* В данной версии отстутсвует подробная информация по командлетам PowerShell

Table of Contents

1 Exchange Server 2010

Exchange Server 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-12-11*

Welcome to Microsoft Exchange Server 2010 Service Pack 2 (SP2)! We know you're eager to get started, but there are a few things you should be aware of before you start working with Exchange 2010 and using this content.

- If you want a quick overview of what's new in Exchange 2010 SP2, check out What's New in Exchange 2010 SP2.
- If you want to learn more about Exchange 2010, check out the Exchange 2010 TechCenter.
- To get started with Exchange 2010, head for Planning and Deployment. It lays out the recommended sequence for preparing for and then installing Exchange 2010, and it includes the following important topics:
  - Exchange 2010 System Requirements
  - Exchange 2010 Prerequisites
  - Exchange 2003 - Planning Roadmap for Upgrade and Coexistence
  - Exchange 2007 - Planning Roadmap for Upgrade and Coexistence
  - Understanding a New Installation of Exchange 2010
  - Install Exchange 2010 Using the Custom Installation Type
  - Understanding Upgrade to Exchange 2010
  - Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3

Exchange 2010 Help

The Help content for Exchange 2010 consists of the following top-level categories:

- Getting Started With Exchange 2010
- Planning and Deployment
- Permissions
- Exchange Management Console
- Exchange Management Shell
- Client Access
- Transport
- Mailbox
- Unified Messaging
- High Availability and Site Resilience
- Messaging Policy and Compliance
- Federation
- Hybrid Deployments
- Multi-Tenant Support
- Performance and Scalability
- About Exchange Documentation

Download the Exchange 2010 SP2 Help File

Looking for an offline version of this Exchange 2010 SP2 Help content? Download the Help file from the Microsoft Download Center.

Note:

Haven't upgraded to Exchange 2010 SP2? You can also download the Help file for previous versions of Exchange.

- Exchange 2010 SP1 Help

- Exchange 2010 RTM Help

Tell us what you think

If you have comments or questions about our topics or about the overall Help experience, we'd love to hear from you. Your feedback will help us provide the most accurate and concise content. There are a couple ways to provide feedback:

- Use the **Click to Rate and Give Feedback** link at the top of any topic. Feedback generated here is sent directly to the Exchange team for review and follow up.
- Add comments or content to the **Community Content** section located at the bottom of any topic. Content here will be seen by anyone viewing the topic.

1.1 Getting Started With Exchange 2010

Getting Started With Exchange 2010

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-28*

Microsoft Exchange Server 2010 Service Pack (SP2) can help you achieve better business outcomes while controlling the costs of deployment, administration, and compliance. Exchange delivers a wide range of deployment options and advanced compliance capabilities.

For more information about Exchange 2010, see Exchange 2010 Overview.

Using Exchange 2010 Help

Exchange 2010 SP2 Help content is organized by feature set. Use the top-level nodes to find the most appropriate Help topics when you're planning, deploying, or managing your Exchange 2010 organization.

Looking for an offline version of this Exchange 2010 SP2 Help content? Download the Help file from the Microsoft Download Center.

Note:

Haven't upgraded to Exchange 2010 SP2? You can also download the Help file for previous versions of Exchange.

- Exchange 2010 SP1 Help
- Exchange 2010 RTM Help

For a discussion of the new features in Exchange 2010 SP2, see What's New in Exchange 2010 SP2.

For a detailed roadmap that helps you get acquainted with all the features in Exchange 2010, see Roadmap for Exchange Features.

New to Exchange?

Before deploying Exchange 2010, your existing infrastructure must meet certain prerequisites. To help you plan the deployment of Exchange 2010 into your production environment, read Planning for Exchange 2010.

Upgrading from Exchange 2007?

Before you go too far in your planning for Exchange 2010, make sure your current Exchange Server 2007 organization meets the requirements for upgrading. To learn about planning considerations and configuration steps for upgrading from Exchange 2007 to Exchange 2010, read Exchange 2007 - Planning Roadmap for Upgrade and Coexistence.

Upgrading from Exchange 2003?

You can deploy Exchange 2010 in an existing Exchange Server 2003 organization that's operating in native mode. Coexistence between these two versions is supported. To learn about planning considerations and configuration steps for deploying Exchange 2003 and Exchange 2010 in a coexistence scenario, read Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

Moving to the cloud?

Exchange 2010 SP2 offers organizations the ability to extend the feature-rich experience and administrative control they have with their existing on-premises Exchange 2003, Exchange 2007, or Exchange 2010 organization to the cloud via a hybrid deployment. Hybrid deployments provide the seamless look and feel of a single Exchange organization between an on-premises organization and a cloud-based organization. In addition, hybrid deployments can serve as an intermediate step to moving completely to a cloud-based Exchange organization. For more information, see Hybrid Deployments.

1.1.1 Exchange Server 2010 Documentation Updates

Exchange Server 2010 Documentation Updates

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2013-02-04*

In response to the feedback we get from you, our customers, the Exchange Server documentation team is pleased to announce the following additions and changes to our content.

January 2013

- **New Content**

  Determine the Exchange Schema Version
  Understanding the Impact of Named Property and Replica Identifier Limits on Exchange Databases

- **Updated Content**

Account Information
Configure the Availability Service for Cross-Forest Topologies
Create a Managed Custom Folder
Determine the Exchange Schema Version
Discontinued Features
Exchange Server Supportability Matrix
HTTP Connectivity with Autodiscover - Unexpected Exception
Implement a Single Sign-On Solution for Live@edu
Issues That Are Fixed in Exchange 2010 SP3

1.1.2 What's New in Exchange 2010 SP3

What's New in Exchange 2010 SP3

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2013-02-20*

This topic provides you with an overview of important new features and functionality in Service Pack 3 (SP3) for Microsoft Exchange Server 2010. This overview can be useful when you're planning, deploying, and administering your organization. The following sections include information about changes to features and functionality that have occurred since the release of Microsoft Exchange Server 2010 Service Pack 2 (SP2):

- Exchange 2013 Coexistence support
- Sent Items Management feature
- Windows Server 2012

In addition to the changes described in this topic, Exchange 2010 SP3 also includes fixes that address issues identified since the release of Exchange 2010 SP2. For a complete list of issues that are fixed in Exchange 2010 SP3, see Issues That Are Fixed in Exchange 2010 SP3. If you're also interested in the release notes for Exchange 2010 SP3, see Release Notes for Exchange Server 2010 SP3.

For more information about the features introduced in previous versions of Exchange 2010, see the following topics:

- What's New in Exchange 2010
- What's New in Exchange 2010 SP1
- What's New in Exchange 2010 SP2

Exchange 2013 Coexistence support

You must install Exchange 2010 SP3 if you want to run Microsoft Exchange Server 2013 in a coexistence mode. You can't perform an in-place upgrade from Exchange 2010 to Exchange 2013. However, you can install an Exchange 2013 CU1 server in the existing Exchange 2010 organization after you install Exchange 2010 SP 3. For more information about how to install an Exchange 2013 server in the existing organization, see Install Exchange 2013 in an Existing Exchange 2010 Organization.

After you perform this procedure, your organization will be running in a coexistence mode. You can maintain this mode indefinitely, or you can immediately complete the upgrade to Exchange 2013 by moving all resources from Exchange 2010 to Exchange 2013, and then decommissioning the Exchange 2010 servers. For more information about how to upgrade to Exchange 2013, see Upgrade from Exchange 2010 to Exchange 2013.

Sent Items Management feature

Exchange 2010 SP3 introduces the Sent Items Management feature to Office Outlook Web Access (OWA). The Sent Items Management feature provides control over whether an item that is "sent as" you, or "on behalf of" you, is copied to your **Sent Items** folder and to the sender's **Sent Items** folder. Before Exchange 2010 SP3, messages that are "sent as" you or "on behalf of" you are copied only to the sender's **Sent Items** folder.

You can configure the Sent Items Management feature in OWA on the **Options** page. After Exchange 2010 SP3 is installed, the **Sent Items Options** settings will be available on the **Options** page in OWA.

Windows Server 2012

Exchange 2010 SP3 can be used together with Windows Server 2012. For more information about operating system supportability, see Exchange Server Supportability Matrix.

1.1.2.1 Release Notes for Exchange Server 2010 SP3

Release Notes for Exchange Server 2010 SP3

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2013-02-26*

For important legal information, see "Legal Notice" later in this document.

Welcome to Service Pack 3 (SP3) for Microsoft Exchange Server 2010. This document contains the following sections:

- Installing Exchange 2010 SP3
- Database Schema Upgrades
- Legal Notice

Installing Exchange 2010 SP3

Consider the following when you deploy Exchange 2010 SP3:

- Exchange 2010 SP3 makes updates to the Active Directory schema. To learn more about these schema changes, see Exchange Server Changes to the Active Directory Schema.
- You can select an option that installs the required Windows operating system roles and features for each selected Exchange 2010 SP3 server role.
- You can install Exchange 2010 SP3 only on computers that are running Windows Server 2008 with Service Pack 2 (SP2), Windows Server 2008 R2, or Windows Server 2012.

For detailed information about the requirements and steps for installing Exchange 2010 SP3, see the following topics:

- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements
- Understanding a New Installation of Exchange 2010
- Understanding Upgrade to Exchange 2010

Database Schema Upgrades

The database schema has been updated in Exchange 2010 SP3. As a result, when Mailbox servers are upgraded to Exchange 2010 SP3, the databases are upgraded to the Exchange 2010 SP3 version of the database schema. After a database has been updated to the Exchange 2010 SP3 schema, it can't be mounted on a pre-Exchange 2010 SP3 Mailbox server.

The database schema upgrade process adds time to the overall service pack upgrade process. During the upgrade, the database is dismounted, and all mailboxes in that database are taken offline. If you're upgrading the Mailbox server from the release to

manufacturing (RTM) version of Exchange 2010 to Exchange 2010 SP3, the database upgrade process could take an additional 30 minutes or longer per database. This is because the upgrade process converts each database from Microsoft Exchange Server 2010 RTM to Microsoft Exchange Server 2010 SP1, from Exchange 2010 SP1 to Exchange 2010 SP2, and then from Exchange 2010 SP2 to Exchange 2010 SP3. If you're upgrading from Exchange 2010 SP2 to Exchange 2010 SP3, the upgrade process takes less time. You can track the progress of the database upgrade process by examining event **1185** in the **Application** event log on the server you're upgrading.

A database availability group (DAG) member that’s running an older version of Exchange 2010 can move its active databases to a DAG member running a newer version of Exchange 2010, but can’t do the reverse. After a DAG member has been upgraded to a newer Exchange 2010 service pack, its active database copies can't be moved to another DAG member that’s running Exchange 2010 RTM or to a service pack that's older than the service pack installed on the DAG member.

Legal Notice

1.1.2.2 Issues That Are Fixed in Exchange 2010 SP3

Issues That Are Fixed in Exchange 2010 SP3

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP3 >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2013-01-25*

This topic lists the issues that are fixed in Microsoft Exchange Server 2010 Service Pack 3 (SP3). For more information about Exchange 2010 SP3, see the following topics:

- To learn more about the new features in Exchange 2010 SP3, see What's New in Exchange 2010 SP3.
- To learn more about known issues that affect Exchange 2010 SP3, see Release Notes for Exchange Server 2010 SP3.
- To obtain Exchange 2010 SP3, see Exchange Server 2010 Service Pack 3.

Issues that are fixed

Exchange 2010 SP3 includes the changes that were made in the following Exchange 2010 SP2 rollups:

- Description of Update Rollup 1 for Exchange Server 2010 Service Pack 2
- Description of Update Rollup 2 for Exchange Server 2010 Service Pack 2
- Description of Update Rollup 3 for Exchange Server 2010 Service Pack 2
- Description of Update Rollup 4 for Exchange Server 2010 Service Pack 2
- Description of Update Rollup 4 Version 2 for Exchange Server 2010 SP2
- Description of Update Rollup 5 version 2 for Exchange Server 2010 Service Pack 2

1.1.3 What's New in Exchange 2010 SP2

What's New in Exchange 2010 SP2

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-11*

This topic provides you with an overview of important new features and functionality in Service Pack 2 (SP2) for Microsoft Exchange Server 2010, which can be useful when you're planning, deploying, and administering your organization. The following sections include information about changes to features and functionality that has occurred since Service Pack 1 (SP1) for Exchange 2010:

- Hybrid Configuration Wizard
- Federated Delegation
- Address Book Policies
- Cross-Site Silent Redirection for Outlook Web App
- Mini Version of Outlook Web App
- Mailbox Replication Service
- Mailbox Auto-Mapping
- Multi-Valued Custom Attributes
- Litigation Hold
- Multi-Tenant Support

In addition to the changes described in this topic, Exchange 2010 SP2 also includes fixes that address issues identified since the release of Exchange 2010 SP1. For a complete list of issues fixed in Exchange 2010 SP2, see Issues That Are Fixed in Exchange 2010 SP2. If

you're also interested in the release notes for Exchange 2010 SP2, see Release Notes for Exchange Server 2010 SP2.

For more information about the features introduced in previous versions of Exchange 2010, see the following topics:

- What's New in Exchange 2010
- What's New in Exchange 2010 SP1

Hybrid Configuration Wizard

Exchange 2010 SP2 introduces the Hybrid Configuration Wizard which provides you with a streamlined process to configure a hybrid deployment between on-premises and Office 365 Exchange organizations. Hybrid deployments provide the seamless look and feel of a single Exchange organization and offer administrators the ability to extend the feature-rich experience and administrative control of an on-premises organization to the cloud. For more information, see Understanding the Hybrid Configuration Wizard.

Federated Delegation

In Exchange 2010 SP1, we recommended that organizations create a sub-domain of "exchangedelegation" for the account namespace in their federation trust with the Microsoft Federation Gateway. Now, in Exchange 2010 SP2, we have updated our recommendation and also automated the configuration process. If you use the Manage Federation or Manage Hybrid Configuration wizards when configuring a new federation trust, a pre-defined string is now automatically combined with an accepted domain for your organization and assigned as the account namespace for the federation trust. The account namespace for an existing federation trust is not modified by these wizards. For more information, see Understanding Federation.

Address Book Policies

Exchange 2010 SP2 introduces the address book policy object which can be assigned to a mailbox user. The ABP determines the global address list (GAL), offline address book (OAB), room list, and address lists that are visible to the mailbox user that is assigned the policy. Address book policies provide a simpler mechanism to accomplish GAL separation for the on-premises organization that needs to run disparate GALs. For more information, see Understanding Address Book Policies.

Cross-Site Silent Redirection for Outlook Web App

With Exchange 2010 SP2, you can enable a silent redirection when a Client Access server receives a client request that is better serviced by a Client Access server located in another Active Directory site. This silent redirection can also provide a single sign-on experience when forms-based authentication is enabled on each Client Access server. For more information, see Understanding Proxying and Redirection.

Mini Version of Outlook Web App

The mini version of Outlook Web App is a lightweight browser-based client, similar to the Outlook Mobile Access client in Exchange 2003. It's designed to be used on a mobile operating system. The mini version of Outlook Web App provides users with the following basic functionality:

- Access to e-mail, calendar, contacts, tasks and the global address list.
- Access to e-mail subfolders.
- Compose, reply to, and forward e-mail messages.
- Create and edit calendar, contact, and task items.
- Handle meeting requests.
- Set the time zone and automatic reply messages.

For more information, see Understanding the Mini Version of Outlook Web App.

Mailbox Replication Service

In Exchange 2010 SP1, if you wanted to move mailboxes from on-premises to Outlook.com or to another forest, you had to enable MRSProxy on the remote Client Access server. To do this, you had to manually configure the web.config file on every Client Access server. In Exchange 2010 SP2, two parameters have been added to the **New-WebServicesVirtualDirectory** and **Set-WebServicesVirtualDirectory** cmdlets so that you don't have to perform the manual configuration: *MRSProxyEnabled* and *MaxMRSProxyConnections*. For more information, see Start the MRSProxy Service on a Remote Client Access Server.

Mailbox Auto-Mapping

In Exchange 2010 SP1, Office Outlook 2007 and Outlook 2010 clients can automatically map to any mailbox to which a user has Full Access permissions. If a user is granted Full Access permissions to another user's mailbox or to a shared mailbox, Outlook, through Autodiscover, automatically loads all mailboxes to which the user has full access. However, if the user has full access to a large number of mailboxes, performance issues may occur when starting Outlook. Therefore, in Exchange 2010 SP2, administrators can turn off the auto-mapping feature by setting the value of the new *Automapping* parameter to `$false` on the **Add-MailboxPermission** cmdlets. For more information, see Disable Outlook Auto-Mapping with Full Access Mailboxes.

Multi-Valued Custom Attributes

Exchange 2010 SP2 introduces five new multi-value custom attributes that you can use to store additional information for mail recipient objects. The *ExtensionCustomAttribute1* to *ExtensionCustomAttribute5* parameters can each hold up to 1,300 values. You can specify multiple values as a comma-delimited list.The following cmdlets support these new parameters:

- **Set-DistributionGroup**
- **Set-DynamicDistributionGroup**
- **Set-Mailbox**
- **Set-MailContact**
- **Set-MailPublicFolder**
- **Set-RemoteMailbox**

Litigation Hold

In Exchange 2010 SP2, you can’t disable or remove a mailbox that has been placed on litigation hold. To bypass this restriction, you must either remove litigation hold from the mailbox, or use the new *IgnoreLegalHold* switch parameter when removing or disabling the mailbox. The *IgnoreLegalHold* parameter has been added to the following cmdlets:

- **Disable-Mailbox**
- **Remove-Mailbox**
- **Disable-RemoteMailbox**

- **Remove-RemoteMailbox**
- **Disable-MailUser**
- **Remove-MailUser**

Multi-Tenant Support

Exchange 2010 SP1 introduced the ability to install in a hosting mode by using the /`hosting` switch when running the installation script. However, in Exchange 2010 SP2, we no longer recommend installing Exchange using the /`hosting` switch. To learn more, see Multi-Tenant Support.

1.1.3.1 Release Notes for Exchange Server 2010 SP2

Release Notes for Exchange Server 2010 SP2

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP2 >

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-12*

For important legal information, see Legal Notice later in this document.

Welcome to Service Pack 2 (SP2) for Microsoft Exchange Server 2010. This document contains the following sections:

Installing Exchange 2010 SP2

Consider the following when you deploy Exchange 2010 SP2:

- Exchange 2010 SP2 makes updates to the Active Directory schema. To learn more about these schema changes, see Exchange Server Changes to the Active Directory Schema.
- You can select an option that installs the required Windows operating system roles and features for each selected Exchange 2010 SP2 server role.
- You can only install Exchange 2010 SP2 on computers running the Windows Server 2008 operating system with Service Pack 2 (SP2) and the Windows Server 2008 R2 operating system.

For detailed information about the requirements and steps for installing Exchange 2010 SP2, see the following topics:

- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements
- Understanding a New Installation of Exchange 2010
- Understanding Upgrade to Exchange 2010

Setup

When you upgrade from a previous version of Exchange 2010 to Exchange 2010 SP2 and you've previously defined the execution policy of Windows PowerShell scripts using group policies, Setup will fail. After Setup fails, Exchange 2010 will no longer work on the affected server and you won't be able to restart Setup.

This issue happens because a required service is stopped by Setup during installation. This service is needed to query Active Directory Domain Services to verify the execution policy of Windows PowerShell scripts that must run as part of Setup.

To avoid this issue, do the following:

1. Use the **Group Policy Management Console** to disable the group policy. The Windows PowerShell execution policy group policy objects must be set to **Undefined**.
2. Install Exchange 2010 SP2.
3. Re-enable the previously defined Windows PowerShell execution policy through the **Group Policy Management Console**.

For more information about this issue, or if you've already run Setup and have encountered an error, see Microsoft Knowledge Base article 2668686, Error message when you try to install Exchange Server 2010 SP2: "AuthorizationManager check failed".

Database Schema Upgrades

The database schema has been updated in Exchange 2010 SP2. As a result, when Mailbox servers are upgraded to Exchange 2010 SP2, the databases are upgraded to the Exchange 2010 SP2 version of the database schema. After a database has been updated to the Exchange 2010 SP2 schema, it can't be mounted on a pre-Exchange 2010 SP2 Mailbox server.

The database schema upgrade process adds time to the overall service pack upgrade process. During the upgrade, the database is dismounted and all mailboxes in that database are taken offline. If you're upgrading the Mailbox server from the release to manufacturing (RTM) version of Exchange 2010 to Exchange 2010 SP2, the database upgrade process could take an additional 30 minutes or longer per database. This is because the upgrade process converts each database from Microsoft Exchange Server 2010 RTM to Microsoft Exchange Server 2010 SP1, and then from Exchange 2010 SP1 to Exchange 2010 SP2. If you're upgrading from Exchange 2010 SP1 to Exchange 2010 SP2, the upgrade process takes less time. You can track the progress of the database upgrade process by examining event **1185** in the **Application** event log on the server you're upgrading.

A database availability group (DAG) member running an older version of Exchange 2010 can move its active databases to a DAG member running a newer version of Exchange 2010, but not the reverse. After a DAG member has been upgraded to a newer Exchange 2010 service pack, its active database copies can't be moved to another DAG member running Exchange 2010 RTM or a service pack that's older than the service pack installed on the DAG member.

Client Access Server Prerequisite Changes

Several new prerequisites have been added when installing the Client Access server role. Prior to installing Exchange 2010 SP2, you must install these new prerequisites on servers that have the Client Access server role installed. If the prerequisites aren't installed, Setup will fail.

To install the prerequisites on Client Access servers, do the following:

Windows Server 2008 SP2

1. Open **Server Manager**.
2. Select **Roles**.
3. Under **Web Server (IIS)**, select **Add Role Services**.
4. In the **Add Role Services** wizard, on the **Select Role Services** page, select the following Windows features:
   - **IIS 6 WMI Compatibility**
   - **ASP.NET**
   - **ISAPI Filters**
   - **Client Certificate Mapping Authentication**
   - **Directory Browsing**
   - **HTTP Errors**
   - **HTTP Logging**
   - **HTTP Redirection**
   - **Tracing**
   - **Request Monitor**
   - **Static Content**
5. Click **Next** and then **Install**.

Windows Server 2008 R2

1. On the **Start** menu, navigate to **All Programs** > **Accessories** > **Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following command:

   ```
   Import-Module ServerManager
   ```

2. Add the prerequisites by running the following command:

   ```
   Add-WindowsFeature Web-WMI,Web-Asp-Net,Web-ISAPI-Filter,Web-Client-Aut
   ```

If you want Exchange to install the new prerequisites during Setup, you can use unattended mode. Run the following command:

```
Setup /Mode:Upgrade /InstallWindowsComponents
```

Role Based Access Control

When you first install Exchange 2010 SP2 on an Exchange 2010 server in your organization, some Role Based Access Control (RBAC) management role definitions are updated in Active Directory. If you have multiple Exchange 2010 servers and you attempt to manage these roles from an Exchange 2010 server that hasn't been upgraded to Exchange 2010 SP2, you might receive one of the following warnings:

- Exchange Management Shell
  WARNING: The object MyMailboxDelegation has been corrupted, and it's in an inconsistent state. The following validation errors happened:
  WARNING: The property value you specified, "15", isn't defined in the Enum type "ScopeType".
- Exchange 2010 Control Panel
  There are multiple warnings. Click here to see more
  The object MyMailboxDelegation has been corrupted, and it's in an inconsistent state. The following validation errors happened:
  The property value you specified, "15", isn't defined in the Enum type "ScopeType".

To resolve the warnings, upgrade the server to Exchange 2010 SP2. The cause of these warnings doesn't prevent Exchange 2010 from functioning correctly and can safely be ignored until the server is upgraded to Exchange 2010 SP2.

Outlook Web App

If you're using redirection for Outlook Web App and aren't requiring Secure Sockets Layer (SSL), redirection will fail after the Client Access server is upgraded to Exchange 2010 SP2. To avoid this problem, after you've completed the upgrade to Exchange 2010 SP2, modify the Outlook Web App web.config file. For directions, go to "Use IIS Manager and Notepad to simplify the Outlook Web App URL when SSL isn't required" in Simplify the Outlook Web App URL. You don't have to make any changes in IIS Manager to prevent redirection from failing. You just have to modify the web.config file.

Mailbox Replication Proxy

When you upgrade to Exchange 2010 SP2, the Mailbox Replication Proxy (MRSProxy) service is disabled by Exchange if it was previously enabled. This happens because the way MRSProxy is enabled has changed in Exchange 2010 SP2 and the settings in the <Exchange Installation Path>\V14\ClientAccess\ExchWeb\EWS\web.config file are not migrated during the upgrade. Until MRSProxy is re-enabled, cross-forest mailbox move requests will not be processed.

In Exchange 2010 SP2, MRSProxy is enabled by using the *MRSProxyEnabled* parameter on the **Set-WebServicesVirtualDirectory** cmdlet. You must manually enable MRSProxy after you upgrade to Exchange 2010 SP2. MRSProxy must be manually re-enabled on each server where it was previously enabled. For more information about how to enable MRSProxy in Exchange 2010 SP2, see Start the MRSProxy Service on a Remote Client Access Server.

Prior to Exchange 2010 SP2, MRSProxy configuration was stored in the *<Exchange Installation Path>*\V14\ClientAccess\ExchWeb\EWS\web.config file. The settings stored in this file are no longer used by MRSProxy in Exchange 2010 SP2 and should not be changed.

Shadow Redundancy Promotion Feature

When you install Service Pack 2 for Exchange 2010, the value of the Shadow Redundancy Promotion feature is reset to False, and the setting is disabled.

If you enabled Shadow Redundancy in your Exchange 2010 SP1 organization, you must re-enable Shadow Redundancy after you install Exchange 2010 SP2. Note that other settings in EdgeTransport.exe.config are not reset when you install Exchange 2010 SP2.

1.1.3.2 Issues That Are Fixed in Exchange 2010 SP2

Issues That Are Fixed in Exchange 2010 SP2

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP2 >

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-29*

This topic provides the list of issues that are fixed in Microsoft Exchange Server 2010 Service Pack 2 (SP2). For additional information about Exchange Server 2010 SP2, see the following:

- To learn more about the new features in Exchange Server 2010 SP2, see What's New in Exchange 2010 SP2.
- To learn more about known issues with SP2, see Release Notes for Exchange Server 2010 SP2.
- To obtain Exchange Server 2010 SP2, see Exchange Server 2010 Service Pack 2.

Issues that are Fixed

Exchange 2010 SP2 includes the changes made in the following Exchange 2010 SP1 rollups:

- Update Rollup 6 for Exchange Server 2010 Service Pack 1
- Update Rollup 5 for Exchange Server 2010 Service Pack 1
- Update Rollup 4 for Exchange Server 2010 Service Pack 1
- Update Rollup 3 for Exchange Server 2010 Service Pack 1
- Update Rollup 2 for Exchange Server 2010 Service Pack 1
- Update Rollup 1 for Exchange Server 2010 Service Pack 1

1.1.3.3 Multi-Tenant Support

Multi-Tenant Support

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-01*

A multi-tenant Exchange deployment is defined in this topic as one where the system has been configured to host multiple and discrete organizations or business units (the tenants) that ordinarily don't share e-mail, data, users, global address lists (GALs), or any other commonly used Exchange objects.

In Exchange 2010 Service Pack 1 (SP1), Exchange introduced the ability to install in a hosting mode by using the `/hosting` switch when running the installation script. However, in Exchange 2010 SP2, we no longer recommend installing Exchange using the `/hosting` switch. To learn more, see the Exchange Team Blog article Future of /Hosting Mode.

In Exchange 2010 SP2, hosting is supported by using the on-premises Exchange installation. For guidance about configuring a multi-tenant organization with Exchange 2010 SP2, download the white paper Multi-Tenancy and Hosting Guidance for Exchange Server 2010 SP2. This paper doesn't provide step-by-step instructions about how to achieve multi-tenancy with Exchange 2010 SP2. Instead, it provides information about the challenges and problems that must be solved, and offers advice and direction to ensure the Exchange environment you build can be supported by Microsoft.

1.1.4 What's New in Exchange 2010 SP1

What's New in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2012-07-23*

This topic provides you with an overview of important new features and functionality in Exchange Server 2010 Service Pack 1 (SP1), which you can use when you're planning, deploying, and administering your organization. The following sections include information about changes to features and functionality that has occurred since Exchange Server 2010 RTM (release to manufacturing) and information about features and functionality first introduced in Exchange 2010 SP1. For more information about the features and functionality that was introduced at Exchange 2010 RTM, see What's New in Exchange 2010.

For information about known issues with Exchange 2010 SP1, see Release Notes for Exchange Server 2010 SP1.

In addition to the changes described in this topic, Exchange 2010 SP1 also includes fixes that address issues identified since the release of Exchange 2010 RTM. For a complete list, see Issues That Are Fixed in Exchange 2010 SP1.

New Deployment Functionality

During an Exchange 2010 SP1 installation, you can now select a new option to install the required Windows roles and features for each selected Exchange 2010 SP1 server role. For more information, see New Deployment Functionality in Exchange 2010 SP1.

Client Access Server Role Improvements

The improvements and new features in the Client Access server role fall under several key areas: Federation certificates, Exchange ActiveSync, SMS Sync, Integrated Rights Management, Microsoft Office Outlook Web App, and virtual directories. Each area is described in more detail in the following sections.

Federation Certificates

In Exchange 2010 SP1, you can use a self-signed certificate instead of a certificate issued by a Certificate Authority to establish a federation trust with the Microsoft Federation Gateway. A self-signed certificate is automatically created and installed on Exchange servers in your organization when you use the **New Federation Trust** wizard in the Exchange Management Console. For more information, see Understanding Federation.

Exchange ActiveSync

In Exchange 2010 SP1, you can manage Exchange ActiveSync devices using the Exchange Control Panel (ECP). Administrators can perform the following tasks:

- Manage the default access level for all mobile phones and devices.
- Set up e-mail alerts when a mobile phone or device is quarantined.
- Personalize the message that users receive when their mobile phone or device is either recognized or quarantined.
- Provide a list of quarantined mobile phones or devices.
- Create and manage Exchange ActiveSync device access rules.
- Allow or block a specific mobile phone or device for a specific user.

For every user, the administrator can perform the following tasks from the user's property pages:

- List the mobile phones or devices for a specific user.
- Initiate remote wipes on mobile phones or devices.
- Remove old mobile phone or device partnerships.
- Create a rule for all users of a specific mobile phone or device or mobile phone type.
- Allow or block a specific mobile phone or device for the specific user.

For more information, see Understanding Exchange ActiveSync.

SMS Sync

SMS Sync is a new feature in Exchange ActiveSync that works with Windows Mobile 6.1 with the Outlook Mobile Update and with Windows Mobile 6.5. SMS Sync is the ability to synchronize messages between a mobile phone or device and an Exchange 2010 Inbox. When synchronizing a Windows Mobile phone with an Exchange 2010 mailbox, users can choose to synchronize their text messages in addition to their Inbox, Calendar, Contacts, Tasks, and Notes. When synchronizing text messages, users will be able to send and receive text messages from their Inbox. This feature is dependent on the user's mobile phones or devices supporting this feature.

Server-Side Information Rights Management Support

Exchange ActiveSync mailbox policies now contain support for Information Rights Management (IRM) functionality. Information Rights Management is enabled when creating a new Exchange ActiveSync mailbox policy. This new functionality allows non-Windows Mobile devices to receive and view protected e-mails. When the *IRMEnabled* property is configured on the Exchange ActiveSync mailbox policy and IRM is enabled for Client Access Servers, the protected e-mail will be decrypted on the server before it is downloaded to the mobile phone or device. The downloaded e-mail will be downloaded

with additional properties that indicate the restrictions sent with the original e-mail. Protected messages will only be decrypted and downloaded if the mobile phone or device connects to the Client Access server using Secure Sockets Layer (SSL).

Outlook Web App Improvements

The following is a list of the new Outlook Web App functionality in Exchange 2010 SP1:

- Improved management of the relationship between Office Communications Server and Outlook Web App. Configuration is stored in Active Directory instead of a web.config file and can be managed via cmdlet.
- Twenty-seven themes are available, and they have new administrative options:
  - Set default theme with the *DefaultTheme* parameter by using either the Set-OwaMailboxPolicy or the Set-OwaVirtualDirectory cmdlet.
  - Create custom themes by modifying existing themes.
  - Control the order themes are listed in Outlook Web App.
- By default, attachment types that are marked as **Force Save** will be excluded from security checks for XML or HTML. You can change this behavior by setting the *ForceSaveAttachmentFilteringEnabled* parameter to `$true` by using either the Set-OwaMailboxPolicy or the Set-OwaVirtualDirectory cmdlet.
- Users can change unexpired passwords by default. In Exchange 2010 SP1, you can also enable users to reset expired passwords. See Configuring the Change Password Feature in Outlook Web App.

Reset Virtual Directory

In Exchange 2010 SP1, you can use the new Reset Client Access Virtual Directory wizard to reset one or more Client Access server virtual directories. The new wizard makes it easier to reset a Client Access server virtual directory. One reason that you might want to reset a Client Access server virtual directory is to resolve an issue related to a damaged file on a virtual directory. In addition to resetting virtual directories, the wizard creates a log file that includes the settings for each virtual directory that you choose to reset. For more information, see Reset Client Access Virtual Directories.

Client Throttling Policies

You can use client throttling policies to help you manage performance of your Client Access servers. Consider the following changes as you use client throttling policies to manage performance when running Exchange 2010 SP1.

- In Exchange 2010 RTM, only the policies to limit the number of concurrent client connections were enabled by default. In Exchange 2010 SP1, all client throttling policies are enabled by default.
- In Exchange 2010 RTM, when the thresholds defined on a latency-based client throttling policy parameter such as *EWSPercentTimeInCAS* were exceeded, Exchange would cause the transactions and connections to fail. In Exchange 2010 SP1, exceeding the thresholds defined on a latency-based throttling policy parameter will not cause a failure. Instead, Exchange will delay transactions and connections until the transaction rate is within the policy limits. Such transaction and connection delays will usually not be apparent to end users. Client throttling policy parameters with a hard quota limits such as *EWSMaxSubscriptions* will cause a failure when exceeded. As an administrator, you can monitor the impact of your performance policies and make adjustments as needed.
- Two new cmdlets, **Get-ThrottlingPolicyAssociation** and **Set-ThrottlingPolicyAssociation,** help you manage and apply client throttling polices to specific objects.

For more information, see Understanding Client Throttling Policies and Managing Performance with Client Throttling Policies.

Improvements in Transport Functionality

The following is a list of new Transport functionality in Exchange 2010 SP1:

- MailTips access control over organizational relationships
- Enhanced monitoring and troubleshooting features for MailTips
- Enhanced monitoring and troubleshooting features for message tracking
- Message throttling enhancements
- Shadow redundancy promotion
- SMTP failover and load balancing improvements
- Support for extended protection on SMTP connections
- Send connector changes to reduce NDRs over well-defined connections

For more information and details about these changes, see New Transport Functionality in Exchange 2010 SP1.

Permissions Functionality

The following is a brief description of new permissions features and enhancements in Exchange 2010 SP1:

- **Database scope support** With database scopes, you can control which databases mailboxes can be created for a given set of administrators and also control which databases they can manage. For more information about database scopes, see Understanding Management Role Scopes.
- **Active Directory split permissions** Active Directory split permissions enable you to completely separate the administrative capabilities of Exchange administrators from your Active Directory administrators. The ability to create and remove Active Directory users and groups and manage non-Exchange attributes of Active Directory objects by Exchange administrators and servers has been removed in Exchange 2010 SP1. For more information about Active Directory split permissions, see Understanding Split Permissions.
- **Improved user interface** You can now create and manage management role groups and management role assignment policies in the Exchange Control Panel (ECP). This includes adding and removing management roles to role groups and role assignment policies, adding and removing members to and from role groups, and assigning users to role assignment policies. For more information about how to manage role groups and role assignment policies, see the following topics:
  - Managing Administrator and Specialist Users
  - Managing End Users

Exchange Store and Mailbox Database Functionality

The following is a list of new store and mailbox database functionality in Exchange 2010 SP1:

- With the **New-MailboxRepairRequest** cmdlet, you can detect and repair mailbox and database corruption issues.
- Store limits were increased for administrative access.
- The Database Log Growth Troubleshooter (Troubleshoot-DatabaseSpace.ps1) is a new script that allows you to control excessive log growth of mailbox databases.
- Public Folders client permissions support was added to the Exchange Management Console (EMC).

For more information and details about each of these features, see New Exchange Core Store Functionality in Exchange 2010 SP1.

Mailbox and Recipients Functionality

The following is a list of new mailbox and recipient functionality included in Exchange 2010 SP1:

- In Outlook 2010 and Outlook 2007, Autodiscover automatically loads any mailbox for which a user has been granted full access permission. Users can't control or disable this behavior.
- Calendar Repair Assistant supports more scenarios than were available in Exchange 2010 RTM.
- Mailbox Assistants are now all throttle-based (changed from time-based in Exchange 2010 RTM).
- Internet calendar publishing allows users in your Exchange organization to share their Outlook calendars with a broad Internet audience.
- Importing and exporting .pst files now uses the Mailbox Replication service and doesn't require Outlook.
- Hierarchical address book support allows you to create and configure your address lists and offline address books in a hierarchical view.
- Distribution group naming policies allow you to configure string text that will be appended or prepended to a distribution group's name when it's created.
- Soft-delete of mailboxes after move completion.

For more information and details about these features, see New Mailbox and Recipient Functionality in Exchange 2010 SP1.

High Availability and Site Resilience Functionality

The following is a list of new high availability and site resilience functionality included in Exchange 2010 SP1:

- Continuous replication - block mode
- Active mailbox database redistribution
- Enhanced datacenter activation coordination mode support
- New and enhanced management and monitoring scripts
- Exchange Management Console user interface enhancements
- Improvements in failover performance

For more information about these features, see New High Availability and Site Resilience Functionality in Exchange 2010 SP1.

Messaging Policy and Compliance Functionality

The following is a list of new messaging policy and compliance functionality included in Exchange 2010 SP1:

- Provision personal archive on a different mailbox database
- Import historical mailbox data to personal archive
- Delegate access to personal archive
- New retention policy user interface
- Opt-in personal tags

- Multi-Mailbox Search preview
- Annotations in Multi-Mailbox Search
- Multi-Mailbox Search data de-duplication
- WebReady Document Viewing of IRM-protected messages in Outlook Web App
- IRM in Exchange ActiveSync for protocol-level IRM
- IRM logging
- Mailbox audit logging

For more information and details about each of these features, see New Messaging Policy and Compliance Functionality in Exchange 2010 SP1.

Unified Messaging Server Role Improvements

The Unified Messaging server role has been improved and has added new features in Exchange 2010 SP1. To use some of these features, you must correctly deploy Microsoft Lync Server 2010 in your environment. The following is an overview of all the new features in Exchange 2010 Unified Messaging:

- **UM reporting** The reports for **Call Statistics** and **User Call Logs** found in the Exchange Management Console are displayed in the Exchange Control Panel.
- **UM management in the Exchange Control Panel** You can usethe ECP to manage UM components in a cross-premises environment.
- **Cross-Forest UM-enabled mailbox migration** In Exchange 2010 SP1, you can use the **New-MoveRequest** cmdlet with the Mailbox Replication Service (MRS) to move a UM-enabled mailbox within a local forest and multiple forests in an enterprise.
- **Outlook Voice Access improvements** Outlook Voice Access users can log on to their Exchange 2010 mailbox and choose the order to listen to unread voice mail messages, from the oldest message first or the newest message first.
- **Caller Name Display support** Exchange 2010 SP1 includes support for enhanced caller ID resolution for displaying names for voice mails from unresolved numbers using Caller Name Display (CND).
- **Test-ExchangeUMCallFlow cmdlet** With this Exchange 2010 SP1 cmdlet, you can test UM connectivity and call flow.
- **New UM Dial Plan wizard** An additional page has been added to the **New UM Dial Plan** wizard that allows you to add a UM server to the dial plan.
- **Lync Server 2010 Support** Migrating SIP URI dial plans and Message Waiting Indicator (MWI) notifications in a cross-premises environment has been added.
- **Secondary UM dial plan support** You can add a secondary UM dial plan for a UM-enabled user.
- **UM language packs added** New UM language packs are now available in Exchange 2010 SP1. In addition, the Spanish (Spain) (es-ES) UM language pack available for Exchange 2010 SP1 now includes Voice Mail Preview, a feature that wasn't available in the Exchange 2010 RTM release of that language pack.
- **Call answering rules improvements** There are three updates to Call Answering Rules for UM-enabled users in SP1.
- **Unified Communications Managed API/speech platform improvements** Beginning with Exchange 2010 SP1, the UM server relies on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and speech processing.
- **UM auto attendant update** In Exchange 2010 SP1, a UM auto attendant will play only the holiday greeting on a holiday.

For more information and details about each of these features, see New Unified

Messaging Functionality and Voice Mail Features in Exchange 2010 SP1.

Audit Logging Improvements

Exchange 2010 SP1 provides improvements in functionality related to administrator audit logging and new functionality for mailbox audit logging:

- **Improvements in administrator audit logging** Exchange 2010 enhances the administrator audit logging functionality by providing you with the ability to perform searches of the admin audit log using the Exchange Management Shell. You can search on cmdlet and parameter names, date, the user who ran the command, and more. The results generated by your search can be displayed on the screen or e-mailed to a recipient you specify and viewed as an XML file. And, because all the administrative interfaces run Shell cmdlets in the background, the actions that occur in all the interfaces can be logged. For more information, see Overview of Administrator Audit Logging.
- **New mailbox audit logging** Exchange 2010 SP1 introduces new mailbox audit logging functionality to allow you to track mailbox access by administrators, delegates, and mailbox owners, and actions taken on mailbox items such as moving or deleting a message, using SendAs or SendOnBehalf rights to send messages, and accessing a mailbox folder or a message. You can use the ECP to generate a report of non-owner mailbox access and use the Shell to search mailbox audit logs. For more information, see Understanding Mailbox Audit Logging.
- The Exchange Control Panel also provides several reports which are generated based on the audit logs in Exchange 2010 SP1.

Support for Hybrid Deployments with Exchange Online

Exchange 2010 SP1 includes the following functionality that supports hybrid deployments with Exchange Online:

- **Migration of UM-enabled mailboxes** The New-MoveRequest cmdlet can be used with the Microsoft Exchange Mailbox Replication service (MRS) to move a UM-enabled mailbox within a hybrid deployment.
- **IRM support for hybrid deployments** IRM is fully supported for hybrid deployments. The tenant administrator can export the trusted publishing domain from the on-premises Active Directory Rights Management Services (AD RMS) server and import it to the cloud-based service. This functionality allows IRM-protected messages to be decrypted in the cloud, and cloud mailbox users to send IRM-protected messages that on-premises mailbox users can decrypt and access.
- **Remote Mailboxes** A new set of SP1 cmdlets allow you to create and manage a mail-enabled user in the on-premises Active Directory site and at the same time create and manage the associated mailbox in the cloud-based service. The cmdlets are:
  - New-RemoteMailbox
  - Set-RemoteMailbox
  - Get-RemoteMailbox
  - Enable-RemoteMailbox
  - Disable-RemoteMailbox
  - Remove-RemoteMailbox
- **Transport** Updated features in Transport help ensure that message flow remains protected between users regardless of where their mailboxes are located. Enhanced Transport features such as MailTips, delivery reports, and message moderation also support this deployment scenario.

Support for Multi-Tenancy

With Exchange 2010 SP1 built-in multi-tenant support, service providers that use Microsoft Service Provider Licensing Agreement (SPLA) no longer need a solution such as Microsoft Hosted Messaging and Collaboration version 4.5 to host multiple organizations. Multi-tenant support in Exchange 2010 SP1 provides the core feature set of Microsoft Exchange that can be deployed to multiple customers in a single installation, and it also provides ease of management and flexibility of provided features to end-users.

In addition to including most of the features and functionality available in Exchange 2010 SP1 Enterprise deployments, the multi-tenant solution available for Exchange 2010 SP1 also includes features and functionality that allow you to create and manage tenant organizations. For more information, see Multi-Tenant Support.

1.1.4.1 New Deployment Functionality in Exchange 2010 SP1

New Deployment Functionality in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2010-07-21*

This topic provides a brief overview of the new functionality available for deploying Microsoft Exchange 2010 Service Pack 1 (SP1). During an Exchange 2010 SP1 installation, you can now select a new option to install the required Windows roles and features for each selected Exchange 2010 SP1 server role.

Exchange 2010 SP1 Install

Exchange 2010 SP1 Setup has been improved to allow you to install the required Windows roles and features. If you select the option to install Windows roles and features, progress is shown and the appropriate roles and features are installed. If a reboot is required, you will have to reboot the server and launch Setup again. When Setup is launched again, Setup will resume where it left off. If you don't select the option to install Windows roles and features, you can manually install the Windows roles and features and continue Setup after the prerequisites are met.

Unattended Install

You can now select the */InstallWindowsComponents* parameter during an unattended install of Exchange 2010 SP1. If you select the option to install Windows roles and features, progress is shown and the appropriate roles and features are installed. If a reboot is required, you will have to reboot the server and launch Setup.com again with the */InstallWindowsComponents* parameter. If the Windows roles and features were correctly installed, Setup.com will continue.

Exchange 2010 RTM to Exchange 2010 SP1 Upgrade

When you run Exchange 2010 unattended install to upgrade from the release to manufacturing (RTM) version of Exchange 2010 to Exchange 2010 SP1, you can use the **Setup.com /m:upgrade /installwindowscomponents** command. If a reboot is required,

you will have to reboot the server and again launch **Setup.com /m:upgrade** with the /*InstallWindowsComponents* parameter. If the Windows roles and features were correctly installed, Setup.com will continue.

1.1.4.2 New Mailbox and Recipient Functionality in Exchange 2010 SP1

New Mailbox and Recipient Functionality in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) provides new functionality for Mailbox servers, mailboxes, and recipients. New functionality is available for the following:

- Mailbox full access permission and Outlook Automapping
- Group naming policies
- Mailbox data
- Move requests
- Archive mailboxes
- Hierarchical address books
- Mailbox folder permissions
- Internet calendar publishing
- Calendar Repair Assistant
- Mailbox Assistants service troubleshooter

Mailbox Full Access Permission and Outlook Automapping

In Microsoft Office Outlook 2010 and Outlook 2007, Autodiscover automatically maps to any mailbox for which a user has full access permissions. After an administrator grants full access permission for a user to access another user's mailbox or if the user has full access permission to a shared mailbox, Autodiscover automatically loads all mailboxes for which the user has full access permissions. This behavior may cause performance issues when Outlook starts if the user has a large number of mailboxes to which they have full access. For example, in some organizations, Exchange administrators have full access to all users' mailboxes in their organization. If that is the case, Outlook attempts to open all mailboxes in the organization.

Note:
Users can’t control or disable this behavior.

For more information, see Allow Mailbox Access and Manage Full Access Permissions.

Group Naming Policies

A *group naming policy* is a template that you can apply to the name of distribution groups created in the organization. You can enforce the application of a prefix, a suffix, or both to distribution groups. You can also block specific words from being used in distribution group names.

For more information, see Create a Distribution Group Naming Policy.

Mailbox Data

Importing and exporting mailbox data has been improved so that you can import or export .pst files in an asynchronous process using the Microsoft Exchange Mailbox Replication service. The following cmdlets have been added in Exchange 2010 SP1 to support this feature:

- Get-MailboxExportRequest
- Get-MailboxExportRequestStatistics
- New-MailboxExportRequest
- Remove-MailboxExportRequest
- Resume-MailboxExportRequest
- Set-MailboxExportRequest
- Suspend-MailboxExportRequest
- Get-MailboxImportRequest
- Get-MailboxImportRequestStatistics
- New-MailboxImportRequest
- Remove-MailboxImportRequest
- Resume-MailboxImportRequest
- Set-MailboxImportRequest
- Suspend-MailboxImportRequest

For more information, see Understanding Mailbox Import and Export Requests.

Move Requests

New functionality in Exchange 2010 SP1 for move requests includes the following:

- In the release to manufacturing (RTM) version of Exchange 2010, when a mailbox move completed, the mailbox on the source database was deleted and wasn't recoverable. If there was a Mailbox server failover on the target database, the mailbox move was interrupted, and data loss for the in-transit mailbox could occur.
  Exchange 2010 SP1 now soft-deletes the mailbox on the source database, so you can recover the mailbox in the event of a Mailbox server failover or data loss. You can restore a soft-deleted mailbox by using the **MailboxRestoreRequest** cmdlets set.
  These soft-deleted mailboxes are visible when running the Get-MailboxStatistics cmdlet against a database and are identifiable by the property **DisconnectReason** with a value of `SoftDeleted`. The soft-deleted mailboxes will be retained in the source database until either the deleted mailbox retention period expires or the mailbox is purged by using the Remove-StoreMailbox cmdlet. If you're performing mailbox moves to reduce the amount of space being used in a database, you must also perform the additional step of purging the soft-deleted mailboxes. Soft-deleted mailboxes can't be reconnected.

  Note:
  You can't view soft-deleted mailboxes by using the Get-MailboxStatistics cmdlet in Exchange versions earlier than Exchange 2010 SP1.

- The **MoveRequest** cmdlet set has been updated to support moving archives to a separate database. For more information, see Understanding Move Requests.

Archive Mailboxes

You can now have a user's primary mailbox and archive mailbox on separate databases. For more information, see Understanding Personal Archives.

Hierarchical Address Books

With hierarchical address book support, you can create and configure your address lists and offline address books (OABs) in a hierarchical view. For more information, see Understanding Hierarchical Address Books.

Mailbox Folder Permissions

A new cmdlet has been added that you can use to modify the mailbox folder permissions. The Set-MailboxFolderPermission cmdlet updates folder-level permissions for all folders within a user's mailbox. The cmdlet differs from the Add-MailboxFolderPermission cmdlet in that it edits an existing permission entry.

Internet Calendar Publishing

In Exchange 2010 RTM, sharing user calendar information required a federation trust and an organization relationship or sharing policy with another federated organization. Exchange 2010 SP1 introduces Internet calendar publishing so that users in your Exchange organization can share their calendars with anyone that has access to the Internet, and not just with other recipients in other federated Exchange organizations. Highlights of Internet calendar publishing include:

- Federation configuration isn't necessary for your Exchange organization.
- Internet users don't need any type of authentication credentials to access user calendars (for example, Exchange or Windows Live).
- Users can invite their friends, family members, or business partners to view their calendar information by providing a link to their published calendar.
- Exchange administrators can control which users can publish their calendars and what can be shared, both organization-wide and on a per-user basis.
- Internet users can access calendar information without having to use a specific mail client; only an Internet browser is necessary.

For more information about sharing policy and calendar publishing, see the following topics:

- Understanding Federated Delegation
- Configure Sharing Policy Properties
- Create a Sharing Policy

You can use the **Test-CalendarConnectivity** cmdlet to verify that Internet calendar sharing is enabled and working properly. The Calendar virtual directory is a subdirectory of the Exchange Outlook Web App virtual directory.

Calendar Repair Assistant

The Calendar Repair Assistant (CRA), which was introduced in Exchange 2010 RTM, is a mailbox assistant that runs within the Microsoft Exchange Mailbox Assistants service on servers running Exchange 2010 with the Mailbox server role installed. CRA automatically detects and corrects inconsistencies that occur for single and recurring meeting items for mailboxes homed on that Mailbox server so that recipients won't miss meeting announcements or have unreliable meeting information. In Exchange 2010 SP1, the Calendar Repair Assistant checks for and detects the following new scenarios:

- The attendee's calendar is missing an occurrence or an exception of a meeting.
- The attendee's start or end time doesn't match the organizer's start or end time, including time zone inconsistencies.
- The attendee's meeting location is different from the organizer's meeting

location.
- The meeting organizer's calendar is missing an item.
- The attendee's recurrence pattern of a meeting series is different from the organizer's recurrence pattern.

For more information, see Understanding Calendar Repair.

Mailbox Assistants Service Troubleshooter

The **Test-AssistantHealth** cmdlet is a new cmdlet that can help you troubleshoot the health of the Microsoft Exchange Mailbox Assistants service (MSExchangeMailboxAssistants). Use the Test-AssistantHealth cmdlet to verify that the Mailbox Assistants service is healthy, to recover from health issues, and to report the status of the diagnosis or recovery action.

1.1.4.3 New High Availability and Site Resilience Functionality in Exchange 2010 SP1

New High Availability and Site Resilience Functionality in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2012-04-25*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) includes new features, as well as enhancements to features introduced in the release to manufacturing (RTM) version of Exchange 2010. The new and improved features extend the scenarios in which you can achieve data and service availability for your Exchange 2010 environment.

The following new features for high availability and improvements to existing high availability features are available in Exchange 2010 SP1:

- Continuous replication - block mode
- Active mailbox database redistribution
- Enhanced datacenter activation coordination mode support
- New and enhanced management and monitoring scripts
- Exchange Management Console user interface enhancements
- Improvements in failover performance
- Extensible Storage Engine recovery on hung I/O

These features are discussed in greater detail below.

Continuous Replication - Block Mode

In the RTM version of Exchange 2010 and in all versions of Exchange Server 2007, continuous replication operates by shipping copies of the log files generated by the active database copy to the passive database copies. Beginning with Exchange 2010 SP1, this form of continuous replication is known as *continuous replication - file mode*. Exchange 2010 SP1 also introduces a new form of continuous replication known as *continuous replication - block mode*. In block mode, as each update is written to the active database copy's active log buffer, it's also shipped to a log buffer on each of the passive mailbox copies. When the log buffer is full, each database copy builds, inspects, and creates the next log file in the generation sequence. If a failure affects the active copy, the passive copies will have been updated with most or all of the latest updates. The active copy

doesn't wait for replication to complete to preclude replication issues from affecting the client experience.

Continuous replication - block mode is only active when continuous replication is up-to-date in file mode. The transition into and out of block mode is performed automatically by the log copier. Block mode dramatically reduces the latency between the time a change is made on the active copy and when the change is replicated to passive copies. In addition to replicating individual log file writes, block mode also changes the activation process for a passive copy. If a copy is in block mode when a failure occurs, the system uses whatever partial log content is available during the activation process. This eliminates the current log file on the active copy from being a single point of failure.

Active Mailbox Database Redistribution

Exchange 2010 SP1 includes a script called RedistributeActiveDatabases.ps1 that can be periodically run by administrators to balance the distribution of active database copies across a database availability group (DAG) based on administrator-configured activation preference. In addition, copy distribution awareness has been added to the Active Manager best copy selection process. Specifically, the first pass of best copy selection for lossless switchovers now sorts the possible targets by preference instead of least loss.

Enhanced Datacenter Activation Coordination Mode Support

Exchange 2010 RTM includes a configuration mode for DAG site resilience support called Datacenter Activation Coordination (DAC) mode. In DAC mode, Exchange cmdlets can be used to perform a data center switchover. In the RTM version, DAC mode is limited to DAGs with at least three members that have at least two or more members in the primary data center.

In Exchange 2010 SP1, DAC mode has been extended to support two-member DAGs that have each member in a separate data center. DAC mode support for two-member DAGs uses the witness server to provide additional arbitration. In addition, DAC mode has been extended to support DAGs that have all members deployed in a single Active Directory site, including single Active Directory sites that have been extended to multiple locations.

New and Enhanced Management and Monitoring Scripts

Exchange 2010 SP1 includes several new and enhanced scripts that greatly improve the management and monitoring experience:

- **CheckDatabaseRedundancy.ps1** *(new)* You can use this script to check the redundancy of replicated databases, and it will generate events if database resiliency is found to be in a compromised state (for example, there's only one healthy copy of a replicated database). The script is accompanied by a Microsoft System Center Operations Manager 2007 management pack change that can be used to monitor databases without redundancy, which is particularly useful in environments without RAID.
- **StartDagServerMaintenance.ps1 and StopDagServerMaintenance.ps1** *(new)* You can use StartDagServerMaintenance.ps1 to take a DAG member out of service for maintenance. It will move active databases off of the server and block databases from moving to that server. It will also make sure all critical DAG support functionality (for example, the Primary Active Manager PAM role) that might be on the server is moved to another server, and blocked from moving back to the server. Another script, StopDagServerMaintenance.ps1, is

provided to complete the operation and remove the blocks.

- **CollectOverMetrics.ps1** *(enhanced)* You can use this script to collect switchover and failover data. This script has been enhanced in Exchange 2010 SP1 to include metrics for continuous replication - block mode, and more details from the replication and replay pipeline. In addition, it also features enhanced reporting.
- **CollectReplicationMetrics.ps1** *(enhanced)* This script is an active form of monitoring because it collects metrics related to continuous replication in real time while the script is running. The script supports parameters that enable you to customize the script's behavior and output.

Enhanced Exchange Management Console User Interface

Exchange 2010 SP1 includes Exchange Management Console (EMC) enhancements for managing DAGs. For example, the EMC now includes support for managing IP addresses and alternate witness server settings for DAGs. It's no longer necessary to use the Exchange Management Shell to configure these settings.

Improved Failover Performance

Exchange 2010 SP1 includes changes to improve failover and switchover performance and behavior. In the RTM version of Exchange 2010, when either a failover or a switchover occurs, the passive copy being activated immediately stops replaying log files that were copied to that passive copy. The active copy is then dismounted (if it's not already), and any remaining log files are copied to the passive copy being activated. Assuming that any missing data is within the automatic database mount dial setting, the passive copy is made the new active copy and the database is mounted in a dirty shutdown state. At this point, all log files that were copied to the previously passive (and now active) copy will be replayed to make the database consistent.

In Exchange 2010 SP1, when either a failover or a switchover occurs, the Microsoft Exchange Replication service on the passive copy being activated continues to replay log files that have been copied to the passive copy until the last log file generated by the active copy is copied to it. This enables a mount operation to be performed against a database that is in a nearly consistent state.

Other performance-enhancing changes involve time-outs and other algorithmic details to improve failover performance as well as I/O performance after failovers.

Extensible Storage Engine Recovery on Hung I/O

Exchange 2010 SP1 includes new recovery logic that makes use of the built-in Windows bugcheck behavior when certain conditions occur. Specifically, Extensible Storage Engine (ESE) has been updated to detect when I/O is hung and to take corrective action to automatically recover the server. ESE maintains an I/O monitoring thread that detects when an I/O has been outstanding for a specific period of time. By default, if an I/O for a database is outstanding for more than one minute, ESE logs an event. If a database has an I/O outstanding for greater than 4 minutes, ESE logs a specific failure event, if it’s possible to do so. ESE event 507, 508, 509, or 510 may or may not be logged, depending on the nature of the hung I/O. If the problem is such that the operating system volume is affected or the ability to write to the event log is affected, the events aren’t logged. If the events are logged, the Microsoft Exchange Replication service (MSExchangeRepl.exe) intentionally terminates the wininit.exe process to cause a bugcheck of Windows.

In some cases, the entire storage stack may be affected by the hang, making it impossible to write failure events to the crimson channel or any other area of the Windows Event Log. ESE also monitors the crimson channel by verifying that the event log can be written to. If writing to the event log fails for a long period of time, MSExchangeRepl intentionally causes a bugcheck of Windows by terminating wininit.exe. When the operating system I/O is hung, the system is obviously unable to write any ESE events to the event log.

Note:

Applications and Services logs are a new category of event logs in Windows Server 2008. These logs store events from a single application or component rather than events that might have system-wide impact. This new category of event logs is referred to as an application's *crimson channel*. For more information, see Monitoring High Availability and Site Resilience

This new bugcheck-based recovery feature in Exchange 2010 SP1 is designed to make recovery from hung I/O or a hung controller fast, rather than re-trying or waiting until the storage stack raises an error that causes failover. When the bugcheck occurs, the error code reads as follows:

```
CRITICAL_OBJECT_TERMINATION (f4)

A process or thread crucial to system operation has unexpectedly exited or been terminated.
```

Warning:

The presence of this bugcheck error code doesn't necessarily mean that Exchange was the cause of the error. Any termination of wininit.exe, including one performed by an administrator using Task Manager or some other task management tool, will cause the same bugcheck error code.

1.1.4.4 New Messaging Policy and Compliance Functionality in Exchange 2010 SP1

New Messaging Policy and Compliance Functionality in Exchange 2010 SP1

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP1 >

[This topic is in progress.]

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2011-01-26*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) includes new features, as well as enhancements to features that were introduced in the release to manufacturing (RTM) version of Exchange 2010.

This topic provides a brief description of new functionality for existing features and information about new features related to messaging policy and compliance in Exchange 2010 SP1.

Personal Archive Functionality

Personal archive functionality in Exchange 2010 SP1 includes the following:

- **Provision personal archive on a different mailbox database** You can provision a user's personal archive on a different mailbox database than the

one where the user's primary mailbox resides. This capability allows you to implement a tiered storage topology.

- **Import historical mailbox data to archive** You can import historical mailbox data from .pst files directly to the user's personal archive using the **New-MailboxImportRequest** cmdlet in the Shell. Data from .pst files can also be imported to the user's primary mailbox, and both the personal archive and the primary mailbox can be exported to .pst files using the **New-MailboxExportRequest** cmdlet.
- **Delegate access to archive** Delegates can access the delegating user's archive mailbox using Microsoft Office Outlook 2010, in addition to the primary mailbox.

For more information, see Understanding Personal Archives.

Messaging Records Management Functionality

Messaging records management functionality in Exchange 2010 SP1 includes the following:

- **New retention policy management features in EMC** You can use the New Retention Policy Tag and New Retention Policy wizards in the Exchange Management Console (EMC) to manage retention tags and retention policies.
- **Support for Notes default folder** You can also create retention policy tags for the Notes default folder.
- **Default retention and archive policy** The default archive policy and retention policy contains retention tags that move messages to the archive and remove messages from the mailbox after a certain period. The policy is automatically applied to a mailbox user when you provision a personal archive for the user.
- **Opt-in personal tags** Users with a retention policy assigned can use the Exchange Control Panel (ECP) to select personal tags not included in their retention policy. Users can then apply these personal tags to mailbox items and custom folders.

For more information, see Understanding Retention Tags and Retention Policies.

Multi-Mailbox Search Functionality

Multi-Mailbox Search functionality in Exchange 2010 SP1 includes the following:

- **Multi-Mailbox Search preview** In Exchange 2010 SP1, discovery managers (that is, users who are members of the Discovery Management management role group) can get an estimate of the number of items returned by a discovery search before the items are copied to the selected discovery mailbox. This functionality allows discovery managers to view the number of hits the specified keywords return, and then modify the search query, if required, before messages returned by the search are copied to the discovery mailbox.
- **Annotations** Discovery managers can also add annotations to messages returned by the discovery search.
- **Data de-duplication** Multi-Mailbox Search includes the optional data de-duplication feature. When selected, Multi-Mailbox Search copies only a single instance of a message returned across multiple folders within the same mailbox, or across different mailboxes.

For more information, see Understanding Multi-Mailbox Search.

Information Rights Management

Functionality

Information Rights Management (IRM) functionality in Exchange 2010 SP1 includes the following:

- **WebReady Document Viewing of IRM-protected attachments** In Exchange 2010 SP1, IRM in Microsoft Office Outlook Web App supports WebReady Document Viewing of supported IRM-protected attachments, allowing users to view IRM-protected attachments without having to download them. Users can preview IRM-protected documents on computers that don't have Microsoft Office installed. Along with the cross-browser and cross-platform support in Outlook Web App, this functionality extends the reach of IRM to various browsers and operating systems. For more information, see Understanding Information Rights Management in Outlook Web App.
- **IRM in Exchange ActiveSync** IRM in Exchange ActiveSync allows users with supported devices to access IRM-protected messages without first having to activate the device for IRM by tethering the device to a computer. For more information, see Understanding Information Rights Management in Exchange ActiveSync.
- **Cross-organization support** Exchange 2010 SP1 IRM features are supported in cross-organization topologies for easier collaboration between two organizations via OWA.
- **IRM logging** In Exchange 2010 SP1, you can enable logging of IRM features on the Mailbox, Hub Transport, Client Access, and Unified Messaging server roles. IRM logs contain detailed transaction and error information, allowing administrators to easily monitor and troubleshoot IRM features. For more information, see Understanding Information Rights Management Logging.
- **Discovery Manager access to IRM-protected messages in a Discovery mailbox** In Exchange 2010 SP1, you can configure IRM to allow members of the Discovery Management role group to access IRM-protected messages returned by discovery search. For more information, see Understanding Information Rights Management.

Mailbox Audit Logging Functionality

Exchange 2010 SP1 includes new logging functionality that allows you to enable logging of mailbox access. Mailbox audit logging enables you to log access to a mailbox by administrators, delegates, and mailbox owners. Actions taken on mailbox items such as access to a message or a folder, copying, and deletion of a message can be logged. You can search mailbox audit logs for a mailbox, and also generate reports of non-owner access to a mailbox from the Exchange Control Panel.

For more information, see Understanding Mailbox Audit Logging.

1.1.4.5 New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1

New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2012-10-30*

The Unified Messaging server role has been improved in Microsoft Exchange Server 2010 Service Pack 1 (SP1), and new features have been added. To use some of these new

features, you must correctly deploy Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 (the next generation of Office Communications Server) in your environment. This topic discusses the new and improved features that are added when you install Exchange 2010 SP1.

UM Features Found in Exchange 2010 SP1

The following is a list of the new features in Exchange 2010 Unified Messaging (UM) and a description of the features:

- **UM management in the Exchange Control Panel** The UM management user interface in the Exchange Control Panel makes it possible to manage all components of Unified Messaging in a Web browser. You can create UM dial plans, UM mailbox policies, UM IP gateways, and UM auto attendants, and enable users for Unified Messaging. This feature is available to tenant administrators (also called specialists) and to administrators in cross-premises Exchange environments. For details, see Managing Administrator and Specialist Users.
  Administrators can also use the Exchange Control Panel to manage some on-premises and cross-premises tasks. The following is a list of some of the additional administrative features available in the Exchange Control Panel for all server roles, including:
  - Text messaging integration
  - Voice messaging integration
  - Multiple mailbox search
  - Additional proxy addresses for mailboxes
  - Moderation and approval for distribution list submission

  In addition, end users can perform common administrative tasks in the Exchange Control Panel without having to call their helpdesk. This helps them to be more productive and reduces support costs.
  Although the Exchange Control Panel is available to Exchange administrators for managing Unified Messaging in a cross-premises environment, as a best practice, the Exchange Management Console and the Exchange Management Shell are the preferred tools for creating and configuring UM components.
- **UM reporting** The UM reporting features added in Exchange 2010 SP1 include call summaries and statistics and call details for UM-enabled users. These reports are displayed in the Exchange Control Panel. You can access Unified Messaging statistic reports by using **Call Statistics** in EMC and access call logs by using **User Call Logs**, also in the EMC. Both tools are located under the Toolbox node. They provide aggregated statistical information about calls for UM servers and calls for UM-enabled users. To support the UM reporting tools in the EMC, the following cmdlets have been added for SP1:
  - **Get-UMCallSummaryReport**
  - **Get-UMCallDataRecord**

  In the EMC toolbox, **Call Statistics** provides aggregated statistical information about calls forwarded to or placed by UM servers and can be used by administrators interested in overall statistics for the Exchange 2010 Unified Messaging servers in their organization. The results of the call statistics reports you request in the EMC are displayed in the Exchange Control Panel user interface. They can be filtered to show call statistics by month or by day for the past 90 days or since UM was deployed in your organization. You can then filter these results by UM dial plan and UM IP gateway within your organization.
  Call statistics reports display:
  - The total number of calls organized by type of call (for example, missed calls, Outlook Voice Access calls, or fax calls).
  - Whether the call was accepted or rejected.
  - The average audio quality.
  - The day or the month covered in the report, or all calls.

You can export the call logs to a Microsoft Office Excel template, or copy the call statistics information to the Clipboard so that it can be pasted into another application. You can use the **Audio Quality Details** button to display more specific information about the call, including:

- Date
- UM dial plan
- UM IP gateway
- Type of audio codec
- NMOS
- NMOS degradation
- Jitter
- Pack loss
- Round trip time
- Burst Loss Duration
- Number of calls sampled

For more information about the specific information that's available for calls, see Using Unified Messaging Tools.

