** You can't specify a distribution group by using this predicate. If you need to create a rule that takes action on messages sent to a distribution group, use the "when any of the recipients in the To field is people" (AnyOfToHeader) predicate instead. The AnyOfToHeader predicate compares the

					actual values of the headers in the message. This differs from the SentTo type of predicates that compare the resolved set of recipients, including recipients found from group expansions.
5	**sent to a member of distribution list**	SentToMemberOf	Addresses	Not applicable	`SentToMemberOf` matches messages that contain recipients who are members of the specified distribution group. The recipients can be listed in the **To**, **Cc**, or **Bcc** fields.
6	**sent to users that are inside or outside the organization, or partners**	SentToScope	ToUserScope	Not applicable	`SentToScope` matches messages that are sent to recipients within the specified scope.
7	**between members of distribution list and distribution list**	BetweenMemberOf	Addresses (`BetweenMemberOf1`)	Addresses (`BetweenMemberOf2`)	`BetweenMemberOf` matches messages that are sent between members of two distribution groups.
8	**when the manager of any sender is people**	ManagerIs	EvaluatedUser (`ManagerForEvaluatedUser`)	Addresses (`ManagerAddresses`)	`ManagerIs` matches messages where the specified user's (sender or recipient) manager exists in the list of specified addresses.
9	**when the**	ManagementR	ManagementR	Not applicable	`ManagementRe`

	sender is the manager of a recipient	elationship	elationship (SenderManagementRelationship)		lationship matches messages where the sender has the specified management relationship with a recipient.
10	**if the sender and recipient's AD Attribute are Evaluation**	ADAttributeComparison	ADAttribute (ADComparisonAttribute)	Evaluation (ADComparisonOperator)	ADAttributeComparison matches messages where the sender's specified Active Directory attribute matches or doesn't match (as specified in the **Evaluation** property) the same attribute of any recipient.
11	**when a recipient's address contains specific words**	RecipientAddressContainsWords	Words	Not applicable	RecipientAddressContainsWords matches messages where a recipient's address contains any of the specified words.
12	**when a recipient's address contains text patterns**	RecipientAddressMatchesPatterns	Patterns	Not applicable	RecipientAddressMatchesPatterns matches messages where a recipient's address matches a specified regular expression.
13	**when a recipient's properties contains specific words**	RecipientAttributeContains	Words* (RecipientADAttributeContainsWords)	Not applicable	RecipientAttributeContains matches messages where the specified attribute of a recipient

					contains a specified string.
14	**when a recipient's properties contains text patterns**	RecipientAttributeMatches	Patterns* (RecipientADAttributeMatchesPatterns)	Not applicable	RecipientAttributeMatches matches messages where the specified attribute of a recipient matches a regular expression.
15	**when any of the recipients in the To field is people**	AnyOfToHeader	Addresses	Not applicable	AnyOfToHeader matches messages where the **To** field includes any of the specified recipients.
16	**when any of the recipients in the "To" field is a member of distribution list**	AnyOfToHeaderMemberOf	Addresses	Not applicable	AnyOfToHeaderMemberOf matches messages where the **To** field contains a recipient who is a member of the specified distribution group.
17	**when any of the recipients in the Cc field is people**	AnyOfCcHeader	Addresses	Addresses	AnyOfCcHeader matches messages where the **Cc** field includes any of the specified recipients.
18	**when any of the recipients in the Cc field is member of distribution list**	AnyOfCcHeaderMemberOf	Addresses	Not applicable	AnyOfCcHeaderMemberOf matches messages where the **Cc** field contains a recipient who is a member of the specified distribution group.
19	**when any of the recipients in the To or Cc fields is**	AnyOfToCcHeader	Addresses	Not applicable	AnyOfToCcHeader matches messages where the **To**

	people				or **Cc** fields include any of the specified recipients.
20	**when any of the recipients in the To or CC fields is a member of a distribution list**	AnyOfToCcHeaderMemberOf	Addresses	Not applicable	`AnyOfToCcHeaderMemberOf` matches messages where the **To** or **Cc** fields contains a recipient who is a member of the specified distribution group.
21	**marked with classification**	HasClassification	Classification	Not applicable	`HasClassification` matches messages that have the specified classification.
22	**when the Subject field contains specific words**	SubjectContains	Words	Not applicable	`SubjectContains` matches messages that have the specified words in the **Subject** field.
23	**when the Subject field or message body contains specific words**	SubjectOrBodyContains	Words	Not applicable	`SubjectOrBodyContains` matches messages that have the specified words in the **Subject** field or message body.
24	**when the message header contains specific words**	HeaderContains	MessageHeader (`HeaderContainsMessageHeader`)	Words (`HeaderContainsWords`)	`HeaderContains` matches messages where the specified message header contains the specified value.
25	**when the From address contains specific words**	FromAddressContains	Words (`FromAddressContainsWords`)	Not applicable	`FromAddressContains` matches messages that contain the specified words in the **From** field.

26	**when the Subject field contains text patterns**	SubjectMatches	Patterns (SubjectMatchesPatterns)	Not applicable	SubjectMatches matches messages where text patterns in the **Subject** field match a specified regular expression.
27	**when the Subject field or the message body contains text patterns**	SubjectOrBodyMatches	Patterns (SubjectOrBodyMatchesPatterns)	Not applicable	SubjectOrBodyMatches matches messages where text patterns in the **Subject** field or message body match a specified regular expression.
28	**when the message header matches text patterns**	HeaderMatches	MessageHeader (HeaderMatchesMessageHeader)	Patterns (HeaderMatchesPatterns)	HeaderMatches matches messages where the specified message header contains a text pattern that matches a specified regular expression.
29	**when the From address matches text patterns**	FromAddressMatches	Patterns (FromAddressMatchesPatterns)	Not applicable	FromAddressMatches matches messages that contain text patterns in the **From** field that match a specified regular expression.
30	**when any attachment file name matches text patterns**	AttachmentNameMatches	Patterns (AttachmentNameMatchesPatterns)	Not applicable	AttachmentNameMatches matches messages that contain text patterns in an attachment that matches a specified regular

					expression.
31	**with a spam confidence level (SCL) rating that is greater than or equal to limit**	SCLOver	SclValue	Not applicable	`SCLOver` matches messages that are assigned a spam confidence level (SCL) matching or exceeding the specified value.
32	**when the size of any attachment is greater than or equal to limit**	AttachmentSizeOver	Size	Not applicable	`AttachmentSizeOver` matches messages that contain attachments larger than the specified value.
33	**marked with importance**	WithImportance	Importance	Not applicable	`WithImportance` matches messages marked with the specified priority.
34	**if the message is Message Type**	MessageTypeMatches	MessageType	Not applicable	`MessageTypeMatches` matches messages of the specified type.
35	**when the sender's properties contain specific words**	SenderAttributeContains	Words* (`SenderADAttributeContainsWords`)	Not applicable	`SenderAttributeContains` matches messages where the specified attribute of the sender matches a specified string.
36	**when the sender's properties match text patterns**	SenderAttributeMatches	Patterns (`SenderADAttributeMatchesPatterns`)	Not applicable	`SenderAttributeMatches` matches messages where the specified attribute of the sender contains text patterns that match a specified regular expression.

37	**not marked with a message classification**	HasNoClassifications	Not applicable	Not applicable	`HasNoClassifications` matches messages that don't have a message classification.
38	**when an attachment's content contains words**	AttachmentContainsWords	Words	Not applicable	`AttachmentContainsWords` matches messages with attachments that contain a specified string.
39	**when an attachment's content matches text patterns**	AttachmentMatchesPatterns	Patterns	Not applicable	`AttachmentMatchesPatterns` matches messages with attachments that contain a text pattern that matches a specified regular expression.
40	**when an attachment is unsupported**	AttachmentIsUnsupported	Not applicable	Not applicable	`AttachmentIsUnsupported` matches messages with attachments that aren't supported.

Return to top

Predicates Available on Edge Transport Servers

Table 2 lists the predicates available on Edge Transport servers.

Note:

Each predicate listed in Table 1 also has an equivalent exception that can be selected from the **Exceptions** page of the New Transport Rule and Edit Transport Rule wizards. In the Shell, the predicates that can be used as exceptions start with `ExceptIf`. For example, for the `FromMemberOf` predicate, the parameter that can be used as an exception in transport rule cmdlets is called *ExceptIfFromMemberOf*.
The same predicate object contains the logic for use in a transport rule condition and exception. Therefore, when you use the **Get-TransportRulePredicate** cmdlet to list predicates, exceptions aren't listed as separate predicates.

Predicates available on Edge Transport servers

No	Predicate	Predicate name	Predicate property	Second predicate property	Description

1	**when the subject field contains specific words**	SubjectContains	Words	Not applicable	`SubjectContains` matches messages that contain the specified words in the **Subject** field.
2	**when the subject field or message body contains specific words**	SubjectOrBodyContains	Words	Not applicable	`SubjectOrBodyContains` matches messages that contain the specified words in the **Subject** field or message body.
3	**when the message header contains specific words**	HeaderContains	MessageHeader	Words	`HeaderContains` matches messages where the value of the specified message header contains the specified words.
4	**when the From address contains specific words**	FromAddressContains	Words	Not applicable	`FromAddressContains` matches messages that contain the specified words in the **From** field.
5	**when any recipient address contains specific words**	AnyOfRecipientAddressContainsWords	Words	Not applicable	`AnyOfRecipientAddressContains` matches messages that contain the specified words in the **To**, **Cc**, or **Bcc** fields of the message.
6	**when the Subject field matches text patterns**	SubjectMatches	Patterns	Not applicable	`SubjectMatches` matches messages where text patterns in the **Subject** field match a specified regular

					expression.
7	**when the Subject field or the message body matches text patterns**	SubjectOrBodyMatches	Patterns	Not applicable	`SubjectOrBodyMatches` matches messages where text patterns in the **Subject** field or message body match a specified regular expression.
8	**when the message header matches text patterns**	HeaderMatches	MessageHeader	Patterns	`HeaderMatches` matches messages where the specified message header field contains text patterns that match a specified regular expression.
9	**when the From address matches text patterns**	FromAddressMatches	Patterns	Not applicable	`FromAddressMatches` matches messages that contain text patterns in the **From** field of the messages that match a specified regular expression.
10	**when any recipient address matches text patterns**	AnyOfRecipientAddressMatches	Patterns	Not applicable	`AnyOfRecipientAddressMatches` matches messages where text patterns in the **To**, **Cc**, or **Bcc** fields of the message match a specified regular expression.
11	**with a spam confidence**	SCLOver	SclValue	Not applicable	`SclOver` matches

	level (SCL) rating that is greater than or equal to limit				messages with an SCL that's equal to or greater than the value specified.
12	**when the size of any attachment is greater than or equal to limit**	AttachmentSizeOver	Size	Not applicable	`AttachmentSizeOver` matches messages that contain attachments larger than the specified value.
13	**From users that are inside or outside the organization**	FromScope	Scope	Not applicable	`FromScope` matches messages that are sent from the specified scope.

Return to top

Predicate Properties

The following table lists the property types used in transport rule predicates.

Table 3 Property types used in transport rule predicates

Predicate	Name	Description
ADAttribute	One of the Active Directory attributes available for use	The `ADAttribute` predicate accepts the name of one of the following Active Directory attributes available for use with this property type in transport rules: • `DisplayName` • `FirstName` • `Initials` • `LastName` • `Office` • `PhoneNumber` • `OtherPhoneNumber` • `Email` • `Street` • `POBox` • `City` • `State` • `ZipCode` • `Country` • `UserLogonName` • `HomePhoneNumber` • `OtherHomePhoneNumber`

		• PagerNumber • MobileNumber • FaxNumber • OtherFaxNumber • Notes • Title • Department • Company • Manager • CustomAttribute1 - CutomAttribute15 When you use the Shell to create a transport rule consisting of the RecipientAddressContains or RecipientAddressMatches predicates, you must specify an attribute name from the preceding list followed by a colon (:) and the word or text pattern you want to match in the specified attribute. The entire notation should be enclosed in quotation marks ("). For example, to specify the attribute City and the values San Francisco or Palo Alto, you must use City:San Francisco, Palo Alto. You can also specify multiple Active Directory attributes and value pairs. For example, "City:San Francisco, Palo Alto","Department:Sales, Finance". In this case, the recipient's City attribute should contain either San Francisco or Palo Alto, and the Department attribute should contain either Sales or Finance.
Addresses and Addresses2	Array of Active Directory mailbox, contact, or distribution group objects	The Addresses and Addresses2 predicates accept a single mailbox, contact, mail-enabled user, or distribution group object.
Classification	Message classification object	The Classification predicate accepts a message classification object. To specify a message classification object, you must use the Get-MessageClassification cmdlet. For example, use the following command to search for messages with the ExCompanyInternal classification and prepend the message subject with

		CompanyInternal. `New-TransportRule "Rule Name" -HasClassification @(Get-MessageClassification ExCompanyInternal).Identity -PrependSubject "CompanyInternal"`
EvaluatedUser	Single value of `Sender` or `Recipient`	The `ManagementRelationship` predicate accepts an `EvaluatedUser` value for the `ManagerForEvaluatedUser` property. It instructs the Transport Rules agent whether the predicate should inspect a message's sender or the recipient.
Evaluation	Single value of `Equal` or `NotEqual`	The `ADAttributeComparison` predicate accepts a value of type `Evaluation` for the `ADComparisonOperator` property. This allows you to compare the specified Active Directory attribute values for the sender and recipient.

FromUserScope	Single value of `InOrganization` or `NotInOrganization`	The `FromScope` predicate accepts a scope value of type `FromUserScope`. This specifies whether the message is sent by a sender who is considered to be inside the organization. The following values can be used:
		• **InOrganization** A sender is considered to be inside the organization if either of the following conditions is true:
		  • The sender is a mailbox, mail-enabled user, distribution group, or public folder that exists in the organization's Active Directory.
		  • The domain of the sender is an accepted domain in the Exchange organization, but isn't an `ExternalRelay` domain. Also, the message must be sent or received by using an authenticated connection.

		Note: To determine whether mail contacts are considered to be inside or outside the organization, the domain part of the sender's address is compared with the configured accepted domains. For more information, see Understanding Accepted Domains • **NotInOrganization** A sender is considered to be outside the organization if the sender's domain isn't an accepted domain in the Exchange organization and is an `ExternalRelay` domain.
Importance	Single value of `High`, `Low`, or `Normal`	The `Importance` predicate accepts the message priority.
ManagementRelationship	Single value of `Manager` or `DirectReport`	The `ManagementRelationship` predicate specifies the relationship between two evaluated users, for example the sender and the recipient. The evaluated user's Active Directory information is located to determine the manager and direct reports.
MessageHeader	Single string	The `MessageHeader` predicate accepts a string that can be used to specify the SMTP message header to examine. This property is used together with the `Words` or `Patterns` properties, which specify the value of the header field to match. You don't need to add a colon (`:`) in the header name.
MessageType	Single message type name	The `MessageType` predicate accepts one of the following message types: • OOF • AutoAccept • AutoForward • Encrypted • Calendaring • PermissionControlled • Voicemail • RSS • Signed • ApprovalRequest • ReadReceipt
Patterns	Array or regular expressions	The `Patterns` predicate accepts a regular expression that can be

		used to match text that follows an identifiable pattern. Enclose the expression in quotation marks ("). For more information, see Regular Expressions in Transport Rules.
SclValue	Single integer	The `SclValue` predicate accepts an integer that can be used to match the spam confidence level (SCL) assigned to a message. SCL values range from -1 through 9.
Size	Single integer with quantifier such as KB or MB	The `Size` predicate accepts an integer that specifies the size of an e-mail attachment. When using the EMC, the value specified is in kilobytes. When using the Shell, you can enter an integer value qualified by one of the following units: • B (bytes) • KB (kilobytes) • MB (megabytes) • GB (gigabytes) For example, `20MB`
ToUserScope	One of the following values: • `InOrganization` • `NotInOrganization` • `ExternalPartner` • `ExternalNonPartner`	The `SentToScope` predicate accepts a scope value of type `ToUserScope`. The `InOrganization` and `NotInOrganization` values are evaluated similar to the `FromUserScope` property, but in the context of the recipient. The following is a description of the other possible values: • **ExternalPartner** These domains are configured to send mail to an external domain by using Domain Secure security • **ExternalNonPartner** These represent all other domains that aren't considered `ExternalPartner` domains.
Words	Array of strings	The `Words` property accepts one string or an array of strings. It's used in all predicates that inspect different parts of a message for specific words or strings. In Exchange 2010, only instances of the word without a prefix or suffix are matched. For example, if you specify the word "contoso",

		the rule will fire only if an exact match is found. The following variations where the word appears as a suffix, a prefix, or between other characters (other than the space character) aren't considered an exact match: • Acontoso • Contosoa • Acontosob The property isn't case-sensitive. The asterisk (*) is treated as a literal character, and not used as a wildcard character.

Return to top

1.11.3.4 Transport Rule Actions

Transport Rule Actions

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-22*

Transport rule actions instruct the rules agent to take the specified action on messages that match all the predicates in a condition, and don't match any of the exceptions. In Microsoft Exchange Server 2010, both the Hub Transport server and Edge Transport server can apply transport rules to e-mail messages routed by them. Some actions are available on both transport server roles, and some are exclusive to either role.

Each action affects e-mail messages in a unique way. For example, an action can cause an e-mail message to be redirected to another address or to be deleted. Each action consists of the action itself, its action property, and the value of the property.

To assign a value to an action, you must determine the available action property for a specific action. For example, you must use the `Address` action property together with the `RedirectMessage` action. (For information about the action properties available for use with Hub Transport servers and Edge Transport servers, see the tables later in this topic.)

Some actions require that you set two or more action properties, because some actions modify specific fields within sections of an e-mail message, such as the message header fields. When you specify an action to modify a message header, one action property specifies the specific header field to modify, and a second action property specifies the new value of the message header. In these cases, you must also specify a value for the second action property, as shown later in this topic in the **Additional action property** table column in either Actions Available on a Hub Transport Server or Actions Available on an Edge Transport Server, depending on the server role. For example, you can configure an action to modify the **X-Test-Message-Source** header field to a specific string, such as `contoso.com`.

You can use either the Exchange Management Console or the Exchange Management Shell to create or modify a transport rule. For relevant procedures, see Transport Rules.

Contents

Actions Available on a Hub Transport Server

The following table lists the actions that can be used with transport rules on a server running Exchange 2010 that has the Hub Transport server role installed. The transport rule action LogEvent isn't available on Exchange 2010 Hub Transport servers.

Transport rule actions available on Hub Transport servers

Supported rule action	Action name	First action property	Additional action property	Description
prepend the subject with string	PrependSubject	Prefix	Not applicable	PrependSubject prepends a string to the start of the Subject field of the message.
apply message classification	ApplyClassification	Classification	Not applicable	ApplyClassification applies a message classification to the e-mail message. For more information, see Understanding Message Classifications.
append disclaimer text and fallback to action if unable to apply	ApplyHtmlDisclaimer	ApplyHtmlDisclaimerLocation	ApplyHtmlDisclaimerText, ApplyHtmlDisclaimerFallbackAction	ApplyHtmlDisclaimer applies an HTML disclaimer to the message. For more information, see Understanding Disclaimers.
rights protect message with RMS template	RightsProtectMessage	RMSTemplateIdentity	Not applicable	RightsProtectMessage applies the specified Rights Management Services (RMS) template to the

				message. For more information, see Understanding Transport Protection Rules.
set the spam confidence level to value	SetScl	SclValue	Not applicable	SetScl sets the spam confidence level (SCL) on an e-mail message. For more information, see Understanding Spam Confidence Level Threshold.
set header with value	SetHeader	MessageHeader	HeaderValue	SetHeader creates a new message header field or modifies an existing message header field.
remove header	RemoveHeader	MessageHeader	Not applicable	RemoveHeader removes the specified message header field from a message.
add a recipient in the To field addresses	AddToRecipient	Addresses	Not applicable	AddToRecipient adds one or more recipients to the To field of the message. The original recipients can see the additional address.
copy the message to addresses	CopyTo	Addresses	Not applicable	CopyTo adds one or more recipients to the carbon copy (Cc) field of the message. The original recipients can see the Cc address.
Blind carbon copy (Bcc) the message to addresses	BlindCopyTo	Addresses	Not applicable	BlindCopyTo adds one or more recipients as blind carbon copy (Bcc) recipients. The original recipients aren't notified and can't see the Bcc addresses.
add the sender's	AddManagerAsR	AddedRecipien	Not applicable	AddManagerAsRe

manager as a specific recipient type	ecipientType	tType		cipientType adds the sender's manager, if defined in the manager attribute in Active Directory, as the specified recipient type.
forward the message to addresses for moderation	ModerateMessageByUser	Addresses	Not applicable	ModerateMessageByUser forwards the message to the specified moderators as an attachment wrapped in an approval request. For more information, see Understanding Moderated Transport.
forward the message to the sender's manager for moderation	ModerateMessageByManager	Not applicable	Not applicable	ModeratedMessageByManager forwards the message to the sender's manager for moderation, if the manager attribute is populated in Active Directory. **Important:** If the sender's manager attribute isn't populated in Active Directory, the message is delivered to recipients without moderation. This action doesn't require any action properties.
redirect the message to addresses	RedirectMessage	Addresses	Not applicable	RedirectMessage redirects the e-mail message to one or more recipients specified by the administrator. The message isn't delivered to the original recipients, and no notification is sent to the

				sender or the original recipients.
send rejection message to sender with enhanced status code	RejectMessage	RejectReason	EnhancedStatusCode	RejectMessage deletes the e-mail message and sends a non-delivery receipt to the sender. The recipient doesn't receive the message or notification.
Delete the message without notifying anyone	DeleteMessage	Not applicable	Not applicable	DeleteMessage deletes the e-mail message without sending a notification to either the recipient or the sender.

Return to top

Actions Available on an Edge Transport Server

The following table lists the actions that can be used with transport rules on Exchange 2010 Edge Transport servers.

Transport rule actions available on Edge Transport servers

Supported rule action	Action name	First action property	Additional action property	Description
log an event with message	LogEvent	EventMessage	Not applicable	LogEvent inserts an event into the Application log of the local computer.
prepend the subject with string	PrependSubject	Prefix	Not applicable	PrependSubject prepends a string to the start of the e-mail message subject field.
set the spam confidence level to value	SetScl	SclValue	Not applicable	SetScl configures the SCL on an e-mail message.
set header with value	SetHeader	MessageHeader	HeaderValue	SetHeader creates a new message header field or modifies an existing message header field.

remove header	RemoveHeader	MessageHeader	Not applicable	RemoveHeader removes the specified message header field from an e-mail message.
add a recipient in the To field addresses	AddToRecipient	Addresses	Not applicable	AddToRecipient adds one or more e-mail addresses to the To address list of the e-mail message. The original recipients can see the additional address.
copy the message to addresses	CopyTo	Addresses	Not applicable	CopyTo adds one or more e-mail addresses to the Cc field of the e-mail message. The original recipients can see the original address.
Blind carbon copy (Bcc) the message to addresses	BlindCopyTo	Addresses	Not applicable	BlindCopyTo adds one or more e-mail addresses to the Bcc address list of the e-mail message. The original recipients aren't notified and can't see the additional address.
drop connection	Disconnect	Not applicable	Not applicable	Disconnect ends the connection between the sending server and the Edge Transport server without generating an NDR message.
redirect the message to addresses	RedirectMessage	Addresses	Not applicable	RedirectMessage redirects the e-mail message to one or more e-mail addresses specified by the administrator. The message isn't delivered to the original recipient, and no notification

				is provided to the recipient or the sender.
Put message in spam quarantine mailbox	`Quarantine`	Not applicable	Not applicable	`Quarantine` redirects the e-mail message to the spam quarantine mailbox configured by using the *QuarantineMailbox* parameter on the **Set-ContentFilterConfig** cmdlet. **Important:** The *QuarantineMailbox* parameter on the **Set-ContentFilterConfig** cmdlet must be populated, and the specified mailbox must exist before you configure the **Put message in spam quarantine mailbox** action. If the *QuarantineMailbox* parameter isn't populated or if the quarantine mailbox doesn't exist, messages sent to the quarantine mailbox will be lost and an NDR will be generated. For more information about the spam quarantine mailbox, see Understanding Spam Quarantine.
reject the message with status code and response	`SmtpRejectMessage`	`StatusCode`	`RejectReason`	`SmtpRejectMessage` deletes the e-mail message and sends a notification to the sender. The recipients don't

				receive the message or notification. This action enables you to specify a specific delivery status notification (DSN) code. For more information about DSNs, see Managing Delivery Status Notifications.
Delete the message without notifying anyone	DeleteMessage	Not applicable	Not applicable	DeleteMessage deletes the e-mail message without sending a notification to either the recipient or the sender.

Return to top

Action Properties for Transport Rules on a Hub Transport or an Edge Transport Server

The following table lists the action properties used by transport rules actions on Exchange 2010 Hub Transport or Edge Transport servers.

Action properties for transport rules on a Hub Transport server or an Edge Transport server

Action property	Expected format	Description
AddedRecipientType	One of the following values: • **To** • **Cc** • **Bcc** • **Redirect**	AddedRecipientType accepts a single value: • To, Cc, and Bcc values are self-explanatory and correspond to the addressing fields of e-mail messages. • Redirect delivers the message only to the specified recipient. The message isn't delivered to any of the original recipients.
Addresses	• **Edge Transport server** Array of SMTP addresses • **Hub Transport server**	On an Edge Transport server, Addresses accepts an array of SMTP addresses that are each enclosed in quotation marks (").

	Array of Active Directory mailbox, contact, mail-enabled user, or distribution group objects	On a Hub Transport server, `Addresses` accepts an array of mailbox, contact, mail-enabled user, or distribution group objects.
`Classification`	Single message classification object	`Classification` accepts a single message classification object. To specify a message classification object, use the Get-MessageClassification cmdlet. For more information about message classifications, see Understanding Message Classifications.
`DisclaimerLocation`	One of the following values: • Append • Prepend	`DisclaimerLocation` specifies where the disclaimer is inserted into the e-mail message: • `Append` (default) adds the disclaimer at the bottom of the message thread. • `Prepend` puts the disclaimer at the start of the newest e-mail message.
`EnhancedStatusCode`	Single DSN code of `5.7.1`, or any value from `5.7.10` through `5.7.999`	`EnhancedStatusCode` specifies the DSN code and related DSN message to display to the senders of messages rejected by the `RejectMessage` transport rule action. The DSN message associated with the specified DSN status code is displayed in the user information portion of the NDR displayed to the sender. The specified DSN code must be an existing default DSN code or a customized DSN status code that you can create by using the **New-SystemMessage** cmdlet.
`EventMessage`	Single string	`EventMessage` accepts a single string displayed in an event log, which is added to the application event log on the local computer.
`FallbackAction`	Single value with the choices of `Wrap`, `Ignore`, or `Reject`	`FallbackAction` specifies what the transport rule should do if a disclaimer can't be applied to an e-mail message such as when a message is encrypted. The default fallback action is `Wrap`. Enclose the value in quotation marks ("). The following list shows each fallback action and its description:

		• **Wrap** If the disclaimer can't be inserted into the original message, Exchange encloses, or *wraps*, the original message in a new message envelope. Then the disclaimer is inserted into the new message. **Important:** If an original message is wrapped in a new message envelope, subsequent transport rules are applied to the new message envelope, and not to the original message. Therefore, you must configure transport rules with disclaimer actions that wrap original messages in a new message body after you configure other transport rules. **Note:** If the original message can't be wrapped in a new message envelope, the original message isn't delivered. The sender of the message receives an NDR that explains why the message wasn't delivered. • **Ignore** If the disclaimer can't be inserted into the original message, Exchange lets the original message continue unmodified. No disclaimer is added. • **Reject** If the disclaimer can't be inserted into the original message, Exchange doesn't deliver the message. The sender of the message receives an NDR that explains why

		the message wasn't delivered.
HeaderValue	Single string	HeaderValue accepts a single string that's applied to the header specified by using the MessageHeader action property. Enclose the string in quotation marks (").
MessageHeader	Single string	MessageHeader accepts a string that specifies which MessageHeader to add or modify. The string that's specified by using the HeaderValue action property is inserted into the header that's specified by MessageHeader. Enclose the string in quotation marks (").
Prefix	Single string	Prefix accepts a string that's prepended to the subject of the e-mail message. Enclose the string in quotation marks ("). To prevent the string that's specified with the Prefix transport rule action from being added to the subject every time that a reply to the message encounters the transport rule, add the SubjectContains exception to the transport rule. The SubjectContains exception should contain the string that you specified with the Prefix transport rule action. If you add the SubjectContains exception to the transport rule, the transport rule doesn't add another instance of the Prefix string to the subject if the Prefix string already appears in the subject.
RejectReason	Single string	RejectReason accepts a string that's used to populate the administrator information portion of the NDR returned to the e-mail sender if an e-mail message is rejected. Enclose the string in quotation marks (").
RMSTemplateIdentity	RMS Template identity	RMSTemplateIdentity accepts an RMS Template identity. You can get a list of RMS templates available on an Active Directory RMS server in the Active Directory forest using the **Get-**

		RMSTemplate cmdlet.
`SclValue`	Single integer	`SclValue` accepts a single integer from 0 through 9, which is used to configure the SCL of the e-mail message. Enclose the integer in quotation marks (").

Regular Expressions in Transport Rules

1.11.3.5 Regular Expressions in Transport Rules

Regular Expressions in Transport Rules

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-21*

You can use regular expressions in Microsoft Exchange Server 2010 transport rule predicates to match text patterns in different parts of a message (such as message headers, sender, recipients, message subject, and body). Predicates are used by conditions and exceptions to determine whether a configured action should be applied to an e-mail message.

Looking for management tasks related to transport rules? See Managing Transport Rules.

Contents

Simple Expressions vs. Regular Expressions

To understand regular expressions, you must first understand simple expressions. A *simple expression* is a specific value that you want to match exactly in a message. Predicates using simple expressions match specific words or strings. An example of a simple expression is the title of a document that your organization doesn't want to be distributed outside the organization, such as Yearly Sales Forecast.doc. A piece of data in

an e-mail message must exactly match a simple expression to satisfy a condition or exception in transport rules.

A *regular expression* is a concise and flexible notation for finding patterns of text in a message. The notation consists of two basic character types:

- **Literal characters** Text that must exist in the target string. These are normal characters, as typed.
- **Metacharacters** One or more special characters that aren't interpreted literally. These indicate how the text can vary in the target string.

You can use regular expressions to quickly parse e-mail messages to find specific text patterns. This enables you to detect messages with specific types of content, such as social security numbers (SSNs), patent numbers, and phone numbers.

You can't reasonably match this data with a simple expression because a simple expression requires that you enter every possible variation of the value that you want to detect. In many cases, using simple expressions for such applications becomes a logistical challenge, and matching a large number of simple expressions in message content can be resource-intensive. Using regular expressions is generally more efficient. Instead of specifying all possible variations, you can configure the transport rule predicate to search for a text pattern.

Regular Expressions in Exchange 2010

In the Exchange Management Shell, you can use regular expressions in any predicate that accepts the **Patterns** predicate property. In the Exchange Management Console, you can use regular expressions with any condition or exception that contains the words **with text patterns**. For more information about predicates, see Transport Rule Predicates.

Caution:

You must carefully test the regular expressions that you construct to make sure that they yield the expected results. An incorrectly configured regular expression could yield unexpected matches and cause unwanted transport rule behavior. This may result in undesirable actions being taken on messages and message content, potentially resulting in data loss when actions such as rejecting or bouncing a message are used. Also, complex regular expressions may affect mail transport performance. Test your regular expressions in a test environment before you implement them in production.

The following table lists the pattern strings that you can use to create a pattern-matching regular expression in Exchange 2010.

Pattern strings

Pattern string	Description
\S	The \S pattern string matches any single character that's not a space.
\s	The \s pattern string matches any single white-space character.
\D	The \D pattern string matches any non-numeric digit.
\d	The \d pattern string matches any single numeric digit.
\w	The \w pattern string matches any single Unicode character categorized as a letter or decimal digit.

\W	The \W pattern string matches any single Unicode character not categorized as a letter or a decimal digit.
|	The pipe (|) character performs an **OR** function.
*	The asterisk (*) character matches zero or more instances of the previous character. For example, ab*c matches the following strings: ac, abc, abbbbc.
( )	Parentheses act as grouping delimiters. For example, a(bc)* matches the following strings: a, abc, abcbc, abcbcbc, and so on.
\	A backslash is used as an escaping character before a special character. Special characters are characters used in pattern strings: • Backslash (\ ) • Pipe (|) • Asterisk (*) • Opening parenthesis (( ) • Closing parenthesis ( )) • Caret (^) • Dollar sign ($) For example, if you want to match a string that contains (525), you would type \(525\).
^	The caret (^) character indicates that the pattern string that follows the caret must exist at the start of the text string being matched. For example, ^fred@contoso matches fred@contoso.com and fred@contoso.co.uk but not alfred@contoso.com.
$	The dollar sign ($) character indicates that the preceding pattern string must exist at the end of the text string being matched. For example, contoso.com$ matches adam@contoso.com and kim@research.contoso.com, but doesn't match kim@contoso.com.au.

Constructing Regular Expressions

By using the preceding table, you can construct a regular expression that matches the pattern of the data that you want to match. Working from left to right, examine each character or group of characters in the data that you want to match. Read the description of each pattern string to determine how it's applied to the data that you're matching. Then, determine which pattern string in the table represents that character or group of characters, and add that pattern string to the regular expression. When finished, you have a fully constructed regular expression.

This example of a regular expression matches North American telephone numbers in the formats 425 555-0100 and 425.555.0100.

```
425(\s|.)\d\d\d(-|.)\d\d\d\d
```

You can expand on this example by adding the telephone format (425) 555-0100, which

uses parentheses around the area code. This example of a regular expression matches all three telephone number formats.

\d\d\d((\s|.|-|\)|\)\s)\d\d\d(\s|.|-)\d\d\d\d

You can analyze the previous example as follows:

- **\d\d\d** This portion requires that exactly three numeric digits appear first.
- **((\s|.|-|\)|\)\s)** This portion requires that a space, a period, or a hyphen exists after the three-digit number. Each character-matching string is contained in the grouping delimiters and is separated by the pipe character. This means that only one of the specified characters inside the grouping delimiters can exist in this location in the string being matched. For the separation between area code and the next three digits, it also looks for a close parenthesis, or close parenthesis and space.
- **\d\d\d** This portion requires that exactly three numeric digits appear next.
- **(\s|.|-)** This portion requires that a space, a period, or a hyphen exists after the three-digit number.
- **\d\d\d\d** This portion requires that exactly four numeric digits appear next.

The above regular expression will match the following sample values:

- (425)555.0100
- 425 555 0100
- 425. 555-0100
- (425) 555-0100
- 425-555-0100
- (425) 555-0100

Creating a Transport Rule That Uses a Regular Expression

This example creates a transport rule in the Shell that uses regular expressions to match SSNs in the subject of an e-mail message.

```
New-TransportRule -Name "Social Security Number Block Rule" -SubjectOrBodyMatches
```

This example lets you view the new transport rule.

```
Get-TransportRule "Social Security Number Block Rule" | Format-List
```

1.11.3.6 Understanding Disclaimers

Understanding Disclaimers

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-22*

Microsoft Exchange Server 2010 includes the ability to add HTML or text disclaimers to e-mail messages that are processed on Hub Transport servers. Disclaimers are typically used to provide legal information, warnings about unknown or unverified e-mail senders, or for other reasons as determined by an organization.

Here's an example of an e-mail disclaimer:

IMPORTANT NOTICE: This e-mail message is intended to be received only by persons entitled to receive the confidential information it may contain. E-mail messages to clients of Contoso may contain information that is confidential and legally privileged. Please do not read, copy, forward, or store this message unless you are an intended recipient of it. If you have received this message in error, please forward it to the sender and delete it completely from your computer system.

Another example of a disclaimer is the use of e-mail signatures. Many organizations require that uniform signatures be applied to e-mail. Details such as the sender's name, title, department, company, location, and contact details may be required in signatures. In addition, organizations may require insertion of logos and other branding elements in signatures.

For details about how to create a disclaimer, see Configure a Disclaimer.

Targeting Disclaimers

Exchange 2010 lets you target disclaimers (assign specific disclaimers to specific e-mail messages) based on conditions and exceptions that are defined in transport rules created on Hub Transport servers. Transport rules give you the flexibility to assign specific disclaimers to e-mail messages based on business needs. For example, you could specify different disclaimers for internal and external messages or for messages sent by users in a specific departments or offices. However, when configuring multiple transport rules to apply disclaimers, carefully consider the transport rule conditions you use and avoid applying multiple disclaimers to the same message. For information about the transport rule predicates you can use to target the disclaimer, see Transport Rule Predicates.

Here are examples of business conditions that might require that you use unique disclaimers:

- Different legal requirements in different countries or regions.
- Different business or regulatory requirements in different countries or regions.
- Different languages.
- Potentially unsafe e-mail messages that are sent to internal users.

Customizing Disclaimers

When you create a disclaimer, you can modify the appearance, position, and behavior of the disclaimer within the e-mail message. You can customize disclaimers by using the following elements:

- Disclaimer text
- HTML tags and in-line CSS Styles
- Using Images in Disclaimers
- Using Active Directory Attributes in Disclaimers and Personalized Signatures
- Use of a separator line
- Placement of the disclaimer
- Behavior with messages that can't be modified

Disclaimer Text

The disclaimer text is the text that's inserted into a message. Exchange 2010 inserts disclaimers into e-mail messages by using the same message format as the original message. For example, if a message is created in HTML, the disclaimer is added in HTML. If the message is created as plain text, HTML tags are stripped from the disclaimer text before it's added to the plain text message.

Important:

In Exchange 2010, the maximum length of disclaimer text is 5,000 characters. This includes any HTML tags and inline Cascading Style Sheets (CSS) styles.

HTML Tags and Inline CSS Styles

Exchange 2010 disclaimer text can include HTML tags. This allows you to create messages with the rich styling functionality available in HTML. Additionally, HTML tags can include inline Cascading Style Sheets (CSS). Messages sent in the HTML format can display the rich disclaimer messages.

Note:
You can also configure a transport rule with text-only disclaimers by not using any HTML tags.

Using Images in Disclaimers

In Exchange 2010, you can add images to an HTML disclaimer by using the IMG tag. For example:

```
<IMG src="http://myserver.mydomain.com/images/companylogo.gif">
```

Note:
Images added by using IMG tags aren't embedded in the message. Images should be located on a Web server that's accessible to the e-mail client.

When determining whether to use IMG tags in a disclaimer, keep in mind that Outlook Web Access, Outlook Web App, and Outlook 2007 and later blocks external Web content (including images) by default. Users may need to perform a specific action if they want to view the blocked external content. Therefore, images added to HTML disclaimers by using the IMG tag may not be visible by default. We recommend that you test disclaimers with IMG tags in the e-mail clients your recipients are likely to use to make sure it meets your requirements.

Using Active Directory Attributes in Disclaimers and Personalized Signatures

In Exchange 2010, you can add Active Directory attributes (such as DisplayName, FirstName, LastName, Department, and Company) to disclaimers and personalized signatures. When a disclaimer rule is triggered, the attribute names are replaced by corresponding values from the sender's Active Directory user account. To use attributes in a disclaimer or personalized signature, you must enclose it in two percent signs (%%). For example, to use the **DisplayName** attribute, you must use %%DisplayName%%.

For a complete list of attributes that can be used in disclaimers and personalized signatures, see the description for the ADAttribute property in Transport Rule Predicates.

Use of a Separator Line

You may want to clearly identify in an e-mail message where a disclaimer starts or ends and where the original message content starts or ends. In Exchange 2010, you can use the HTML tag <HR> to create a separator line. You can also use inline CSS styles in HTML tags to add lines or borders around the HTML disclaimer message.

Placement of the Disclaimer

When configuring a transport rule to add a disclaimer, Exchange lets you decide whether to prepend or append the disclaimer to the message. When you prepend the disclaimer to the message, the disclaimer is inserted before the text of the newest message. When you append the disclaimer to the message, the disclaimer is inserted at the bottom of the message thread. Exchange doesn't check whether previous disclaimers have been added.

The following is an example of disclaimer text used to create a HTML disclaimer with an IMG tag and embedded CSS:

```
<div style="font-size:9pt;  font-family: 'Calibri',sans-serif;">
%%displayname%%</br>
%%title%%</br>
%%company%%</br>
%%street%%</br>
%%city%%, %%state%% %%zipcode%%</div>
```

```
 </br>
<div style="background-color:#D5EAFF; border:1px dotted #003333; padding:.8em; ">
<div><img alt="Fabrikam"  src="http://fabrikam.com/images/fabrikamlogo.png"></div
<span style="font-size:12pt;  font-family: 'Cambria','times new roman','garamond'
<p style="font-size:8pt; line-height:10pt; font-family: 'Cambria','times roman',s
<span style="padding-top:10px; font-weight:bold; color:#CC0000; font-size:10pt; f
</div>
```

Note:
The preceding HTML disclaimer is used as an example. It isn't intended for use as-is.