You can use **User Call Logs** in the EMC toolbox to view the call statistics for a selected UM-enabled user. The report is displayed in the Exchange Control Panel and is useful in helpdesk-type situations where you have to gather information about specific calls for a UM-enabled user to assist them in diagnosing and fixing issues. After you click **Select a user** and specify the user, the following information will be displayed for calls of the UM-enabled user you selected:

- Date and time
- Duration of the call
- Type of call
- The calling number
- The called number
- The UM IP gateway
- Audio quality

You can copy the user's call statistics to the Clipboard and then paste them into another application. You can use the **Audio Quality Details** button to display more specific information about the call including:

- Date
- UM dial plan
- UM IP gateway
- Type of audio codec
- NMOS
- NMOS degradation
- Jitter
- Pack loss
- Round trip time
- Burst Loss Duration

For more information about the specific information that's available for calls, see Using Unified Messaging Tools.

- **Cross-forest migration of UM-enabled mailboxes** Before Exchange 2010 SP1, there wasn't a way to efficiently move UM-enabled mailboxes from a source Exchange 2010 forest to a target Exchange 2010 forest when performing any kind of Enterprise cross-forest migration. The only way to do this was to first disable the mailbox for UM in the source forest, and then move the mailbox to the target forest. If you were moving an Exchange Server 2007 mailbox, you would use the **Move-Mailbox** cmdlet. If you were moving an Exchange 2010 mailbox, you would use the **New-MoveRequest** cmdlet. After you moved the mailbox to the target forest, you would then enable the mailbox for UM.

  Following this process created several issues. The process took a long time to complete, the user's voice mail was taken offline, and the UM-enabled user's

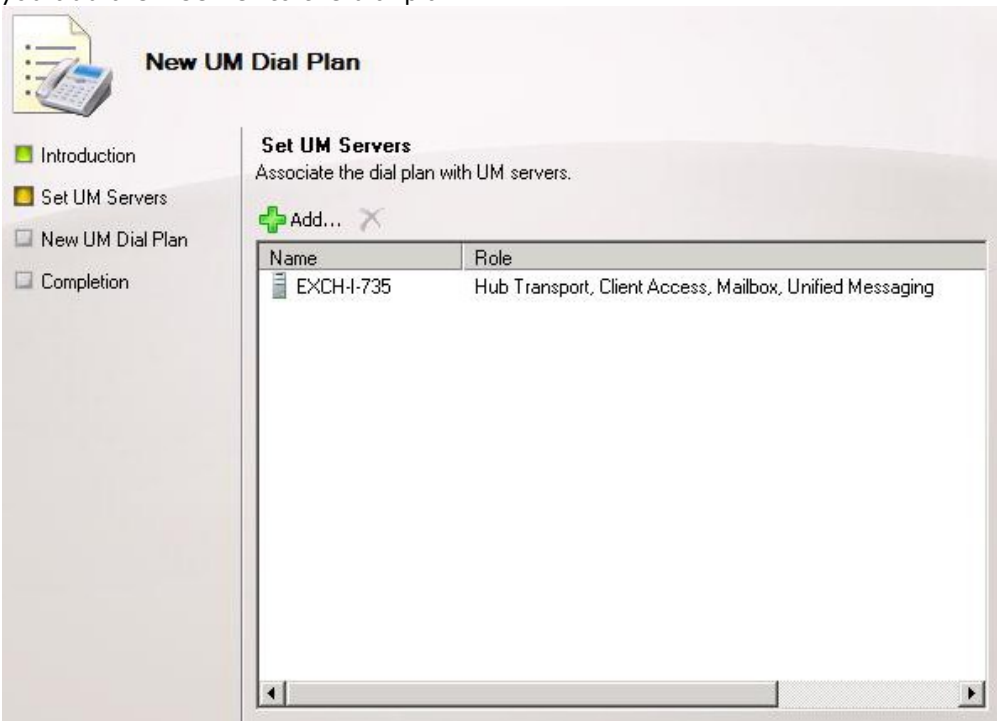
PIN would be reset, which forced the user to set up a new PIN for Outlook Voice Access.
In SP1, the **New-MoveRequest** cmdlet is used with the Mailbox Replication service (MRS) to move a UM-enabled mailbox within a forest, or between multiple forests in on-premises deployments. Using the **New-MoveRequest** cmdlet with the MRS to move the UM-enabled mailbox lets you speed up the process, leaves the user's voice mail online, and doesn't require an Outlook Voice Access user to reset their PIN.
The process for moving UM-enabled mailboxes works as follows in Exchange 2010 SP1:
In your source forest, you have UM-enabled mailboxes that are associated with a UM mailbox policy in the same source forest. You then:

- Identify the target UM mailbox policy that you want to associate with the UM-enabled mailboxes after you have moved them to the target forest.
- Use the **Set-UMMailboxPolicy** cmdlet and specify the name of the UM mailbox policy in the source forest using the *SourceForestPolicyNames* parameter on the UM mailbox policy in the target forest.
- Start moving the UM-enabled mailboxes to the target forest without disabling them. As you migrate the mailboxes, the mailboxes in the source forest will continue to receive voice mail messages and e-mail messages.
- Directly after the migration of the UM-enabled mailbox, the MRS will automatically disable the mailboxes in the source forest.
- In addition to the UM mailbox policy in the target forest, the MRS must have the extension numbers that are already assigned to the users whose mailboxes were moved. The MRS will use the extension numbers to locate the matching UM mailbox policy in the target forest by searching the *SourceForestPolicyNames* parameter on the UM mailbox policy. After the extension numbers and the name of the UM mailbox policy are found, MRS will UM-enable the mailboxes in the target forest.

Note:
The MRS uses RPC over HTTP for cross-forest migrations and RPC over TCP for intra-forest migrations.

- **Outlook Voice Access improvements** In Exchange 2007 and the RTM version of Exchange 2010, UM-enabled users can listen to their voice messages using Outlook Voice Access. By default, a Unified Messaging server retrieves and lists voice messages by date in descending order. For example, if two voice messages are sent, one at 10:00 a.m. and another at 1:00 p.m. the same day, UM will first play the voice message left at 1:00 p.m. and then play the voice message that was left earlier. Now, in SP1, when Outlook Voice Access users sign in to their Exchange 2010 mailbox, they can chose the play order for unread voice mail messages, either oldest first or newest first. Users can configure this order by using the **Voice Mail** tab in Outlook Web App, by managing their voice mail settings in Microsoft Outlook 2010, and by using the menu system in Outlook Voice Access.
- **Caller Name Display** Caller ID resolution has been enhanced in SP1. Names can now be displayed for voice messages from unresolved numbers using Caller Name Display. With Caller Name Display, IP gateways or IP PBXs pass caller name information as part of the SIP FROM header. In some countries, including the United States, the public telephone networks can supply the name of the registered subscriber for the calling phone number. This is administered by the telephone service provider that provides service to the caller. Phones with alphanumeric displays will show the registered name for the caller when the call offers it. With Caller Name Display, instead of displaying “Voice Mail from 4255551234”, the Unified Messaging server can send a voice message that displays “Voice Mail from Tony Smith”.
- **New UM Dial Plan Wizard and Set-UMServer** When you deployed Unified Messaging in Exchange 2010 RTM, you had to add or associate a UM server with a UM dial plan after you created the dial plan. In SP1, you can add or associate a UM server with a UM dial plan when you create a UM dial plan. An

additional page has been added to the **New UM Dial Plan** wizard that lets you add a UM server to the dial plan.



- **Microsoft Lync Server 2010 feature support (cross-premises)** You must deploy Lync Server 2010 if you're deploying UM in a cross-premises environment. UM is fully supported and functional with Lync Server 2010, including Message Waiting Indicator (MWI) notifications.
- **Office Communications Server migration (non-cross-premises)** If you're deploying or migrating from Exchange 2007 to Exchange 2010 and your Exchange deployment is integrated with Office Communications Server, Exchange 2010 SP1 includes support for migration of SIP URI dial plans that are used with Communications Server. Also, in Exchange 2010 SP1, it's no longer required that you have a Communications Server location profile that has the same name as the phone context property of the SIP URI dial plan. The following table summarizes the supported deployments for Microsoft Exchange, Office Communications Server, and Lync Server 2010.

Supported Deployments

	Exchange 2007 SP1, SP2, or SP3 Unified Messaging	Exchange 2010 RTM Unified Messaging	Exchange 2010 SP1 Unified Messaging
Office Communications Server 2007	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Not supported
Office Communications Server 2007 R2	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone

	contexts must match.	contexts must match.	contexts don’t have to match.
Lync Server 2010	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an Enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported in a cross- premises or Enterprise deployment. Location profile names and UM dial plan phone contexts don’t have to match.

Note:
Exchange Server 2010 SP1 Unified Messaging no longer supports Office Communications Server 2007. You must use Office Communications Server 2007 R2 or Microsoft Lync Server 2010.

- **Secondary UM dial plan support** In SP1, you can add a secondary UM dial plan for a UM-enabled user. Secondary dial plans allow administrators to assign two extension numbers to a UM-enabled user. Or, you can assign a primary extension number in a UM-enabled user's primary dial plan on one PBX or IPX PBX and a secondary extension for that user within a secondary dial plan that exists on a different PBX or IP PBX.
  When an Exchange 2007 or Exchange 2010 user’s mailbox is enabled for UM, the administrator is required to specify an extension number and a UM mailbox policy. The extension number is needed by a UM server to identify the user when they call in to Outlook Voice Access to access their mailbox. The UM mailbox policy contains a collection of configuration properties, with values that UM uses to apply to a UM-enabled mailbox that's associated with that UM mailbox policy. One of the properties on the UM mailbox policy is the UM dial plan. The dial plan also contains a set of configurable properties that includes a numbering plan. The numbering plan defined on the UM dial plan doesn't allow for duplicate extension numbers. This ensures that the extension number is unique within the dial plan. By linking the extension number to a user in the UM dial plan, Unified Messaging uniquely identifies a UM-enabled user in an organization.
- **New UM language packs** Unified Messaging language packs make it possible for the Exchange 2010 UM server to speak additional languages to callers and recognize languages other than US English (en-US) when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. The following is a list of additional UM language packs that are now available but don't contain support for Voice Mail Preview:
  - Catalan (ca-ES)
  - Chinese (Hong Kong) (zh-HK)
  - Danish (Denmark) (da-DK)
  - English (India) (en-IN)
  - Finnish (Finland) (fi-FI)
  - Norwegian (Bokmal) (nb-NO)
  - Russian (ru-RU)

  The following is a list of additional UM language packs that are now available that do contain support for Voice Mail Preview:
  - English (Canada) (en-CA)
  - Polish (pl-PL)
  - Portuguese (Portugal) (pt-PT)
  - Spanish (Spain) (es-ES)

Note:
The RTM version of the Spanish (Spain) (es-ES) UM language pack didn't include support for Voice Mail Preview. Voice Mail Preview

support was added in SP1. For more information about Voice Mail Preview, see Voice Mail Preview for End Users.

By default, when you install the Exchange 2010 Unified Messaging server role, the server will send voice mail previews to UM-enabled users if a supported UM language pack is installed.
There are Exchange 2010 Unified Messaging Voice Mail Preview partners that offer enhanced transcription support for the Voice Mail Preview feature. These partners employ people to correct voice mail transcriptions that were created using Automatic Speech Recognition (ASR). Each Voice Mail Preview partner must meet a set of requirements to be certified to interoperate with Exchange 2010 Unified Messaging.
If you determine that the voice mail previews sent to your users aren't accurate enough, you can contact one of the certified Voice Mail Preview partners listed on the Microsoft PinPoint web page and sign up with them at an additional cost. For more information, see Voice Mail Preview Advisor for Exchange 2010.
You can download the Exchange 2010 UM language packs for SP1 from the Microsoft Download Center. For details, see Install a Unified Messaging Language Pack on a UM Server.

Important:
To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don’t install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that is configured on the dial plan but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won’t work in the language by the user without having both the UM language pack and the Client and Server Language Pack installed. To download and install additional client and server language packs on servers in your organization, see Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

- **Call Answering Rules improvements** Using Call Answering Rules, end users can control how their incoming calls should be handled. Call Answering Rules are applied to incoming calls much as Inbox rules are applied to incoming e-mail messages. For details, see Understanding Call Answering Rules.
  There are two updates to Call Answering Rules in Exchange 2010 SP1:
  - In the RTM version, when a caller who's greeted by a call answering rule selects the voice mail option, a UM server first plays the called party's voice mail greeting before prompting the caller with the instruction to leave a voice message. This can be confusing if the user has created custom greetings. In Exchange 2010 SP1, the voice mail greeting is skipped if the caller has chosen to leave a voice message via a call answering rule that's configured.
  - In Exchange 2010 SP1, a missed call notification won't be left for a user if the inbound call reaches the called party using the Find Me feature, if a call transfer succeeds, or if a voice message is successfully left for the user.
- **Unified Communications Managed API/Speech Platform improvements** Beginning with Exchange 2010 SP1, the UM server relies on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and speech processing. This dependency requires that the UCMA platform and prerequisites be installed on the UM server before Exchange 2010 UM SP1 installation or upgrade. For details, see Overview of Unified Messaging.
  As part of this integration with UCMA, you receive the following benefits when you've integrated UM and Lync Server 2010:
  - Unified Messaging reports Quality of Experience (QoE) data to Lync Server 2010 Quality of Experience Monitoring or QMS servers. This is available in both on-premises and cross-premises integrated environments.
  - UM doesn't drop the first incoming call if the first call to the UM server is

being made from an Enterprise Voice user who's connected the Internet.
- In earlier versions of Office Communications Server, the A/V Edge resources that were associated with the Office Communications Server pool didn't communicate with a specific UM server for a specific call. This led to less-than-optimal media quality in some scenarios. With SP1, you can set, on a per UM-server basis, the Office Communications Server pool and associated A/V Edge server resources that should be used for all calls to and from that specific UM server.

- **UM auto attendant update** In the RTM version of Exchange 2010, a UM auto attendant would play the after hours greeting and the holiday greeting on holidays. In SP1, UM auto attendant will play only the holiday greeting on a holiday.
- **Exchange 2010 UM Troubleshooting Tool** Use the **Test-ExchangeUMCallFlow** cmdlet to test call flow between UM servers, IP gateways, and SIP servers. With the **Test-ExchangeUMCallFlow** cmdlet, you can diagnose configuration errors found in telephony components, Exchange 2010 SP1 Unified Messaging settings, and connectivity issues between on-premises and cross-premises Unified Messaging deployments.
  The **Test-ExchangeUMCallFlow** cmdlet can be used to diagnose configuration errors specific to call answering scenarios and to test whether voice mail is functioning correctly in Office Communications Server 2007 R2 or Microsoft Lync Server 2010 and non-Office Communication Server 2007 R2 or Lync Server 2010 deployments for both on-premises and cross-premises UM deployments. This cmdlet emulates calls, runs a series of diagnostic tests, and outputs the cause and possible solutions for potential issues that are detected. It also outputs general audio quality metrics for diagnosing audio quality issues related to network connectivity such as jitter and average packet loss. The **Test-ExchangeUMCallFlow** cmdlet supports testing UM components in Secured, SIP Secured, and Unsecured calls and can be run either in `Gateway` or `SIPClient` modes.

  Important:
  The **Test-ExchangeUMCallFlow** cmdlet must be used to test only the voice mail functionality of a Microsoft Exchange Server 2010 Unified Messaging server that has Service Pack 1 (SP1) installed.

  The **Test-ExchangeUMCallFlow** cmdlet can be installed on a local Unified Messaging server or on another 64-bit computer running:
  - The Windows Vista or Windows 7 operating system
  - The Windows Server 2008 or Windows Server 2008 R2 operating system

  The **Test-ExchangeUMCallFlow** cmdlet requires the components below be installed on a Windows 7, Windows Vista, or Windows Server 2008 64-bit computer prior to installing the cmdlet:
  - Microsoft .NET Framework 3.5 Service Pack 1 (SP1) To download the service pack, see Microsoft .NET Framework 3.5 Service Pack 1.
  - Microsoft .NET Framework 3.5 Family Update for Windows Vista x64 and Windows Server 2008 x64 updates if the tool will be run on a Windows Vista or Windows Server 2008 computer To download the update, see Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64.
  - Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) For more information, see Microsoft Knowledge Base article 968930, Windows Management Framework core package (Windows PowerShell 2.0 and WinRM 2.0).
  - Unified Communications Managed AP1 2.0, Core Runtime (64-bit) To download the UcmaRuntimeWebDownloadX64.msi program file, see Unified Communications Managed API 2.0, Core Runtime (64-bit).

The **Test-ExchangeUMCallFlow** cmdlet isn't included on the Exchange 2010 SP1 DVD or the Exchange 2010 SP1-only download. However, you can download the cmdlet from the

Microsoft Download Center.

1.1.4.6 New Exchange Core Store Functionality in Exchange 2010 SP1

New Exchange Core Store Functionality in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2010-07-13*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) includes new features, as well as enhancements to features introduced in the release to manufacturing (RTM) version of Exchange Server 2010. This topic describes the new functionality in Exchange 2010 SP1 that's available for the following:

- Microsoft Exchange Information Store
- Mailbox databases
- Public folders and public folder databases

Exchange Information Store

Exchange 2010 RTM introduced store limits to prevent a single application or single user from using all the available connections to the Microsoft Exchange Information Store. In Exchange 2010 SP1, for any connections by users with administrative privileges, the session limits have been increased to 64,000 maximum sessions per server.

For more information, see Exchange Store Limits.

Mailbox Databases

The following describes new functionality related to mailbox databases in Exchange 2010 SP1:

- **Mailbox Database Repair Requests** In Exchange 2010 RTM and earlier, you could repair a mailbox with the Information Store Integrity Checker (Isinteg.exe) tool. To repair mailboxes, you needed to dismount the mailbox database on which that mailbox resided and run the fixes while the database was offline. Exchange 2010 SP1 introduces the **New-MailboxRepairRequest** cmdlet that allows you to detect and repair a corrupted mailbox while leaving the mailbox database online.
  For more information, see the following topics:
  - Managing Repair Requests
  - New-MailboxRepairRequest
- **Database Log Growth Troubleshooter** The Database Log Growth Troubleshooter script (Troubleshoot-DatabaseSpace.ps1) detects and takes action on excessive log growth that can cause the health of the Mailbox server to be at risk. By default, the configurable troubleshooter runs every 15 minutes to determine the amount of space available on the hard drive. If the hard drive space is less than 25 percent, the troubleshooter runs an algorithm to determine if the problem is caused by excessive log growth. If excessive log growth is the problem, the troubleshooter quarantines or throttles the mailboxes that are causing the excessive log growth. For more information, see Manage Database Log Growth by Using the Troubleshoot-DatabaseSpace.ps1 Script in the Shell.

- Database Latency Troubleshooter The Database Latency Troubleshooter script (Troubleshoot-DatabaseLatency.ps1) detects and takes action on high latencies on a database. For more information, see Manage Database Latencies by Using the Troubleshoot-DatabaseLatency.ps1 Script in the Shell.

Remove-StoreMailbox

The new Remove-StoreMailbox cmdlet allows you to permanently remove soft-deleted and disconnected mailboxes.

Public Folders and Public Folder Databases

The following changes were made to public folders and public folder databases in Exchange 2010 SP1:

- The AggregatePFData.ps1 script now aggregates statistics across all public folder replicas. For more information, see View Public Folder Item Statistics.
- You can now use the Exchange Management Console to configure client permissions for public folders. For more information, see Use the Public Folder Management Console to Manage Public Folder Settings.
- The New-PublicFolderDatabaseRepairRequest cmdlet has been added to allow you to detect and correct replication issues in the public folder database. This cmdlet replaces the Isinteg.exe tool. For more information, see Create a Public Folder Database Repair Request.

1.1.4.7 New Transport Functionality in Exchange 2010 SP1

New Transport Functionality in Exchange 2010 SP1

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2012-07-19*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) includes new features, as well as enhancements to features introduced in the release to manufacturing (RTM) version of Exchange 2010.

This topic provides an overview of the following new features and improvements for Transport in Exchange 2010 SP1:

- MailTips functionality
- Message tracking functionality
- Throttling enhancements
- Shadow redundancy promotion
- SMTP failover and load balancing improvements
- Support for Extended Protection on SMTP communications
- Send connectors over reliable connections

MailTips Functionality

Here is a brief overview of MailTips features that were added in Exchange 2010 SP1:

- **MailTips access control over organizational relationships** You have granular control over the way MailTips are shared between your organization and other organizations with which you configured an organizational sharing relationship. You can control the types of MailTips that are shared and even designate a specific group of users for which to return MailTips.
- **MailTips monitoring and troubleshooting** Several new monitoring capabilities for MailTips were added in Exchange 2010 SP1. New capabilities include changes to event log entries, alerts, and performance monitor counters.

For more information, see Understanding MailTips.

Message Tracking Functionality

Here is a brief overview of message tracking features that were added in Exchange 2010 SP1:

- **Improved error messages for delivery reports** There may be situations where a user attempts to access delivery reports for a specific message but is unable to view the report. For example, a user may attempt to access delivery reports for a message immediately after sending it, but before the tracking information for that message is inserted into the logs. In these types of scenarios, the messages displayed to the users have been greatly improved, providing specific explanations as to why the information isn't available.
- **Message tracking monitoring and troubleshooting** Several new monitoring capabilities for message tracking were added in Exchange 2010 SP1. These include new event log entries, alerts, and performance monitor counters.
- **Message tracking trace levels** When you're troubleshooting message tracking, you can now request complete logs of every operation that was executed by a Client Access server processing a delivery report request.

For more information, see Understanding Message Tracking.

Throttling Enhancements

Transport servers in Exchange 2010 SP1 keep track of the current state of the overall Exchange organization and modify the way they handle messages accordingly. This allows the Transport servers to respond proactively to potentially problematic situations, improving the reliability of the overall message delivery.

In Exchange 2010 SP1, Transport servers maintain a running average delivery cost of messages sent by individual senders. If a user keeps sending costly messages, such as those addressed to large audiences or tha have large attachments, Transport servers start to give priority to other messages that have a lower cost before it processes messages from that sender. For example, if a user is sending multiple messages that have 10MB attachments, Transport starts to first process other messages that don’t have attachments before it handles additional messages from this particular sender.

Transport also keeps track of the RPC utilization of mailbox servers. A Hub Transport server makes RPC connections to a mailbox server for message delivery. If a Hub Transport server detects that a mailbox server is under RPC resource pressure, it scales back the RPC sessions that it opens to that mailbox server. This way, interactive client connections to the mailbox server take precedence over message delivery when it comes to utilizing RPC resources on a mailbox server.

Back pressure is a system resource monitoring feature of the Microsoft Exchange Transport service that exists on Hub Transport and Edge Transport servers In Exchange 2010. Exchange Transport can detect when vital resources, such as available hard disk

space and memory, are under pressure, and take action to try to prevent service unavailability. All configuration options for back pressure are available in the EdgeTransport.exe.config application configuration file.

In Exchange 2010 Service Pack 1, the default values in EdgeTransport.exe.config are revised for following parameters:

- *SmtpStartThrottlingDelayInterval*: decreased from 10 seconds to 1 second
- *SmtpStepThrottlingDelayInterval*: decreased from 5 seconds to 1 second

For more information about the EdgeTransport.exe.config file, see Understanding the EdgeTransport.exe.Config File.

For more information about back pressure configuration, see Understanding Back Pressure.

For more information about throttling, see Understanding Message Throttling.

Shadow Redundancy Promotion

Exchange 2010 introduced the shadow redundancy feature to minimize the loss of any message during delivery after it enters the Exchange organization. Exchange Transport servers achieve this by using the shadow redundancy SMTP protocol extension.

However, in any organization Exchange Transport servers need to communicate with other third-party SMTP servers that may not support the shadow redundancy protocol. This is especially true with Edge Transport servers that handle message traffic with various hosts on the Internet. When receiving messages from hosts that don't support shadow redundancy in Exchange 2010 RTM, Transport servers delay sending acknowledgement to incoming messages until they verify final delivery within the organization. However, when a specific threshold was reached, the Transport server issued an acknowledgement even if final delivery wasn't verified. This presented a scenario where messages received from hosts that don't support shadow redundancy can be lost in transit.

To address this issue, a new feature called *shadow redundancy promotion* is introduced in Exchange 2010 SP1. When faced with the scenario described above, instead of issuing an acknowledgment without delivery confirmation, a Transport server now routes the message to any other Transport server within the site so that the message is protected by shadow redundancy.

There are additional details about how this scenario works. To learn more, see Understanding Shadow Redundancy.

SMTP Failover and Load Balancing Improvements

Exchange 2010 SP1 improves the way Transport servers detect unhealthy servers and use enhanced DNS. Enhanced DNS distributes the load evenly when all servers are healthy, but in the case of an unavailable server, the load distribution among the remaining healthy servers may not be evenly balanced.

To address this issue, each Exchange 2010 SP1 Transport server maintains a list of unavailable servers. When routing a message, each server uses this information to filter out the known unavailable servers from the set of target servers. For example, assume that a Hub Transport server needs to route several messages to another Active Directory site which has three Hub Transport servers (Hub1, Hub2, and Hub3). If the server knows

that Hub2 is unavailable, it'll remove that server from the list of possible targets and only route to Hub1 and Hub3. It'll assume only two servers, Hub1 and Hub3, exist in the remote Active Directory site when load balancing messages.

As a result, Exchange 2010 SP1 Transport servers always distribute the load evenly between healthy servers and avoid any servers that are unavailable for any reason. For more information, see Understanding SMTP Failover and Load Balancing in Transport.

Support for Extended Protection on SMTP Communications

Windows offers channel binding to protect NTLM authentication over encrypted channels from authentication relay attacks. In Exchange 2010, all services provided by Exchange have been updated to support Extended Protection for Authentication. For more information, see Microsoft Knowledge Base article 968389, Extended Protection for Authentication.

To support this feature in Transport, the Receive connectors have been updated. You can allow, require, or disable Extended Protection for Authentication on your Receive connectors. For more information, see Understanding Receive Connectors.

Send Connectors over Reliable Connections

With Exchange 2010 SP1, several new features were added to the Send connectors. Most changes are to support coexistence with Exchange Online. In addition, the ability to downgrade connection failures was added to the Send connectors.

You may have dedicated Send connectors that are responsible for transmitting messages over well-defined communication channels that are expected to always be available, such as a Send connector dedicated to send messages to Exchange Online. On such connections, many of the typical errors that are possible on ordinary destinations on the Internet aren't expected. In this scenario, you may want to treat any communication errors as transient as opposed to issuing non-delivery reports (NDRs). With Exchange 2010 SP1, you can configure a Send connector to downgrade authentication and name resolution errors, which would normally result in an NDR, to transient errors. In these cases, Exchange will attempt delivery again instead of issuing an NDR.

For more information, see Understanding Send Connectors.

1.1.4.8 Release Notes for Exchange Server 2010 SP1

Release Notes for Exchange Server 2010 SP1

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP1 >

Applies to: *Exchange Server 2010 SP1*

Topic Last Modified: *2011-04-19*

For important legal information, see Legal Notice later in this document.

Welcome to Microsoft Exchange Server 2010. This document contains the following sections:

Functionality Available in Exchange 2010 SP1

Exchange 2010 Service Pack 1 (SP1) adds new and revised functionality. For more information, see What's New in Exchange 2010 SP1.

Installing Exchange 2010 SP1

Consider the following when you deploy Exchange 2010 SP1:

- You can now select a new option that installs the required Microsoft Windows operating system roles and features for each selected Exchange 2010 SP1 server role.
- You can only install Exchange 2010 SP1 on computers running Windows Server 2008 Service Pack 2 (SP2) and Windows Server 2008 R2.
- Although it isn't a recommended configuration, single-label Domain Name System (DNS) domain names are now supported for use with Exchange 2010 SP1.
- If you're running the beta release of Exchange 2010, you must uninstall the beta release before you install the SP1 version of Exchange 2010.
- If you upgrade an Edge Transport server that's running Forefront Threat Management Gateway (TMG) and has Forefront Protection for Exchange Server (FPE) enabled for SMTP protection, the Forefront TMG Managed Control service may fail to start.

For detailed information about the requirements and steps for installing Exchange 2010 SP1, see the following topics:

- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements
- Understanding a New Installation of Exchange 2010
- Understanding Upgrade to Exchange 2010
- Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3

Mailbox Moves

The process for moving mailboxes has changed to help make sure that no data is unintentionally lost due to issues that may occur around the same time as a move, such as a lossy failover on the target database.

When mailboxes are moved from an Exchange 2010 SP1 database to any other database, Exchange no longer fully deletes the mailbox from the source database immediately upon completion of the move. Instead, the mailbox in the source mailbox database is switched to a *soft-deleted* state, which allows mailbox data to be accessed during a mailbox restore operation by using the new **MailboxRestoreRequest** set of cmdlets.

These soft-deleted mailboxes are visible when running the Get-MailboxStatistics cmdlet against a database and can be identified by having the property **DisconnectReason** with a value of `SoftDeleted`. The soft-deleted mailboxes will be retained in the source

database until either the deleted mailbox retention period expires or the mailbox is purged by using the Remove-StoreMailbox cmdlet. As a result of this change, if you're performing mailbox moves to reduce the amount of space being used in a database, you must also perform the additional step of purging the soft-deleted mailbox. Soft-deleted mailboxes can't be reconnected.

Note:

You won't be able to view soft-deleted mailboxes by using the Get-MailboxStatistics cmdlet in Exchange versions earlier than Exchange 2010 SP1.

If necessary, you can restore data from these soft-deleted mailboxes by using the **MailboxRestoreRequest** set of cmdlets, which is initiated with the New-MailboxRestoreRequest cmdlet. The **MailboxRestoreRequest** cmdlets replace the legacy **Restore-Mailbox** cmdlet. In addition to having the same capabilities as the **Restore-Mailbox** cmdlet, the **MailboxRestoreRequest** cmdlets perform additional tasks, including the ability to:

- Restore from rehomed or soft-deleted mailboxes that aren't in a recovery database.
- Be processed asynchronously (like a mailbox move in Exchange 2010).
- Restore data into an archive mailbox.

Known Issues with Mailbox Moves

The following are known issues associated with mailbox moves.

MRSProxy

An Exchange 2010 SP1 change to the Mailbox Replication Proxy (MRSProxy) service requires you to apply a Microsoft .NET Framework hotfix before you can move mailboxes across forests. If you don't apply the .NET Framework hotfix, you may receive transient exceptions on the remote forest due to MRSProxy failures, which leads to a series of "another administrator is moving the mailbox" error messages. Sometimes, the move request recovers and retries the move, but eventually the move will fail due to too many transient failures. In Event Viewer on the Client Access server, you will receive an error message similar to the following:

Log Name: Application

Source:.NET Runtime

Date:6/14/2010 3:56:55 PM

Event ID: 1023

Task Category: None

Level: Error

Keywords: Classic

User: N/A

Computer: CAS01.contoso.com

Description: .NET Runtime version 2.0.50727.4200 - Fatal Execution Engine Error (000007FEF884664E) (80131506)

You need to apply the hotfix to all Exchange 2010 SP1 Client Access servers in both forests. For more information about this hotfix and how to download it, see Microsoft Knowledge Base article 971030, FIX: An access violation occurs when you run a .NET

Framework 2.0-based application that has a virtual call the IList<T>, IEnumerable<T>, or ICollection<T> interface in an LCG method.

Move Request Versioning

When performing a cross-forest mailbox move, the Exchange 2010 RTM version of the Microsoft Exchange Mailbox Replication service (MRS) and the MRSProxy service can't log into an Exchange 2010 SP1 Mailbox server. This functionality is intentional. It prevents errors when moving mailboxes across Exchange versions to provide for new functionality such as soft-deletes. To prevent this issue from occurring, you can do one of the following:

- Make sure that all Client Access servers in the remote and local forests are running the same or a later version of Exchange than the Mailbox servers in the remote and local forests.
- In the remote forest, make sure you haven't mixed Exchange servers of different versions behind the same network load balancer (NLB) end point.
- Initiate cross-forest moves from the later version of Exchange.

Autodiscover

In the RTM version of Exchange 2010, when you move a mailbox across forests, the source mailbox is converted to a mail-enabled user. If the mailbox has a personal archive, after the move is complete, the **msExchArchiveDatabaseLink** attribute isn't cleared from the mail-enabled user in the source forest, and the new mailbox in the target forest also gets this attribute stamped with the database in which the archive now resides. If this attribute is present on the mail-enabled user, it will point to a database in the source forest.

As a result, when you upgrade to Exchange 2010 SP1, Autodiscover and Outlook can't determine where the mailbox resides because the mail-enabled user object and the mailbox object are pointing to different databases within different forests.

Therefore, before you upgrade to Exchange 2010 SP1, you must clear the **msExchArchiveDatabaseLink** attribute manually from Active Directory for each affected mail-enabled user. You can use a tool such as ADSIEdit to remove this property. For more information, see Microsoft Knowledge Base article 2387770, When using Autodiscover Outlook fails to connect to an Exchange 2010 SP1 mailbox with "Unable to open your default e-mail folders" if the user was moved cross forest.

Unified Messaging

Consider the following issues when you install and configure Exchange 2010 SP1 with Unified Messaging.

UM Language Packs

The Unified Messaging (UM) language packs for Exchange 2010 SP1 are intended to be used only on Unified Messaging servers running Exchange 2010 SP1. They must not be installed on 64-bit Unified Messaging servers running the release to manufacturing (RTM) version of Exchange 2010.

These new UM language packs allow a Unified Messaging server running Exchange 2010 SP1 to speak additional languages to callers and recognize other languages when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. UM language packs contain:

- Prerecorded prompts, for example: "After the tone, please record your message. When you've finished recording, hang up, or press the # key for more options." These prompts are in the language of the UM language pack.
- Text-to-Speech (TTS) data and executable code so that text content (such as e-mail, calendar, and contact information) can be read to callers in the language of the UM language pack.

- ASR data and executable code, which allows callers to interact with Unified Messaging using the voice user interface (Outlook Voice Access) in the language of the UM language pack.
- Support for Voice Mail Preview, which adds a text version of voice mail messages that can be read from e-mail clients such as Microsoft Outlook or Microsoft Office Outlook Web App. The Voice Mail Preview feature isn't available in all UM language packs.

The following is a list of UM language packs in Exchange 2010 SP1 that contain support for Voice Mail Preview. The language packs marked with an asterisk (*) are new in SP1:

- English (United States) (en-US)
- English (Canada) (en-CA) *
- French (France) (fr-FR)
- Italian (Italy) (it-IT)
- Polish (pl-PL) *
- Portuguese (Portugal) (pt-PT) *
- Spanish (Spain) (es-ES) *

Known Issues

The following are known issues associated with UM language packs:

- **Installation issues**
  When you're installing a UM language pack, you may encounter the following error message: "This specified role, UmLanguagePack, isn't defined in the configuration file." To work around the problem, you can delete the C:\Program Files\Microsoft\Exchange Server\V14\Bin\en\ExBPA.Config.xml file, and then restart the language pack installation.
- **General recommendations and considerations when you're using UM language packs for name pronunciation**. The following issues are associated with name pronunciation:
  - The actual names should be recorded by UM-enabled users when they're setting up their voice mail (signing in to Outlook Voice Access for the first time).
  - If a recorded name is available, it will always be spoken to a caller by Unified Messaging.
  - If a recorded name isn't available, Unified Messaging will try to speak the user's display name phonetically. This requires the Unified Messaging server to use TTS synthesis to speak the user's name.
  - If a phonetic display name isn't available for the user, Unified Messaging will try to speak the user's display name. This also requires TTS synthesis.
  - The problems (described later in this document) with the pronunciation of names refer to the cases in which a recorded name or phonetic display name is used by a Unified Messaging server to speak the name of the user.
- **Language-specific issues**. Some language packs may have problems with the pronunciation of names. The following problems are listed by language pack:
  - **Japanese**
    In the case of some Romaji names (Japanese names spelled using Roman characters), instead of pronouncing the name in its entirety, Unified Messaging may read the name spelled out letter-by-letter, for example, instead of "Sugimoto," Unified Messaging may read "s-u-g-i-m-o-t-o."
    In addition, Unified Messaging may not read English names spelled out using Roman characters, remaining silent in place of a name.
  - **Russian**
    Some Romanized Russian names, as well as English names, might be pronounced in an unnatural manner.
  - **English (India)**
    While attempting to switch the language used to read e-mail messages in Outlook Voice Access, Unified Messaging may not

recognize the name of the requested culture. To work around this issue, try to use alternative names, for example, instead of "Chinese," use "Chinese P.R.C." or "Chinese Hong Kong."

Caution:

Deploying the Exchange 2010 SP1 English (India) (en-IN) Unified Messaging language pack in organizations that include Exchange Server 2007 servers running on Windows Server 2003 will cause the Exchange 2007 servers to fail.

- **English (US)**
  Unified Messaging may not pronounce names written with characters from non-Roman alphabets.
- **Chinese (Hong Kong)**
  Unified Messaging may not pronounce names written using characters from alphabets other than Chinese (H.K.).
- **Danish**
  When reporting hours, Unified Messaging may unnecessarily repeat the word "klokken," for example, "ankom I går klokken klokken 8:21."

Exchange 2010 UM Troubleshooting Tool

You can use the **Test-ExchangeUMCallFlow** cmdlet to test call flow between Unified Messaging servers, IP gateways, and Session Initiation Protocol (SIP) servers. This cmdlet can be used to diagnose configuration errors found in telephony components, Exchange 2010 SP1 Unified Messaging settings, and connectivity issues between on-premises and cross-premises Unified Messaging deployments.

The **Test-ExchangeUMCallFlow** cmdlet can also be used to diagnose configuration errors specific to call answering scenarios and to test whether voice mail is functioning correctly, both on-premises and cross-premises, for the following:

- Deployments that use Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010
- Deployments that aren't using Communications Server 2007 R2 or Lync Server 2010

This cmdlet emulates calls and runs a series of diagnostic tests that provide reasons, and possible solutions, for issues that are detected. It also provides metrics for diagnosing audio quality issues related to network connectivity, such as jitter and average packet loss. The **Test-ExchangeUMCallFlow** cmdlet supports testing Unified Messaging components Secured, SIP Secured, and Unsecured modes and can be run either in Gateway or SIPClient modes.

Important:

The **Test-ExchangeUMCallFlow** cmdlet must be used to test only the voice mail functionality of an Exchange 2010 Unified Messaging server that has Exchange 2010 SP1 installed.

The **Test-ExchangeUMCallFlow** cmdlet can be installed on a local Unified Messaging server or on another 64-bit computer that's running the:

- Windows Vista or Windows 7 operating system.
- Windows Server 2008 or Windows Server 2008 R2 operating system.

The **Test-ExchangeUMCallFlow** cmdlet requires that the components in the following list be installed on a computer running Windows Vista, Windows 7, or the 64-bit version of Windows Server 2008 before the cmdlet is installed:

- .NET Framework 3.5 SP1. For details, see Microsoft .NET Framework 3.5 Service Pack 1.
- .NET Framework 3.5 Family Update for the 64-bit version of Windows Vista, and the 64-bit version updates of Windows Server 2008 if the tool will be run

on a computer running Windows Vista or Windows Server 2008. For details, see Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64.

- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu). For details, see Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
- Microsoft Unified Communications Managed API 2.0 Core Runtime (UcmaRuntimeWebDownloadX64.msi). For details, see Unified Communications Managed API 2.0, Core Runtime (64-bit).

The **Test-ExchangeUMCallFlow** cmdlet isn't included on the Exchange 2010 SP1 DVD or in the download for Exchange 2010 SP1 only. However, you can download the **Test-ExchangeUMCallFlow** cmdlet from the Microsoft Download Center. For details, see Unified Messaging Troubleshooting Tool.

Important:

The *Diversion* parameter in the UM troubleshooting tool doesn't currently accept multiple History-Info headers. When you're running the tool in `Gateway` mode, the *Diversion* parameter must be provided. This can be in the form of a Diversion or a History-Info header. When you specify diversion numbers using History-Info headers, Unified Communications Managed API 2.0 requires that at least two History-Info headers be provided. For example: "<sip:66242@10.197.22.149;user=phone >; index=1, \ < sip:66242@10.197.22.149?Reason=SIP; cause=480; \ text="Request Timeout">;index=1.1, \ ;index=1.2"

Office Communications Server 2007 and Lync Server 2010

Office Communications Server 2007 R2 or Microsoft Lync Server 2010 (the next generation of Office Communications Server) is required with Unified Messaging in Exchange 2010 SP1. The following table describes supported deployments.

Supported deployments

Office Communications Server or Lync Server version	Exchange Server 2007 SP1, SP2, or SP3 Unified Messaging.	Exchange 2010 RTM Unified Messaging.	Exchange 2010 SP1 Unified Messaging.
Office Communications Server 2007	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Not supported.
Office Communications Server 2007 R2	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts don't have to match.
Lync Server 2010	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported only in an enterprise deployment. Location profile names and UM dial plan phone contexts must match.	Supported in a cross-premises or enterprise deployment. Location profile names and UM dial plan phone contexts don't have to match.

Note:

Exchange 2010 SP1 Unified Messaging no longer supports Office Communications Server 2007. You must use Office Communications Server 2007 R2 or Lync Server 2010.

1.1.4.9 Issues That Are Fixed in Exchange 2010 SP1

Issues That Are Fixed in Exchange 2010 SP1

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 SP1 >

Topic Last Modified: *2012-03-07*

This topic provides the list of issues that are fixed in Microsoft Exchange Server 2010 Service Pack 1 (SP1). For more information about Exchange 2010 SP1, see the following topics:

- To learn more about the new features in Exchange 2010 SP1, see What's New in Exchange 2010 SP1.
- To learn more about known issues that affect SP1, see Release Notes for Exchange Server 2010 SP1.
- To obtain Exchange 2010 SP1, visit the following Microsoft Download Center website: Microsoft Exchange Server 2010 Service Pack 1 (SP1).

Issues that are Fixed

Exchange 2010 SP1 includes the changes made in the following Exchange 2010 RTM rollups:

- Description of Update Rollup 5 for Microsoft Exchange Server 2010 Release to Manufacturing
- Description of Update Rollup 4 for Microsoft Exchange Server 2010 Release To Manufacturing
- Description of Update Rollup 3 for Microsoft Exchange Server 2010 Release to Manufacturing
- Description of Update Rollup 2 for Exchange Server 2010: February 18, 2010
- Update Rollup 1 for Exchange Server 2010

1.1.5 What's New in Exchange 2010

What's New in Exchange 2010

Applies to: *Exchange Server 2010*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 brings a new and rich set of technologies, features, and services to the Exchange Server product line. New features and functionality in Exchange 2010 support several key concepts:

- Flexible and reliable
- Anywhere access
- Protection and compliance

The following sections provide you with an overview of some of the important new features and functionality, which you can use when you're planning, deploying, and administering your Exchange 2010 organization.

(For information about features that have been discontinued or de-emphasized from Microsoft Exchange Server 2003 or Exchange Server 2007 to Exchange 2010, see Discontinued Features.)

For information about the features and changes that have been added in Exchange 2010 SP1, see What's New in Exchange 2010 SP1.

Flexible and Reliable

The pressure to optimize your IT infrastructure to respond to changing business conditions demands agility and that means investing in solutions that provide you and your organization choice. Exchange 2010 gives you the flexibility to tailor your deployment based on your organization's unique needs and a simplified way to help keep e-mail continuously available for your users.

High Availability Functionality

Exchange 2010 integrates high availability into the core architecture of Exchange to enable customers of all sizes and in all segments to economically deploy a messaging continuity service in their organization.

Exchange 2010 includes many changes to its core architecture. In Exchange 2010, new features such as *incremental deployment*, *mailbox database copies*, and *database availability groups* work with other features such as shadow redundancy and transport dumpster to provide a new, unified platform for high availability and site resilience.

For more information about high availability features, see New High Availability and Site Resilience Functionality.

Exchange Store and Mailbox Database Functionality

The following is a list of core store functionality that's included or has been changed in Exchange 2010:

- Deprecated storage groups
- Mailbox databases no longer connected to the server object
- Improvements in Extensible Storage Engine (ESE) for high availability, performance, and database mobility
- Flattened Outlook store schema
- Enhanced reporting with public folders

For more information about Exchange store and mailbox database features, see New Exchange Core Store Functionality.

Permissions Functionality

In Exchange 2010, Role Based Access Control (RBAC) replaces the permissions model used in Exchange 2007. Using RBAC, you can define extremely broad or extremely precise permissions models based on the roles of your administrators and users.

For administrators and specialist users, management role groups define what these users can manage in the organization. Role groups associate role group members to a set of management roles that define what the members can do. By adding or removing users as members of role groups, and adding or removing role assignments to or from a role group, you can control what aspects of the organization the members can manage.

For end users, management role assignment policies define what users can configure on their own mailbox. Assignment policies are applied to every mailbox either by default or manually, and enable you to control whether users can change their personal information, contact information, distribution group membership, and so on.

Both role groups and role assignment policies are assigned management roles. Management roles control access to the cmdlets and parameters required to perform a task. For example, if a cmdlet exists on a management role, and that role is assigned to a role group, the members of that role group can then use that cmdlet.

For more information about RBAC features, see Understanding Permissions.

Transport and Routing Functionality

The following is a list of new transport and routing functionality included in Exchange 2010:

- Shadow redundancy
- MailTips
- Moderated transport
- Federated delivery
- Latency service level agreement (SLA) management
- End-to-end message tracking
- Incremental EdgeSync
- Transport rules integration with AD RMS
- Transport dumpster improvements
- Transport database improvements

For more information about transport features, see New Transport Functionality.

Exchange Server 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Administration Functionality in the Exchange Management Console

The following is a list of the new core Exchange Management Console (EMC) features included in Exchange 2010. The core EMC refers to new functionality that affects how you use the EMC, and not how you use specific features:

- Ability to add Exchange forests to the console tree
- Customer Feedback start tab
- Community and Resources
- EMC command logging
- Property dialog box command exposure
- RBAC permissions aware for the EMC
- Online Exchange Help

For more information about EMC features, see New Administrative Functionality in the Exchange Management Console.

Administration Functionality in the Exchange Management Shell

The following is a list of features available in the new Exchange Management Shell:

- **Remote administration** With the new Shell, you can connect to remote servers running Exchange 2010 across the network with only Windows Management Framework installed, which includes Windows PowerShell. For more information, see Overview of Exchange Management Shell.
- **RBAC integration** The Shell works with RBAC to give you and your users access only to the cmdlets and parameters you and they are allowed to use. If your permissions don't allow you to configure a certain feature, you aren't given access to the cmdlets, parameters, or both, that manage that feature. For more information, see Understanding Role Based Access Control.
- **Administrator audit logging** Actions that result in the modification of Exchange organization configuration and other object properties in the EMC, the Web management interface, and the Shell can now be logged for later review. For more information, see Overview of Administrator Audit Logging.
- **Improved multiple-valued property syntax** Instead of running multiple commands to add and remove values from a single property, you can now add and remove values with a single command. For more information, see Modifying Multivalued Properties.

Exchange Control Panel

Administrators can use the Exchange Control Panel for Outlook Web App to manage some on-premises tasks. The following is a list of the administrative features available:

- Text messaging integration
- Voice messaging integration
- Multiple mailbox search
- Additional proxy addresses for mailboxes
- Moderation and approval for distribution list submission

In addition, users have self-service capabilities in that they can perform administrative tasks via the Exchange Control Panel. The ECP enables users to perform common tasks without having to call the help desk. This allows your users to be more productive and

allows IT staff to deliver more, while reducing support costs.

For more information, see Configure ECP Virtual Directory Properties.

Mailbox and Recipient Functionality

The following is a list of the new mailbox and recipient functionality that's included or has been changed in Exchange 2010:

- Ability for users to share information, such as calendar free/busy information and contacts with users who reside in a different organization
- Improved scheduling and configuring for resource mailbox calendar processing
- Ability to move a mailbox while the end user is still accessing it
- Additional parameters added to distribution group cmdlets to allow users to create and manage their own distribution groups in Outlook Web App and Exchange 2010
- Ability to appoint a moderator to regulate the flow of messages sent to a distribution group
- Ability to manage folder-level permissions for all folders within a user's mailbox
- Expanded bulk recipient management to allow you to bulk manage recipient properties
- Ability to send mail to recipients from the EMC

For more information about mailbox and recipient features, see New Mailbox and Recipient Functionality.

Exchange Web Services Managed API 1.0

The Microsoft Exchange Web Services (EWS) Managed API 1.0 provides a managed interface for developing client applications that use Exchange Web Services. Beginning with Exchange 2007 Service Pack 1 (SP1), the EWS Managed API simplifies the implementation of applications that communicate with Exchange. Built on the Exchange Web Services SOAP protocol and Autodiscover, the EWS Managed API provides a .NET interface to Exchange Web Services that's designed to be easy to learn, use, and maintain.

For more information, see Introducing the Exchange Web Services Managed API 1.0 and Microsoft Exchange Web Services Managed API 1.0.

Client Throttling Functionality to Manage System Performance

Exchange 2010 uses client throttling policies to manage the performance of your Exchange organization. To do this, Exchange tracks the resources that each user consumes and enforces connection bandwidth limits as necessary.

Some of the benefits of client throttling include making sure that:

- Users aren't intentionally or unintentionally taxing the system.
- Users of various connectivity methods are proportionally sharing resources.

You manage client throttling policies with Shell cmdlets. For more information about client throttling policies, see Understanding Client Throttling Policies.

Anywhere Access

Enhancements in Exchange 2010 helps users get more done by helping them to access all of their communications—e-mail, voice mail, instant messaging—from virtually any platform, Web-browser, or device through industry standard protocols. Managing the flow of information into and out of an individual’s inbox daily can create overload and affect productivity and profitability. In response to this challenge, Exchange 2010 adds new productivity features that can help users more easily organize and effectively prioritize their communications.

Unified Messaging Features

The following is a list of new Unified Messaging features included in Exchange 2010:

- Call answering rules
- Additional language support included in Outlook Voice Access
- Enhancements to name lookup from caller ID
- Voice Mail Preview
- Message Waiting Indicator
- Missed call and voice mail notifications using text messaging
- Protected Voice Mail
- Incoming fax support
- Addressing to groups (personal distribution lists) support
- Built-in Unified Messaging administrative roles

For more information about Unified Messaging and voice mail features, see New Unified Messaging Functionality and Voice Mail Features.

Outlook Web App Features

The following is a list of new features in Outlook Web App included in Exchange 2010:

- Favorites in the navigation pane
- Search folders
- Message filtering
- Ability to set categories in the message list
- Options in the Web management interface for Outlook Web App
- Side-by-side view for calendars
- Multiple client language support
- Ability to attach messages to messages
- Expanded right-click capabilities
- Integration with Office Communicator, including presence, chat, and a contact list
- Conversation view
- Ability to send and receive text messages from Outlook Web App
- Outlook Web App mailbox policies

For more information about Outlook Web App features, see Understanding Outlook Web App.

Exchange ActiveSync Features

The following is a list of new Exchange ActiveSync features included in Exchange 2010:

- Conversation grouping of e-mail messages
- Ability to synchronize or not synchronize an entire conversation
- Synchronization of SMS messages with a user's Exchange mailbox
- Support for viewing of message reply status
- Support for availability information for contacts

Text Messaging Features

The following is a list of new text messaging features included in Exchange 2010:

- Missed call and voice mail notifications
- Calendar and agenda updates
- Text messages sent and received through Outlook Web App and Outlook 2010
- Text message synchronization with a mobile phone

POP3 and IMAP4 Cross-Site Connectivity Support

Cross-site POP3 and IMAP4 client connectivity is supported by default in Exchange 2010. For more information about POP3 and IMAP4 client connectivity features, see Understanding POP3 and IMAP4.

Protection and Compliance

Exchange 2010 delivers new, integrated e-mail archiving and retention functionality, including granular multi-mailbox search and immediate legal hold. Exchange 2010 also helps you to better protect your company's communications and e-mail through centrally managed information control capabilities. This includes the ability to more effectively intercept, moderate, encrypt, and block e-mail messages. Together, this functionality provides you with a flexible range of protection and control options, whether you want to automatically enforce controls or empower users to implement their own data protection.

Messaging Policy and Compliance Features

Exchange 2010 compliance features make retention independent of users' mailbox management and filing habits, and ensure retention policies are applied continuously. The following is a list of new messaging and compliance features included in Exchange 2010:

- Additional messaging records management (MRM) functionality to apply message retention policies
- Personal Archive feature to provide users with online archive mailboxes and help eliminate .pst files
- Mailbox search features for cross-mailbox search with Advanced Query Syntax (AQS) support
- Additional transport rules predicates and actions

For more information about messaging policy and compliance features, see New Messaging Policy and Compliance Functionality.

IRM-Protected E-Mail Functionality with Active Directory Rights Management Services

The following is a list of new Information Rights Management (IRM)-protected e-mail functionality with Active Directory Rights Management Services (AD RMS) included in Exchange 2010:

- Microsoft Outlook protection rules, to apply IRM-protection to messages in Outlook 2010
- Transport protection rules, to apply IRM protection to messages based on rule conditions
- Persistent protection of attachments in IRM-protected messages
- Support for AD RMS templates
- Support for IRM in Microsoft Office Outlook Web App
- Transport decryption, to decrypt IRM-protected messages to apply messaging policies
- Journal report decryption, to attach a decrypted copy of IRM-protected messages to journal reports
- AD RMS protection for Unified Messaging voice mail messages

For more information about IRM features, see Information Rights Management.

1.1.5.1 New Administrative Functionality in the Exchange Management Console

New Administrative Functionality in the Exchange Management Console

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 >

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic describes the changes to the Exchange Management Console (EMC) in Microsoft Exchange Server 2010.

Contents

Need help finding features in the EMC? Check out Roadmap for Exchange Features.

Feature Changes

This section briefly describes the new features that have been added to the EMC.

New Features in the Organization Configuration Node

Database management has moved from the **Server Configuration** node to the **Organization Configuration** node. In addition, the following wizards have been added to the node:

- **New Federation Trust wizard** Use this wizard to create a federation trust. A federation trust establishes a trust relationship between an Exchange organization and the Microsoft Federation Gateway. The trust is a prerequisite for enabling calendar free/busy sharing or federated delivery between two Exchange organizations, or allowing users to share their calendar and contacts with external recipients. For details, see Create a Federation Trust.
- **New Organization Relationship wizard** Use this wizard to create a relationship with an external Exchange 2010 organization for the purpose of sharing free/busy information, securing delivery of cross-premises e-mail using federated delivery, and moving mailboxes between on-premises Exchange servers and Microsoft Office Outlook Web App. For details, see Create an Organization Relationship.
- **New Sharing Policy wizard** Use this wizard to create a sharing policy to regulate how users inside your organization can share calendar and contact information with users outside the organization. For details, see Create a Sharing Policy.
- **New Outlook Web App Mailbox Policy wizard** Use this wizard to create an Outlook Web App mailbox policy to apply a common set of policy settings, such as attachment settings. Outlook Web App mailbox policies are useful for applying and standardizing settings for specific groups of users. For details, see Create Outlook Web App Mailbox Policy.

New Features in the Server Configuration Node

You can no longer manage mailbox or public folder databases from the **Server Configuration** node. Now, they're managed from the **Organization Configuration** node. However, you can view mailbox database properties (from the work pane of **Server Configuration** > **Mailbox**).

In addition, the following features have been added to the node:

- **Manage Diagnostic Logging Properties wizard** Use this wizard to modify the diagnostic logging level for processes used by Exchange 2010. Modifying these levels can help you troubleshoot issues that may occur in your organization. For details, see Manage Diagnostic Logging Levels.
- **Exchange Certificates tab** Use this tab to assign services to an Exchange certificate, remove or renew a certificate, or view the certificate's properties. For details, see the following topics:
  - Assign Services to a Certificate

  - Renew an Exchange Certificate
  - View Exchange Certificate Properties
- **New Exchange Certificate wizard** Use this wizard tohelp you determine what type of certificates you need for the features in your organization to function correctly. For details, see Create a New Exchange Certificate.
- **Import Exchange Certificate wizard** Use this wizard to help import a certificate with a valid private key to a specified Exchange server. For details, see Import an Exchange Certificate.

New Features in the Recipient Configuration Node

The following features have been added to the **Recipient Configuration** node:

- **Send Mail** Click this button to send mail to a recipient from the EMC. Before you can send mail, you need to set up an e-mail account on the computer from which you are sending mail.
- **Resource scheduling** The property pages for resource mailboxes now include tabs for configuring calendaring and scheduling. For details, see Configure User and Resource Mailbox Properties.
- **Archive mailboxes** You can enable or disable archive mailboxes directly from the EMC. In addition, you can manage the archive settings for users from the property page of their mailbox. For details, see Managing Archives.
- **Move requests** If you want to move mailboxes, you can use the New Local Move Request or New Remote Move Request wizards. You can also keep track of move requests that are in progress by using the **Move Requests** node. For details, see Managing Move Requests.

Core EMC Changes

The following new functionality affects how you use the EMC, but not how you use specific features. Expand each of these new feature sections to learn more.

Add Exchange Forests to the EMC Console Tree

You can now add Exchange forests to the EMC. The first forest will always be named **Microsoft Exchange On-Premises**. This is the default forest for your organization. You can add additional forests by using the Add Exchange Forest wizard. For details, see View Local Forest Properties.

Customer Experience Improvement Program

The Customer Experience Improvement Program (CEIP) collects anonymous information about how you use Exchange and the problems that you encounter. Microsoft uses this information to improve the products and features you use most often and to help solve problems. Participation in the program is voluntary, and the end results are software improvements to better meet your needs. For more information about the CEIP, see Microsoft Customer Experience Program FAQ. For details about how to opt-in or opt-out of the program, see Opt-in or Opt-out of the Customer Experience Improvement Program.

Organizational Health

The Organizational Health report lets you increase productivity by giving you a quick view of your organization and its operating characteristics. The report provides an organizational summary. This includes health and licensing information, and also a summary of Exchange servers and recipients.

Important:
This report is for information only. If errors occur while collecting the information, the report may not be accurate.

Exchange doesn't automatically gather the organizational information. You must use the Collect Organizational Health Data wizard to view a summary of your organization's health. For details, see Collect Organizational Health Data.

Customer Feedback

The **Customer Feedback** tab is located in the result pane of the **Microsoft Exchange On-Premises** node. The tab is divided into two sections:

- **Customer Feedback Options** This section allows you to run the Customer Experience Improvement Program wizard, which allows you to opt-in or out of the CEIP. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.
- **Help and Feedback** This section provides a link to the Exchange Server TechCenter and allows you to submit feedback or to report bugs directly to the Exchange team.

Exchange Management Shell Command Log

The Exchange Management Shell Command Log records the commands that you execute in the EMC. For example, if you view the list of recipients from the **Mailbox** node, the **Get-Recipient** cmdlet is executed, and the Exchange Management Shell Command Log records that action.

Note:
The command log doesn't save the logging information. After you close the EMC, the log is erased. However, you can export the command log to tab-delimited or comma-delimited files.

To view the command log, from the EMC toolbar, click **View**, and then click **View Exchange Management Shell Command Log**.

For information about command logging, see Using the Exchange Management Shell Command Log to Track Tasks Performed in the EMC.

Property Dialog Command Exposure

Exposing the commands for actions executed in property pages allows you to see the Microsoft Windows PowerShell command and the parameters required to change object properties. To view the command, click the arrow icon located in the bottom left corner of the property page. To copy the command, select the command and press **CTRL+C**.

Note:
The command viewer is made available only after you make a property change.

Role Based Access Control in the EMC

When you open the EMC, Exchange checks to see what Role Based Access Control (RBAC) permissions you have. You can only view or configure features and items for which you have the correct permissions. If an administrator has permission to view an object but not edit it, the field text will appear dimmed and a caution icon will display. For more information about RBAC, see Understanding Role Based Access Control.

Exchange Help

The Exchange Help files are no longer downloaded to Exchange. Instead, they're hosted on Microsoft TechNet. This ensures that you're always viewing the most up-to-date Help topics.

Exchange 2010 contains two new cmdlets for managing Exchange Help:

- **Set-ExchangeAssistanceConfig** Using this cmdlet, you can modify the URLs that the Exchange Help client uses to connect to the source of the Exchange 2010 documentation. By default, TechNet is used as the source. For details, see Set-ExchangeAssistanceConfig.
- **Get-ExchangeAssistanceConfig** Using this cmdlet, you can view the configuration information for the URLs that the Exchange Help client uses to connect to the source of the Exchange 2010 documentation. For details, see Get-ExchangeAssistanceConfig.

1.1.5.2 New Exchange Core Store Functionality

New Exchange Core Store Functionality

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-28*

Microsoft Exchange Server 2010 includes many improvements to the Exchange database architecture:

- Public folder reporting has been enhanced.
- Databases are no longer associated with storage groups. Storage groups have been removed.
- Investments in store schema and Extensible Storage Engine (ESE) optimizations have reduced IOPS by 70 percent.

The following sections describe these improvements in more detail.

Contents

Enhanced Reporting for Public Folders

Public folder reporting has been enhanced to view user-initiated changes to any item in the public folder. You can view this information by using the **Get-PublicFolderStatistics** cmdlet in the Exchange Management Shell. For more information, see Exchange Management Shell.

Database Management

Databases are no longer associated with storage groups. In Exchange 2010, storage group functionality has been moved to the database.

In Exchange 2010, you can manage mailbox and public folder databases in the **Organization Configuration** node of the EMC. (In Exchange Server 2007, database management was performed in the **Server Configuration** node.)

Although public folder database management has been moved from the **Server Configuration** node to the **Organization Configuration** node with the mailbox databases, the functionality of public folder databases hasn't changed in Exchange 2010. Just like in Exchange 2007, you can't create database copies of public folder databases, and you can't add public folder databases to a database availability group (DAG). However, public folder databases can be hosted on Mailbox servers that are part of a DAG, although public

folder databases won't be subject to log shipping or any other DAG features.

Database Cmdlet Changes

With the removal of storage groups in Exchange 2010, the storage group cmdlets used in Exchange 2007 were deleted and the Exchange 2010 database cmdlets now provide the functionality, as shown in the following tables.

Database cmdlets in Exchange 2010 that replace Exchange 2007 storage group cmdlets

Exchange 2007 cmdlet	Description of functionality change in Exchange 2010
New-StorageGroup	This cmdlet has been deleted, and configuration parameters were moved to the **New-MailboxDatabase** and **New-PublicFolderDatabase** cmdlets.
Remove-StorageGroup	This cmdlet has been deleted, and configuration parameters were moved to the **Remove-MailboxDatabase** and **Remove-PublicFolderDatabase** cmdlets.
Set-StorageGroup	This cmdlet has been deleted, and configuration parameters were moved to the **Set-MailboxDatabase** and the **Set-PublicFolderDatabase** cmdlets.
Get-StorageGroup	This cmdlet has been deleted, and configuration parameters were moved to the **Get-MailboxDatabase** and **Get-PublicFolderDatabase** cmdlets.
Move-StorageGroupPath	This cmdlet has been deleted, and configuration parameters were moved to the **Move-DatabasePath** cmdlet.

Database cmdlets in Exchange 2010 that have extended functionality from Exchange 2007 cmdlets

Exchange 2010 cmdlet	Description of extended functionality in Exchange 2010
New-MailboxDatabase **New-PublicFolderDatabase**	These cmdlets have been extended with the parameters and functionality from the **New-StorageGroup** cmdlet. They also update the server object with a link to the new database and the database object with the hosting server name.
Remove-MailboxDatabase **Remove-PublicFolderDatabase**	These cmdlets have been extended with the parameters and functionality from the **Remove-StorageGroup** cmdlet. In addition, they also update the server object with the link to the new database and the database object with the hosting server name.
Set-MailboxDatabase **Set-PublicFolderDatabase**	These cmdlets have been extended with the parameters and functionality from the **Set-StorageGroup** cmdlet. When changing the host servers, they also update the server

	object with the link to the new database and the database object with the hosting server name.
Get-MailboxDatabase **Get-PublicFolderDatabase**	These cmdlets have been extended with the parameters and functionality from the **Get-StorageGroup** cmdlet. The *Status* parameter is extended to return the status information currently returned by the **Get-StorageGroupCopyStatus** cmdlet.
Move-DatabasePath	This cmdlet has been extended with the parameters and functionality from the **Move-StorageGroupPath** cmdlet.

In addition to the preceding cmdlet changes, the **StorageGroupCopy** cmdlets have been deleted. For more information, see Managing Mailbox Database Copies.

Store Changes

In Exchange 2010, the store schema has been changed to remove the dependency of mailbox databases on the server object. In addition, the new schema has been improved to help reduce database I/O per second (IOPS) by refactoring the tables used to store information. Refactoring the tables allows higher logical contiguity and locality of reference. These changes reduce the store's reliance on the secondary indexes maintained by ESE. As a result, the store is no longer sensitive to performance issues related to the secondary indexes.

Store resilience and health has also been improved by adding several features related to detecting and correcting errors and providing alerts, such as the following:

- Mailbox quarantine on rogue mailboxes
- Transport cutoff to databases with less than 1 GB of space
- Thread time-out detection and reporting

For more information about store resilience and health, see Understanding the Exchange 2010 Store.

Core store functionality has received many changes to improve high availability features. High availability has been integrated into the core architecture of Exchange 2010 to enable organizations of all sizes and in all industry segments to economically deploy a messaging continuity service. For more information about the high availability changes in Exchange 2010, see Understanding High Availability and Site Resilience.

New ESE Functionality

Extensible Storage Engine (ESE) has been improved in Exchange 2010 to achieve the following goals:

- Larger I/O and sequential I/O to reduce IOPS
- Optimization for commodity storage
- Database management reduction
- Online defragmentation
- Online database scanning

Larger and Sequential I/O

By increasing the size of the I/O and reducing the frequency of read/writes in Exchange 2010, ESE is able to increase performance. In addition, ESE can increase performance by

making the data in the database more sequential, which increases the likelihood that related data is in the same vicinity in the B-tree.

In Exchange, all data inside the database is stored in B-trees, and the B-trees are then divided into pages. In Exchange 2007 and earlier, the data stored in the B-trees isn't contiguous. In fact, previous versions of Exchange performed random read/writes to the database. This means that related data may not be in the same vicinity on the hard disk. Non-contiguous data requires more passes to read and write to the hard disk.

B-Tree Defragmentation

The B-tree defragmentation process has been improved to reduce I/O operations by maintaining contiguous data in the B-tree.

B-tree defragmentation is performed in-place (as opposed to creating a new B-tree and renaming the indexes and tables) with three new operations:

- **Page move** A page move consists of moving all data from one page to a newly allocated page.
- **Partial left merge** A partial left merge is the same as a right merge in Exchange 2007 or earlier, except that data is moved from the left page to the right page.
- **Full left merge** A full left merge is the same as a full right merge in Exchange 2007 or earlier.

Defragmentation has been changed from right merges to left merges to optimize performance. Data is read from or written to the hard disk from right to left. If the database is being defragmented in the same direction as the read/writes, defragmentation will conflict with the read/writes. In addition, space allocation allows the next page in an extent to be allocated, but not the previous page. Because a page move needs to allocate a new page, defragging the database from left to right is much more efficient.

The Defragmentation Manager is a new event in ESE that monitors which B-trees require defragmenting and which B-trees have already been defragmented. The Defragmentation Manager compiles a list of the B-trees in all mounted databases that should be defragmented. As fragmented B-trees are discovered, they're registered with the Defragmentation Manager, and the Defragmentation Manager will process them.

Page Size Increase to 32 KB

All data inside the database is stored in B-trees, and the B-trees are divided into pages. The page size is the minimum size for reading and writing to the database; it's also the unit size used for database caching. Reading from the disk is slower than performing operations in memory; therefore, by increasing the page size to 32 KB, ESE reduces IOPS, which increases performance by caching the larger page size in memory.

Optimize for Commodity Storage

Another of the goals of ESE in Exchange 2010 is to reduce the capital and operational costs of deploying Exchange. This can be done by reducing storage costs and optimizing for commodity storage using JBOD and SATA class hard disks.

Disk subsystems are more efficient at handling fewer but larger I/O. In Exchange 2010 or earlier, the page size is the minimum read/write size and the minimum size for database caching. Coalescing I/Os refers to the process of combining database page operations into a single I/O operation, thereby producing fewer and bigger I/O operations.

Increasing the average database I/O sizes via coalescing I/Os has the following benefits:

- **Increased disk use efficiency** Disks are more efficient at processing large I/Os. The more efficiently the disk is utilized, the more mailboxes can be hosted on that disk.
- **Increased cache warming rate** Cache warming is a process that helps reduce the execution times by preloading the initial queries that were

executed against a database the last time the database was started. After a server restart, failover, or switchover, the larger I/O allows ESE to increase the rate at which the cache is warmed.