Behavior of the Disclaimer with Messages That Can't Be Modified

Some messages, such as encrypted messages, prevent Exchange from modifying the content of the original message. Exchange allows you to control how your organization handles these messages. When you create a disclaimer, you can decide whether to wrap a message that can't be modified in a message envelope that contains the disclaimer, reject the message if a disclaimer can't be added, or ignore the disclaimer action and deliver the message without a disclaimer.

The following list describes each fallback action:

- **Wrap** If the disclaimer can't be inserted into the original message, Exchange encloses, or "wraps," the original message in a new message envelope. Then the disclaimer is inserted into the new message.

  Important:
  If an original message is wrapped in a new message envelope, subsequent transport rules are applied to the new message envelope, not to the original message. Therefore, you must configure transport rules with disclaimer actions that wrap original messages in a new message body after you configure other transport rules.

  Note:
  If the original message can't be wrapped in a new message envelope, the original message is not delivered. The sender of the message receives a non-delivery report (NDR) that explains why the message was not delivered.

- **Reject** If the disclaimer can't be inserted into the original message, Exchange doesn't deliver the message. The sender of the message receives an NDR that explains why the message wasn't delivered.
- **Ignore** If the disclaimer can't be inserted into the original message, Exchange delivers the original message unmodified. No disclaimer is added.

Using Exchange Hosted Services

Transport messaging policies are enhanced by or are also available as a service from Microsoft Exchange Hosted Services.

Exchange Hosted Services is a set of four distinct hosted services:

- Hosted Filtering, which helps organizations protect themselves from e-mail-borne malware
- Hosted Archive, which helps them satisfy retention requirements for compliance
- Hosted Encryption, which helps them encrypt data to preserve confidentiality
- Hosted Continuity, which helps them preserve access to e-mail during and after emergency situations

These services integrate with any on-premises Exchange servers that are managed in-house or Hosted Exchange e-mail services that are offered through service providers. For more information about Exchange Hosted Services, see Microsoft Exchange Hosted Services.

1.11.3.7 Understanding Ethical Walls

Understanding Ethical Walls

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-09-30*

An *ethical wall* is a zone of non-communication between distinct departments of a business or organization. This zone is established to help prevent conflicts of interest that might result in the inappropriate release of sensitive information .

An ethical wall typically spans multiple methods of communication, such as telephone, e-mail, postal mail, and direct person-to-person communication. To make sure that no communication occurs between those regulated by an ethical wall, some organizations go so far as to put whole departments on separate floors or buildings and to require that employees use separate entrances.

One example of where an ethical wall could be used is in an investment organization where brokers aren't allowed to talk to market researchers who may have information that isn't available to the general public. Because market researchers may have confidential information that might influence a broker, regulatory requirements frequently state that those two groups must be prevented from communicating in any way.

How Does Exchange 2010 Help You Implement Ethical Walls?

Exchange 2010 uses transport rules configured on Hub Transport servers. Correctly configured transport rules support ethical walls by helping to prevent e-mail messages from being sent between specific groups of recipients within your organization.

Important:

Exchange 2010 includes features that may help you prevent breaches of an ethical wall. However, Exchange 2010 doesn't prevent individuals from using other methods of communication, such as private e-mail accounts located outside the Exchange organization, network file shares, or phone calls, to share information. Consider Exchange 2010 transport rules as part of an overall suite of tools or processes that you deploy throughout your organization to help enforce an ethical wall policy.

Transport rules are applied by Hub Transport servers across your whole organization. Because all the messages that flow into or out of the Exchange 2010 organization or that are sent within the organization pass through Hub Transport servers, you can consistently apply transport rules to every message.

It doesn't matter whether both the sender's mailbox and the recipient's mailbox reside in the same mailbox database, on the same Mailbox server, or whether their mailboxes are in separate sites. When the sender sends the message to the recipient, the message passes through the Hub Transport server where transport rules are applied.

In a typical configuration, when a sender tries to send a message to a recipient who is on the other side of an ethical wall, Exchange 2010 rejects the message and returns a non-delivery report (NDR) to the sender. By default, the NDR informs the sender that his or her message couldn't be delivered because of policy restrictions. However, you can easily modify the NDR by customizing the delivery status notification (DSN) code and message that are used in the NDR. This capability enables you to provide the sender with specific instructions or hypertext links that relate directly to the policies or regulations that prevented delivery.

For more information about how to customize DSN codes and messages that are used in transport rules and NDRs, see Associate a DSN Message with a Transport Rule.

Implementing an Ethical Wall

The most common method of implementing an ethical wall is to make each affected mailbox a member of one of two distribution groups and then configure the transport rule to reject any messages sent between members of those two distribution groups. Before you use transport rules to implement ethical walls, consider the following important practices:

- **Route messages through a Hub Transport server** For transport rules to be applied to e-mail messages, a route must exist that enables the message to enter and leave a server that applies transport rules. Also, the message must not be subject to an administrator-configured transport restriction that prevents delivery of the message. If a transport restriction prevents delivery of a message, the Transport Rules agent can't act on that message. Also, Transport Rules agent events are logged.
- **Define an appropriate scope** Ethical walls can block all messages if you don't define an appropriate scope. When you create a transport rule to enforce an ethical wall, you must specify conditions to define which recipients and senders to prohibit from sending messages to each other. If you don't specify any conditions, you must specify exceptions to narrow the scope of the transport rule. If you don't specify conditions or exceptions, the transport rule will block all messages sent to or from recipients or senders in your organization.
- **Test transport rules in a test environment first** Before you modify existing transport rules or create new transport rules in your production environment, we recommend that you use a test environment to make sure that the modifications or new rules perform as you intend.

Understanding Transport Rules

Understanding How Transport Rules Are Applied

1.11.3.8 Managing Transport Rules

Managing Transport Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-04-16*

Create a Transport Rule

Modify a Transport Rule

View a Transport Rule

Enable or Disable a Transport Rule

Remove a Transport Rule

Export and Import Transport Rules

1.11.3.8.1 Create a Transport Rule

Create a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Transport rules can be created on a Hub Transport or an Edge Transport server. Both server roles have many common predicates and actions, but some predicates and actions are exclusive to each transport server role. This topic describes how to create a transport rule by using either the EMC or the Shell.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Caution:
Before you create or modify transport rules in your production environment, we recommend that you use a test environment to understand how transport rules work. Test all rules before creating them in a production environment.

Important:
For transport rules to be applied to e-mail messages, a route must exist that enables the message to enter and leave a server that applies transport rules. Also, the message must not be subject to an administrator-configured transport restriction that prevents its delivery. If a transport restriction prevents delivery of a message, the Transport Rules agent can't act on that message, and no Transport Rules agent events are logged.

What Do You Want to Do?

- Use the EMC to create a transport rule
- Use the Shell to create a transport rule

Use the EMC to create a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. Navigate to **Organization Configuration > Hub Transport**.
2. In the result pane, click the **Transport Rules** tab.
3. In the action pane, click **New Transport Rule**.
4. On the **Introduction** page, complete the following fields:
   - 4.a. **Name** Type a name for the transport rule.
   - 4.b. **Comment** (optional) You can use this field to describe the rule's functionality and relevant details such as a change request or trouble ticket number, date, and name of administrator. Text in the comments field has no impact on rule functionality.
   - 4.c. **Enable Rule** New rules are enabled by default. If you want the rule to be created in a disabled state, clear the check box.

5. On the **Conditions** page, complete the following fields:
   5.a. In the **Step 1. Select condition(s)** box, select all the conditions that you want to apply to this rule.

   Important:
   If you want this rule to be applied to all e-mail messages, don't select any conditions in this step.

   5.b. If you selected conditions in the Select Conditions box, in the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.
   5.c. When you click a blue underlined word, a new window opens to prompt you for the values to apply to the condition. Select the values that you want to apply, or type the values manually. If the window requires that you manually add values to a list, type a value. Then click **Add**. Repeat this process until you have entered all the values, and then click **OK** to close the window.
   5.d. Repeat the previous step for each condition that you selected. After you configure all the conditions, click **Next**.
6. On the **Actions** page, complete the following fields:
   6.a. In the **Step 1. Select actions** box, select all the actions that you want to apply to this rule.
   6.b. In the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.
   6.c. In the new window that appears, select the items that you want to apply, or type the values manually, and then click **OK** to close the window.
   6.d. Repeat the previous step for each action that you selected. After you configure all the actions, click **Next**.
7. On the **Exceptions** page, complete the following fields:
   7.a. In the **Step 1. Select exceptions if necessary** box, select all the exceptions that you want to apply to this rule. You don't have to select any exceptions.
   7.b. If you selected exceptions in the previous step, in the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.
   7.c. When you click a blue underlined word, a new window opens to prompt you to select the items that you want to add, or to type the values manually. When you have finished, click **OK** to close the window.
   7.d. Repeat the previous step for each exception that you selected. After you configure all the exceptions, click **Next**.

8. On the **Create Rule** page, review the **Configuration Summary**. If you're satisfied with the configuration of the new rule, click **New**.

9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   9.a. A status of **Completed** indicates that the wizard completed the task successfully.
   9.b. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

This example creates a new transport rule that prepends "`Sales DG:`" to messages sent from outside the organization to the DG-Sales distribution group.

```
New-TransportRule -Name "Rule1-SalesList" -FromScope NotInOrganization -SentTo "D
```

Note:
The rule parameters and action used in the above procedure are for illustration only. Review all the available transport rule predicates and actions to determine which ones meet your requirements.

Transport Rule Actions

Transport Rules

1.11.3.8.2 Modify a Transport Rule

Modify a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can modify existing transport rules when you want to make changes to messaging policy.

Caution:
Before you modify transport rules in your production environment, we recommend that you use a test environment to understand how transport rules work, and test all rules before creating them in a production environment.

Important:
For transport rules to be applied to e-mail messages, a route must exist that enables the message to enter and leave a server that applies transport rules. Also, the message must not be subject to an administrator-configured transport restriction that prevents delivery of the message. If a transport restriction prevents delivery of a message, the Transport Rules agent can't act on that message, and no Transport Rules agent events are logged.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Prerequisites

- A transport rule has been created.

What Do You Want to Do?

- Use the EMC to modify a transport rule
- Use the Shell to modify a transport rule

Use the EMC to modify a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. In the console tree, expand the forest you want and navigate to **Organization Configuration > Hub Transport**.
2. In the result pane, click the **Transport Rules** tab, and then select the transport rule you want to modify.
3. In the action pane, click **Edit Rule.**
4. On the **Introduction** page, modify the **Name** or the **Comment** field as required.
5. On the **Conditions** page, modify the conditions listed in **Step 1: Select condition(s):** by either clearing the check boxes for existing selected conditions or by selecting new conditions as required.
6. On the **Actions** page, modify the rule actions by either clearing the check boxes for existing actions or by selecting a new action as required.
7. On the **Exceptions** page, modify the exceptions by either clearing the check boxes for existing exceptions or by selecting new exceptions as required.
8. On the **Update Rule** page, review the changes displayed in the **Configuration Summary**. If you're satisfied with the configuration, click **Update**. If you want to make a revision, click **Back**.
9. On the **Completion** page, click **Finish**.

Use the Shell to modify a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

This command modifies a transport rule so that it's applied to messages sent to recipients outside the Exchange organization.

```
Set-TransportRule -Identity GlobalDislciamer -SentToScope NotInOrganization
```

For detailed syntax and parameter information, see Set-TransportRule.

Other Tasks

After you modify a transport rule, you may also want to:

- Enable or Disable a Transport Rule
- View a Transport Rule
- Remove a Transport Rule

For More Information

Overview of Transport Rules

Understanding How Transport Rules Are Applied

View a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When managing transport rules, you may want to enumerate all rules or view the properties of a rule, such as the predicates and their values used to form conditions and exceptions, or the actions the rules apply.

When you view transport rules on a Hub Transport server, you can view any transport rule that is configured in the Exchange organization, except transport rules that are configured on Edge Transport servers. If you view transport rules on an Edge Transport server, you can only view the transport rules on the local computer. To view transport rules on another Edge Transport server, you must open the Exchange Management Console on that computer.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Prerequisites

One or more transport rules exist on a Hub Transport or an Edge Transport server.

What Do You Want to Do?

- Use the EMC to view transport rules
- Use the shell to view transport rules

Use the EMC to view transport rules

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Note:

The procedure for viewing a transport rule on a Hub Transport server is slightly different from the procedure for viewing a transport rule on an Edge Transport server.

Use the EMC to view transport rules on a Hub Transport server

1. Open the EMC on the Hub Transport server.
2. In the console tree, click **Organization Configuration**, and then click **Hub Transport**.
3. In the result pane, on the **Transport Rules** tab, right-click the rule that you want to view, and then click **Edit Rule**.
4. Click **Next** to navigate through the Transport Rule wizard to view the configuration of the transport rule.
5. Click **Cancel** when you're finished viewing the transport rule and haven't made any changes.

Use the EMC to view transport rules on an Edge Transport server

1. Open the EMC on the Edge Transport server that contains the transport rule that you want to view.
2. In the console tree, click **Edge Transport**.

3. In the result pane, on the **Transport Rules** tab, right-click the rule that you want to view, and then click **Edit Rule**.
4. Click **Next** to navigate through the Transport Rule wizard to view the configuration of the transport rule.
5. Click **Cancel** when you're finished viewing the transport rule and haven't made any changes.

Use the Shell to view transport rules

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

In the Shell, you can view a summary list of all transport rules that are configured on all Hub Transport servers or on the local Edge Transport server, or you can view the detailed configuration of a single transport rule.

Use the Shell to view a summary list of all transport rules

You can view a summary list of all transport rules configured on all Hub Transport servers or an Edge Transport server by using the following command:

```
Get-Transport Rule
```

Use the Shell to view properties of a single transport rule

To view the detailed configuration of a transport rule in the Shell, you must pipe the output of the **Get-TransportRule** command to the **Format-List** command by using the following command:

```
Get-Transport Rule <transport rule GUID or name> | Format-List
```

For more information about pipelining, see Pipelining. For more information about how to work with the information that is returned by a command, see Working with Command Output.

Other Tasks

After you view transport rules, you may also want to:

- Create a Transport Rule
- Enable or Disable a Transport Rule
- Remove a Transport Rule

For More Information

Understanding Transport Rules

Transport Rule Predicates

Transport Rule Actions

1.11.3.8.4 Enable or Disable a Transport Rule

Enable or Disable a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Transport Rule agent must be enabled before you can apply transport rules to e-mail messages that enter and leave a Hub Transport server. The Edge Rule agent must be enabled before you can apply transport rules to messages that enter and leave the Edge Transport server. You can run the **Get-TransportAgent** cmdlet on both the Hub Transport server and Edge Transport server to determine whether the Transport Rule agent or Edge Rule agent is running on the respective server role.

To temporarily stop the Rules agent on a Hub Transport server or the Edge Transport server from executing a transport rule, you can disable the rule.

When you enable or disable transport rules on a Hub Transport server, the modified transport rule is replicated across the Exchange 2007 organization to all the Hub Transport servers. When you enable or disable transport rules on an Edge Transport server, the modified transport rule is modified only on the local Edge Transport server.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Prerequisites

One or more transport rules must exist.

Disable a Transport Rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Use the EMC to disable a transport rule on a Hub Transport server

1. Open EMC on the Hub Transport server on which you want to disable a transport rule.
2. In the console tree, click **Organization Configuration**, and then click **Hub Transport**.
3. In the result pane, click the **Transport Rules** tab.
4. Right-click the transport rule that you want to disable. Click **Disable Rule**.

Use the EMC to disable a transport rule on an Edge Transport server

1. Open the EMC on the Edge Transport server on which you want to disable a transport rule.
2. In the console tree, click **Edge Transport**.
3. In the result pane, click the **Transport Rules** tab.
4. Right-click the transport rule that you want to disable. Click **Disable Rule**.

Use the Shell to disable a transport rule

Run the following command:

```
Disable-TransportRule "TR-Project Hamilton"
```

Enable a Transport Rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Use the EMC to enable a transport rule on a Hub Transport server

1. Open EMC on the Hub Transport server on which you want to enable a transport rule.
2. In the console tree, click **Organization Configuration**, and then click **Hub Transport**.
3. In the result pane, click the **Transport Rules** tab.
4. Right-click the transport rule that you want to enable. Click **Enable Rule**.

Use the EMC to enable a transport rule on an Edge Transport server

1. Open the EMC on the Edge Transport server on which you want to enable a transport rule.
2. In the console tree, click **Edge Transport**.
3. In the result pane, click the **Transport Rules** tab.
4. Right-click the transport rule that you want to enable. Click **Enable Rule**.

Use the Shell to enable a transport rule

Run the following command:

```
Enable-TransportRule "TR-Project Hamilton"
```

Other Tasks

After you disable or enable a transport rule, you may also want to:

- View a Transport Rule
- Modify a Transport Rule
- Remove a Transport Rule
- Create a Transport Rule

1.11.3.8.5 Remove a Transport Rule

Remove a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-13*

Transport rules are used to apply messaging policies to messages routed by a Hub Transport or an Edge Transport server. Rules can be disabled if they aren't immediately required. Rules that are no longer required can be removed permanently using the following procedures.

Important:

If you remove a transport rule from a Hub Transport server, the rule is removed from Active Directory. It's no longer available to any Hub Transport server in the Exchange 2010 organization. Edge Transport servers store transport rules in the Active Directory Lightweight Directory Services (AD LDS) instance locally, and the transport rules are managed on the Edge Transport server.

Prerequisites

A transport rule has been created on a Hub Transport server or an Edge Transport server.

What Do You Want to Do?

- Use the EMC to remove a transport rule
- Use the Shell to remove a transport rule

Use the EMC to remove a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Remove a transport rule on a Hub Transport server

1. Open the EMC on the Hub Transport server.
2. In the console tree, click **Organization Configuration**, and then click **Hub Transport**.
3. On the **Transport Rules** tab, right-click the rule that you want to remove, and then click **Remove**.
4. Click **Yes** if you're sure that you want to remove the transport rule.

Remove a transport rule on an Edge Transport server

1. Open the EMC on the Edge Transport server that contains the transport rule that you want to remove.
2. In the console tree, click **Edge Transport**.
3. On the **Transport Rules** tab, right-click the rule that you want to remove, and then click **Remove**.
4. Click **Yes** if you're sure that you want to remove the transport rule. The transport rule that you select is removed from the Active Directory Lightweight Directory Services instance on that Edge Transport server.

Important:

If you have more than one Edge Transport server deployed, you may need to remove the rule on all of them.

Use the Shell to remove a transport rule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

When using the Shell, the process to remove a transport rule from the Hub Transport and the Edge Transport server is identical.

1. Run the following command to see how transport rules will be affected without making any modifications:

```
Remove-TransportRule "Messages From DG-Sales" -WhatIf
```

Note:

Use the *WhatIf* parameter to verify that the results of the operation are what you expect. For more information about the *WhatIf* parameter, see WhatIf, Confirm, and ValidateOnly Switches.

2. Run the following command to remove the transport rule:

```
Remove-TransportRule "Messages From DG-Sales"
```

Other Tasks

After you remove a transport rule, you may also want to:

- View a Transport Rule
- Create a Transport Rule

For More Information

Understanding Transport Rules

Transport Rule Predicates

Transport Rule Actions

Managing Transport Rules

Transport Rules: End-to-End Tasks

1.11.3.8.6 Export and Import Transport Rules

Export and Import Transport Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You may need to export and import the transport rule collection from one transport server running Microsoft Exchange Server 2010 or Exchange Server 2007 to another transport server in the following scenarios:

- **Duplicate transport rule configuration on Edge Transport servers** Make sure all Edge Transport servers or a set of Edge Transport servers apply the same transport rules. Hub Transport servers store their configuration in Active Directory. The configuration is replicated to all domain controllers in the organization. Edge Transport servers store their configuration in the local instance of Active Directory Lightweight Directory Services (AD LDS), which is not automatically replicated.
  Depending on your Exchange deployment and message routing topology, you may want to have different sets of Edge Transport servers use different transport rules. For example, you may want to apply different rules on the Edge Transport servers that receive inbound e-mail than the ones on the Edge Transport servers that send outbound e-mail. If you want all Edge Transport servers in your organization to apply the same set of transport rules, you can use this procedure to duplicate the transport rule configuration.
  If you want to replicate the entire Exchange configuration from one Edge Transport server to another, we recommend that you use a cloned configuration. This configuration includes the configuration of transport rules on an Edge Transport server. For more information about how to clone Edge Transport servers, see Understanding Edge Transport Server Cloned Configuration.

  Important:
  If you expect frequent changes to the transport rule configuration on Edge Transport servers, we recommend that you designate one Edge Transport server as a source server and perform modifications on that server. Configure

the other Edge Transport servers to automatically update their transport rule configuration from the source Edge Transport server by using a Shell script that performs the procedures later in this topic. For more information about how to run scripts in the Shell, see Scripting with the Exchange Management Shell.

- **During coexistence with Exchange 2007 Hub Transport servers** Exchange 2010 includes many new transport rule predicates and actions, and changes to some predicates and actions found in Exchange 2007. When you install the first Exchange 2010 server in your Exchange 2007 organization, Exchange Setup creates a container in Active Directory to hold Exchange 2010 rules, resulting in rules for both versions being stored in different locations. Any existing transport rules from Exchange 2007 are converted, and a copy is stored in the Exchange 2010 container. After setup, the Exchange organization has the same set of transport rules for both Exchange server versions.
  Subsequently, if you make any changes to the transport rule configuration on Exchange 2007 or Exchange 2010, both versions will have a different set of rules. To ensure both Exchange server versions have the same transport rules and to apply the same messaging policies, make sure that any changes you make to the transport rule configuration on Exchange 2007 are also made to the Exchange 2010 configuration. This procedure helps you export rules from Exchange 2007 and import them in Exchange 2010.

  Important:
  To export Exchange 2007 transport rules to an Exchange 2010 server, you must run the **Export-TransportRuleCollection** cmdlet on an Exchange 2010 server. The **Export-TransportRuleCollection** cmdlet includes the option to export Exchange 2007 rules.
  When you import Exchange 2007 transport rules to an Exchange 2007 server, you must run the **Import-TransportRuleCollection** cmdlet on an Exchange 2007 server.
  You can't export Exchange 2010 rules and import them to an Exchange 2007 server.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Use the Shell to export Exchange 2010 transport rules from a Hub Transport or an Edge Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Note:
You can't use the EMC to export Exchange 2010 transport rules from a Hub Transport or an Edge Transport server.

The procedure to export Exchange 2010 transport rules is the same for both Hub Transport and Edge Transport servers. On the Hub Transport server, you may want to export transport rules to be imported on an Exchange 2010 Hub Transport server during coexistence. Or you may want to export transport rules for backup purposes.

On Edge Transport servers, you may want to export transport rules to duplicate them on another Edge Transport server, or to back up the transport rules on that Edge Transport server.

This example exports transport rules on an Exchange 2010 Hub Transport or Edge Transport server. Rule data is exported to the variable $file, and then written to the Exchange2010TransportRules.xml file in the C:\MyDocs folder.

```
$file = Export-TransportRuleCollection
Set-Content -Path "C:\MyDocs\Exchange2010TransportRules.xml" -Value $file.FileDat
```

For detailed syntax and parameter information, see Export-TransportRuleCollection.

Use the Shell to export Exchange 2007 transport rules from an Exchange 2010 Hub Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Note:

You can't use the EMC to export Exchange 2007 transport rules from an Exchange 2010 Hub Transport server.

You may need to export Exchange 2007 transport rules to import them to an Exchange 2010 Hub Transport server during a period of coexistence when you have both Exchange versions in your organization. When you set up the first Exchange 2010 server in your Exchange 2007 organization, Exchange Setup copies the rules from the Exchange 2007 transport rule container to the Exchange 2010 container. You need to perform this procedure only if you have made changes to transport rules on an Exchange 2007 server, and need to make the same changes to the Exchange 2010 server to make sure both servers have the same transport rules.

This example exports legacy transport rules created in Exchange 2007. Run the command from an Exchange 2010 Hub Transport server.

```
$ file = Export-TransportRuleCollection -ExportLegacyRules
Set-Content -Path "C:\MyDocs\LegacyRules.xml" -Value $file.FileData -Encoding Byt
```

For detailed syntax and parameter information, see Export-TransportRuleCollection.

Use the Shell to import transport rules on an Exchange 2010 Hub Transport or Edge Transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

Note:

You can't use the EMC to import transport rules on an Exchange 2010 Hub Transport or Edge Transport server.

Use this procedure to import Exchange 2010 or Exchange 2007 transport rules on an Exchange 2010 Hub Transport or Edge Transport server. Both the server roles use the same procedure and cmdlet to import transport rules.

Caution:
Importing a transport rule collection from a .xml file removes or overwrites all preexisting transport rules defined for the Transport Rules agent. Make sure that you have a backup of your current transport rule collection before you import and overwrite the transport rules.
On Hub Transport servers, the **Import-TransportRuleCollection** cmdlet overwrites all transport rules configured in the Exchange 2010 organization, except for transport rules on Edge Transport servers. On Edge Transport servers, this command overwrites transport rules configured on the local computer only.

Important:
Although similar in concept and implementation, the Hub Transport and Edge Transport server roles use different transport rule predicates and actions designed to meet different requirements. You shouldn't import transport rules exported from an Edge Transport server from either Exchange version to a Hub Transport server of either version. Similarly, you shouldn't import rules exported from a Hub Transport server from either Exchange version to an Edge Transport server of either version.

This example imports transport rules from the ExportedRules.xml file.

```
[Byte[]]$Data = Get-Content -Path "C:\MyDocs\ExportedRules.xml" -Encoding Byte -R
Import-TransportRuleCollection -FileData $Data
```

For detailed syntax and parameter information, see Import-TransportRuleCollection.

1.11.3.9 Transport Rules: End-to-End Tasks

Transport Rules: End-to-End Tasks

Exchange Server 2010 > Messaging Policy and Compliance > Transport Rules >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-11*

Transport rules provide many predicates and actions that you can use to implement your organization's messaging policies and messaging hygiene. These are listed in Transport Rule Predicates and Transport Rule Actions.

Depending on your organization's requirements, you can use transport rules to accomplish a wide range of tasks. This section contains information about the following scenarios made possible by transport rules:

- Configure a Catch-All Mailbox
- Configure a Disclaimer
- Configure an Ethical Wall
- Configure a Transport Rule for Messages That Have a Blank Subject
- Associate a DSN Message with a Transport Rule

Looking for general management tasks related to transport rules? For topics about basic management functionality, such as how to create, modify, enable, disable, and remove transport rules, see Managing Transport Rules.

Configure a Catch-All Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure transport rules on Edge Transport servers to copy or redirect messages received by your organization to the *catch-all mailbox*. A catch-all mailbox is typically a mailbox in your organization used to collect all the e-mail messages sent to your organization. Depending on your preferences, the catch-all mailbox may receive all messages or only messages sent to mailboxes that don't exist.

To configure a catch-all mailbox, you must perform the following steps:

1. Create a mailbox.
2. Disable recipient filtering.
3. Configure a transport rule to copy or redirect messages to the catch-all mailbox.

Looking for other management tasks related to mailboxes? Check out Managing Mailbox Servers.

Prerequisites

Before you disable recipient filtering (as required in step 2), you should understand the benefits of running the Recipient Filter agent and understand what features depend on it. For more information about the Recipient Filter agent and how it helps reduce the effect of spam, denial of service attacks (DoS), and other threats, see Understanding Recipient Filtering.

Note:

Recipients are resolved before messages pass through the Transport Rules agent on Hub Transport servers. Therefore, transport rules on Hub Transport servers can't be used to copy or redirect messages to a catch-all mailbox.

Step 1: Create a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "User mailboxes" entry in the Mailbox Permissions topic.

You must create a mailbox to receive the messages that are copied or redirected to it by transport rules. Because the messages delivered to the new mailbox may contain sensitive information, restrict access to the mailbox.

1. Create the catch-all mailbox. For details, see Create a Mailbox.
2. Complete one or both of the following, depending on the volume of messages delivered to the mailbox:
   - Increase the mailbox quota limits. For more information, see Configure Storage Quotas for a Mailbox.
   - Configure messaging records management (MRM) to automatically remove messages from the mailbox that are older than a configured age. For more information, see Create a Retention Tag and Create Managed Content Settings.
3. After you create the mailbox, note the SMTP address assigned to the mailbox.

Step 2: Disable recipient filtering

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" and "Anti-spam features – Edge Transport" entry in the Transport Permissions topic.

You must disable recipient filtering on each Edge Transport server that you want to configure transport rules to copy or redirect messages to a catch-all mailbox. You must do this because messages pass through the Recipient Filter agent before passing through the Edge Rule agent, and the Recipient Filter agent will reject messages addressed to mailboxes that don't exist.

Use the EMC on an Edge Transport server to disable recipient filtering

1. Open the EMC on the Edge Transport server where you want to create the transport rule.
2. In the console tree, click **Edge Transport**.
3. In the work pane, click the **Anti-spam** tab, and then select **Recipient Filtering**.
4. In the action pane, click **Disable**.

Use the Shell on an Edge Transport server to disable recipient filtering

This example disables recipient filtering.

```
Set-RecipientFilterConfig -Enabled $false
```

For detailed syntax and parameter information, see Set-RecipientFilterConfig.

Step 3: Configure a transport rule to copy or redirect messages to the catch-all mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

After you create a mailbox to accept messages and you disable recipient filtering, you must create a transport rule to copy or redirect messages to the catch-all mailbox. You must configure this transport rule on each Edge Transport server on which you want to copy or redirect messages.

Your organization's requirements should determine whether you copy messages to the catch-all mailbox or redirect messages to the catch-all mailbox. The differences between the two actions are as follows:

- When a message is copied to the catch-all mailbox (using the Cc line or Bcc line text box), the message also continues to the original recipient. If the original recipient doesn't exist, the sender receives a non-delivery report (NDR).
- When a message is redirected to the catch-all mailbox, the message doesn't continue to the original recipient. The message is sent only to the catch-all mailbox. If the original recipient doesn't exist, the sender doesn't receive an NDR.

You should also configure the **except when the text patterns appears in any recipient address** exception to avoid copying or redirecting messages to the catch-all mailbox for SMTP addresses that already exist in your organization. This exception uses regular expressions to prevent the transport rule from copying or redirecting messages to the

catch-all mailbox if the SMTP address exists in your organization. You must manually configure the exception with the SMTP addresses in your organization and enclose each SMTP address with the ^ and $ pattern strings.

For more information about regular expressions, see Regular Expressions in Transport Rules.

Important:
A message sent to your organization won't be copied or redirected to the catch-all mailbox if one or more SMTP addresses are included in the message recipients and are configured on the transport rule exception. This is true even if one or more of the SMTP addresses on the message doesn't exist in your organization.

Use the EMC to configure a transport rule to copy or redirect a message to the catch-all mailbox

1. Open the EMC on the Edge Transport server on which you want to create the transport rule.
2. In the console tree, click **Edge Transport**.
3. In the result pane, click the **Transport Rules** tab, and then in the **Actions** pane, click **New Transport Rule**.
4. In the **Name** field of the Transport Rule wizard, type the name of the transport rule.
5. If you have notes for this rule, in the **Comments** field, type the notes.
6. If you want the rule to be created in a disabled state, clear the **Enable Rule** check box. Otherwise, leave the **Enable Rule** check box selected. Click **Next**.
7. In the **Step 1. Select Condition(s)** box, select the **from users that are inside or outside the organization** check box.
8. In the **Step 2. Edit the rule description by clicking an underlined value** box, click **inside the organization**.
9. In the **From scope** list, select **Outside the organization**, and then click **OK**.
10. If you want to add conditions, do so now. After you configure all the conditions, click **Next**.
11. In the **Step 1. Select Action(s)** box, select **copy the message to addresses** if you want to copy messages to the catch-all mailbox. Select **redirect the message to addresses** if you want to redirect messages to the catch-all mailbox. Don't select both actions in the same transport rule.
12. In the **Step 2. Edit the rule description by clicking an underlined value** box, click **addresses**.
13. In the **Specify recipients** dialog box, type the SMTP address of the catch-all mailbox in the **E-mail addresses of recipients** box, click **Add**, and then click **OK**.
14. If you want to configure additional actions, do so now. After you configure all the actions, click **Next**.
15. In the **Step 1. Select Exceptions if necessary** box, select the **except when any recipient address matches text patterns** check box.
16. In the **Step 2. Edit the rule description by clicking an underlined value** box, click **text patterns**.
17. In the **Text patterns** box, type the SMTP addresses of existing mailboxes in your organization. Enclose each SMTP address with the ^ and $ pattern strings. For example, if the SMTP address is david@contoso.com, enter: **^david@contoso.com$**. After you enter each SMTP address, click **Add**. When you have finished, click **OK** to close the window.
18. If you want to configure additional exceptions, do so now. After you configure all the exceptions, click **Next**.
19. Review the **Configuration Summary**. If the configuration of the new rule is satisfactory, click **New**, and then click **Finish**.

Use the Shell to configure a transport rule to copy or redirect a message to the catch-all mailbox

Before you begin, you must be familiar with how to create a transport rule using the Shell. For more information, see "Use the Shell to create a transport rule" in Create a Transport Rule.

To configure a transport rule to copy or redirect messages to a catch-all mailbox, you must configure the transport rule condition that directs the transport rule to apply the action only to messages sent from senders outside the organization. To do this, use the FromScope transport rule predicate together with the New-TransportRule cmdlet.

The following example configures a transport rule to copy messages from senders outside the organization to the catch-all mailbox:

```
New-TransportRule -Name "Catch-all Mailbox" -FromScope
NotInOrganization -Actions RedirectMessage <Catch_All_Mailbox _Address>
```

Use the Shell to configure the transport rule condition to copy messages to a catch-all mailbox on an Edge Transport server

This example configures the transport rule condition to:

- Select messages only from senders outside the organization.
- Copy a message to the catch-all mailbox.
- Specify the SMTP address of the catch-all mailbox.
- Avoid copying messages sent to SMTP addresses that exist in your organization.
- Create a transport rule that copies messages to a catch-all mailbox.

```
New-TransportRule -Name "Copy messages to catch-all mailbox" -FromScope
NotInOrganization -CopyTo "catch-all@contoso.com" -
ExceptIfAnyOfRecipientAddressMatchesPatterns "^david@contoso.com$",
"^brian@contoso.com$"
```

For detailed syntax and parameter information, see Get-TransportRulePredicate, Get-TransportRuleAction, or New-TransportRule.

Use the Shell to redirect messages to a catch-all mailbox on an Edge Transport server

This example configures the transport rule condition to:

- Select messages only from senders outside the organization.
- Copy a message to the catch-all mailbox.
- Specify the SMTP address of the catch-all mailbox.
- Avoid redirecting messages sent to SMTP addresses that exist in your organization.
- Create a transport rule that redirects messages to a catch-all mailbox.

```
New-TransportRule -Name "Redirect messages to catch-all mailbox" -
FromScope NotInOrganization -RedirectMessage "catch-all@contoso.com" -
ExceptIfAnyOfRecipientAddressMatchesPatterns "^david@contoso.com$",
"^brian@contoso.com$"
```

For detailed syntax and parameter information, see Get-TransportRulePredicate, Get-TransportRuleAction, or New-TransportRule.

1.11.3.9.2 Configure a Disclaimer

Configure a Disclaimer

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Disclaimers are statements, generally of a legal nature, added to e-mail messages that enter or leave a Microsoft Exchange Server 2010 organization. It's possible to apply multiple disclaimers to a single e-mail message. If a message matches more than one transport rule, and a disclaimer action is configured on each transport rule, the transport rule applies each disclaimer action to the message.

The procedure that you use to create a disclaimer is the same procedure used to create a transport rule. This is because a disclaimer is a configurable action available to transport rules on a Hub Transport server.

As with transport rules, when you create a new disclaimer, you can configure conditions and exceptions to control which e-mail messages receive the disclaimer. If you want the disclaimer to apply to all e-mail messages that enter and leave the Exchange 2010 organization, don't configure any conditions or exceptions.

Important:

For transport rules to be applied to e-mail messages, a route must exist that enables the message to enter and leave a server that applies transport rules. Also, the message must not be subject to an administrator-configured transport restriction that prevents delivery of the message. If a transport restriction prevents delivery of a message, the Transport Rules agent can't act on that message, and no Transport Rules agent events are logged.

Caution:

To apply disclaimers, you must create or modify a transport rule. Before you modify or create transport rules in your production environment, use a test environment to test rules thoroughly. The following procedures aren't intended to be run in a production environment without modification to support your organization.

Looking for other management tasks related to transport rules? Check out Managing Transport Rules.

Prerequisites

To apply Exchange 2010 transport rules, all Hub Transport servers in the organization should be running Exchange 2010.

Use the EMC to Configure a Disclaimer

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. Navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **Transport Rules** tab.
3. In the action pane, click **New Transport Rule**. On the **Introduction** page, complete the following fields:
   - **Name** Type a name for the transport rule.
   - **Comment** (Optional) Comments can be used to describe rule functionality and relevant details such as a change request or trouble ticket number, date, and name of an administrator. Text in the comments field has no effect on rule functionality.
   - **Enable Rule** New rules are enabled by default. If you want the rule to be created in a disabled state, clear the check box.
4. On the **Conditions** page, complete the following fields:
   - In the **Step 1. Select Condition(s)** field, select all the conditions that you

want to apply to this rule.

Important:
If you want this rule to be applied to all e-mail messages, don't select any conditions in this step.

- In the **Step 2. Edit the rule description by clicking an underlined value** field, for each condition selected in the **Select Conditions** box, click each blue, underlined word.
- When you click a blue, underlined word, a window opens to prompt you for the values to apply to the condition. Select the values that you want to apply, or type the values manually. If the window requires that you manually add values to a list, type a value. Then click **Add**. Repeat this process until you have entered all the values, and then click **OK** to close the window.
- Repeat the previous step for each condition that you selected. After you configure all the conditions, click **Next**.

5. On the **Actions** page, complete the following fields:
   - In the **Step 1. Select actions** field, select the **append disclaimer text and fallback to action if unable to apply** check box.
   - In the **Step 2. Edit the rule description by clicking an underlined value** field, complete the following fields:
     - Click **disclaimer text**. In the **Specify disclaimer text** dialog box, type the plaintext or HTML disclaimer text that you want to add to messages.
     - (Optional) To change the position of the disclaimer in messages, click **append**. From the **Select position** dialog box, select **prepend**.
     - (Optional) To change the fallback action, click **wrap**. In the **Select fallback action** dialog box, select the desired fallback action.
6. On the **Exceptions** page, complete the following fields:
   - In the **Step 1. Select exceptions if necessary** box, select all the exceptions that you want applied to this rule. You aren't required to select any exceptions.
   - If you selected exceptions in the previous step, in the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue, underlined word.
   - When you click a blue, underlined word, a window opens to prompt you to select the items that you want to add, or to type the values manually. After you finish, click **OK** to close the window.
   - Repeat the previous step for each exception that you selected. After you configure all the exceptions, click **Next**.

Note:
If you don't apply an exception to this transport rule and all the transport rule conditions are met, a disclaimer is added to every message. The **append disclaimer text and fallback to action if unable to apply** action doesn't verify that a disclaimer has already been applied to a message. To avoid having a disclaimer text added repeatedly to messages that meet the conditions of this transport rule, add the **except when the Subject field or message body contains specific words** exception, and then edit the **specific words** value to include text that's unique to the disclaimer you created.

7. On the **Create Rule** page, review the **Configuration Summary**. If you're satisfied with the configuration of the new rule, click **New**.

8. On the **Completion** page, click **Finish**. A status of **Completed** indicates that the wizard completed the task successfully. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an

explanation, and then click **Back** to make any additional changes.

Use the Shell to Configure a Disclaimer

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

This example creates a transport rule to apply a disclaimer to all messages sent outside the organization. The disclaimer is appended to messages, and the fallback action is set to wrap.

```
New-TransportRule -Name ExternalDisclaimer -Enabled $true -SentToScope 'NotInOrga
```

For detailed parameter and syntax information, see New-TransportRule.

Other Tasks

After you configure a disclaimer, you may also want to:

- View a Transport Rule
- Enable or Disable a Transport Rule
- Remove a Transport Rule

1.11.3.9.3 Configure an Ethical Wall

Configure an Ethical Wall

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-12-11*

An *ethical wall* is a zone of non-communication between distinct departments of a business or organization that is established to prevent conflicts of interest that might result in the inappropriate release of sensitive information. You can use Microsoft Exchange Server 2010 to configure ethical walls that comply with your organization's compliance policies and with regulations and laws that apply to your organization. For more information about ethical walls, see Understanding Ethical Walls.

To create an ethical wall, use the same procedure that you use to create a transport rule. When you implement an ethical wall by creating a transport rule, you can configure conditions and exceptions to control which e-mail messages the ethical wall blocks.

Caution:

Before you create or modify transport rules in your production environment, we recommend that you use a test environment to understand how transport rules work. Test all rules before you create them in a production environment.
Ethical walls block all messages if you don't define an appropriate scope. When you create a transport rule to enforce an ethical wall, you must specify conditions to define which recipients and senders are prohibited from sending messages to each other. If you don't specify any conditions, you must specify exceptions to narrow the scope of the transport rule. If you don't specify conditions or exceptions, the transport rule blocks all messages sent to or from recipients and senders in your organization.

Prerequisites

Although you are not required to use an Exchange 2010 Hub Transport server, you must route e-mail messages through an Exchange 2010 Hub Transport server to apply transport rules to the messages.