Database Maintenance

One of the goals of ESE in Exchange 2010 is to reduce the cost of maintaining and managing a database. Database maintenance is comprised of several tasks that manage and keep the integrity of your mailbox database.

Database maintenance is divided into the following:

- Store mailbox maintenance
- ESE database maintenance

In Exchange 2007, ESE database maintenance was disk-intensive. In Exchange 2010, improvements have been made to increase performance. In Exchange 2010, on large or very heavy profile servers, the store mailbox maintenance task only lasts approximately 45 minutes, while ESE database maintenance usually took from six to eight hours per night to complete on large Exchange 2007 databases (2 GB quotas).

In Exchange 2010, improvements have been made to support both large mailboxes as well as to support JBOD storage and storage without the use of RAID.

Note:

All Exchange Store-focused online database maintenance functions such as recovery item cleanup are the same in Exchange 2010 as they are in Exchange 2007. Only ESE functions, online defragmentation, and database checksumming have changed.

Database Defragmentation

Defragmentation makes the internal pages of an Exchange database contiguous. Defragmentation can either be performed automatically by the system while the database is online (online defragmentation) or manually by an administrator when the database is offline (offline defragmentation).

Online Defragmentation

In Exchange 2010, the architecture for online defragmentation has changed. Online defragmentation was moved out of the Mailbox database maintenance process. Online defragmentation now runs in the background 24×7. Because online defragmentation runs all the time, Exchange no longer posts events to the event log indicating the amount of white space in the database. During background database maintenance, items marked for removal from the database are removed, which frees up database pages. The percentage of white space is constantly changing due to the efforts of the continuous online defragmentation process.

You can estimate the amount of white space in the database by knowing the amount of mail sent and received by the users with mailboxes in the database. For example, if you have 100 2-GB mailboxes (total of 200 GB) in a database where users send and receive an average of 10 MB of mail per day, the amount of white space is approximately 1 GB (100 mailboxes × 10 MB per mailbox). The amount of white space can exceed this estimate if background database maintenance isn't able to complete a full pass.

You don't need to configure any settings for this feature. Exchange monitors the database as it's being used, and small changes are made over time to keep it defragged for space and contiguity. If the database analyzes a range of pages and finds that they aren't as sequential as they should be, it starts an async thread to defragment that section of the B-tree/table. Online defragmentation is also throttled so it doesn't have a negative impact on client performance.

Use the ESE performance counter set MSExchange Database ==> Defragmentation Tasks to see the tasks that are performed. For more information, see How to Enable Extended ESE Performance Counters.

Offline Defragmentation

Offline defragmentation is a manual process that is performed by an administrator while the database is in a dismounted (offline) state. In this process, the ESEUTIL tool is used to read the database file and write a new database file using the contents in a contiguous fashion. The offline defragmentation process doesn't copy the white space from the original database; therefore, the size of the newly created database file is smaller than the original database on disk (potentially much smaller, depending on the amount of white space in the database). Historically, the typical reasons for performing an offline defragmentation of a database included the following:

- To shrink the size of the database file on disk
- To reclaim white space in a database
- To avoid low free disk space
- To repair a damaged database (the second step in the repair following ESEUTIL /p)

Offline defragmentation has never been part of regular maintenance for Exchange databases and, for some time now, Microsoft has recommended against regular, proactive offline defragmentation of databases. This recommendation was made for a variety of reasons, including the following:

- It results in downtime because you have to take the database offline.
- In a replicated mailbox database environment, it results in the need to re-seed all passive copies of an active copy that has been defragmented offline, and it results in the need to re-seed any passive copy that has been defragmented offline. (Thus, you should never perform an offline defragmentation of a passive database copy.)
- It results in the creation of a new database, with a new database signature, and that eliminates the ability to restore log files from a backup of the database that was taken prior to offline defragmentation.

As an alternative to offline defragmentation, we recommend that customers create a new database and move the mailboxes to the newly created database. In an Exchange 2010 environment, the mailboxes are moved online with no interruption in service to end users. In addition, when you move all mailboxes from an existing database to a new database, the end result is the same: A defragmented database with pages written contiguously and with no appreciable white space in the database file. After that process is complete, you simply delete the old (now empty) database. This guidance only covers proactive offline defragmentation to reclaim white space. You should still perform defragmentation if directed to do so by Microsoft Customer Support Services.

Online Database Scanning

Online database scanning (also known as database checksumming) has also changed. In Exchange 2007 Service Pack 1 (SP1), there was an option to use half of your online defragmentation time for this database scanning process (to ensure Exchange read every page from your database in a specific period of time to detect any corruptions).

In Exchange 2010, online database scanning checksums the database and performs post Exchange 2010 Store crash operations. Space can be leaked due to crashes, and online database scanning finds and recovers lost space. The system in Exchange 2010 is designed with the expectation that every database is fully scanned once every seven days. A warning event is fired if a database isn't completely scanned in this timeframe. In Exchange 2010, there are now two modes to run online database scanning on active database copies:

- Run as the last task in the scheduled Mailbox Database Maintenance process. You can configure how long it runs by changing the Mailbox Database Maintenance schedule. You can use this option for smaller databases that are less than 1 terabyte (TB) in size, which require less time to complete a full scan.
- Run in the background 24×7, the default behavior. This option works well for all database sizes, but it's recommended for large database sizes (1-2 TB in size). Exchange scans the database no more than once per day. This read I/O

is 100 percent sequential (which makes it easy on the disk) and equates to a scanning rate of about 5 megabytes (MB)/sec on most systems.

For more information about configuring database maintenance, see Maintain Mailbox Databases.

1.1.5.3 New High Availability and Site Resilience Functionality

New High Availability and Site Resilience Functionality

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-11*

Microsoft Exchange Server 2010 reduces the cost and complexity of deploying an e-mail solution that provides the highest levels of server availability and site resilience. Building on the native replication capabilities introduced in Exchange Server 2007, the new high availability architecture in Exchange 2010 provides a simplified, unified framework for both high availability and disaster recovery. Exchange 2010 integrates high availability into the core architecture of Exchange, enabling customers of all sizes and in all segments to be able to economically deploy a messaging continuity service in their organization.

Lessons Learned from Exchange Server 2007

Exchange 2007 decreased the costs of high availability and made site resilience much more economical by introducing new technologies such as local continuous replication (LCR), cluster continuous replication (CCR), and standby continuous replication (SCR). Still, some challenges remained:

- Some administrators were intimidated by the complexity of Windows failover clustering.
- Achieving a high level of uptime can require a high level of administrator intervention.
- Each type of continuous replication was managed differently and separately.
- Recovering from a failure of a single database on a large Mailbox server could result in a temporary disruption of service to all users on the Mailbox server.
- Site resilience solutions were not seamless.
- The transport dumpster feature of the Hub Transport server could only protect messages destined for mailboxes in an LCR or CCR environment. If a Hub Transport server fails while processing messages and can't be recovered, it could result in data loss.

Exchange 2010 includes significant core changes that integrate high availability deep in its architecture, making it even less costly and easier to deploy and maintain than Exchange 2007 for all customers. Organizations can now deploy a fully redundant Exchange organization with just two servers, and benefit from database-level failovers. Customers benefit from automatic, database-level failover capabilities without having to become experts in Windows failover clustering. Moreover, you can add site resilience to your existing high availability deployments with less complexity.

Exchange 2007 introduced many new architectural changes designed to make deploying high availability and site resilience solutions for Exchange faster and simpler. These improvements included an integrated Setup experience, optimized out-of-box configuration settings, and the ability to manage most aspects of the high availability

solution using native Exchange management tools.

Still, management of an Exchange 2007 high availability solution required administrators to master some clustering concepts, such as the concept of moving network identities and managing cluster resources. In addition, when troubleshooting issues related to a clustered Mailbox server, administrators had to use Exchange tools and cluster tools to review and correlate logs and events from two different sources: one from Exchange and one from the cluster.

Two other limiting aspects of the Exchange 2007 architecture have also been re-evaluated and re-engineered based on customer feedback:

- Clustered Exchange 2007 servers require dedicated hardware. Only the Mailbox server role could be installed on a node in the cluster. This meant that a minimum of four Exchange servers were required to achieve full redundancy of the primary components of a deployment, that is, the core server roles (Mailbox, Hub Transport, and Client Access).
- In Exchange 2007, failover of a clustered Mailbox server occurs at the server level. As a result, if a single database failure occurred, the administrator had to fail over the entire clustered Mailbox server to another node in the cluster (which resulted in brief downtime for all users on the server, and not just those users with a mailbox on the affected database), or leave the users on the failed database offline (potentially for hours) while restoring the database from backup.

Mailbox Resiliency

Exchange 2010 has been re-engineered around the concept of *mailbox resiliency*, in which the architecture has changed so that automatic failover protection is now provided at the individual mailbox database level instead of at the server level. In Exchange 2010, this is known as *database mobility*. As a result of this and other database cache architectural changes, failover actions now complete much faster than in previous versions of Exchange. For example, failover of a clustered Mailbox server in a CCR environment running Exchange 2007 with Service Pack 2 (SP2) completes in about two minutes. By comparison, failover of a mailbox database in an Exchange 2010 environment completes in 30 seconds or less (measured from the time when the failure is detected to when a database copy is mounted, assuming an available copy that's healthy and up to date with log replay). The combination of database-level failovers and significantly faster failover times dramatically improves an organization's overall uptime.

The mailbox resiliency architecture built into Exchange 2010 provides new benefits for organizations and their messaging administrators:

- Multiple server roles can coexist on servers that provide high availability. This enables small organizations to deploy a two-server configuration that provides redundancy of mailbox data and service, while also providing redundant Client Access and Hub Transport services.
- An administrator no longer needs to build a failover cluster to achieve high availability. Failover clusters are now created by Exchange 2010 in a way that's invisible to the administrator. Unlike previous versions of Exchange clusters which used an Exchange-provided cluster resource DLL named ExRes.dll, Exchange 2010 no longer needs or uses a cluster resource DLL. Exchange 2010 isn't a clustered application, and it uses only a small portion of the failover cluster components, namely, its heartbeat capabilities and the cluster database, to provide database mobility.
- Administrators can add high availability to their Exchange 2010 environment after Exchange has been deployed, without having to uninstall Exchange and then redeploy in a highly availability configuration.
- Exchange 2010 provides a view of the event stream that coalesces and combines the events from the operating system with the events from Exchange.

- Because storage group objects no longer exist in Exchange 2010, and because mailbox databases are portable across all Exchange 2010 Mailbox servers, it's easy to move databases when needed.

For more information, see High Availability and Site Resilience.

Flexible Mailbox Protection

Exchange 2010 includes several new features and core changes that, when deployed and configured correctly, can provide flexible mailbox protection that eliminates the need to make traditional backups of your data. Using the high availability features built into Exchange 2010 to minimize downtime and data loss in the event of a disaster can also reduce the total cost of ownership of the messaging system. By combining these features with other built-in features, such as Legal Hold, organizations can reduce or eliminate their dependency on traditional point-in-time backups and realize the cost savings of doing so.

In addition to determining whether Exchange 2010 enables you to move away from traditional point-in-time backups, we also recommend that you evaluate the cost of your current backup infrastructure. Consider the cost of end-user downtime and data loss when attempting to recover from a disaster using your existing backup infrastructure. Also, include hardware, installation and license costs, as well as the management cost associated with recovering data and maintaining the backups. Depending on the requirements of your organization, it is quite likely that a pure Exchange 2010 environment with at least three mailbox database copies will provide lower total cost of ownership than one with backups.

For more information about flexible mailbox protection, see Understanding Backup, Restore and Disaster Recovery.

Changes to High Availability from Previous Versions of Exchange

Exchange 2010 includes many changes to its core architecture. Exchange 2010 combines the key availability and resilience features of CCR and SCR into single high availability solution which handles both onsite data replication and offsite data replication. Mailbox servers can be defined as part of a database availability group (DAG) to provide automatic recovery at the individual mailbox database level instead of at the server level. Each mailbox database can have up to 16 copies. Other new high availability concepts are introduced in Exchange 2010, such as *database mobility* and *incremental deployment*. The concepts of an organization without backups and RAID are also being introduced in Exchange 2010.

To summarize, the key aspects to data and service availability for the Mailbox server role and mailbox databases are:

- Exchange 2010 uses an enhanced version of the same continuous replication technology introduced in Exchange 2007. For more information, see Changes to Continuous Replication from Exchange Server 2007 later in this topic.
- Storage groups no longer exist in Exchange 2010. Instead, there are simply mailbox databases, mailbox database copies, and public folder databases. The primary management interfaces for Exchange databases has moved within the Exchange Management Console from the Mailbox node under **Server Configuration** to the Mailbox node under **Organization Configuration**.
- Some Windows Failover Clustering technology is used by Exchange 2010, but it's now completely managed by Exchange. Administrators don't need to install, build, or configure any aspects of failover clustering when deploying highly available Mailbox servers.

- Each Mailbox server can host as many as 100 databases, and each database can have as many as 16 copies.
- In addition to the transport dumpster feature, a new Hub Transport server feature named *shadow redundancy* has been added. Shadow redundancy provides redundancy for messages for the entire time they're in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport database is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting back successful delivery, the message is resubmitted for delivery to that next hop. For more information about shadow redundancy, see Understanding Shadow Redundancy.

Incremental Deployment

In previous versions of Exchange, service availability for the Mailbox server roles was achieved by deploying Exchange in a Windows failover cluster. To deploy Exchange in a cluster, you had to first build a failover cluster, and then install the Exchange program files. This process created a special Mailbox server called a clustered Mailbox server (or Exchange Virtual Server in previous versions of Exchange). If you had already installed the Exchange program files on a non-clustered server and you decided you wanted a clustered Mailbox server, you had to build a cluster using new hardware, or remove Exchange from the existing server, install failover clustering, and reinstall Exchange.

Exchange 2010 introduces the concept of incremental deployment, which enables you to deploy service and data availability for all Mailbox servers and databases after Exchange is installed. Service and data redundancy is achieved by using new features in Exchange 2010 such as DAGs and database copies.

Database Availability Groups

A DAG is a set of up to 16 Mailbox servers that provide automatic database-level recovery from failures that affect individual databases. Any server in a DAG can host a copy of a mailbox database from any other server in the DAG. When a server is added to a DAG, it works with the other servers in the DAG to provide automatic recovery from failures that affect mailbox databases, such as a disk failure or server failure.

For more information about DAGs, see Understanding Database Availability Groups.

Mailbox Database Copies

The high availability and site resilience features first introduced in Exchange 2007 are used in Exchange 2010 to create and maintain database copies, thereby enabling you to achieve your availability goals in Exchange 2010. Exchange 2010 also introduces the new concept of database mobility, which is Exchange-managed database-level failovers.

Database mobility disconnects databases from servers, adds support for up to 16 copies of a single database, and provides a native experience for adding database copies to a database. In Exchange 2007, a feature called database portability also enabled you to move a mailbox database between servers. A key distinction between database portability and database mobility, however, is that with database mobility, all copies of a database have the same GUID.

Other key characteristics of database mobility are:

- Because storage groups have been removed from Exchange 2010, continuous replication now operates at the database level. In Exchange 2010, transaction logs are replicated to one or more Mailbox servers and replayed into a copy of a mailbox database that's stored on those servers.

- A failover is an automatic activation process that can occur at either the database level or at the server level. A switchover is a manual activation process that you can perform at the database, server, or data center (site) level.
- Database names for Exchange 2010 must be unique within the Exchange organization.
- When a mailbox database has been configured with one or more database copies, the full path for all database copies must be identical on all Mailbox servers that host a copy.
- Any mailbox database copy (the active or any passive copy) can be backed up using an Exchange-aware Volume Shadow Copy Service (VSS)-based backup application.

For more information about mailbox database copies, see Understanding Mailbox Database Copies.

Changes to Continuous Replication from Exchange Server 2007

The underlying continuous replication technology previously found in CCR and SCR remains in Exchange 2010, and it's been further evolved to support new high availability features such as database copies, database mobility, and DAGs. Some of these new architectural changes are briefly described as follows:

- Because storage groups have been removed from Exchange 2010, continuous replication now operates at the database level. Exchange 2010 still uses an Extensible Storage Engine (ESE) database that produces transaction logs that are replicated to one or more other locations and replayed into one or more copies of a mailbox database.
- Because the log replay functionality that was performed by the Microsoft Exchange Replication service in Exchange 2007 has been moved into the Exchange 2010 version of the Microsoft Exchange Information Store service (store.exe), the performance hit associated with failovers and switchovers (because a new database cache was put into use) no longer exists. When a failover or switchover occurs, the activated database has a warm cache that's ready for use.
- Log shipping and seeding no longer uses Server Message Block (SMB) for data transfer. Exchange 2010 continuous replication uses a single administrator-defined TCP port for data transfer. In addition, Exchange 2010 includes built-in options for network encryption and compression for the data stream.
- Log shipping no longer uses a pull model, where the passive copy pulls closed log files from the active copy. Instead, the active copy pushes the log files to each configured passive copy.
- Seeding is no longer restricted to using only the active copy of the database. Passive copies of mailbox databases can now be specified as sources for database copy seeding and reseeding.
- Database copies are for mailbox databases only. For redundancy and high availability of public folder databases, we recommend that you use public folder replication. Unlike CCR, where multiple copies of a public folder database couldn't exist in the same cluster, each DAG member can host a public folder database, and you can use public folder replication to replicate public folders between public folder databases hosted on DAG members.
- The LogReplayer component of the Microsoft Exchange Replication service includes new logic to suspend log replay if the copy queue length increases beyond a specific threshold. If the number of logs in the copy queue is greater than the number of log files that have been copied to the passive database copy, but not inspected by the passive copy, then the Microsoft Exchange Replication service will suspend log replay for the passive copy and log

Warning event 4110 in the event log. When the number of log files in the copy queue drops below the number of non-inspected copied log files, the Microsoft Exchange Replication service will resume replay for the passive copy and log Informational event 4111 in the event log.

Several concepts used in Exchange 2007 continuous replication also remain in Exchange 2010. These include the concepts of *failover management*, *divergence*, the use of the *auto database mount dial*, and the use of public and private networks.

Changes to Routing Behavior When Hub Transport and Mailbox are Co-Located in a DAG

When the Hub Transport server is co-located with a Mailbox server that is a member of a DAG, there are changes in routing behavior to ensure that the resiliency features in both server roles will provide the necessary protection for messages sent and received by users on that server. The Hub Transport server role was modified so that it now attempts to re-route a message for a local Mailbox server to another Hub Transport server in same site if the Hub Transport server is also a DAG member and it has a copy of the mailbox database mounted locally. This extra hop was added in order to put the message in transport dumpster on a different Hub Transport server.

For example, EX1 hosts the Hub Transport and Mailbox role and is a member of a DAG. When a message arrives in transport for EX1 that is destined for a recipient whose mailbox is also on EX1, transport will re-route the message to another Hub Transport server in the site (for example, EX2), and that server will deliver the message to the mailbox on EX1.

There is a second similar behavior change with respect to the Microsoft Exchange Mail Submission service. This service was modified so that it would prefer to not submit messages to a local Hub Transport role when the Mailbox and Hub Transport server is a member of a DAG. In this scenario, the behavior of transport is to load balance submission requests across other Hub Transport servers in same Active Directory site, and fall back to local Hub Transport server if there are no other available Hub Transport servers in the same site.

End-to-End Availability

Exchange 2010 also includes many features designed to increase end-to-end availability of the system. These features include:

- Transport resilience
- Online move mailbox
- Exchange native data protection
- Incremental resync
- Third Party Replication API

Transport Resilience

Exchange 2007 introduced the transport dumpster feature of the Hub Transport server. The transport dumpster maintains a queue of messages that were delivered to recipients whose mailbox was in a CCR (and in Exchange 2007 SP1, in an LCR) environment. This feature was designed to help protect against data loss by providing an administrator with the option to have a clustered Mailbox server automatically come online on another node with a limited amount of data loss. This is referred to as a lossy failover. When a lossy failover occurred, the system automatically re-delivered the recent e-mail messages sent to users on the failed clustered Mailbox server, by using the transport dumpster where

the e-mail messages were still stored. Although this solution helped to minimize the amount of data lost in a lossy failover, the solution only protected from data loss within a site, and it didn't provide protection for messages in transit.

Exchange 2010 introduces core architectural changes that address both issues. Because DAGs can be stretched across Active Directory sites, it's possible for an individual mailbox database to move between Active Directory sites. Because of this design change, the transport dumpster re-delivery request upon a lossy database failover is now issued to Hub Transport servers in both the database's original and new Active Directory sites.

One other significant change to the transport dumpster is that it now receives feedback from the replication pipeline. When messages in the transport dumpster have been replicated to all mailbox database copies, they're removed from the transport dumpster. This ensures that only non-replicated data is held in the transport dumpster.

In addition to the transport dumpster feature, a new Hub Transport server feature named *shadow redundancy* has been added. Shadow redundancy provides redundancy for messages for the entire time they're in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport database is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting back successful delivery, the message is resubmitted for delivery to that next hop. For more information about shadow redundancy, see Understanding Shadow Redundancy.

Online Move Mailbox

Exchange 2010 includes a new feature that enables you to move mailboxes asynchronously. In Exchange 2007, when you used the **Move-Mailbox** cmdlet to move a mailbox, the cmdlet logged into both the source database and the target database and moved the content from one mailbox to the other mailbox. There were several disadvantages to having the cmdlets perform the move operation:

- Mailbox moves typically took hours to complete, and during the move, users weren't able to access their mailbox.
- If the command window used to run **Move-Mailbox** cmdlet was closed, the move was terminated and had to be restarted from the beginning.
- The computer used to perform the move participated in the data transfer. If an administrator ran the cmdlets from their workstation, the mailbox data would flow from the source server to the administrator's workstation and then to the target server.

The new move request cmdlets in Exchange 2010 can be used to perform asynchronous moves. Unlike Exchange 2007, the cmdlets don't perform the actual move. The move is performed by the Microsoft Exchange Mailbox Replication Service, a new service that runs on the Client Access server. The **New-MoveRequest** cmdlet sends requests to the Mailbox Replication Service. For more information about online move mailbox, see Understanding Move Requests.

Exchange Native Data Protection

There are several changes to the core architecture of Exchange 2010 that have a direct effect on how you protect your mailbox databases and the mailboxes they contain.

One significant change is the removal of storage groups. In Exchange 2010, each database is associated with a single log stream, represented by a series of 1 megabyte (MB) log files. Each server can host a maximum of 100 databases.

Another significant change for Exchange 2010 is that databases are no longer closely tied to a specific Mailbox server. Database mobility expands the system's use of continuous replication by replicating a database to multiple different servers. This provides better protection of the database and increased availability. In the case of failures, the other servers that have copies of the database can mount the database.

The ability to have multiple copies of a database hosted on multiple servers, means that if you have a sufficient number of database copies, you can use these copies as your backups. For more information on this strategy, see Understanding Backup, Restore and Disaster Recovery.

Incremental Resync

Exchange 2007 introduced the concepts of lost log resilience (LLR) and incremental reseed. LLR is an internal component of ESE that enables you to recover Exchange mailbox databases even if one or more of the most recently generated transaction log files have been lost or damaged. LLR enables a mailbox database to mount even when recently generated log files are unavailable. LLR works by delaying writes to the database until the specified number of log generations have been created. LLR delays recent updates to the database file for a short time. The length of time that writes are delayed depends on how quickly logs are being generated.

Note:
LLR is hard-coded to one log file for all Exchange 2010 mailbox databases.

Incremental reseed provided the ability to correct divergences in the transaction log stream between a source and target storage group, by relying on the delayed replay capabilities of LLR. Incremental reseed didn't provide a means to correct divergences in the passive copy of a database after divergent logs had been replayed, which forced the need for a complete reseed.

In Exchange 2010, *incremental resync* is the new name for the feature that automatically corrects divergences in database copies under the following conditions:

- After an automatic failover for all of the configured copies of a database
- When a new copy is enabled and some database and log files already exist at the copy location
- When replication is resumed following a suspension or restarting of the Microsoft Exchange Replication Service

When divergence between an active database and a copy of that database is detected, incremental resync performs the following tasks:

- It searches historically in the log file stream to locate the point of divergence.
- It locates the changed database pages on the diverged copy.
- It reads the changed pages from the active copy and then copies the necessary log files from the active copy.
- It applies the database page changes to the diverged copy.
- It runs recovery on the diverged copy and replays the necessary log files into the database copy.

Third Party Replication API

Exchange 2010 also includes a new Third Party Replication API that enables organizations to use third-party synchronous replication solutions instead of the built-in continuous replication feature. For information about partner products for Exchange 2010, see the Exchange 2010 Partners Web site. If you're a partner seeking information on the Third Party Replication API, please contact your Microsoft representative.

Features Cut from Exchange Server 2007

The following features in Exchange 2007 and Exchange 2007 SP1 no longer exist in Exchange 2010. Their replacements are noted in the table.

Feature	Replacement
Cluster continuous replication (CCR)	Database availability groups and mailbox

	database copies
Standby continuous replication (SCR)	Database availability groups and mailbox database copies
Local continuous replication (LCR)	Database availability groups and mailbox database copies
Single copy clusters (SCC)	Database availability groups and mailbox database copies; built-in third-party synchronous API available to replace third-party data replication used with SCC
Clustered Mailbox servers	Database availability groups and mailbox database copies
Storage groups	Databases
Recovery Storage Group	Recovery database

1.1.5.4 New Messaging Policy and Compliance Functionality

New Messaging Policy and Compliance Functionality

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-01*

Microsoft Exchange Server 2010 has new messaging policy and compliance features that allow organizations to comply with regulations related to messaging retention, protection of personal information, and fulfilling legal discovery requests for messaging records.

Contents

Messaging Records Management

Messaging records management (MRM) is the records management technology in Exchange that helps organizations to reduce legal risks associated with e-mail and other communications. In Exchange 2010, MRM is accomplished by using the following new retention features:

- **Retention tags** Retention tags are used to apply retention settings to messages and folders. There are three types of retention tags:
  - Default policy tags (DPTs)

  - Retention policy tags (RPTs)
  - Personal tags
- **Retention policies** A retention policy is a group of retention tags that can be applied to a mailbox.

Applying retention policies to the mailboxes in your organization allows you to apply message retention settings without impacting your users' e-mail workflow or e-mail organization methods. Also, with retention tags, users can tag messages and folders based on retention requirements. They no longer need to move messages to folders only for retention purposes (as was required by the managed folders feature in Exchange Server 2007).

Note:
Managed folders, the MRM technology introduced in Exchange 2007, is still available in Exchange 2010. For more information, see Understanding Managed Folders.

To learn more about the retention features in Exchange 2010, see Understanding Retention Tags and Retention Policies.

Return to top

Multi-Mailbox Search

In Exchange 2010, Multi-Mailbox Search helps organizations facing legal discovery requirements (as part of organizational policy, compliance requirements, or lawsuits), to search for relevant content in Exchange mailboxes. Exchange 2010 provides a seamless experience for searching e-mail content in mailboxes across the entire Exchange organization.

To learn more about Multi-Mailbox Search, see Understanding Multi-Mailbox Search.

Return to top

Litigation Hold

In Exchange 2010, Multi-Mailbox Search allows a user who is assigned the Discovery Management role to search mailbox content to comply with discovery requests. However, users who own the mailbox or have permissions to access it can delete messages. Furthermore, if a retention policy or a managed folder mailbox policy is applied to the mailbox, messages can be removed from the mailbox by the Managed Folder Assistant.

In Exchange 2010, you can place mailboxes on litigation hold to protect against intentional, policy-based, or accidental message deletion. This allows deleted messages to be indexed by Exchange Search. As a result, these messages are returned when Multi-Mailbox Search is used to search the mailbox. After a mailbox is placed on litigation hold, any changes made to messages are also preserved as different versions.

To learn more about litigation hold, see Understanding Litigation Hold.

Return to top

Information Rights Management Protection

Protecting critical business information is an important aspect of information protection. Regulations in many countries, regions, and industries (such as financial services and

healthcare), require organizations to protect personal information collected from customers and employees. Most business communication occurs over e-mail, and many users also use e-mail as an information and document repository.

To help protect this critical information, Exchange 2010 includes the following Information Rights Management (IRM) features:

- Support for Active Directory Rights Management Services (AD RMS) rights policy templates.
- Persistent protection of attachments in IRM-protected messages.
- Outlook protection rules protect messages in Microsoft Outlook 2010 based on rule conditions.
- Transport protection rules protect messages based on transport rule conditions.
- Transport decryption decrypts IRM-protected messages on Hub Transport servers, which allows you to apply messaging policies.
- Journal report decryption attaches a decrypted copy of IRM-protected messages to journal reports.
- Support for IRM in Microsoft Office Outlook Web App.
- IRM-protection for Unified Messaging voice mail messages.

To learn more about IRM features, see Understanding Information Rights Management.

Return to top

Personal Archive

Personal archives provide your users with an alternate storage location for storing historical messaging data. Using Outlook 2010 and Outlook Web App, users have seamless access to their personal archive. Using either of these client applications, they can view a personal archive and move or copy messages between their primary mailbox and the archive. Messages can also be automatically moved from the primary mailbox to the archive by using an archive policy.

Personal archives allow you to present your users with a consistent view of their messaging data, and they also eliminate the user overhead required to manage .pst files. Eliminating use of .pst files significantly reduces your organization's exposure to several risks.

To learn more about personal archives, see Understanding Personal Archives.

Return to top

Transport Rule Predicates and Actions

Transport rules inspect messages for conditions specified in the rule. Messages that meet the conditions, and none of the exceptions, have the specified actions applied to them. Exchange 2010 includes several new predicates and actions, providing additional flexibility when creating rules. To learn more, see Transport Rule Predicates and Transport Rule Actions.

The **New-TransportRule** and **Set-TransportRule** cmdlets are also enhanced, allowing you to specify all predicates and actions in a single command. All predicates and actions are now available for use as parameters with these cmdlets. To learn more about these cmdlets, see New-TransportRule and Set-TransportRule.

1.1.5.5 New Unified Messaging Functionality and Voice Mail Features

New Unified Messaging Functionality and Voice Mail Features

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-19*

New functionality and many new features have been added to Microsoft Exchange Server 2010 Unified Messaging (UM). This topic explains the new features for Unified Messaging and voice mail that are included in Exchange 2010.

Contents

Call Answering Rules

In Exchange 2010, the Unified Messaging server role allows UM-enabled users to create and customize call answering rules to enhance the experience of people who call them. At the time a user becomes enabled for UM, no call answering rules exist. The Exchange 2010 voice mail is the default call answering behavior. However, users can create up to nine call answering rules.

Call answering rules are similar to the Exchange Server 2007 UM auto attendants. There is usually a greeting, a menu prompt, and a list of options to choose from. The key difference between an auto attendant and a call answering rule that, when the call answering rule processes an incoming call, Unified Messaging already knows who the call is for.

Using call answering rules, a caller can:

- Leave a voice message for the UM-enabled user.
- Transfer to an alternate contact of the UM-enabled user.
- Transfer to the alternate contact's voice mail.
- Transfer to other phone numbers that the UM-enabled user has configured.
- Use the Find-Me feature or locate the UM-enabled user via a supervised transfer.

Additional Language Support

In Exchange 2007, each UM language pack included a Text-to-Speech (TTS) engine and the prerecorded prompts for a specified language. UM language packs for Exchange 2007 are offered in 16 different languages. However, not all the UM language packs contain support for Automatic Speech Recognition (ASR). For ASR, there was only one language—US English.

For Exchange 2010, all available language packs contain the Text-to-Speech (TTS) engine and the prerecorded prompts for a specified language and ASR support. However, only some of the language packs contain support for Voice Mail Preview. The US English (en-US) language pack is included on the Exchange 2010 DVD and additional UM language packs can be downloaded from the Microsoft Download Center.

For more information about UM language packs, see the following topics:

- Client Language Support for Unified Messaging
- Understanding Unified Messaging Languages

Improvements to Name Lookup from a Caller ID

In Exchange 2007 Unified Messaging, a voice message was created after a call was diverted to a Unified Messaging server because of a ring-no-answer or busy condition. After the call was answered, Exchange 2007 Unified Messaging tried to resolve the caller ID. It did this so that it could insert a name, rather than a number, into the sender information.

In Exchange 2007, name lookups for voice mail messages were done using information about the caller who was in the same dial plan as the user being called. Name lookups were performed by using an Exchange Unified Messaging proxy address (EUM proxy address), using the personal contacts of the user receiving the call, or using the **msRTCSIP-Line** attribute in Active Directory if Service Pack 1 (SP1) for Exchange 2007 was installed and Exchange 2007 was integrated with Office Communications Server 2007.

In Exchange 2010, the name lookup methods used in Exchange 2007 have been enhanced. Although Exchange 2010 includes methods that were used to resolve calling IDs in Exchange 2007, eight other Active Directory attributes have been added for resolving a caller ID to a name. You can use the following steps to look up a name from the calling party's information:

1. Use the caller's name if the caller is signed in to their mailbox from Outlook Voice Access or if they use a Unified Communications client such as Office Communicator 2007 or Office Communicator Phone Edition to place the call. The caller's identity is known because they've already been authenticated by Outlook Voice Access, Office Communicator 2007 or Office Communicator Phone Edition.
2. Use the EUM proxy addresses in Active Directory. If the proxy address contains an at sign (@), it's considered to be a Session Initiation Protocol (SIP) Uniform Resource Identifier (URI). If the proxy address begins with a plus sign (+), it's considered to be an E.164 number. If neither of these symbols is present, the address is considered to be an extension within the same dial plan as the called party or an equivalent dial plan.
3. If the caller ID is a valid SIP URI, use Active Directory to resolve the SIP URI using the EUM proxy addresses.
4. If the caller ID is a valid E.164 number, use Active Directory to resolve the number using the calling party's name. For this to work correctly, you must manually configure the `UMCallingLineIds` parameter on the UM-enabled

mailbox for each user. This is useful when you don't want to publish a telephone number, such as a personal cell phone number, in Active Directory, but still want to resolve the calling party's name by using this phone number.

5. Use Active Directory heuristic matching, if it is enabled, to resolve the number using the calling party's name. Active Directory heuristic matching must be enabled on the dial plan, and the user's account in Active Directory must contain information in at least one of the following Active Directory attributes:
   5.a.TelephoneNumber
   5.b.HomePhone
   5.c.Mobile
   5.d.FacsimileTelephoneNumber
   5.e.OtherTelephone
   5.f.OtherHomePhone
   5.g.OtherMobile
   5.h.OtherFacsimileTelephoneNumber
6. Use the personal Contacts of the called party to resolve the number using the calling party's name.
7. If the calling party's name is not resolved using one the methods described previously, the phone number is used in the voice mail message.

Voice Mail Preview

In Exchange 2010, the Unified Messaging server role uses ASR on newly created voice mail messages. When users receive voice messages, the messages contain both a recording and text that's been created from the voice recording. Users see the voice message text displayed in an e-mail message from within Outlook Web App, Outlook 2007, or Outlook 2010.

Message Waiting Indicator

Message Waiting Indicator is a feature found in most legacy voice mail systems and can refer to any mechanism that indicates the existence of a new message. In Exchange 2007, this functionality was provided by a third-party application, which indicated receipt of a new voice message by lighting the lamp on the desk phone. This feature has been added to Exchange 2010, and third-party software isn't needed. Enabling or disabling Message Waiting Indicator is done on the user's mailbox or on a UM mailbox policy.

Missed Call and Voice Mail Notifications Using SMS

When users are members of a hosted or consumer dial plan, and they configure their voice mail settings with their mobile phone number and configure call forwarding, they can receive notifications about missed calls and new voice messages on their cell phones in a text message via the Short Messaging Service (SMS). However, to receive these types of notifications, the users must first configure text messaging and also enable **Notifications** on their account.

Protected Voice Mail

Protected Voice Mail is Unified Messaging functionality that enables users to send private mail. This mail is protected by Active Directory Rights Management Services (AD RMS), and users are restricted from forwarding, copying, or extracting the voice file from e-mail. Protected Voice Mail increases the confidentiality of Unified Messaging, and lets users rely on Unified Messaging if they want to limit the audience for voice messages. This functionality is similar to the way private e-mail messages were handled in Exchange

2007. In Exchange 2010, it applies to voice mail messages as well.

Incoming Fax Support

Exchange 2007 provided built-in support for fax message creation through the Unified Messaging server role. A user with a UM-enabled mailbox could receive fax messages from calls placed to his or her phone number. There's no support in Exchange 2007 UM for inbound fax routing, or for outgoing fax.

In Exchange 2010, direct support for fax has been removed from the Unified Messaging server role. Customers who require a fax solution that works with Exchange 2010 will need to deploy a fax partner solution. Fax partner solutions are available from several fax partners. The fax partner solutions are designed to be tightly integrated with Exchange 2010 and allow UM-enabled users to receive incoming fax messages.

Group Addressing Using Outlook Voice Access

In Exchange 2007, users could use either the telephone user interface (TUI) or voice user interface (VUI) in Outlook Voice Access to send e-mail and voice messages when they logged on to their mailbox. However, users could only send a single e-mail message to a single user in their personal Contacts, to multiple recipients from the directory by adding each recipient individually, or by adding the name of a distribution list from the global address list. In Exchange 2010, when a user signs in to their mailbox using Outlook Voice Access, they can also send e-mail and voice messages to users in a group stored in their personal Contacts.

Built-in Unified Messaging Administrative Roles

A set of roles for managing Unified Messaging and voice mail features have been defined within Exchange 2010. Administrative roles that included UM were available in Exchange 2000. The following UM-specific administrative roles have been added for Exchange 2010:

- UM Mailboxes
- UM Prompts
- Unified Messaging

1.1.5.6 New Mailbox and Recipient Functionality

New Mailbox and Recipient Functionality

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

This topic lists the new functionality available for Mailbox servers, mailboxes, and recipients in Microsoft Exchange Server 2010.

For information about the other mailbox features, see the following topics:

- New Exchange Core Store Functionality
- New High Availability and Site Resilience Functionality

Contents

Calendaring

In Exchange 2010, your users can share information with external users. This information includes calendar, contacts, and free/busy data. For more information about accessing free/busy data from different organizations, see Managing Federated Delegation.

Note:

Contact sharing will be available with the release of Microsoft Outlook 2010. For information about when Outlook 2010 will be available, visit Microsoft Office Online.

Before you can share any information between organizations, a federation trust must be established. For more information, see Federation.

The **MailboxCalendarSettings** commands have been removed. The functionality is replaced by the following cmdlets:

- Get-MailboxCalendarConfiguration
- Set-MailboxCalendarConfiguration
- Get-CalendarProcessing
- Set-CalendarProcessing

Return to top

Calendar Repair Assistant

Calendar Repair Assistant (CRA) is a configurable, time-based mailbox assistant that runs within the Microsoft Exchange Mailbox Assistants service on Exchange 2010 Mailbox servers. CRA automatically detects and corrects inconsistencies for single and recurring meeting items in mailboxes. With this functionality, recipients won't miss meetings or have unreliable meeting information.

For more information about CRA, see Understanding Calendar Repair.

Return to top

Resource Scheduling

You can now use the Exchange Management Console (EMC) to manage resource scheduling by editing the resource mailbox's properties. For more information, see Configure User and Resource Mailbox Properties.

Return to top

Moving Mailboxes

Exchange 2010 includes cmdlets that allow you to move a mailbox while the end user is still accessing it. These cmdlets are for use in moving Exchange 2010 mailboxes between Exchange 2010 databases. Use the **Move-Mailbox** cmdlet in Exchange Server 2007 to move legacy Exchange mailboxes.

For more information, see Understanding Move Requests or Managing Move Requests.

Mailbox moves are now managed by the following cmdlets:

- New-MoveRequest This cmdlet begins the process to move a mailbox. You can test the readiness of a mailbox by including the *WhatIf* parameter in the command.
- Get-MoveRequest This cmdlet retrieves statistics about the status of an ongoing mailbox move that was initiated by using the **New-MoveRequest** cmdlet.
- Remove-MoveRequest This cmdlet cancels an ongoing mailbox move that was initiated by using the **New-MoveRequest** cmdlet.

Return to top

Distribution Groups

Exchange 2010 includes new functionality for both moderated and user-created distribution groups.

Moderated Distribution Groups

You can appoint a moderator to regulate the flow of messages sent to a distribution group. Anyone can send a message to the distribution group alias, but before the message is delivered to all participants, a moderator must review and approve it. This helps prevent inappropriate e-mail messages from being delivered to large audiences. For more information, see Understanding Moderated Transport.

User-Created Distribution Groups

The following is a list of new functionality for user-created distribution groups:

- New parameters have been added to the distribution group cmdlets to allow users to create and manage their own distribution groups in Microsoft Office Outlook Web App and Outlook 2010.
- A new user interface (UI) has been added to allow administrators to manage the distribution group ownership, including how users can be added to the group.
  To view the new UI, open a distribution group's property dialog box (right-click the group, and then click **Properties**). The **Group Information** and the **Membership Approval** tabs include the new functionality.

The following table lists the new parameters that support user-created distribution groups.

New parameters added to distribution group cmdlets

New parameter	Used in cmdlets
MemberDepartRestriction	New-DistributionGroup Set-DistributionGroup

MemberJoinRestriction	New-DistributionGroup Set-DistributionGroup
BypassSecurityGroupManagerCheck	Remove-DistributionGroup Set-DistributionGroup Add-DistributionGroupMember Remove-DistributionGroupMember
MemberDepartRestriction	Set-DistributionGroup
MemberJoinRestriction	Set-DistributionGroup

Also, the *ManagedBy* parameter has been updated to indicate ownership of a distribution group. Users specified in the *ManagedBy* parameter can modify the distribution group settings.

Note:
The *ManagedBy* parameter functionality for dynamic distribution groups didn't change.

For more information about distribution groups, see Understanding Recipients and Managing Distribution Groups.

Return to top

Permission Management for Mailbox Folders

You can manage folder-level permissions for all folders within a user's mailbox. Sharing mailbox folders and calendar folders is managed through a new set of cmdlets. These cmdlets allow you to view, remove, and add permissions for specific users on all designated mailbox folders:

- Add-MailboxFolderPermission
- Get-MailboxFolderPermission
- Remove-MailboxFolderPermission

Return to top

Bulk Recipient Management in the EMC

Exchange 2007 Service Pack 1 (SP1) introduced bulk recipient management for moving, removing, disabling, and enabling mailboxes in the EMC. In Exchange 2010, this functionality is expanded to include the following tasks:

- **Properties** You can select multiple recipients in the result pane, and then click **Properties** in the action pane. Properties that you can't bulk edit are unavailable.

  Note:
  You can only bulk edit recipient properties when the same recipient types are selected.

- **Send Mail** You can select multiple recipients in the result pane, and then click **Send Mail** in the action pane to send an e-mail to multiple recipients. For more information, see the Send Mail section later in this topic.

Return to top

Personal Archive

A personal archive is a specialized mailbox associated with a user's primary mailbox. It appears alongside the primary mailbox folders in Outlook 2010 or Outlook Web App. Users have direct access to e-mail within the archive just as they would their primary mailbox. Users can drag e-mail from .pst files into the personal archive for easier online access.

Through the use of retention policies, e-mail items from the primary mailbox can be automatically offloaded to the personal archive. This reduces the mailbox size and improves application and network performance. In addition, users can use Outlook 2010 or Outlook Web App to search both their personal archive and primary mailbox.

To learn more, see Understanding Personal Archives.

Return to top

Send Mail

You can send mail to multiple recipients from the EMC. Select multiple recipients in the result pane, and then click **Send Mail** in the action pane. You must configure an e-mail account on the computer from which you are sending mail. You can send mail to the following recipient types:

- User mailboxes
- Mail contacts
- Mail users
- Dynamic distribution groups
- Distribution groups

You can't send mail to resource mailboxes.

Return to top

1.1.5.7 New Transport Functionality

New Transport Functionality

Exchange Server 2010 > Getting Started With Exchange 2010 > What's New in Exchange 2010 >

Applies to: *Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-11*

The following is a list of new or improved transport and routing functionality that's included in Microsoft Exchange Server 2010:

- **MailTips** MailTips provide extra information that's displayed to senders while they're composing e-mail messages. MailTips provide information about the messages such as details about the recipients and their availability, or reasons the message wouldn't be delivered. For example, if the person the message is addressed to is out of the office, senders will be informed about this while they're composing the message. To learn more about MailTips, see Understanding MailTips.
- **Shadow redundancy** Messages that are submitted to an Exchange 2010 Hub

Transport server are stored in the transport database until the next hop reports successful delivery of the message. If the next hop doesn't report successful delivery and it fails, the message is resubmitted for delivery. To learn more about shadow redundancy, see Understanding Shadow Redundancy.

- **Moderated transport** Exchange 2010 provides an approval workflow for sending messages to recipients. When you configure a recipient for moderation, all messages sent to that recipient must go through an approval process. To learn more about moderated transport, see Understanding Moderated Transport.
- **End-to-end message tracking** Exchange 2010 transport provides users with the ability to track messages from submission to the final destination. There is a new message tracking tool that makes it easy for any user role, from end-user to administrator, to track messages. For more information, see Understanding Message Tracking.
- **Support for disabling TLS for WAN topologies** In certain topologies where WAN Optimization Controller (WOC) devices are used, the TLS encryption of SMTP traffic may be undesirable. Exchange 2010 supports disabling TLS for hub-to-hub communications for these specific scenarios. For more information, see Disabling TLS Between Active Directory Sites to Support WAN Optimization.
- **Incremental EdgeSync** In Exchange 2010, the EdgeSync process has been changed to keep track of synchronized information and only synchronize the changes since the last replication cycle. This significantly reduces network traffic and greatly improves synchronization efficiency. For more information, see Understanding Edge Subscriptions.
- **Transport rule predicates and actions** Transport rules inspect messages for conditions specified in the rules. Messages that meet the conditions, and none of the exceptions, get the specified actions applied to them. Exchange 2010 includes several new predicates and actions, providing additional flexibility in creating rules and additional options for actions that can be applied to messages. For more information, see Transport Rule Predicates and Transport Rule Actions.
- **Transport rule cmdlet improvements** The **New-TransportRule** and **Set-TransportRule** cmdlets have been enhanced, allowing you to specify all predicates and actions in a single command. All predicates and actions are now available for use as parameters with these cmdlets. For more information, see New-TransportRule and Set-TransportRule.
- **Transport rules integration with AD RMS** Exchange 2010 provides you the ability to create rules that require Active Directory Rights Management Services (AD RMS) protection based on keywords or patterns. For more information, see Understanding Transport Protection Rules.
- **Distribution group expansion improvements** The handling of distribution group expansion has improved in Exchange 2010. First, the amount of memory that's used for caching distribution group membership has been capped by a configurable limit. This change prevents the cache from consuming too much memory, and thereby impacting performance in large environments. Exchange 2010 also queries Active Directory in a more efficient manner when processing large distribution groups with delivery restrictions, improving the performance of message delivery to large distribution groups.
- **Message throttling improvements** In Exchange 2010, you can configure a Receive connector to monitor the rate of message submissions by users, IP addresses, or both. If you configure a Receive connector to monitor the message submission rate for users, it ensures that a specific user doesn't exceed the message rate that it's allowed, regardless of the IP address the connections are coming from. The default client Receive connector created on the Hub Transport servers is configured this way.
- **Latency management** With Exchange 2010 transport, you can measure service levels delivered relative to your service level agreement (SLA) goals. Exchange 2010 provides you the ability to measure latencies for each hop, as well as end-to-end latency.

1.1.6 Discontinued Features

Discontinued Features

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-10*

This topic discusses the components, features, and functionalities that have been removed, discontinued, or replaced in Microsoft Exchange Server 2010. For information about API and development tool changes, see Migrating from Earlier Technologies to Exchange 2010.

Contents

Discontinued Features from Exchange 2010 RTM to Exchange 2010 SP1

This section lists the Microsoft Exchange Server 2010 RTM features that are discontinued in Microsoft Exchange Server 2010 SP1.

Feature	Comments and mitigation
Export-Mailbox and **Import-Mailbox** cmdlets	Use export requests or import requests. For more information, see Understanding Mailbox Import and Export Requests.
Enable-AntispamUpdates	Use Forefront Security for Exchange Server to obtain automatic anti-spam updates. For more information, see Forefront Online Protection for Exchange.
Federated Delivery	Use Tenant Mail Flow control. For more information, see Understanding Transport Options.
ISInteg	Use New-MailboxRepairRequest or New-PublicFolderDatabaseRepairRequest.
Managed folders in the Exchange Management Console (EMC)	In Exchange 2010 SP1, use the Exchange Management Shell to administer managed folder features such as managed default folders, managed custom folders, and managed folder mailbox policies. You can use the EMC and the Shell to manage

	retention policies and retention tags, the new messaging records management (MRM) feature introduced in Exchange 2010. For more information, see Deploying Messaging Records Management.

Discontinued Features from Exchange 2007 to Exchange 2010 RTM

This section lists the Microsoft Exchange Server 2007 features that are discontinued in Exchange 2010.

APIs and Development Features

Feature	Comments and mitigation
Exchange WebDAV	Use Introduction to Web Services or Differences between the EWS Managed API and EWS. Alternatively, you can maintain an Exchange 2007 server for mailboxes that are managed by applications that use WebDAV. For more information, see Migrating from WebDAV to Exchange 2010.

Architecture Features

Feature	Comments and mitigation
DSProxy	Exchange 2010 uses the RPC Client Access service and the Address Book service to perform this functionality. For more information, see Understanding RPC Client Access and Understanding the Address Book Service.
Storage groups	Exchange 2010 uses database copy functionality. For information, see Understanding Mailbox Database Copies.
Extensible Storage Engine (ESE) streaming backup APIs	Exchange 2010 uses Volume Shadow Copy Service (VSS)-based copies, such as Windows Server Backup and the VSS-plug-in included with Exchange 2010. For information, see Understanding Backup, Restore and Disaster Recovery.
User Datagram Protocol (UDP) notifications	Support for User Datagram Protocol (UDP) notifications is removed from Exchange 2010. This impacts the experience when Outlook 2003 clients connect to their mailboxes on an Exchange 2010 server. For more information, see Microsoft Knowledge Base article 2009942, Folders take a long time to update when an Exchange Server 2010 user uses Outlook 2003 in online mode. **Note:** Support for User Datagram Protocol (UDP) notifications is added in Microsoft Exchange Server 2010 Service Pack 1 (SP1) Rollup 3

	(RU3). To obtain Exchange 2010 SP1 Update RU3, see Microsoft Knowledge Base article 2009942, Folders take a long time to update when an Exchange Server 2010 user uses Outlook 2003 in online mode.

High Availability Features

Feature	Comments and mitigation
Cluster continuous replication (CCR)	Exchange 2010 uses database availability groups (DAGs) and mailbox database copies. For information, see High Availability and Site Resilience.
Local continuous replication (LCR)	Exchange 2010 uses DAGs and mailbox database copies. For information, see High Availability and Site Resilience.
Standby continuous replication (SCR)	Exchange 2010 uses DAGs and mailbox database copies. For information, see High Availability and Site Resilience.
Single copy cluster (SCC)	Exchange 2010 uses DAGs and mailbox database copies. For information, see High Availability and Site Resilience.
Setup /recoverCMS	Exchange 2010 uses Setup /m:recoverServer. For information, see Recover a Database Availability Group Member Server.
Clustered mailbox servers	Exchange 2010 uses DAGs and mailbox database copies. For information, see High Availability and Site Resilience.

Client Access Features

Feature	Comments and mitigation
Client authentication using Integrated Windows authentication (NTLM) for POP3 and IMAP4 users	NTLM isn't supported for POP3 or IMAP4 client connectivity in the RTM version of Exchange 2010. Connections from POP3 or IMAP4 client programs using NTLM will fail. If you're running the RTM version of Exchange 2010, the recommended POP3 and IMAP4 setting alternatives to NTLM are: • Kerberos (GSSAPI) • Plain Text Authentication with SSL If you're using the RTM version of Exchange 2010, to use NTLM, you must retain an Exchange 2003 or Exchange 2007 server in your Exchange 2010 organization. Support for NTLM authentication for POP3 and IMAP4 connectivity has been brought back in Exchange 2010 SP1. For more information, see Set-PopSettings and Set-ImapSettings.

Outlook Web App Features

Feature	Comments and mitigation
Document access	Can't use Microsoft Office Outlook Web App to access Microsoft Office SharePoint document libraries and Microsoft Windows file shares.
Web Parts	Web Parts aren't supported in Exchange 2010 RTM. This feature has been brought back in Exchange 2010 SP1.
User-selectable themes	Users can't change the theme in Outlook Web App RTM. This feature has been brought back in Exchange 2010 SP1.
Reading pane at the bottom of the page	There is no option to display the reading pane at the bottom of the Outlook Web App window. This feature has been brought back in Exchange 2010 SP1.

Recipient Related Features

Feature	Comments and mitigation
Move-Mailbox cmdlet set	Use move requests to move mailboxes. For information, see Understanding Move Requests.

Return to top

Discontinued Features from Exchange 2003 to Exchange 2010

This section lists the Exchange Server 2003 features that are discontinued in Exchange 2010.

APIs and Development Features

Feature	Comments and mitigation
Proxy address generators	Use the Shell.
ExCDO 1.2.1	Use Introduction to Web Services.
MAPI32	Use Introduction to Web Services.
CDOEX (CDO 3.0)	Use Introduction to Web Services.
Exchange WebDAV extensions	Use Introduction to Web Services.
ExOLEDB	Use Introduction to Web Services.
Store events	Use Introduction to Web Services.

Return to top

Architecture Features

Feature	Comments and mitigation
Routing groups	Exchange 2010 uses Active Directory site-

	based routing. For information, see Understanding Message Routing.
Administrative groups	Exchange 2010 uses the Exchange 2007 split permissions model that's based on universal security groups. For information, see Understanding Split Permissions.
Intelligent Message Filter	Exchange 2010 uses anti-spam agents in the Hub Transport and Edge Transport server roles. For information, see Understanding Anti-Spam and Antivirus Functionality.
Link state routing	Exchange 2010 uses Active Directory site-based routing. For information, see Understanding Message Routing.
Routing objects	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
Network-attached storage	Exchange 2010 supports Internet SCSI (iSCSI).
Exchange Installable File System (ExIFS)	Use Introduction to Web Services or MAPI.
Event service	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
Recovery storage group	Exchange 2010 uses the recovery database. For information, see Recovery Databases.
User Datagram Protocol (UDP)	Support for User Datagram Protocol (UDP) notifications is removed from Exchange 2010. This impacts the experience when Outlook 2003 clients connect to their mailboxes on an Exchange 2010 server. For more information, see Microsoft Knowledge Base article 2009942, Folders take a long time to update when an Exchange Server 2010 user uses Outlook 2003 in online mode.

Connector Features

Feature	Comments and mitigation
Microsoft Exchange Connector for Novell GroupWise and migration tools	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
Microsoft Exchange Connector for Lotus Notes	Use the appropriate tools for coexisting and migrating from Lotus Notes. These tools are available at the Interoperability Bridges and Lab Center Web site.

Protocol Features

Feature	Comments and mitigation

Network News Transfer Protocol (NNTP)	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
POP3 or IMAP4 graphical user interface (GUI) management	Use the Exchange Management Console (EMC) or the Exchange Management Shell. For information, see Managing POP3 and IMAP4.
X.400 message transfer agent (MTA)	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
SMTP virtual server instances	Use Exchange 2010 SMTP connectors. For information, see Understanding Send Connectors and Understanding Receive Connectors.

Public Folder Features

Feature	Comments and mitigation
Non-MAPI top-level hierarchies in a public folder store	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
Public folder access by using NNTP	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.
Public folder access by using IMAP4	If you need this functionality, retain an Exchange 2003 server in your Exchange 2010 organization.

Client Access Features

Feature	Comments and mitigation
Client authentication using Integrated Windows authentication (NTLM) for POP3 and IMAP4 users	NTLM isn't supported for POP3 or IMAP4 client connectivity. The recommended POP3 and IMAP4 setting alternatives to NTLM are: • Kerberos (GSSAPI) • Plain Text Authentication with SSL Connections from POP3 or IMAP4 client programs to Exchange 2010 will fail. If you need this functionality, retain an Exchange 2003 or Exchange 2007 server in your Exchange 2010 organization.

Outlook Web App Features

Feature	Comments and mitigation
Calendar search	The search feature isn’t available for the Calendar folder in Outlook Web App.
Views in the Contacts folder	The Address Cards and Detailed Address Cards views are no longer available in Outlook Web App. The option is to use the Reading Pane when viewing Contacts.

	Contacts can't be sorted by location.
Printing	Contacts and Tasks don't include a print option in Exchange 2010 Outlook Web App.

Recipient-Related Features

Feature	Comments and mitigation
Exchange extensions in Active Directory Users and Computers	Exchange 2010 includes recipient management in the EMC. For information, see Managing Mailbox Servers.
Exchange Server Mailbox Merge wizard (ExMerge.exe)	In Exchange Server 2010 RTM, use the **Export-Mailbox** cmdlet or the Move Request cmdlet set. In Exchange Server 2010 SP1, use the Mailbox Repair Request cmdlet set or the Move Request cmdlet set. For information, see Recipient Cmdlets.
Mailbox Manager Policies	Use retention policies, the MRM feature introduced in Exchange 2010, or managed folder mailbox policies, the MRM feature introduced in Exchange 2007 (also available in Exchange 2010). For more information, see Understanding Messaging Records Management.
Recipient Update Service	Use the Update-AddressList and Update-EmailAddressPolicy cmdlets. To replace the full functionality of the Recipient Update Service, you can use the Task Scheduler to schedule these Shell commands. For information, see Task Scheduler.

Tools and Management Features

Feature	Comments and mitigation
Monitoring and status node	Use a monitoring solution such as System Center 2012 Cloud & Datacenter Management.
Message Tracking Center node and tracking mechanism	Use the Tracking Log Explorer and Message Tracking tools. For information, see Understanding Message Tracking.
Mailbox Recovery Center	Use the Restore-Mailbox cmdlet.
Mailbox Management Service	Use messaging records management (MRM) or retention policies. For information, see Understanding Messaging Records Management and Understanding Retention Tags and Retention Policies.
Clean Mailbox tool	In Exchange Server 2010 RTM, use the **Export-Mailbox** cmdlet or the Move Request cmdlet set. In Exchange 2010 SP1, use the **Mailbox**

	Repair Request cmdlet set or the **Move Request** cmdlet set. For information, see Recipient Cmdlets.
Migration wizard	Use the New-MoveRequest cmdlet or the Local Move Request and Remote Move Request wizards to move mailboxes from Exchange 2003 to Exchange 2010. For information, see Understanding Move Requests.
Exchange Profile Redirector tool (ExProfRe)	Use the Autodiscover service. For information, see Understanding the Autodiscover Service.

1.1.7 Overview of Exchange 2010 Server Roles

Overview of Exchange 2010 Server Roles

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-20*

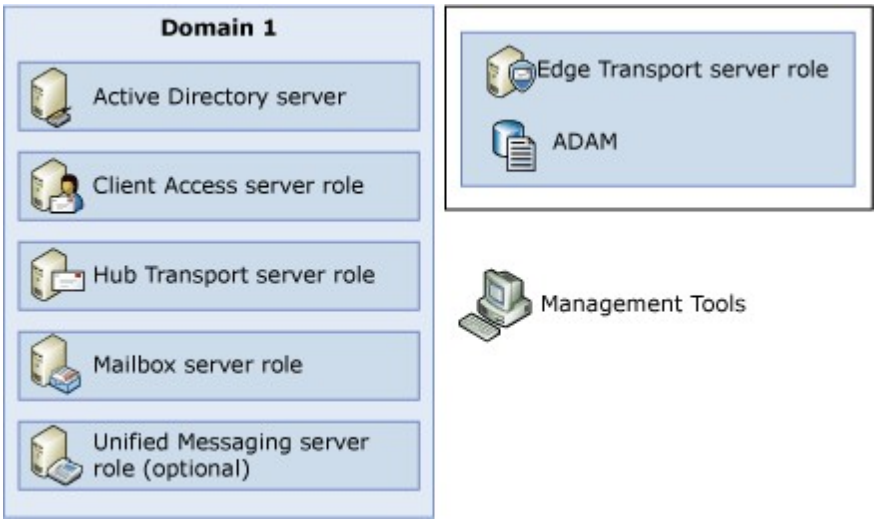
Because organizations tend to group their management tasks around a core set of server roles, Exchange 2010 maps Exchange Server management to this same approach.

A server role is a unit that logically groups the required features and components needed to perform a specific function in the messaging environment. The requirement of a server role is that it is a server that could be run as an atomic unit of scalability. A server role is composed of a group of features.

Server roles, the primary unit of deployment, enable administrators to easily choose which features are installed on an Exchange server. Logically grouping features in server roles offers the following advantages:

- Reduces attack surface on an Exchange server.
- Allows you to install and configure an Exchange server the way you intend to use it.
- Offers the ability to fully customize a server to support your business goals and needs.

The following figure illustrates a domain with each server role deployed.



Exchange 2010 includes the following server roles:

- **Mailbox Server** This server hosts mailboxes and public folders. For more information about the Exchange 2010 Mailbox server role, see Overview of the Mailbox Server Role.
- **Client Access Server** This is the server that hosts the client protocols, such as Post Office Protocol 3 (POP3), Internet Message Access Protocol 4 (IMAP4), Secure Hypertext Transfer Protocol (HTTPS), Outlook Anywhere, Availability service, and Autodiscover service. The Client Access Server also hosts Web services. For more information about the Exchange 2010 Client Access server role, see Client Access.
- **Unified Messaging Server** This is the server that connects a Private Branch eXchange (PBX) system to Exchange 2010. For more information about the Exchange 2010 Unified Messaging server role, see Unified Messaging.
- **Hub Transport Server** This is the mail routing server that routes mail within the Exchange organization. For more information about the Exchange 2010 Hub Transport server role, see Transport and Overview of the Hub Transport Server Role.
- **Edge Transport Server** This is the mail routing server that typically sits at the perimeter of the topology and routes mail in to and out of the Exchange organization. For more information about the Exchange 2010 Edge Transport server role, see Transport and Overview of the Edge Transport Server Role.

1.1.8 Roadmap for Exchange Features

Roadmap for Exchange Features

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This roadmap helps you get acquainted with all the features in Microsoft Exchange Server 2010. The first section lists all the features that can be managed by using either the Exchange Management Console (EMC) or the Exchange Management Shell. This section also shows you how to navigate to the feature in the EMC and provides a link to the

corresponding management topic.

However, not all features and tasks can be managed in the EMC. Therefore, the second section lists the features that can be managed only in the Shell and provides links to the corresponding cmdlet reference topic.

Important:

If you're looking for a feature that was in Exchange Server 2007 or Exchange Server 2003 and you can't find it in this topic, the feature may have been renamed or removed in Exchange 2010. For more information, see Discontinued Features.

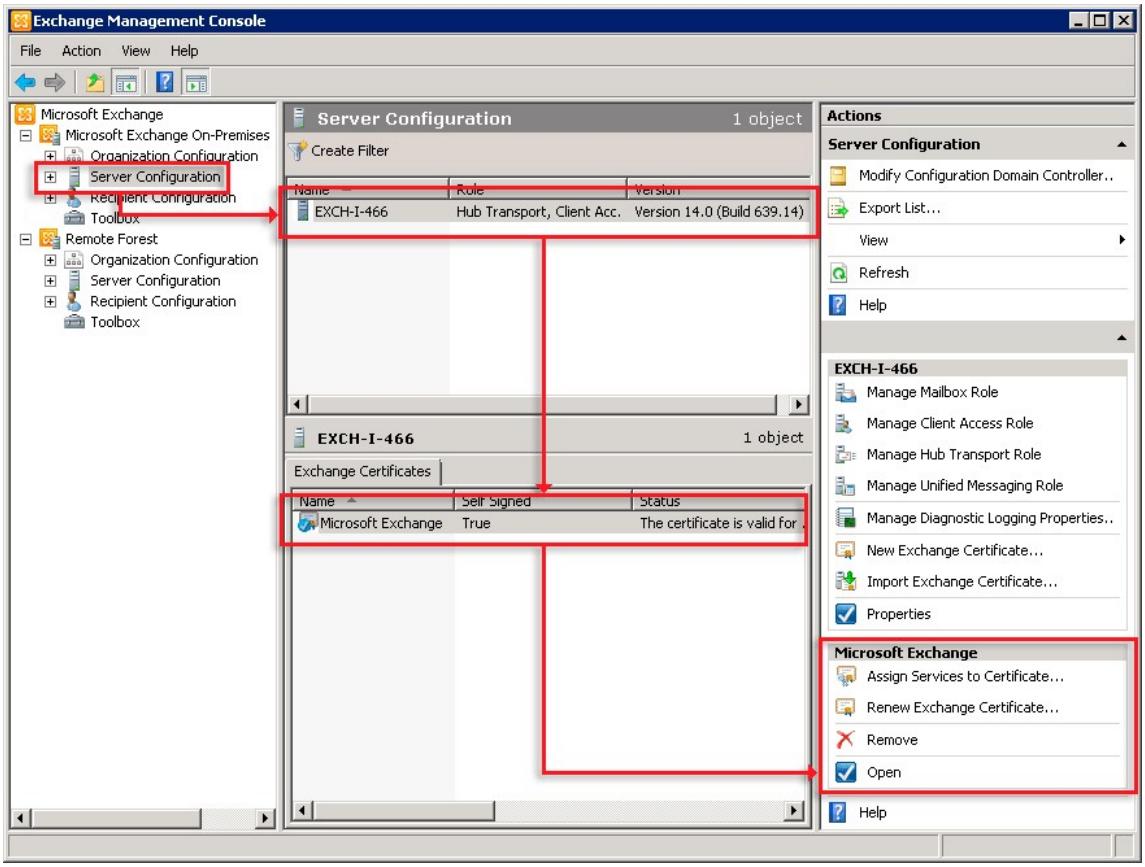
Features Managed in the EMC and the Shell

The following table is organized alphabetically by feature. It includes the click path that shows you how to get to the feature and the related topics that explain how to manage the feature.

Note:

This table shows how to locate features in the EMC. However, because all features can be managed by using the Shell, the management topics include both the EMC and Shell procedures.

The click paths follow the EMC layout from left to right, starting in the console tree and working toward the action pane. For example, consider the following click path for managing Exchange certificates: **Server Configuration** > *(Select Server)* > **Exchange Certificates** > *(Select Certificate)*. The following illustration maps this click path from the console tree, to the result pane, to the work pane, and then finally to the action pane that lists options for managing the specified certificate.