Use the EMC to create an ethical wall

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the action pane, click **New Transport Rule**.
3. On the **Introduction** page, complete the following fields:
   - **Name** Enter a name for the transport rule.
   - **Comment** [optional] Type any notes for the rule.
   - **Enable Rule** If you want the rule to be created in a disabled state, clear this check box.
4. On the **Conditions** page, complete the following steps:
   - In the **Step 1. Select condition(s)** box, select all the conditions that you want to apply to this rule.

     Note:
     The **between members of distribution list and distribution list** condition is well suited for transport rules that enforce ethical walls.

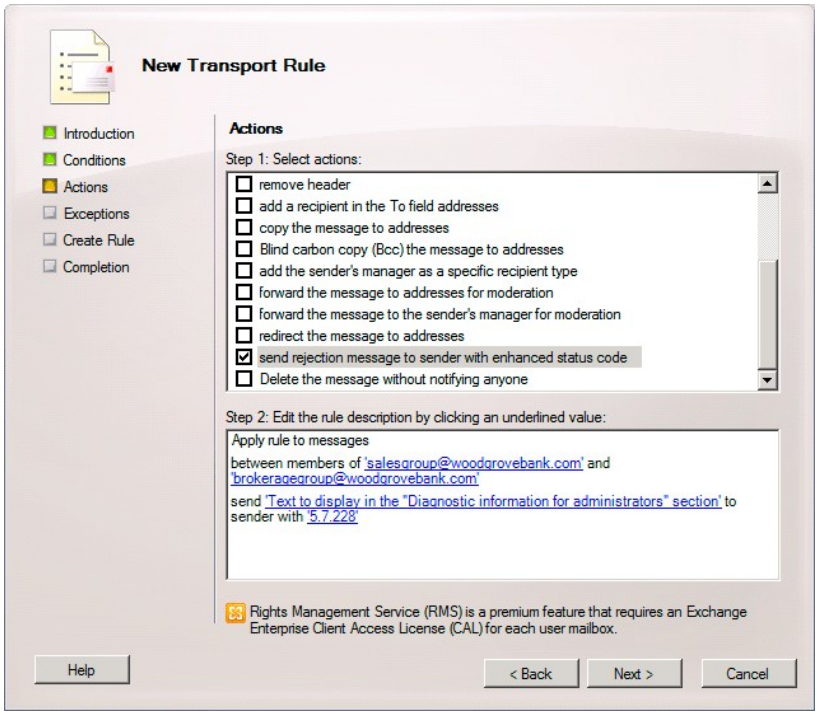
   - If you selected conditions in the previous step, click each blue underlined word in the **Step 2. Edit the rule description by clicking an underlined value** box.

     Note:
     When you click a blue underlined word, you are prompted for the values to apply to the condition. Select the values that you want to apply, or type the values manually. If the prompt window requires that you manually add values to a list, enter a value, and then click **Add**. Repeat this process until you have entered all the values, and then click **OK** to close the window.

   - Repeat the previous step for each condition that you selected. After you configure all the conditions, click **Next**.
5. On the **Actions** page, complete the following steps:
   - In the **Step 1. Select actions** box, click **send rejection message to sender with enhanced status code**. This transport rule action deletes the message and returns a non-delivery report (NDR) to the sender of the message.
   - In the **Step 2. Edit the rule description by clicking an underlined value** box, follow these steps:
     5..a.Click **rejection message**.
     5..b.In the **Specify rejection message** dialog box, enter the text to display in the **Diagnostic information for administrators** section of the NDR that's sent to the sender of the rejected message. When you're finished, click **OK**.
     5..c.Click **enhanced status code**.
     5..d.In the **Specify Enhanced Status Code** dialog box, enter the delivery status notification (DSN) code you want to display in the **Diagnostic information for administrators** section of the NDR that's sent to the sender of the rejected message. Valid enhanced status code values are 5.7.1 and any value from 5.7.10 through 5.7.999. When you're

finished, click **OK**.

Note:
For more information about how Exchange 2010 associates a DSN code with a transport rule, see Associate a DSN Message with a Transport Rule.



- If you want to add more actions, repeat the previous step, and select the transport rule actions that you want to apply. After you configure all the actions, click **Next**.

6. On the **Exceptions** page, complete the following optional steps:
   - In the **Step 1. Select exceptions if necessary** box, select all the exceptions that you want to apply to this rule. You aren't required to select any exceptions.
   - If you selected exceptions, in the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.

     Note:
     When you click a blue underlined word, you are prompted to select the items that you want to add or to type the values manually. When you're finished, click **OK** to close the window.Repeat the previous step for each exception that you selected.

   - After you configure all the exceptions, click **Next**.
7. On the **Create Rule** page, review the **Configuration Summary**. If you're satisfied with the configuration of the new rule, click **New**, and then click **Finish**.

Use the Shell to create an ethical wall

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

In this example, Woodgrove Bank wants to prevent members of its Brokerage group and

the Sales group from communicating. The bank decides to implement an ethical wall between the two groups by using a transport rule.

Predicate The `BetweenMemberOf` transport rule predicate is used to prohibit the members of the Brokerage Group distribution group and the Sales Group distribution group from communicating with each other. The `BetweenMemberOf` transport rule predicate is well suited for transport rules that enforce ethical walls. For more information about transport rule predicates, see Transport Rule Predicates.

Exception Woodgrove Bank wants to create an exception to this policy that allows members of the Executive Group distribution group to communicate with one other. Members may belong to either of the two groups,. The `ExceptIfFromMemberOf` predicate is used to implement this exception.

Action The `RejectMessage` transport rule action is used to block messages that are sent to a prohibited recipient. When the `RejectMessage` transport rule action is applied to a message, an NDR is returned to the sender of the message, and the message itself is deleted. You can configure the user information text and the DSN code and message that are displayed in the administrator section of the NDR.

You can modify the text that's displayed to the sender in the **Diagnostic information for administrators** section of the NDR. This text can provide helpful information to enable the administrator to understand why the message was rejected.

DSN Codes By default, the `RejectMessage` transport rule action uses the enhanced status code `5.7.1`. You can modify the DSN code returned by specifying a custom DSN code. A custom DSN code must be associated with a custom DSN message. The DSN message appears in the user information section of the NDR. You can specify a custom DSN code to be able to provide the sender more detailed information. You can also refer the sender to an internal or public Web page that contains more information about the specific policy or regulation.

The following example specifies a new, unused, custom DSN code in the **RejectMessageEnhancedStatusCode** property.

```
New-TransportRule "Sample Ethical Wall" -Enabled $true -BetweenMemberOf1 Brokerag
```

This example then creates the custom DSN code and specifies the text that should be displayed when a message is returned with that DSN code.

```
New-SystemMessage -DsnCode 5.7.228 -Internal $true -Language En -Text "A message
```

For more information about which values are accepted and about how Exchange 2010 associates a DSN code with a transport rule, see Associate a DSN Message with a Transport Rule.

For detailed syntax and parameter information, see New-TransportRule and New-SystemMessage.

1.11.3.9.4 Configure a Transport Rule for Messages That Have a Blank Subject

Configure a Transport Rule for Messages That Have a Blank Subject

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Transport rules perform specified actions on messages based on message properties such as sender, recipients, message scope, message subject, and message body. Creating a transport rule for messages that have a blank subject line requires the use of regular expressions.

Caution:

Before you configure new transport rules in your production environment, use a test environment to learn how to create transport rules and test them thoroughly. The following procedures aren't intended to be run in a production environment without modification to support your organization.

Important:

For transport rules to be applied to e-mail messages, a route must exist that enables the message to enter and leave a server that applies transport rules. Also, the message must not be subject to an administrator-configured transport restriction that prevents delivery of the message. If a transport restriction prevents delivery of a message, the Transport Rules agent can't act on that message, and no Transport Rules agent events are logged.

The ^$ Regular Expression

To detect messages that have blank subject lines, the following procedures use the ^$ regular expression. This regular expression consists of two pattern strings, ^ and $. Pattern strings are used in regular expressions to match patterns in text that can vary. When the ^ and $ pattern strings are used in this order, the transport rule condition matches only the exact string that's between the two pattern strings. Because there's no string between the ^ and $ pattern strings in the ^$ regular expression, it matches only an empty string, such as a blank subject line.

For more information about regular expressions, see Regular Expressions in Transport Rules.

The RejectMessage Transport Rule Action

The `RejectMessage` transport rule action is used to reject messages and provide an enhanced status code for the rejection. In this example, the `RejectMessage` transport rule action is used to reject a message and return a non-delivery report (NDR). The `RejectMessage` transport rule action is available only on Hub Transport servers.

You can modify the text that's displayed to the sender in the **Diagnostic information for administrators** section of the NDR. This text can provide helpful information to enable you to understand why the message was rejected.

You can also modify the delivery status notification (DSN) code and message that appears in the user information section of the NDR by specifying a customized DSN code. A customized DSN code is associated with a customized DSN message. It's useful to specify this code so that you can refer the user to an HTML link to a specific policy or regulation. By default, the NDR associated with the 5.7.1 DSN code is sent.

For example, if you want to refer users to the Information Technology department if their message is rejected, you can specify a new, unused, customized DSN code in the **EnhancedStatusCode** property. After you specify a new customized DSN code, if the customized DSN code isn't already defined, you must use the **New-SystemMessage** cmdlet to create the DSN code and specify the text that should be displayed when that DSN code is referenced. For an example of how to do this, see Use the Shell to create a

transport rule for messages that have a blank subject later in this topic.

Note:
The `RejectReason` transport rule action is available only on Hub Transport servers. If you want to reject messages that have a blank subject line on Edge Transport servers, you must use the `SmtpRejectMessage` transport rule action. You can only specify the DSN code when you use the `SmtpRejectMessage` transport rule action. You can't specify an alternative message to display to the user or administrator.
For more information about the `SmtpRejectMessage` transport rule action, see "Actions Available on an Edge Transport Server" in Transport Rule Actions.

For more information about what values are accepted and how Microsoft Exchange Server 2010 associates a DSN code with a transport rule, see Associate a DSN Message with a Transport Rule.

Use the EMC to create a transport rule for messages that have a blank subject

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. Open the New Transport Rule wizard. Depending on whether you're performing this procedure on a Hub Transport or Edge Transport server, use the following navigation:
   - Hub Transport servers: In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
   - Edge Transport servers: In the console tree, click **Edge Transport**.
2. In the action pane, click **New Transport Rule**.
3. On the **Introduction** page, complete the following fields:
   - **Name** Type the name for the transport rule.
   - **Comments** (optional) You can use this field to describe the rule's functionality and relevant details. Text in the comments field has no impact on rule functionality.
   - **Enable Rule** New rules are enabled by default. If you want the rule to be created in a disabled state, clear this check box.
4. On the **Conditions** page, complete the following fields:
   - In the **Step 1. Select condition(s)** box, select the **when the Subject field matches text patterns** condition.
   - In the **Step 2. Edit the rule description by clicking an underlined value** box, click the blue underlined **text patterns**.
   - In the **Specify text patterns** dialog box, type **^$**, and then click **Add**. Click **OK** to close the dialog box, and then click **Next**.
5. On the **Actions** page, complete the following fields:
   - In the **Step 1. Select actions** box, select all the actions that you want to apply to this rule. You must select at least one action to create a transport rule.
   - In the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.
   - In the new dialog box that appears, select the items that you want to apply, or type the values manually, and then click **OK** to close the dialog box.
   - Repeat the previous step for each action that you selected. After you configure all the actions, click **Next**.
6. On the **Exceptions** page, complete the following fields:
   - In the **Step 1. Select exceptions if necessary** box, select all the exceptions that you want to apply to this rule. You don't have to select any

exceptions.
- If you selected exceptions in the previous step, in the **Step 2. Edit the rule description by clicking an underlined value** box, click each blue underlined word.
- In the new dialog box that appears, select the items that you want to apply, or type the values manually, and then click **OK** to close the dialog box.
- Repeat the previous step for each exception that you selected. After you configure all the exceptions, click **Next**.

7. On the **Create Rule** page, review the **Configuration Summary**. If you're satisfied with the configuration of the new rule, click **New**.
8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a transport rule for messages that have a blank subject

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

This example creates the transport rule Blank Line Rule to reject messages that have a blank subject. The rule uses the enhanced status code 5.7.1 and includes the explanatory text "The message has a blank subject field."

```
New-TransportRule -Name "Blank Line Rule" -Enabled $true -SubjectMatchesPatterns
```

This example creates the transport rule Blank Line Rule to reject messages that have a blank subject on a Hub Transport server. The rule uses the customized DSN code 5.7.228 and includes the explanatory text "Messages must have a subject in the subject line or they are rejected."

Note:

When using a customized DSN code, you must define the DSN code and customized message using the **New-SystemMessage** cmdlet. For more information, see Associate a DSN Message with a Transport Rule.

```
New-TransportRule -Name "Blank Line Rule" -Enabled $true -SubjectMatchesPatterns
```

This example creates a customized DSN code and message.

```
New-SystemMessage -DsnCode 5.7.228 -Internal $True -Language En -Text "This messa
```

For detailed syntax and parameter information, see New-TransportRule or New-SystemMessage.

Associate a DSN Message with a Transport Rule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 allows you to use a transport rule to reject messages based on conditions specified in the rule. The `RejectMessage` transport rule action is used to reject messages. When a message is rejected, a non-delivery report (NDR) is returned to the sender and the original message is deleted. When you create a transport rule on an Exchange 2010 Hub Transport server to reject messages, Exchange 2010 allows you to specify a delivery status notification (DSN) code, also known as an enhanced status code, and a rejection message.

For more information about transport rules, see Understanding Transport Rules.

Exchange 2010 also lets you customize the contents of the NDR that is returned to the sender by creating a custom DSN message. The custom content can contain information that you want to send to the recipient of the NDR, such as policy information and specific troubleshooting or contact information. For more information about how to customize DSN messages, see Managing Delivery Status Notifications.

The RejectMessage Transport Rule Action

To reject messages and specify a DSN message by using a transport rule, you must create the rule on a Hub Transport server. In the Shell, the transport rule action is known by the `RejectMessage` identifier. The same action is displayed using the descriptive string **send rejection message to sender with enhanced status code** in the EMC. The `RejectMessage` action lets you specify the following properties:

- **Enhanced Status Code** The enhanced status code you specify is displayed in the **Diagnostic information for administrators** section of the NDR. The value that's specified with this property can be 5.7.1, or any value from 5.7.10 through 5.7.999, inclusively. Enhanced status codes are also associated with a descriptive message that's displayed in the user information section of the NDR. If you use the Shell to create a transport rule, you must use the `RejectMessageEnhancedStatusCode` parameter to specify the enhanced status code.
- **Reject Reason** The text that's specified in this property is displayed in the **Diagnostic information for administrators** section of the NDR. If you use the Shell to create the rule, you can use the `RejectMessageReasonText` parameter to specify the reject reason.

Note:

If you use the Shell to create a transport rule that uses the `RejectMessage` action, you can create the rule without specifying the rejection message. If you don't specify the rejection message, the following default rejection message is used: `Delivery not authorized, message refused`. If you use the New Transport Rule wizard in EMC to create the rule, you must specify both the rejection message and the enhanced status code.

When you create a new transport rule with the `RejectMessage` transport rule action, Exchange 2010 searches the DSN message list for a DSN code that matches the value that is specified in the `RejectMessageEnhancedStatusCode` property of the transport rule. If a matching DSN code is found, Exchange 2010 automatically associates that DSN message with the transport rule action. If no matching DSN code is found, Exchange 2010

displays the following warning when you create the transport rule: `No custom DSN text is configured for the enhanced status code '5.7.xxx'. You can use the New-SystemMessage cmdlet to customize DSNs.`

Note:

If you specify a DSN code other than 5.7.1, you must create a custom DSN message to associate with that DSN code. If a matching DSN code doesn't exist, Exchange 2010 uses the 5.7.0 DSN code.

Use the EMC to create a transport rule to reject messages and provide a custom DSN code

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

1. On the **Conditions** page, select the **between members of distribution list and distribution list** condition, and then select the distribution groups that you want the transport rule to be applied to. For example, the following figure shows that the Sales Group distribution group and Brokerage Group distribution group have been selected for use with the condition.

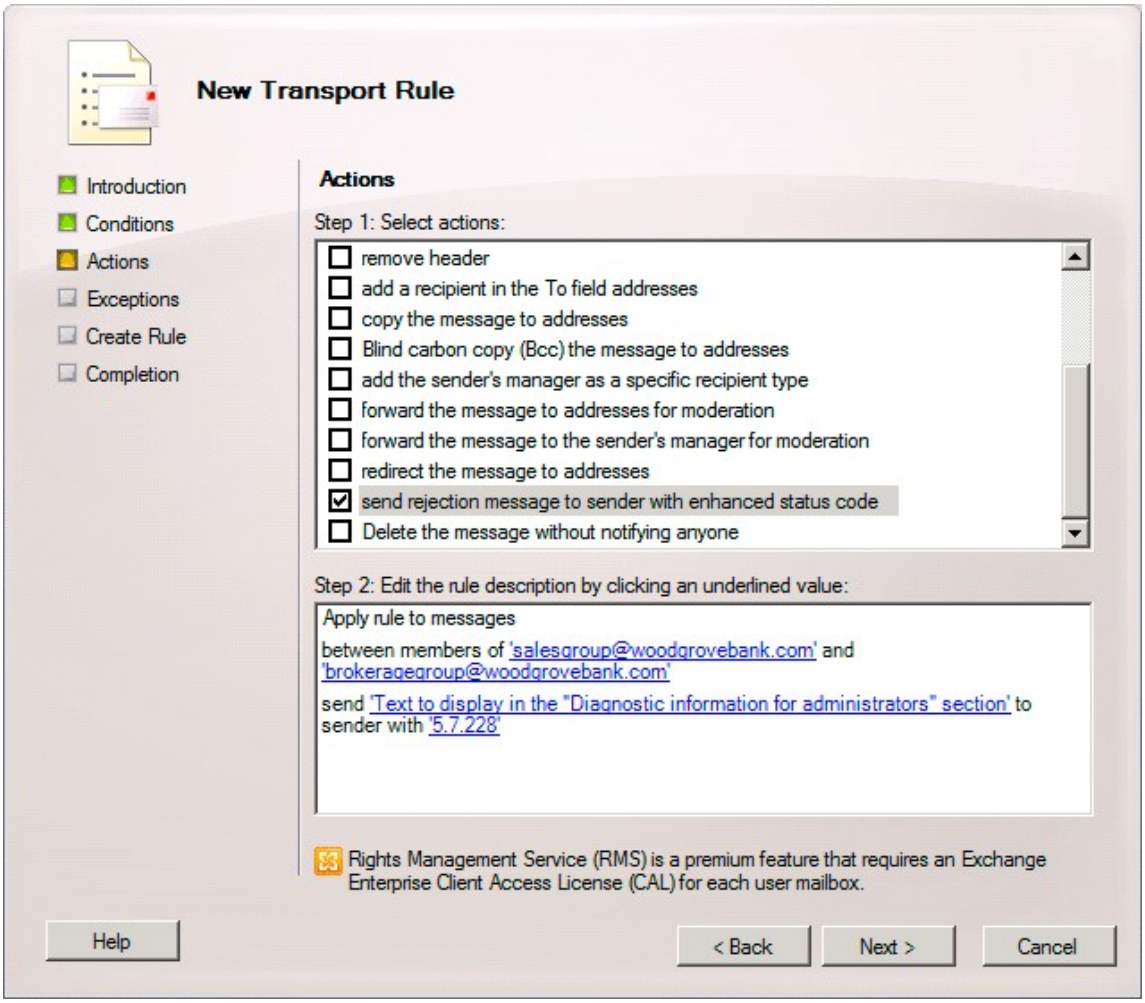
   Note:

   The **between members of distribution list and distribution list** predicate used in step 1 is an example. You can use any condition to suit your requirements.

2. On the **Actions** page, select the **send rejection message to sender with enhanced status code** action, and then type the text for the rejection message. To provide a helpful DSN message that explains why the message was rejected, specify a custom DSN code. For example, the following figure specifies that the rejection message **Text to display in the "Diagnostic information for administrators" section** will be included in the rejection message and will also include the custom DSN code 5.7.228. This code is associated with a new custom DSN message that's created by the command shown in DSN Message Association later in this topic.

Note:

You can check whether a custom DSN message already exists for a particular DSN code. Use the Get-SystemMessage cmdlet to list all custom DSN messages. You can also list standard DSN codes and the associated DSN messages by using the **Get-SystemMessage** cmdlet with the *Original* switch



For more information about how to create transport rules and how to configure an ethical wall, see the following topics:

- Create a Transport Rule
- Configure an Ethical Wall

Use the Shell to create a transport rule to reject messages and provide a custom DSN code

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Transport rules" entry in the Messaging Policy and Compliance Permissions topic.

This example creates the transport rule SalesBrokerageEthicalWall to reject messages between the Sales and Brokerage distribution groups and use the custom DSN code 5.7.228 in the rejection response.

Note:

The `BetweenMemberOf` predicate used in this procedure is an example. You can use any condition to suit your requirements.

```
New-TransportRule SalesBrokerageEthicalWall -BetweenMemberOf1 "Sales" -BetweenMem
```

For detailed syntax and parameter information, see New-TransportRule.

Custom DSN Message Association

You use the New-SystemMessage cmdlet to create a custom DSN message for a DSN code. After the custom DSN message is created, Exchange 2010 automatically uses it when rejecting a message with the specified DSN code. If you specify the same custom DSN code in multiple transport rules, the DSN message is inserted in the NDRs that are generated by those transport rules.

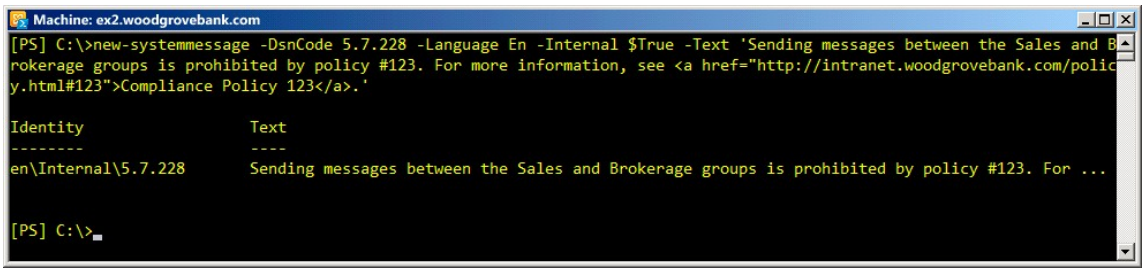
Note:

If you want to change the default text associated with the 5.7.1 DSN code, you must create a new custom DSN message by using the **New-SystemMessage** cmdlet. However, if you do this, the new text will be displayed any time that the 5.7.1 DSN code is used, including for messages that are rejected by other components of Exchange transport. Therefore, we recommend that you create a new DSN code for specific transport rule actions.

This example creates a custom DSN message with the DSN code 5.7.228. The DSN message is created in English. The message also includes a link to an internal Web site, which can provide more details about the organization's messaging policies.

```
New-SystemMessage -DsnCode 5.7.228 -Language En -Internal $True -Text 'Sending me
```

The following figure shows the result of entering the preceding command in the Shell.



Note:

You can create custom DSN messages in additional languages and also remove the English versions of DSN messages completely. For a list of supported languages that you can use with DSN messages, see Supported Locales for Use with System Messages.

Example of an NDR with a Custom DSN Message

After you've created a custom DSN message for the DSN code you specified in the `RejectMessage` transport rule action, Exchange 2010 can use the custom DSN code and message in NDRs to senders whose messages are blocked by that transport rule.

For example, the following figure shows an NDR that was sent to Mark Steele who is a member of the Brokerage Group distribution group. He received the NDR because he tried to send a message to Jason McCue, who is a member of the Sales Group distribution group. A transport rule was created to enforce an ethical wall between the Brokerage Group and Sales Group. This transport rule prevents members of these groups from sending messages to each other.

The DSN message in the following figure also shows the link to the relevant corporate compliance policy. By clicking this link, Mark can read the policy that prohibits communication between the two groups.

Every day, information workers use e-mail to exchange sensitive information such as financial reports and data, legal contracts, confidential product information, sales reports

and projections, competitive analysis, research and patent information, and customer and employee information. Because people can now access their e-mail from just about anywhere, mailboxes have transformed into repositories containing large amounts of potentially sensitive information. As a result, information leakage can be a serious threat to organizations. To help prevent information leakage, Microsoft Exchange Server 2010 includes the Information Rights Management (IRM) features, which provide persistent online and offline protection of e-mail messages and attachments.

Contents

What is Information Leakage?

Leakage of potentially sensitive information can be costly for an organization and have wide-ranging impact on the organization and its business, employees, customers, and partners. Local and industry regulations increasingly govern how certain types of information are stored, transmitted, and secured. To avoid violating applicable regulations, organizations must protect themselves against intentional, inadvertent, or accidental information leakage.

The following are some consequences resulting from information leakage:

- **Financial damage** Depending on the size, industry, and local regulations, information leakage may result in financial impact due to loss of business or due to fines and punitive damages imposed by courts or regulatory authorities. Public companies may also risk losing market capitalization due to adverse media coverage.
- **Damage to image and credibility** Information leakage can damage an organization's image and credibility with customers. Moreover, depending on the nature of communication, leaked e-mail messages can potentially be a source of embarrassment for the sender and the organization.
- **Loss of competitive advantage** One of the most serious threats from information leakage is the loss of competitive advantage in business. Disclosure of strategic plans or disclosure of merger and acquisition information can potentially lead to loss of revenue or market capitalization. Other threats include loss of research information, analytical data, and other intellectual property.

Return to top

Traditional Solutions to Information Leakage

Although traditional solutions to information leakage may protect initial access to data, they often don't provide constant protection. The following table lists some traditional solutions and their limitations.

Traditional solutions

Solution	Description	Limitations
Transport Layer Security (TLS)	TLS is an Internet standard protocol used to secure communications over a network by means of encryption. In a messaging environment, TLS is used to secure server/server and client/server communications. By default, Exchange 2010 uses TLS for all internal message transfers. Opportunistic TLS is also enabled by default for sessions with external hosts. Exchange first attempts to use TLS encryption for the session, but if a TLS connection can't be established with the destination server, Exchange uses SMTP. You can also configure domain security to enforce mutual TLS with external organizations. For more information, see Understanding Domain Security.	TLS only protects the SMTP session between two SMTP hosts. In other words, TLS protects information in motion, and it doesn't provide protection at the message-level or for information at rest. Unless the messages are encrypted using another method, messages in the sender's and recipients' mailboxes remain unprotected. For e-mail sent outside the organization, you can require TLS only for the first hop. After a remote SMTP host outside your organization receives the message, it can relay it to another SMTP host over an unencrypted session. Because TLS is a transport layer technology, it can't provide control over what the recipient does with the message.
E-mail encryption	Users can use technologies such as S/MIME to encrypt messages.	Users decide whether a message gets encrypted. There are additional costs of a public key infrastructure (PKI) deployment, with the accompanying overhead of certificate management for users and protection of private keys. After a message is decrypted, there's no control over what the recipient can do with the information. Decrypted information can be copied, printed, or forwarded. By default, saved attachments aren't protected. Messages encrypted using

		technologies such as S/MIME can't be accessed by your organization. The organization can't inspect message content, and therefore can't enforce messaging policies, scan messages for viruses or malicious content, or take any other action that requires accessing the content.

Finally, traditional solutions often lack enforcement tools that apply uniform messaging policies to prevent information leakage. For example, a user sends a message containing sensitive information and marks it as **Company Confidential** and **Do Not Forward**. After the message is delivered to the recipient, the sender or the organization no longer has control over the information. The recipient can willfully or inadvertently forward the message (using features such as automatic forwarding rules) to external e-mail accounts, subjecting your organization to substantial information leakage risks.

Return to top

IRM in Exchange 2010

Warning:

The IRM feature in Exchange 2010 is not compatible with AD RMS Cryptographic Mode 2. If the Exchange 2010 IRM features are critical for your organization, we recommend that you do not switch your AD RMS clusters to Cryptographic Mode 2.

In Exchange 2010, you can use IRM features to apply persistent protection to messages and attachments. IRM uses Active Directory Rights Management Services (AD RMS), an information protection technology in Windows Server 2008. With the IRM features in Exchange 2010, your organization and your users can control the rights recipients have for e-mail. IRM also helps allow or restrict recipient actions such as forwarding a message to other recipients, printing a message or attachment, or extracting message or attachment content by copying and pasting. IRM protection can be applied by users in Microsoft Outlook or Microsoft Office Outlook Web App, or it can be based on your organization's messaging policies and applied using transport protection rules or Outlook protection rules. Unlike other e-mail encryption solutions, IRM also allows your organization to decrypt protected content to enforce policy compliance.

AD RMS uses extensible rights markup language (XrML)-based certificates and licenses to certify computers and users, and to protect content. When content such as a document or a message is protected using AD RMS, an XrML license containing the rights that authorized users have to the content is attached. To access IRM-protected content, AD RMS-enabled applications must procure a use license for the authorized user from the AD RMS cluster.

Note:

In Exchange 2010, the Prelicensing agent attaches a use license to messages protected using the AD RMS cluster in your organization. For more details, see Prelicensing later in this topic.

Applications used to create content must be RMS-enabled to apply persistent protection to content using AD RMS. Microsoft Office applications, such as Word, Excel, PowerPoint

and Outlook are RMS-enabled and can be used to create and consume protected content.

IRM helps you do the following:

- Prevent an authorized recipient of IRM-protected content from forwarding, modifying, printing, faxing, saving, or cutting and pasting the content.
- Protect supported attachment file formats with the same level of protection as the message.
- Support expiration of IRM-protected messages and attachments so they can no longer be viewed after the specified period.
- Prevent IRM-protected content from being copied using the Snipping Tool in Microsoft Windows.

However, IRM can't prevent information from being copied using the following methods:

- Third-party screen capture programs
- Use of imaging devices such as cameras to photograph IRM-protected content displayed on the screen
- Users remembering or manually transcribing the information

To learn more about AD RMS, see Active Directory Rights Management Services.

AD RMS Rights Policy Templates

AD RMS uses XrML-based rights policy templates to allow compatible IRM-enabled applications to apply consistent protection policies. In Windows Server 2008, the AD RMS server exposes a Web service that can be used to enumerate and acquire templates. Exchange 2010 ships with the Do Not Forward template. When the Do Not Forward template is applied to a message, only the recipients addressed in the message can decrypt the message. The recipients can't forward the message, copy content from the message, or print the message. You can create additional RMS templates on the AD RMS server in your organization to meet your IRM protection requirements.

IRM protection is applied by applying an AD RMS rights policy template. Using policy templates, you can control permissions that recipients have on a message. Actions such as replying, replying to all, forwarding, extracting information from a message, saving a message, or printing a message can be controlled by applying the appropriate rights policy template to the message.

For more information about rights policy templates, see AD RMS Policy Template Considerations.

For more information about creating AD RMS rights policy templates, see AD RMS Rights Policy Templates Deployment Step-by-Step Guide.

Return to top

Applying IRM Protection to Messages

In Exchange 2010, IRM protection can be applied to messages using the following methods:

- **Manually by Outlook users** Your Outlook users can IRM-protect messages with the AD RMS rights policy templates available to them. This process uses the IRM functionality in Outlook, and not Exchange. However, you can use Exchange to access messages, and you can take actions (such as applying transport rules) to enforce your organization's messaging policy. For more information about using IRM in Outlook, see Introduction to using IRM for e-mail messages.
- **Manually by Outlook Web App users** When you enable IRM in Outlook Web App, users can IRM-protect messages they send, and view IRM-protected messages they receive. In Exchange 2010 Service Pack 1 (SP1), Outlook Web

App users can also view IRM-protected attachments using Web-Ready Document Viewing. For more information about IRM in Outlook Web App, see Understanding Information Rights Management in Outlook Web App.

- **Manually by Windows Mobile and Exchange ActiveSync device users** In the release to manufacturing (RTM) version of Exchange 2010, users of Windows Mobile devices can view and create IRM-protected messages. This requires users to connect their supported Windows Mobile devices to a computer and activate them for IRM. In Exchange 2010 SP1, you can enable IRM in Microsoft Exchange ActiveSync to allow users of Exchange ActiveSync devices (including Windows Mobile devices) to view, reply to, forward, and create IRM-protected messages. For more information about IRM in Exchange ActiveSync, see Understanding Information Rights Management in Exchange ActiveSync.
- **Automatically in Outlook 2010** You can create Outlook protection rules to automatically IRM-protect messages in Outlook 2010. Outlook protection rules are deployed automatically to Outlook 2010 clients, and IRM-protection is applied by Outlook 2010 when the user is composing a message. For more information about Outlook protection rules, see Understanding Outlook Protection Rules.
- **Automatically on Hub Transport servers** You can create transport protection rules to automatically IRM-protect messages on Exchange 2010 Hub Transport servers. For more information about transport protection rules, see Understanding Transport Protection Rules.

Note:
IRM protection isn't applied again to messages that are already IRM-protected. For example, if a user IRM-protects a message in Outlook or Outlook Web App, IRM protection isn't applied to the message using a transport protection rule.

Return to top

Scenarios for IRM Protection

Scenarios for IRM protection are described in the following table.

Scenarios for IRM protection

Sending IRM-protected messages	Supported	Requirements
Within the same on-premises Exchange 2010 deployment	Yes	For requirements, see IRM Requirements later in this topic.
Between different forests in an on-premises deployment	Yes	For requirements, see Configuring AD RMS to Integrate with Exchange Server 2010 Across Multiple Forests.
Between an on-premises Exchange 2010 deployment and a cloud-based Exchange 2010 organization	Yes	• Use an on-premises AD RMS server. • Export the trusted publishing domain from your on-premises AD RMS server. • Import the trusted publishing domain in your cloud-based organization.
To external recipients	No	Exchange 2010 doesn't include a solution for sending IRM-protected

		messages to external recipients in a non-federated organization. AD RMS offers solutions using trust policies. You can configure a trust policy between your AD RMS cluster and Windows Live ID. For messages sent between two organizations, you can create a federated trust between the two Active Directory forests using Active Directory Federation Services (AD FS). To learn more, see Understanding AD RMS Trust Policies.

Return to top

Decrypting IRM-Protected Messages to Enforce Messaging Policies

To enforce messaging policies and for regulatory compliance, you must be able to access encrypted message content. To meet eDiscovery requirements due to litigation, regulatory audits, or internal investigations, you must also be able to search encrypted messages. To help with these tasks, Exchange 2010 includes the following IRM features:

- **Transport decryption** To apply messaging policies, transport agents such as the Transport Rules agent should have access to message content. Transport decryption allows transport agents installed on Exchange 2010 servers to access message content. For more information, see Understanding Transport Decryption.
- **Journal report decryption** To meet compliance or business requirements, organizations can use journaling to preserve messaging content. The Journaling agent creates a journal report for messages subject to journaling and includes metadata about the message in the report. The original message is attached to the journal report. If the message in a journal report is IRM-protected, journal report decryption attaches a cleartext copy of the message to the journal report. For more information, see Understanding Journal Report Decryption.
- **IRM decryption for Exchange Search** With IRM decryption for Exchange Search, Exchange Search can index content in IRM-protected messages. When a discovery manager users Multi-Mailbox Search to perform a discovery search, IRM-protected messages that have been indexed are returned in search results. For more information, see Understanding Exchange Search. For more information about Multi-Mailbox Search, see Understanding Multi-Mailbox Search.

  Note:
  In Exchange 2010 SP1, members of the Discovery Management role group can access IRM-protected messages returned by a discovery search and residing in a discovery mailbox. To enable this functionality, use the *EDiscoverySuperUserEnabled* parameter with Set-IRMConfiguration cmdlet. For more information, see Configure IRM for Exchange Search and Discovery.

To enable these decryption features, Exchange servers must have access to the message. This is accomplished by adding the Federation mailbox, a system mailbox created by Exchange Setup, to the super users group on the AD RMS server. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Return to top

Prelicensing

To view IRM-protected messages and attachments, Exchange 2010 automatically attaches a prelicense to protected messages. This prevents the client from having to make repeated trips to the AD RMS server to retrieve a use license, and enables offline viewing of IRM-protected messages and attachments. Prelicensing also allows IRM-protected messages to be viewed in Outlook Web App. When you enable IRM features, prelicensing is enabled by default.

Return to top

IRM Agents

In Exchange 2010, IRM functionality is enabled on Hub Transport servers using transport agents. IRM agents are installed by Exchange Setup on a Hub Transport server. You can't control IRM agents using the management tasks for transport agents.

Note:

In Exchange 2010, IRM agents are built-in agents. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more information, see Understanding Transport Agents.

The following table lists the IRM agents implemented on Hub Transport servers.

IRM agents on Hub Transport servers

Agent	Event	Function
RMS Decryption agent	OnEndOfData (SMTP) and OnSubmittedMessage	Decrypts messages to allow access to transport agents.
Transport Rules agent	OnRoutedMessage	Flags messages that match rule conditions in a transport protection rule to be IRM-protected by the RMS Encryption agent.
RMS Encryption agent	OnRoutedMessage	Applies IRM protection to messages flagged by the Transport Rules agent and re-encrypts transport decrypted messages.
Prelicensing agent	OnRoutedMessage	Attaches a prelicense to IRM-protected messages.
Journal Report Decryption agent	OnCategorizedMessage	Decrypts IRM-protected messages attached to journal reports and embeds cleartext versions along with the original encrypted messages.

For more information about transport agents, see Understanding Transport Agents.

Return to top

IRM Requirements

To implement IRM in your Exchange 2010 organization, your deployment must meet the requirements described in the following table.

IRM requirements

Server	Requirements

AD RMS cluster	• **Operating system** Windows Server 2008 R2 or Windows Server 2008 SP2 with the hotfix Active Directory Rights Management Services role in Windows Server 2008 is required.
	• **Service connection point** Exchange 2010 and AD RMS-aware applications use the service connection point registered in Active Directory to discover an AD RMS cluster and URLs. AD RMS allows you to register the service connection point from within AD RMS Setup. If the account used to set up AD RMS isn't a member of the Enterprise Admins security group, service connection point registration can be performed after setup is complete. There is only one service connection point for AD RMS in an Active Directory forest.
	• **Permissions** Read and Execute permissions to the AD RMS server certification pipeline (`ServerCertification.asmx` file on AD RMS servers) must be assigned to the following:
	  • Exchange Servers group or individual Exchange servers
	  • AD RMS Service group on AD RMS servers
	By default, the ServerCertification.asmx file is located in the `\inetpub\wwwroot\_wmcs\certification\` folder on AD RMS servers. For details, see Set Permissions on the AD RMS Server Certification Pipeline.
	• **AD RMS super users** To enable transport decryption, journal report decryption, IRM in Outlook Web App, and IRM for Exchange Search, you must add the Federation mailbox, a system mailbox created by Exchange 2010 Setup, to the super users group on the AD RMS cluster. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Exchange	• Exchange 2010 is required. • The hotfix FIX: ArgumentNullException exception error message when a .NET Framework 2.0 SP2-based application tries to process a response with zero-

	length content to an asynchronous ASP.NET Web service request: "Value cannot be null" is recommended for Microsoft .NET Framework 2.0 SP2.
Outlook	• Users can IRM-protect messages in Outlook. Beginning with Outlook 2003, AD RMS templates for IRM-protecting messages is supported. • Outlook protection rules are an Exchange 2010 and Outlook 2010 feature. Previous versions of Outlook don't support this feature.
Exchange ActiveSync	• Devices supporting Exchange ActiveSync protocol version 14.1, including Windows Mobile devices, can support IRM in Exchange ActiveSync. The mobile e-mail application on a device must support the **RightsManagementInformation** tag defined in Exchange ActiveSync protocol version 14.1. In Exchange 2010 SP1, IRM in Exchange ActiveSync allows users with supported devices to view, reply to, forward, and create IRM-protected messages without requiring the user to connect the device to a computer and activate it for IRM. For details, see Understanding Information Rights Management in Exchange ActiveSync.

Note:

AD RMS cluster is the term used for an AD RMS deployment in an organization, including a single server deployment. AD RMS is a Web service. It doesn't require that you set up a Windows Server 2008 failover cluster. For high availability and load-balancing, you can deploy multiple AD RMS servers in the cluster and use Network Load Balancing.

Important:

In a production environment, installing AD RMS and Exchange on the same server isn't supported.

Exchange 2010 IRM features support Microsoft Office file formats. You can extend IRM protection to other file formats by deploying custom protectors. For more information about custom protectors, see Information Protection and Control Partners in Independent Software Vendors.

Return to top

Configuring and Testing IRM

You must use the Exchange Management Shell to configure IRM features in Exchange 2010. To configure individual IRM features, use the Set-IRMConfiguration cmdlet. You can enable or disable IRM for internal messages, transport decryption, journal report decryption, Exchange Search, and Outlook Web App. For more information about configuring IRM features, see Managing Information Rights Management.

After you set up an Exchange 2010 server, you can use the Test-IRMConfiguration cmdlet to perform end-to-end tests of your IRM deployment. These tests are useful to verify IRM functionality immediately after initial IRM configuration and on an ongoing basis. The cmdlet performs the following tests:

- Inspects IRM configuration for your Exchange 2010 organization.
- Checks the AD RMS server for version and hotfix information.
- Verifies whether an Exchange server can be activated for RMS by retrieving a Rights Account Certificate (RAC) and client licensor certificate.
- Acquires AD RMS rights policy templates from the AD RMS server.
- Verifies that the specified sender can send IRM-protected messages.
- Retrieves a super user use license for the specified recipient.
- Acquires a prelicense for the specified recipient.