Exchange 2010 features managed in the EMC and Shell

Feature	How to get there in the EMC	Related management topics
Accepted domains	**Organization Configuration** > **Hub Transport** > **Accepted Domains** tab **Edge Transport** > **Accepted Domains** tab	Managing Accepted and Remote Domains
Address book policies	**Organization Configuration** > **Mailbox** > **Address Book Policies** tab	Managing Address Book Policies
Address book policies, apply to user	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Settings** tab > **Address Book Policy** > **Properties**	Assign an Address Book Policy to a Mail User
Address lists	**Organization Configuration** > **Mailbox** > **Address Lists** tab	Managing Address Lists
Archive quotas, apply to mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Settings** tab > **Archive Quota** > **Properties**	Configure Archive Quotas for a Personal (On-Premises) Archive

Best Practices Analyzer	**Toolbox** > **Best Practices Analyzer** > **Open Tool**	Microsoft Exchange Analyzers
Calendar settings, apply to mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) **Properties** > **Calendar Settings** tab	Managing User Mailboxes
Client Access server settings	**Server Configuration** > **Client Access** > (*Select Server*) > **Properties**	Managing Client Access Servers
Content filtering	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **Content Filtering**	Configure Content Filtering Properties
Customer Experience Improvement Program, opt-in or opt-out organization	**Microsoft Exchange On-Premises** > **Customer Feedback** tab	Opt-in or Opt-out of the Customer Experience Improvement Program
Customer Experience Improvement Program, opt-in or opt-out servers	**Server Configuration** > (*Select Server*) > **Properties** > **Customer Feedback Options** tab **Server Configuration** > (*Select Server Role Node*) > (*Select Server*) > **Properties** > **Customer Feedback Options** tab	Opt-in or Opt-out of the Customer Experience Improvement Program
Database availability group networks	**Organization Configuration** > **Mailbox** > **Database Availability Groups** tab > (*Select Database Availability Group*) > **Networks** tab	Create a Database Availability Group Network Configure Database Availability Group Network Properties
Database availability groups	**Organization Configuration** > **Mailbox** > **Database Availability Groups** tab	Managing Database Availability Groups
Database copies	**Organization Configuration** > **Mailbox** > **Database Management** tab > (*Select Mailbox Database*) > **Database Copies** tab	Managing Mailbox Database Copies
Database switchover	**Organization Configuration** > **Mailbox** > **Database Management** tab **Organization Configuration** > **Mailbox** > **Database Management** tab > (*Select Mailbox Database*) > **Database Copies** tab	Switchovers and Failovers
Databases	**Organization Configuration** > **Mailbox** > **Database Management** tab	Managing Mailbox Databases Managing Public Folder

		Databases
Details Templates Editor	**Toolbox** > **Details Templates Editor** > **Open Tool**	Managing Details Templates
Diagnostic logging	**Server Configuration** > **Mailbox** > (*Select Server*) > **Manage Diagnostic Logging Properties**	Manage Diagnostic Logging Levels
Distribution groups	**Recipient Configuration** > **Distribution Group**	Managing Distribution Groups
Dynamic distribution groups	**Recipient Configuration** > **Distribution Group**	Managing Distribution Groups
Edge Subscriptions	**Organization Configuration** > **Hub Transport** > **Edge Subscriptions** tab	Managing Edge Subscriptions
Edge Transport server settings	**Edge Transport** > (*Select Server*) > **Properties**	Managing Transport Servers
E-mail address policies	**Organization Configuration** > **Hub Transport** > **E-mail Address Policies** tab	Managing E-Mail Address Policies
E-mail addresses, apply to public folder	**Toolbox** > **Public Folder Management Console** > **Default Public Folders** > (*Select Mail-Enabled Public Folder*) > **Properties** > **E-Mail Addresses** tab	Configure Public Folder Properties
E-mail addresses, apply to recipient	**Recipient Configuration** > (*Select Recipient*) > **Properties** > **E-Mail Addresses** tab	Configure User and Resource Mailbox Properties Configure Mail User Properties Configure Mail Contact Properties Configure Distribution Group Properties Configure Dynamic Distribution Group Properties
Exchange ActiveSync mailbox policies	**Organization Configuration** > **Client Access** > **Exchange ActiveSync Mailbox Policies** tab	Managing Exchange ActiveSync with Policies
Exchange ActiveSync mailbox policies, apply to mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **Exchange ActiveSync** > **Properties**	Add Users to an Exchange ActiveSync Mailbox Policy

Exchange Control Panel Web site	**Server Configuration** > **Client Access** > **Exchange Control Panel** tab > (*Select Web Site*) > **Properties**	Configure ECP Virtual Directory Properties
External Client Access domains	**Server Configuration** > **Client Access** > **Configure External Client Access Domain**	Configure External Client Access Namespaces
Federation trusts	**Organization Configuration** > **Federation Trust** tab	Managing Federation
Full Access permission, mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Manage Full Access Permission**	Manage Full Access Permissions
Hub Transport server settings	**Server Configuration** > **Hub Transport** > (*Select Server*) > **Properties**	Managing Transport Servers
IMAP4, configure	**Server Configuration** > **Client Access** > **POP3 and IMAP4** tab > **IMAP4** > **Properties**	View or Configure IMAP4 Properties
IMAP4, enable, disable, or specify the MIME format for a mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **IMAP4**	Enable or Disable IMAP4 Access for a User
IP Allow List providers	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **IP Allow List Providers**	Configure IP Allow List Providers Properties
IP Allow lists	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **IP Allow List**	Configure IP Allow List Properties
IP Block lists	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **IP Block List**	Configure IP Block List Properties
IP Block List providers	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **IP Block List Providers**	Configure IP Block List Providers Properties
Journal rules	**Organization Configuration** > **Hub Transport** > **Journal Rules** tab	Managing Journaling
License, input key	**Server Configuration** > **Enter Product Key Group**	Enter Product Key
License, view server and client licensing information	**Microsoft Exchange On-Premises** > **Collect Organizational Health Data** tab	Collect Organizational Health Data
Mail contacts	**Recipient Configuration** > **Mail Contact**	Managing Mail Contacts and Mail Users

Mail Flow Troubleshooter	**Toolbox** > **Mail Flow Troubleshooter** > **Open Tool**	NA
Mail users	**Recipient Configuration** > **Mail Contact**	Managing Mail Contacts and Mail Users
Mailbox server settings	**Server Configuration** > **Mailbox** > (*Select Server*) > **Properties**	Managing Mailbox Servers
Mailboxes, configure	**Recipient Configuration** > **Mailbox**	Managing User Mailboxes
Mailboxes, disconnected	**Recipient Configuration** > **Disconnected Mailbox**	Connect to the Disconnected Mailbox Server Connect a Disconnected Personal (On-Premises) or Cloud-Based Archive
Mailboxes, move	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **New Local Move Request** or **New Remote Move Request**	Managing Move Requests
Mailboxes, remote	**Recipient Configuration** > **Mail Contact**	Managing User Mailboxes
MAPI, enable or disable for mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **MAPI**	Enable or Disable MAPI for a User Mailbox
Message delivery	**Organization Configuration** > **Hub Transport** > **Global Settings** tab > (*Select Transport Settings*) > **Properties** > **Message Delivery** tab	Configure Transport Settings Properties
Message delivery restrictions, apply to recipient	**Recipient Configuration** > (*Select Recipient*) > **Properties** > **Mail Flow Settings** tab > **Message Delivery Restrictions** > **Properties**	Configure Message Delivery Restrictions
Message size restrictions, apply to recipient	**Recipient Configuration** > (*Select Recipient*) > **Properties** > **Mail Flow Settings** tab > **Message Size Restrictions** > **Properties**	Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder
Message tracking	**Toolbox** > **Message Tracking** > **Open Tool** > (*Log On to Outlook Web App*) > (*Select to Manage My Organization*) > **Reporting** > **Delivery Reports** tab	Track Messages with Delivery Reports
Messaging records	**Organization Configuration**	Deploying Messaging Records

management (MRM) 2.0: Retention policies	> **Mailbox** > **Retention Policies** and **Retention Policy Tags** tabs	Management
Move request, view or remove	**Recipient Configuration** > **Move Request**	Managing Move Requests
Offline address book virtual directory, configure	**Server Configuration** > **Client Access** > **Offline Address Book Distribution** tab	Configure Offline Address Book Distribution Properties
Offline address books (OABs)	**Organization Configuration** > **Mailbox** > **Offline Address Book** tab	Managing Offline Address Books
Organization relationships	**Organization Configuration** > **Organization Relationships** tab	Managing Federated Delegation
Organizational health, update	**Microsoft Exchange On-Premises** > **Organizational Health** tab> **Collect Organizational Health Data**	Collect Organizational Health Data
Organizational health, view	**Microsoft Exchange On-Premises** > **Organizational Health Data** tab	Collect Organizational Health Data
Outlook Anywhere, configure	**Server Configuration** > **Client Access** > (*Select Server*) > **Properties** > **Outlook Anywhere** tab	Managing Outlook Anywhere
Outlook Anywhere, enable or disable	**Server Configuration** > **Client Access** > (*Select Server*) > **Enable Outlook Anywhere**	Enable Outlook Anywhere Disable Outlook Anywhere
Outlook Web App mailbox policies	**Organization Configuration** > **Client Access** > **Outlook Web App Mailbox Policies** tab	Managing Outlook Web App Mailbox Policies
Outlook Web App mailbox policies, apply to mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **Outlook Web App** > **Properties**	Apply an Outlook Web App Mailbox Policy to a Mailbox
Outlook Web App virtual directories, configure	**Server Configuration** > **Client Access** > **Outlook Web App** tab	Managing Outlook Web App Virtual Directories
Performance Monitor	**Toolbox** > **Performance Monitor** > **Open Tool**	Performance and Reliability Monitoring Step-by-Step Guide for Windows Server 2008
Performance Troubleshooter	**Toolbox** > **Performance Troubleshooter** > **Open Tool**	NA

Personal archive, disconnected	**Recipient Configuration** > **Disconnected Mailbox**	Connect a Disconnected Personal (On-Premises) or Cloud-Based Archive
Personal archive, create	**Recipient Configuration** > **New Mailbox**	Create a Personal (On-Premises) or Cloud-Based Archive for a New Mailbox
Personal archive, enable or disable archive on existing mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Enable Archive** or **Disable Archive**	Enable a Personal (On-Premises) or Cloud-Based Archive for an Existing Mailbox
Personal archive, move	**Recipient Configuration** > **Mailbox** > *(Select Archive Mailbox)* > **New Local Move Request** or **New Remote Move Request** > **Move only the archive mailbox**	Create a Local Move Request Create a Remote Move Request That has Exchange 2010 in Both Forests
POP3, configure	**Server Configuration** > **Client Access** > (*Select Server*) > **POP3 and IMAP4** tab > **POP3** > **Properties**	Managing POP3 and IMAP4
POP3, enable or disable for mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **POP3**	Enable or Disable POP3 Access for a User
Public folder databases	**Organization Configuration** > **Mailbox** > **Database Management** tab	Managing Public Folder Databases
Public folder client permissions	**Toolbox** > **Public Folder Management Console** > **Default Public Folders** > (*Select Public Folder*) > **Manage Settings**	Use the Public Folder Management Console to Manage Public Folder Settings
Public folder replication settings	**Toolbox** > **Public Folder Management Console** > **Default Public Folders** > (*Select Public Folder*) > **Properties** > **Replication** tab	Configure Public Folder Replication
Public folder replication update	**Toolbox** > **Public Folder Management Console** > **Default Public Folders** > (*Select Public Folder*) > **Update Content**	Configure Public Folder Replication
Public folders	**Toolbox** > **Public Folder Management Console** > **Default Public Folders**	Managing Public Folders
Queue Viewer	**Toolbox** > **Queue Viewer** > **Open Tool**	Using Queue Viewer
Receive connectors	**Server Configuration** > **Hub Transport** > **Receive Connectors**	Managing Connectors

	Edge Transport > **Receive Connectors**	
Recipient filtering	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **Recipient Filtering**	Managing Anti-Spam and Antivirus Features
Remote Connectivity Analyzer	**Toolbox** > **Remote Connectivity Analyzer** > **Open Tool**	Exchange Remote Connectivity Analyzer Tool
Remote domains	**Organization Configuration** > **Hub Transport** > **Remote Domains** tab	Managing Accepted and Remote Domains
Reset Exchange Client Access server virtual directories	**Server Configuration** > **Client Access** > (*Select Server*) > **Reset Virtual Directory**	Reset Client Access Virtual Directories
Resource mailbox, configure	**Recipient Configuration** > (*Select Resource Mailbox*) > **Properties**	Managing Resource Mailboxes and Scheduling
Role Based Access Control (RBAC) User Editor	**Toolbox** > **Role Based Access Control (RBAC) User Editor** > **Open Tool** > (*Log On to Outlook Web App*) > **Administrator Roles** tab and **User Roles** tab	Administrator Roles Tab User Roles Tab
Routing Log Viewer	**Toolbox** > **Routing Log Viewer** > **Open Tool**	Using the Routing Log Viewer
Send As permissions, mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Manage Send As Permission**	Manage Send As Permissions for a Mailbox
Send As permissions, mail-enabled public folder	**Toolbox** > **Public Folder Management Console** > **Default Public Folders** > (*Select Mail-Enabled Public Folder*) > **Manage Send As Permission**	Manage Send As Permissions for Mail-Enabled Public Folders
Send connectors	**Organization Configuration** > **Hub Transport** > **Send Connectors** tab **Edge Transport** > **Send Connectors** tab	Managing Connectors
Send on behalf, mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mail Flow Settings** tab > **Delivery Options** > **Properties**	Configure User and Resource Mailbox Properties
Send on behalf, mail-enabled public folder	**Toolbox** > **Public Folder Management Console** >	Configure Public Folder Properties

	Default Public Folders > (*Select Mail-Enabled Public Folder*) > **Properties** > **Mail Flow Settings** tab > **Delivery Options** > **Properties**	
Sender filtering	**Edge Transport** > (*Select Server*) > **Anti-spam** tab> **Sender Filtering**	Managing Anti-Spam and Antivirus Features
Sender ID	**Edge Transport** > (*Select Server*) > **Anti-spam** tab > **Sender ID**	Managing Anti-Spam and Antivirus Features
Sender reputation	**Edge Transport** > (*Select Server*) > **Anti-spam** tab> **Sender Reputation**	Managing Anti-Spam and Antivirus Features
Server switchover	**Server Configuration** > **Mailbox** > (*Select Server*) > **Switchover Server**	Perform a Server Switchover
Sharing policies	**Organization Configuration** > **Mailbox** > **Sharing Policies** tab	Managing Federated Delegation
Sharing policies, apply to mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Settings** tab > **Sharing** > **Properties**	Managing Federated Delegation
Storage quotas, configure for a mailbox	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Settings** tab > **Storage Quotas** > **Properties**	Configure Storage Quotas for a Mailbox
Tracking Log Explorer	**Toolbox** > **Tracking Log Explorer** > **Open Tool**	NA
Transport dumpster	**Organization Configuration** > **Hub Transport** > **Global Settings** tab > **Transport Settings** > **Properties** > **General** tab	Configure Transport Settings Properties
Transport limits	**Organization Configuration** > **Hub Transport** > **Global Settings** tab > (*Select Transport Settings*) > **Properties** > **General** tab	Configure Transport Settings Properties
Transport rules	**Organization Configuration** > **Hub Transport** > **Transport Rules** tab **Edge Transport** > **Transport Rules** tab	Managing Transport Rules

Transport settings	**Organization Configuration** > **Hub Transport** > **Global Settings** tab	Configure Transport Settings Properties
UM auto attendants	**Organization Configuration** > **Unified Messaging** > **UM Auto Attendants** tab	Managing UM Auto Attendants
UM dial plans	**Organization Configuration** > **Unified Messaging** > **UM Dial Plans** tab	Managing UM Dial Plans
UM hunt groups	**Organization Configuration** > **Unified Messaging** > **UM IP Gateways** tab > (*Select IP Gateway*) > **UM Hunt Groups** tab	Managing UM Hunt Groups
UM IP gateways	**Organization Configuration** > **Unified Messaging** > **UM IP Gateways** tab	Managing UM IP Gateways
UM mailbox policies	**Organization Configuration** > **Unified Messaging** > **UM Mailbox Policies** tab	Managing UM Mailbox Policies
UM-enabled users	**Recipient Configuration** > **Mailbox** > (*Select Mailbox*) > **Properties** > **Mailbox Features** tab > **Unified Messaging** > **Properties**	Managing Unified Messaging Users
Unified Messaging server settings	**Server Configuration** > **Unified Messaging** > **Properties**	Managing Unified Messaging Servers
Unified Messaging server, enable or disable	**Server Configuration** > **Unified Messaging** > (*Select UM Server*) > **Disable Immediately** or **Disable After Calls**	Enable Unified Messaging on Exchange 2010 Disable Unified Messaging on Exchange 2010

Features Managed Only in the Shell

The following table lists features managed only by using the Shell and includes links to the corresponding cmdlet reference topics.

Exchange 2010 features managed only in the Shell

Feature	Manage by using
Address rewriting	**AddressRewriteEntry** cmdlet set See Transport Cmdlets
Administrator audit logging	Get-AdminAuditLogConfig Set-AdminAuditLogConfig New-AdminAuditLogSearch

	Search-AdminAuditLog Write-AdminAuditLog
Attachment filter agent	**AttachmentFilterEntry** cmdlet set **AttachmentFilterListConfig** cmdlet set See Anti-Spam Cmdlets
Client access array	**ClientAccessArray** cmdlet set See Client Access Cmdlets
Cmdlet extension agents	**CmdletExtensionAgent** cmdlet set See Cmdlet Extension Agent Cmdlets
Database availability group network encryption and compression	Set-DatabaseAvailabilityGroup
Database availability groups: Datacenter Activation Coordination mode	Set-DatabaseAvailabilityGroup
Database availability groups: replication port	Set-DatabaseAvailabilityGroup
Delivery agent connectors	**DeliveryAgentConnector** cmdlet set See Transport Cmdlets
Edge synchronization (EdgeSync) service settings, configure	**EdgeSyncServiceConfig** cmdlet set See Transport Cmdlets
EdgeSync, forcing or testing	Start-EdgeSynchronization Test-EdgeSynchronization
Exchange ActiveSync connectivity, test	Test-ActiveSyncConnectivity
Exchange ActiveSync log, export	Export-ActiveSyncLog
Exchange Control Panel connectivity, test	Test-EcpConnectivity
Exchange Search	Set-MailboxDatabase, with the *-IndexEnabled* parameter Test-ExchangeSearch Get-FailedContentIndexDocuments
Global address lists (GALs)	**GlobalAddressList** cmdlet set See Mailbox Cmdlets
IMAP4 connectivity, test	Test-ImapConnectivity

Import\export mailbox data	**MailboxImportRequest** cmdlet set **MailboxExportRequest** cmdlet set See Understanding Importing and Exporting Files in the Exchange Management Shell
Information Rights Management (IRM), configure	**IRMConfiguration** cmdlet set See Messaging Policy and Compliance Cmdlets
IP Allow and Block List providers, test	Test-IPAllowListProvider Test-IPBlockListProvider
IP site link costs, Exchange-specific	**ADSiteLink** cmdlet set See Transport Cmdlets
Mailbox audit logging, configure and search	See Managing Mailbox Audit Logging
Message flow, test	Test-Mailflow
Messaging records management (MRM) 1.0: Managed folders	**ManagedFolder** cmdlet set **ManagedFolderMailboxPolicy** cmdlet set Start-ManagedFolderAssistant See Messaging Policy and Compliance Cmdlets
Multi-Mailbox Search	**MailboxSearch** cmdlet set See Messaging Policy and Compliance Cmdlets
Offline address book virtual directory, create	New-OABVirtualDirectory
Outlook client connectivity, test end-to-end	Test-OutlookConnectivity
Outlook Protection Rules	**OutlookProtectionRule** cmdlet set See Messaging Policy and Compliance Cmdlets
Outlook Web App connectivity, test	Test-OwaConnectivity
Outlook Web App virtual directories, create or remove	New-OwaVirtualDirectory Remove-OwaVirtualDirectory
Outlook Web services connectivity, test	Test-OutlookWebServices
POP3 connectivity, test	Test-PopConnectivity
PowerShell, test connectivity	Test-PowerShellConnectivity
PowerShell, virtual directories	**PowerShellVirtualDirectory** cmdlet set See Client Access Cmdlets

RBAC management role assignment Policies	**RoleAssignmentPolicy** cmdlet set See Permissions Cmdlets
RBAC management role groups	**RoleGroup** cmdlet set **RoleGroupMember** cmdlet set See Permissions Cmdlets
RBAC management roles	**ManagementRole** cmdlet set See Permissions Cmdlets
RBAC management role entries	**ManagementRoleEntry** cmdlet set See Permissions Cmdlets
RBAC management role assignments	**ManagementRoleAssignment** cmdlet set See Permissions Cmdlets
RBAC management scopes	**ManagementScope** cmdlet set See Permissions Cmdlets
Recovery database, create	New-MailboxDatabase
Recovery database, extract data	Restore-Mailbox
Recovery items	Set-Mailbox, using the following parameters: • *RecoverableItemsQuota* • *RecoverableItemsWarningQuota* • *SingleItemRecoveryEnabled*
Routing group connectors	**RoutingGroupConnector** cmdlet set See Transport Cmdlets
Safelist aggregation, force	**Update-SafeList** cmdlet set See Transport Cmdlets
Search mailbox and delete items	Search-Mailbox
Sender ID, test	Test-SenderId
Service e-mail channel	**ServiceEmailChannel** cmdlet set See Client Access Cmdlets
Transport agents	**TransportAgent** cmdlet set See Transport Cmdlets
Transport latency, calculating	**MessageLatencyReport** cmdlet set See Transport Cmdlets
Transport pipeline analysis	Get-TransportPipeline
UM connectivity, test	Test-UMConnectivity

UM incoming calls, view active	Get-UMActiveCalls
Web services connectivity, test	Test-WebServicesConnectivity
X.400 authoritative domains	**X400AuthoritativeDomains** cmdlet set See Transport Cmdlets

1.1.9 Exchange 2010: Editions and Versions

Exchange 2010: Editions and Versions

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-04*

Microsoft Exchange Server 2010 is available in two server editions: Standard Edition and Enterprise Edition. Enterprise Edition can scale to 100 databases per server; Standard Edition is limited to 5 databases per server.

These licensing editions are defined by a product key. When you enter a valid license product key, the supported edition for the server is established. Product keys can be used for the same edition key swaps and upgrades only; they can't be used for downgrades. You can use a valid product key to move from the evaluation version (Trial Edition) of Exchange Server 2010 to either Standard Edition or Enterprise Edition. You can also use a valid product key to move from Standard Edition to Enterprise Edition.

You can also license the server again using the same edition product key. For example, if you had two Standard Edition servers with two keys, but you accidentally used the same key on both servers, you can change the key for one of them to the other key that you were issued. You can take these actions without having to reinstall or reconfigure anything. After you enter the product key and restart the Microsoft Exchange Information Store service, the edition corresponding to that product key will be reflected.

No loss of functionality will occur when the Trial Edition expires, so you can maintain lab, demo, training, and other non-production environments beyond 120 days without having to reinstall the Trial Edition of Exchange 2010.

As mentioned earlier, you can't use product keys to downgrade from Enterprise Edition to Standard Edition, nor can you use them to revert to the Trial Edition. These types of downgrades can only be done by uninstalling Exchange 2010, reinstalling Exchange 2010, and entering the correct product key. For more information, see Enter Product Key.

Exchange 2010 Versions

Service Pack 2 (SP2) for Exchange Server 2010 is available and is the most recent version of the product.

Service Pack 1 (SP1) for Exchange Server 2010 and the release to manufacturing (RTM) version of Exchange Server 2010 are also available.

Exchange 2010 Build Versioning

The SP1 version of Exchange 2010 is 14.01.0218.015. The RTM version of Exchange 2010 is 14.00.0639.021. This version information is consistently displayed in the Exchange Management Console, the Exchange Management Shell, and in the **About Exchange**

Server 2010 Help dialog box.

You can also use the Get-ExchangeServer cmdlet and examine the **AdminDisplayVersion** property for the Exchange 2010 build version. For more information about deploying fixes and update rollups for Exchange 2010, see Exchange 2010 Servicing.

Exchange 2010 License Types

Exchange 2010 on-premises is licensed in the Server/Client Access License (CAL) model in the same way that Exchange Server 2007 was licensed. There are three types of licenses:

- **Server Licenses** A license must be assigned for each instance of the server software that is being run. The Server license is sold in two server editions: Standard Edition and Enterprise Edition.
- **Client Access Licenses (CALs)** Exchange 2010 also comes in two client access license (CAL) editions, which are referred to as a Standard CAL and an Enterprise CAL. You can mix and match the server editions with the CAL types. For example, you can use Enterprise CALs with Exchange 2010 Standard Edition. Similarly, you can use Standard CALs with Exchange 2010 Enterprise Edition.
- **External Connector Licenses** This license type allows an unlimited number of clients to access an Exchange server in scenarios where the number of CALs is uncertain.

For more information about Exchange license types, see Licensing and Microsoft Exchange How to Buy.

1.1.10 Exchange Server Build Numbers and Release Dates

Exchange Server Build Numbers and Release Dates

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2, Exchange Server 2010 SP1, Exchange Server 2010*

Topic Last Modified: *2013-02-26*

This topic provides you a central resource for build numbers and release dates for versions of Microsoft Exchange. You can use the information in this topic to verify the version of Exchange that is running in your organization.

This topic is organized in sections that correspond to the major releases of Exchange. Each section lists the build numbers for each service pack level of the specific Exchange release. The "For More Information" section in this topic contains information to help you determine the build number and version of Exchange Server that you're running.

Exchange Server 2010

This section provides the build numbers and general release dates for each version of Microsoft Exchange Server 2010.

To view the build number for the version of Exchange 2010 that you're running, run the following command in the Exchange Management Shell:

```
Get-ExchangeServer | fl name,edition,admindisplayversion
```

Note:
After you install an update rollup for Exchange 2010, the version of Exchange Server isn't updated to show that the update rollup is installed. This issue occurs because the version number that is displayed by the Exchange Management Console or by other administrative mechanisms is obtained from the Exchange Server Object in Active Directory.

For information about the servicing strategy for Exchange 2010, see Exchange 2010 Servicing. For more information about installing an update rollup for Exchange 2010, see Install the Latest Update Rollup for Exchange 2010.

Exchange Server 2010 SP3 build numbers

Product name	Release date	Build number
Microsoft Exchange Server 2010 Service Pack 3 (SP3)	February 12, 2013	14.03.0123.004

Exchange Server 2010 SP2 build numbers

Product name	Release date	Build number
Update Rollup 6 for Microsoft Exchange Server 2010 Service Pack 2 (SP2)	February 12, 2013	14.02.0342.003
Update Rollup 4 v2 for Exchange Server 2010 Service Pack 2	October 9, 2012	14.02.0318.004
Update Rollup 4 for Exchange Server 2010 Service Pack 2	August 13, 2012	14.02.0318.002
Update Rollup 3 for Exchange Server 2010 Service Pack 2	May 29, 2012	14.02.0309.002
Update Rollup 2 for Exchange Server 2010 SP2	April 16, 2012	14.02.0298.004
Update Rollup 1 for Exchange Server 2010 SP2	February 13, 2012	14.02.0283.003
Exchange Server 2010 SP2	December 4, 2011	14.2.247.5

Exchange Server 2010 SP1 build numbers

Product name	Release date	Build number
Update Rollup 7 v2 for Exchange Server 2010 SP1	October 10, 2012	14.01.0421.002
Update Rollup 7 for Exchange Server 2010 SP1	August 8, 2012	14.01.0421.000
Update Rollup 6 for Exchange Server 2010 SP1	October 27, 2011	14.01.0355.002
Update Rollup 5 for Exchange Server 2010 SP1	August 23, 2011	14.1.339.1
Update Rollup 4 for Exchange Server 2010 SP1	July 27, 2011	14.1.323.6
Update Rollup 3 for Exchange	April 6, 2011	14.01.0289.007

Server 2010 SP1		
Update Rollup 2 for Exchange Server 2010 SP1	December 9, 2010	14.01.0270.001
Update Rollup 1 for Exchange Server 2010 SP1	October 4, 2010	14.1.255.2
Exchange Server 2010 SP1	August 23, 2010	14.01.0218.015

Exchange Server 2010 RTM build numbers

Product name	Release date	Build number
Update Rollup 5 for Exchange Server 2010	December 13, 2010	14.0.726.0
Update Rollup 4 for Exchange Server 2010	June 10, 2010	14.0.702.1
Update Rollup 3 for Exchange Server 2010	April 13, 2010	14.0.694.0
Update Rollup 2 for Exchange Server 2010	March 4, 2010	14.0.689.0
Update Rollup 1 for Exchange Server 2010	December 9, 2009	14.0.682.1
Exchange Server 2010	November 9, 2009	14.00.0639.021

Exchange Server 2007

The following table lists the build numbers and general release dates for each version of Microsoft Exchange Server 2007.

The version information for Service Pack 1 (SP1) of Exchange Server 2007 is displayed correctly in the Exchange Management Console, in the Exchange Management Shell, and in the **About Exchange Server 2007** Help dialog box. However, after you apply Exchange 2007 SP1 to an Edge Transport server that is running the release to manufacturing (RTM) version of Exchange 2007, the version information for the Edge Transport server isn't updated in the Exchange Management Console unless the Edge Transport server is resubscribed to the Active Directory site. This is because the Edge Transport server doesn't directly update Active Directory by using any configuration information. Instead, the version information for Edge Transport servers is recorded in Active Directory during the creation of an Edge Subscription.

To view the build number for the version of Exchange 2007 that you're running, run the following command in the Shell:

```
Get-ExchangeServer | fl name,edition,admindisplayversion
```

Exchange Server 2007 SP3 build numbers

Product name	Release date	Build number
Update Rollup 9 for Exchange Server 2007 SP3	December 10, 2012	08.03.0297.002
Update Rollup 8-v3 for Exchange Server 2007 SP3	November 13, 2012	08.03.0279.006

Update Rollup 8–v2 for Exchange Server 2007 SP3	October 9, 2012	08.03.0279.005
Update Rollup 8 for Exchange Server 2007 SP3	August 13, 2012	08.03.0279.003
Update Rollup 7 for Exchange Server 2007 SP3	April 16, 2012	08.03.0264.000
Update Rollup 6 for Exchange Server 2007 SP3	January 26, 2012	8.03.0245.002
Update Rollup 5 for Exchange Server 2007 SP3	September 21, 2011	8.03.0213.001
Update Rollup 4 for Exchange Server 2007 SP3	May 28, 2011	8.03.0192.001
Update Rollup 3-v2 for Exchange Server 2007 SP3	March 30, 2011	8.03.0159.002
Update Rollup 2 for Exchange Server 2007 SP3	December 10, 2010	8.03.0137.003
Update Rollup 1 for Exchange Server 2007 SP3	September 9, 2010	8.03.0106.002
Exchange Server 2007 SP3	June 7, 2010	8.03.0083.006

Exchange Server 2007 SP2 build numbers

Product name	Release date	Build number
Update Rollup 5 for Exchange Server 2007 SP2	December 7, 2010	8.2.305.3
Update Rollup 4 for Exchange Server 2007 SP2	April 9, 2010	8.2.254.0
Update Rollup 3 for Exchange Server 2007 SP2	March 17, 2010	8.2.247.2
Update Rollup 2 for Exchange Server 2007 SP2	January 22, 2010	8.2.234.1
Update Rollup 1 for Exchange Server 2007 SP2	November 19, 2009	8.2.217.3
Exchange Server 2007 SP2	August 24, 2009	8.02.0176.002

Exchange Server 2007 SP1 build numbers

Product name	Release date	Build number
Update Rollup 10 for Exchange Server 2007 SP1	April 13, 2010	8.1.436.0
Update Rollup 9 for Exchange Server 2007 SP1	July 16, 2009	8.1.393.1
Update Rollup 8 for Exchange Server 2007 SP1	May 19, 2009	8.1.375.2
Update Rollup 7 for Exchange	March 18, 2009	8.1.359.2

Server 2007 SP1		
Update Rollup 6 for Exchange Server 2007 SP1	February 10, 2009	8.1.340.1
Update Rollup 5 for Exchange Server 2007 SP1	November 20, 2008	8.1.336.1
Update Rollup 4 for Exchange Server 2007 SP1	October 7, 2008	8.1.311.3
Update Rollup 3 for Exchange Server 2007 SP1	July 8, 2008	8.1.291.2
Update Rollup 2 for Exchange Server 2007 SP1	May 9, 2008	8.1.278.2
Update Rollup 1 for Exchange Server 2007 SP1	February 28, 2008	8.1.263.1
Exchange Server 2007 SP1	November 29, 2007	8.01.0240.006

Exchange Server 2007 RTM build numbers for update rollup packages

Product name	Release date	Build number
Update Rollup 7 for Exchange Server 2007	July 8, 2008	8.0.813.0
Update Rollup 6 for Exchange Server 2007	February 21, 2008	8.0.783.2
Update Rollup 5 for Exchange Server 2007	October 25, 2007	8.0.754.0
Update Rollup 4 for Exchange Server 2007	August 23, 2007	8.0.744.0
Update Rollup 3 for Exchange Server 2007	June 28, 2007	8.0.730.1
Update Rollup 2 for Exchange Server 2007	May 8, 2007	8.0.711.2
Update Rollup 1 for Exchange Server 2007	April 17, 2007	8.0.708.3
Exchange Server 2007	March 8, 2007	8.0.685.25

Exchange Server 2003

The following table lists the build numbers and general release dates for each version of Microsoft Exchange Server 2003. To view the build number of Exchange Server 2003, open the **Properties** dialog box of the server object.

Exchange Server 2003 build numbers

Product name	Release date	Build number
Exchange Server 2003 post-SP2	August 2008	6.5.7654.4

Exchange Server 2003 post-SP2	March 2008	6.5.7653.33
Exchange Server 2003 SP2	October 19, 2005	6.5.7683
Exchange Server 2003 Service Pack 1	May25, 2004	6.5.7226
Exchange Server 2003	September 28, 2003	6.5.6944

Exchange 2000 Server

The following table lists the build numbers and general release dates for each version of Microsoft Exchange 2000 Server. To view the build number of Exchange 2000 Server, open the **Properties** dialog box of the server object.

Exchange 2000 Server build numbers

Product name	Release date	Build number
Exchange 2000 Server post-SP3	August 2008	6.0.6620.7
Exchange 2000 Server post-SP3	March 2008	6.0.6620.5
Exchange 2000 Server post-SP3	August 2004	6.0.6603
Exchange 2000 Server post-SP3	April 2004	6.0.6556
Exchange 2000 Server post-SP3	September 2003	6.0.6487
Exchange 2000 Server SP3	July 18, 2002	6.0.6249
Exchange 2000 Server Service Pack 2	November 29, 2001	6.0.5762
Exchange 2000 Server Service Pack 1	June 21, 2001	6.0.4712
Exchange 2000 Server	November 29, 2000	6.0.4417

Exchange Server 5.5

The following table lists the build numbers and general release dates for each version of Microsoft Exchange Server version 5.5.

Exchange Server 5.5 build numbers

Product name	Release date	Build number
Exchange Server version 5.5 Service Pack 4	November 1, 2000	5.5.2653
Exchange Server version 5.5 Service Pack 3	September 9, 1999	5.5.2650

Exchange Server version 5.5 Service Pack 2	December 23, 1998	5.5.2448
Exchange Server version 5.5 Service Pack 1	August 5, 1998	5.5.2232
Exchange Server version 5.5	February 3, 1998	5.5.1960

Exchange Server 5.0

The following table lists the build numbers and general release dates for each version of Microsoft Exchange Server 5.0.

Exchange Server 5.0 build numbers

Product name	Release date	Build number
Exchange Server 5.0 Service Pack 2	February 19, 1998	5.0.1460
Exchange Server 5.0 Service Pack 1	June 18, 1997	5.0.1458
Exchange Server 5.0	May 23, 1997	5.0.1457

Exchange Server 4.0

The following table lists the build numbers and general release dates for each version of Microsoft Exchange Server 4.0.

Exchange Server 4.0 build numbers

Product name	Release date	Build number
Exchange Server 4.0 Service Pack 5	May5, 1998	4.0.996
Exchange Server 4.0 Service Pack 4	March 28, 1997	4.0.995
Exchange Server 4.0 Service Pack 3	October 29, 1996	4.0.994
Exchange Server 4.0 Service Pack 2	July 19, 1996	4.0.993
Exchange Server 4.0 Service Pack 1	May 1, 1996	4.0.838
Exchange Server 4.0 Standard Edition	June 11, 1996	4.0.837

For More Information

For more information about how to determine the build number and version of Microsoft Exchange that you're running, see Microsoft Knowledge Base article 152439, How to determine the version number, the build number, and the service pack level of Exchange Server.

For more information about Exchange Server 2010 versions, see Exchange 2010: Editions and Versions.

For more information about Exchange Server 2007 versions, see Exchange Server 2007: Platforms, Editions, and Versions.

For more information about how to determine build numbers and version information after you install an update rollup, see the following:

- **Exchange 2010** After you install an update rollup for Exchange 2010, the version of Exchange Server isn't updated to show that the update rollup is installed. This issue occurs because the version number that is displayed by the Exchange Management Console or by other administrative mechanisms is obtained from the Exchange Server Object in Active Directory.
- **Exchange 2007** See How to View the Exchange Server 2007 Version Number After You Install an Update Rollup.

1.1.11 Exchange 2010 Language Support

Exchange 2010 Language Support

[This topic is in progress.]

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 has enhanced language support for both servers and clients. This topic provides information about language packs, including the specific languages that are supported for both servers and clients in Exchange 2010.

Other topics in this section include:

- Language Support for Exchange Management Interfaces
- Client Language Support for Outlook
- Client Languages for Outlook Web App
- Client Language Support for Unified Messaging

Exchange 2010 Language Packs

An Exchange 2010 language pack contains the necessary resources for a supported Exchange language. Language packs are installed during installation of Exchange 2010. Client and server language packs come grouped into a single bundle containing both client and server resource and support files. There are no performance issues with installing all the languages because they're just stored when not in use.

For organizations that have users in multiple languages, we recommend that you do the following:

- On Unified Messaging (UM) servers, only install the UM language pack that you need for your organization. The addition of extra UM language packs introduces more processing when the server builds speech grammar for each language.

UM Language Packs

For a specific language that's supported by Exchange 2010 Unified Messaging, UM language packs allow an Exchange 2010 Unified Messaging server to speak additional languages to callers and recognize other languages when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. UM language packs contain:

- Pre-recorded prompts, for example, "After the tone, please record your message. When you've finished recording, hang up, or press the # key for more options." in the language of the UM language pack.
- Grammar files that are used by a Unified Messaging server to look up the names of specific users in the directory in the language of the UM language pack.
- Text-to-Speech (TTS) translation so that content (for example, e-mail, calendar, or contact information) can be read to callers in the language of the UM language pack.
- Support for ASR, which allows callers to interact with Unified Messaging using the Voice User Interface (VUI) in the language of the UM language pack.
- Support for Voice Mail Preview, which allows users to read the transcript of voice mail messages in a specific language from within a supported e-mail client such as Microsoft Outlook or Outlook Web App.

The U.S. English (en-US) language pack contains UM prompts, TTS, ASR, and Voice Mail Preview support for this language.

Important:

The UM language pack must only be installed as an add-in to Exchange 2010 Unified Messaging.

For more information about installing UM language packs, see Install a Unified Messaging Language Pack on a UM Server.

Supported Server Languages for Exchange 2010

The following server languages are supported and available for Exchange 2010:

- Chinese (Simplified)
- Chinese (Traditional)
- English
- French
- German
- Italian
- Japanese
- Korean
- Portuguese
- Russian
- Spanish

Beginning in SP1 of Exchange 2010, the following additional languages are supported:

- Arabic
- Hebrew

Supported Client Languages for Exchange 2010

The following client languages are supported and available for Exchange 2010:

Note:

The Windows Server 2008 operating system Multilingual User Interface (MUI) packs aren't needed for client localization.

- Chinese (Simplified)
- English
- French
- German
- Japanese
- Chinese (Traditional)
- Italian
- Korean
- Portuguese
- Russian
- Spanish
- Arabic
- Czech
- Danish
- Dutch
- Finnish
- Greek
- Hebrew
- Hungarian
- Norwegian
- Polish
- Portuguese (Portugal)
- Swedish
- Turkish
- Romanian
- Thai
- Filipino (Philippines)
- Hindi
- Indonesian
- Latvian
- Malay
- Ukrainian
- Vietnamese
- Bulgarian
- Croatian
- Estonian
- Lithuanian
- Serbian
- Slovak
- Slovenian
- Basque
- Catalan
- Chinese (Hong Kong S.A.R.)
- Persian
- Icelandic
- Kazakh
- Serbian (Cyrillic, Serbia)
- Urdu

1.1.11.1 Language Support for Exchange Management Interfaces

Language Support for Exchange Management Interfaces

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-16*

Microsoft Exchange Server 2010 offers a fully localized administrative experience in many languages. Administrators can use the fully localized management interface to administer Exchange 2010 in their chosen language. This topic indicates the languages supported in each type of management interface.

Exchange Management Console and Exchange Management Shell

The following languages are supported in both the Exchange Management Console and the Exchange Management Shell:

- Chinese (Simplified)
- Chinese (Traditional)
- English
- French
- German
- Italian
- Japanese
- Korean
- Portuguese
- Russian
- Spanish

For Service Pack 1 (SP1) of Exchange Server 2010, the following additional languages are supported:

- Arabic
- Hebrew

Exchange Control Panel

The Exchange Control Panel (ECP) is localized in the Exchange client languages. For more information about client language support, see Exchange 2010 Language Support.

1.1.11.2 Client Language Support for Outlook

Client Language Support for Outlook

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-17*

In Exchange Server 2010, there are 48 supported languages that Office Outlook 2007 users can use to access their Microsoft Exchange mailbox.

Outlook Client Access

The language of the Outlook user interface that an Outlook user sees, including the content generated by Exchange, depends on the following:

- The language the user is using in Outlook
- Whether the language they're using in Outlook is supported by Exchange 2010
- Whether the language they're using in Outlook has been configured to be available on the Exchange 2010 server

Consider the following scenarios:

- When an Outlook user who's set their language to <Language A> signs in to their Exchange 2010 mailbox and both Outlook and Exchange 2010 support the language the user has specified, <Language A>, the user will see all messages and Exchange-generated mailbox components, for example, the Inbox, in Language A.
- When an Outlook user who's set their language to <Language A> signs in to their Exchange 2010 mailbox that's been set to <Language B>, the Outlook user will see the Outlook user interface in Language A, but will see the content generated by Exchange. For example, by default, folder names such as **Inbox**, **Deleted Items**, and **Sent Items** display in <Language B>.

You can change the Exchange mailbox language setting on the server using Exchange Management Console or the Exchange Management Shell. For information about how to use the Shell to change the language setting for a mailbox on a server, see Set-MailboxRegionalConfiguration.

Supported Languages for Components and Features of Exchange 2010

The following table includes information about the languages that are supported for client and administrative features in Exchange 2010.

Supported languages for Exchange Server 2010

Language	Country/Region	Outlook 2007 client support
Arabic	Saudi Arabia	Available
Basque	Spain	Available
Bulgarian	Bulgaria	Available
Catalan	Spain	Available
Chinese (Cantonese)	China	Available
Chinese (Hong Kong)	China	Available
Chinese (Mandarin)	China	UM language only
Chinese (Simplified)	China	Available
Chinese (Traditional)	Taiwan	Available
Croatian	Croatia	Available
Czech	Czech Republic	Available

Danish	Denmark	Available
Dutch	Netherlands	Available
English	Australia	UM language only
English	United Kingdom	UM language only
English	United States	Available
Estonian	Estonia	Available
Filipino (Tagalog)	Philippines	Available
Finnish	Finland	Available
French	Canada	UM language only

Thai	Thailand	Available
Turkish	Turkey	Available
Ukrainian	Ukraine	Available
Urdu	Pakistan	Available
Vietnamese	Vietnam	Available

1.1.11.3 Client Languages for Outlook Web App

Client Languages for Outlook Web App

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-07*

The Exchange 2010 Outlook Web App user interface is available in 54 languages.

For more information about the languages that are supported in Outlook Web App, see Configure Language Settings for Outlook Web App.

Contents

Language and Locale

There are three language settings that you can configure for Outlook Web App.

- The sign-in and error language setting applies to individual Outlook Web App virtual directories. The sign-in and error language is the language that will be used for errors and the forms-based authentication sign-in page. If a value isn't set for this language, the default value is *0*. This means that the default sign-in and error language isn't defined. If the sign-in and error language isn't defined, Outlook Web App will default first to the language set on the Web browser on the client computer. If the language set on the Web browser on the client computer isn't supported by Outlook Web App, Outlook Web App will use the language of the Client Access server.
- The default client language setting applies to individual Outlook Web App virtual directories. The default client language is the client language that's used by Outlook Web App unless the user uses **Regional Settings** in Outlook

Web App to change the language and time zone. The default value for this setting is *0*. This means the default client language isn't defined. If the default client language isn't defined, users will be prompted to choose a language and time zone the first time that they sign in to Outlook Web App. If the default client language value is defined, users won't be prompted to choose a language and the Outlook Web App time zone will use the time zone of the Client Access server. Defining the default client language causes the default folders to be renamed based on the specified language. Users can change the client language and time zone by using **Regional Settings** in Outlook Web App and can rename the default folders after they sign in.

- The client languages are set on individual mailboxes and affect the language that's used in Outlook and Outlook Web App. If multiple languages are configured, the first language in the list that's supported by the Web browser will be used. If none of the languages in the default languages list is supported by the Web browser, the Client Access server language will be used.

Outlook Web App Spelling Checker

In Exchange 2010 Outlook Web App, users can check spelling in 16 languages.

1.1.11.4 Client Language Support for Unified Messaging

Client Language Support for Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-30*

Microsoft Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange Server 2007, there have been separate releases for UM language packs, including Exchange 2007 RTM, Exchange 2007 SP1, SP2, and SP3, the RTM version of Exchange Server 2010, and Exchange 2010 SP1 and SP2. Both 32-bit and 64-bit downloads are available for some of these releases, but only 64-bit downloads are available for others.

It's very important that you install the correct version and platform of the UM language packs on a UM server. Don't install UM language packs on a Unified Messaging server that's running an earlier version of Exchange or that's designed for a 32-bit platform. This topic describes Unified Messaging (UM) language packs and their availability in Microsoft Exchange Server 2010.

What Are Unified Messaging Language Packs?

Unified Messaging language packs allow an Exchange 2010 UM server to speak additional languages to callers and recognize other languages when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. UM language packs contain:

- Pre-recorded prompts in the language of the UM language pack, for example, "After the tone, please record your message. When you've finished recording, hang up, or press the # key for more options."
- Grammar files in the language of the UM language pack that are used by a UM server to look up the names of users in the directory.
- Text-to-Speech (TTS) translation so that content, such as e-mail, calendar, and contact information, can be read to callers in the language of the UM language pack.
- Support for ASR, which allows callers to interact with UM using the voice user interface (VUI) in the language of the UM language pack.

In addition, UM language packs provide support for Voice Mail Preview, which allows users to quickly triage their voice messages by reading their transcripts from within a supported

e-mail client such as Outlook or Outlook Web App.

All UM language packs are single files that can be downloaded. These language packs include the pre-recorded prompts, grammar files, Text-to-Speech (TTS) translation, and ASR. However, not all the UM language packs contain support for Voice Mail Preview.

The following UM language packs contain support for all the components and features, including Voice Mail Preview:

1. English (US) - (en-US)
2. French (France) - (fr-FR)
3. Italian - (it-IT)English (Canada) (en-CA)
4. Polish (pl-PL)
5. Portuguese (Portugal) (pt-PT)
6. Spanish (Spain) (es-ES)

Note:

For more information about Voice Mail Preview, see Voice Mail Preview for End Users

By default, when you install the Exchange 2010 Unified Messaging server role, the server will send voice mail previews to UM-enabled users if a supported UM language pack is installed.

There are Exchange 2010 Unified Messaging Voice Mail Preview partners that offer enhanced transcription support for the Voice Mail Preview feature. These partners employ people to correct voice mail transcriptions that were created using Automatic Speech Recognition (ASR). Each Voice Mail Preview partner must meet a set of requirements to be certified to interoperate with Exchange 2010 Unified Messaging.

If you determine that the voice mail previews sent to your users aren't accurate enough, you can contact one of the certified Voice Mail Preview partners listed on the Microsoft PinPoint web page, and sign up with that partner at an additional cost. For more information, see Voice Mail Preview Advisor for Exchange 2010.

The following table includes the supported languages for Exchange 2010 Unified Messaging.

Supported languages for Exchange 2010 UM language packs

Language	Country/ Region	Culture ID	Availability	Prompts	Text-to-Speech	ASR	Voice Mail Preview
Catalan	Spain	ca-ES	Download available	√	√	√	
Chinese (Hong Kong)	China	zh-HK	Download available	√	√	√	
Chinese (Simplified)	China	zh-CN	Download available	√	√	√	
Chinese (Traditional)	Taiwan	zh-TW	Download available	√	√	√	
Danish	Denmark	da-DK	Download available	√	√	√	
Dutch	Netherlands	nl-NL	Download available	√	√	√	

English	Australia	en-AU	Download available	√	√	√	
English	Canada	en-CA	Download available	√	√	√	√
English	India	en-IN	Download available **Caution:** Deploying the Exchange 2010 SP1 English (India) (en-IN) Unified Messaging language pack in organizations that include Exchange Server 2007 servers running on Windows Server 2003 will cause the Exchange 2007 servers to fail. Further details are contained in this Microsoft Knowledge Base article.	√	√	√	
English	United Kingdom	en-GB	Download available	√	√	√	
English	United States	en-US	Download available	√	√	√	√
Finnish	Finland	fi-FL	Download available	√	√	√	
French	Canada	fr-CA	Download available	√	√	√	
French	France	fr-FR	Download available	√	√	√	√
German	Germany	de-DE	Download available	√	√	√	
Italian	Italy	it-IT	Download available	√	√	√	√

	Japan	ja-JP	Download available	√	√	√	
Korean	Korean	ko-KR	Download available	√	√	√	
Norwegian (Bokmal)	Norway	nb-NO	Download available	√	√	√	
Polish	Poland	pl-PL	Download available	√	√	√	√
Portuguese	Brazil	pt-BR	Download available	√	√	√	
Portuguese	Portugal	pt-PT	Download available	√	√	√	√
Russian	Russia	ru-RU	Download available	√	√	√	
Spanish	Spain	es-ES	Download available	√	√	√	√
Spanish	Mexico	es-MX	Download available	√	√	√	
Swedish	Sweden	sv-SE	Download available	√	√	√	

Important:

To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don't install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that's configured on the dial plan but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won't work in the language selected by the user without having both the UM language pack and the Client and Server Language Pack installed. The language pack bundle for Exchange Server 2010 Service Pack 2 (SP2) is integrated into the download for Exchange 2010 SP2. To download SP2 for Exchange 2010, see Microsoft Exchange Server 2010 Service Pack 2 (SP2). However, the language pack bundle for Exchange 2010 SP1 is still available. To download and install additional client and server language packs for Exchange 2010 SP1 on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

Client Language Selection Process

Exchange 2010 UM language packs enable callers and Outlook Voice Access users to interact with the Unified Messaging system in multiple languages. After you install additional language packs on a Unified Messaging server, callers and Outlook Voice Access users can hear e-mail messages and interact with the Unified Messaging system, and Outlook Web App and Outlook 2010 users can view the transcript of a voice message using Voice Mail Preview in a specific language.

To support a specific language, a UM client language pack for that language must be installed on each UM server in the UM dial plan.

In some cases, if a UM language pack for a specific language hasn't been installed and isn't available, a client fallback language may be used instead of the language that's

needed. For some languages, fallback UM client languages are available to be used, but for other languages, no fallback language is available. If there isn't a UM language pack installed for a specific language, and no fallback language is available for that language, en-US (US English) will be used. By default, the en-US UM language pack is installed on all Unified Messaging servers when you install the Unified Messaging server role. The en-US UM language pack can't be uninstalled.

The following table includes a list of client languages and the fallback languages that are used when a specific UM language pack hasn't been installed on a Unified Messaging server.

Client Fallback Languages for UM

Language	Country/ Region	Culture ID	First language chosen, if installed	Second language chosen, if installed	Third language chosen, if installed
Catalan	Spain	ca-ES	ca-ES	en-US	
Chinese (Hong Kong)	China	zh-HK	zh-HK	zh-CN	zh-TW
Chinese (Simplified)	China	zh-CN	zh-CN	zh-HK	zh-TW
Chinese (Traditional)	Taiwan	zh-TW	zh-TW	zh-HK	zh-CN
Danish	Denmark	da-DK	da-DK	en-US	
Dutch	Netherlands	nl-NL	nl-NL	en-US	
English	Australia	en-AU	en-AU	en-US	
English	Canada	en-CA	en-CA	en-US	
English	India	en-IN	en-IN	en-US	
English	United Kingdom	en-GB	en-GB	en-US	
English	United States	en-US	en-US		
Finnish	Finland	fi-FL	fi-FL	en-US	
French	Canada	fr-CA	fr-CA	fr-FR	en-US
French	France	fr-FR	fr-FR	fr-CA	en-US
German	Germany	de-DE	de-DE	en-US	
Italian	Italy	it-IT	it-IT	en-US	
Japanese	Japan	ja-JP	ja-JP	en-US	
Korean	Korea	ko-KR	ko-KR	en-US	
Norwegian (Bokmal)	Norway	nb-NO	nb-NO	en-US	
Polish	Poland	pl-PL	pl-PL	en-US	
Portuguese	Brazil	pt-BR	pt-BR	pt-PT	en-US

Portuguese	Portugal	pt-PT	pt-PT	pt-BR	en-US
Russian	Russia	ru-RU	ru-RU	en-US	
Spanish	Spain	es-ES	es-ES	es-MX	en-US
Spanish	Mexico	es-MX	es-MX	es-ES	en-US

1.1.12 Exchange 2010 Support for RFC Standards

Exchange 2010 Support for RFC Standards

Exchange Server 2010 > Getting Started With Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-27*

This topic is intended to be a reference for the Request for Comments (RFC) and other standards that are supported in Microsoft Exchange Server 2010. Although every effort has been made to verify this information, omission of an RFC from this list does not necessarily mean that Exchange does not fully or partially support the RFC. RFCs are guidelines, and they frequently contain two types of information: required and optional. Microsoft and other vendors may choose not to implement optional requirements, or they may interpret sections of RFCs differently.

If you are experiencing a problem that you believe is caused because Exchange does not correctly support a particular RFC, open a support incident through Microsoft Customer Support Services (CSS).

Important:
The information that is contained in this topic represents the current view of Microsoft Corporation about the issues discussed as of the date of publication. Because Microsoft must respond to changing market conditions, this information should not be interpreted to be a commitment on the part of Microsoft. Microsoft cannot guarantee the accuracy of any information that is presented in this topic after the date of publication.
This topic is for informational purposes only. MICROSOFT MAKES NO WARRANTIES, EXPRESS OR IMPLIED, AS TO THE INFORMATION IN THIS DOCUMENT.

RFC Implementation Statements

All document references are listed in the following format:

Document/RFC: Document or RFC index
Title: Description or title of document
Updated by: RFCs that update this document
Updates: RFCs that are updated by this document
Obsoletes: RFCs that are replaced by this document or are obsolete
Exchange 2010 specific: RFCs that are implemented by or supported by Exchange 2010; if applicable, the component and any other notes about support for the applicable RFC; links to additional information

Note:
For the purposes of this topic, "implemented" means that the RFC has been implemented natively within Exchange 2010, and "supported" means that a technology that is outside Exchange 2010 has implemented the RFC but that Exchange 2010 uses that implementation.

Not all document references contain all fields that are shown in the sample format. In some cases, the information has been merged. Refer to the document source for the latest information.

RFC: 3974 http://www.ietf.org/rfc/rfc3974.txt

Title: SMTP Operational Experience in Mixed IPv4/v6 Environments

Exchange 2010 specific: Supported by Exchange 2010 Transport service

RFC: 4120 http://www.ietf.org/rfc/rfc4120.txt

Title: The Kerberos Network Authentication Service (V5)

Updated by: 4537, 5021

Obsoletes: 1510

Exchange 2010 specific: Supported by Exchange 2010 Mailbox, Client Access, Hub Transport, and Unified Messaging (UM) servers that have the MSRPC protocol, and by the Exchange POP3, IMAP4, and SMTP services

RFC: 4262 http://www.ietf.org/rfc/rfc4262.txt

Title: X.509 Certificate Extension for Secure/Multipurpose Internet Mail Extensions (S/MIME) Capabilities

Exchange 2010 specific: Supported by Exchange 2010 Outlook Web App and S/MIME control

RFC: 4346 http://www.ietf.org/rfc/rfc4346.txt

Title: The Transport Layer Security (TLS) Protocol Version 1.1

Updated by: 4366, 4680, 4681

Obsoletes: 2246

Exchange 2010 specific: Implemented by Exchange 2010 Transport Service, and by POP3, SMTP, and IMAP4 services

RFC: 4406 http://www.ietf.org/rfc/rfc4406.txt

Title: Sender ID: Authenticating E-Mail

Exchange 2010 specific: Partially implemented; Exchange 2010 does not support MTA forwarding of mail

RFC: 4409 http://www.ietf.org/rfc/rfc4409.txt

Title: Message Submission for Mail

Obsoletes: 2476

Exchange 2010 specific: Partially implemented; Exchange 2010 does not always return

554 DSN (for example, 550 5.7.1)

RFC: 4559 http://www.ietf.org/rfc/rfc4559.txt

Title: SPNEGO-based Kerberos and NTLM HTTP Authentication in Microsoft Windows

Exchange 2010 specific: Supported by Exchange 2010 Autodiscover Service and by Exchange Web Services

RFC: 4853 http://www.ietf.org/rfc/rfc4853.txt

Title: Cryptographic Message Syntax (CMS) Multiple Signer Clarification

Updates: 3852

Exchange 2010 specific: Implemented by Exchange 2010 Outlook Web Access and S/MIME control

RFC: 4954 http://www.ietf.org/rfc/rfc4954.txt

Title: SMTP Service Extension for Authentication

Updates: 3463

Obsoletes: 2554

Exchange 2010 specific: Implemented by Exchange 2010 Transport Service

RFC: 5008 http://www.ietf.org/rfc/rfc5008.txt

Title: Suite B in Secure/Multipurpose Internet Mail Extensions (S/MIME)

Exchange 2010 specific: Supported by Exchange 2010 Outlook Web App and S/MIME control

RFC: 1734 http://www.ietf.org/rfc/rfc1734.txt

Title: POP3 Authentication command

Exchange 2010 specific: Implemented by Exchange 2010 POP3 service (Windows Integrated Authentication – NTLM and GSSAPI)

RFC: 5035 http://www.ietf.org/rfc/rfc5035.txt

Title: Enhanced Security Services (ESS) Update: Adding CertID Algorithm Agility

Updates: 2634

Exchange 2010 specific: Supported by Exchange 2010 Outlook Web App and by S/MIME control

For More Information

For more information about Exchange Server RFC and standards compliance in earlier versions of Exchange, see Microsoft Knowledge Base article 262986, Exchange Server RFC

and standards compliance.

1.2 Planning and Deployment

Planning and Deployment

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-16*

Use this information to help you deploy Microsoft Exchange Server 2010. The following topics are gateways to information about planning for and then deploying Exchange Server 2010.

Planning for Exchange 2010

Topics in this section provide important information to assist you in planning your Exchange 2010 organization, including details about system requirements and upgrading from a previous version of Microsoft Exchange.

Deploying Exchange 2010

Topics in this section can help you understand and manage your deployment of Exchange 2010, whether a new deployment or an upgrade from a previous version of Exchange.

Note:
For information about hybrid deployments, see Hybrid Deployments. For information about cloud-only deployments, see Understanding Cloud-Only Deployments with Exchange 2010 SP3.

In addition to these topics, we also recommend you read:

Exchange 2010 Language Support

Understanding Permissions

Understanding Role Based Access Control

High Availability and Site Resilience

1.2.1 Planning for Exchange 2010

Planning for Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-03*

These topics can help you plan the deployment of Microsoft Exchange Server 2010 into your production environment. Use the following links to access the information to help you make your planning decisions.

After you have completed the planning phase and are ready to deploy, see Deploying Exchange 2010. Also, see Establish a Test Environment later in this topic about installing Exchange 2010 in a test environment prior to deploying into production.

Exchange 2010 System Requirements

Before you install Exchange 2010, make sure that your organization meets the system requirements.

Planning Roadmap for New Deployments

Read this topic to get an overview of the things you need to consider before you begin a new Exchange 2010 deployment.

Exchange 2003 - Planning Roadmap for Upgrade and Coexistence

This topic provides an overview of the things you need to consider before you deploy Exchange 2010 into an Exchange Server 2003 organization.

Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

This topic provides an overview of the things you need to consider before you deploy Exchange 2010 into an Exchange 2007 organization.

Exchange Server Deployment Assistant

Use this tool to generate a customized checklist for planning, installing, or upgrading to Exchange 2010.

Workforce Planning for Exchange

This topic can help you make informed decisions when determining the appropriate workforce levels for your Exchange Server environment.

Planning for High Availability and Site Resilience

Consult this topic to help you with planning to achieve your high availability and site resilience requirements.

Planning Active Directory

Learn about Active Directory requirements and its interaction with your Exchange organization.

Understanding Disjoint Namespace Scenarios

This topic discusses the supported scenarios for deploying Exchange 2010 in a domain that has a disjoint namespace.

Mailbox Server Storage Design

This group of topics discusses storage design, which is a critical piece of a successful Exchange 2010 Mailbox server role deployment.

Understanding Exchange 2010 Virtualization

Read this topic to learn more about how you can deploy Exchange 2010 in a virtualized environment.

Planning for Internal and Third-Party Applications

This topic links to important information about Application Programming Interfaces that are available for applications that use Exchange 2010.

Exchange 2010 Deployment Permissions Reference

Consult this topic to learn about the permissions that are required to set up an Exchange 2010 organization.

Exchange Network Port Reference

Use this topic to find information about ports, authentication, and encryption for all data paths used by Exchange 2010.

Exchange Server Supportability Matrix

Consult this topic to learn about the level of support available for any configuration or required component for all versions of Microsoft Exchange.

Exchange 2010 Solution Accelerator

This topic links to a guide related to infrastructure planning and design for Service Pack 1 for Exchange 2010. The guide provides a step-by-step process for successfully designing an Exchange 2010 infrastructure.

Note:

You can't upgrade an existing Exchange 2000 organization directly to Exchange 2010. You must first upgrade the Exchange 2000 organization to either an Exchange 2003 or Exchange 2007 organization, and then you can upgrade the Exchange 2003 or Exchange 2007 organization to Exchange 2010. We recommend that you upgrade your organization from Exchange 2000 to Exchange 2003, and then upgrade from Exchange 2003 to Exchange 2010. For more information about upgrading from Exchange 2000, see Planning an Upgrade from Exchange 2000 and Upgrading to Exchange 2007.

Establish a Test Environment

Before installing Exchange 2010 for the first time, we recommend that you install it in an isolated test environment. This approach reduces the risk of end-user downtime and negative ramifications to the production environment.

The test environment will act as your “proof of concept” for your new Exchange 2010 design and make it possible to move forward or roll back any implementations before deploying into your production environments. Having an exclusive test environment for validation and testing allows you to do pre-installation checks for your future production environments. By installing in a test environment first, we believe that your organization will have a better likelihood of success in a full production implementation.

For many organizations, the costs of building a test lab may be high because of the need to duplicate the production environment. To reduce the hardware costs associated with a prototype lab, we recommend the use of virtualization by using Windows Server 2008 R2 Hyper-V technologies. Hyper-V enables server virtualization, allowing multiple virtual operating systems to run on a single physical machine.

For more detailed information about Hyper-V, see Virtualization with Hyper-V. For information about Microsoft support of Exchange 2010 in production on hardware virtualization software, see "Hardware Virtualization" in Exchange 2010 System Requirements.

1.2.1.1 Exchange 2010 System Requirements

Exchange 2010 System Requirements

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-02-26*

Before you install Microsoft Exchange Server 2010, we recommend that you review this topic to ensure that your network, hardware, software, clients, and other elements meet the requirements for Exchange 2010. In addition, make sure you understand the coexistence scenarios that are supported for Exchange 2010 and earlier versions of Exchange.

Supported Coexistence Scenarios

The following table lists the scenarios in which coexistence between Exchange 2010 and earlier versions of Exchange are supported.

Coexistence of Exchange 2010 and earlier versions of Exchange Server

Exchange version	Exchange organization coexistence
Exchange 2000 Server	Not supported
Exchange Server 2003	Supported
Exchange 2007	Supported
Mixed Exchange 2007 and Exchange Server 2003 organization	Supported

Exchange 2000 Server

You can't upgrade an existing Exchange 2000 organization directly to Exchange 2010. You must first upgrade the Exchange 2000 organization to either an Exchange 2003 or Exchange 2007 organization, and then you can upgrade the Exchange 2003 or Exchange 2007 organization to Exchange 2010. We recommend that you upgrade your organization from Exchange 2000 to Exchange 2003, and then upgrade from Exchange 2003 to Exchange 2010. For more information about upgrading from Exchange 2000, see Planning an Upgrade from Exchange 2000 and Upgrading to Exchange 2007.

Network and Directory Servers

The following table lists the requirements for the network and the directory servers in your Exchange 2010 organization.

Network and directory server requirements for Exchange 2010

Component	Requirement
Schema master	By default, the schema master runs on the first Windows Server 2003, Windows Server 2008, Windows Server 2008 R2, or Windows Server 2012 domain controller installed in a forest. The schema master must be running any of the following: • Windows Server 2003 Standard Edition with Service Pack 2 (SP2) or later (32-bit or 64-bit)

	• Windows Server 2003 Enterprise Edition with SP2 or later (32-bit or 64-bit) • Windows Server 2008 Standard or Enterprise (32-bit or 64-bit) • Windows Server 2008 R2 Standard or Enterprise • Windows Server 2012
Global catalog server	In each Active Directory site where you plan to install Exchange 2010, you must have at least one global catalog server running any of the following: • Windows Server 2003 Standard Edition with SP2 or later (32-bit or 64-bit) • Windows Server 2003 Enterprise Edition with SP2 or later (32-bit or 64-bit) • Windows Server 2008 Standard or Enterprise (32-bit or 64-bit) • Windows Server 2008 R2 Standard or Enterprise • Windows Server 2012 For more information about global catalog servers, see What is the Global Catalog.
Domain controller	In each Active Directory site where you install Exchange 2010, Exchange 2010 must be able to contact at least one writeable domain controller of the domain of which Exchange 2010 is a member. The domain controller can run any of the following: • Windows Server 2003 Standard Edition with SP2 or later (32-bit or 64-bit) • Windows Server 2003 Enterprise Edition with SP2 or later (32-bit or 64-bit) • Windows Server 2008 Standard or Enterprise SP1 or later (32-bit or 64-bit) • Windows Server 2008 R2 Standard or Enterprise SP1 or later • Windows Server 2008 Datacenter RTM or later • Windows Server 2008 R2 Datacenter RTM or later • Windows Server 2012
Active Directory forest	Active Directory must be at Windows Server 2003 forest functionality mode or higher.
IPv6 Support	IPv6 is supported only when IPv4 is also used; a pure IPv6 environment isn't supported. Using IPv6 addresses and IP address ranges is supported only when both IPv6 and IPv4 are enabled on that computer, and the network supports both IP address versions. If Exchange 2010 is deployed in this configuration, all server roles can send data to and receive data from devices, servers, and clients that use IPv6 addresses. Exchange 2010 support is similar to support for Exchange Server 2007. For more information, see Understanding IPv6 Support

	in Exchange 2010.

Directory Server Architecture

The use of 64-bit Active Directory domain controllers increases directory service performance for Exchange 2010. For more information about Exchange 2010, the Mailbox server role and Active Directory ratios, see the "Active Directory Server and Mailbox Server Ratios" section in Understanding Server Role Ratios and Exchange Performance.

Note:

In multi-domain environments, on Windows Server 2008 domain controllers that have the Active Directory language locale set to Japanese, your servers may not receive some attributes that are stored on an object during inbound replication. For more information, see Microsoft Knowledge Base article 949189, A Windows Server 2008 domain controller that is configured with the Japanese language locale may not apply updates to attributes on an object during inbound replication.

Installing Exchange 2010 on Directory Servers

For security and performance reasons, we recommend that you install Exchange 2010 only on member servers and not on Active Directory directory servers. However, you can't run DCPromo on a computer running Exchange 2010. After Exchange 2010 is installed, changing its role from a member server to a directory server, or vice versa, isn't supported.

Hardware

The recommended hardware requirements for Exchange 2010 servers vary depending on a number of factors including the server roles that are installed and the anticipated load that will be placed on the servers. For information about minimum, maximum, and recommended hardware configurations for Exchange 2010 servers, see Performance and Scalability.

Hardware requirements for Exchange 2010

Component	Requirement	Notes
Processor	• x64 architecture-based computer with Intel processor that supports Intel 64 architecture (formerly known as Intel EM64T) • AMD processor that supports the AMD64 platform • Intel Itanium IA64 processors not supported	It's supported to install the Exchange management tools on a computer that has a 64-bit processor. For more information, see Install the Exchange 2010 Management Tools and Prepare Active Directory and Domains.
Memory	Varies depending on Exchange features that are installed	For detailed information about memory requirements for Exchange 2010, see Understanding Memory Configurations and Exchange Performance.
Paging file size	The page file size minimum and maximum must be set to physical RAM plus 10 MB	The recommended page file size also accounts for the memory that's needed to collect

		information if the operating system stops unexpectedly. On 64-bit operating systems, memory can be written as a dump file to the paging file. This file must reside on the boot volume of the server. For more information about the configuration options that are available for memory dump data, see Knowledge Base article 254649, Overview of memory dump file options for Windows Vista, Windows Server 2008 R2, Windows Server 2008, Windows Server 2003, Windows XP, and Windows 2000.
Disk space	• At least 1.2 GB on the drive on which you install Exchange • An additional 500 MB of available disk space for each Unified Messaging (UM) language pack that you plan to install • 200 MB of available disk space on the system drive • A hard disk that stores the message queue database on an Edge Transport server or Hub Transport server with at least 500 MB of free space	The minimum space requirements detailed here don't account for disk subsystem requirements for adequate performance.
Drive	DVD-ROM drive, local or network accessible	None.
Screen resolution	800 x 600 pixels or higher	None.
File format	Disk partitions formatted as NTFS file systems, which applies to the following partitions: • System partition • Partitions that store Exchange binary files • Partitions containing transaction log files • Partitions containing database files • Partitions containing other Exchange files	None.