Return to top

1.11.4.2 Understanding Transport Protection Rules

Understanding Transport Protection Rules

Exchange Server 2010 > Messaging Policy and Compliance > Information Rights Management >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-21*

E-mail messages and attachments increasingly contain business critical information such as product specifications, business strategy documents, and financial data, or personally identifiable information (PII) such as contact details, social security numbers, credit card numbers, and employee records. There are a number of industry-specific and local regulations in many parts of the world that govern the collection, storage, and disclosure of PII.

To help protect sensitive information, organizations create messaging policies that provide guidelines about how to handle this information. In Exchange Server 2010, you can use transport protection rules to implement these messaging policies by inspecting message content, encrypting sensitive e-mail content, and using rights management to control access to the content.

Looking for management tasks related to managing IRM? See Managing Information Rights Management.

Transport Protection Rules and AD RMS

Transport protection rules allow you to use transport rules to IRM-protect messages by applying an Active Directory Rights Management Services (AD RMS) rights policy template.

Note:

AD RMS is an information protection technology that works with Rights Management Service (RMS)-enabled applications and clients to protect sensitive information online and offline. To use IRM protection in an on-premise Exchange deployment, Exchange 2010 requires an on-premise deployment of the Windows Server 2008 operating system AD RMS.

AD RMS uses XML-based policy templates to allow compatible IRM-enabled applications to apply consistent protection policies. In Windows Server 2008, the AD RMS server exposes a Web service that can be used to enumerate and acquire templates. Exchange 2010 ships with the Do Not Forward template.

When the Do Not Forward template is applied to a message, only the recipients addressed in the message can decrypt the message. The recipients can't forward the message to anyone else, copy content from the message, or print the message.

Additional RMS templates can be created in the on-premises AD RMS deployment to meet rights protection requirements in your organization.

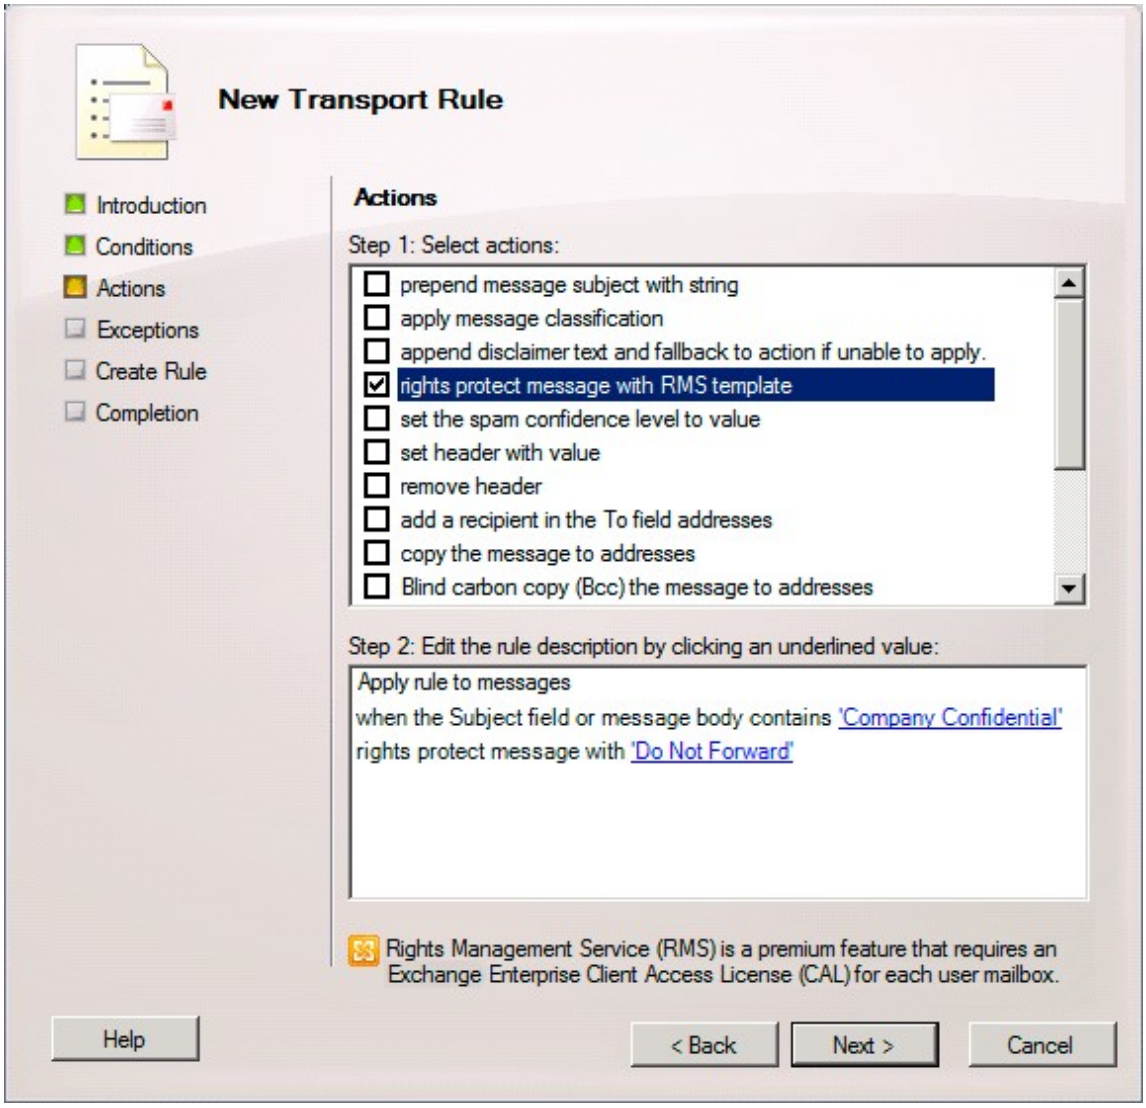
Important:

If a rights policy template is removed from the AD RMS server, you must modify any transport protection rules that use the removed template. If a transport protection rule continues to use a rights policy template that's been removed, the AD RMS server will fail to license the content to any of the recipients, and a non-delivery report (NDR) will be delivered to the sender.
In Windows Server 2008, rights policy templates can be archived instead of deleted. Archived templates can still be used to license content, but when you create or modify a transport protection rule, archived templates aren't included in the list of templates.

For more information about creating AD RMS templates, see AD RMS Rights Policy Templates Deployment Step-by-Step Guide.

Automatic Protection Using Transport Protection Rules

Messages containing business critical information or PII can be identified by using a combination of transport rule conditions, including regular expressions to identify text patterns such as social security numbers. Organizations require different levels of protection for sensitive information. Some information may be restricted to employees, contractors, or partners; while other information may be restricted only to full-time employees. The desired level of protection can be applied to messages by applying an appropriate rights policy template. For example, users may mark messages or e-mail attachments as Company Confidential. As illustrated in the following figure, you can create a transport protection rule to inspect message content for the words "Company Confidential", and automatically IRM-protect the message.



For more information about creating transport rules to enforce rights protection, see Create a Transport Protection Rule.

Persistent Protection of E-Mail Attachments

Users send business critical information and PII in e-mail attachments using common Microsoft Office file formats such as Microsoft Office Word, Excel, and PowerPoint. All of these file formats support persistent protection via IRM, and you can make sure that the business critical information and PII in these documents are properly protected. Transport protection rules apply the same protection to e-mail messages and attachments in supported file formats.

Transport Rules Agent and Encryption Agent

When you use transport protection rules to IRM-protect messages based on rule conditions, the Transport Rules agent on the Hub Transport server inspects messages. If they meet all the conditions and none of the exceptions, it flags the message to be IRM-protected. The Encryption agent, a built-in transport agent that fires on the **OnRoutedMessage** event, actually applies IRM protection to the message. The Encryption agent acts on messages only if IRM is enabled for internal messages. For more information about enabling IRM, see Enable or Disable IRM for Internal Messages.

When the transport service is restarted, and it processes the first message that requires IRM encryption, the Encryption agent must be able to reach an AD RMS server in the organization. For subsequent messages, the agent doesn't need to contact the AD RMS server. Upon failure to encrypt a message due to transient conditions, Exchange retries the message three times at 10-minute intervals. After three retries, if the message can't be encrypted, it isn't delivered to recipients. An NDR is sent to the sender. We recommend that you plan your AD RMS deployment for high availability to make sure message flow isn't impacted.

When planning to use transport protection rules, you must consider the type of information you want to protect and plan on creating rules accordingly. In Exchange 2010, transport rules have a large number of predicates that allow you to inspect message content, including supported attachments, message headers, sender and recipient addresses, their Active Directory attributes such as department, distribution group membership, and management relationships of the sender with recipients. For more details about transport rule predicates available in Exchange 2010, see Transport Rule Predicates.

You must also consider the messaging traffic in your organization, and the number of messages that will be protected using transport protection rules. Applying IRM protection to a large number of messages requires more resources on the Hub Transport server. Additionally, protecting a large number of messages or all messages also impacts the client experience, particularly for Microsoft Outlook users.

1.11.4.3 Understanding Outlook Protection Rules

Understanding Outlook Protection Rules

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-13*

Information workers exchange sensitive information such as financial reports and data, customer and employee information, and confidential product information and specifications, by e-mail everyday. In Microsoft Exchange Server 2010, Microsoft Outlook, and Microsoft Office Outlook Web App, users can apply Information Rights Management (IRM) protection to messages by applying an Active Directory Rights Management Services (AD RMS) rights policy template. This requires an AD RMS deployment in the organization. For more information about AD RMS, see Active Directory Rights Management Services.

However, when left to the discretion of users, messages may be sent in clear text without IRM protection. In organizations that use e-mail as a hosted service, there's a risk of information leakage as a message leaves the client and is routed and stored outside the boundaries of an organization. Although e-mail hosting companies may have well-defined procedures and checks to help mitigate the risk of information leakage, after a message leaves the boundary of an organization, the organization loses control of the information. Outlook protection rules can help protect against this type of information leakage.

Looking for management tasks related to managing IRM? See Managing Information Rights Management.

Automatic IRM Protection in Outlook 2010

In Exchange 2010, Outlook protection rules help your organization protect against the risk of information leakage by automatically applying IRM-protection to messages in

Outlook 2010. Messages are IRM-protected before they leave the Outlook client. This protection is also applied to any attachments using supported file formats.

When you create Outlook protection rules on an Exchange 2010 server, the rules are automatically distributed to Outlook 2010 by using Exchange Web Services. For Outlook 2010 to apply the rule, the AD RMS rights policy template you specify must be available on users' computers.

Important:

If a rights policy template is removed from the AD RMS server, you must modify any Outlook protection rules that use the removed template. If an Outlook protection rule continues to use a rights policy template that's been removed, and transport decryption is enabled in the organization, the Decryption agent will fail to decrypt the message protected with a template that's no longer available. If transport decryption is configured as mandatory, the Hub Transport server will reject the message and send a non-delivery report (NDR) to the sender. For more details about transport decryption, see Understanding Transport Decryption. For more details about AD RMS rights policy templates, see AD RMS Policy Template Considerations.
In Windows Server 2008, rights policy templates can be archived instead of deleted. Archived templates can still be used to license content, but when you create or modify an Outlook protection rule, archived templates aren't included in the list of templates.

Outlook protection rules are similar to transport protection rules. Both are applied based on message conditions, and both protect messages by applying an AD RMS rights protection template. However, transport protection rules are applied on the Hub Transport server by the Transport Rules agent. Outlook protection rules are applied in Outlook 2010, before the message leaves the user's computer. Messages protected by an Outlook protection rule enter the transport pipeline with IRM protection already applied. Additionally, messages protected with an Outlook protection rule are also saved in an encrypted format in the Sent Items folder of the sender's mailbox.

Note:

If transport decryption is enabled in your Exchange organization, messages that are IRM-protected by an Outlook protection rule using the AD RMS server in your organization can be decrypted by the Decryption agent on Hub Transport servers. Message content can be inspected by the Transport Rules agent and other transport agents installed on the Hub Transport server. For more details about transport decryption, see Understanding Transport Decryption.

When you use transport protection rules, users have no indication of whether a message is going to be automatically protected on the Hub Transport server. When an Outlook protection rule is applied to a message in Outlook 2010, users know if a message will be IRM-protected. If required, users can also select a different rights policy template.

Creating Outlook Protection Rules

To create Outlook protection rules, you must use the New-OutlookProtectionRule cmdlet in the Exchange Management Shell. For detailed instructions, see Create an Outlook Protection Rule.

When creating a rule, you can specify whether the user can override it, either by removing IRM-protection or by applying a different AD RMS rights policy template than the one specified in the rule. If a user overrides the IRM protection applied by an Outlook protection rule, Outlook 2010 inserts the `X-MS-Outlook-Client-Rule-Overridden` header in the message, which allows you to determine that the rule was overridden by the user.

Predicates in Outlook Protection Rules

Outlook protection rules allow you to use three predicates to automatically apply IRM protection in Outlook 2010:

- **FromDepartment** The *FromDepartment* predicate looks up the sender's department attribute in Active Directory and automatically IRM-protects the message if the sender's department matches the department specified in the rule. For example, you can create an Outlook protection rule to automatically protect all messages sent by the Research department.
- **SentTo** Your organization may need to protect messages sent to certain sensitive recipients, such as the All Company or Finance distribution groups. Using the *SentTo* predicate, you can create an Outlook protection rule to automatically IRM-protect messages sent to specified recipients.
- **SentToScope** The *SentToScope* predicate allows you to create an Outlook protection rule to automatically IRM-protect messages sent inside or outside the organization. For example, you can use the *SentToScope* predicate with the *FromDepartment* predicate to IRM-protect messages sent by a particular department to internal users.

1.11.4.4 Understanding Transport Decryption

Understanding Transport Decryption

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-28*

In Microsoft Exchange Server 2010, Microsoft Outlook 2010, and Microsoft Office Outlook Web App, users can use Information Rights Management (IRM) to protect their messages. You can create Outlook protection rules to automatically apply IRM protection to messages before they're sent from an Outlook 2010 client. You can also create transport protection rules to apply IRM protection to messages in transit that match the rule conditions. Transport decryption allows access to IRM-protected messaging content to enforce messaging policies.

Looking for management tasks related to managing IRM? See Managing Information Rights Management.

Limitations of Other Encryption Solutions

If it's critical that your organization protects sensitive information, including high business impact (HBI) information and personally identifiable information (PII), consider encrypting e-mail messages and attachments. E-mail encryption solutions such as S/MIME have been available for a long time. These encryption solutions have seen varying degrees of adoption in organizations of different types. However, such solutions present the following challenges:

- **Inability to apply messaging policies** Organizations also face compliance requirements that require inspection of messaging content to make sure it adheres to messaging policies. However, messages encrypted with most client-based encryption solutions, including S/MIME, prevent content inspection on the server. Without content inspection, an organization can't validate that all messages sent or received by its users comply with messaging policies. For

example, to comply with a legal regulation, you've configured a transport rule to detect PII, such as a social security number, and automatically apply a disclaimer to the message. If the message is encrypted, the Transport Rules agent on the Hub Transport server can't access message content, and therefore won't apply the disclaimer. This results in a violation of the policy.

- **Decreased security** Antivirus software is unable to scan encrypted message content, further exposing an organization to risk from malicious content such as viruses and worms. Encrypted messages are generally considered to be trusted by most users, thereby increasing the likelihood of a virus spreading throughout your organization. For example, you've configured an Outlook protection rule to automatically apply IRM protection to all messages sent to the All Employees distribution list with the Company Confidential rights management service (RMS) template. A user's workstation is infected with a virus that propagates by automatically using Reply All to reply to messages. If the message carrying the virus is encrypted, the antivirus scanner can't scan the message.
- **Impact to custom transport agents** Many organizations develop custom transport agents for different purposes, such as meeting additional processing requirements for compliance, security, or custom message routing. Custom transport agents developed by an organization to inspect or modify messages are unable to process encrypted messages. If the custom transport agents developed by your organization can't access message content, message encryption may prevent your organization from meeting the goals for which the custom transport agents are developed.

Using Transport Decryption for Encrypted Content

In Exchange 2010, IRM features address these challenges. If messages are IRM-protected, transport decryption allows you to decrypt them in transit. IRM-protected messages are decrypted by the Decryption agent, a compliance-focused transport agent.

Note:

In Exchange 2010, the Decryption agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more details, see Understanding Transport Agents.

The Decryption agent decrypts the following types of IRM-protected messages:

1. Messages IRM-protected by the user in Outlook Web App.
2. Messages IRM-protected by the user in Outlook 2010.
3. Messages IRM-protected automatically by Outlook protection rules in Outlook 2010.

Important:

Only messages IRM-protected by the AD RMS server in your organization are decrypted by the Decryption agent.

Note:

Messages protected in-transit using transport protection rules aren't required to be decrypted by the Decryption agent. The Decryption agent fires on the **OnEndOfData** and **OnSubmit** transport events. Transport protection rules are applied by the Transport Rules agent, which fires on the **OnRoutedMessage** event, and IRM-protection is applied by the Encryption agent on the **OnRoutedMessage** event. For more information about transport agents and a list of SMTP events on which they can be registered, see Understanding Transport Agents.

Transport decryption is performed on the first Exchange 2010 Hub Transport server that handles a message in an Active Directory forest. If a message is transferred to a Hub Transport server in another Active Directory forest, the message is decrypted again. After

decryption, unencrypted content is available to other transport agents on that server. For example, the Transport Rules agent on a Hub Transport server can inspect message content and apply transport rules. Any actions specified in the rule, such as applying a disclaimer or modifying the message in any other way, can be taken on the unencrypted message. Third-party transport agents, such as antivirus scanners, can scan the message for viruses and malware. After other transport agents have inspected the message and possibly made modifications to it, it's encrypted again with the same user rights that it had before being decrypted by the Decryption agent. The same message isn't decrypted again by other Hub Transport servers in the organization.

Messages decrypted by the Decryption agent don't leave the Hub Transport server without being encrypted again. If a transient error is returned when decrypting or encrypting the message, the Hub Transport server retries the operation twice. After the third failure, the error is treated as a permanent error. If any permanent errors occur, including when transient errors are treated as permanent errors after retries, the Hub Transport server treats them as follows:

- If the permanent error occurs during decryption, a non-delivery report (NDR) is sent only if transport decryption is set to `Mandatory`, and the encrypted message is sent with the NDR. For more details about the configuration options available for transport decryption, see Configuring Transport Decryption later in this topic.
- If the permanent error occurs during re-encryption, an NDR is always sent without the decrypted message.

Important:

Any custom or third-party agents installed on a Hub Transport server have access to the decrypted message. You must consider the behavior of such transport agents. We recommend that you test all custom and third-party transport agents thoroughly before you deploy them in a production environment.
After a message is decrypted by the Decryption agent, if a transport agent creates a new message and embeds (attaches) the original message to the new one, only the new message is protected. The original message, which becomes an attachment to the new message, doesn't get re-encrypted. A recipient receiving such a message can open the attached message and take actions such as forwarding or replying, which would bypass rights enforcement.

Configuring Transport Decryption

Transport decryption is configured by using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. However, before you configure transport decryption, you must provide Exchange 2010 servers the right to decrypt content protected by your AD RMS server. This is done by adding the Federation mailbox to the super users group configured on the AD RMS cluster in your organization.

Important:

In cross-forest AD RMS deployments where you have an AD RMS cluster deployed in each forest, you must add the Federation mailbox to the super users group on the AD RMS cluster in each forest to allow an Exchange 2010 Hub Transport server to decrypt the messages protected against each AD RMS cluster.

For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Exchange 2010 allows two different settings when enabling transport decryption:

- **Mandatory** When transport decryption is set to `Mandatory`, the Decryption agent rejects the message and returns an NDR to the sender if a permanent error is returned when decrypting a message. If your organization doesn't want a message to be delivered if it can't be successfully decrypted and actions such as antivirus scanning and transport rules are applied, you must choose this setting.

- **Optional** When transport decryption is set to Optional, the Decryption agent uses a best-effort approach. Messages that can be decrypted are decrypted, but messages with a permanent error on decryption are also delivered. If your organization prioritizes message delivery over messaging policy, you must use this setting.

For more information about configuring transport decryption, see Enable or Disable Transport Decryption.

1.11.4.5 Understanding Journal Report Decryption

Understanding Journal Report Decryption

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-17*

In Microsoft Exchange Server 2010, Information Rights Management (IRM) allows Microsoft Outlook 2010 and Microsoft Office Outlook Web App users to protect their messages. You can create Outlook protection rules to automatically apply IRM-protection to messages before they're sent from an Outlook 2010 client. You can also create transport protection rules to apply IRM protection to messages in transit that match the rule conditions.