For more information about planning your hardware for Exchange 2010, see the following

topics:

- Understanding Processor Configurations and Exchange Performance
- Understanding Memory Configurations and Exchange Performance
- Understanding Server Role Ratios and Exchange Performance

Operating System

The following table lists the supported operating systems for Exchange 2010.

Supported operating systems for Exchange 2010

Component	Requirement
Operating system on a computer that has a 64-bit processor	One of the following: • 64-bit edition of Windows Server 2008 Standard with Service Pack 2 (SP2) • 64-bit edition of Windows Server 2008 Enterprise with SP2 • 64-bit edition of Windows Server 2008 R2 Standard with SP1 • 64-bit edition of Windows Server 2008 R2 Enterprise with SP1 • Windows Server 2008 Datacenter RTM or later • Windows Server 2008 R2 Datacenter RTM or later • Windows Server 2012 (Requires Exchange 2010 SP3 or later)
Operating system for installing the Exchange management tools on a computer that has a 64-bit processor	One of the following: • Windows Vista with SP2 for management tools only installation • 64-bit edition of Windows Server 2008 Standard with SP2 • 64-bit edition of Windows Server 2008 Enterprise with SP2 • 64-bit edition of Windows Server 2008 R2 Standard • 64-bit edition of Windows Server 2008 R2 Enterprise • Windows Server 2012 • 64-bit edition of Windows 7 • Windows 8 (Requires Exchange 2010 SP3 or later)

Important:

The release-to-manufacturing (RTM) version of Exchange 2010 doesn't support being run on computers with the United States Federal Information Processing Standards (FIPS) compliant settings enabled. If you have FIPS enabled on computers running Windows Server 2008 SP2 or Windows Server 2008 R2, Exchange 2010 RTM will not function correctly. For more information, see Knowledge Base article 811833, The effects of enabling the "System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing" security setting in Windows XP and in later versions of Windows.

Support for Outlook and Entourage

Exchange 2010 supports the following versions of Microsoft Office Outlook and Microsoft Entourage for Mac:

- Outlook 2010

- Outlook 2007
- Outlook 2003
- Entourage 2008 for Mac, Web Services Edition
- Outlook for Mac 2011

If you haveclients running Outlook 2003, be aware of the following when you upgrade your organization to Exchange 2010:

- On clients running Outlook 2003, you may notice that folder updates don't occur automatically in a timely manner. This was a known issue in Exchange 2010 RTM and SP1, but it has been resolved in Exchange 2010 SP1 Rollup Update 3. For more information about how to install an Update Rollup, see Install the Latest Update Rollup for Exchange 2010. For more background information about this issue, see Knowledge Base article 2009942, In Outlook 2003, e-mail messages take a long time to send and receive when you use an Exchange 2010 mailbox. Outlook 2007 and Outlook 2010 are not affected by this issue.
- Exchange 2010 RTM: Clients running Outlook 2003 don't use RPC encryption, which RPC Client Access requires by default. You will either need to turn off the RPC encryption requirement or configure Outlook 2003 to use RPC encryption. However, Outlook 2007 and later versions are automatically compatible with the change to RPC Client Access because they support RPC encryption by default. For more information, see Understanding RPC Client Access.
- Exchange 2010 SP1: In Exchange 2010 SP1, the RPC encryption requirement is disabled by default. Any new Client Access Servers (CAS) deployed in the organization will not require encryption. However, any CA servers deployed prior to Exchange 2010 SP1 or upgraded to Exchange 2010 SP1 will retain the existing RPC encryption requirement setting.

For more information, see Concern: Is having Outlook 2003 clients going to prevent me from deploying Exchange 2010?.

Hardware Virtualization

Microsoft supports running Exchange 2010 in production on hardware virtualization software. For more information, see Understanding Exchange 2010 Virtualization.

1.2.1.2 Planning Roadmap for New Deployments

Planning Roadmap for New Deployments

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Before proceeding with deployment of Microsoft Exchange Server 2010, we recommend that you read this topic to help you prepare your organization for deployment.

Exchange Organization Planning

Before deploying Exchange 2010, your existing infrastructure must meet certain prerequisites. Review the following topics to help ensure that your organization is ready for Exchange 2010:

- Exchange 2010 System Requirements
- Exchange 2010 Prerequisites

Exchange 2010 Supported Topologies

Exchange 2010 supports the following topologies:

- Single forest, multiple Active Directory sites.
- Multiple forests (resource forest model); multiple Active Directory sites.
- Single Active Directory site.

Exchange 2010 doesn't support the following topologies:

- Installing earlier version of Exchange into a newly created Exchange 2010 organization.

Important:
The addition of earlier versions of Exchange to an Exchange 2010–only organization is not supported.

For more information, see Deploy Multiple Forest Topologies.

Exchange Server 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Active Directory Planning

Exchange 2010 uses Active Directory Lightweight Directory Service (AD LDS) to store and share directory information with Microsoft Windows. For more information, see Planning Active Directory.

Network and Name Resolution Planning

Make sure that you correctly register host records for servers that run Exchange 2010 in the Domain Name System (DNS) server for the Active Directory forest. Clients and other servers use DNS as the name resolution service to locate Exchange servers. You need to confirm that name resolution is correctly configured for your environment. For more information, see the following topics:

- Domain Name System
- Understanding Disjoint Namespace Scenarios
- Exchange Network Port Reference

Hub Transport Server Planning

The Hub Transport server role is a required role in an Exchange 2010 organization that provides routing within a single organizational network by using Active Directory sites. Deployed inside the Active Directory forest, computers that have the Hub Transport server role installed handle all mail flow inside the organization, apply transport rules, apply journal rules, and deliver messages to recipients' mailboxes. Messages that are sent to the Internet are relayed by the Hub Transport server to the Edge Transport server role that is deployed in the perimeter network. Messages that are received from the Internet are processed by the Edge Transport server before they are relayed to the Hub Transport server. The Hub Transport server role stores all its configuration information in Active Directory.

When you plan to deploy the Hub Transport server role, you should consider the following

issues:

- **Topology options** Begin by planning where you will put your Hub Transport servers in the Exchange physical topology. Exchange uses Active Directory sites to route messages; therefore, you must deploy at least one Hub Transport server in each Active Directory site in which you deploy Mailbox servers. For more information about how to plan for placement of the Hub Transport server, see Overview of the Hub Transport Server Role.
- **Server capacity** Planning for server capacity includes determining how you will conduct performance monitoring of the Hub Transport server. Performance monitoring will help you set a performance baseline for your servers. This information will help determine the capacity of your hardware configuration.
- **Transport features** Determine the transport features that you will enable at the Hub Transport server and how they will be configured.
- **Security** The Hub Transport server role is deployed inside the Exchange organization. Planning for Hub Transport server security includes delegation of administrative roles and verification that IP connections are only enabled from authorized servers. Additionally, you should verify that no nonessential services are running and that no unnecessary ports are open. For more information, see Deployment Security Checklist

Internet Connectivity for Hub Transport Servers

To complete mail flow configuration for the Exchange organization and to send and receive e-mail to and from the Internet, you must configure Send connectors and Receive connectors that enable at least one Hub Transport server to connect to the Internet. You can configure Internet connectivity for a Hub Transport by using any of the following methods:

- You can deploy an Edge Transport server and subscribe it to the Exchange organization. This is the recommended deployment method. By default, when you create the Edge Subscription, the required Send connectors are automatically created. You don't have to modify the configuration of the default Receive connector on the Hub Transport server for this scenario. For more information, see Configure Internet Mail Flow Through a Subscribed Edge Transport Server.
- You can deploy an Edge Transport server without subscribing it to the Exchange organization. In this scenario, you would have to manually configure the Send and Receive connectors on your Edge Transport and Hub Transport servers, and you won't be able to use features like recipient filtering or safelist aggregation because there is no data replication. For more information, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync.
- You can send and receive Internet e-mail by relaying through Microsoft Exchange Hosted Services or another third-party SMTP gateway server. In this scenario, you have to create a Send connector and a Receive connector between the Hub Transport server and the external SMTP servers that process and route Internet e-mail. For more information, see Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway.
- You can establish Internet mail flow directly through a Hub Transport server. In this scenario, you have to create a Send connector that routes e-mail to the Internet. Also, you have to modify the configuration of the default Receive connector to accept anonymous e-mail submissions. In this scenario, the Exchange 2010 Hub Transport server can be reached directly through the Internet. We don't recommend this topology because it increases security risks by exposing to the Internet the Exchange 2010 server and all roles installed on that server. Instead, we recommend that you implement a perimeter network-based SMTP gateway, such as the Edge Transport server. For more information, see Configure Internet Mail Flow Directly Through a Hub Transport Server.

Note:
If you choose to establish Internet mail flow directly through your Hub Transport servers, we recommend that you install the anti-spam agents on your Hub Transport servers so that they can provide anti-spam protection for your Exchange organization. For more information, see Enable Anti-Spam Functionality on a Hub Transport Server.

Important:
If you configure an Internet-facing Hub Transport server, you can't configure a Send connector to attach a particular IP address to messages that are sent from the Hub Transport server. For example, if more than one IP address is assigned to the Hub Transport server, you can't select which IP address is used by a Send connector to relay e-mail to the Internet. If you use an SMTP relay, such as an Edge Transport server, the IP address of that computer is affixed as the message source.

High Availability and Load Balancing for Hub Transport Servers

Exchange 2010 Transport servers feature shadow redundancy, which provides redundancy for messages for the entire time they are in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport databases is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting back successful delivery, the message is resubmitted for delivery to that next hop.

Shadow redundancy is enabled by default in your Exchange 2010 environment. To learn more about shadow redundancy, see Understanding Shadow Redundancy.

You achieve load balancing for Hub Transport servers when you install more than one Hub Transport server in the same Active Directory site. By default, connections to Hub Transport servers are automatically load balanced if more than one Hub Transport server is deployed in an Active Directory site. If one Hub Transport server is unavailable, the operational Hub Transport servers continue to accept connections. If all Hub Transport servers in an Active Directory site are unavailable, messages are queued until a Hub Transport server becomes available or the messages expire.

Load balancing of outbound connections to remote domains is achieved by specifying more than one Hub Transport server in the same Active Directory site as a source server for the corresponding Send connector. Load balancing doesn't occur when the source servers for a Send connector are located in different Active Directory sites.

Note:
If the Hub Transport server is installed on the same hardware as the Mailbox server role, load balancing may not occur. When the Hub Transport server role is on the same hardware as the Mailbox server role, the local server is preferred for all messages that are sent by users who have mailboxes on that server. Therefore, in this scenario, true load balancing does not occur.

Network Load Balancing (NLB) can be used to provide high availability in the following scenarios:

- Load balancing of inbound SMTP connections for POP and IMAP client connections to the default Receive connector named "Client *<Server Name>*" that is created only on Hub Transport servers.
- Load balancing of inbound SMTP connections for applications that submit e-mail to the Exchange organization.

NLB should not be used to distribute connections for internal routing between Hub Transport servers.

For more information about how to configure Network Load Balancing, see the Network Load Balancing Technical Reference.

Edge Transport Server Planning

The Edge Transport server role is designed to provide improved anti-spam protection for the Exchange organization. The Edge Transport server also applies policies to messages in transport between organizations. This server role is deployed in the perimeter network and outside the Active Directory forest. Edge Transport servers don't have access to Active Directory for configuration and recipient information as do the other Exchange 2010 server roles. The Edge Transport server uses the Active Directory Lightweight Directory Service (AD LDS) to store configuration and recipient information.

You can add an Edge Transport server to an existing Exchange organization making any organizational changes. You don't have to perform any Active Directory preparation steps when you install the Edge Transport server.

When an Edge Transport server is deployed to support an Exchange organization that has not yet deployed Exchange 2010, a limited set of features are available. You can't create an Edge Subscription in this scenario. Therefore, you can't use the Recipient Lookup or safelist aggregation features until you have deployed Exchange 2010 in your organization.

When you're planning to deploy Edge Transport servers, you should consider the following issues:

- **Server Capacity** Planning for server capacity includes planning to conduct performance monitoring of the Edge Transport server. Performance monitoring will help you understand how hard the server is working. This information will determine the capacity of your current hardware configuration.
- **Transport Features** The Edge Transport server can provide anti-spam protection at the edge of the network. As part of your planning process, you should determine the anti-spam features that you will enable at the Edge Transport server and how they will be configured.
- **Security** The Edge Transport server role is designed to have a minimal attack surface. Therefore, it's important to correctly secure and manage both the physical access and network access to the server. Planning for security will help you make sure that IP connections are only enabled from authorized servers and from authorized users. For more information, see the Deployment Security Checklist.
  The recommended practice is to put the Edge Transport server within a perimeter network. To make sure that the server can send and receive e-mail and receive recipient and configuration data updates from the Microsoft Exchange EdgeSync service, you must allow communication through the ports that are listed in the following table.

Communication port settings for Edge Transport servers

Network interface	Open port	Protocol	Note
Inbound from and outbound to the Internet	25/TCP	SMTP	This port must be open for mail flow to and from the Internet.
Inbound from and outbound to the internal network	25/TCP	SMTP	This port must be open for mail flow to and from the Exchange organization.
Local only	50389/TCP	LDAP	This port is used to

			make a local connection to AD LDS.
Inbound from the internal network	50636/TCP	Secure LDAP	This port must be open for EdgeSync synchronization.
Inbound from the internal network	3389/TCP	RDP	Opening this port is optional. It provides more flexibility in managing the Edge Transport servers from inside the internal network by letting you use a remote desktop connection to manage the Edge Transport server.

Note:

The Edge Transport server role uses non-standard LDAP ports. The ports that are specified in this topic are the LDAP communication ports that are configured when the Edge Transport server role is installed. For more information, see Modify AD LDS Configuration.

- **EdgeSync** You can create an Edge Subscription to subscribe the Edge Transport server to the Exchange organization. When you create an Edge Subscription, recipient and configuration data is replicated from Active Directory to AD LDS. You subscribe an Edge Transport server to an Active Directory site. Then the Microsoft Exchange EdgeSync service that is running on the Hub Transport servers in that site periodically updates AD LDS by synchronizing data from Active Directory. The Edge Subscription process automatically provisions the Send connectors that are required to enable mail flow from the Exchange organization to the Internet through an Edge Transport server. If you're using the recipient lookup or safelist aggregation features on the Edge Transport server, you must subscribe the Edge Transport server to the organization.

Configuring DNS Settings for the Edge Transport Server Role

The Edge Transport server role is deployed outside the Exchange organization as a stand-alone server in the perimeter network or as a member of a perimeter network Active Directory domain. You must manually configure the correct DNS suffix for the Edge Transport server role before you install Exchange 2010. If a DNS suffix isn't configured, setup will fail.

Because the Edge Transport server is typically deployed in the perimeter network, it has network interfaces that are connected to multiple network segments. Each of these network segments has a unique IP configuration. The network interface that is connected to the external, or public, network segment should be configured to use a public DNS server for name resolution. This enables the server to resolve SMTP domain names to MX resource records and route mail to the Internet.

The network interface that is connected to the internal, or private, network segment should be configured to use a DNS server in the perimeter network that can resolve the names of the Hub Transport servers in your organization, or should have a Hosts file available. The Edge Transport servers and the Hub Transport servers must be able to use DNS host resolution to locate each other.

To enable name resolution of Hub Transport servers by Edge Transport servers, use one of the following methods:

- Manually create A resource records for Hub Transport servers in a forward lookup zone on the DNS server that's configured on the internal network adapter of the Edge Transport server.
- Edit the Hosts file on the Edge Transport server to include the Host records for the Hub Transport servers. The Hosts file is a local text file in the same format as the 4.3 Berkeley Software Distribution (BSD) UNIX /etc/hosts file. This file maps host names to IP addresses, and the file is stored in the \%Systemroot %\System32\Drivers\Etc folder.

To enable name resolution of Edge Transport servers by Hub Transport servers, use one of the following methods:

- Manually create A resource records for Edge Transport servers in a forward lookup zone on the DNS server that's configured on the Hub Transport server.
- To include the Host records for the Edge Transport servers, edit the Hosts file on the Hub Transport servers that are located in the Active Directory sites to which Edge Transport servers are subscribed.

You must follow these steps to configure DNS settings for the Edge Transport server:

1. Verify that the DNS server settings for each network interface are correct for the network segment.
2. Configure the DNS suffix for the Edge Transport server name using the following steps:
   2.a. Click **Start**, click **Control Panel**, and then double-click **System** to open the **System Properties**.
   2.b. Click the **Computer Name** tab.
   2.c. Click **Change**.
   2.d. On the **Computer Name Changes** page, click **More**.
   2.e. In the **Primary DNS suffix of this computer:** field, type a DNS domain name and suffix for the Edge Transport server.
   This name can't be changed after the Edge Transport server role is installed.
3. Configure DNS host name resolution for Edge Transport servers and Hub Transport servers.

Overriding DNS Settings

In your environment, you may want to specify a DNS server to route mail that differs from the DNS server that is configured in the Exchange server's IP properties. To accomplish this, modify the Internal DNS Lookups and External DNS Lookups settings of the transport server's properties. These settings override the settings on the network adapter to route e-mail messages. For more information, see Configure Edge Transport Server Properties.

Mailbox Server Planning

The Exchange 2010 Mailbox server role hosts mailbox databases and provides e-mail storage and advanced scheduling services for information workers. The Mailbox server role can also host a public folder database, which provides a foundation for workflow, document sharing, and other forms of collaboration. Servers on which the Mailbox server role is installed are called Mailbox servers.

Before installation, we recommend that you take the time to plan for your Mailbox server role deployment. You must consider several factors when planning the size of your mailbox databases.

Sizing Databases

The recommended maximum database size for Exchange 2010 is greater than the recommended maximum size in previous versions of Exchange.

When planning for the size of your databases, you should also plan for how you will enforce limits on database size, either at the database level or at the individual mailbox level. For more information about mailbox limits, see the following topics:

- Understanding Mailbox Database and Log Capacity Factors
- Exchange 2010 Mailbox Server Role Design Example
- Mailbox Server Storage Design

Public Folder Planning

Public folders are an optional feature in Exchange 2010. If all client computers in your organization are running Microsoft Office Outlook 2007 or later, public folders are an optional feature. However, if Outlook 2003 clients are in use, public folders are required. In addition, if you're currently using public folders for collecting, organizing, or sharing documents and other information and you want to continue doing so, you can use public folder replication to move your public folder data to Exchange 2010.

For more information about public folders, see Understanding Public Folders.

Client Access Server Planning

The Client Access server role receives all client connections for Exchange 2010. Computer-based clients, such as Microsoft Outlook and Microsoft Entourage, mobile phones, and browser-based clients all connect through the Client Access server role. The Client Access server role provides the following functionality:

- MAPI access
- POP3 and IMAP4 access

  Note:
  Integrated Windows authentication (formerly called NTLM) isn't supported for POP3 or IMAP4 client connectivity. For more information, see the "Client Access Features" sections in Discontinued Features.

- Outlook Web App access
- The Autodiscover Service which configures client computers that are running Outlook 2010, Outlook 2007, Entourage, and other client applications. The Autodiscover service can also configure supported mobile devices.
- The Availability Service improves information workers' calendaring and meeting scheduling experience by providing secure, consistent and up-to-date free and busy information to computers running Outlook 2007 and later.

When planning your Exchange 2010 deployment, you must have at least one computer with the Client Access server role installed in every Active Directory site that contains Exchange 2010 mailboxes. You can have multiple computers with the Client Access server role installed within each Active Directory site. To provide external client access, at least one Client Access server within your organization must be Internet-facing.

For more information about namespace planning and Client Access servers, see Understanding Client Access Server Namespaces.

Unified Messaging Server Planning

The Unified Messaging server role is designed to provide Unified Messaging (UM) for Exchange 2010 recipients. UM combines voice messaging, fax, and e-mail messaging into one store that can be accessed from a telephone, a user's computer, and a mobile device. Users can access voice messages, e-mail, and calendar information that are located in their Exchange 2010 mailbox from e-mail clients, such as Outlook and Outlook Web App.

The Unified Messaging server depends on the Client Access server, Hub Transport server

and Mailbox server. All voice mail messages that are submitted from a Unified Messaging server for a UM-enabled user are first submitted to an Exchange 2010 Hub Transport server as an SMTP message and then are submitted from a Hub Transport server to the UM-enabled user's mailbox. For a recipient to use Unified Messaging, they must have an Exchange 2010 mailbox. For details, see Understanding Unified Messaging.

Generally, the simpler the Unified Messaging topology, the easier Unified Messaging is to deploy and maintain. Install as few Unified Messaging servers and create as few Unified Messaging objects in Active Directory as you need to support your business and organizational goals. Large enterprises with complex network and telephony environments, multiple business units, or other complexities will require more planning than smaller organizations with relatively straightforward Unified Messaging needs.

Planning Your UM Deployment

You must understand the different aspects of Exchange 2010 Unified Messaging and each component and feature so that you can plan your Unified Messaging infrastructure and deployment appropriately. For details, see Understanding Unified Messaging Components and Understanding Unified Messaging Features.

The following are some of the areas that you should consider and evaluate when planning for Exchange 2010 in your organization:

- Your business needs for Unified Messaging
- Your telephony network and your current voice mail system
- Your current data network design
- Your current Active Directory environment
- The number of users that you will have to support
- The number of Unified Messaging servers you will need
- The storage requirements for users
- The placement of IP gateways, telephony equipment, and Unified Messaging servers

For more information, see Overview of Unified Messaging.

Many deployment options are available for Unified Messaging; each option has several steps in common that are required to create a scalable and highly available system to support large numbers of users. These steps are as follows:

1. Deploy and configure your telephony components for Unified Messaging.
2. Verify that you've correctly installed the Exchange 2010 server roles that are required by Unified Messaging.
3. Install the Unified Messaging server role.
4. Create and configure the required Unified Messaging Active Directory components including UM dial plans, UM IP gateways, UM hunt groups, and UM mailbox policies.
5. Perform post-deployment tasks including deploying certificates for mutual TLS, creating UM auto attendants, and configuring faxing.

For details about deploying Unified Messaging, see the following topics:

- Deploy a New Exchange 2010 RTM UM Environment
- Checklist: Deploy a New Exchange 2010 RTM UM Environment
- Deploy and Configure Incoming Faxing

If you're integrating your Unified Messaging environment with Office Communications Server, there are additional planning considerations. For details, see Understanding Unified Messaging and Communications Server 2007 R2. After you have read Understanding Unified Messaging and Communications Server 2007 R2, details about deploying Unified Messaging and Office Communications Server can be found in the following topics:

- Deploy Unified Messaging and Communications Server 2007 R2
- Checklist: Deploy Office Communications Server 2007 R2 and Exchange 2010

Unified Messaging

Exchange Client Planning

Before you deploy your Exchange 2010 organization, verify that client computers and mobile devices in your organization meet the following requirements.

Requirements	Check
All MAPI clients are running a supported version of Outlook, including Microsoft Outlook 2007, Outlook 2003.	[ ]
All Outlook Web App clients are running a supported Web browser. To use the complete set of features available in Outlook Web App, clients can use the following browsers on a computer running Windows XP, Windows 2003, Windows Vista, or Windows 7: • Internet Explorer 7 and later versions. • Firefox 3.0.1 and later versions. • Chrome 3.0.195.27 and later versions. On a computer running Max OS X, clients can use: • Safari 3.1 and later versions. • Firefox 3.0.1 and later versions. On a computer running Linux, clients can use: • Firefox 3.0.1 and later versions. Clients using a Web browser that doesn't support the full feature set will automatically be directed to the light version of Outlook Web App. The light version of Outlook Web App is optimized for accessibility, such as for users who are blind or have low vision. The light version provides fewer features and is faster for some operations. Clients may want to use the light version if they are on a slow connection or using a computer with unusually strict browser security settings. The light version can be used with almost any browser and has the same features across all browsers.	[ ]
All mobile devices are running a supported operating system. Windows Mobile phones that are Direct Push compatible or mobile phones running another operating system that is compatible with Exchange ActiveSync.	[ ]

1.2.1.3 Exchange 2003 - Planning Roadmap for Upgrade and Coexistence

Exchange 2003 - Planning Roadmap for Upgrade and Coexistence

Exchange Server 2010 > Planning and Deployment > Planning for Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can deploy Microsoft Exchange Server 2010 in an existing Microsoft Exchange Server 2003 organization operating in native mode. Coexistence with these two Exchange versions is supported. This topic provides an overview of the planning considerations and configuration steps that you must take when Exchange 2010 will coexist with Exchange 2003.

Existing Exchange Organization Planning

Before you continue in your planning for Exchange 2010, make sure your current Exchange 2003 organization meets the requirements discussed in the following topics:

- Exchange 2010 System Requirements
- Exchange 2010 Prerequisites

Coexistence

Any organization upgrading from Exchange 2003 will experience a period of coexistence. In a coexistence scenario, any combination of the following versions of Microsoft Exchange is deployed in a single Exchange organization: Exchange 2003, Exchange 2007, and Exchange 2010. This topic is concerned primarily with the coexistence of Exchange 2003 and Exchange 2010.

In a coexistence scenario, multiple versions of Exchange communicate with each other and share data resources, recipient information, and configuration information. Parts of the organization still use Exchange 2003 functionality, and other parts have completed the upgrade to Exchange 2010.

Important:

You can only install additional Exchange 2003 servers in your organization if an Exchange 2003 server was there when the first Exchange 2010 server was installed.

Be aware of the following coexistence issues:

- **Active Directory and domains** When upgrading from Exchange 2003 to Exchange 2010, you must first grant specific Exchange permissions in each domain in which you have run Exchange 2003 DomainPrep. To do this, you run the `setup /PrepareLegacyExchangePermissions` command. Granting these permissions is part of preparing Active Directory and your domains for installing Exchange 2010. For detailed instructions, see Prepare Active Directory and Domains.
- **Management interfaces** In Exchange 2010, you can manage Exchange 2010 servers and mailboxes by using either the Exchange Management Console (EMC) or the Exchange Management Shell. You can also use the EMC to view some attributes on Exchange 2003 servers. For more information, see Exchange Management Console Interoperability.
- **Server role features** The Exchange 2010 server role features available to clients in the Exchange organization during the coexistence period depend on the version of the Exchange server where the user's mailbox is stored and the version of the e-mail client application used to access Exchange.
- **Routing groups** A large organization that has many routing groups must plan its routing topology to maintain mail flow during the coexistence period. When you plan for a period of coexistence between Exchange 2003 and Exchange 2010, you need to understand how each version determines its routing topology. For more information about routing and coexistence, see Upgrade from Exchange 2003 Transport.
- **Native mode** You can only deploy Exchange 2010 in an Exchange 2003 organization that operates in native mode. For more information about how to change your Exchange 2003 organization to native mode, see Understanding

Upgrade to Exchange 2010.

Administration Differences

Exchange 2003 uses administrative groups to organize Exchange objects for delegating permission to manage those objects. Exchange 2010 doesn't use administrative groups as a logical management unit for administrative delegation.

However, to support coexistence between Exchange 2003 and Exchange 2010, all Exchange 2010 servers are automatically put in a single administrative group when Exchange 2010 is installed. This administrative group is recognized in Exchange System Manager of earlier versions of Exchange as Exchange Administrative Group (FYDIBOHF23SPDLT).

Caution:

Don't move Exchange 2010 servers out of Exchange Administrative Group (FYDIBOHF23SPDLT) and don't rename Exchange Administrative Group (FYDIBOHF23SPDLT) by using a low-level directory editor. Exchange 2010 must use this administrative group for configuration data storage. Moving Exchange 2010 servers out of Exchange Administrative Group (FYDIBOHF23SPDLT) or the renaming of Exchange Administrative Group (FYDIBOHF23SPDLT) isn't supported.

You must use Exchange System Manager and utilities to manage the Exchange 2003 servers. In Exchange 2010, you must manage Exchange 2010 servers and mailboxes by using the EMC or the Shell. However, you can use the EMC to view some attributes on Exchange 2003 servers. For more information about EMC interoperability, see Exchange Management Console Interoperability.

Exchange 2007 and Exchange 2003 Mixed Mode Coexistence

When you're ready to upgrade a mixed mode environment, upgrade each Active Directory site individually. If you have Active Directory sites with only Exchange 2007 or Exchange 2003 in them, follow the instructions for upgrade from that version for that Active Directory site. For example, if you have Exchange 2007 in Active Directory site A, follow the upgrade instructions for Exchange 2007. If you have Exchange 2003 installed in Active Directory site B, follow the upgrade instructions for Exchange 2003. For more information about upgrading your Exchange 2003 and Exchange 2007 versions, see Understanding Upgrade to Exchange 2010.

If you have Active Directory sites with both Exchange 2003 and Exchange 2007 installed, follow the upgrade instructions from both Exchange 2003 and Exchange 2007, and perform the upgrade steps required by both. For more information about upgrading to Exchange 2010 in this scenario, see the following topics:

- Understanding Upgrade to Exchange 2010
- Install Exchange 2010 in a Mixed Exchange 2003 and Exchange 2007 Organization

Upgrade Process from Exchange 2003 to Exchange 2010

Here is a high-level overview of the upgrade steps that you follow to upgrade from Exchange 2003 to Exchange 2010.

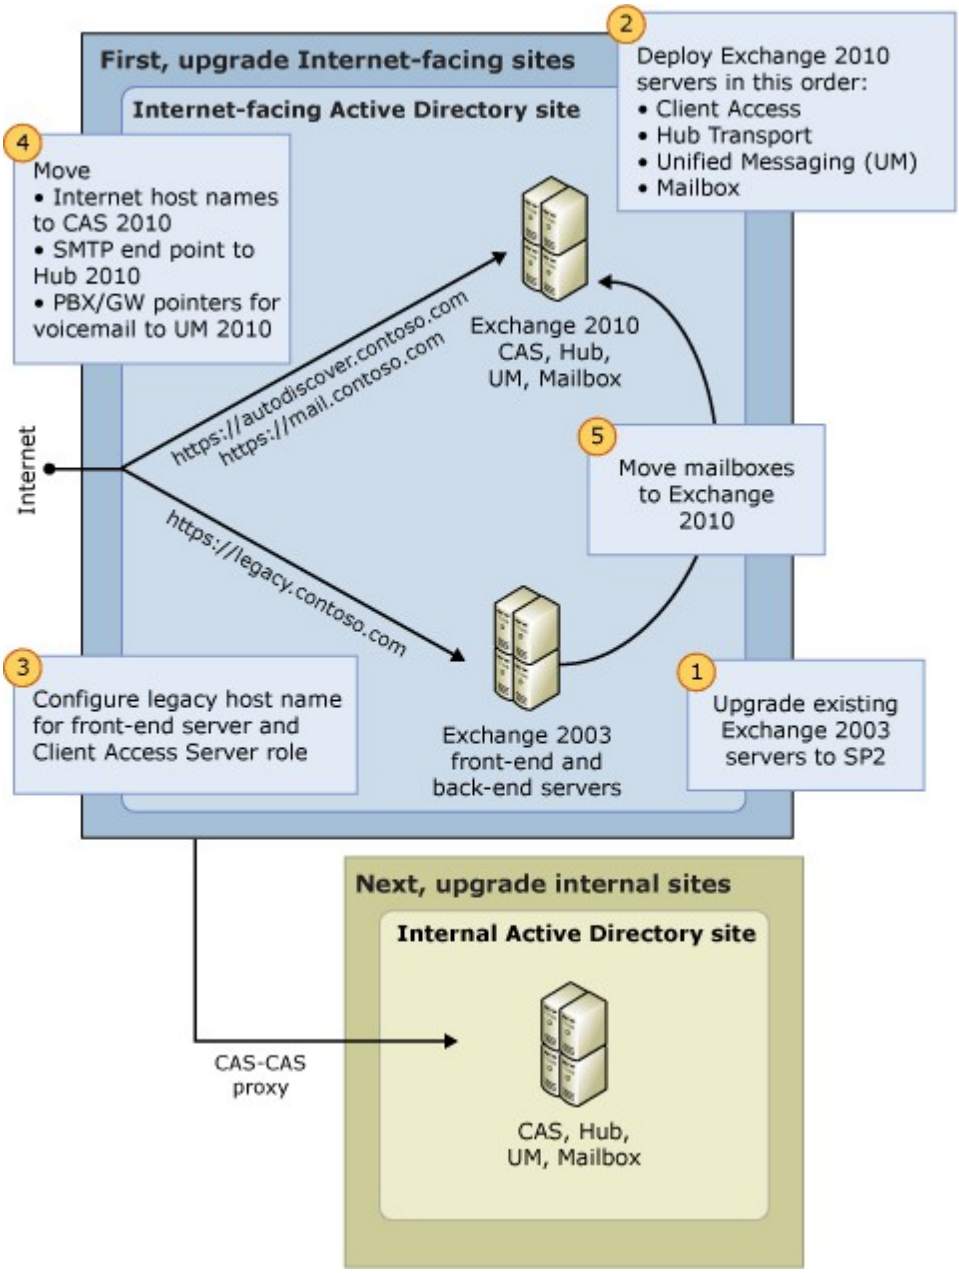
First, you upgrade all Internet-facing Active Directory sites by doing the following:

1. Upgrade existing Exchange 2003 servers to Exchange 2003 Service Pack 2 (SP2).
2. Deploy Exchange 2010 servers in this order:
   2.a. Client Access
   2.b. Hub Transport
   2.c. Unified Messaging

2.d.Mailbox
3. Configure the Exchange 2003 front-end server and the Exchange 2010 Client Access server.
4. Configure the Exchange 2010 Hub Transport server and the Unified Messaging servers.
5. Move mailboxes from Exchange 2003 to Exchange 2010

Then, upgrade all internal Active Directory sites in the same manner.

The following figure illustrates the overview of the upgrade process from Exchange 2003 to Exchange 2010.



Order of Active Directory Sites for Upgrade

As shown in the preceding figure, when you're upgrading your organization to Exchange

2010, you must begin with your servers in the Internet-accessible Active Directory sites, and then upgrade your internal Active Directory sites. This approach is necessary because Client Access server to Client Access server proxying is only supported from the newer Client Access server role versions (Exchange 2010) to the older Client Access server role versions (Exchange 2007) and not the reverse.

Order of Server Roles for Upgrade

Within the first Active Directory site or sites you're upgrading, the first Exchange 2010 server role you install is the Client Access server role. We recommend that you upgrade a single Active Directory site at a time to Exchange 2010. Depending on the size of your Active Directory site, this might be a single Client Access server computer or a load-balanced array of Exchange 2010 Client Access server computers.

We recommend the following order when installing the Exchange 2010 server roles:

1. Client Access server role
2. Hub Transport server role
3. Unified Messaging (UM) server role
4. Mailbox server role

Note:
When upgrading to Exchange 2010, you can't perform an in-place server upgrade on an existing Exchange server.

For detailed information about upgrading server roles, see the following topics:

- Upgrade from Exchange 2003 Client Access
- Upgrade from Exchange 2003 Transport
- Upgrade from Exchange 2003 Mailbox
- Install Exchange 2010 in an Existing Exchange 2003 Organization

You can add the Unified Messaging server role later, or if you want to install it at the same time as the other server roles, you can do so by selecting **Custom Exchange Server Installation**.

Note:
You must deploy the Edge Transport server role in the perimeter network and outside the secure Active Directory forest.

Exchange 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Server Role Coexistence

This section provides details about each Exchange 2010 server role in a coexistence scenario.

Client Access Server Coexistence

The Client Access server role provides new features in addition to all the functionality provided by a front-end server in Exchange 2003. All client connectivity (including Microsoft Outlook MAPI connectivity) now goes through the Client Access server role. There are no longer any clients directly connecting to the Mailbox server role. The Client Access server role can coexist with Exchange 2003 servers. The following list describes the Exchange 2010 Client Access server dependencies and requirements for coexistence with Exchange 2003:

- Whether a user sees the Outlook Web App client of Exchange 2003 or the Outlook Web App client of Exchange 2010 depends on the location of the user's mailbox. For example, if the user's mailbox is located on an Exchange 2003 back-end server and the Client Access server is running Exchange 2010, the user will see Outlook Web Access, the Exchange 2003 client.
- The version of Microsoft Exchange ActiveSync that clients use depends on the server version hosting the user's mailbox. The user's mailbox must be located on a server running Exchange 2003 SP2 or Exchange 2010 to have Direct Push enabled for Exchange ActiveSync.
- When you perform an upgrade from Exchange 2003 to Exchange 2010, you typically upgrade all the Exchange servers in a specific routing group or Active Directory site to Exchange 2010 at the same time, configure coexistence, and then upgrade the next site.

Important:

When upgrading an Exchange 2003 organization, an Exchange 2003 front-end server is required to support the upgrade. For each Exchange 2010 Client Access server, you can only configure one Outlook Web Access 2003 URL for redirection. You can accomplish this with a single Exchange 2003 front-end server or a load-balanced array of Exchange 2003 front-end servers.

For more information about Client Access server coexistence between Exchange 2003 and Exchange 2010, and for information about new Exchange 2010 features, see Upgrade from Exchange 2003 Client Access.

Exchange 2007 introduced the Autodiscover and Availability services, and Exchange 2010 continues to rely on these services:

- The Autodiscover service configures client computers running Microsoft Outlook 2010, Outlook 2007, Entourage, and other client applications. The Autodiscover service can also configure supported mobile devices. The Autodiscover service provides access to Exchange features for Outlook 2010 clients connected to your Exchange messaging environment.
- The Availability service improves information workers' calendaring and meeting scheduling experience by providing secure, consistent, and up-to-date free and busy information to computers running Outlook 2007 or Outlook 2010.

For more information, see Understanding the Autodiscover Service and Understanding the Availability Service.

Hub Transport Server Coexistence

The Hub Transport server role is designed to handle all mail flow for the Exchange organization. It's also responsible for handling transport rules, journaling policies, and message delivery. This server is deployed in the Active Directory forest and is required for Exchange 2010 mailboxes to send and receive messages. Messages sent to the Internet are relayed by the Hub Transport server to the Edge Transport server or a third-party smart host.

You can add an Exchange 2010 Hub Transport server to an existing Exchange organization after you successfully deploy Exchange 2010 Client Access servers. When you introduce Exchange 2010 Hub Transport servers in your Exchange 2003 environment, all Exchange 2010 Hub Transport servers are placed in a single, separate routing group.

To enable mail flow between the Exchange 2010 deployment and your existing Exchange 2003 organization, you need to create a routing group connector. This routing group connector is created during the setup of your first Exchange 2010 Hub Transport server.

To learn more about introducing Exchange 2010 Hub Transport servers to your Exchange 2003 organization, see Upgrade from Exchange 2003 Transport.

Mailbox Server Coexistence

For Exchange 2010 and Exchange 2003 Mailbox servers to coexist, you must be able to send mail among the mailboxes. Exchange 2010 uses the Hub Transport server to send mail. An Exchange 2010 Hub Transport server must be deployed in each Active Directory site that contains an Exchange 2010 Mailbox server. You also need a Client Access server in each Active Directory site where there's a Mailbox server. For more information about upgrading to an Exchange 2010 Mailbox server, see Upgrade from Exchange 2003 Mailbox.

If you move a mailbox from Exchange 2003 to Exchange 2010, and the mailbox is part of an e-mail address policy, the e-mail addresses for that mailbox are automatically updated based on the configuration of the e-mail address policy. If the mailbox had a primary SMTP address that differs from the e-mail address enforced by the e-mail address policy, that SMTP address becomes a secondary SMTP address, and the e-mail address generated by the e-mail address policy becomes the primary SMTP address. For information about how to move mailboxes, see Managing Move Requests.

You can replicate public folder data between Exchange 2010 and Exchange 2003 public folder databases. To do this, you must create a replica of the public folder using the Exchange 2003 Exchange System Manager. For more information about Exchange 2010 and Exchange 2003 public folder coexistence, see Understanding Public Folders.

Unified Messaging Server Coexistence

The Unified Messaging server role is designed to provide Unified Messaging for Exchange 2010 recipients. Unified Messaging combines voice messaging and e-mail messaging into one store that can be accessed from a telephone, a user's computer, or a mobile device. Users can access voice messages, e-mail, and calendar information located in their Exchange 2010 mailbox from e-mail clients, such as Outlook and Outlook Web App.

The Unified Messaging server depends on the Hub Transport server and Mailbox server. All SMTP mail submitted from a Unified Messaging server must be submitted to an Exchange 2010 Hub Transport server. For a recipient to use Unified Messaging, they must have an Exchange 2010 mailbox.

Versions of Exchange earlier than Exchange 2007 can't be upgraded and require you to deploy an Exchange 2010 organization with all the Exchange server roles, including Unified Messaging, and then move the Exchange 2003 (or earlier) mailboxes to an Exchange 2010 Mailbox server. For details, see Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers.

Edge Transport Server Coexistence

The Edge Transport server role is designed to provide improved antivirus and anti-spam protection for the Exchange organization. The Edge Transport server also applies policies to messages in transport between organizations. This server role is deployed in the perimeter network and outside the Active Directory forest. The Edge Transport server can be deployed as a smart host and SMTP-relay server for an existing Exchange 2003 organization.

You can add an Edge Transport server to an existing Exchange organization without upgrading the internal Exchange servers or making any organizational changes. You don't have to perform any Active Directory preparation steps when you install the Edge Transport server.

If you're using the Exchange Intelligent Message Filter in Exchange 2003 to perform anti-spam tasks, you can use the Edge Transport server to provide an additional layer of anti-spam protection. The Edge Transport server provides antivirus and anti-spam protection as messages enter the network.

When an Exchange 2010 Edge Transport server is deployed to support an Exchange organization that hasn't yet deployed Exchange 2010, a limited set of features is available. You can't create an Edge Subscription in this scenario. Therefore, you can't use

the Recipient Lookup or safelist aggregation features. For more information about Edge Transport servers and coexistence, see Upgrade from Exchange 2003 Transport.

Supported Topologies

Exchange 2010 supports the following topologies:

- Single forest with multiple Active Directory sites
- Multiple forests (resource forest model) with multiple Active Directory sites
- Single Active Directory site

For more information, see the following topics:

- Deploy Multiple Forest Topologies
- Deploy Exchange 2010 in a Cross-Forest Topology
- Deploy Exchange 2010 in an Exchange Resource Forest Topology

Exchange 2010 doesn't support the following topologies:

- Coexistence with Exchange 2000 Server or earlier
- Coexistence with Exchange 2003 versions prior to SP2
- Installing an older version of Exchange into a newly created Exchange 2010 organization

1.2.1.4 Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can deploy Microsoft Exchange Server 2010 in an existing Microsoft Exchange Server 2007 organization. This topic provides an overview of the planning considerations and configuration steps that you must take when Exchange 2010 will coexist with Exchange 2007.

Existing Exchange Organization Planning

Before you continue in your planning for Exchange 2010, make sure your current Exchange 2007 organization meets the requirements discussed in the following topics:

- Exchange 2010 System Requirements
- Exchange 2010 Prerequisites

Coexistence

Any organization that upgrades from Exchange 2007 to Exchange 2010 will experience a period of coexistence when parts of the organization still use Exchange 2007 functionality and other parts have completed the upgrade to Exchange 2010.

Important:

You can only install additional Exchange 2007 servers in your organization if an Exchange

2007 server was there when the first Exchange 2010 server was installed.

Be aware of the following coexistence issues:

- **Management interfaces** In Exchange 2010, you can manage Exchange 2010 servers and mailboxes by using either the Exchange Management Console (EMC) or the Exchange Management Shell. You can also use the EMC to view some attributes on Exchange 2007 servers. For more information, see Exchange Management Console Interoperability.
- **Server role features** The Exchange 2010 server role features available to clients in the Exchange organization during the coexistence period depend on the version of the Exchange server where the user's mailbox is stored and the version of the e-mail client application used to access Exchange.
  For more information about how server-to-server communication occurs, see Understanding Transport Pipeline.
- **Routing groups** A large organization that has many routing groups requires a routing topology that maintains mail flow during the coexistence period. When you plan for a period of coexistence between Exchange 2010 and Exchange 2007, you need to understand how each version determines its routing topology. For more information about routing and coexistence, see Upgrade from Exchange 2007 Transport.

Upgrade Process from Exchange 2007 to Exchange 2010

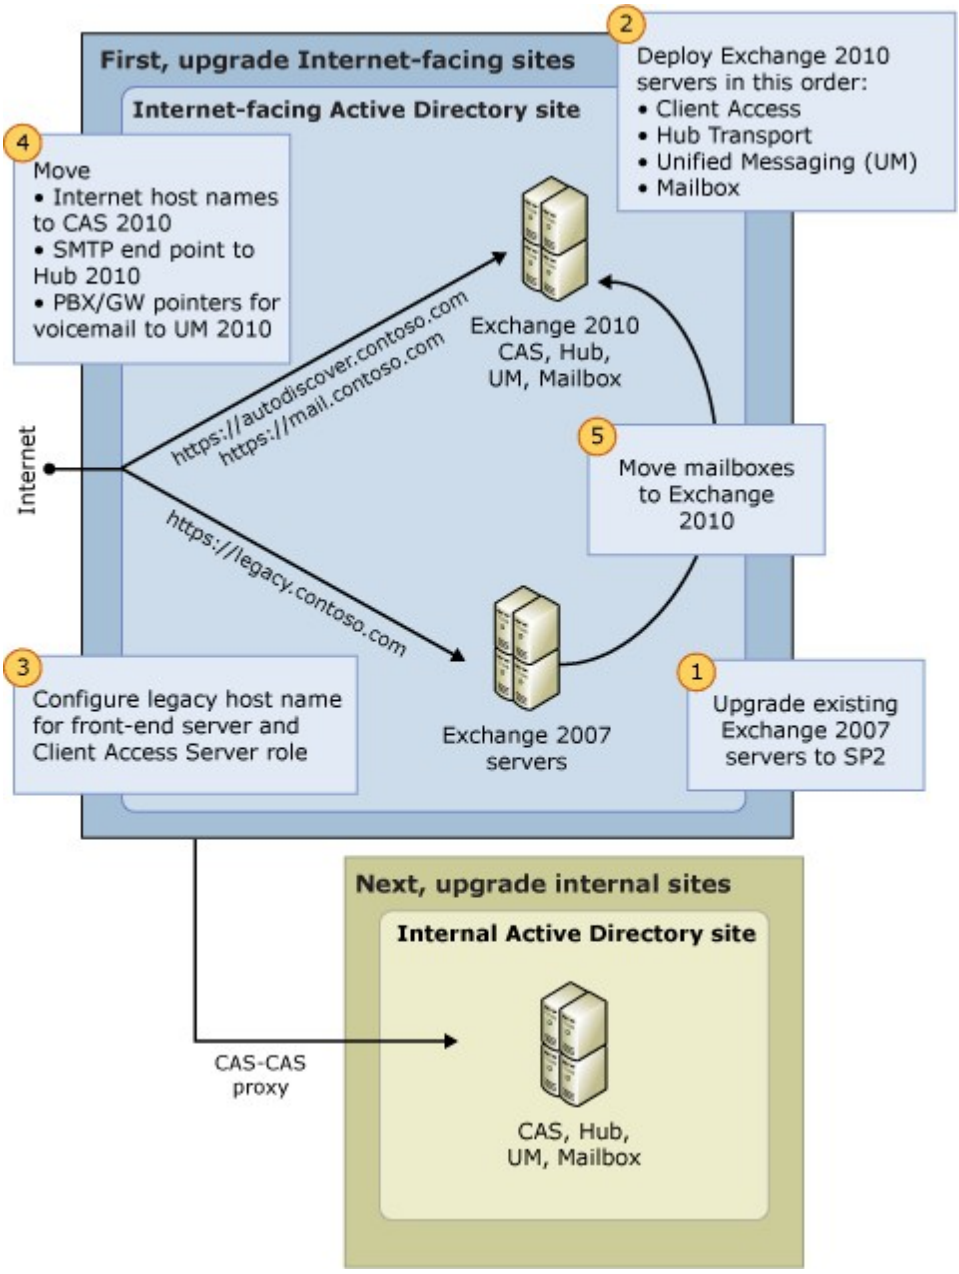
Here is a high-level overview of the upgrade steps that you follow to upgrade from Exchange 2007 to Exchange 2010.

First, you upgrade all Internet-facing Active Directory sites by doing the following:

1. Upgrade existing Exchange 2007 servers to Exchange 2007 Service Pack 2 (SP2).
2. Deploy Exchange 2010 servers in this order:
   2.a.Client Access
   2.b.Hub Transport
   2.c.Unified Messaging
   2.d.Mailbox
3. Configure the Exchange 2010 Client Access server.
4. Configure the Exchange 2010 Hub Transport server and the Unified Messaging servers.
5. Move mailboxes from Exchange 2007 to Exchange 2010

Then, upgrade all internal Active Directory sites in the same manner.

The following figure illustrates the overview of the upgrade process from Exchange 2007 to Exchange 2010.



Order of Active Directory Sites for Upgrade

When you're upgrading your organization to Exchange 2010, you must begin with your servers in the Internet-accessible Active Directory sites, and then upgrade your internal Active Directory sites. Upgrading an internal Active Directory site before all your Internet-accessible sites have been upgraded isn't supported. This is because Client Access server to Client Access server proxying is only supported from the newer Client Access server role versions (Exchange 2010) to older Client Access server role versions (Exchange 2007) and not the reverse.

Order of Server Roles for Upgrade

Within the first Active Directory site or sites you're upgrading, the first Exchange 2010 server role you install is the Client Access server role. We recommend that you upgrade a single Active Directory site at a time to Exchange 2010. Depending on the size of your Active Directory site, this might be a single Client Access server computer or a load-balanced array of Exchange 2010 Client Access server computers.

We recommend the following order when installing the Exchange 2010 server roles:

1. Client Access server role
2. Hub Transport server role
3. Mailbox server role
4. Unified Messaging (UM) server role
5. Edge Transport server role

Note:
When upgrading to Exchange 2010, you can't perform an in-place server upgrade on an existing Exchange server.

For detailed information about upgrading server roles, see the following topics:

- Upgrade from Exchange 2007 Client Access
- Upgrade from Exchange 2007 Transport
- Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging
- Upgrade from Exchange 2007 Mailbox

Exchange 2007 and Exchange 2003 Mixed Mode Coexistence

When you're ready to upgrade a mixed mode environment, upgrade each Active Directory site individually. If you have Active Directory sites with only Exchange 2007 or Exchange 2003 in them, follow the instructions for upgrade from that version for that Active Directory site. For example, if you have Exchange 2007 in Active Directory site A, follow the upgrade instructions for Exchange 2007. If you have Exchange 2003 installed in Active Directory site B, follow the upgrade instructions for Exchange 2003. For more information about upgrading your Exchange 2003 and Exchange 2007 versions, see Understanding Upgrade to Exchange 2010.

If you have Active Directory sites with both Exchange 2003 and Exchange 2007 installed, follow the upgrade instructions from both Exchange 2003 and Exchange 2007, and perform the upgrade steps required by both. For more information about upgrading to Exchange 2010 in this scenario, see the following topics:

- Understanding Upgrade to Exchange 2010
- Install Exchange 2010 in a Mixed Exchange 2003 and Exchange 2007 Organization

Administration Differences

The Exchange Management Console (EMC) is available in both Exchange Server 2010 and Exchange Server 2007. The following lists the tasks and actions that can be performed using the EMC in either Exchange 2010 or Exchange 2007:

- Actions that create objects, such as new mailboxes or a new offline address book (OAB), can only be performed on a version of the EMC that's the same as the target object. For example, creating a mailbox on an Exchange 2007 Mailbox server must be performed with the EMC in Exchange 2007. The following applies:
  - Exchange 2007 Mailbox databases can't be managed from the EMC in Exchange 2010, although these databases can be viewed.
  - The EMC in Exchange 2010 can't enable or disable Exchange 2007 Unified Messaging mailboxes.
  - The EMC in Exchange 2010 can't manage Exchange 2007 mobile devices.
- Actions that require viewing of objects can be performed from any version of the EMC to any version of Exchange objects, with a few exceptions:
  - Exchange 2010 and Exchange 2007 transport rule objects can only be viewed from their corresponding version of the EMC.
  - Exchange 2010 and Exchange 2007 servers can only be viewed from their corresponding version of the EMC.
  - The Queue Viewer tool in the EMC in Exchange 2010 can't connect to an Exchange 2007 server to view queues or messages.

Note:
If an Exchange 2007 object (such as a storage group) is no longer present in Exchange 2010, there's no interoperability expected or provided because Exchange 2010 isn't aware of the feature.

- You can't use message tracking configuration tasks between Exchange 2010 and Exchange 2007. You must use Exchange 2007 messaging tracking tools within your Exchange 2007 servers, and Exchange 2010 messaging tracking tools within your Exchange 2010 servers.

Client Access Server Coexistence

The Client Access server role can coexist with Exchange 2007 Client Access servers. Before you upgrade the first Active Directory site, you must install Exchange 2007 Service Pack 2 (SP2) on all Exchange 2007 Client Access servers within your organization.

After the first Exchange 2010 Client Access server or Client Access server array has been installed in your organization, the Autodiscover service on the Exchange 2007 Client Access servers will redirect users with mailboxes on an Exchange 2010 Mailbox server to the appropriate Exchange 2010 Client Access endpoint.

Installation of Exchange 2010 within your organization requires the creation of a second Domain Name System (DNS) host name. When you install the first Exchange 2010 Client Access server in your organization, you also need to create a host name. If your current host name is http://contoso.com, we recommend creating http://legacy.contoso.com. You install the first Exchange 2010 Client Access server or Client Access server array, copy the appropriate Microsoft Outlook Web Access, Microsoft Exchange ActiveSync, POP3, IMAP4, Exchange Web Services, and Autodiscover service settings, and then configure http://legacy.contoso.com to point to the Exchange 2007 Client Access servers and http://contoso.com to point to the Exchange 2010 Client Access server or Client Access server array. You need the appropriate Secure Sockets Layer (SSL) certificate for both host names. We recommend a Subject Alternative Name that can support multiple host names. For more information, see Upgrade from Exchange 2007 Client Access.

Exchange ActiveSync Coexistence

For coexistence with Exchange ActiveSync, you configure a legacy DNS host name. Users with mailboxes on Exchange 2007 Mailbox servers will be proxied from Exchange 2010 to Exchange 2007.

Note:
When moving a user's mailbox from Exchange 2007 to Exchange 2010, some users are prompted to perform a full synchronization of their mailbox. This is a requirement for many mobile phones and only occurs during the first synchronization of the user phone after the mailbox is moved.

When a user's mailbox is on Exchange 2007, the user will experience the Exchange 2007 version of Exchange ActiveSync during coexistence. That user will have the Exchange 2010 functionality of Exchange ActiveSync when the mailbox is moved to Exchange 2010. For more information about coexisting with Exchange ActiveSync, see Upgrade from Exchange 2007 Client Access.

Outlook Web App Coexistence

If a user with a mailbox on an Exchange 2007 Mailbox server connects to an Exchange 2010 Client Access server in the same Active Directory site, the user will be redirected to an Exchange 2007 Client Access server within that site. If a user with a mailbox on an Exchange 2007 Mailbox server connects to an Exchange 2010 Client Access server in a different Active Directory site and there's no Internet-accessible Client Access server in the destination Active Directory site, the user will be proxied to an Exchange 2007 Client Access server within the destination Active Directory site. As with Exchange 2007, if a user accesses an Exchange 2010 Client Access server in an Active Directory site different from the one where the mailbox resides and there's an Internet-accessible Client Access

server in the Active Directory site that contains the user's mailbox, the user will be redirected to the Client Access server in the destination Active Directory site. When a user's mailbox is on Exchange 2007, the user will experience the Exchange 2007 versions of Microsoft Office Outlook Web App during coexistence. That user will have the Exchange 2010 functionality of Outlook Web App when the mailbox is moved to Exchange 2010.

When upgrading Outlook Web App, there are different authentication scenarios that need to be examined:

- **Forms-based authentication terminating at an Exchange 2007 Client Access server** In this scenario, the Exchange 2010 Client Access server will redirect the user to the legacy Client Access server, and a second sign-on won't be required.
- **Third-party authentication solution in front of the Exchange 2007 Client Access server** This scenario requires a Microsoft Internet Security and Acceleration (ISA) Server or other authentication solution in front of the Exchange servers. In this situation, users will only be required to authenticate at the authentication solution, which will pass the credentials to any required Exchange 2010 or Exchange 2007 servers.
- **Non-forms based authentication terminating at an Exchange 2007 Client Access server** Outlook Web App will redirect the user to a legacy Exchange 2007 Client Access server. Whether the user needs to reauthenticate depends on the authentication mechanism used. For example, if Integrated Windows authentication is used, the user will experience a single sign-on. If Basic authentication is used, the user will need to authenticate twice.

The upgrade and coexistence steps you must take for Outlook Web App depend on which authentication scenario you have chosen. For more information about coexisting with Outlook Web App, see Upgrade from Exchange 2007 Client Access.

Hub Transport Server Coexistence

The Hub Transport server role is designed to handle all mail flow for the Exchange organization. It's also responsible for handling transport rules, journaling policies, and message delivery. This server is deployed in the Active Directory forest and is required for Exchange 2010 mailboxes to send and receive messages. Messages sent to the Internet are relayed by the Hub Transport server to the Edge Transport server or a third-party smart host.

You can add an Exchange 2010 Hub Transport server to an existing Exchange organization after you successfully deploy Exchange 2010 Client Access servers. After you introduce Exchange 2010 Hub Transport servers to your Exchange 2007 environment, you still need to maintain your Exchange 2007 Hub Transport servers. Exchange 2010 Mailbox servers can only communicate with Exchange 2010 Hub Transport servers, and Exchange 2007 Mailbox servers can only communicate with Exchange 2007 Hub Transport servers. When a message is sent from a mailbox on an Exchange 2010 Mailbox server to a mailbox on an Exchange 2007 Mailbox server, the message is first submitted to the closest Exchange 2010 Hub Transport server in the site. This server then relays the message to an Exchange 2007 Hub Transport server in the same site, which finally delivers the message to the Exchange 2007 Mailbox server.

To learn more about introducing Exchange 2010 Hub Transport servers to your Exchange 2007 organization, see Upgrade from Exchange 2007 Transport.

Mailbox Server Coexistence

The Exchange 2010 Mailbox server role can coexist with Exchange 2007 Mailbox servers. If you move a mailbox from Exchange 2007 to Exchange 2010, and the mailbox is part of an e-mail address policy, the e-mail addresses for that mailbox are automatically updated based on the configuration of the e-mail address policy. If the mailbox had a primary SMTP address that differs from the e-mail address enforced by the e-mail address policy, that SMTP address becomes a secondary SMTP address, and the e-mail address generated by the e-mail address policy becomes the primary SMTP address. For information about how

to move mailboxes, see Managing Move Requests.

You can replicate public folder data between Exchange 2010 and Exchange 2007 public folder databases. For more information about Exchange 2010 and Exchange 2007 public folder coexistence, see Understanding Public Folders.

Edge Transport Server Coexistence

The Edge Transport server role is designed to provide improved antivirus and anti-spam protection for the Exchange organization. The Edge Transport server also applies policies to messages in transport between organizations. This server role is deployed in the perimeter network and outside the Active Directory forest. The Edge Transport server can be deployed as a smart host and SMTP-relay server for an existing Exchange 2007 organization.

You can add an Edge Transport server to an existing Exchange organization without upgrading the internal Exchange servers or making any organizational changes. You don't have to perform any Active Directory preparation steps when you install the Edge Transport server. The Edge Transport server provides antivirus and anti-spam protection as messages enter the network.

When an Exchange 2010 Edge Transport server is deployed to support an Exchange organization that hasn't yet deployed Exchange 2010, a limited set of features is available. You can't create an Edge Subscription in this scenario. Therefore, you can't use the Recipient Lookup or safelist aggregation features. For more information about Edge Transport servers and coexistence, see Upgrade from Exchange 2007 Transport.

Unified Messaging Server Coexistence

When you install the first Exchange 2010 Unified Messaging server and add it to an existing Exchange 2007 organization, you must first add the Exchange 2010 Unified Messaging server to an existing UM dial plan that contains Exchange 2007 Unified Messaging servers. Then, configure each IP gateway or IP Private Branch eXchange (PBX) to send all incoming calls to the Exchange 2010 Unified Messaging servers within the UM dial plan and not to the Exchange 2007 Unified Messaging servers. When an incoming call is received by an Exchange 2010 Unified Messaging server and the Unified Messaging-enabled user's mailbox is located on an Exchange 2010 Mailbox server, the Exchange 2010 Unified Messaging server will process the incoming call. If the user's mailbox is located on an Exchange 2007 Mailbox server, the incoming call will be redirected to an Exchange 2007 Unified Messaging server within the same UM dial plan, and the incoming call will be processed.

After all Unified Messaging-enabled user mailboxes have been migrated to an Exchange 2010 Mailbox server, the Exchange 2007 Unified Messaging servers can be removed from the UM dial plan. For more information, see Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging.

Supported Topologies

Exchange 2010 supports the following topologies:

- Single forest with multiple Active Directory sites
- Multiple forests (resource forest model) with multiple Active Directory sites
- Single Active Directory site

For more information, see the following topics:

- Deploy Multiple Forest Topologies
- Deploy Exchange 2010 in a Cross-Forest Topology
- Deploy Exchange 2010 in an Exchange Resource Forest Topology

Exchange 2010 doesn't support the following topologies:

- Coexistence with Exchange 2000 Server or earlier

- Coexistence with Exchange 2003 versions prior to SP2
- Installing an older version of Exchange into a newly created Exchange 2010 organization

1.2.1.5 Exchange Server Deployment Assistant

Exchange Server Deployment Assistant

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-15*

Microsoft Exchange Server 2010 introduces the Exchange Server Deployment Assistant or *ExDeploy*, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment. To access ExDeploy, see Exchange Server 2010 Deployment Assistant.

You can use ExDeploy for the following scenarios:

- On-Premises Only
  - Upgrade from Exchange Server 2003
  - Upgrade from Exchange 2007
  - Upgrade from mixed Exchange 2003 and Exchange Server 2007
  - New installation of Exchange 2010

  For more information about this scenario, see Deploying Exchange 2010.
- Hybrid Deployment (On-Premises + Cloud)
  - Exchange 2003
  - Exchange 2007
  - Exchange 2010

  For more information about this scenario, see Hybrid Deployments.
- Cloud Only

  For more information about this scenario, see Understanding Cloud-Only Deployments.

1.2.1.6 Workforce Planning for Exchange

Workforce Planning for Exchange

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-03-08*

You may wonder: "How many IT professionals do I need to manage my Microsoft Exchange Server environment?" Unfortunately, there is no simple answer to this question. But to help you in your planning, this topic describes several major factors you must consider to calculate your optimal workforce level. This topic will help you assess the many facets of your organization so that you can make an informed decision about workforce

levels.

Note:
Although this topic focuses on Microsoft Exchange Server 2010 deployments, you can use its guidance to also estimate workforces for administering previous versions of Exchange.

At a high level, workforce levels are based on organizational maturity and required tasks. Organizational maturity is built on the following principles: operational process maturity, experience, hardware, reliability, and design. The required tasks will vary from company to company, and it's up to the Exchange administrator to assess and manage the process.

Organizational Maturity

Essentially, organizational maturity is determined by the level to which an organization has developed its internal policies and procedures. For example, an organization with very few defined procedures for managing the messaging environment and that has no standard operating procedures for server configuration may experience more incidents and outages than another organization that has carefully documented policies about driver updates, patch installation, and server configuration.

However, organizational maturity is not restricted to the use of policies. It also includes the *means* by which administrators manage an environment. For example, an administrator can apply hotfixes to 10 servers by logging into each server, and then downloading and installing the hotfixes on each one in turn. This process is extremely inefficient. By contrast, one administrator using an automated patch deployment system could easily deploy hotfixes to 100 servers in a few minutes, exponentially increasing efficiency. However, that patch management solution would, itself, have to be actively managed. This requirement would demand more resources, and would have to follow specific policies and procedures to ensure a healthy, accurate solution.

Organizational maturity is built on the following principles:

- **Operational process maturity**: Typically, if you have created well-documented and repeatable operational practices, the need for constant or reactive maintenance is reduced because most tasks will be automated.
- **Experience**: The level of knowledge and relevant work experience possessed by the operations team members has a positive impact on the team's ability to manage an enterprise messaging solution.
- **Hardware**: Efficient systems and good storage practices help maintain a high degree of user satisfaction and can greatly reduce the number of support calls or outages.
- **Reliability**: Related to hardware, reliability is a function of the combination of hardware, software, features that are in use, and the demands on the system. Often, a reliable solution is one that is chosen specifically to meet the full demands of a given workload.

  Note:
  Reliability is *not* a synonym for clustering. A clustering solution introduces additional complexity that may be unsuitable for organizations that don't have experience.

- **Design**: An appropriate design of the Exchange environment increases the effectiveness of all the aforementioned principles. Conversely, a poor design can cause the hardware or staff experience to be less effective.

The principles of organizational maturity are organized into organizational profiles that are known as the *Infrastructure Optimization* model, as shown in the following table.

Infrastructure Optimization model

Level	Characterization

Basic	Systems are complex and incompatible. Most IT personnel spend their time reacting to problems and are just trying to keep things running. If there are few standards and automated tools in use, IT support is labor-intensive and expensive.
Standardized	IT departments are more centralized and effective. But systems remain complex, incompatible, and expensive to maintain. Pockets of standalone systems reside in business groups.
Rationalized	IT and business groups develop strategies and define IT policies, which are enforced through technology. Through standards and careful engineering, applications work together with improved compatibility.
Dynamic	Business agility takes priority over cost savings. IT systems are highly automated, flexible, and respond quickly to changing business conditions.

For more information about Infrastructure Optimization, see Microsoft Infrastructure Optimization.

The key differentiator among the levels of the Infrastructure Optimization model is how technology is used and the standardization of systems across many levels and groups. Generally, the higher the organizational maturity level, the lower the required staffing level for managing the environment. However, technology by itself doesn't increase an organization's maturity level. All solutions must be managed to successfully support accuracy, efficiency, reliability, and stability. An organization's policies should be driven by business need, and the technology should support or facilitate those policies.

Defining Roles and Assigning Tasks

Staffing levels are also heavily dependent upon the demands placed on the enterprise messaging team. These demands can vary greatly from organization to organization. An organization that asks its messaging administrators to deploy, configure, manage, and maintain only the Exchange Server 2010 systems will require fewer staff than one which asks administrators to manage Exchange, backups, messaging hygiene, mobile devices, network, storage, and virtualization technologies.

The following list includes some of the critical questions to consider when you evaluate the role of the messaging administrator in your organization:

- Does your Exchange team have primary responsibility for the underlying Windows operating system on the servers that are running Exchange?
- Is your Exchange team responsible for other technologies, such as Active Directory Domain Services, Microsoft SharePoint Foundation 2010, or Microsoft SQL Server?
- Does your Exchange team manage the physical hardware of the Exchange environment, such as servers, network, and storage? Or, if your Exchange servers are virtualized, do the Exchange administrators manage the virtualization solution?
- Does your Exchange team manage backups (tape-based or disk-based) for the Exchange servers?
- Does your Exchange team manage the messaging hygiene infrastructure?

Does your Exchange team manage non-Exchange software or hardware?
- Does your organization separate the roles of operations and design/ architecture for messaging?
- Does your Exchange team manage network or perimeter security for messaging?
- Does your Exchange team perform direct end-user support? If so, does the team receive all messaging-related tickets or only those that have been escalated from tier 1 and tier 2?
- Do Exchange team members perform standard daily, weekly, monthly, quarterly, or yearly tasks? If so, what are those tasks? What additional tasks should be added to the list?
- Are Exchange team members responsible for responding to security issues involving messaging resources?
- Are Exchange team members asked to perform discovery searches and handle other compliance-related matters?
- Do Exchange team members perform capacity management?

This list isn't exhaustive. There may be critical tasks for messaging administrators in your organization that are not listed above. Additionally, there are other positions, such as operations manager, whose job description and required tasks are markedly different from those of messaging administrator. It's important to consider all positions in the context of the entire team rather than focus on individual positions.

The following list describes the potential responsibilities assigned to roles and functions that are common to many large and medium enterprise messaging deployments. In many cases, the listed role is a subset of an existing role (for example, Director) instead of a specific position. For example, this is the case of Operations Engineers.

- **Director**
  - Provides messaging technology vision based technology capabilities and business need.
  - Coordinates activities of messaging operations and messaging system engineering.
  - Represents all aspects of the enterprise's messaging system to internal and external sources.
- **Manager, Messaging Operations**
  - Makes sure that the messaging system is functioning at peak performance.
  - Makes sure that the messaging operations team is aware of system slowdowns and performance degradation before these problems affect users.
  - Makes sure that all messaging operations technicians and all operations analysts have the tools they need to do their jobs.
  - Represents messaging operations to users.
- **Manager, Messaging System Engineering**
  - Drives the messaging team towards constant analysis and design review with the goal of improving the messaging system's performance.
  - Makes sure that the messaging team has the necessary tools and training to do their jobs.
  - Responds to appropriate escalations from the operations team and allocates resources to those escalations.
- **Associate Operations Analyst**
  - Installs, configures, and documents new production servers in the messaging environment.
  - Performs rudimentary troubleshooting of messaging system problems.
- **Operations Analyst**
  - Installs, configures, and documents new production servers in the messaging environment.
  - Performs all troubleshooting of messaging system problems.
  - Ensures that problems are correctly documented in the daily log.

- **Senior Operations Analyst**
  - Assists with mentoring new Operations Analysts; performs duties of the Operations Analyst when required.
  - Handles escalation issues not resolved by Operations Analyst and Technicians.
  - Makes sure that the daily log remains a useful repository of system troubleshooting information.
- **Associate Operations Engineer**
  - Works with Operations Analysts and Technicians to perform rudimentary analysis and design.
  - Brings ideas and recommendations to other members of the engineering team for further discussion.
- **Operations Engineer**
  - Works with Operations Analysts and Technicians to perform detailed analysis and design.
  - Handles initial escalations from the operations side
  - Troubleshoots and follows up on all escalations from operations team.
  - Evaluates features of released products for usability in the enterprise messaging system.
- **Senior Operations Engineer**
  - Evaluates released and unreleased messaging systems.
  - Provides detailed test plans for features to be implemented.
  - Attempts to minimize all impacts of next generation releases of message product.
  - Handles extreme escalations and interfaces with Microsoft Technical Support, if necessary.
- **Messaging Operations Technician**
  - Handles day-to-day monitoring and reporting on the messaging system.
  - Ensures that events are properly recorded in the daily log.
  - Ensures that all events that transpired during his or her shift have been recorded and reported to appropriate personnel.
  - Also handles escalation requests from standard "PC Helpdesk" department.

To increase the accuracy of any workforce staffing level calculations, it helps if you clearly define the roles of the various messaging team members and then objectively assess the demands of those roles.

Assessing Technology Impact

After your organization has defined the various roles and responsibilities, the next step is to assess the technology, and then map the desired tasks to the technical components of the solution. Often, improvements in the software may let administrators complete specific tasks much quicker than in previous versions, may enable administrators to automate common workflows, or may enable administrators to delegate specific tasks to other individuals or other teams.

Consider this example. Woodgrove Bank administrators often receive requests to restore mailboxes to retrieve mistakenly deleted items. These requests require the involvement of a messaging engineer (who has the necessary permissions to access the Exchange Server 2003 systems), as well as a backup engineer (who handles the actual restore operation). The requirement to restore deleted content will still be present after Woodgrove Bank deploys Exchange Server 2010, but if they choose to enable single item recovery for all users, the actual restoration work could be performed by a messaging administrator (who was granted the appropriate permissions via Role Based Access Control) or by a compliance administrator in the Human Resources department. Because the backup engineer is no longer involved in the restoration operation, the overall process is simpler and presumably can be completed in less time.

Exchange Server 2010 includes several features that could potentially let management reassign tasks at different levels, to different teams, or eliminate the need for the task completely. The following table describes several major features in Exchange Server 2010, together with the changes to tasks that these features may support. The features described in this table aren't an exhaustive list. Of course, you may choose to employ these features at your discretion.

Feature	Possible changes to tasks
Database Availability Groups	By having three or more database copies, Exchange administrators can adopt a native data protection strategy, reducing the demands on the backup team.
Single Item Recovery	Eliminate the need for restoring backups simply to recover a single deleted item.
Role Based Access Control (RBAC)	Lets administrators delegate tasks at a granular level without exposing the organization to major security risks.
PowerShell (expanded in Exchange Server 2010, also present in Exchange Server 2007)	Lets administrators automate common tasks, including many user, group, mailbox, and database maintenance tasks , via PowerShell scripts.
Multi-mailbox search	Combined with RBAC, lets administrators delegate discovery to other individuals, most likely in Human Resources. Lets trusted individuals perform discovery against mailboxes in the environment without third-party tools.
Exchange Control Panel	Lets users manage certain aspects of their messaging experience, including distribution groups and message tracking, thus reducing the demands on the help desk.
Personal Archive	Lets administrators absorb functionality formerly provided by Personal Folders (.pst files), thus removing a common source of support calls.
Retention Policies	Lets administrators control the e-mail lifecycle (by setting a maximum e-mail message age), possibly reducing the number of compliance issues in the messaging environment.

While the above list is specific to Exchange Server 2010, the principle of matching task to technology holds true no matter which version is in use. Using the technology to its fullest lets administrators perform their duties in the most efficient manner possible, freeing their time for other tasks and reducing the demands on other teams as well.

Calculating Staffing Levels

As stated at the beginning of this topic, there is no simple formula to provide a specific recommended number of staff to manage a given Exchange organization. The range of factors is too complex and too varied. Two organizations of similar size and scope may

require vastly different staffing levels based on the required duties of the administrators, the administrators' experience managing Exchange, and the degree of automation in the environment.

The most important factor to consider when calculating staffing levels is the amount of time that is needed to perform all required tasks given the current infrastructure. It may also be appropriate to calculate the amount of time that is required to perform all desired tasks given an idealized infrastructure, if significant changes will be made to the environment which would increase the operational maturity level. The sum total of hours is then translated into a recommended staffing level, taking into account other factors including the length of the work day, the length of the work week, and the average number of vacation and sick days. The staffing level should always be rounded up to the next integer value to ensure that staffing levels exceed the required time rather than fall short.

The following sample Exchange Operations task checklist indicates the level to which tasks should be detailed before staffing levels are calculated.

SAMPLE - Exchange Operations Task Checklist (per location)

Activity	Est. Time (hrs)	Frequency	Annual Work Effort
Planning			
Participation in next-version assessment discussions	8	Annually	8
Feedback from operations	2	Quarterly	8
SLA definitions	4	Annually	4
Operations documentation	1	Annually	1
Exchange Administration			
Backup and Restore	1	Daily	260
Perform regular backup	1	Daily	260
Backup Active Directory system state	1	Daily	260
Verify back up media	1	Monthly	12
Offsite back up media	1	Daily	260
Change backup media regularly	1	Daily	260
Set mailbox and message retention times on all client servers	1	Quarterly	4

Defragment mailbox and public folder stores	1	Monthly	12
Verify integrity of the mailbox and public folder stores	1	Weekly	52
Risk Management			
Identification	1	Annually	1
Analysis and prioritization	.5	Annually	.5
Mitigation and contingency planning	.5	Annually	.5
Additional Work as Assigned			
New projects	100	Annually	100
Help desk escalation support	1	Daily	260
Review open service tickets	2	Daily	520
On-site visit (travel time)	2	Monthly	24
Total			9791.5
Available Hours per Man Year			1635
Percentage of work consumed by Exchange tasks			599%

In this example, the organization determined that the total number of tasks requires 9,792 hours. Given that a full-time employee works 1,635 hours, this analysis suggests that the organization requires 600 percent of a single individual—or, more appropriately, six FTEs—to manage their Exchange organization. Note that this sample task list is for the operations team only. The customer has to perform the same analysis for the engineering and help desk teams, as well.

The number of positions also depends on the complexity and size of the organization. Small organizations may combine roles or omit them entirely, while large organizations may have multiple individuals in certain roles. For example, one large financial services corporation has a messaging team which manages resources for 45,000 users on a 24 hours a day, seven days a week basis. Their messaging services staff typically includes 30-32 individuals in the positions shown in the following table (whose roles and responsibilities are defined in "Defining Roles and Assigning Tasks" earlier in this topic).

Position title	Number of staff
Director	1
Manager, Messaging Operations	1
Sr. Operations Analyst	2

Operations Analyst	3
Assoc. Operations Analyst	0-1
Technicians	17
Manager, Messaging System Engineering	1
Sr. Operations Engineer	2
Operations Engineer	2
Assoc. Operations Engineer	1

Conclusion

To determine the number of engineers, administrators, and other support personnel that are required to manage a specific Exchange environment, you must carefully gather business requirements, consider a variety of factors, and, above all, plan. You can determine your required staffing level only after you determine the needs of the user community, define the roles to fulfill those needs, assess the technology, match the technology to the roles, and then, finally, calculate the time required to perform the desired tasks. It's an involved process, but the ultimate results should closely align the capabilities of the messaging team to the needs of the business (and users) without unnecessarily encumbering either organization or team with superfluous head count.

1.2.1.7 Planning Active Directory

Planning Active Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-19*

Microsoft Exchange Server 2010 uses Active Directory to store and share directory information with Microsoft Windows.

Active Directory forest design for Exchange 2010 is similar to Exchange 2007. The main change in Active Directory for Exchange 2010 is in the introduction of Role Based Access Control (RBAC). In Exchange 2007, Active Directory provides ways for you to delegate administrative authority to directory objects by using access control lists (ACLs). In Exchange 2010, you don't need to modify and manage ACLs. RBAC enables you to control, at both broad and granular levels, what administrators and end-users can do. For more information about RBAC, see Understanding Role Based Access Control.

Active Directory and a New Exchange 2010 Organization

For more information about planning for Active Directory in a new Exchange 2010 organization, see the following topics:

- Prepare Active Directory and Domains
- Understanding the Active Directory Driver
- Planning for Access to Active Directory
- Planning to Use Active Directory Sites for Routing Mail

Active Directory and Legacy Exchange Organizations

For more information about planning for Active Directory when your organization includes legacy versions of Exchange, see the following topics:

- Exchange 2010 Active Directory Schema Changes
- Prepare Active Directory and Domains
- Understanding the Active Directory Driver
- Planning for Access to Active Directory
- Planning to Use Active Directory Sites for Routing Mail
- Prepare Legacy Exchange 2003 Permissions
- Exchange Server 2003 and Active Directory
- Discontinued Features

For More Information

For comprehensive Active Directory deployment information, see the Windows Server 2003 Deployment Guide.

For more information about Active Directory forest design for your Exchange organization, see Guidance on Active Directory design for Exchange Server 2007 at the Exchange Team Blog.

Note:

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

1.2.1.7.1 Determine the Exchange Schema Version

Determine the Exchange Schema Version

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-12-26*

To verify that the Exchange schema version has been updated correctly, determine the value of the **rangeUpper** attribute on the property page of the **ms-Exch-Schema-Version-Pt** schema attribute.

To look up the value of the rangeUpper attribute, use a tool such as ADSI Edit, LDP.exe, or DSQuery.

What Do You Want to Do?

- Determine the Exchange Schema version by using ADSI Edit
- Determine the Exchange Schema version by using LDP.exe
- Determine the Exchange Schema version by using DSQuery

Determine the Exchange schema version

by using ADSI Edit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Organization Management" entry in the Understanding Management Role Groups topic.

1. Sign on to a domain controller in your Active Directory forest.
2. Click **Start**, click **Run**, type **ADSIEdit.msc**, and then click **OK**.
3. In the ADSI Edit console, right-click **ADSI Edit** in the navigation pane, and then click **Connect to**.
4. In the **Connection Settings** dialog box, select **Schema** in the **Select a well known Naming Context** list, and then click **OK**.
5. Expand the schema node in the navigation pane, and then click **CN=Schema,CN=Configuration,DC=contoso,DC=com**.
6. Right-click **CN=ms-Exch-Schema-Version-Pt**, and then click **Properties**.
7. On the property page, locate **rangeUpper** in the **Attribute** list.
8. Verify that the value is correct for the expected Exchange Schema.

Note:

To view the schema version table, see Exchange Server Build Numbers and Release Dates

Determine the Exchange schema version by using LDP.exe

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Organization Management" entry in the Understanding Management Role Groups topic.

1. Sign on to a domain controller in the Active Directory Forest.
2. Click **Start**, click **Run**, type **LDP.exe**, and then click **OK**.
3. In **Ldp**, click **Bind** on the **Connection** menu.
4. In the **Bind type** area, click **Bind as currently logged on user**, and then click **OK**.
5. On the **View** menu, click **Tree**.
6. In the **Tree View** dialog box, select **CN=Schema,CN=Configuration,DC=contoso,DC=com**in the **BaseDN** list, and then click **OK**.
7. Expand the schema node in the navigation pane, and then click **ms-Exch-Schema-Version-Pt**.

   Note:

   If the **ms-Exch-Schema-Version-Pt** schema attribute is not listed, click **General** on the **Options** menu, increase the value of the **Max children** buffer size, click **OK**, and then repeat step 5.
8. In the right pane, scroll down to the bottom and locate the **rangeUpper** attribute.
9. Verify that the value is correct for the expected Exchange schema.

Note:

To view the schema version table, see Exchange Server Build Numbers and Release Dates

Determine the Exchange schema version by using DSQuery

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Organization Management" entry in the Understanding

Management Role Groups topic.

1. Sign on to a domain controller in the Active Directory forest.
2. At a command prompt, type the following command, and then press Enter:
   dsquery * CN=ms-Exch-Schema-Version-Pt,cn=schema,cn=configuration,dc=<Domain>,dc=<local> -scope base -attr rangeUpper

For More Information

Dsquery

DSQUERY Commands

1.2.1.7.2 Exchange 2010 Active Directory Schema Changes

Exchange 2010 Active Directory Schema Changes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Microsoft Exchange Server 2010 adds new attributes to the Active Directory domain service schema and also makes other modifications to existing classes and attributes. For more information about Active Directory changes when you install Exchange 2010, as well as changes from previous versions of Exchange, see Exchange Server Changes to the Active Directory Schema.

1.2.1.7.3 Prepare Active Directory and Domains

Prepare Active Directory and Domains

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-01-04*

Before you install Microsoft Exchange Server 2010 on any servers in your organization, you must prepare Active Directory and domains.

For information about preparing your domains with legacy Exchange permissions, see Prepare Legacy Exchange 2003 Permissions.

Prerequisites

- The computers on which you plan to install Exchange 2010 must meet the system requirements. For details, see Exchange 2010 System Requirements.
- Your domains and the domain controllers must meet the system requirements in "Network and Directory Servers" in Exchange 2010 System Requirements.
- In each domain in which you install Exchange 2010, you must have at least one domain controller running any of the following:
  - Windows Server 2003 Standard Edition with Service Pack 1 (SP1) or later (32-bit or 64-bit)

- Windows Server 2003 Enterprise Edition with SP1 or later (32-bit or 64-bit)
- Windows Server 2008 Standard or Enterprise (32-bit or 64-bit)
- Windows Server 2008 R2 Standard or Enterprise

- For multiple domain organizations running the following /Prepare* commands, we recommend the following:
  - Run the /Prepare* commands from an Active Directory site with an Active Directory server from every domain.
  - Run the first server role installation or Exchange 2010 service pack upgrade from an Active Directory site with a writeable global catalog server from every domain.
  - Verify that replication of objects from the preceding actions is completed on the global catalog server in the Active Directory site before installing the first Exchange 2010 server (or SP1 upgrade) to that site.
- If you're running the release to manufacturing (RTM) version of Exchange 2010 Setup.com, in each domain (including child domains) where you have the Exchange Enterprise Servers and Exchange Domains Servers security groups (and therefore must run **Setup /PrepareLegacyExchangePermissions**), you must have at least one domain controller running any of the following:
  - Windows Server 2003 Standard Edition with SP1 or later (32-bit or 64-bit)
  - Windows Server 2003 Enterprise Edition with SP1 or later (32-bit or 64-bit)
  - Windows Server 2008 Standard or Enterprise (32-bit or 64-bit)
  - Windows Server 2008 R2 Standard or Enterprise
- If you run the Exchange 2010 Setup wizard with an account that has the permissions required (Schema Admins, Domain Admins, and Enterprise Admins) to prepare Active Directory and the domain, the wizard will automatically prepare Active Directory and the domain. For more information, see Install Exchange Server 2010. However, if you're deploying a new Exchange organization, and you're preparing your Active Directory schema and domains using a computer running Windows Server 2008, you must first install the Active Directory management tools on the Windows Server 2008 computer prior to preparing the schema or domains. To do this, run the following command.

```
ServerManagerCmd -i RSAT-ADDS
```

Prepare Active Directory and domains

To track the progress of Active Directory replication, you can use the Active Directory Replication Monitor tool (replmon.exe), which is installed as part of the Windows Server 2003 Support Tools Setup. By default, it's located at %programfiles%\support tools\. Add your domain controllers as monitored servers so that you can track the progress of replication throughout the domain.

1. If you have any computers in your organization running Microsoft Exchange Server 2003, open a Command Prompt window, and then run one of the following commands:
   - To prepare legacy Exchange permissions in every domain in the forest that contains the Exchange Enterprise Servers and Exchange Domain Servers groups, run the following command.

     setup /PrepareLegacyExchangePermissions or **setup /pl**
   - To prepare legacy Exchange permissions in a specific domain, run the following command.

     setup /PrepareLegacyExchangePermissions:< *FQDN of domain you want to prepare* **>** or **setup /pl:<***FQDN of domain you want to prepare***>**

Note:

You can skip this step and prepare the legacy Exchange permissions as part of Step 2 or Step 3. The advantages of running each step separately are

that you can run each step with an account that has the minimum permissions required for that step, and you can verify completion, success, and replication before continuing to the next step.

Note the following:

- To run this command to prepare every domain in the forest, you must be a member of the Enterprise Admins group. To run this command to prepare a specific domain, or if the forest has only one domain, you must be delegated the Exchange Organization Management role, and you must be a member of the Domain Admins group in the domain that you will prepare.
- If you don't specify a domain, the domain in which you run this command must be able to contact all domains in the forest. If the server can't contact a domain that must have legacy Exchange permissions prepared, it prepares the domains that it can contact, and then returns an error message that it was unable to contact some domains.
- You can run this command from any Windows Server 2008 server in the forest.
- You must run this command on a computer in the same domain and in the same Active Directory site as the schema master. Setup will make all configuration changes to the schema master to avoid conflicts because of replication latency. For more information, see Identify the schema master.
- After you run this command, you must wait for the permissions to replicate across your Exchange organization before continuing to the next step. If the permissions haven't replicated, the Recipient Update Service on your Exchange 2003 computers could fail. The amount of time that replication takes depends on your Active Directory site topology.
- For detailed information about the permissions set by this command, see Prepare Legacy Exchange 2003 Permissions.

2. From a Command Prompt window, run the following command.
setup /PrepareSchema or **setup /ps**

Note:
You can skip this step and prepare the schema as part of Step 3.

Important:
If you have multiple forests in your organization, make sure that you run your forest preparation from the correct Exchange forest. Setup preparation makes configuration changes to your forest, and it could configure a non-Exchange forest incorrectly.

Note:
It isn't supported to use the LDIF Directory Exchange tool (LDIFDE) to manually import the Exchange 2010 schema changes. You must use Setup to update the schema.

This command performs the following tasks:

- Connects to the schema master and imports LDAP Data Interchange Format (LDIF) files to update the schema with Exchange 2010 specific attributes. The LDIF files are copied to the Temp directory, and then deleted after they are imported into the schema.

Note the following:

- To run this command, you must be a member of the Schema Admins group and the Enterprise Admins group.
- You must run this command on a 64-bit computer in the same domain and in the same Active Directory site as the schema master.
- If you haven't completed Step 1, **setup /PrepareSchema** will automatically perform the **PrepareLegacyExchangePermissions** step. To complete the **PrepareLegacyExchangePermissions** step, the domain in which you run this command must be able to contact all domains in the forest. The advantages of running each step separately are that you can run each step with an account that has the minimum permissions required for that

step, and you can verify completion, success, and replication before continuing to the next step.

- If you use the */DomainController* parameter with this command, you must specify the domain controller that is the schema master.
- After you run this command, you should wait for the changes to replicate across your Exchange organization before continuing to the next step. The amount of time this takes is dependent upon your Active Directory site topology.
- For more information, see Exchange Server Changes to the Active Directory Schema.

3. From a Command Prompt window, run the following command.
setup /PrepareAD [/OrganizationName: <*organization name*> **]** or **setup /p [/on:<***organization name***>]**
This command performs the following tasks:
   - If the Microsoft Exchange container doesn't exist, this command creates it under CN=Services,CN=Configuration,DC=<*root domain*>.
   - If no Exchange organization container exists under CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain* >, you must specify an organization name using the */OrganizationName* parameter. The organization container will be created with the name that you specify.
     The Exchange organization name can contain only the following characters:
     A through Z
     a through z
     0 through 9
     Space (not leading or trailing)
     Hyphen or dash
     The organization name can't contain more than 64 characters.
     The organization name can't be blank. If the organization name contains spaces, you must enclose the name in quotation marks (").
   - Verifies that the schema has been updated and that the organization is up to date by checking the **objectVersion** property in Active Directory. The **objectVersion** property is in the CN=<*your organization*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*domain*> container. The **objectVersion** value for Exchange 2010 SP2 is 14247. The **objectVersion** value for Exchange 2010 SP1 is 13214. The **objectVersion** value for Exchange 2010 RTM is 12640.
   - If the containers don't exist, creates the following containers and objects under CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>, which are required for Exchange 2010:
     CN=Address Lists Container,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=Addressing,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=Administrative Groups,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=Client Access,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=Connections,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=ELC Folders,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=ELC Mailbox Policies,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
     CN=Global Settings,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>

CN=Mobile Mailbox Policies,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=Recipient Policies,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=System Policies,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=Transport Settings,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=UM AutoAttendant,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=UM DialPlan,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=UM IPGateway,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>
CN=UM Mailbox Policies,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>

- If it doesn't exist, creates the default Accepted Domains entry, based on the forest root namespace, under CN=Transport Settings,CN=<*Organization Name*>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*>.
- Assigns specific permissions throughout the configuration partition.
- Imports the Rights.ldf file. This adds the extended rights required for Exchange to install into Active Directory.
- Creates the Microsoft Exchange Security Groups organizational unit (OU) in the root domain of the forest and assigns specific permissions on this OU.
- Creates the following management role groups within the Microsoft Exchange Security Groups OU:

  Organization Management
  Recipient Management
  Server Management
  View-Only Organization Management
  Public Folder Management
  UM Management
  Hygiene Management
  Records Management
  Discovery Management
  Delegated Setup
  Exchange All Hosted Organizations
  Exchange Servers
  Exchange Trusted Subsystem
  Exchange Windows Permissions
  Help Desk
  ExchangeLegacyInterop

- Adds the new universal security groups (USGs) that are within the Microsoft Exchange Security Groups OU to the **otherWellKnownObjects** attribute stored on the CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<*root domain*> container.
- Creates the Unified Messaging Voice Originator contact in the Microsoft Exchange System Objects container of the root domain.
- Prepares the local domain for Exchange 2010. For information about what tasks are completed to prepare a domain, see Step 4.

Note the following:

- To run this command, you must be a member of the Enterprise Admins group.
- The computer where you run this command must be able to contact all domains in the forest on port 389.
- You must run this command on a computer in the same domain and in the same Active Directory site as the schema master. Setup will make all configuration changes to the schema master to avoid conflicts because of

replication latency.

- If you haven't completed Step 1, **setup /PrepareAD** will automatically perform the **PrepareLegacyExchangePermissions** step. To complete the **PrepareLegacyExchangePermissions** step, the domain in which you run this command must be able to contact all domains in the forest. If you're also a member of the Schema Admins group, and if you haven't completed Step 2, **setup /PrepareAD** will automatically perform the PrepareSchema step. The advantages of running each step separately are that you can run each step with an account that has the minimum permissions required for that step, and you can verify completion, success, and replication before continuing to the next step.
- After you run this command, you should wait for the changes to replicate across your Exchange organization before continuing to the next step. The amount of time this takes is dependent upon your Active Directory site topology.
- To verify that this step completed successfully, make sure that there is a new OU in the root domain called **Microsoft Exchange Security Groups**. This OU should contain the following new Exchange USGs:

  Exchange Security Groups OU:
  Organization Management
  Recipient Management
  Server Management
  View-Only Organization Management
  Public Folder Management
  UM Management
  Hygiene Management
  Records Management
  Discovery Management
  Delegated Setup
  Exchange All Hosted Organizations
  Exchange Servers
  Exchange Trusted Subsystem
  Exchange Windows Permissions
  Help Desk
  ExchangeLegacyInterop

4. From a Command Prompt window, run one of the following commands:
   - Run **setup /PrepareDomain** or **setup /pd** to prepare the local domain. You don't need to run this in the domain where you ran Step 3. Running **setup /PrepareAD** prepares the local domain.
   - Run **setup /PrepareDomain:**<*FQDN of domain you want to prepare*> to prepare a specific domain.
   - Run **setup /PrepareAllDomains** or **setup /pad** to prepare all domains in your organization.

   These commands perform the following tasks:
   - If this is a new organization, creates the Microsoft Exchange System Objects container in the root domain partition in Active Directory and sets permissions on this container for the Exchange Servers, Exchange Organization Administrators, and Authenticated Users groups. This container is used to store public folder proxy objects and Exchange-related system objects, such as the mailbox database's mailbox.
   - Sets the **objectVersion** property in the Microsoft Exchange System Objects container under DC=<*root domain*>. This **objectVersion** property contains the version of domain preparation. The version for Exchange 2010 RTM is 12640. The version for Exchange 2010 SP1 and SP2 is 13040.
   - Creates a domain global group in the current domain called Exchange Install Domain Servers. The command places this group in the Microsoft Exchange System Objects container. It also adds the Exchange Install Domain Servers group to the Exchange Servers USG in the root domain.

   Note:

The Exchange Install Domain Servers group is used if you install Exchange 2010 in a child domain that is an Active Directory site other than the root domain. The creation of this group allows you to avoid installation errors if group memberships haven't replicated to the child domain.

- Assigns permissions at the domain level for the Exchange Servers USG and the Exchange Recipient Administrators USG.

Note the following:

- To run **setup /PrepareAllDomains**, you must be a member of the Enterprise Admins group.
- To run **setup /PrepareDomain**, if the domain that you're preparing existed before you ran **setup /PrepareAD**, you must be a member of the Domain Admins group in the domain. If the domain that you're preparing was created after you ran **setup /PrepareAD**, you must be a member of the Exchange Organization Administrators group, and you must be a member of the Domain Admins group in the domain.
- For domains in an Active Directory site other than the root domain, **/PrepareDomain** might fail with the following messages:
  "PrepareDomain for domain <*YourDomain*> has partially completed. Because of the Active Directory site configuration, you must wait at least 15 minutes for replication to occur, and run PrepareDomain for <*YourDomain*> again."
  "Active Directory operation failed on <*YourServer*>. This error is not retriable. Additional information: The specified group type is invalid.
  Active Directory response: 00002141: SvcErr: DSID-031A0FC0, problem 5003 (WILL_NOT_PERFORM), data 0
  The server cannot handle directory requests."
  If you see these messages, wait for or force Active Directory replication between this domain and the root domain, and then run **/PrepareDomain** again.
- You must run this command in every domain in which you will install Exchange 2010. You must also run this command in every domain that will contain mail-enabled users, even if the domain doesn't have Exchange 2010 installed.

To verify that this step completed successfully, confirm the following:

- You have a new global group in the Microsoft Exchange System Objects container called Exchange Install Domain Servers.

Note:
To view the Microsoft Exchange System Objects container in Active Directory Users and Computers, on the **View** menu, click **Advanced Features**.

- The Exchange Install Domain Servers group is a member of the Exchange Servers USG in the root domain.
- On each domain controller in a domain in which you will install Exchange 2010, the Exchange Servers USG has permissions on the Domain Controller Security Policy\Local Policies\User Rights Assignment\Manage Auditing and Security Log policy.

1.2.1.7.4 Understanding the Active Directory Driver

Understanding the Active Directory Driver

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-02*

The Active Directory driver is the core Microsoft Exchange component that allows Exchange services to create, modify, delete, and query for Active Directory Domain Services (AD DS) data. The Active Directory driver also uses Microsoft Exchange Active Directory Topology (MSExchangeADTopology), which allows the Active Directory driver to use Directory Service Access (DSAccess) topology data. This data includes the list of available domain controllers and global catalog servers available to handle Exchange requests. This topic discusses the relationship between the Active Directory driver and DSAccess.

DSAccess provides directory lookup services for components such as SMTP, message transfer agent (MTA), and the Exchange store. Client requests use the DSProxy service for directory access.

DSAccess implementation has several benefits that Exchange components use, especially related to topology discovery and simplification of Active Directory topology complexity. DSAccess also has several limitations related to paging of results, especially in dealing with large multivalued attributes. One of the major differences between the Active Directory driver and DSAccess is that the Active Directory driver doesn't access and store directory information in a cache. In Microsoft Exchange Server 2010, the Exchange component using DSAccess implements the appropriate cache when needed.

In Exchange 2010, the following services use DSAccess. In these cases, DSAccess is used only to obtain the current topology information and to provide a consistent topology view through all Exchange services running on the server:

- Microsoft Exchange Active Directory Topology (MSExchangeADTopology)
- Microsoft Exchange Information Store (MSExchangeIS)
- Microsoft Exchange System Attendant (MSExchangeSA)
- World Wide Web Publishing Service (WWW service or W3SVC)

1.2.1.7.5 Planning for Access to Active Directory

Planning for Access to Active Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 stores all configuration and recipient information in the Active Directory directory service database. When a computer that is running Exchange 2010 requires information about recipients and information about the configuration of the Exchange organization, it must query Active Directory to access the information. Active Directory servers must be available for Exchange 2010 to function correctly.

This topic explains how Exchange 2010 stores and retrieves information in Active Directory

so that you can plan access to Active Directory. This topic also discusses issues you should be aware of if you try to recover deleted Exchange 2010 Active Directory objects.

Exchange Information Stored in Active Directory

The Active Directory database stores information in three types of logical partitions that are described in the following sections:

- The schema partition
- The configuration partition
- The domain partition

The Schema Partition

The schema partition stores two types of information: schema classes and schema attributes. Schema classes define all the types of objects that can be created and stored in Active Directory. Schema attributes define all the properties that can be used to describe the objects that are stored in Active Directory.

When you install the first Exchange 2010 server role in the forest or run the Active Directory preparation process, the Active Directory preparation process adds many classes and attributes to the Active Directory schema. The classes that are added to the schema are used to create Exchange-specific objects, such as agents and connectors. The attributes that are added to the schema are used to configure the Exchange-specific objects and the mail-enabled users and groups. These attributes include properties, such as Microsoft Office Outlook Web Access settings and Microsoft Exchange Unified Messaging (UM) settings. Every domain controller and global catalog server in the forest contains a complete replica of the schema partition.

For more information about schema modifications in Exchange 2010, see Exchange 2010 Active Directory Schema Changes.

The Configuration Partition

The configuration partition stores information about the forest-wide configuration. This configuration information includes the configuration of Active Directory sites, Exchange global settings, transport settings, mailbox policies, and UM dial plans. Each type of configuration information is stored in a container in the configuration partition. Exchange configuration information is stored in a subfolder under the configuration partition's Services container. The information that is stored in this container includes the following:

- Address lists
- Address and display templates
- Administrative groups
- Client access settings
- Connections
- Messaging records management, mobile, and UM mailbox policies
- Global settings
- E-mail address policies
- System policies
- Transport settings

Every domain controller and global catalog server in the forest contains a complete replica of the configuration partition.

The Domain Partition

The domain partition stores information in default containers and in organizational units that are created by the Active Directory administrator. These containers hold the domain-specific objects. This data includes Exchange system objects and information about the computers, users, and groups in that domain. When Exchange 2010 is installed, Exchange

updates the objects in this partition to support Exchange functionality. This functionality affects how recipient information is stored and accessed.

Each domain controller contains a complete replica of the domain partition for the domain for which it is authoritative. Every global catalog server in the forest contains a subset of the information in every domain partition in the forest.

How Exchange 2010 Accesses Information in Active Directory

Exchange 2010 uses an Active Directory API to access information that is stored in Active Directory. The Active Directory Topology service runs on all Exchange 2010 server roles. This service reads information from all Active Directory partitions. The data that is retrieved is cached and is used by Exchange 2010 servers to discover the Active Directory site location of all Exchange services in the organization. For more information about topology and service discovery, see Planning to Use Active Directory Sites for Routing Mail.

Exchange 2010 is an Active Directory site-aware application that prefers to communicate with the directory servers that are located in the same site as the Exchange server to optimize network traffic. Each Exchange 2010 organizational server role must communicate with Active Directory to retrieve information about recipients and information about the other Exchange 2010 server roles. The data that each server role obtains is described in the following sections.

By default, whenever an Exchange 2010 server starts, it binds to a randomly selected domain controller and global catalog server in its own site. You can view the selected directory servers by viewing the properties of the Exchange 2010 server in the Exchange Management Console or by using the **Get-ExchangeServer** cmdlet in the Exchange Management Shell. You can also use the **Set-ExchangeServer** cmdlet to configure a static list of domain controllers to which an Exchange 2010 server should bind or a list of domain controllers that should be excluded.

Important:

A Windows Server 2008 domain controller can be configured as a read-only directory server. This configuration is useful when you want to deploy a domain controller or global catalog server in a remote site for authentication and authorization purposes, but you don't want to allow administrators in that site to write changes to Active Directory. However, you can't deploy an Exchange 2010 server in any site that contains only read-only directory servers.

Hub Transport Server Role

The Hub Transport server role contacts Active Directory when it performs message categorization. The categorizer must query Active Directory to perform recipient lookup and routing resolution. The information that the categorizer retrieves during recipient lookup includes the location of the recipient's mailbox and any restrictions or permissions that may apply to the recipient. The categorizer must also query Active Directory to expand the membership of distribution lists and to perform the Lightweight Directory Access Protocol (LDAP) query processing that is required when mail is sent to a dynamic distribution list.

During routing resolution, the categorizer uses the topology information that is cached by the Active Directory Topology service to discover the routing path for a message. The Hub Transport server uses Active Directory site configuration information to determine the location of other servers and connectors in the topology.

When the Hub Transport server has resolved the location of the recipient's mailbox, it uses Active Directory site information to locate the mailbox store. If the mailbox store is in the same Active Directory site as the Hub Transport server, the Hub Transport server delivers the message directly to the user's mailbox. If the mailbox store is in a different

Active Directory site than the Hub Transport server, the Hub Transport server delivers the message to a Hub Transport server in the remote Active Directory site.

The Hub Transport server stores all configuration information in Active Directory and accesses Active Directory to retrieve this information. The configuration information includes the details of any transport rules, journal rules, and connectors.

Client Access Server Role

The Client Access server role receives connections from the Internet for users who access their mailbox by using Outlook Web App, (POP3, IMAP4, or Microsoft Exchange ActiveSync). When a user connection is received, the Client Access server contacts Active Directory to authenticate the user and to determine the location of the user's mailbox server. If the user's mailbox is in the same Active Directory site as the Client Access server, the user is connected directly to their mailbox. If the user's mailbox is in a different Active Directory site than the Client Access server that received the initial connection, the connection is redirected to a Client Access server in the remote Active Directory site.

Unified Messaging Server Role

The Unified Messaging server role accesses Active Directory to retrieve global configuration information, such as dial plans, IP gateways, and hunt groups. When a message is received by the Unified Messaging server, it searches for Active Directory recipients to match the telephone number to a recipient address. When it has resolved this information, the Unified Messaging server can determine the location of the recipient's mailbox store and then submit the message to a Hub Transport server for routing to the mailbox.

Mailbox Server Role

The Mailbox server role stores configuration information about mailbox users and stores in Active Directory. Additionally, the configuration for agents, address lists, and policies is stored in Active Directory. The Mailbox server retrieves this information to enforce mailbox policies and global settings.

Edge Transport Server Role

The Edge Transport server role is deployed in the perimeter network and is not a domain member. The Edge Transport server doesn't have access to Active Directory and uses Active Directory Lightweight Directory Services (AD LDS, formerly known as Active Directory Application Mode or ADAM) to store schema and configuration information. You can create an Edge Subscription to subscribe the Edge Transport server to an Active Directory site. The Hub Transport servers in that Active Directory site use the Microsoft Exchange EdgeSync service to synchronize Active Directory data to AD LDS.

We recommend that you create an Edge Subscription for each Edge Transport server. This process will automatically provision the Send connectors that are required for end-to-end mail flow. You must create an Edge Subscription if you will be using the recipient lookup or safe list aggregation anti-spam features.

Recovery of Deleted Exchange Objects

Active Directory Recycle Bin helps minimize directory service downtime by enhancing your ability to preserve and recover accidentally deleted Active Directory objects without restoring Active Directory data from backups, restarting Active Directory Domain Services (AD DS), or rebooting domain controllers.

The most important thing to understand about recovering deleted Exchange-related Active Directory objects is that Exchange objects don't exist in isolation. For example, when you mail-enable a user, several different policies and links are calculated for the user based on your current Exchange configuration. Two problems that may arise when you restore a deleted Exchange configuration or recipient object are:

- **Collisions** Some Exchange attributes must be unique across a forest. For example, proxy (e-mail) addresses must not be the same for two different users. Active Directory doesn't enforce proxy address uniqueness—Exchange administrative tools check for uniqueness. Exchange e-mail address policies also automatically resolve possible conflicts in proxy address assignment based on deterministic rules. Therefore, it's possible to restore an Exchange user object and, as a result, create a collision with proxy addresses or other attributes that should be unique.
- **Misconfigurations** Exchange has automated rules that assign various policies or settings. If you delete a recipient, and then change the rules or policies, restoring an Exchange user object may result in a user being assigned to the wrong policy (or even to a policy that no longer exists).

The following guidelines will help you minimize problems or issues when you recover deleted Exchange -related objects:

- If you deleted an Exchange configuration object using Exchange management tools, do not restore the object. Instead, re-create the object using the Exchange management tools (Exchange Management Console or Exchange Management Shell).
- If you deleted an Exchange configuration object without using the Exchange management, recover them as soon as possible. The more administrative and configuration changes that have been made in the system since the deletion, the more likely it is that restoring the objects will result in misconfiguration.
- If you recover deleted Exchange recipients (contacts, users, or distribution groups), monitor closely for collisions and errors relating to the recovered objects. If Exchange policies or other configuration relating to recipients may have been modified since the deletion, re-apply current policies to the restored recipients to ensure that they are configured correctly.

For more information about using Active Directory Recycle Bin, see Active Directory Recycle Bin Step-by-Step Guide.

1.2.1.7.6 Planning to Use Active Directory Sites for Routing Mail

Planning to Use Active Directory Sites for Routing Mail

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-07*

Microsoft Exchange Server 2010 uses Active Directory site topology to determine how messages are transported in the organization. Exchange 2010 uses the existing Active Directory site topology to transport messages between server roles.

The Hub Transport server role provides message transport inside the Exchange organization. When you're deploying a pure Exchange 2010 organization, or introducing Exchange 2010 into a pure Exchange Server 2007 organization, no additional configuration is required to establish routing in the forest. If you're deploying Exchange 2010 in an existing Exchange Server 2003 organization, you must follow specific configuration steps to enable routing between Exchange 2010 and Exchange 2003. For more information about how to configure the Hub Transport server role for coexistence with Exchange 2003, see Upgrade from Exchange 2003 Transport.

Contents

Determining Site Membership

Overview of IP Site Links

Exchange 2010 Placement in Active Directory Sites

How Exchange 2010 Uses Site Membership

Exchange 2010 is a site-aware application. Site-aware applications can determine their own Active Directory site membership and the Active Directory site membership of other servers by querying Active Directory. Exchange 2010 uses site membership to determine which domain controllers and global catalog servers to use for processing Active Directory queries. Additionally, when a server running Exchange has to determine the Active Directory site membership of another Exchange server, it can query Active Directory to retrieve the site name.

In Exchange 2010, the Microsoft Exchange Active Directory Topology service is responsible for updating the site attribute of the Exchange server object. Because the Active Directory site membership is a server object attribute, Exchange doesn't have to query the Domain Name System (DNS) to resolve a server address to a subnet associated with an Active Directory site. Stamping the Active Directory site attribute on an Exchange server object also enables Active Directory site membership to be assigned to a server that isn't a domain member, such as a subscribed Edge Transport server.

The Exchange 2010 server roles use Active Directory site membership information as follows:

- **Mail submission** The Mailbox server role uses Active Directory site membership information to determine which Hub Transport servers are located in the same Active Directory site as the Mailbox servers with the same server version. The Mailbox server submits messages for routing and transport to a Hub Transport server that has the same Active Directory site membership and the same server version as the Mailbox server.
- **Mail delivery** The Hub Transport server performs recipient resolution and queries Active Directory to match an e-mail address to a recipient account. The recipient account information includes the fully qualified domain name (FQDN) of the user's Mailbox server. The Hub Transport server queries Active Directory to determine the Active Directory site of the user's Mailbox server. If the Mailbox server is in the same site as the Hub Transport server, it will deliver the message to that Mailbox server. Otherwise, it will relay the message to another Hub Transport server in the same site as the target Mailbox server for delivery.
- **Message routing** Exchange 2010 Hub Transport servers retrieve information from Active Directory to determine how mail should be routed inside the organization. When a message is submitted to the Microsoft Exchange Transport service, the categorizer uses the header information in the message to query Active Directory for information about where the message must be delivered. If the recipient's mailbox is located on a Mailbox server in the same Active Directory site as the Hub Transport server and the version of the Mailbox server matches the Hub Transport server, the message is delivered directly to that mailbox. If the recipient's mailbox is located on a Mailbox server that has a different server version than the Hub Transport server, the message is relayed to a Hub Transport server in the site that matches the version of the Mailbox server. If the recipient's mailbox is located on a Mailbox server in a different Active Directory site, the message is relayed to a Hub Transport server in that site and then delivered to the Mailbox server.
- **Unified Messaging message submission** The Unified Messaging server role

uses Active Directory site membership information to determine which Hub Transport servers are located in the same Active Directory site as the Unified Messaging server. The Unified Messaging server submits messages for routing to a Hub Transport server within the same Active Directory site. The Hub Transport server performs recipient resolution and queries Active Directory to match a telephone number, or another Unified Messaging property, to a recipient account. After the recipient resolution completes, the Hub transport server will deliver the message to the target mailbox in the same way as a regular e-mail message.

- **Client connections to Client Access server** When the Client Access server receives a user connection request, it queries Active Directory to determine which Mailbox server is hosting the user's mailbox. The Client Access server then retrieves the Active Directory site membership of that Mailbox server. If the Client Access server that received the initial user connection isn't located in the same site as the user's Mailbox server, the connection is redirected to a Client Access server in the same site as the Mailbox server.
- **Public folder referrals** Active Directory site membership and IP site link information is used to prioritize the list of servers used for public folder referrals. Users are directed first to the default public folder database for their mailbox database. If a replica of the public folder being accessed doesn't exist in the default public folder database, the Mailbox store where the default public folder database resides will provide a prioritized referral list of Mailbox servers that hold a replica to the client. Public folder databases in the same Active Directory site as the default public folder database are listed first, and additional referral locations are prioritized based on Active Directory site proximity. Active Directory site proximity is determined by aggregating the costs of the IP site links between the Active Directory site where the default public folder database resides and the Active Directory sites where public folder replicas exist. The list of referrals is prioritized from lowest cost to highest cost. The connecting client will try each referral in the list until a connection is made or all attempts fail.

Determining Site Membership

Active Directory clients assume site membership by matching their assigned IP address to a subnet defined in Active Directory Sites and Services and associated with an Active Directory site. The client then uses this information to determine which domain controllers and global catalog servers exist in that site and communicates with those directory servers for authentication and authorization purposes. Exchange 2010 takes advantage of this relationship by also preferring to retrieve information about recipients from directory servers in the same site as the Exchange 2010 server.

All computers that are part of the same Active Directory site are considered well connected, with a high-speed, reliable network connection. By default, when an Active Directory forest is first deployed, there's a single site named Default-First-Site-Name. If no other sites are manually configured by the administrator, all server and client computers in the forest are considered members of Default-First-Site-Name.

When more than one site is defined, the Active Directory administrator must define the subnets present in the organization and associate those subnets with Active Directory sites.

The Microsoft Exchange Active Directory Topology service checks the site membership attribute on the Exchange server object when the server starts. If the site attribute has to be updated, the Microsoft Exchange Active Directory Topology service stamps the attribute with the new value. The Microsoft Exchange Active Directory Topology service verifies the site attribute value every 15 minutes and updates the value if site membership has changed. The Microsoft Exchange Active Directory Topology service uses the Net Logon service to obtain current site membership. The Net Logon service updates

site membership every five minutes. This means that up to a 20 minute latency period may pass between the time that site membership changes and the new value is stamped on the site attribute.

Overview of IP Site Links

Relationships between Active Directory sites are defined by IP site links. The IP site link consists of two or more Active Directory sites. All Active Directory sites that are part of the link communicate at the same cost. The IP site link properties include a cost assignment, a schedule, and an interval. The schedule and interval properties are only used for determining Active Directory replication frequency. Exchange 2010 uses the cost assignment to determine the lowest cost route for traffic to follow when multiple paths exist to the destination. The cost of the route is determined by aggregating the cost of all site links in a transmission path. The Active Directory administrator assigns the cost to a link based on relative network speed and available bandwidth compared to other available connections.

By default, the Hub Transport server always tries a direct connection to a Hub Transport server in another Active Directory site. Messages in transport don't relay through each Hub Transport server in a site link path. However, Hub Transport servers in intermediate Active Directory sites along the routing path may perform message relay in the following scenarios:

- Direct relay between Hub Transport servers won't occur when a hub site exists along the least cost routing path. You can configure an Active Directory site as a hub site so that messages are routed to the hub site to be processed before the messages are relayed to the target server. Hub sites are discussed later in this topic.
- Exchange 2010 uses the routing path derived from IP site link information when communication to the destination Active Directory site fails. If no Hub Transport server in the destination Active Directory site responds, message delivery backs off along the least cost routing path until a connection is made to a Hub Transport server in an Active Directory site along the routing path. The messages are queued in that Active Directory site and the queue will be in a retry state. This behavior is called *queue at point of failure*.
- The Hub Transport server can also use the IP site link information to optimize routing of messages sent to multiple recipients. The Hub Transport server delays bifurcation of messages until it reaches a fork in the routing paths to the recipients. The bifurcated message is relayed to each recipient destination by a Hub Transport server in the Active Directory site that represents the fork in the individual routing paths. This functionality is called *delayed fan-out*.

Designating Hub Sites

By default, the Hub Transport servers located in Active Directory sites along the path between the source server and the destination server don't process or relay the messages. You can use the **Set-AdSite** cmdlet to override this behavior by configuring an Active Directory site as a hub site. When a hub site exists along the least cost routing path between two Hub Transport servers, the messages are routed to the hub site for processing before they are relayed to the destination server. For this routing behavior to occur, the hub site must exist along the least cost routing path between two Hub Transport servers. This configuration should only be used when it's required by the network topology, such as when firewalls exist between Active Directory sites and prevent direct relay of SMTP communications.

Setting an Exchange-Specific Cost on an IP Site Link

You can use the **Set-AdSiteLink** cmdlet in the Exchange Management Shell to configure an Exchange-specific cost to an Active Directory IP site link. The Exchange-specific cost is a separate attribute used instead of the Active Directory-assigned cost to determine the

Exchange routing path. This configuration is useful when the Active Directory IP site link costs don't result in an optimal Exchange message routing topology.

Setting Message Size Restrictions on IP Site Links

By default, Exchange 2010 doesn't impose a maximum message size limit on messages relayed between Hub Transport servers in different Active Directory sites. If you use the **Set-AdSiteLink** cmdlet to configure a maximum message size on an Active Directory IP site link, routing generates a non-delivery report (NDR) for any message that has a size larger than the maximum message size limit configured on any Active Directory site link in the least cost routing path. This configuration is useful for restricting the size of messages sent to remote Active Directory sites that must communicate over low-bandwidth connections.

Exchange 2010 Placement in Active Directory Sites

For message routing between Exchange 2010 roles to occur correctly, all roles deployed in the forest must belong to an Active Directory site. Make sure that the IP addresses that you have assigned are in subnets that are correctly associated with Active Directory sites.

The first step in planning the placement of Exchange 2010 servers in the Active Directory site topology is to document the current topology. Your documentation should include the following:

- Sites
- Subnets and their site association
- IP site links and their member sites
- IP site link costs
- Directory servers in each site
- Physical network connections
- Firewall locations

After you have diagrammed these objects, plan the placement of Exchange servers. Consider the following information when deciding where to put servers:

- A Hub Transport server must be able to communicate directly with a global catalog server to perform Active Directory lookups.
- Mailbox servers should be located in the same site as a Hub Transport server. We recommend that you deploy more than one Hub Transport server in each Active Directory site to provide load balancing and fault tolerance.
- Unified Messaging servers submit messages to a Hub Transport server for transport to a Mailbox server. A Unified Messaging server may be located in a hub site or near the IP or Voice over IP (VoIP) gateway or IP Private Branch eXchange (IP PBX). The Hub Transport server that has the same site membership as the Unified Messaging server will receive messages for transport and route the messages to other Hub Transport servers and Mailbox servers in the organization.
- Client Access servers provide a connectivity point to the Exchange organization for users who are accessing Exchange remotely. A Client Access server must be deployed in each site that contains Mailbox servers.

After you plan Exchange 2010 server placement, you may identify areas where you can modify the Active Directory site topology to improve communication flow. You may want to adjust IP site links and site link costs to optimize delayed fan-out and queue at point of failure. An efficient Active Directory topology doesn't require any changes to support Exchange 2010.

1.2.1.8 Understanding Disjoint Namespace Scenarios

Understanding Disjoint Namespace Scenarios

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-28*

This topic provides information about the concept of disjoint namespaces and the supported scenarios for deploying Microsoft Exchange Server 2010 in a domain that has a disjoint namespace.

First, some background. Every computer that is on the Internet has a Domain Name System (DNS) name. This is also known as the *machine name* or *host name*. Every computer running the Microsoft Windows operating system with networking capabilities also has a NetBIOS name.

A computer running Windows in an Active Directory directory service domain has both a DNS domain name and a NetBIOS domain name. The DNS domain name consists of one or more subdomains separated by a dot (**.**) and is terminated by a top-level domain name. For example, in the DNS domain name corp.contoso.com, the subdomains are corp and contoso, and the top-level domain name is com. Typically, the NetBIOS domain name is the subdomain of the DNS domain name. For example, if the DNS domain name is contoso.com, the NetBIOS domain name is contoso. If the DNS domain name is corp.contoso.com, the NetBIOS domain name is corp.

A computer in an Active Directory domain also has a primary DNS suffix and can have additional DNS suffixes. By default, the primary DNS suffix is the same as the DNS domain name. For detailed steps about how to change the primary DNS suffix, see the procedures later in this topic.

You define the DNS domain name and NetBIOS domain name of an Active Directory domain when you configure the first domain controller in the domain. For more information about configuring domain controllers, see Domain controller role: Configuring a domain controller.

The procedures in this topic describe how to view the following items on a computer that is running Windows Server 2008 or Windows Server 2003:

- DNS host name
- Primary DNS suffix
- DNS domain name
- NetBIOS name
- NetBIOS domain name

Disjoint Namespaces

In most domain topologies, the primary DNS suffix of the computers in the domain is the same as the DNS domain name.

In some cases, you may require these namespaces to be different. This is called a *disjoint namespace*. For example, a merger or acquisition may cause you to have a topology with a disjoint namespace. In addition, if DNS management in your company is split between administrators who manage Active Directory and administrators who manage networks, you may need to have a topology with a disjoint namespace.

A disjoint namespace scenario is one in which the primary DNS suffix of a computer does not match the DNS domain name where that computer resides. The computer with the

primary DNS suffix that does not match is said to be disjoint. Another disjoint namespace scenario occurs if the NetBIOS domain name of a domain controller does not match the DNS domain name.

Exchange 2010 and Disjoint Namespaces

In Microsoft Exchange 2010, there are three supported scenarios for deploying Exchange in a domain that has a disjoint namespace. The supported scenarios are as follows:

- **Scenario 1** The primary DNS suffix of the domain controller is not the same as the DNS domain name. Computers that are members of the domain can be either disjoint or not disjoint.
- **Scenario 2** A member computer in an Active Directory domain is disjoint, even though the domain controller is not disjoint.
- **Scenario 3** The NetBIOS domain name of the domain controller is not the same as the subdomain of the DNS domain name of that domain controller.

These scenarios are detailed in the following sections.

Note:

It is supported to run Exchange 2010 in the disjoint namespace scenarios described above. If you have a disjoint namespace scenario that is not one of the three scenarios described in this topic, you must work with Microsoft Services to deploy Exchange 2010. For more information, see Microsoft Services.

Scenario 1

In this scenario, the primary DNS suffix of the domain controller isn't the same as the DNS domain name. The domain controller is disjoint in this scenario. Computers that are members of the domain, including Exchange servers and Microsoft Outlook client computers, can have a primary DNS suffix that either matches the primary DNS suffix of the domain controller or matches the DNS domain name.

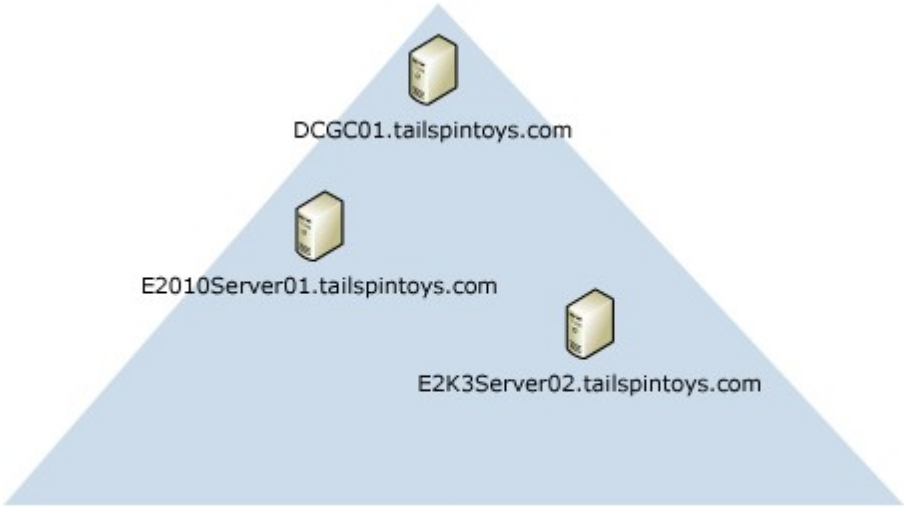
Scenario 2

In this scenario, the primary DNS suffix of a member computer on which Exchange 2010 is installed isn't the same as the DNS domain name, even though the primary DNS suffix of the domain controller is the same as the DNS domain name. In this scenario, you have a domain controller that isn't disjoint and a member computer that is disjoint. Member computers that are running Outlook can have a primary DNS suffix that either matches the primary DNS suffix of the disjoint Exchange server or matches the DNS domain name.

Scenario 3

In this scenario, the NetBIOS domain name of the domain controller isn't the same as the DNS domain name of the same domain controller.

NetBIOS domain name does not match DNS domain name



DNS domain name: tailspintoys.com
Primary DNS suffix for DCGC01, E2010Server01, and E2K3Server02: tailspintoys.com
NetBIOS domain name: CORP

Allow Exchange 2010 servers to access domain controllers that are disjoint

To allow Exchange 2010 servers to access domain controllers that are disjoint, you must modify the **msDS-AllowedDNSSuffixes** Active Directory attribute on the domain object container. You must add both of the DNS suffixes to the attribute. For detailed steps about how to modify the attribute, see The computer's primary DNS suffix does not match the FQDN of the domain where it resides.

In addition, to make sure that the DNS suffix search list contains all DNS namespaces that are deployed within the organization, you must configure the search list for each computer in the domain that is disjoint. The list of namespaces should include not only the primary DNS suffix of the domain controller and the DNS domain name, but also any additional namespaces for other servers with which Exchange may interoperate (such as monitoring servers or servers for third-party applications). You can do this by setting Group Policy for the domain. For more information about Group Policy, see the following topics:

- Group Policy Frequently Asked Questions (FAQ)
- New group policies for DNS in Windows Server 2003

For detailed steps about how to configure the DNS suffix search list Group Policy, see Configure the DNS Suffix Search List for a Disjoint Namespace.

View the DNS host name, primary DNS suffix, DNS domain name, NetBIOS name, and NetBIOS domain name of a computer running Windows Server 2008

1. Click **Start**, right-click **Computer**, and then click **Properties**.
2. In **System**, the DNS host name and primary DNS suffix are displayed under **Computer name, domain, and workgroup settings**, next to **Full computer name**. The DNS domain name is displayed next to **Domain**.
3. Click **Change settings**.
4. In **System Properties**, on the **Computer Name** tab, click **Change**.
5. In **Computer Name/Domain Changes**, click **More**. The primary DNS suffix is displayed under **Primary DNS suffix of this computer**. The NetBIOS computer name is displayed under **NetBIOS computer name**.
   To change the primary DNS suffix, type the new primary DNS suffix under **Primary DNS suffix of this computer**, and then click **OK**.
6. From a Command Prompt window, type **set**. The variable USERDNSDOMAIN displays the DNS domain name. The variable USERDOMAIN displays the

NetBIOS domain name.

View the DNS host name, primary DNS suffix, DNS domain name, NetBIOS name, and NetBIOS domain name of a computer running Windows Server 2003

1. Click **Start**, right-click **My Computer**, and then click **Properties**.
2. In **System Properties**, click the **Computer Name** tab. The DNS host name and primary DNS suffix are displayed next to **Full computer name**. The DNS domain name is displayed next to **Domain**.
3. On the **Computer Name** tab, click **Change**.
4. On the **Computer Name Changes** page, click **More**. The primary DNS suffix is displayed under **Primary DNS suffix of this computer**. The NetBIOS computer name is displayed under **NetBIOS computer name**.
   To change the primary DNS suffix, type the new primary DNS suffix under **Primary DNS suffix of this computer**, and then click **OK**.
5. From a Command Prompt window, type **set**. The variable USERDNSDOMAIN displays the DNS domain name. The variable USERDOMAIN displays the NetBIOS domain name.

Note:
You can also run the command **ipconfig /all** from a Command Prompt window to view the primary DNS suffix. However, if you have a policy that overrides the primary DNS suffix, this command will not display the correct primary DNS suffix.

1.2.1.8.1 Configure the DNS Suffix Search List for a Disjoint Namespace

Configure the DNS Suffix Search List for a Disjoint Namespace

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-08*

You can use the Group Policy Management console (GPMC) to configure the Domain Name System (DNS) suffix search list. In some Microsoft Exchange 2010 scenarios, if you have a disjoint namespace, you must configure the DNS suffix search list to include multiple DNS suffixes.

For more information about Group Policy, see Windows Server Group Policy. For more information about disjoint namespace scenarios, see Understanding Disjoint Namespace Scenarios.

Prerequisites

Confirm that you have installed .NET Framework 3.0 on the computer on which you will install GPMC.

Note:
The current version of GPMC that you can download from the Microsoft Download Center operates on the 32-bit versions of the Windows Server 2003 and Windows XP operating systems and can remotely manage Group Policy objects on 32-bit and 64-bit domain controllers. This version of GPMC doesn't include a 64-bit version, and the 32-bit version doesn't run on 64-bit platforms. The 32-bit version of Windows Server 2008 and the 32-bit version of Windows Vista both include a 32-bit version of GPMC. The 64-bit version of Windows Server 2008 and the 64-bit version of Windows Vista both include a 64-bit version of GPMC.

Configure DNS suffix search list

To perform this procedure, the account you use must be delegated membership in the Domain Admins group.

1. On a 32-bit computer in your domain, install GPMC with Service Pack 1 (SP1). For download information, see Group Policy Management Console with Service Pack 1.

   Note:
   If you have a computer in your domain running Windows Server 2008 or Windows Vista, you can skip this step.

2. Click **Start**, click **Programs**, click **Administrative Tools**, and then click **Group Policy Management**.
3. In **Group Policy Management**, expand the forest and the domain in which you will apply Group Policy. Right-click **Group Policy Objects**, and then click **New**.
4. In **New GPO**, type a name for the policy, and then click **OK**.
5. Right-click the new policy that you created in Step 4, and then click **Edit**.
6. In **Group Policy Management Editor**, expand **Computer Configuration**, expand **Policies**, expand **Administrative Templates**, expand **Network**, and then click **DNS Client**.
7. Right-click **DNS Suffix Search List**, click **All Tasks**, and then click **Edit**.
8. On the **DNS Suffix Search List Properties** page, select **Enabled**. In the **DNS Suffixes** box, type the primary DNS suffix of the disjoint computer, the DNS domain name, and any additional namespaces for other servers with which Exchange may interoperate, such as monitoring servers or servers for third-party applications. Click **OK**.
9. In **Group Policy Management**, expand **Group Policy Objects**, and then select the policy that you created in Step 4. On the **Scope** tab, scope the policy so that it applies to only the computers that are disjoint.

1.2.1.9 Mailbox Server Storage Design

Mailbox Server Storage Design

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-08*

Storage design is a critical piece of a successful Microsoft Exchange Server 2010 Mailbox server role deployment. Multiple requirements such as storage performance, capacity, manageability, and cost must all be considered to achieve the optimal storage design for Exchange 2010. This section covers the storage design process as well as the storage design options, support criteria, and best practices related to the Exchange 2010 Mailbox server role. Information is also provided about required storage inputs and storage testing and validation.

Other topics in this section include:

Mailbox Storage Design Process

Understanding High Availability Factors

1.2.1.9.1 Mailbox Storage Design Process

Mailbox Storage Design Process

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

We recommend breaking the storage design process into three steps. The following sections provide detailed information about each of the design steps, including mailbox storage requirements and best practices.

Step 1: Gather Storage Input Requirements

Several Exchange 2010 architectural factors influence mailbox storage design. The following table lists the most important factors that affect mailbox storage design.

Architectural factors in mailbox storage design

Design factor	Description	Storage design impact
Mailbox count	The maximum number of mailboxes targeted to be hosted on a specific Mailbox server.	**Performance** More mailboxes equal more messages delivered and opened per server. This generates more log and database I/O. **Capacity** More mailboxes equal more capacity to store mailbox content. This affects the number of databases and size of databases per server. More mailboxes also equal more logs generated per server per day.

		Reliability In general, the more mailboxes hosted on the Mailbox server, the greater the need for high availability.
Mailbox concurrency	The percentage of users that connect to the Mailbox server at the same time measured over a one hour period.	**Performance** Higher concurrency equals more messages delivered and opened per server. This generates more log and database I/O. In general, 100 percent concurrency is used for standard information worker storage sizing. **Capacity** Higher concurrency equals more logs generated per server per day.
Mailbox size	The maximum mailbox quota per mailbox, for example, maximum mailbox size equals 10 GB. This includes capacity required for the primary mailbox, personal archive, and recoverable items (dumpster) data.	**Performance** Larger primary mailboxes equal more content to process for infrequent database operations, for example, full Microsoft Outlook offline folder files (.ost) sync and new view creation in Microsoft Office Outlook Web App. This can generate slightly more log and database I/O. **Capacity** Larger mailboxes equal more capacity to store mailbox content. This affects the number of databases and size of databases per server.
Mailbox usage profile	The usage characteristics of users on the Mailbox servers, generally defined as messages sent and received per day and average message size in kilobytes (KB).	**Performance** The more intensive the mailbox usage profile, the more log and database I/O that can be generated. **Capacity** A more intensive mailbox usage profile equals more logs generated per server per day.
E-mail client types	The types and percentages of different e-mail clients, for example, Outlook 2003 Cached Exchange Mode, Windows Mobile, Microsoft Exchange ActiveSync, and	**Performance** Different clients exhibit different performance characteristics on the server.

	Microsoft Office Outlook Web App.	
E-mail client extensions	Microsoft and third-party applications that extend the functionality of the e-mail client, for example, Office Communicator and Windows Desktop Search clients.	**Performance** Depending upon implementation, e-mail client extension applications can have a light to very heavy I/O impact on the Mailbox server database I/O.
Server applications	Applications that either run on or against Exchange Mailbox servers, for example, third-party mobile device applications and antivirus applications.	**Performance** Depending on implementation, server applications can have a light to very heavy I/O impact on Mailbox server database I/O.
High availability requirements	Whether Exchange 2010 high availability is used and how it's configured, for example, number of copies, number of sites, and lagged copies.	**Performance** High availability solutions may require slightly more I/O than non-high availability solutions to handle the additional log volume I/O produced by log replication. **Capacity** Using high availability increases the amount of database file storage required (depending upon the number of copies). If circular logging is used, log capacity may be reduced. Using high availability equals more logs generated per server per day. **Reliability** Deploying high availability increases the viable number of storage options. Less reliable storage, storage without RAID or just a bunch of disks (JBOD), may be used when multiple database copies are used in a high availability deployment.

For more information about the features mentioned in the preceding table, see the following topics:

- Understanding Database Availability Groups
- Understanding High Availability and Site Resilience
- Understanding Recoverable Items
- Understanding the Exchange 2010 Store
- Managing Mailbox Databases

Step 2: Design Storage Architecture Based on I/O and Capacity Requirements

After you've completed gathering the Exchange 2010 storage input requirements, you need to design your storage architecture based on I/O and capacity requirements. There are several ways to configure your storage architecture. You can calculate the requirements for the storage architecture manually, or you can use the Exchange 2010 Mailbox Server Role Requirements Calculator. Calculating your requirements manually requires a deeper understanding of mailbox storage design, which is provided by the topics listed in "Calculate the Mailbox Server Role Requirements Manually" later in this topic. When you use the Mailbox Server Role Calculator, it allows you to input your information, and then it provides a recommended best practice for your design.

Calculate the Mailbox Server Role Requirements Manually

Complete the following steps to derive your Mailbox server role architecture:

1. To determine your high availability model, see Understanding High Availability Factors.
2. To calculate your database and log capacity requirements, see Understanding Mailbox Database and Log Capacity Factors.
3. To determine your memory requirements, see Understanding the Mailbox Database Cache.
4. To calculate your database and log performance requirements, see Understanding Database and Log Performance Factors.
5. To determine your logical unit number (LUN) architecture based on your requirements, see Understanding Exchange 2010 LUN Architecture.
6. To determine your storage architecture based on your requirements, see Understanding Storage Configuration.
7. To determine your CPU requirements, see Mailbox Server Processor Capacity Planning.

To see how all this information comes together, review Exchange 2010 Mailbox Server Role Design Example.

Use the Mailbox Server Role Requirements Calculator

The Exchange 2010 Mailbox Server Role Requirements Calculator enables you to determine your requirements for the Mailbox server role by specifying a set of input factors. The calculator can determine the requirements for memory, storage (I/O performance, capacity, and storage configuration), optimal LUN layout, and CPU megacycles. Many variables need to be accounted for before you can design an optimal solution for an Exchange 2010 Mailbox server, and the calculator can help you in your design process. For more information about the calculator (and to download the calculator), see the Exchange Server Team Blog article Exchange 2010 Mailbox Server Role Requirements Calculator.

Note:

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

Step 3: Validate Storage for Performance and Reliability

Before implementing a storage solution in a production environment, it's important that you validate that the solution is configured correctly. This section provides guidance for successfully testing a storage solution for Exchange, beginning with a program that includes solutions that have already been tested.

In addition, you'll find information about several tools that can help you manage, test, and monitor your storage solution. For more information about understanding and troubleshooting I/O performance, see Understanding Database and Log Performance Factors.