To learn about Outlook protection rules, see Understanding Outlook Protection Rules.

Limitations of Standard Encryption Solutions

If your organization encrypts messages by using traditional solutions such as S/MIME, your records managers won't be able to inspect or search the encrypted content. Archiving encrypted messages that contain inaccessible and unsearchable content may not meet business, regulatory, or compliance requirements. When faced with an electronic discovery (eDiscovery) request, an inability to decrypt, search, and present content from encrypted messages can be a challenge, and failure to do so may expose your organization to legal and financial risks.

Also, your organization's messaging policies may require journaled messages to be decrypted so the content can be accessible to eDiscovery tools, automated processes, or records managers who access a journaling mailbox. Journal report decryption in Exchange 2010 can help you meet these requirements.

To learn more about journaling, see Understanding Journaling and Understanding Journal Reports.

Journal Report Decryption

Journal report decryption allows you to save a clear-text copy of IRM-protected messages in journal reports, along with the original, IRM-protected message. If the IRM-protected message contains any supported attachments that were protected by the Active Directory Rights Management Services (AD RMS) cluster in your organization, the attachments are also decrypted.

Important:

To use journal report decryption, you must have an Exchange Enterprise client access

license (CAL). Journal report decryption only supports premium journaling.

Decryption is performed by the Journal Report Decryption agent, a compliance-focused transport agent. The Journal Report Decryption agent fires on the **OnCategorizedMessage** event. Messages protected in-transit using transport protection rules are already encrypted by the Encryption agent, which fires on the **OnRoutedMessage** event, before they get to the Journal Report Decryption agent. The Journal Report Decryption agent decrypts these messages.

Note:
In Exchange 2010, the Journal Report Decryption agent is a built-in agent. Built-in agents aren't included in the list of agents returned by the **Get-TransportAgent** cmdlet. For more details, see Understanding Transport Agents.

The agent decrypts the following types of IRM-protected messages:

1. Messages that were IRM-protected by the user in Outlook Web App.
2. Messages that were IRM-protected by the user in Outlook 2010.
3. Messages that were IRM-protected automatically in Outlook 2010 by using Outlook protection rules.
4. Messages that were IRM-protected automatically in transit by using transport protection rules.

Important:
Only messages that were IRM-protected by the AD RMS server in your organization are decrypted by the Journal Report Decryption agent. The agent doesn't decrypt an attachment if it isn't protected at the same time as the message (and therefore doesn't have the same use license), or if an IRM-protected file is attached to an unprotected message.

Configuring Journal Report Decryption

Journal report decryption is configuredb using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. However, before you configure journal report decryption, you must assign Exchange 2010 servers the permissions to decrypt content that's IRM-protected by your AD RMS server. To do this, you add the Federation mailbox to the super users group configured on your organization's AD RMS cluster. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.

Important:
In cross-forest AD RMS deployments where you have an AD RMS cluster deployed in each forest, you must add the Federation mailbox to the super users group on the AD RMS cluster in each forest to allow Exchange 2010 Hub Transport servers to decrypt the messages protected against each AD RMS cluster.

For details about how to configure journal report decryption, see Enable or Disable Journal Report Decryption.

After you enable journal report decryption, the journaling mailbox may contain journal reports with sensitive information in an unencrypted form. As a best practice, we recommend that access to the journaling mailbox be monitored closely and restricted only to authorized individuals. This is a best-practice even if you're not using IRM protection for e-mail.

1.11.4.6 Understanding Information Rights Management in Outlook Web App

Understanding Information Rights Management in Outlook Web App

Exchange Server 2010 > Messaging Policy and Compliance > Information Rights Management >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

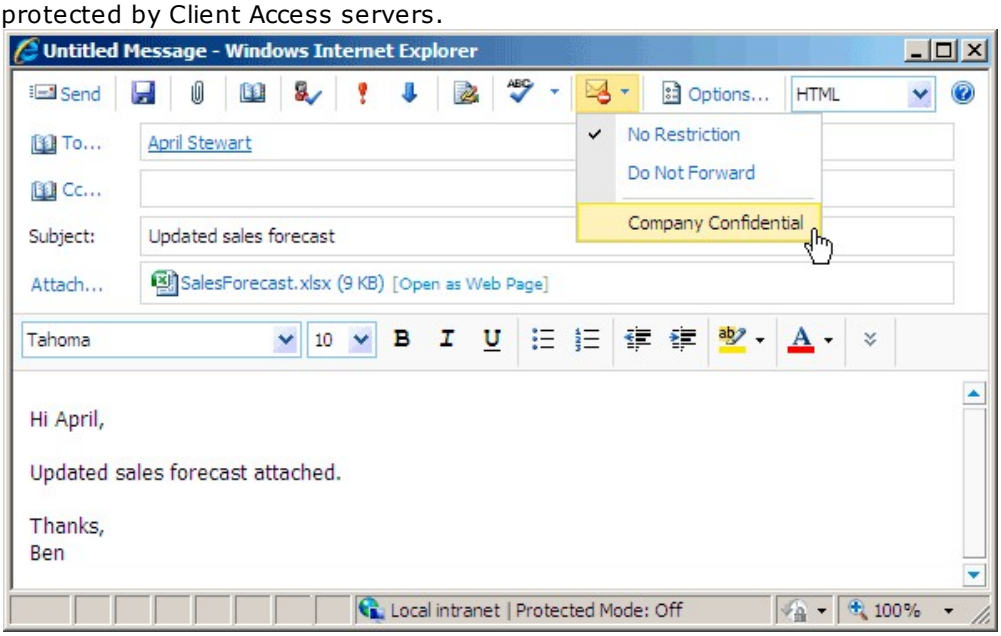
Topic Last Modified: *2010-08-10*

Information workers increasingly use e-mail to exchange sensitive information. To help secure this information, organizations can use Information Rights Management (IRM) to apply persistent protection to messaging content. Prior to Microsoft Exchange Server 2010, effective use of IRM protection was limited to Outlook clients. In Exchange Server 2007, Microsoft Outlook Web Access users were required to download the Rights Management add-in for Microsoft Internet Explorer so they could access IRM-protected content.

In Exchange 2010, IRM in Outlook Web App allows your users to access the rich IRM functionality offered by Exchange to apply persistent IRM-protection to messaging content.

The following IRM functionality is available in Outlook Web App:

- **Send IRM-protected messages** As shown in the following figure, Outlook Web App users can use the permissions drop-down list and select a rights policy template to apply to the message. This allows users to send IRM-protected messages from within Outlook Web App. Messages are IRM-protected by Client Access servers.



- **IRM-protected attachments** When users send an IRM-protected message from Outlook Web App, any files attached to the message also receive the same IRM protection and are protected by using the same rights policy template as the message. In Exchange 2010, IRM protection is applied to files associated with Microsoft Office Word, Excel, and PowerPoint, as well as .xps files and e-mail messages. IRM protection is applied to an attachment only if it's not already IRM-protected. To learn more about Active Directory Rights Management Services (AD RMS) rights policy templates, see Understanding Information Rights Management.

Note:
IRM in Outlook Web App protects only the supported file attachments mentioned in this section. Attachments that use unsupported file formats aren't protected. When Outlook Web App users protect a message and attach a file of an unsupported type, a notification is displayed informing the users that only supported file types are protected.

Important:
IRM protection can't be applied to a message that's already signed or encrypted by using S/MIME. To apply IRM protection, S/MIME signature and encryption must be removed from the message. The same applies for IRM-protected messages; users can't sign or encrypt them by using S/MIME.

- **Read IRM-protected messages** Messages protected by senders using your organization's AD RMS cluster are rendered in the preview pane in Outlook Web App. No add-ins need to be installed, and the computer doesn't need to be enrolled in the AD RMS deployment. When a user opens a message or views it in the preview pane, the message is decrypted by using the use license added by the Pre-licensing agent. After decryption, the message is displayed in the preview pane. If a pre-license isn't available, Outlook Web App requests one from the AD RMS server and then renders the message. When reading IRM-protected attachments in Outlook Web App, Web-Ready Document Viewing isn't available.

  Note:
  IRM in Outlook Web App can't prevent users from taking screen captures by using Print Screen functionality in the way Outlook and other Office applications do. This impacts the EXTRACT right, which prevents message content from being copied, if specified in the AD RMS rights policy template.

- **Cross-browser, multiple platform IRM support** IRM in Outlook Web App offers cross-browser, multiple platform IRM support. IRM in Outlook Web App is supported in all browsers supported by Exchange 2010, including on Apple Macintosh and Linux operating systems. To learn more about supported browsers and operating systems, see Outlook Web App Supported Browsers.
- **WebReady Document Viewing** In Exchange 2010 SP1, users can view supported IRM-protected attachments by using WebReady Document Viewing. This allows users to view supported attachments without having to download the attachment use the associated application. To learn more about WebReady Document Viewing, including the supported file formats, see Understanding File and Data Access for Outlook Web App.

Looking for management tasks related to managing IRM? See Managing Information Rights Management.

Enabling IRM in Outlook Web App

To enable IRM in Outlook Web App, you must add the Federation mailbox, a system mailbox created by Exchange 2010 Setup, to the super users group in AD RMS. For details, see Add the Federation Mailbox to the AD RMS Super Users Group. This allows Exchange 2010 servers to access IRM-protected messages.

You must also enable IRM in Outlook Web App by using the Set-IRMConfiguration cmdlet in the Exchange Management Shell. This enables IRM in Outlook Web App for your Exchange 2010 organization. You can disable or enable IRM in Outlook Web App for an Outlook Web App virtual directory. You can also control IRM in Outlook Web App at the following levels of granularity:

- **Per-Outlook Web App virtual directory** To enable or disable IRM in Outlook Web App for an Outlook Web App virtual directory, use the **Set-OWAVirtualDirectory** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to disable IRM in Outlook Web App for one virtual directory on an Exchange 2010 Client Access server, while keeping it enabled on another virtual directory on a different Client Access server.
- **Per-Outlook Web App mailbox policy** To enable or disable IRM in Outlook Web App for an Outlook Web App mailbox policy, use the **Set-OWAMailboxPolicy** cmdlet and set the *IRMEnabled* parameter to `$false` or `$true` (default). This allows you to enable IRM in Outlook Web App for one set of users and disable it for another set of users by assigning them a different

Outlook Web App mailbox policy.

For more information, see Enable or Disable Information Rights Management on Client Access Servers.

1.11.4.7 Understanding Information Rights Management in Exchange ActiveSync

Understanding Information Rights Management in Exchange ActiveSync

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-14*

Information workers often use e-mail to exchange sensitive information. To help secure this information, organizations can use Information Rights Management (IRM) to apply persistent protection to messaging content. Because mobile devices are increasingly being used to access e-mail, it's important that your mobile device users be able to create and consume IRM-protected content.

Contents

Looking for management tasks related to IRM? See Managing Information Rights Management.

Differences Between Mobile IRM Protection in Exchange 2010 RTM and Exchange 2010 SP1

To enable IRM protection for mobile devices in the release to manufacturing (RTM) version of Microsoft Exchange Server 2010, the following requirements must be met:

- The mobile devices must be running Windows Mobile 6.0 or later.
- The Active Directory Rights Management Services (AD RMS) administrator must allow Read permissions and Read and Execute permissions on the mobile certification pipeline (using the MobileDeviceCertification.asmx file in the Inetpub\wwwroot_wmcs\Certification folder on the AD RMS server). For more information, see Enable Certification of Mobile Devices.
- Users must connect the device to a computer and activate it for IRM using one of the following methods:
  - Using the Windows Mobile Device Center on computers running the Windows 7 or Windows Vista operating systems
  - Using the Microsoft ActiveSync client application on computers running the Windows XP operating system

In Exchange 2010 Service Pack 1 (SP1), IRM in Microsoft Exchange ActiveSync allows your users to access rich IRM functionality on any supported Exchange ActiveSync device without having to configure AD RMS permissions or connect the device to a computer and activate it for IRM. Also, the mobile device doesn't need to be running Windows. Exchange ActiveSync is licensed by Microsoft to mobile device manufacturers, original equipment manufacturers (OEMs), and others. For a list of current Exchange ActiveSync licensees, see Exchange ActiveSync Protocol.

Using IRM in Exchange ActiveSync, mobile device users can:

- Create IRM-protected messages.
- Read IRM-protected messages.
- Reply to and forward IRM-protected messages.

Return to top

Requirements

The following requirements apply:

- The Client Access servers in your organization must be running Exchange 2010 SP1.
- An AD RMS server must be deployed in your organization.
- IRM must be enabled for internal messages. This is a prerequisite for all IRM features in Exchange 2010. For details, see Enable or Disable IRM for Internal Messages.
- IRM must be enabled in the Exchange ActiveSync mailbox policy. You can enable or disable IRM for different sets of users using different Exchange ActiveSync mailbox policies.
- Devices that support Exchange ActiveSync protocol version 14.1, including Windows phones, can support IRM in Exchange ActiveSync. The device's mobile e-mail application must support the RightsManagementInformation tag defined in Exchange ActiveSync version 14.1.

Return to top

Security

When you enable IRM in Exchange ActiveSync, the Client Access server decrypts IRM-protected messages before providing the messages for access by the supported mobile device. Upon synchronization, IRM-protected messages reside on the mobile device in an unencrypted format. IRM protection is enforced by the IRM-capable e-mail client application on the mobile device.

IRM in Exchange ActiveSync doesn't decrypt IRM-protected attachments on the Client Access server. Access to IRM-protected files is enforced by the application used to create or view the file. For example, on a Windows phone, IRM protection for Microsoft Office files is enforced by Microsoft Office Mobile. To access IRM-protected Office files, users must connect the device to a computer and activate Office Mobile with the RMS server.

When enabling IRM in Exchange ActiveSync, we recommend using the Exchange ActiveSync policy settings shown in the following table to help secure mobile devices.

Exchange ActiveSync policy settings

Setting	Configure using the New Exchange ActiveSync Mailbox Policy wizard	Configure using the New-ActiveSyncMailboxPolicy cmdlet

Require that the user enter a password to access information on their mobile device.	Select the **Require password** check box.	Set the *DevicePasswordEnabled* parameter to `$true`.
Enable encryption for the mobile device.	Select the **Require password** check box, and then select the **Require encryption on device** check box.	Set the *RequireDeviceEncryption* parameter to `$true`. **Important:** When you set the *RequireDeviceEncryption* parameter to `$true`, mobile devices that don't support device encryption will be unable to connect.
Don't allow non-provisionable mobile devices to synchronize with the Exchange server.	Clear the **Allow non-provisionable devices** check box.	Set the *AllowNonProvisionableDevices* parameter to `$false`.

To learn more, see Understanding Exchange ActiveSync Mailbox Policies.

Return to top

Enabling IRM in Exchange ActiveSync

To enable IRM in Exchange ActiveSync, perform the following tasks:

1. Add the Federation mailbox (a system mailbox created by Exchange 2010 Setup) to the super users group in AD RMS. This allows Exchange 2010 servers to access IRM-protected messages. For details, see Add the Federation Mailbox to the AD RMS Super Users Group.
2. Use the Set-IRMConfiguration cmdlet in the Exchange Management Shell to enable IRM on the Client Access server. This enables IRM in Exchange ActiveSync and IRM in Microsoft Office Outlook Web App for your organization. For details, see Enable or Disable Information Rights Management on Client Access Servers.

1.11.4.8 Understanding Information Rights Management Logging

Understanding Information Rights Management Logging

Exchange Server 2010 > Messaging Policy and Compliance > Information Rights Management >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-01*

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), Information Rights Management (IRM) operations performed on Exchange 2010 Mailbox, Client Access, Hub Transport, and Unified Messaging servers are logged in IRM logs. IRM logs help you monitor and troubleshoot interactions between the Rights Management Services (RMS) client on an Exchange 2010 SP1 server and the Active Directory Rights Management Services (AD RMS) cluster in your organization.

To learn about IRM, see Understanding Information Rights Management.

Contents

Looking for management tasks related to IRM? See Managing Information Rights Management.

Structure of IRM Logs

By default, IRM logs are located in C:\Program Files\Microsoft\Exchange Server\V14\Logging\IRMLogs.

The naming convention for IRM log files is *<Process>*_*<Process identifier* or *IIS AppPool identifier>*_IRMLOG*yyyymmdd-nnnn*.log, where:

- *<Process>* = process that creates the log file. For example, on Hub Transport servers, this will be EdgeTransport.
- *<Process identifier* or *IIS AppPool identifier>* = numerical ID of the process.
- *yyyymmdd* = Coordinated Universal Time (UTC) date when the log file was created.
- *nnnn* = instance number, which starts at 1 for each day.

An example IRM log file name is EdgeTransport_1056_IRMLOG20101201-1.log.

The following table shows the logs generated on different server roles.

Logs on server roles

Server role	IRM log file name	Description
Hub Transport	EdgeTransport_*<Process identifier>*_IRMLOG*yyyymmdd-nnnn*.log	This log is used to record all RMS transactions made by the transport pipeline on Hub Transport servers (for example, transport protection rules and journal report decryption). The process identifier (PID) of the edgetransport.exe process is used to generate the log file name.
Mailbox	msftefd_*<Process identifier>*_IRMLOG*yyyymmdd-nnnn*.log	This log is used to record all RMS transactions that occur during search and index requests. Exchange 2010 Mailbox servers use the msftefd.exe process for content indexing. The PID of the msftefd.exe process is used to generate the log file name.

Client Access	w3wp_MSExchangeOWAAppOol_IRMLOG*yyyymmdd-nnnn*.log	This log is used to record all transactions for IRM in Microsoft Office Outlook Web App.
All Exchange 2010 server roles except Edge Transport	w3wp_MSExchangePowerShellAppPool_IRMLOG*yyyymmdd-nnnn*.log	This log is used to record all IRM RMS transactions issued from Windows PowerShell, for example, when issuing the **Test-IRMConfiguration** cmdlet.

Return to top

Logging Process

Information is written to the log file until the file size reaches its maximum specified value. When the maximum size is reached, a log file that has an incremental instance number is created. This process is repeated throughout the day. Circular logging deletes the oldest log files when the IRM log directory reaches its maximum specified size or when a log file reaches the maximum age specified in the IRM logging configuration on each server.

Return to top

Information Written to IRM Logs

IRM log files are text files that contain data in comma-separated value (CSV) format. Each IRM log has a header that contains the following information:

- **#Software** Name of the software that created the IRM log file. Typically, the value is `Microsoft Exchange Server`.
- **#Version** Version number of the software that created the IRM log file.
- **#Log-type** Log type value, which is `Rms Client Manager Log`.
- **#Date** The UTC date and time when the log file was created. The UTC date and time is represented in the ISO 8601 date-time format: *yyyy-mm-dd*T*hh*:*mm*:*ss.fff*Z, where:
  - yyyy = year
  - *mm* = month
  - *dd* = day
  - T = time designator used to show the start of the time component
  - *hh* = hour
  - *mm* = minute
  - *ss* = second
  - *fff* = fractions of a second
  - Z = Zulu, which is another way to denote UTC
- **#Fields** Comma-delimited field names used in IRM log files.
  The IRM log stores each RMS transaction event on a single line, organized in comma-separated fields. The following table lists the fields in IRM logs for all server roles that have IRM features enabled.

Fields used in IRM logs

Field	Description
Date-time	Lists the UTC timestamp.
Feature	Lists the RMS client feature used. Valid values include: • `RacClc`

	• Template • Prelicense • UseLicense • Signature verification • ServerInfo
Event-Type	Lists the event type. Valid values include: • Acquire An RMS license or template is requested. • Success An RMS license or template is acquired successfully. • Exception An error has occurred. • Queued A request is pending.
Tenant-Id	Reserved for internal Microsoft use.
Server-url	Lists the RMS server URL accessed during the operation.
Context	Used by the calling process to tie multiple RMS transactions together. Valid values include: • MessageID: <Actual message ID> • MailboxGuid: <Mailbox GUID> • AttachmentFileName: <File name>
Transaction-id	Identifies a unique transaction. All events that occur during one transaction have the same transaction ID.

Return to top

Managing IRM Logs

On each server role that has IRM features enabled, IRM logging is enabled by default. For each server role, you can modify the following IRM log configuration by using the server role's corresponding **Set** cmdlet. For example, to configure IRM logging on a Mailbox server, you use the **Set-MailboxServer** cmdlet.

Configuration parameters for IRM logs

Parameter	Description
IrmLogEnabled	Enables logging of IRM transactions. IRM logging is enabled by default. To disable IRM logging for a server role, set the parameter to $false.
IrmLogMaxAge	Specifies the maximum age for an IRM log file. Files older than the specified age are deleted. The default value is 30.00:00:00 (30 days).