Exchange Solution Reviewed Program

When selecting a storage solution, we recommend you choose a solution that has been reviewed by the Microsoft Exchange Solution Reviewed Program (ESRP) for storage, known as ESRP-Storage. ESRP-Storage is an Exchange-specific test, best practices publication framework, and review process to facilitate the creation of known, good Exchange storage solutions. The goals of ESRP-Storage are to:

- Provide storage vendors with prescriptive guidance about Exchange storage testing and best practices publication.
- Develop a mechanism to review storage solutions to make sure that they meet Exchange best practices.
- Provide customers with well-tested and high-quality storage solutions targeted for Exchange deployments.

For more information, see Microsoft Exchange Solution Reviewed Program (ESRP).

Note:
ESRP-Storage isn't a Microsoft certification, qualification, or logo program.

Because storage can be configured in many ways, evaluating tested configurations and using best practices can reduce costs and decrease the time to deployment.

Storage Testing

Before testing a solution, some work is required to understand what it is you're trying to achieve by testing. Some of the keys to successful storage testing include:

- Determine testing goals. For example, consider the performance, throughput, and capacity numbers needed.
- Test with as many servers attached to the storage as you will have in production. This includes non-Exchange servers and workloads.
- Test with production-size databases with the physical disk capacities filled to production level. Most physical disk performance characteristics will change based on the data set size.
- Determine that storage meets the transactional I/O requirements, and determine the maximum performance of the solution within acceptable latencies.
- Determine that storage meets the backup throughput and performance requirements to meet your backup and restore service level agreement (SLA).

Storage-Related Tools

The Microsoft Exchange Server Jetstress tool accurately simulates Exchange I/O characteristics. It includes both a stress test and a performance test, which show the maximum performance of a LUN within acceptable latencies. The Exchange Load Generator simulates Microsoft Office Outlook clients.

Both tools simulate Outlook. Simulating Outlook clients is the only way to measure actual client latency (rather than just the server disk latency). For more information about these tools, including how to download them, see Tools for Performance and Scalability Evaluation.

Important:
The Exchange Jetstress tool should be used on systems prior to placing production data on the server. Jetstress shouldn't be used on systems containing production data.

Important:
The Exchange Load Generator is intended for use in test environments, not in production environments.

Monitoring Server Storage Health

Monitoring your storage solution is critical in identifying hardware and software warnings and error conditions before they lead to data corruption or downtime.

The following tools can help monitor your storage solution. These tools are available in the **Toolbox** node of the Exchange Management Console:

- Best Practices Analyzer Tool
- Performance Monitor
- Performance Troubleshooter

In addition, you can also use Microsoft System Center Operations Manager 2007 to monitor your storage solution, as well as several other aspects of your Exchange organization.

Performance Monitor (perfmon.exe) is the Microsoft Management Console (MMC) performance snap-in for Exchange 2010. Perfmon, which uses the MSExchangeIS performance object to retrieve counter information, provides information that allows you to gauge the health of your storage solution. For more information, see Performance and Scalability Counters and Thresholds.

Monitoring Storage Solution Health

On many storage solutions, there's a way to see performance metrics. Monitoring these metrics can catch performance issues before they affect Exchange. If available, System Center Operations Manager 2007 integration from the storage vendor can assist in making sometimes proprietary metrics easy to understand. Some of the general metrics to watch include:

- **Disk Utilization Percentage** How busy are the physical disks?
- **Read Cache Hit Ratio** How well is the storage controller cache being utilized?
- **Write Pending Requests** How often is the controller waiting for the physical disk?
- **Storage Processor Utilization Percentage** How busy is the storage controller processor?

1.2.1.9.2 Understanding High Availability Factors

Understanding High Availability Factors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-02*

When planning a highly available Mailbox server and database architecture, design decisions must be considered, such as:

- Will you deploy multiple database copies?
- How many database copies will you deploy?
- Will you have an architecture that provides site resilience?
- What kind of Mailbox server resiliency model will you deploy?
- How many Mailbox servers will you deploy?
- How will you distribute database copies?
- What backup model will you use?
- What storage architecture will you use?

Microsoft Exchange Server 2010 enables you to deploy your Mailbox server infrastructure using standalone Mailbox servers or Mailbox servers configured for mailbox resiliency. Mailbox servers configured for mailbox resiliency employ a database availability group (DAG) with multiple database copies efficiently distributed throughout the DAG. By deploying multiple database copies, you can:

- Design a solution that mitigates the most common reason for using a backup. Database copies provide protection against hardware, software, and data center failures.
- Increase database sizes up to 2 terabytes because your recovery mechanism is another database copy and not restoration from backup.
- Consider storage architecture alternatives to a traditional RAID configuration like just a bunch of disks (JBOD), if you deploy three or more database copies. The combination of JBOD and less expensive disks can result in cost savings for your organization.

By distributing active databases across all the servers that participate within a DAG, you can maximize the efficiency of your hardware.

For more detailed information, see Planning for High Availability and Site Resilience and Understanding Backup, Restore and Disaster Recovery.

Contents

Looking for management tasks related to high availability? See Managing High Availability and Site Resilience.

Planning the Number of Database Copies to Deploy

As discussed in Understanding Mailbox Database Copies, a DAG member can host one copy of each mailbox database, with a maximum of 100 databases per server in the Enterprise Edition of the product (both active and passive copies count toward this limit). This means that there is a limit of 1,600 databases supported by a 16-member DAG (100 database copies per server × 16 servers per DAG ÷ 1 copy per database = 1,600 databases per DAG).

In a high availability configuration, there's no value to deploying a single copy of a database because it doesn't provide data redundancy. You use a formula to determine the number of databases a specific DAG can support. For example, if you choose D to be the number of databases being deployed, C to be the number of copies of each database,

and S to be the number of servers, the following applies:

- D × C = total number of database copies in the DAG
- (D × C) ÷ S = database copies per server

Note:
The resulting number of databases per server must be 100 or less when using the Enterprise Edition and 5 or less when using the Standard Edition.

For example, let's assume that you have a DAG with 6 servers and 84 mailbox databases, with 3 copies of each database. (Note that 6 servers is an integer multiple of 3 copies.) The following applies:

- 84 databases × 3 copies = 252 databases total
- 252 databases ÷ 6 servers = 42 database copies per server

In another example, you have a DAG with 4 servers and 136 mailbox databases, with 3 copies of each database. The following applies:

- 136 databases × 3 copies = 408 databases total
- 408 databases ÷ 4 servers = 102 database copies per server

Because 102 is greater than 100, the proposed scenario isn't a valid DAG design.

Return to top

Database Copy Types

There are two types of database copies:

- Highly available database copies
- Lagged database copies

Highly available database copies are copies configured with a replay lag time of zero. As their name implies, highly available database copies are kept up-to-date by the system, can be automatically activated by the system, and are used to provide high availability for mailbox service and data.

Lagged database copies are copies configured to delay transaction log replay for a period of time. Lagged database copies are designed to provide point-in-time protection, which can be used to recover from store logical corruptions, administrative errors (for example, deleting or purging a disconnected mailbox), and automation errors (for example, bulk purging of disconnected mailboxes).

Typically, lagged database copies aren't activated due to the Active Manager Best Copy Selection algorithm. Because lagged database copies are deployed to mitigate operational risks, they shouldn't be activated. If activated and if a mount request is issued, log replay begins, replaying all required log files to bring the database up-to-date and in a clean shutdown state, thus losing the point-in-time capability.

For more information about how to block activation at the Mailbox server level or suspend activation for one or more database copies to prevent a database copy (such as a lagged database copy) from being automatically activated, see Set-MailboxServer and Suspend-MailboxDatabaseCopy.

Return to top

Site Resilience

Your environment may consist of multiple data centers. As part of your Exchange 2010 design, determine if you will deploy the Exchange infrastructure in a single data center or

distribute it across two or more data centers. Your organization's recovery service level agreements (SLAs) should define what level of service is required following a primary data center failure.

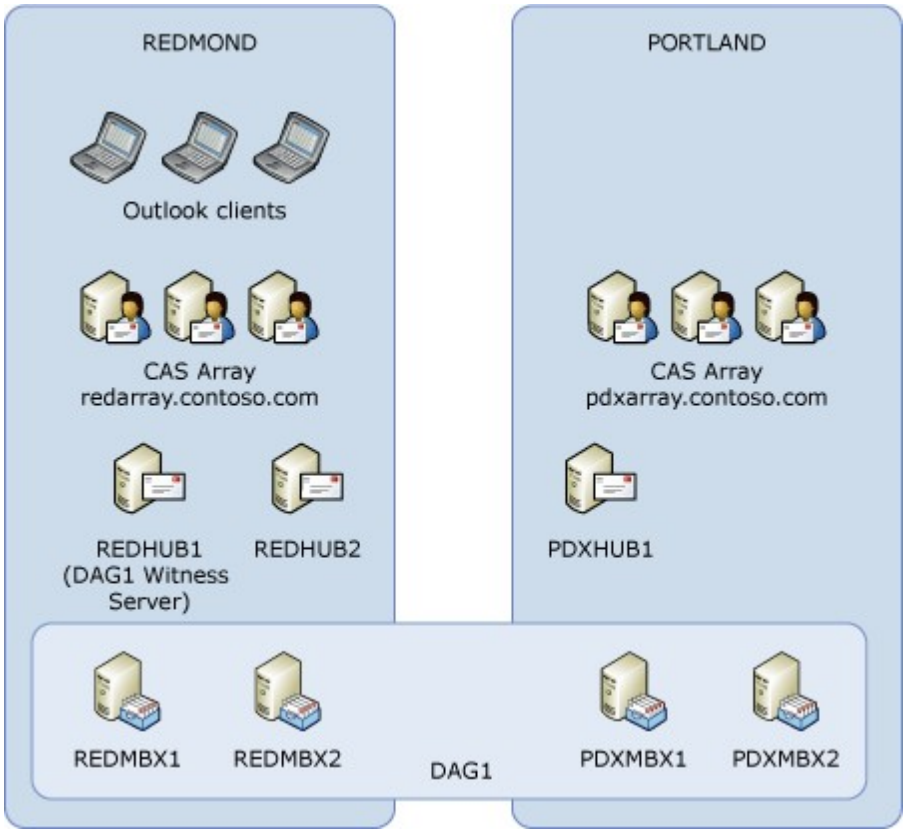
If your Exchange deployment will be deployed across multiple data centers to support site resilience goals, consider which user distribution model applies. There are two types of user distribution models, based on the mailbox locality with respect to the data center:

- Active/passive user distribution model
- Active/active user distribution model

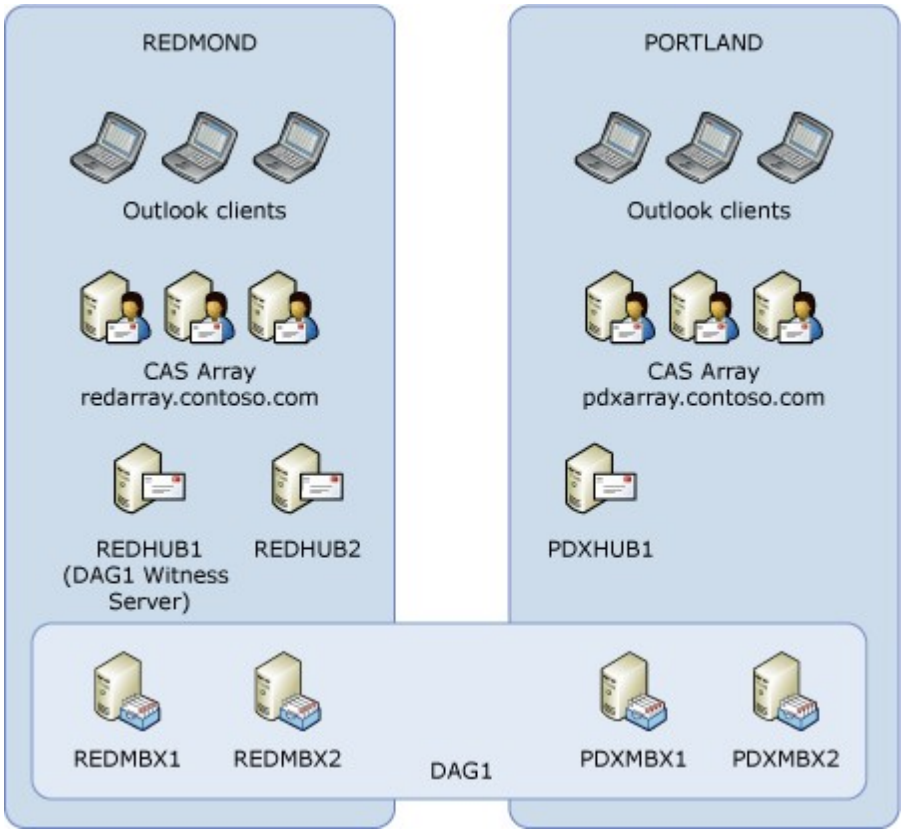
If user mailboxes are primarily located in a single data center (or if users access their data through a single data center) and there's an SLA requirement that the users continue to access their data via the primary data center during normal operations, your architecture is an active/passive user distribution model.

If user mailboxes are dispersed across data centers and there's an SLA requirement that the users continue to access their data via the primary data center during normal operations, your architecture is an active/active user distribution model.

In an active/passive user distribution model, you can deploy your architecture as shown in the following figure, where the active mailboxes are hosted from the primary data center, but database copies are deployed in the secondary data center.

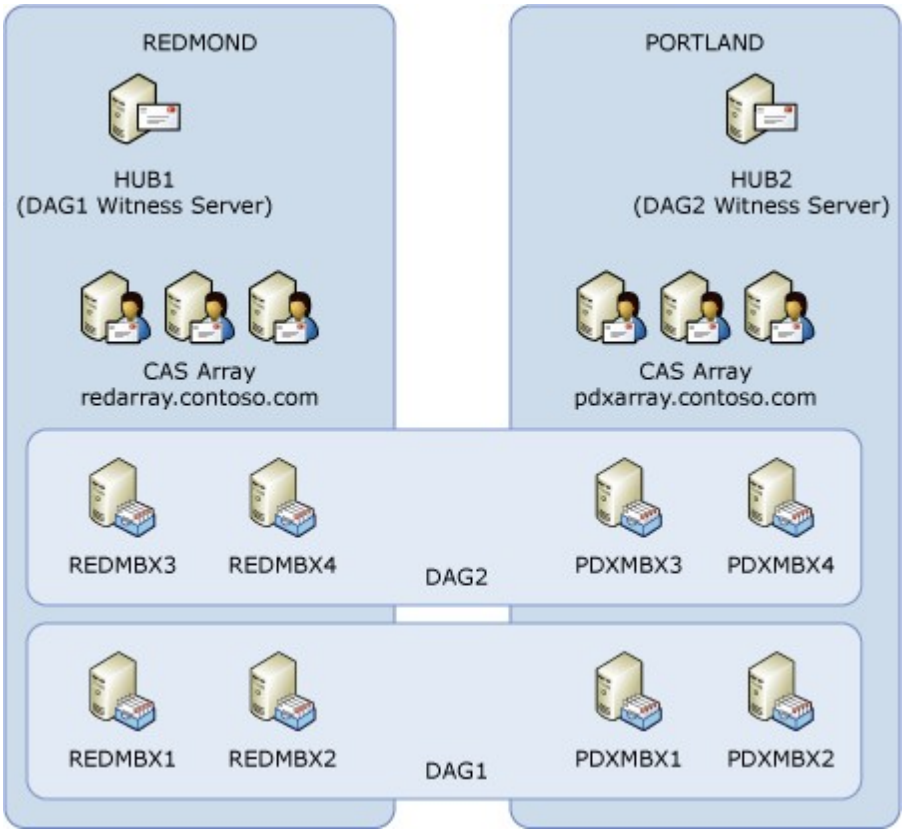


The architecture shown in the following figure could potentially be used for an active/ active user distribution model.



However, there's a risk with the architecture shown in the preceding figure. The wide area network (WAN) is a single point of failure for the DAG. The loss of the WAN will result in the loss of quorum for the DAG members in the second data center. In this example, the Windows failover cluster has a total of five votes (four DAG members plus the witness server), requiring three votes to be available at all times for the failover cluster to remain operational. Three of the votes are located in the Redmond data center, and two of the votes are located in the Portland data center. The loss of the WAN connection results in the Portland data center hosting only two of the votes, which isn't sufficient to maintain quorum. The Redmond data center has three votes, and thus can maintain quorum and continue to service the active mailboxes (as long as those three votes are operational).

To mitigate this risk for active/active user distribution models, we recommend deploying two DAGs, as shown in the following figure.



DAG1 hosts the active mailboxes for the Redmond data center and is implemented as an active/passive user distribution model, with passive database copies deployed in the Portland data center. DAG2 hosts the active mailboxes for the Portland data center and is implemented as an active/passive user distribution model, with passive database copies deployed in the Redmond data center.

This architecture can survive the loss of the WAN:

- In the Redmond data center, the Mailbox server members for DAG2 go into a failed state due to loss of quorum, but the active Mailbox server members for DAG1 remain operational, servicing users.
- In the Portland data center, the Mailbox server members for DAG1 go into a failed state due to loss of quorum, but the active Mailbox server members for DAG2 remain operational, servicing users.

For more information, see Planning for High Availability and Site Resilience.

Return to top

Planning the Mailbox Server Resilience Model

A key aspect to Exchange 2010 Mailbox server capacity planning is determining how many database copies you plan to activate on a per-server basis when configured for mailbox resiliency. A range of designs are possible, but two models are recommended, as described in the following sections.

Design for All Database Copies Activated

You can design your server architecture to handle 100 percent of all hosted database

copies becoming active. For example, if your server hosts 35 database copies, you design the processor and memory to accommodate all 35 databases being active during the peak period of user activity. This solution is usually deployed in pairs. For example, if deploying four servers, one pair is servers 1 and 2, and the second pair is servers 3 and 4. In addition, when designing for this scenario, you size each server for no more than 40 percent available resources for normal run-time operations.

Of the two models discussed in this topic, this model has a higher server count.

Design for Targeted Failure Scenarios

You can design your server architecture to handle the active mailbox load during the worst failure case you plan to accommodate. There are many factors to consider in this model, including site resiliency; RAID storage vs. JBOD; DAG size; and database copy count. This capacity planning model provides a balance between capital costs, availability, and client performance characteristics.

Assuming the database copies are randomly and evenly distributed:

- Design for automatic, single-member server failure in two-member or three-member DAG configurations with two highly available database copies per mailbox database.
- Design for double-member server failure (manual activation after second failure) in three-member DAG configurations with three highly available database copies per mailbox database.
- Design for automatic, double-member server failures where the DAG has four or more members and three or more highly available database copies per mailbox database.

If you choose this capacity planning model, we strongly recommend that you restrict the number of databases that can be activated per server so that a single server doesn't become overloaded and provide a poor client experience.

You can restrict the number of databases by configuring the maximum active databases setting. You can configure this limit in the Exchange Management Shell by running: `Set-MailboxServer -MaximumActiveDatabases`. Configure this limit on each server in the DAG to match the maximum active databases supported by your deployment.

For more information, see Database Availability Group Design Examples.

Return to top

Planning the Number of Mailbox Servers to Deploy

When determining the number of Mailbox servers to deploy, use a multiple of the number of database copies being deployed. For example, if you plan to deploy three database copies, start the design with either 3, 6, 9, 12, or 15 servers.

After you determine the starting point for the number of servers within the DAG, scale the DAG members appropriately based on the number of mailboxes, the failure design model, and other design constraints that may either increase or reduce the number of Mailbox servers required.

One design constraint that many organizations have is a maximum number of mailboxes that can be placed on a server. For example, if an organization has 20,000 mailboxes and only 25 percent can be impacted during a failure event, the maximum number of mailboxes that can be deployed on a single server is 5,000. This requires deploying a minimum of four Mailbox servers.

The selected server hardware and storage model may also cause an adjustment to the number of mailboxes or number of database copies you deploy per server, which can affect the total number of Mailbox servers.

Multiple Role Servers vs. Stand-Alone Role Servers

In Exchange Server 2007, the Client Access and Hub Transport server roles are required to be on servers separate from clustered Mailbox servers. In Exchange 2010, clustered Mailbox servers no longer exist so this restriction no longer applies. Client Access and Hub Transport server roles can be hosted on DAG members, providing improved deployment options.

When deploying multiple role servers (Mailbox, Client Access, and Hub Transport server roles on the same server), most architectures are simplified. Other than the Edge Transport and Unified Messaging servers, all Exchange 2010 servers can be identical. These servers can have the same hardware, software installation process, and configuration options. Consistency across servers can simplify the administration of Exchange implementation.

The multiple role server (in high scale environments) provides more efficient use of high-core-count servers, which provide high megacycle capabilities. Each role, when deployed individually, has a recommended maximum of two populated processor sockets. When combining roles, the recommended maximum number of processor sockets is four. Servers can have larger workloads, which can reduce the overall number of servers in an organization. Deploying fewer servers reduces the cost of managing those servers, because the multiple role server changes cost from a recurring operational expense to a one-time capital expense. A reduced server count can result in significant power, cooling, and data center space reductions, which can further reduce recurring operational expenses.

Although the multiple role concept is efficient, stand-alone server roles may still be appropriate. For example, stand-alone role deployments might be appropriate in certain virtualized environments or when certain hardware architectures (for example, a blade server infrastructure where you can't isolate the hardware appropriately) are being utilized.

When deploying multiple role servers, you must design the processor and memory architecture appropriately. From a processor perspective, you should ensure that the Mailbox server role doesn't consume more than 40 percent of the available megacycles during the failure mode, leaving 40 percent for the Hub Transport and Client Access server roles. To ensure that adequate memory is available for all server roles, follow the memory guidance defined in Understanding the Mailbox Database Cache.

For more information, see Understanding Multiple Server Role Configurations in Capacity Planning.

Return to top

Planning the Database Copy Layout

As part of the high availability design, you need to design a balanced database copy layout. The following design principles should be used when planning the database copy layout:

- Ensure that you minimize multiple database copy failures of a specific mailbox database by isolating each copy. For example, don't place more than a single database copy of a specific mailbox database within the same server rack or in the same storage array. Otherwise, a rack or array failure will result in the failure of multiple copies of the same database, which affects the availability of the database.

- Lay out the database copies in a consistent, distributed way to ensure that the active mailbox databases are evenly distributed after a failure. The sum of the activation preferences of each database copy on any specific server must be equal or close to equal, because this results in an approximately equal distribution after failure, assuming replication is healthy and up-to-date.

For more information, see Database Copy Layout Design.

Return to top

Planning the Backup Model Architecture

Exchange 2010 includes several features and architectural changes that, when deployed and configured correctly, can provide native data protection, which eliminates the need to make traditional backups of your data. Use the following table to decide whether you need to continue utilizing a traditional backup model or whether you can implement the native data protection features in Exchange 2010.

Issue	Mitigation
Software failures	Mailbox resiliency (multiple database copies)
Hardware failures	Mailbox resiliency (multiple database copies)
Site or data center failures	Mailbox resiliency (multiple database copies)
Accidental or malicious deletion of items	Single item recovery and deleted item retention with a window that meets or exceeds the item recovery SLA
Physical corruption scenarios	Single page restore (highly available database copies)
Logical corruption scenarios	Single item recovery Calendar Repair Assistant Mailbox moves **New-MailboxRepairRequest** cmdlet Point-in-time backup
Administrative errors	Point-in-time backup
Automation errors	Point-in-time backup
Rogue administrators	Point-in-time backup (isolated)
Corporate or regulatory compliance requirements	Point-in-time backup (isolated)

Logical corruption is typically a scenario that requires a point-in-time backup. However, with Exchange 2010, there are several options available that can mitigate the need for a point-in-time backup:

- With single item recovery, if the user changes certain properties of an item in any mailbox folder, a copy of the item is saved in the Recoverable Items folder before the modification is written to the database. If the modification of the message results in a corrupted copy, the original item can be restored.
- The Calendar Repair Assistant detects and corrects inconsistencies that occur for single and recurring meeting items for mailboxes homed on that Mailbox

server so that recipients won't miss meeting announcements or have unreliable meeting information.
- During mailbox moves, the Microsoft Exchange Mailbox Replication service detects corrupted items and won't move those items to the target mailbox database.
- Exchange 2010 Service Pack 1 (SP1) introduces the New-MailboxRepairRequest cmdlet, which can fix corruptions with search folders, item counts, folder views, and parent/child folder issues.

A point-in-time backup can be either a traditional backup or a lagged database copy, which both provide the same capabilities. The choice between the two depends on your recovery SLA. The recovery SLA defines the recovery point objective (if a disaster occurs, the data must be restored within a certain timeframe), as well as how long the backups must be retained. If the recovery SLA is 14 days or less, a lagged database copy can be utilized. If the recovery SLA is greater than 14 days, a traditional backup must be used. For the rogue administrator and for corporate or regulatory compliance scenarios, the point-in-time backup typically is maintained separately from the messaging infrastructure and messaging IT staff, which dictates a traditional backup solution.

If you choose to maintain a point-in-time backup, several aspects of the design may change:
- Deploying lagged database copies has storage implications. Additional space must be allocated for the transaction logs on the lagged database copy due to the *ReplayLagTime* settings. In addition, the placement of the lagged database copy can affect your storage architecture. (For details, see "Planning the Storage Model Architecture" later in this topic.)
- Deploying a traditional backup solution has implications on the logical unit number (LUN) layout, depending on the type of Volume Shadow Copy Service (VSS) solution, because hardware-based VSS cloning solutions require two LUNs per database architecture.

Depending on the storage architecture, utilizing a traditional backup solution may require significantly reducing desired user mailbox sizes to meet your backup and restore timeframe SLAs.

When deploying Exchange native data protection, you enable circular logging on the mailbox databases. When enabling circular logging, ensure that sufficient capacity is built into the system so that the solution can survive disaster events that prevent log truncation. At a minimum, you should ensure that there is at least three days of transaction log capacity (excluding lagged copy requirements). For more information about how circular logging functions with continuous replication, see Understanding Backup, Restore and Disaster Recovery.

For additional information about planning backups, see:
- Understanding Exchange 2010 LUN Architecture
- Understanding Mailbox Database and Log Capacity Factors
- Understanding Calendar Repair
- Understanding Recoverable Items

Return to top

Planning the Storage Model Architecture

Exchange 2010 provides flexibility in storage design. Exchange 2010 includes improvements in performance, reliability, and high availability that enable organizations to run Exchange on a range of storage devices. Building on improvements to disk input/output (I/O) introduced in Exchange 2007, the latest version of Exchange requires less storage performance and is more tolerant of storage failures.

Select a storage platform that ensures you're balancing the capacity requirements with the I/O requirements, while ensuring the solution provides acceptable disk latency and a responsive user experience.

RAID or JBOD

Determine whether to implement the storage platform using RAID technology or a JBOD approach (assuming the storage platform allows JBOD configurations). From an Exchange perspective, JBOD means having both the database and its associated logs stored on a single disk. To deploy on JBOD, you must deploy a minimum of three highly available database copies. Utilizing a single disk is a single point of failure, because when the disk fails, the database copy residing on that disk is lost. Having a minimum of three database copies ensures fault tolerance by having two additional copies in the event that one copy (or disk) fails. However, placement of three highly available database copies, as well as the use of lagged database copies, can affect storage design. The following table shows guidelines for RAID or JBOD considerations.

RAID or JBOD considerations

Data center servers	Two highly available copies (total)	Three highly available copies (total)	Two or more highly available copies per data center	One lagged copy	Two or more lagged copies per data center
Primary data center servers	RAID	RAID or JBOD (2 copies)	RAID or JBOD	RAID	RAID or JBOD
Secondary data center servers	RAID	RAID (1 copy)	RAID or JBOD	RAID	RAID or JBOD

To deploy on JBOD with the primary data center servers, you need three or more highly available database copies within the DAG. If mixing lagged copies on the same server hosting highly available database copies (for example, not using dedicated lagged database copy servers), you need at least two lagged database copies.

For the secondary data center servers to use JBOD, you should have at least two highly available database copies in the secondary data center. The loss of a copy in the secondary data center won't result in requiring a reseed across the WAN or having a single point of failure in the event the secondary data center is activated. If mixing lagged database copies on the same server hosting highly available database copies (for example, not using dedicated lagged database copy servers), you need at least two lagged database copies.

For dedicated lagged database copy servers, you should have at least two lagged database copies within a data center to use JBOD. Otherwise, the loss of disk results in the loss of the lagged database copy, as well as the loss of the protection mechanism.

For more information, see Understanding Storage Configuration.

Return to top

Understanding Mailbox Database and Log Capacity Factors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-24*

This topic explains the factors that you should consider when you plan mailbox database and log capacity as part of your mailbox server storage design in Microsoft Exchange Server 2010.

Mailbox Database Capacity

Many factors influence a sizing capacity plan for Exchange Server 2010 Mailbox databases. This section discusses the following:

- Mailbox storage quotas
- Database white space
- Mailbox database recoverable items
- Actual mailbox size
- Content indexing
- Offline database maintenance
- Recovery database
- Database size
- Database growth overhead

Mailbox Storage Quotas

The first metric to understand is the storage size limit, known as the mailbox *storage quota*, that's in effect in your organization. Knowing the amount of data that an end user is allowed to store in his or her mailbox allows you to determine how many user mailboxes can be housed on the server. Although mailbox storage quotas can change in response to changing organizational requirements, having a goal for the mailbox storage quota is the first step in determining your needed mailbox database capacity.

For example, if you have a server with 5,000 250-MB user mailboxes on it, you need at least 1.25 TB of disk space, excluding space requirements for recoverable items. If a limit isn't set for mailbox storage quotas, you'll find it difficult to estimate database capacity. Mailbox storage quotas for Exchange 2010 need to include the space for both the primary mailbox and personal archive mailbox (when used). For more information, see Managing Mailbox Servers and Managing Archives.

Database White Space

The database size on the physical disk isn't just the number of users multiplied by the mailbox storage quota. When the majority of users aren't approaching their mailbox storage quota, the databases consume less space and white space isn't a capacity concern. The database itself will always have free pages, or white space, spread throughout. During background database maintenance, items marked for removal from the database are removed, which frees these pages. The percentage of white space is constantly changing due to the efforts of the 24x7 online defragmentation process.

You can estimate the amount of white space in the database by knowing the amount of mail sent and received by the users with mailboxes in the database. For example, if you have 100 2-GB mailboxes (total of 200 GB) in a database where users send and receive an average of 10 MB of mail per day, the amount of white space is approximately 1 GB (100 mailboxes × 10 MB per mailbox). The amount of white space can exceed this approximation if background database maintenance isn't able to complete a full pass.

Return to top

Mailbox Database Recoverable Items

Each database has a dumpster that stores soft-deleted items. By default, soft-deleted items are stored for 14 days and calendar items are stored for 120 days in Exchange 2010.

In addition, Exchange 2010 also includes the ability to prevent the purging of data before the deleted item retention window has passed. This functionality is known as *single item recovery*. Single item recovery is disabled by default. However, when single item recovery is enabled, there is an additional 1.2 percent increase in the size of the mailbox for a 14-day deleted item retention window. For calendar version logging data, there is an additional 3 percent increase in the size of the mailbox. Calendar version logging data is enabled by default.

The formula for determining the dumpster space requirements for 14 days of deleted item retention with single item recovery and calendar version logging enabled is:

Dumpster Size = (Daily Incoming/Outgoing Mail x Average Message Size x Deleted Item Retention Window) + (Mailbox Quota Size x 0.012) + (Mailbox Quota Size x 0.03)

For example, if the mailbox size is 2 GB, enabling single item recovery for 14 days of deleted item retention requires an additional 25 MB of space, and the calendar logging feature requires an additional 61 MB.

For more information, see the following topics:

- Exchange 2010 Mailbox Server Role Design Example
- Understanding Recoverable Items
- Managing Recoverable Items
- Understanding Calendar Repair
- Managing Calendars

Actual Mailbox Size

Over time, user mailboxes will reach the mailbox storage quota, so an amount of mail equivalent to the incoming mail will need to be deleted to remain under the mailbox storage quota. This requirement means that the dumpster will increase to a maximum size equivalent to the amount of e-mail sent and received each day multiplied by the number of days within the deleted item retention window. If the majority of users haven't reached the storage quota, only some of the incoming/outgoing mail is deleted. Therefore, the growth is split between the dumpster and the increase in mailbox size.

To determine database size using a 2-GB mailbox without using the personal archive feature, see the "Mailbox Capacity Requirements" section in the Exchange 2010 Mailbox Server Role Design Example topic.

After you have determined the projected actual mailbox size, you can use that value to determine the maximum number of users per database. Divide projected mailbox size by the recommended database size. This value will also help you determine how many databases you will need to handle the projected user count, assuming fully populated databases. Be aware that due to non-transactional input/output (I/O) or because of hardware limitations, you may have to modify the number of users placed on a single server. Some administrators will prefer to use more databases to further reduce the database size. This approach can assist with backup and restore windows at the cost of more complexity in managing more databases per server.

Content Indexing

Content indexing creates an index, or catalog, that allows users to easily and quickly search through their mail items rather than manually search through the mailbox. Exchange 2010 creates an index that is about 10 percent of the total database size, which is placed on the same LUN as the database. Therefore, an additional 10 percent

needs to be factored into the database LUN size for content indexing.

Return to top

Offline Database Maintenance

A database that needs to be compacted offline requires capacity equal to the size of the target database plus 10 percent. Whether you allocate enough space for a single database, or a backup set, additional space must be available to perform these operations.

Important:

Offline maintenance procedures should only be implemented by request of Microsoft Customer Service and Support because offline maintenance procedures invalidate all database copies and require a full reseed of the database.

Recovery Database

If you plan to use a recovery database as part of your disaster recovery plans, sufficient capacity must be available to handle all the databases you want to be able to simultaneously restore on that server. For more information, see Recovery Databases.

Database Size

The database size ultimately determines how many mailboxes you deploy within each database and how many databases you deploy. The database size you deploy depends on several factors:

- **Backup/restore service level agreements (SLAs)** The database size ultimately dictates how fast you can backup and restore the data within a reasonable amount of time.
- **High availability architecture** If you plan to have multiple database copies, you can design your databases to be 2 TB in size because your copies become your first line of defense in terms of recovery operations.
- **Storage architecture** If you plan to deploy on JBOD storage (one disk houses both the database and its corresponding transaction logs), then the size of the disk you use dictates the maximum database size. For example, on a 1 TB disk (with a formatted capacity of about 917 GB), you also need to include space for transaction logs and the content index, and ensure you don't consume all available space.

Database Growth Overhead

After all factors have been considered and calculated, we recommend that you include an additional overhead factor of 20 percent for the database logical unit number (LUN). This value accounts for the other data that resides in the database that isn't necessarily seen when calculating mailbox sizes and white space.

Return to top

Log Capacity

The transaction log files are a record of every transaction performed by the database engine. All transactions are written to the log first, and then lazily written to the database. Unlike Exchange Server 2003, the transaction log files in Exchange 2010 have been reduced in size from 5 MB to 1 MB. This change was made to support the continuous replication features and to minimize the amount of data loss if primary storage fails.

You can use the following table to estimate the number of transaction logs that are generated on an Exchange 2010 Mailbox server where the average message size is 75 KB.

The value for *Number of transaction logs generated per day* is based on the message profile selected and the average message size. It indicates how many transaction logs will be generated per mailbox per day. The log generation numbers per message profile account

for:

- Message size impact
- Amount of data sent/received
- Database health maintenance operations
- Records Management operations
- Data stored in a mailbox that is not a message (tasks, local calendar appointments, contacts)
- Forced log rollover (a mechanism that periodically closes the current transaction log file)

Number of transaction logs generated per mailbox profile

Message profile (75 KB average message size)	Number of transaction logs generated per day
50	10
100	20
150	30
200	40
250	50
300	60
350	70
400	80
450	90
500	100

You can use the following guidelines to understand how message size affects the generation rate of transaction logs:

- If the average message size doubles to 150 KB, the logs generated per mailbox increases by a factor of 1.9. This number represents the percentage of the database that contains the attachments and message tables (message bodies and attachments).
- Thereafter, as message size doubles beyond 150 KB, the log generation rate per mailbox also doubles, increasing from 1.9 to 3.8.

For example, if you have a 100 messages per day and:

- An average message size of 150 KB, the logs generated per mailbox are 20 × 1.9 = 38.
- An average message size of 300 KB, the logs generated per mailbox are 20 × 3.8 = 76.

The following sections discuss factors that affect your log sizing capacity:

- Backup and restore factors
- Move mailbox operations
- Log growth overhead
- High availability factors
- LUN capacity planning

Backup and Restore Factors

Log LUN sizing is partly dependent on your backup and restore design. For example, if your design allows you to go back two weeks and replay all the logs generated since then, you will need two weeks of log file space. If your backup design includes weekly full

and daily differential backups, the log LUN needs to be larger than an entire week of log file space to allow both backup and replay during restore. Most enterprises that perform a nightly full backup allocate two to three times the required daily log generation capacity. This approach is taken to prevent a backup failure from causing the log drive to fill, which would dismount the database.

If you plan on using the mailbox resiliency and single item recovery features within Exchange 2010 as your backup infrastructure (and thus enabling circular logging), as a best practice, you should ensure that you allocated three times the required daily log generation capacity. This ensures that, when replication is suspended or not functioning under normal parameters, the databases don't dismount due to truncation failures.

Move Mailbox Operations

Moving mailboxes is a primary capacity factor for large mailbox deployments. Many large companies move a percentage of their user mailboxes on a nightly or weekly basis to different databases, servers, or sites. If your organization does this, you may find it necessary to provide extra capacity to the log LUN to accommodate mailbox moves.

Although the source server logs the record deletions, which are small, the target server must write all transferred data first to transaction logs. If you generate 10 GB of log files in one day, and keep a three-day buffer of 30 GB, moving 50 2-GB mailboxes (100 GB) would fill your target log LUN and cause downtime. In cases such as these, you may have to allocate additional capacity for the log LUNs to accommodate your move mailbox practices.

Log Growth Overhead Factor

For most deployments, we recommend that you add an overhead factor of 20 percent to the log size (after all other factors have been considered) when creating the log LUN to ensure necessary capacity exists in moments of unexpected log generation.

High Availability Factors

High availability influences log capacity requirements in three significant ways:

- **Database copy count** The log capacity of the entire system is increased based on the number of database copies chosen in the high availability deployment. If you have three database copies spread across three servers, you need to provision log capacity for each copy on each server.
- **Log truncation mechanism** High availability in Exchange 2010, with the ability to have up to 16 copies of each mailbox database, provides the foundation to use continuous replication circular logging as the log truncation/deletion mechanism as opposed to running Full/Incremental backups to truncate/delete the older logs. For more information, see the "Log Truncation without Backups" section in Understanding Backup, Restore and Disaster Recovery and High Availability and Site Resilience.
- **Database copy replay lag** High availability in Exchange 2010 provides the option to lag log replay on passive database copies (configured on a per copy basis). This feature is used to provide a delay for when logs get played in to lagged database copies. This delay can be useful to protect against events which would cause undesirable content to be replicated to all database copies. The content can be stopped from being played in to the lagged database copy by suspending replay before the logs with the undesired content are played in to the database.
  When replay lag is enabled for a database copy, the log capacity requirements change accordingly. If you have a 14-day lag configured, you need to provision for 17 days worth of logs. The additional log capacity is only required for the database copy that has the lag configured, other copies of that database, which don't have a lag, will have normal (non-lagged) log capacity requirements.

For more information, see Understanding High Availability Factors.

LUN Capacity Planning

The capacity requirements for the LUN will be based on the size of the data set (database, transaction logs, content index, and recovery space) and some additional free space. Most operations management programs have capacity thresholds that provide an alert when a LUN is more than 80 percent utilized.

You can use the following formula to determine the appropriate size of the LUN:

LUN Capacity = Data Size / (1 - Free Space Percentage Requirement)

For example, if you had a data size requirement of 3000 MB and a free space requirement of 20 percent, then the LUN that hosts this data must be 3750 MB in size.

Preventing the total consumption of transaction log disk space

To avoid having all your transaction log disk space be consumed, you must first calculate a baseline of your environment to determine the typical log generation rate per day. Second, you must set up monitoring, and take action regarding any alerts that are generated. You should monitor for the following items:

- Transaction Log LUN disk space. Set up several thresholds and different alert mechanisms. For example, if you know your typical log generation baseline, you can set up a threshold to report when you are 20 percent over the baseline.
- Successful completion of your backups (if you aren't leveraging Exchange Native Data Protection).
- The truncation of events in the Application Log.
- Your database copy replication health.

Troubleshooting unexplained growth in Transaction logs

To help troubleshoot unexplained growth in Transaction logs, see Manage Database Log Growth by Using the Troubleshoot-DatabaseSpace.ps1 Script in the Shell.

1.2.1.9.4 Understanding the Mailbox Database Cache

Understanding the Mailbox Database Cache

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-04-23*

The Extensible Storage Engine (ESE) engine uses database cache to reduce I/O operations. In general, the more database cache that is available, the less I/O that is generated on a Microsoft Exchange Server 2010 Mailbox server. The database I/O reduction primarily depends on the amount of database cache available to the server and the user message profile.

Improved Database Cache Effectiveness

The database cache effectiveness has been improved in Exchange 2010 due to several technical changes. One of the most significant changes is increasing the log checkpoint depth target. The log checkpoint depth target is used to ensure that changes made to the log/database cache are written to the database file in a reasonable amount of time. It has been increased from 20 MB per database to 100 MB per database when a database has more than one copy (in a database availability group, or DAG). The following table provides the default log checkpoint depth targets for Exchange 2010.

Default log checkpoint depth target configuration per mailbox database

Database configuration	Log checkpoint depth target (MB)
Stand-alone (one database copy)	20
Mailbox resiliency: Active database copy with two or more copies (DAG)	100
Passive database copy	5

Due to this change, the database write I/O for an active database with two or more copies can be up to 40 percent less than the database write I/O for a stand-alone database. When the database has a higher checkpoint depth target, it's able to retain database file changes in memory for a longer period; thus, improving its ability to combine I/Os (coalescing) and by reducing repeated write I/Os (I/Os that can be saved by delaying the write long enough so multiple database changes can be made in memory prior to writing the change to the database file).

This change was only made for mailbox resiliency solutions because a deeper checkpoint depth target can significantly increase the time it takes the active database to recover the failed database after a failure. This problem has been addressed in mailbox resiliency configurations because if the active database fails, a failover is automatically triggered to another healthy copy. Log replay operations will resume when the failed database is recovered.

The checkpoint depth target has subsequently been reduced on passive database copies to reduce the time a database switchover/failover takes. A passive database copy with a 5 MB checkpoint depth target can be activated much faster than a copy with a higher checkpoint depth target (there are fewer logs to play through when transitioning between the passive and active state). A passive database copy does not have transactional I/O so there is spare capacity to handle the additional write I/O with the lower Checkpoint Depth Target.

Database Cache Minimum Requirements

To ensure the ESE database has sufficient memory to work effectively, there is a required minimum amount of physical memory per server based on database count. These requirements apply to both active and passive database copies. See the following table for the requirements.

Required minimum memory per mailbox server

Database count	Exchange 2010 minimum required physical memory
1-10	2 GB
11-20	4 GB
21-30	6 GB
31-40	8 GB
41-50	10 GB
51-60	12 GB
61-70	14 GB
71-80	16 GB
81-90	18 GB

91-100	20 GB

Database Cache Metrics

In previous versions of Exchange, one of the key metrics needed for sizing storage was the amount of database I/O per second (IOPS) consumed by each user. The two most important factors that can be used to predict Exchange 2010 Mailbox IOPS are the amount of database cache per mailbox and the number of messages each user sends and receives per day.

The following table provides estimated values for IOPS per mailbox based on message activity and database cache. You can use the information in the table to help predict baseline Exchange 2010 mailbox I/O requirements.

These estimates are only valid for database cache sizes between 3 MB and 30 MB per mailbox. These estimates have been validated with users with the following characteristics: High percentage Exchange Cache Mode clients in either Microsoft Office Outlook 2007 or Outlook 2010; 2-GB mailboxes; and a high percentage of Exchange ActiveSync usage. The average message size used for the estimates is 75 KB, but message size isn't a primary factor for IOPS. Other client types and usage scenarios may yield inaccurate results.

Estimated IOPS per mailbox based on message activity and mailbox database cache

Messages sent/ received per mailbox per day (~75KB average message size)	Database cache per user (MB)	Single database copy (Stand-alone): Estimated IOPS per mailbox	Multiple database copies (mailbox resiliency): Estimated IOPS per mailbox
50	3	.060	.050
100	6	.120	.100
150	9	.180	.150
200	12	.240	.200
250	15	.300	.250
300	18	.360	.300
350	21	.420	.350
400	24	.480	.400
450	27	.540	.450
500	30	.600	.500

After you have determined the database cache size requirements, the next step is to determine the minimum memory requirements per server to ensure the database cache size requirements can be met. The database cache size must be factored in to the sizing process to ensure the amount of physical memory per server is adequate to meet the needs of the mailbox count with a given user profile.

The following table lists the default mailbox database cache sizes for both single role Mailbox servers as well as multiple role servers.

Default mailbox database cache sizes

Server physical memory (RAM)	Database cache size: (Mailbox role only)	Database cache size: Multiple-role (for example,

		Mailbox + Hub Transport)
2GB	512 MB	Not supported
4GB	1 GB	Not supported
8GB	3.6 GB	2 GB
16GB	10.4 GB	8 GB
24GB	17.6 GB	14 GB
32GB	24.4 GB	20 GB
48GB	39.2 GB	32 GB
64GB	53.6 GB	44 GB
96GB	82.4 GB	68 GB
128GB	111.2 GB	92 GB

Note:
You can modify the default database cache size values by making changes to the **msExchESEParamCacheSizeMax** and **msExchESEParamCacheSizeMin** attributes in Active Directory. For additional details, see How to modify the Store Database maximum cache size in Exchange 2000 Server. Use 32KB pages for the cache sizing calculations.

To determine server memory requirements, see Exchange 2010 Mailbox Server Role Design Example, which provides information about designing your Mailbox Server role to determine the appropriate memory, capacity, I/O, and CPU performance.

1.2.1.9.5 Understanding Database and Log Performance Factors

Understanding Database and Log Performance Factors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-12-05*

This topic discusses database and log I/O performance factors in Microsoft Exchange Server 2010. An understanding of these factors is important to your Mailbox server storage design solution. For more information about other key aspects of the design process, see Mailbox Server Storage Design.

Contents

Transactional I/O

Transactional I/O is generally defined as the I/O generated by user activity. Examples of user activity include receiving, sending, and deleting items; syncing a Windows Mobile

client; and logging on via Microsoft Office Outlook Web App.

Transactional I/O is a critical piece of Exchange 2010 storage design because the I/O latency (how long it takes to execute the I/O operation) can directly affect the user experience of online clients such as Microsoft Outlook Online Mode and Outlook Web App. Cached Exchange Mode in Outlook can also be affected by high I/O latency when it's being used for tasks such as delegate access and configuring rules. All clients can be affected by e-mail delivery delays caused by high latency I/O. Transactional I/O can be divided into database volume I/O and log volume I/O.

The transactional I/O requirements in Exchange 2010 have been reduced from those in Exchange Server 2007. Not all I/O that occurs against the Mailbox database and log volumes is considered transactional. For more information, see Understanding the Exchange 2010 Store.

Return to top

Understanding IOPS

For all versions of Exchange, it's important to understand the amount of database I/O per second (IOPS) consumed by each user because it's one of the key transactional I/O metrics needed for adequately sizing storage. The following sections discuss factors that affect IOPS when designing your Mailbox server role storage.

Database Cache

A 64-bit edition of the Windows Server operating system running the 64-bit version of Exchange 2010 substantially increases the virtual address space and allows Exchange to increase its database cache, reduce database read I/O, and enable up to 100 databases per server.

The database read reduction depends on the amount of database cache available to the server and the user message profile. For guidance about memory and databases, see Understanding the Mailbox Database Cache. Following the guidance in that topic can result in up to a 90 percent transactional I/O reduction over Exchange Server 2003. The amount of database cache per user is a key factor in the actual I/O reduction.

The following table demonstrates the increase in actual database cache per mailbox when comparing the default 900 megabytes (MB) of database cache per mailbox in Exchange 2003 versus 6 MB of database cache per mailbox in Exchange 2010 for a user population that uses a 100 messages / day profile. It's the additional database cache In Exchange 2010 that enables more read hits in cache, thus reducing database reads at the disk level.

Database cache sizes based on mailbox count

Mailbox count	Exchange 2003 database cache per mailbox (MB)	Exchange 2010 database cache per mailbox (MB)	Database cache increase over Exchange 2003
4000	0.225	6	27 times
2000	0.45	6	13 times
1000	0.9	6	7 times
500	1.8	6	5 times

Return to top

Determining the Exchange 2010 Mailbox IOPS Profile

The two most significant factors that can be used to predict Exchange 2010 database IOPS are the amount of database cache per user and the number of messages each user sends and receives per day. The following table is based on a standard worker who uses Outlook 2010 in Cached Exchange Mode. The information has been tested to be accurate within plus or minus 20 percent. Other client types and usage scenarios may yield inaccurate results. The predictions are only valid for user database cache sizes between 3 MB and 30 MB. The information hasn't been validated in a scenario where users send and receive over 500 messages per day. The average message size for validation was 75 KB, but message size isn't a primary factor for IOPS.

The table provides estimated values for IOPS per user that you can use to predict your baseline Exchange 2010 IOPS requirements and includes all database I/O (database, content indexing, and NTFS metadata). It doesn't include log volume I/O.

Database cache and estimated IOPS per mailbox based on message activity

Messages sent/ received per mailbox per day	Database cache per mailbox (MB)	Single database copy (stand-alone): Estimated IOPS per mailbox	Multiple database copies (mailbox resiliency): Estimated IOPS per mailbox
50	3	0.06	0.05
100	6	0.120	0.100
150	9	0.18	0.150
200	12	0.240	0.200
250	15	0.300	0.250
300	18	0.360	0.300
350	21	0.420	0.350
400	24	0.480	0.400
450	27	0.540	0.450
500	30	0.600	0.500

Mailbox resiliency refers to a unified high availability and site resilience solution in Exchange 2010. For more information, see Understanding High Availability and Site Resilience.

Return to top

Database Volume I/O

Database volume I/O is I/O associated with database file (.edb) read/write activity, content indexing read/write activity, as well as NTFS metadata read/write activity.

In Exchange 2003, the database read/write ratio is typically 2:1 or 66 percent reads. With Exchange 2010, the larger database cache decreases the number of reads to the database on disk causing the reads to shrink as a percentage of total I/O.

If you follow the recommended memory guidelines, you can expect to see the following I/O ratios for active database copies. For more information about the memory guidelines, see Understanding Memory Configurations and Exchange Performance. This measurement includes all database volume I/O (database, content indexing and NTFS metadata); it doesn't include log volume I/O.

Mailbox database I/O read/write ratios

Messages sent/received per mailbox per day	Stand-alone databases	Databases participating in mailbox resiliency
50	1:1	3:2
100	1:1	3:2
150	1:1	3:2
200	1:1	3:2
250	1:1	3:2
300	2:3	1:1
350	2:3	1:1
400	2:3	1:1
450	2:3	1:1
500	2:3	1:1

For example, if you deploy 24,000 mailboxes across Mailbox servers within a database availability group (DAG) that maintains three database copies, each database has a database read to write ratio of 3:2. Or, in other words, 60 percent of all I/Os to the logical unit number (LUN) hosting the database are read I/Os.

Having more writes as a percentage of total I/O has specific implications when choosing a redundant array of independent disks (RAID) type that has significant costs associated with writes, such as RAID5 or RAID6. For more information about selecting the appropriate RAID solution for your servers, see Understanding Storage Configuration.

Calculating IOPS per Mailbox Server

Calculating IOPS per Mailbox server in Exchange 2010 requires more steps than in previous versions of Exchange because of the following:

- You can now combine databases and logs on the same volume,
- You can host both active and passive database copies on the same server,
- The addition of sequential I/O background tasks (for example, background database maintenance).

Pure sequential I/O operations aren't factored in the IOPS per Mailbox server calculation because storage subsystems can handle sequential I/O much more efficiently than random I/O. These operations include background database maintenance, log transactional I/O, and log replication I/O.

IOPS per Mailbox server is calculated slightly differently depending on how your storage is designed:

- Database files and log files share a single volume.
- Database files are stored on different disk volumes than the transaction log files.

For both storage designs, use Performance Monitor (perfmon.exe) to measure the peak two hour period (at a 5-second sampling interval). This is the time of day where the system is under the most load generated by client activity (for example, 10 A. M. -12 P. M.). This period is often twice the load of the 10 hour daily average (Peak:Average ratio = 2:1).

IOPS per Mailbox Server: Database Files and Log Files Share a Single Volume

In this configuration, the database files and log files are stored on the same disk volume. This example assumes each database is on a different volume backed by a dedicated disk. Fill in the following table for all databases from the collected performance monitor log (described in the previous section).

Database Name	Logical Disk -> Disk Reads/sec	Logical Disk -> Disk Writes/sec	MSExchange DatabaseInstances ->Database Maintenance IO Reads/sec	MSExchange DatabaseInstances ->I/O Database Reads (Recovery) /sec	MSExchange DatabaseInstances ->I/O Database Writes (Recovery) /sec	MSExchange DatabaseInstances ->IO Log Writes/sec
Database 1						
Database 2						
Database 3						
Database 4						
Any additional databases						
Total						

Add the totals from each column, and then perform the following calculation to determine IOPS per Mailbox server.

Calculation summary: Sum of Logical Disk IO - (sum of database maintenance IO + recovery (log replay) IO + Log IO) divided by the number of mailboxes hosted per server during the performance monitor log measurement.

Calculation Detail: ((Logical Disk -> Disk Reads/sec + Logical Disk -> Disk Writes/sec) - (MSExchange Database ==> Instances -> Database Maintenance IO Reads/sec + MSExchange Database ==> Instances -> I/O Database Reads (Recovery)/sec + MSExchange Database ==> Instances -> I/O Database writes (Recovery)/sec + MSExchange Database ==> Instances -> IO Log Writes/sec))/ Number of mailboxes hosted per server during the performance monitor log measurement = IOPS per Mailbox server.

Return to top

IOPS/Mailbox: Dedicated Database File Volume

In this configuration, the database files are stored on different disk volumes than the transaction log files. This example assumes each database is on a different volume backed by a dedicated disk. Fill in the following table for all databases from the collected perfmon log (described in the previous section).

Database Name	Logical Disk -> Disk Reads/sec	Logical Disk -> Disk Writes/sec	MSExchange Database ==> Instances ->Database Maintenance IO Reads/sec	MSExchange Database ==> Instances ->I/O Database Reads (Recovery)/ sec	MSExchange Database ==> Instances ->I/O Database Writes (Recovery)/ sec

Database 1					
Database 2					
Database 3					
Database 4					
Any additional databases					
Total					

Note:
By default, the **MSExchange Database ==> Instances ->Database Maintenance IO Reads/sec** performance counter is not visible in Exchange 2010. You must enable this counter to view it. For more information about how to enable this performance counter, see How to Enable Extended ESE Performance Counters

To determine IOPS per Mailbox server, add the totals from each column and perform the following calculation.

Calculation summary: Sum of Logical Disk IO - (Sum of database maintenance IO + recovery (log replay) IO) divided by the number of mailboxes hosted per server during the perfmon log measurement.

Calculation Detail: ((Logical Disk -> Disk Reads/sec + Logical Disk ->Disk Writes/sec) - (MSExchange Database ==> Instances -> Database Maintenance IO Reads/sec + MSExchange Database ==> Instances -> I/O Database Reads (Recovery)/sec + MSExchange Database ==> Instances -> I/O Database writes (Recovery)/sec))/ Number of mailboxes hosted per server during the performance monitor log measurement = IOPS per Mailbox server.

Measure Baseline IOPS

If you're using a previous version of Exchange, and you have calculated your baseline IOPS, keep in mind that Exchange 2010 affects your baseline in the following ways:

- The number of users on the server affects the overall database cache per user.
- The amount of RAM influences how large your database cache can grow, and a larger database cache causes more cache read hits. This reduces your database read I/O.

The key to this process is that the IOPS on a specific server isn't enough information to plan an entire enterprise. This is because the amount of RAM, number of users, and number of databases will be different on each server. After you have your actual IOPS numbers, always apply a 20 percent I/O overhead factor to your calculations to add some reserve capacity. You don't want a poor user experience because activity is heavier than normal.

Desktop Search Engines and Outlook Online Mode Clients

Unlike Cached Exchange Mode clients, all Online Mode client operations occur against the database. Because of the changes in the store schema and Extensible Storage Engine (ESE), Outlook Online Mode clients now generate the same I/O profile as Outlook Cached Exchange Mode Clients.

In terms of mailbox search capabilities, end users have two options:

- They can use the built-in content index that's available on the Mailbox server.
- They can install a desktop search engine client and have a local index generated on the client of the mailbox's data and perform local searches.

End users that use desktop search engine clients with Outlook Online Mode may incur additional read I/O operations against the database. Currently, the only known desktop search engine that doesn't incur additional read I/Os is Windows Desktop Search 4.0. Windows Desktop Search 4.0 uses synchronization protocols that are similar to how Outlook Cached Exchange Mode synchronization protocols index the mailbox contents.

Therefore, use the following guidelines if you intend to deploy Outlook Online Mode clients with desktop search engines other than Windows Desktop Search 4.0:

- 256 MB Online Mode clients will increase database read operations by a factor of 1.5 when compared with Cached Exchange Mode clients. Below 256 MB, the impact is negligible.
- As mailbox size doubles, the database read IOPS will also double (assuming equal item distribution between key folders remains the same).

As a result of this data, we have two recommendations:

- Deploy Cached Exchange Mode clients where appropriate. For more information, see the "Item Count per Folder" section later in this topic. Otherwise, replace the desktop search engine with Windows Desktop Search 4.0.
- Consider the I/O requirements when you're designing the database storage.

For additional IOPS factors, such as third-party clients, see Optimizing Storage for Exchange Server 2003.

Return to top

Log Volume I/O

Log volume I/O is I/O associated with database logging read/write activity and NTFS metadata read/write activity. Log volume I/O is sequential in nature and, when using a battery-backed write caching array controller, the I/O overhead of log volume I/O is minimal and not a significant factor for Exchange storage sizing.

Because of the reduction in database reads in Exchange 2010, combined with the smaller log file size and the ability to have more databases, the log-to-database write is 40 percent for stand-alone databases and 50 percent for databases that participate in mailbox resiliency. For example, if the database that's participating in mailbox resiliency consumes 12 write I/Os, the log LUN consumes approximately 6 write I/Os.

On Mailbox servers that are hosting databases that are participating in mailbox resiliency, there is overhead associated with using continuous replication. Closed transaction logs must be read and sent to the target database copies. This overhead is an additional 10 percent in log reads for each active database copy that's hosted on the Mailbox server. For example, if the Mailbox server is hosting 10 active database copies, and each transaction log stream is generating 6 write I/Os, you can expect an additional 0.6 read I/Os for each of those 10 active database copies (or a total of 6 read I/Os).

After you measure or predict the transactional log I/O, apply a 20 percent I/O overhead factor to ensure adequate room for busier-than-normal periods.

Item Count per Folder

One way to reduce server I/O is to use Outlook in Cached Exchange Mode. The initial mailbox synchronization is a disk intensive operation, but over time, as the mailbox size grows, the disk subsystem burden is shifted from the Exchange server to the Outlook client. With use of Cached Exchange Mode, having a large number of items in a user's Inbox or a user searching a mailbox will have little effect on the server. This approach also means that Cached Exchange Mode users with large mailboxes may need faster computers than those with small mailboxes (depending on the individual user threshold for acceptable performance).

When you deploy client computers that are running Outlook 2007 in Cached Exchange Mode, consider the following guidelines with respect to mailbox/.ost file sizes:

- **Up to 5 gigabytes (GB)** This size should provide a good user experience on most hardware.
- **Between 5 GB and 10 GB** This size is typically hardware dependent. Therefore, if you have a fast hard disk and a lot of RAM, your experience will be better. However, slower hard drives, such as drives that are typically found on laptops or early generation solid-state drives (SSDs), experience some application pauses when the drives respond.
- **More than 10 GB** This is the size at which short pauses begin to occur on most hardware.
- **Very large, such as 25 GB or larger** This size increases the frequency of the short pauses, especially while you're downloading new e-mail messages. Alternatively, you can use Send/Receive groups to manually synchronize your mail.

This guidance is based on the installation of a cumulative update for Outlook 2007 Service Pack 1 or later, as described in Microsoft Knowledge Base Article 961752, Description of the Outlook 2007 hotfix package (Outlook.msp): February 24, 2009.

If you experience performance-related issues with Outlook 2007 in Cached Exchange Mode deployment, see Knowledge Base Article 940226, How to troubleshoot performance issues in Outlook 2007. For more information about the improvements that are available, see Knowledge Base article 968009, Outlook 2007 improvements in the February 2009 cumulative update.

A challenging scenario occurs when a user has exceeded the number of indexes that Exchange will store. This is 11 indexes in Exchange 2010. When the user chooses to sort a new way, and thereby creates a twelfth index, this causes additional disk I/O activity. Because the index isn't stored, this additional disk activity cost occurs every time that this sort is performed. Because of the high I/O activity that can be generated in this scenario, we strongly recommend that you store no more than 100,000 items in core folders, such as the Inbox and Sent Items folders, and no more than 10,000 items in the Calendar and Contacts folders. The creation of more top-level folders, or of subfolders beneath the Inbox and Sent Items folders, greatly reduces the costs that are associated with this index creation. This is true as long as the number of items in any folder doesn't exceed 100,000.

Return to top

Content Index I/O

In Exchange 2010, messages are indexed as they're received, causing little database disk I/O overhead (because the message is still in the database cache when it's retrieved for indexing). However, write I/O is associated with updating the search catalog store. Because of the overall database I/O reductions in Exchange 2010, the percentage of search catalog I/O is now 10 percent to 15 percent of the database files I/O (depending upon profile). Search catalog read I/O occurs when clients issue search queries, and it's a rare enough occurrence not to be relevant to Exchange 2010 storage design.

Return to top

Non-Transactional I/O

Transactional I/O occurs in response to direct user action and usually has the highest priority, and therefore, it's the focus for storage design. Non-transactional I/O either occurs in the background and is tuned to have a minimal performance impact, or it occurs during a defined maintenance window.

The following sections discuss some of the non-transactional I/O that occurs in the background. Although non-transactional I/O isn't the focus of storage design, it can impact your storage design. For more information, see New Exchange Core Store Functionality.

Background Database Maintenance (Checksumming)

Background database maintenance I/O is sequential database file I/O associated with checksumming both active and passive database copies. Background database maintenance has the following characteristics:

- On active databases, it can be configured to run either 24 × 7 or during the online maintenance window. Background database maintenance (Checksum) runs against passive database copies 24 × 7. For more information, see "Online Database Scanning" in the New Exchange Core Store Functionality topic.
- Reads approximately 5 MB per second for each actively scanning database (both active and passive copies). The I/O is 100 percent sequential, so the storage subsystem can process the I/Os efficiently.
- Stops scanning the database if the checksum pass completes in less than 24 hours.
- Issues a warning event if the scan doesn't complete within three days (not configurable).

Messaging Records Management

Messaging records management (MRM) is the records management technology in Exchange 2010 that helps organizations reduce the legal risks associated with e-mail. MRM makes it easier to retain the messages that are needed to comply with company policy, government regulations, or legal needs, and to remove content that has no legal or business value.

These actions are accomplished through the use of retention policies or managed folders. The Managed Folder Assistant is a Microsoft Exchange Mailbox Assistant that applies message retention settings configured in retention policies or managed folder mailbox policies. The disk I/O required by the assistant depends on the number of mailbox items processed. We recommend that the assistant not run at the same time as either backup or online maintenance. For more information, see Configure the Managed Folder Assistant.

Online Maintenance

You can use the Exchange Management Tools to set the maintenance schedule for a database or allow 24 × 7 database maintenance. Online defragmentation no longer works in Exchange 2010 as it did in previous versions of Exchange. Online defragmentation is continuously performed while the database is being read from and written to. For more information, see "Online Database Scanning" in the New Exchange Core Store Functionality.

1.2.1.9.6 Understanding Storage Configuration

Understanding Storage Configuration

Planning and Deployment > Planning for Exchange 2010 > Mailbox Server Storage Design >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-30*

Understanding storage options and requirements for the Mailbox server role in Microsoft Exchange Server 2010 is an important part of your Mailbox server storage design solution. For additional information about other key aspects of the design process, see Mailbox Server Storage Design.

Contents

Storage Architectures

The following table describes supported storage architectures, and provides best practice guidance for each type of storage architecture, where appropriate.

Supported storage architectures

Storage architecture	Description	Best practice
Direct-attached storage (DAS)	DAS is a digital storage system directly attached to a server or workstation, without a storage network in between. For example, DAS transports include Serial Attached Small Computer System Interface (SCSI) and Serial Attached Advanced Technology Attachment (ATA).	Not available.
Storage area network (SAN): Internet Small Computer System Interface (iSCSI)	SAN is an architecture to attach remote computer storage devices (such as disk arrays and tape libraries) to servers in such a way that the devices appear as locally attached to the operating system (for example, block storage). iSCSI SANs encapsulate SCSI commands within IP packets and use standard networking infrastructure as the storage transport (for example, Ethernet).	Don't share physical disks backing up Exchange data with other applications. Use dedicated storage networks. Use multiple network paths for stand-alone configurations.
SAN: Fibre Channel	Fibre Channel SANs encapsulate SCSI commands within Fibre Channel packets and generally utilize specialized Fibre Channel networks as the storage transport.	Don't share physical disks backing up Exchange data with other applications. Use multiple Fibre Channel network paths for stand-alone configurations. Follow storage vendor's best

		practices for tuning Fibre Channel host bus adapters (HBAs), for example, Queue Depth and Queue Target.

Return to top

Physical Disk Types

The following table provides a list of supported physical disk types and provides best practice guidance for each physical disk type where appropriate.

Supported physical disk types

Physical disk type	Description	Supported or best practice
Serial ATA (SATA)	SATA is a serial interface for ATA and integrated device electronics (IDE) disks. SATA disks are available in a variety of form factors, speeds, and capacities. In general, choose SATA disks for Exchange 2010 mailbox storage when you have the following design requirements: • High capacity • Moderate performance • Moderate power utilization	Supported: 512-byte sector disks for Windows Server 2008 and Windows Server 2008 R2. In addition, 512e disks are supported for Windows Server 2008 R2 with the following: • The hotfix described in Microsoft Knowledge Base article 982018, An update that improves the compatibility of Windows 7 and Windows Server 2008 R2 with Advanced Format Disks is available. • Windows Server 2008 R2 with Service Pack 1 (SP1) and Exchange Server 2010 SP1. Support requires that all copies of a database reside on the same physical disk type. For example, it is not a supported configuration to host one copy of a given database on a 512-byte sector disk and another copy of that same database on a 512e disk. Also be aware that 4-kilobyte (KB) sector disks are not supported for any version of Microsoft Exchange and 512e disks are not supported for any version of Exchange prior to Exchange Server 2010 SP1. Best practice: Consider enterprise class SATA disks, which generally have better heat, vibration, and reliability characteristics.

Serial Attached SCSI	Serial Attached SCSI is a serial interface for SCSI disks. Serial Attached SCSI disks are available in a variety of form factors, speeds, and capacities. In general, choose Serial Attached SCSI disks for Exchange 2010 mailbox storage when you have the following design requirements: • Moderate capacity • High performance • Moderate power utilization	Supported: 512-byte sector disks for Windows Server 2008 and Windows Server 2008 R2. In addition, 512e disks are supported for Windows Server 2008 R2 with the following: • The hotfix described in Microsoft Knowledge Base article 982018, An update that improves the compatibility of Windows 7 and Windows Server 2008 R2 with Advanced Format Disks is available. • Windows Server 2008 R2 with Service Pack 1 (SP1) and Exchange Server 2010 SP1. Support requires that all copies of a database reside on the same physical disk type. For example, it is not a supported configuration to host one copy of a given database on a 512-byte sector disk and another copy of that same database on a 512e disk. Also be aware that 4-kilobyte (KB) sector disks are not supported for any version of Microsoft Exchange and 512e disks are not supported for any version of Exchange prior to Exchange Server 2010 SP1. Best practice: Physical disk-write caching must be disabled when used without a UPS.
Fibre Channel	Fibre Channel is an electrical interface used to connect disks to Fibre Channel-based SANs. Fibre Channel disks are available in a variety of speeds and capacities. In general, choose Fibre Channel disks for Exchange 2010 mailbox storage when you have the following design requirements: • Moderate capacity • High performance • SAN connectivity	Supported: 512-byte sector disks for Windows Server 2008 and Windows Server 2008 R2. In addition, 512e disks are supported for Windows Server 2008 R2 with the following: • The hotfix described in Microsoft Knowledge Base article 982018, An update that improves the compatibility of Windows 7 and Windows Server 2008 R2 with Advanced Format Disks is available. • Windows Server 2008 R2 with Service Pack 1

		(SP1) and Exchange Server 2010 SP1. Support requires that all copies of a database reside on the same physical disk type. For example, it is not a supported configuration to host one copy of a given database on a 512-byte sector disk and another copy of that same database on a 512e disk. Also be aware that 4-kilobyte (KB) sector disks are not supported for any version of Microsoft Exchange and 512e disks are not supported for any version of Exchange prior to Exchange Server 2010 SP1. Best practice: Physical disk-write caching must be disabled when used without a UPS.
Solid-state drive (SSD) (flash disk)	An SSD is a data storage device that uses solid-state memory to store persistent data. An SSD emulates a hard disk drive interface. SSD disks are available in a variety of speeds (different I/O performance capabilities) and capacities. In general, choose SSD disks for Exchange 2010 mailbox storage when you have the following design requirements: • Low capacity • Extremely high performance	Supported: 512-byte sector disks for Windows Server 2008 and Windows Server 2008 R2. In addition, 512e disks are supported for Windows Server 2008 R2 with the following: • The hotfix described in Microsoft Knowledge Base article 982018, An update that improves the compatibility of Windows 7 and Windows Server 2008 R2 with Advanced Format Disks is available. • Windows Server 2008 R2 with Service Pack 1 (SP1) and Exchange Server 2010 SP1. Support requires that all copies of a database reside on the same physical disk type. For example, it is not a supported configuration to host one copy of a given database on a 512-byte sector disk and another copy of that same database on a 512e disk. Also be aware that 4-kilobyte (KB) sector disks are not supported for any version of Microsoft Exchange and 512e disks are not supported for any version of Exchange prior to Exchange Server 2010 SP1. Best practice: Physical disk-write

		caching must be disabled when used without a UPS. In general, Exchange 2010 Mailbox servers don't require the performance characteristics of SSD storage.

Factors to Consider When Choosing Disk Types

There are several trade-offs when choosing disk types for Exchange 2010 storage. The correct disk is one that balances performance (both sequential and random) with capacity, reliability, power utilization, and capital cost. The following table of supported physical disk types provides information to help you when considering these factors.

Factors in disk type choice

Disk speed (RPM)	Disk form factor	Interface or transport	Capacity	Random I/O performance	Sequential I/O performance	Power utilization
5,400	2.5-inch	SATA	Average	Poor	Poor	Excellent
5,400	3.5-inch	SATA	Excellent	Poor	Poor	Above average
7,200	2.5-inch	SATA	Average	Average	Average	Excellent
7,200	2.5-inch	Serial Attached SCSI	Average	Average	Above average	Excellent
7,200	3.5-inch	SATA	Excellent	Average	Above average	Above average
7,200	3.5-inch	Serial Attached SCSI	Excellent	Average	Above average	Above average
7,200	3.5-inch	Fibre Channel	Excellent	Average	Above average	Average
10,000	2.5-inch	Serial Attached SCSI	Below average	Excellent	Above average	Above average
10,000	3.5-inch	SATA	Average	Average	Above average	Above average
10,000	3.5-inch	Serial Attached SCSI	Average	Above average	Above average	Below average
10,000	3.5-inch	Fibre Channel	Average	Above average	Above average	Below average
15,000	2.5-inch	Serial Attached SCSI	Poor	Excellent	Excellent	Average
15,000	3.5-inch	Serial Attached	Average	Excellent	Excellent	Below average

		SCSI				
15,000	3.5-inch	Fibre Channel	Average	Excellent	Excellent	Poor
SSD: enterprise class	Not applicable	SATA, Serial Attached SCSI, Fibre Channel	Poor	Excellent	Excellent	Excellent

Return to top

Best Practices for Supported Storage Configurations

This section provides best practice information about supported disk and array controller configurations.

Redundant Array of Independent Disks (RAID) is often used to both improve the performance characteristics of individual disks (by striping data across several disks) as well as to provide protection from individual disk failures. With the advancements in Exchange 2010 high availability, RAID is no longer a required component for Exchange 2010 storage design. However, RAID is still an essential piece to Exchange 2010 storage design for stand-alone servers as well as high availability solutions that require either additional performance or greater storage reliability. The following table provides guidance for the common RAID types that can be used with the Exchange 2010 Mailbox server.

Supported data types for the Exchange 2010 Mailbox server role

Data type	Stand-alone: supported or best practice	High availability: supported or best practice
OS, system, or pagefile volume	Supported: All RAID types. Best practice: RAID1/10. Use a dedicated array group; don't host both system LUN and data LUNs on the same array group.	Supported: All RAID types. Best practice: RAID1/10. Use a dedicated array group; don't host both system LUN and data LUNs on the same array group.
Exchange mailbox database (.edb) file volume	Supported: All RAID types. Best practice: 5,400 or 7,200 disks = RAID1/10 only. RAID5* = Maximum of 7 disks per array group and array controller high priority scrubbing and surface scanning enabled. RAID6* = High priority scrubbing and surface scanning enabled.	Supported: All RAID types. Just a bunch of disks (JBOD) (not RAID) (three or more database copies). Best practice: 5,400 or 7,200 disks = RAID1/10 only or JBOD. When lagged, database copies should have two or more lagged copies, or lagged copies should be protected with RAID. RAID5* = Maximum of 7 disks

		per array group and array controller high priority scrubbing and surface scanning enabled. RAID6* = High priority scrubbing and surface scanning enabled.
Exchange mailbox database log volume	Supported: All RAID types. Best practice: RAID1/10.	Supported: All RAID types. JBOD (not RAID) (three or more database copies). Best practice: RAID1/10. When lagged, database copies should have two or more lagged copies, or lagged copies should be protected with RAID.

*Includes RAID variations such as RAID50 or RAID51 for RAID5

The following table provides guidance about storage array configurations for Exchange 2010.

Supported RAID types for the Exchange 2010 Mailbox server role

RAID type	Description	Supported or best practice
Disk array RAID stripe size (KB)	The stripe size is the per disk unit of data distribution within a RAID set. Stripe size is also referred to as *block size*.	Best practice: 256 KB or greater. Follow storage vendor best practices.
Storage array cache settings	The cache settings are provided by a battery-backed caching array controller.	Best practice: 75 percent write cache and 25 percent read cache (battery-backed cache). Follow storage vendor best practices.
Physical disk write caching	The settings for the cache are on each individual disk.	Supported: Physical disk write caching must be disabled when used without a UPS.

The following table provides guidance about database and log file choices.

Database and log file choices for the Exchange 2010 Mailbox server role

Database and log file options	Description	Stand-alone: supported or best practice	High availability: supported or best practice
File placement:	Database per log isolation refers to placing	Best practice: For recoverability, move	Supported: Isolation of logs and databases isn't

database per log isolation	the database file and logs from the same mailbox database onto different volumes backed by different physical disks.	database (.edb) file and logs from the same database to different volumes backed by different physical disks.	required.
File placement: database files per volume	Database files per volume refers to how you distribute database files within or across disk volumes.	Best practice: Based on your backup methodology.	Supported: When using JBOD, divide a single disk into two volumes (one for database; one for log stream).
File placement: log streams per volume	Log streams per volume refers to how you distribute database log files within or across disk volumes.	Best practice: Based on your backup methodology.	Supported: When using JBOD, divide a single disk into two volumes (one for database; one for log stream). Best practice: When using JBOD, single database per log per volume.
Database size	Database size refers to the disk database (.edb) file size.	Supported: Approximately 16 terabytes. Best practice: • 200 gigabytes (GB) or less. • Provision for 120 percent of calculated maximum database size.	Supported: Approximately 16 terabytes. Best practice: • 2 terabytes or less. • Provision for 120 percent of calculated maximum database size.
Log truncation method	Log truncation method is the process for truncating and deleting old database log files. There are two mechanisms: • Circular logging, in which Exchange deletes the logs. • Log truncation, which occurs after a successful full or incremental Volume Shadow Copy Service (VSS)	Best practice: • Use backups for log truncation (for example, circular logging disabled). • Provision for three days of log generation capacity.	Best practice: • Enable circular logging for deployments that use Exchange 2010 data protection features. • Provision for three days beyond replay lag setting of log generation capacity.

	backup.		

The following table provides guidance about Windows disk types.

Windows disk types for the Exchange 2010 Mailbox server role

Windows disk type	Description	Stand-alone: supported or best practice	High availability: supported or best practice
Basic disk	A disk initialized for basic storage is called a basic disk. A basic disk contains basic volumes, such as primary partitions, extended partitions, and logical drives.	Supported. Best practice: Use basic disks.	Supported. Best practice: Use basic disks.
Dynamic disk	A disk initialized for dynamic storage is called a dynamic disk. A dynamic disk contains dynamic volumes, such as simple volumes, spanned volumes, striped volumes, mirrored volumes, and RAID-5 volumes.	Supported.	Supported.

The following table provides guidance on volume configurations.

Volume configurations for the Exchange 2010 Mailbox server role

Volume configuration	Description	Stand-alone: supported or best practice	High availability: supported or best practice
GUID partition table (GPT)	GPT is a disk architecture that expands on the older master boot record (MBR) partitioning scheme. The maximum NTFS formatted partition size is 256 terabytes.	Supported. Best practice: Use GPT partitions.	Supported. Best practice: Use GPT partitions.
MBR	An MBR, or partition sector, is the 512-byte boot sector that is the first sector (LBA Sector 0) of a partitioned data storage device such as a hard disk. The maximum NTFS formatted partition size is 2 terabytes.	Supported.	Supported.

Partition alignment	Partition alignment refers to aligning partitions on sector boundaries for optimal performance.	Supported: The Windows Server 2008 default is 1 megabyte (MB).	Supported: The Windows Server 2008 default is 1 MB.
Volume path	Volume path refers to how a volume is accessed.	Supported: Drive letter or mount point. Best practice: Mount point host volume must be RAID enabled.	Supported: Drive letter or mount point. Best practice: Mount point host volume must be RAID-enabled.
File system	File system is a method for storing and organizing computer files and the data they contain to make it easy to find and access the files.	Supported: NTFS support only.	Supported: NTFS support only.
NTFS defragmentation	NTFS defragmentation is a process that reduces the amount of fragmentation in Windows file systems. It does this by physically organizing the contents of the disk to store the pieces of each file close together and contiguously.	Supported. Best practice: Not required and not recommended.	Supported. Best practice: Not required and not recommended.
NTFS allocation unit size	NTFS allocation unit size represents the smallest amount of disk space that can be allocated to hold a file.	Supported: All allocation unit sizes. Best practice: 64 KB for both .edb and log file volumes.	Supported: All allocation unit sizes. Best practice: 64 KB for both .edb and log file volumes.
NTFS compression	NTFS compression is the process of reducing the actual size of a file stored on the hard disk.	Supported: Not supported for Exchange database or log files.	Supported: Not supported for Exchange database or log files.
NTFS Encrypting File System (EFS)	EFS enables users to encrypt individual files, folders, or entire data drives. Because EFS provides strong encryption through industry-standard algorithms and public key cryptography, encrypted files are confidential even if an	Supported: Not supported for Exchange database or log files.	Not supported for Exchange database or log files.

	attacker bypasses system security.		
Windows BitLocker (volume encryption)	Windows BitLocker is a data protection feature in Windows Server 2008. BitLocker protects against data theft or exposure on computers that are lost or stolen, and it offers more secure data deletion when computers are decommissioned.	Supported: All Exchange database and log files.	Supported: All Exchange database and log files. Windows failover clusters require Windows Server 2008 R2 or Windows Server 2008 R2 SP1 and the following hotfix: You cannot enable BitLocker on a disk volume in Windows Server 2008 R2 if the computer is a failover cluster node. Exchange volumes with Bitlocker enabled are not supported on Windows failover clusters running earlier versions of Windows. For more information about Windows 7 BitLocker encryption, see BitLocker Drive Encryption in Windows 7: Frequently Asked Questions.

Return to top

Windows Disk Timeouts

Starting with Exchange 2010 Service Pack 1 (SP1), intelligence is included to deal with hung I/O. Before Exchange 2010, Exchange reported slow I/O in the event log, but does not take any other action. Exchange 2010 SP1 will actively fail (bugcheck) the server if the hung I/O is affecting active databases on a DAG node.

The new recovery logic in Exchange 2010 SP1 leverages the built-in Windows bugcheck behavior when certain conditions occur. Specifically, when hung IO occurs. The Extensible Storage Engine (ESE) has been updated to detect hung IO and to take corrective action to automatically recover the server.

ESE maintains an IO watchdog thread that detects when an IO has been outstanding for a specific period of time. By default, if an IO for a database is outstanding for more than one minute, ESE logs an event. If a database has an IO that has been outstanding for more than four minutes, ESE logs a specific failure event, if it is possible to do so.

ESE Event 507, 508, 509, or 510 may or may not be logged, depending on the nature of the hung IO. If the nature of the problem is such that the OS volume is affected or the ability to write to the event log is affected, the events are not logged. If the events are logged, the Microsoft Exchange Replication service (MSExchangeRepl.exe) detects that

condition, and intentionally cause a bugcheck of Windows by terminating the wininit.exe process. The following table describes the recovery logic behavior in Exchange 2010 SP1 and earlier versions.

Exchange Version	I/O Type	I/O Time	Behavior
Exchange Server 2003	Completed	>60 seconds	Write to Event Log
Exchange Server 2007	Completed	>60 seconds	Write to Event Log
Exchange 2010 RTM	Completed	>60 seconds	Write to Event Log ESE performs clean-page overwrite on pages affected by slow I/O
Exchange 2010 SP1	In Flight	>60 seconds	Write to Event Log
Exchange 2010 SP1	In Flight	>4 minutes	Terminate wininit.exe process and bugcheck the server
Exchange Server 2010 SP1	Completed	>30 seconds	Write to event log ESE performs clean-page overwrite on pages affected by slow I/O

Note:

In the **I/O Type** column of the table, **In Flight** describes a slow I/O operation that has not yet successfully finished. and **Completed** describes a slow I/O operation that took more than 30 seconds to finish. The concept of detecting slow I/O in-flight operations is new in Exchange 2010. In earlier versions of Microsoft Exchange, the program reported only after the I/O had finished.

We recommend that you do not change the new recovery logic behavior in Exchange 2010 SP1. However, if you must change the new behavior, see New High Availability and Site Resilience Functionality in Exchange 2010 SP1 for more information about how to do this.

The following table outlines the recommended guidance for setting the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Disk\TimeOutValue** registry subkey for servers that are running the Exchange 2010 Mailbox role.

Scenario	Recommendation
Direct-Attached Storage	Reduce Windows disk TimeOutValue to 20 seconds Refer to hardware manufacturer's guidance Hardware manufacturer's guidance takes priority in the event of a clash
SAN-Attached RAID Storage	Reduce Windows disk TimeOutValue to 20 seconds Refer to hardware manufacturer's guidance

	Hardware manufacturer's guidance takes priority in the event of a clash
JBOD Storage	Increase Windows disk TimeOutValue to 180 seconds Refer to hardware manufacturer's guidance Hardware manufacturer's guidance takes priority in the event of a clash

For more information, see the Exchange Server Team Blog article Windows Disk Timeouts and Exchange Server 2010.

1.2.1.9.7 Understanding Exchange 2010 LUN Architecture

Understanding Exchange 2010 LUN Architecture

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-22*

In many cases, the physical disk, or optimal logical unit number (LUN), that the operating system recognizes is abstracted from the hardware used to present the disk to the operating system. LUN architecture is used in Microsoft Exchange Server 2010.

Although there are many ways to design LUNs in Exchange 2010, we recommend the following designs to limit complexity:

- One LUN per Database
- Two LUNs per Database
- Two LUNs per Backup Set

One LUN per Database

Single LUN per database architecture means that both the database and its corresponding log files are placed on the same LUN. To deploy a LUN architecture that only uses a single LUN per database, you must have a database availability group (DAG) that has two or more copies, and not be using a hardware-based Volume Shadow Copy Service (VSS) solution.

Some of the benefits of this strategy include:

- Simplifies storage administration with fewer LUNs to manage.
- Reduces (potentially) the number of backup jobs.
- Provides flexibility to isolate the performance between databases when not sharing spindles between LUNs.

A concern with this strategy is that it limits the ability to perform hardware-based VSS backup and restore procedures (for example, clone snapshots). For VSS details, see Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003.

Return to top

Two LUNs per Database

With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend upon your backup strategy. If your recovery time objective is small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. This approach will exceed the number of available drive letters; therefore, volume mount points must be used.

Some of the benefits of this strategy include:

- Enables hardware-based VSS at a database level, providing single database backup and restore.
- Provides flexibility to isolate the performance between databases when not sharing spindles between LUNs.
- Increases reliability because a capacity or corruption problem on a single LUN will only impact one database. This is an important consideration when you aren't leveraging the built-in mailbox resiliency features.

Some of the concerns with this strategy include:

- 100 databases require 200 LUNs, which could exceed some storage array maximums.
- A separate LUN for each database causes more LUNs per server, which increases administrative costs and complexity.

Return to top

Two LUNs per Backup Set

A backup set is the number of databases fully backed up in a night. A solution that performs a full backup on 1/7th of the databases nightly (for example, using a weekly or bimonthly full backup with daily incremental or differential backups) can reduce complexity by placing all of the databases to be backed up on the same log and database LUN. This can reduce the number of LUNs on the server.

Some of the benefits of this strategy include:

- Simplifies storage administration with fewer LUNs to manage.
- Reduces (potentially) the number of backup jobs.

Some of the concerns with this strategy include:

- The ability to perform hardware-based VSS backup and restore procedures (for example, clone snapshots) is limited. For VSS details, see Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003.
- A capacity or corruption problem on a single LUN could impact more than one database.

1.2.1.9.8 Understanding Exchange 2010 Page Zeroing

Understanding Exchange 2010 Page Zeroing

Planning and Deployment > Planning for Exchange 2010 > Mailbox Server Storage Design >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

By default, most storage systems (file systems and databases) don't write over the actual data when it's deleted. They delete the pointer to the data and add the pages and blocks backing the data to a free or available list. The data is eventually deleted when the pages and blocks are re-used. *Data zeroing* is a mechanism that writes either zeros or a binary pattern over deleted data in an attempt to make the data much more difficult to recover. This action is taken for security reasons. Data zeroing occurs prior to the pages and blocks being re-used by the storage system.

Page Zeroing in Exchange 2010 SP1

In Service Pack 1 (SP1) for Exchange Server 2010, page zeroing is on by default. There is no mechanism to disable it. Page zeroing operations are recorded in the transaction log files so that all copies of a database are page-zeroed in a similar manner. That is, zeroing a page on the active database causes the page to get zeroed on a passive database after the passive database replays the transaction log with the page zeroing log record. There is no mechanism for the Extensible Storage Engine (ESE) to prioritize the reutilization of zeroed pages over allocating new space. Tables which have sequential space allocation assigned will intentionally skip fragmented or zeroed pages in favor of using new or free sequential pages. This approach reduces the database I/O footprint of the server.

In Exchange 2010 SP1, improvements to database page zeroing help to reduce the performance impact on servers when they're performing zeroing functions. Key improvements are:

- **Optimized storage and network capacity** The Extensible Storage Engine (ESE) writes a page-zeroing record to the transaction log file instead of logging the entire page image. This approach reduces log write I/O, keeps the capacity footprint of the logs as low as possible, and reduces the bandwidth requirements to ship the logs from active to passive copies.
- **Optimized database disk I/O** In previous versions of Exchange 2010, page zeroing occurred only during a backup or scheduled maintenance process (when configured), and caused significant database disk I/O. In Exchange 2010 SP1, page zeroing occurs by default and happens primarily at transaction time. For the majority of cases, the zeroing occurs immediately after the hard delete. This design allows the database to utilize the checkpoint depth capability of the engine, which ensures dirty pages stay in cache for a certain amount of time so additional page updates that occur in close time proximity don't cause additional database write I/O. Because of this design, page zeroing has no significant database I/O impact, which is why it's enabled by default.

Implementation of Page Zeroing in the ESE Database

The ESE database uses pages as its unit of storage and has implemented *page zeroing*. ESE page zeroing writes a binary pattern once over a hard-deleted record. The page-zeroing pattern is specific to the ESE engine operation and is different for run-time operations vs. maintenance operations. The following table lists the fill patterns that correspond to specific run-time operations.

Fill pattern of page zeroing per ESE run-time operation

ESE run-time operation	Fill pattern
Replace	R
Record/long value delete	D

Freed page space	H

The following table lists the fill patterns that correspond to specific operations that occur during ESE background database maintenance.

Fill pattern of page zeroing per ESE background database maintenance operation

ESE background database maintenance operation	Fill pattern
Record delete	D
Long value delete	L
Freed page space of partially used page	Z
Freed page space of unused page	U

Background Database Maintenance

Configured by default, background database maintenance is a process which continuously checksums and scans the database in the background. Its primary function is to checksum the database pages, but it also handles cleaning up after Exchange 2010 Store crashes (cleaning up space and zeroing out records and pages which did not occur due to the crash). Background database maintenance processes approximately 5 MB per second per database. If timely page zeroing is a priority, you can reduce database sizes to ensure page zeroing occurs for the crash recovery cases in a shorter time period (for example, 24 hours). For more information, see New Exchange Core Store Functionality.

Background database maintenance is a continuous process, so there are no events associated with its start and completion. You can track the progress of background database maintenance completion with the following performance counter:

- MSExchange Database =>Instances->Database Maintenance Duration: This performance counter indicates the number of seconds that have passed since maintenance last completed for a given database.

Process of ESE Database Page Zeroing

The following table discusses database delete scenarios, and when page zeroing functions occur.

ESE background database maintenance operation

Database delete scenario	ESE process and timeframe to zero database data
• Scenario 1: Single item recovery is disabled and user purges item from the Recoverable Items folder. • Scenario 2: Single item recovery is disabled and the Recoverable Items retention period is set to zero. • Scenario 3: Single item recovery is enabled and the item expires based on the deleted item retention period.	An asynchronous thread writes a binary pattern over the deleted data. This action occurs within milliseconds of the record deletion. If the Store process crashes while the asynchronous zeroing work is still outstanding (or version store cleanup is cancelled due to version store growth), the zeroing is completed when background database maintenance (24x7) processes that section of the database. For more

	information about background database maintenance, see New Exchange Core Store Functionality.
View Scenario: Expiration of items from Outlook/ Outlook Web Access folder view (for example, Conversation view)	Data zeroing occurs when background database maintenance (24x7) processes this section of the database.
Move Mailbox/Delete Mailbox Scenario: Deletion of source mailbox (expiry of deleted mailbox from dumpster)	Data zeroing occurs when background database maintenance (24x7) processes this section of the database.

Monitoring Page Zeroing Behavior

You can measure and monitor page zeroing functionality with the following ESE performance counters:

- MSExchange Database->Database Maintenance Pages Zeroed: This performance counter indicates the number of pages zeroed by the database engine since the performance counter was invoked.
- MSExchange Database->Database Maintenance Pages Zeroed/sec: This performance counter indicates the rate at which pages are zeroed by the database engine.

Note:
To learn how to enable these counters, see How to Enable Extended ESE Performance Counters.

Page zeroing is a database maintenance function, so performance information related to both page zeroing for run-time transactions and page zeroing due to background database maintenance is included in these counters.

Exchange 2010 Mailbox Data and Page Zeroing

Only the Mailbox database file (.edb) has provisions for page zeroing. The following Exchange 2010 Mailbox data types have no provisions for page zeroing:

- Mailbox database transaction logs (.log)
  When transaction logs are deleted (due to truncation via backup or circular logging), there is no process to zero the blocks in the NTFS file system backing the log file. It's likely that NTFS will quickly re-utilize that free space for newly created logs, but there is no guarantee that this will happen.
- Content index catalog files
  Exchange 2010 uses Exchange Search (MSExchangeSearch) for search indexing functionality. The search index catalog is comprised of several dozen files stored on the same volume as the mailbox database file. When a message is hard-deleted from the mailbox database, the associated content in the search catalog isn't immediately deleted. The content deletion occurs when MS Search does a shadow, or master merge, of many small catalog files in to a single larger file. After the master merge completes, the smaller catalog files are deleted. There is no process to zero the blocks which backed the deleted catalog files. To ensure the catalog files are fully zeroed, use the following process:
  .1.Stop the MSExchangeSearch and Microsoft Search (MSSearch) processes on affected servers.

.2.Delete the catalog directory for each affected database (on all copies).
.3.Re-start the MSExchangeSearch and MSSearch processes.
.4.Zero-out the freed block using a NTFS block zeroing tool.

Note:
Deleting the content index catalog files severely impacts the client user experience on the Exchange 2010 server. Outlook Web App and Exchange ActiveSync server searches will be broken until the content index rebuilds the catalog by re-crawling each database. This rebuild could take several days to several weeks to complete.

1.2.1.9.9 Mailbox Server Processor Capacity Planning

Mailbox Server Processor Capacity Planning

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-19*

Mailbox server capacity planning has changed significantly from previous versions of Exchange due to mailbox resiliency provided in Microsoft Exchange Server 2010. Exchange 2010 has been reengineered with the concept of mailbox resiliency, in which the architecture changed so that automatic failover protection is now provided at the individual mailbox database level instead of at the server level. There are two primary changes that affect the Mailbox server role capacity planning process:

- Hosting active and passive database copies on the same server
- Providing database copy count

You can use the information in this topic to better understand these changes and as design guidance for sizing Mailbox servers when configured for mailbox resiliency.

Contents

Hosting Active and Passive Database Copies on the Same Server

In Exchange 2010, you can host both active and passive database copies on the same server when the server is configured for mailbox resiliency. The processors on each server service the workload from both active mailboxes (hosted on active, mounted databases) as well as passive mailboxes (hosted on passive databases). The processor requirements for passive mailboxes and databases must be considered when performing Exchange 2010 mailbox capacity planning. A passive database copy uses CPU resources to check or validate replicated logs, to replay replicated logs into the database, and to maintain the content index associated with the database copy. In general, each passive mailbox

(hosted on a passive database copy) equates to 15 percent of the CPU utilization required to host the active mailbox (hosted on an active database copy).

A key aspect of Exchange 2010 mailbox capacity planning is determining how many database copies you plan to activate on a per-server basis when configured for mailbox resiliency. There is a range of designs from which you can choose, but we recommend the following models:

- **Design for all database copies activated** In this model, you design your server to handle 100 percent of hosted database copies becoming active.
- **Design for targeted failure scenarios** In this model, you design your server to handle the active mailbox load during the worst failure case.

For more information, see the following topics:

- Understanding High Availability Factors
- Understanding Processor Configurations and Exchange Performance
- Understanding Memory Configurations and Exchange Performance

Return to top

Database Copy Count

Using Exchange 2010 mailbox resiliency, you can configure multiple database copies (up to 16 copies per database). Each additional database copy increases the CPU work the server hosting the active copy must do. This additional work on the server with the active copy is primarily log replication and content indexing because each passive copy will retrieve content to index from the active copy.

The per-mailbox CPU requirements of the server hosting the active database copy must be increased by 10 percent for each additional database copy (for example, one copy = 10 percent, two copies = 20 percent, and so on). This factor is only applied to the CPU requirements for the server hosting the active database copy. The CPU used to host passive database copies isn't applied to this calculation. For more information, see Understanding Processor Configurations and Exchange Performance.

Return to top

Design Steps

Due to new sizing factors, additional steps are required to size Mailbox servers when configured for mailbox resiliency. The general steps are as follows:

1. Consider high availability requirements for the overall solution architecture. Consider mailbox resiliency or a stand-alone solution, site resiliency, the number of database copies required, and the number of servers or database availability groups (DAGs) to handle common failure cases.
2. If using mailbox resiliency, choose which database activation model to design for. (Design for targeted failure scenario or design for all database copies activated.)
3. Use the following table to estimate CPU and memory requirements based on design. Consider CPU and memory requirements for active mailboxes, CPU requirements for passive mailboxes, and CPU requirements on the active mailbox for additional database copies. Use the activation model choice to define the maximum number of mailboxes the design can accommodate.

The following table provides estimated values based on user profile. The estimated values are based on a peak two-hour period during the knowledge worker workday (for example, from 10:00 until noon). This peak period is often twice the 8 to 10-hour daily average load. The user profile description has been omitted because the range of profiles has grown as e-mail usage has increased.

Per mailbox database cache, IOPS, and CPU estimates based on user profile and message activity

Messages sent or received per mailbox per day	Database cache per mailbox in megabytes (MB)	Single database copy (stand-alone) with estimated IOPS per mailbox	Multiple database copies (mailbox resiliency) with estimated IOPS per mailbox	Megacycles for active mailbox or stand-alone mailbox	Megacycles for passive mailbox
50	3	0.06	0.05	1	0.15
100	6	0.12	0.1	2	0.3
150	9	0.18	0.15	3	0.45
200	12	0.24	0.2	4	0.6
250	15	0.3	0.25	5	0.75
300	18	0.36	0.3	6	0.9
350	21	0.42	0.35	7	1.05
400	24	0.48	0.4	8	1.2
450	27	0.54	0.45	9	1.35
500	30	0.6	0.5	10	1.5

Note:
You must increase the megacycles per active mailbox by 10 percent for each additional database copy after the one active copy.

Calculating the Megacycles for Different Processor Configurations

The example in the next section "Example of Capacity Planning for a Mailbox Server" uses a baseline processor configuration, 2 x 4 core Intel Xeon x5470 3.33-gigahertz (GHz) processors, which yields 3,333 megacycles per processor core. However, this processor configuration most likely isn't the processor configuration you're deploying. You can use the following steps to perform a megacycle adjustment to determine the available megacycles your server design can support.

1. Open a Web browser, and then go to Standard Performance Evaluation Corporation.
2. Click **results**, highlight **CPU2006**, and then select **Search CUP2006 Results**.
3. In the **Available Configurations** drop-down box, select **SPECint2006 Rates**. In **Search Form Request**, select the **Simple** option and then click **Go**. Under **Simple Request**, enter the search criteria (for example, **Processor Matches x5550**).
4. Find the server and processor you're planning to deploy, click **Execute Simple Fetch**, and note the resulting value.

For example, consider that you're deploying a Dell PowerEdge M710 8-core server with Intel x5550 2.67GHz processors (2,670 megahertz (MHz)). For this configuration, the SPECint_rate2006 results value is 240, with a value of 30 per core (known in the formula as *new platform per core value*).

The baseline system HP DL380 G5 x5470 3.33GHz, 8 cores (3,333 MHz), has a

SPECint_rate2006 results value of 150, or 18.75 per core (known in the formula as *baseline per core value*).

To determine the megacycles of the M710 platform example, use the following formula:

((New platform per core value) × (Hertz per core of baseline platform)) ÷ (Baseline per core value) = Adjusted megacycles per core

30 × 3,333 ÷ 18.75 = 5,333 megacycles per core or 42,662 megacycles per server

Example of Capacity Planning for a Mailbox Server

The following example illustrates the processor sizing process. The example has the following design assumptions:

- **Mailbox count** 12,000.
- **Mailbox profile** 150 messages sent or received per day.
- **Availability requirements** Mailbox resiliency within a single site, tolerance for double-server failures.
- **Storage architecture** Just a bunch of disks (JBOD) (not RAID) storage with three database copies, 300 mailboxes per database, 40 databases with 30 database copies per server (or 120 database copies per DAG). The three database copies are randomly distributed across the four nodes so no two servers look alike.
- **Activation model** Targeted failure scenario, where double-server failures are tolerated with minimal outage. This results in 20 databases out of 30 copies per server being activated after two server failure events.
- **Server platform** 2 x 4 core Intel Xeon x5470 3.33-GHz processors.

The following process applies.

1. **Calculate server count** A four-node DAG is required to tolerate double-server failures, so the design needs to begin with four Mailbox servers within the DAG.
2. **Calculate maximum active mailboxes per server based on the activation model** Assuming the active databases are equally distributed across the nodes, each server would ideally host 3,000 active mailboxes (12,000 ÷ 4). To calculate the active mailbox count after a double-node failure (based on this example), the mailbox count would be divided by the remaining two nodes, which equals 6,000 active mailboxes per node (12,000 ÷ 2).
   In this example, the *MaximumActiveDatabases* parameter on the **Set-MailboxServer** cmdlet is configured for 20.
3. **Calculate active mailbox CPU requirements** Multiply the maximum number of active mailboxes (20 × 300 = 6,000 active mailboxes) by the megacycles per active mailbox (6,000 × 3 megacycles = 18,000 megacycles), based on the preceding table. Multiply this value by 10 percent for each additional database copy.
   In this example, there's one active copy and two passive copies for every database, so the 18,000 megacycles is increased by 20 percent (18,000 × 1.2 = 21,600 megacycles).
4. **Calculate passive mailbox CPU requirements** Multiply the number of passive mailboxes (when a server is hosting the maximum number of active mailboxes) by the megacycles per passive mailbox (3,000 × .45 megacycles = 1,350 megacycles), based on the preceding table.
5. **Add active and passive CPU requirements to get total CPU requirement** In this example, 21,600 active mailbox megacycles + 1,350 passive mailbox megacycles = 22,950 megacycles total CPU requirement.
6. **Apply total CPU requirement to hardware platform** This example uses a 2 x 4 core Intel Xeon x5470 3.33-GHz processor-based server. This equates to 26,664 megacycles (8 × 3,330 MHz). Divide the required megacycles by the available megacycles based on the server platform to estimate the CPU utilization at peak period after a double-node failure (22,950 ÷ 26,664 = 86

percent predicted CPU utilization). The 86 percent CPU utilization rate represents a fully utilized server with almost no space, but because this is based on a double-failure condition that occurs during the peak period, this rate may be acceptable.
We recommend that stand-alone servers be designed to not exceed 70 percent utilization during peak period, and two-node and three-node configurations that can only tolerate a single-node failure be designed not to exceed 80 percent utilization at the peak period (during a node failure).

Virtualization

If you're sizing a new virtualized deployment, you don't want to oversubscribe processors. Therefore, you want to have a 1:1 ratio of logical cores to virtual CPUs on your host. From there, use the physical sizing guidance discussed in this topic and then account for 10 percent hypervisor CPU overhead. For example, if you sized your physical deployment for 500 users per core, your virtual deployment would be sized for 450 users per core.

Calculating the Number of Required Mailbox Cores per Data Center

As discussed in Understanding Server Role Ratios and Exchange Performance, you will need to size your Hub Transport server, Client Access server, and global catalog server based on the load of the Mailbox servers.

It's a common assumption that the processor core ratio guidance is based on the total number of mailbox cores being deployed; however, that isn't the case. Generally, the Mailbox servers aren't running at 100 percent CPU utilization 100 percent of the time. A well-designed solution should never have 100 percent CPU utilization for an extended duration of time based on the 70 percent and 80 percent design thresholds described in the previous section.

To calculate the minimum number of Hub Transport server, Client Access server, and global catalog server processor cores, you need to determine the number of mailbox cores required to support the active mailbox databases during the worst failure model.

The formula to calculate the required mailbox cores within a data center is:

Required mailbox cores = (active mailbox CPU requirements) ÷ (adjusted megacycles per core) × (number of remaining servers) × (number of DAGs)

If you aren't deploying a high availability solution, the formula is:

Required mailbox cores = (active mailbox CPU requirements) ÷ (adjusted megacycles per core) × (number of Mailbox servers within the data center)

Example of Calculating the Number of Required Mailbox Cores per Data Center

Continuing with the previous example, the solution can sustain two server failures, with each remaining server requiring 18,000 megacycles. Therefore:

Required mailbox cores = (18,000 ÷ 3,333) × 2

= 5.4 × 2

= 11 total cores

This means that, within this data center, a total of 11 cores will be used out of the available 16 mailbox cores during the targeted failure model (or 5.5 cores per remaining Mailbox server).

Based on this data, the minimum number of processor cores that should be deployed

within the data center for the Hub Transport server, Client Access server, and global catalog server is:

Minimum Hub Transport server (with antivirus) processor cores per data center = (number of required mailbox cores per data center) ÷ 5

= 11 ÷ 5

= 3 cores

Minimum Client Access server processor cores per data center = (number of required mailbox cores per data center) × 3 ÷ 4

= 11 × 3 ÷ 4

= 33 ÷ 4

= 9 cores

Minimum global catalog server (64-bit) processor cores per data center = (number of required mailbox cores per data center) ÷ 8

= 11 ÷ 8

= 2 cores

1.2.1.9.10 Exchange 2010 Mailbox Server Role Design Example

Exchange 2010 Mailbox Server Role Design Example

Planning and Deployment > Planning for Exchange 2010 > Mailbox Server Storage Design >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-01*

This topic provides an example of how to determine the appropriate memory, capacity, I/O, and CPU performance requirements for the Mailbox server role and its accompanying architecture.

You can use the Exchange Server 2010 Mailbox Server Role Requirements Calculator to determine the appropriate requirements for the Mailbox server role by specifying your set of input factors. The calculator can determine the requirements discussed in this example. For more information about the calculator (and to download it), see the Exchange Server Team Blog article Exchange 2010 Mailbox Server Role Requirements Calculator.

Note:

The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

For more information about the Mailbox Server role storage design, see Mailbox Server Storage Design.

The scenario used in this example is that of a three database copy solution that makes use of JBOD (just a bunch of disks) storage. For the purposes of this example, consider the following architecture requirements:

- Six Mailbox servers participating in a single database availability group (DAG)
- Exchange Mailbox server also hosts the Hub Transport and Client Access server roles
- Three high availability mailbox database copies, no lagged database copies
- 7.2 K (7,200 RPM) 1-terabyte SATA spindles are used
- JBOD storage configuration (1 logical unit number (LUN) / Database LUN architecture)
- For backup architecture, using the native data protection features provided via single item recovery and mailbox resiliency
- A restore LUN is deployed for maintenance and recovery operations
- Each LUN has at minimum 20 percent free space
- The solution should survive double server failure events
- The only server role installed is the Mailbox server role

Contents

Mailbox Capacity Requirements

The following example illustrates appropriate sizing for an environment in which there are 24,000 2-GB 100 messages per day profile mailboxes spread across six Mailbox servers that are participating within a DAG with each database having three copies. These mailboxes receive an average of 37 MB of mail per five-day work week, with an average message size of 75 KB. Single item recovery is enabled with a 14-day deleted item retention window. The following calculations are used to determine the mailbox size:

Mailbox Size = Mailbox Limit + Whitespace + Dumpster

Whitespace = 100 messages per day x 75/1024 MB = 7.32 MB

Dumpster = (100 messages per day x 75/1024 MB * 14 days) + (2048 MB x 0.012) + (2048 MB x 0.03) = 188.6 MB

Example values for determining actual mailbox size on disk

Mailbox quota	Dumpster size (two weeks)	White space	Total size on disk
2 GB	188.7 MB	7.3 MB	2.19 GB (+12%)

Because this environment leverages JBOD storage, the maximum database size that can be deployed is dependent on the size of the disk. To determine the maximum database size for the JBOD scenario, use the following formula where the formatted capacity of a 1TB disk is 931 GB, the Free Space Percentage Requirement is 20 percent, and the Content Index Percentage is 10 percent:

Maximum Database Size = [Formatted Disk Capacity x (1 – Free Space Percentage Requirement)] / (1 + Content Index Percentage)

= [931 GB x (1 - .2)] / (1+ .10)

= 744.8 GB / 1.1

= 677 GB

In this environment, each user's mailbox consumes 2.25 GB of disk space. To support 24,000 mailboxes, with a 677 GB database size, it's necessary to have 102 databases. This requirement results in a final count of 235 mailboxes per database.

However, because this solution is leveraging a JBOD storage architecture, it's vital to ensure that the number of mailboxes per database not exceed the amount of random I/O that can be achieved on the single disk. Because this solution is leveraging large form factor 7.2K SATA spindles, the spindle can achieve a maximum of 55 random I/O per second (IOPS) when fully utilized. Factoring in a 20 percent I/O overhead growth buffer, this means that the spindle can handle a total of 44 random IOPS.

Provided that the user base has a 100 messages per day profile, each mailbox is expected to consume 0.1 IOPS; therefore, the disk can support a maximum of 440 mailboxes with this IOPS profile. Because the capacity calculations determined that the maximum number of mailboxes that can be supported is 235 and this is below the 440 mailboxes determined based on the IOPS profile, this solution can be deployed on a single disk.

To determine the actual database size, use the following formula:

Database Size = Number of Mailboxes x Mailbox Size on Disk x Database Overhead Growth Factor

Based on the number of mailboxes, the actual size of the mailboxes, and the database growth overhead factor of 20 percent, the database size is 619 GB as shown in the following table.

Database capacity requirements

Mailboxes per database	Total number of databases	Database size requirements
235	102	619 GB

To ensure that the Mailbox server doesn't sustain any outages as a result of space allocation issues, the transaction logs also need to be sized to accommodate all of the logs that will be generated during the backup set. Provided that this architecture is leveraging the mailbox resiliency and single item recovery features as the backup architecture, the log capacity should allocate for three times the daily log generation rate in the event that a failed copy isn't repaired for three days. (Any failed copy prevents log truncation from occurring.)

A 100 messages per day profile mailbox generates 20 transaction logs per day on average, so a 24,000 mailbox environment will generate 576,000 transaction logs each day. Therefore, each database will generate 5,647 logs per day. One percent of the mailboxes are moved per week on one day (Saturday). The solution makes use of the native data protection features within Exchange and, therefore, doesn't perform backups and is sized to tolerate three days without log truncation.

As shown in the following table, this server requires 23 GB of space for each database copy.

Log capacity requirements

Logs per database	Log file size	Daily log size	Move mailbox size ÷ database	Truncation failure tolerance	Log size requirements
5647	1 MB	5.65 GB	6 GB (240 × 2.19 GB x 1.2 / 102)	16.5 GB (3 × 5.65 GB)	23 GB (16.5 GB + 6 GB)

Provided that this is a Mailbox Resiliency and JBOD configuration with three copies, each database and its corresponding transaction logs will be placed on the same LUN. The LUN size required is:

LUN Capacity = Database Size ÷ (1 - Free Space Percentage Requirement)

= (Database Size + Transaction Log Size + Content Index Size) ÷ (1 - 0.2)

= (619 GB + 23 GB + 61.9 GB) / 0.8

= 879 GB

Determining required LUN size

Database size	Transaction log size	Content index size	Database LUN size
619 GB	23 GB	61.9 GB	879 GB

Return to top

Database Copy Requirements

Provided that there are a total of 102 databases required to support 24,000 mailboxes and that each database has three copies, the DAG will support a total of 306 databases. 306 databases spread across six Mailbox servers means that each Mailbox server will house 51 database copies. The database copies should be distributed across the servers in the DAG in such a way that server level failures cause active databases to fail over to as many remaining servers as possible (database copies aren't distributed in a symmetric fashion).

To maximize the efficiency of the Mailbox servers participating in the DAG, the active databases will be equally distributed across all Mailbox servers. As a result, when all six Mailbox servers are functioning, each server should be hosting 17 active database copies.

In the event that a single Mailbox server fails, the 17 databases will be redistributed across the remaining Mailbox servers increasing the active database copy count per server to 21.

In the event that two Mailbox servers fail, the 34 databases will be redistributed across the remaining Mailbox servers, increasing the active database copy count per server to 26. It's this active copy count that will be used to size the memory and CPU requirements for the Mailbox server.

For more information about how to distribute the database copies across the Mailbox servers, see Database Copy Layout Design.

Return to top

Mailbox Memory Requirements

With a message profile of 100 messages / day, the minimum required memory per mailbox to support the database cache is 6 MB. With a worst case active mailbox database count per server being 26, each server could host a total of 6,110 live mailboxes. In addition, there are a total of 51 databases per server. The Mailbox server requires a minimum database cache of 12 GB. Therefore, the amount of memory required to support the database cache is:

Minimum Required Database Cache = MAX((Number of Live Mailboxes x Memory Required / Mailbox), Minimum Memory for Databases)

= MAX(6110 x 6/1024 GB, 12 GB)

= MAX (36 GB, 12 GB)

= 36 GB

When deploying a multi-role architecture, the total physical memory required to support this configuration is 64 GB, based on the table in Understanding the Mailbox Database Cache.

Return to top

Mailbox I/O Requirements

Each mailbox sends or receives 100 messages / day. Therefore, each mailbox has an IOPS profile of 0.1. Each database houses 235 mailboxes. Therefore, the total amount of database volume I/O is:

Database Volume I/O = Number of Mailboxes x IOPS Profile x (1 + I/O Overhead Growth Factor)

= 235 x 0.1 x 1.2

= 28.2 IOPS

The amount of database read I/O percentage for this architecture is 60 percent. Therefore, each database volume generates 16.92 IOPS of read I/O and 11.28 IOPS of write I/O.

In this architecture, each log stream generates 50 percent of the database write I/O. Therefore, the log write I/O per volume is 5.64 IOPS.

The 26 active database copies also generate log read I/O that's 10 percent of the log write I/O; therefore the log read I/O for these databases is 0.56 IOPS.

Considering each large form factor 7.2K SATA disk generates 55 random IOPS, there are no concerns that the disk can't handle the I/O requirements of the database.

Return to top

Mailbox CPU Requirements

During a double server failure event, the remaining servers each host 26 databases for a total of 6,110 active mailboxes per server. Based on the calculations found in Mailbox Server Processor Capacity Planning, each server has the following CPU megacycle

requirements.

Determining CPU megacycle requirements

Active mailbox CPU megacycle requirements	Passive mailbox CPU megacycle requirements	Total CPU megacycle requirements
14,682	1,765	16,447

Provided that the chosen server platform can support a total of 26,400 megacycles, the server CPU platform can support the environment during a double server failure event.

1.2.1.10 Understanding Exchange 2010 Virtualization

Understanding Exchange 2010 Virtualization

Exchange Server 2010 > Planning and Deployment > Planning for Exchange 2010 >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-11-13*

You can deploy Microsoft Exchange Server 2010 in a virtualized environment. This topic provides an overview of the scenarios that are supported for deploying Exchange 2010 on hardware virtualization software.

Contents

The following terms are used in this topic to discuss Exchange virtualization:

- **Cold boot** Refers to the action of bringing a system from a power-off state into a clean start of the operating system. No operating system state has been persisted in this case.
- **Saved state** When a virtual machine is powered off, hypervisors typically have the ability to save the state of the virtual machine, so when the machine is powered back on, it returns to that saved state rather than going through a cold boot startup.
- **Planned migration** When a system administrator initiates the move of a virtual machine from one hypervisor host to another, the action is a *planned migration*. The action could be a single migration, or a system administrator could configure automation to move the virtual machine on a timed basis. A planned migration could also be the result of some other event that occurs in the system, other than hardware or software failure. The key point is that the Exchange virtual machine is operating normally and needs to be relocated for some reason. This relocation can be done via technology, like Live Migration or vMotion. However, if the Exchange virtual machine or the hypervisor host where the virtual machine is located experiences some sort of failure condition, the outcome isn't characterized as a planned migration.

Requirements for Hardware Virtualization

Microsoft supports Exchange 2010 in production on hardware virtualization software only when all the following conditions are true:

- The hardware virtualization software is running one of the following:
  - Windows Server 2008 with Hyper-V technology
  - Windows Server 2008 R2 with Hyper-V technology
  - Microsoft Hyper-V Server 2008
  - Microsoft Hyper-V Server 2008 R2
  - Microsoft Hyper-V Server 2012
  - Any third-party hypervisor that has been validated under the Windows Server Virtualization Validation Program.

  Note:
  Deployment of production Exchange servers on Windows Azure virtual machines is not supported.
- The Exchange guest virtual machine has the following conditions:
  - It is running Exchange 2010. This includes Exchange 2010 Hosting Mode, available in Exchange 2010 SP1 and Exchange 2010 SP2.
  - It is deployed on Windows Server 2008 with SP2 (or later versions) or on Windows Server 2008 R2 RTM (or later versions).

  Note:
  When you install Exchange 2010 in a Hyper-V environment, you may receive the following error message: "Hub Transport Server role installation failed." For virtualized Active Directory servers, we recommend that you disable the time sync integration component, and then set the time to a reliable external time provider before you install the Hub Transport role. This recommendation is especially important if your host is joined to the domain that the virtual machine is hosting.

For deployments of Exchange 2010 SP2 or of Exchange 2010 SP1:

- All Exchange 2010 server roles, including Unified Messaging, are supported in a virtual machine. Unified Messaging virtual machines have the following special requirements:
  - Four virtual processors are required for the virtual machine. Memory should be sized using standard best practices guidance. For more information, see Understanding Memory Configurations and Exchange Performance.
  - Four physical processor cores are available for use by each Unified Messaging role virtual machine at all times. This requirement means that no processor oversubscription can be in use. This requirement affects the ability of the Unified Messaging role virtual machine to use physical processor resources. For more information, see the Virtualizing Unified Messaging Servers section.
- Exchange server virtual machines (including Exchange Mailbox virtual machines that are part of a database availability group, or DAG), may be combined with host-based failover clustering and migration technology, as long as the virtual machines are configured such that they will not save and restore state on disk when moved or taken offline. All failover activity must result in a cold boot when the virtual machine is activated on the target node. All planned migration must either result in shutdown and cold boot, or an online migration that makes use of a technology like Hyper-V Live Migration. Hypervisor migration of virtual machines is supported by the hypervisor vendor; therefore, you must ensure that your hypervisor vendor has tested and supports migration of Exchange virtual machines. Microsoft supports Hyper-V Live Migration of these virtual machines.

For deployments of the release to manufacture (RTM) version of Exchange 2010:

- Exchange 2010 server roles except for Unified Messaging are supported in a virtual machine.
- Microsoft doesn't support combining Exchange high availability solutions (such as DAGs) with hypervisor-based clustering, high availability, or migration solutions that will move or automatically failover mailbox servers that are members of a DAG between clustered root servers. DAGs are supported in hardware virtualization environments, provided the virtualization environment doesn't employ clustered root servers, or the clustered root servers have been configured to never failover or automatically move mailbox servers that are members of a DAG to another root server.
- The storage used by the Exchange guest machine for storage of Exchange data (for example, mailbox databases or Hub transport queues) can be virtual storage of a fixed size (for example, fixed virtual hard disks (VHDs) in a Hyper-V environment), SCSI pass-through storage, or Internet SCSI (iSCSI) storage. Pass-through storage is storage that's configured at the host level and dedicated to one guest machine. All storage used by an Exchange guest machine for storage of Exchange data must be block-level storage because Exchange 2010 doesn't support the use of network attached storage (NAS) volumes. Also, NAS storage that's presented to the guest as block-level storage via the hypervisor isn't supported. The following virtual disk requirements apply for volumes used to store Exchange data:
  - Virtual disks that dynamically expand aren't supported by Exchange.
  - Virtual disks that use differencing or delta mechanisms (such as Hyper-V's differencing VHDs or snapshots) aren't supported.

  Note:
  In a Hyper-V environment, each fixed VHD must be less than 2,040 GB. For supported third-party hypervisors, check with the manufacturer to see whether any disk size limitations exist.
- Only management software (for example, antivirus software, backup software, or virtual machine management software) can be deployed on the physical root machine. No other server-based applications (for example, Exchange, SQL Server, Active Directory, or SAP) should be installed on the root machine. The root machine should be dedicated to running guest virtual machines.
- Some hypervisors include features for taking snapshots of virtual machines. Virtual machine snapshots capture the state of a virtual machine while it's running. This feature enables you to take multiple snapshots of a virtual machine and then revert the virtual machine to any of the previous states by applying a snapshot to the virtual machine. However, virtual machine snapshots aren't application aware, and using them can have unintended and unexpected consequences for a server application that maintains state data, such as Exchange. As a result, making virtual machine snapshots of an Exchange guest virtual machine isn't supported.
- Many hardware virtualization products allow you to specify the number of virtual processors that should be allocated to each guest virtual machine. The virtual processors located in the guest virtual machine share a fixed number of logical processors in the physical system. Exchange supports a virtual processor-to-logical processor ratio no greater than 2:1. For example, a dual processor system using quad core processors contains a total of 8 logical processors in the host system. On a system with this configuration, don't allocate more than a total of 16 virtual processors to all guest virtual machines combined.
- When you calculate the total number of virtual processors required by the root machine, you must also account for both I/O and operating system requirements. In most cases, the equivalent number of virtual processors required in the root operating system for a system hosting Exchange virtual machines is 2. This value should be used as a baseline for the root operating system virtual processor when calculating the overall ratio of physical cores to virtual processors. If performance monitoring of the root operating system indicates you're consuming more processor utilization than the equivalent of 2

processors, you should reduce the count of virtual processors assigned to guest virtual machines accordingly, and verify that the overall virtual processor-to-physical core ratio is no greater than 2:1.

- The operating system for an Exchange guest machine must use a disk that has a size equal to at least 15 GB plus the size of the virtual memory that's allocated to the guest machine. This requirement is necessary to account for the operating system and paging file disk requirements. For example, if the guest machine is allocated 16 GB of memory, the minimum disk space needed for the guest operating system disk is 31 GB.
  In addition, it's possible that guest virtual machines may be prevented from directly communicating with fibre channel or SCSI host bus adapters (HBAs) installed in the root machine. In this event, you must configure the adapters in the root machine's operating system and present the LUNs to guest virtual machines as either a virtual disk or a pass-through disk.
- Exchange Jetstress 2010 is supported for use in virtual guest instances deployed on one of the following hypervisors. Jetstress is not supported when used in virtual guest instances running under any other hypervisor.
  - Windows Server 2008 R2 (or newer) with Hyper-V technology
  - Hyper-V Server 2008 R2 (or newer)
  - VMware ESX 4.1 (or newer)

We support running the Microsoft Exchange Server Jetstress 2010 tool in a guest virtual machine if it’s deployed on one of the following host computers:

1. Microsoft Windows Server 2008 R2, or a later version
2. Microsoft Hyper-V Server 2008 R2, or a later version
3. VMware ESX 4.1, or a later version

Root Machine Storage Requirements

The minimum disk space requirements for each root machine are as follows:

- Root machines in some hardware virtualization applications may require storage space for an operating system and its components. For example, when running Windows Server 2008 with Hyper-V, you will need a minimum of 10 GB to meet the requirements for Windows Server 2008. For more details, see Windows Server 2008 R2 System Requirements. Additional storage space is also required to support the operating system's paging file, management software, and crash recovery (dump) files.
- Some hypervisors maintain files on the root machine that are unique to each guest virtual machine. For example, in a Hyper-V environment, a temporary memory storage file (BIN file) is created and maintained for each guest machine. The size of each BIN file is equal to the amount of memory allocated to the guest machine. In addition, other files may also be created and maintained on the host machine for each guest machine.

Exchange Storage Requirements

Requirements for storage connected to a virtualized Exchange server are as follows:

- Each Exchange guest machine must be allocated sufficient storage space on the root machine for the fixed disk that contains the guest's operating system, any temporary memory storage files in use, and related virtual machine files that are hosted on the host machine. In addition, for each Exchange guest machine, you must also allocate sufficient storage for the message queues on the Hub Transport and Edge Transport servers and sufficient storage for the databases and log files on Mailbox servers.
- Storage used by Exchange should be hosted in disk spindles that are separate from the storage that's hosting the guest virtual machine's operating system.
- Configuring iSCSI storage to use an iSCSI initiator inside an Exchange guest virtual machine is supported. However, there will be reduced performance in

this configuration if the network stack inside a virtual machine isn't full-featured (for example, not all virtual network stacks support jumbo frames).

Exchange Memory Requirements and Recommendations

Some hypervisors have the ability to oversubscribe or dynamically adjust the amount of memory available to a specific guest machine based on the perceived usage of memory in the guest machine as compared to the needs of other guest machines managed by the same hypervisor. This technology makes sense for workloads in which memory is needed for brief periods of time and then can be surrendered for other uses. However, it doesn't make sense for workloads that are designed to use memory on an ongoing basis. Exchange, like many server applications with optimizations for performance that involve caching of data in memory, is susceptible to poor system performance and an unacceptable client experience if it doesn't have full control over the memory allocated to the physical or virtual machine on which it's running.

Many of the performance gains in recent versions of Exchange, especially those related to reduction in I/O, are based on highly efficient usage of large amounts of memory. When that memory is no longer available, the expected performance of the system can't be achieved. For this reason, memory oversubscription or dynamic adjustment of virtual machine memory should be disabled for production Exchange servers.

Size the memory for guest machines using the same methods as used for physical deployments. You can find details about memory sizing for Exchange 2010 server roles in Understanding Memory Configurations and Exchange Performance. For additional guidance, see the "Application Considerations" section of a white paper written by the Microsoft Hyper-V team, available for download at Implementing and Configuring Dynamic Memory.

Host-based Failover Clustering and Migration for Exchange

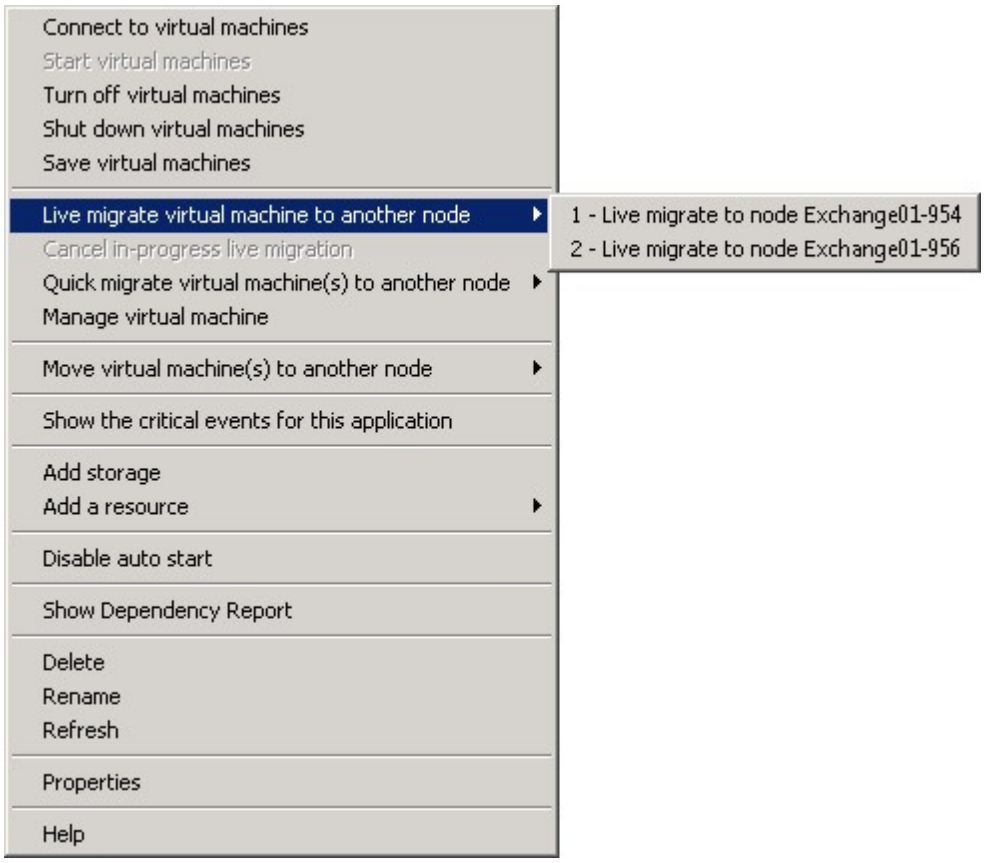
Here are answers to some frequently asked questions about host-based failover clustering and migration technology with Exchange 2010 DAGs.

- **Does Microsoft support third-party migration technology?**
  Microsoft can't make support statements for the integration of third party hypervisor products using these technologies with Exchange, because these technologies aren't part of the Server Virtualization Validation Program (SVVP). The SVVP covers the other aspects of our support for third-party hypervisors. You need to ensure that your hypervisor vendor supports the combination of their migration and clustering technology with Exchange. Simply put, if your hypervisor vendor supports their migration technology with Exchange, then we support Exchange with their migration technology.
- **How does Microsoft define host-based failover clustering?**
  Host-based failover clustering refers to any technology that provides the automatic ability to react to host-level failures and start affected virtual machines on alternate servers. Use of this technology is supported given that, in a failure scenario, the virtual machine is coming up from a cold boot on the alternate host. This technology helps to make sure that the virtual machine never comes up from a saved state that is persisted on disk because it will be stale relative to the rest of the DAG members.
- **What does Microsoft mean by migration support?**
  Migration technology refers to any technology that allows a planned move of a virtual machine from one host machine to another host machine. This move could also be an automated move that occurs as part of resource load balancing, but it isn't related to a failure in the system. Migrations are

supported as long as the virtual machines never come up from a saved state that is persisted on disk. This means that technology that moves a virtual machine by transporting the state and virtual machine memory over the network with no perceived downtime is supported for use with Exchange. A third-party hypervisor vendor must provide support for the migration technology, while Microsoft will provide support for Exchange when used in this configuration.

Warning:

In the case of Microsoft Hyper-V, the live migration option is supported, but the quick migration option is not supported. It's important to note that when you select the Move operation on a virtual machine in a Hyper-V environment, the default behavior is actually to perform a quick migration. To stay in a supported state with Exchange SP1 and Exchange SP2 DAG members, it's critical that you use the live migration option, as shown in the following figure.



Virtualizing Unified Messaging Servers

Unlike Exchange 2010 RTM, Exchange 2010 SP1 and SP2 support the Unified Messaging (UM) role on Hyper-V and other supported hypervisors. Exchange 2010 SP1 or Exchange 2010 SP2 must be deployed for UM support because the UM role is dependent on a media component provided by Microsoft Lync. Prior to the release of Exchange 2010 SP1, the Lync engineering team had enabled high-quality, real-time audio processing in a virtual deployment. Beginning with Exchange 2010 SP1, the changes were integrated into the UM role.

1.2.1.11 Planning for Internal and Third-Party Applications

Planning for Internal and Third-Party Applications

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 introduces many changes to the set of Application Programming Interfaces (APIs) that are available for application development. Upgrading your Exchange servers to Exchange 2010 can affect both internal applications and third-party applications that may use the Exchange APIs over the network or on your Exchange server. Use the sections in this topic to review potential effects on your internal or third-party applications that interact with Exchange 2010.

Important:
We recommend that you contact third-party software vendors to confirm that the products you use are supported for use with Exchange 2010.

Use this topic as a guide to help you investigate whether your Exchange Server applications will be affected by an upgrade to Exchange 2010.

Exchange 2010 APIs

Exchange 2010 supports fewer APIs than previous versions of Exchange Server support. For a list of Exchange 2010 APIs, see Development Technologies for Exchange 2010 on MSDN.

Earlier versions of Exchange Server contain APIs that have been removed from Exchange 2010. For a list of APIs that are available in earlier versions of Exchange, see the following topics on MSDN:

- Development Technologies for Exchange 2007
- Development Technologies for Exchange 2003

The following table identifies the development technologies that are available for use with Exchange 2010.

Development Technology	Exchange 2003	Exchange 2007	Exchange 2010
Exchange Web Services		X	X
Exchange Web Services Managed API (available as a separate download.)		X	X
Messaging Application Programming Interface (MAPI)	X	X	X
Outlook Object Model (OOM) (available as a separate download.)	X	X	X
Outlook web application	X	X	X
Outlook web		X	X

application customization			
Transport Agents		X	X

The following table lists the development technologies that are not available in Exchange 2010, and the product versions that they are available in.

Development Technology	Exchange 2003	Exchange 2007
Active Directory Services Interface (ADSI)	X	X
Collaboration Data Objects for Windows 2000 (CDOSYS)	X	X
CDOSYS SMTP/NNTP Event Sinks	X	X
Collaboration Data Objects for Exchange (CDOEX)	X	X
CDOEXM	X	
CDOWF	X	
Exchange Backup and Restore API	X	X
Exchange Writer for the Windows Volume Shadow Copy Service	X	X
Exchange OLE DB Provider	X	X
Exchange Store Event Sinks	X	X
Incremental Change Synchronization (ICS)	X	X
Lightweight Directory Access Protocol (LDAP)	X	X
SMTP Event Sinks	X	X
Web Forms	X	X
WebDAV	X	X
WebDAV Notifications	X	X
Windows Management Instrumentation (WMI)	X	

Migrating Applications to Exchange 2010

For information about migration your applications to Exchange 2010 technologies, see Migrating from Exchange 2000, Exchange 2003, and Exchange 2007 APIs on MSDN.

Exchange 2007 and Exchange 2010 Application Coexistence

Exchange Web Services does not allow delegation of mailbox access across versions. If either the principal's or the delegate's mailbox is on an Exchange server that is running a different version of Exchange, delegate access attempts will not succeed.

Exchange HTTP Proxying

Cross-site proxying to a site that has an external URL set for an Exchange server that is running the Client Access server role is only allowed for the delegate access scenario where the source and destination mailboxes are in different Active Directory sites or when accessing public folders. The preferred method is to use Autodiscover to get the correct Client Access server URL to directly access a mailbox instead of using the cross-site Client Access server to Client Access server proxy feature. For more information about Client Access server proxying, see Understanding Proxying and Redirection.

1.2.1.12 Exchange 2010 Deployment Permissions Reference

Exchange 2010 Deployment Permissions Reference

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic describes the permissions that are required to set up a Microsoft Exchange Server 2010 organization. The universal security groups (USGs) that are associated with management role groups, and other Windows security groups and security principals, are added to the access control lists (ACLs) of various Active Directory objects. ACLs control what operations can be performed on each object. By understanding what permissions are granted to each role group, security group, or security principal, you can determine what minimum permissions are required to install Exchange 2010.

In some cases, the ACL isn't applied on the usual property, **ntSecurityDescriptor**, but on another property, such as **msExchMailboxSecurityDescriptor**. The directory service can't enforce security that isn't specified in the Windows security descriptor. In most cases, these ACLs are replicated to store ACLs on appropriate objects by the store service. Unfortunately, there is no tool to view these ACLs as anything other than raw binary data.

The columns of each permissions table include the following information:

- **Account** The security principal granted or denied the permissions.
- **ACE type** Access control entry (ACE) type
  - **Allow ACE** An allow ACE allows the user or group associated with the ACE to access an item.
  - **Deny ACE** A deny ACE prevents the user or group associated with the ACE from accessing an item.
- **Inheritance** The type of inheritance used for child objects.
  - **All** indicates that the permissions apply to the object and all sub-objects.
  - **Desc** indicates the permissions apply to the object class listed in the **On Property/Applies To**row.
  - **None** indicates those permissions only apply the object.

- **Permissions** The permissions granted to the account.
- **On Property/Applies To** In some cases, permissions apply only to a given property, property set, or object class. These limited permissions are specified here.
- **Comments** When applicable, this column explains why the permissions are required or provides other information about the permissions.

The permissions are generally listed in the table by the names that are used on the Active Directory Service Interfaces (ADSI) Edit (AdsiEdit.msc) **Security** property page in the **Advanced** view on the **View/Edit** tab. The ADSI Edit **Security** property page lists a much more condensed view of the permissions. The LDP tool (Ldp.exe) displays the access mask directly as a numeric value. The setup code refers to the permissions by predefined constants.

The following table shows the relationships between these values.

ADSI Edit Summary page	ADSI Edit Advanced view, View/Edit tab	ACL entries applied to a given object	Binary value (access mask in LDP)
Full Control	Full Control	WRITE_OWNER | WRITE_DAC | READ_CONTROL | DELETE | ACTRL_DS_CONTROL_ACCESS | ACTRL_DS_LIST_OBJECT | ACTRL_DS_DELETE_TREE | ACTRL_DS_WRITE_PROP | ACTRL_DS_READ_PROP | ACTRL_DS_SELF | ACTRL_DS_LIST | ACTRL_DS_DELETE_CHILD | ACTRL_DS_CREATE_CHILD	0x000F01FF
Read	List Contents + Read All Properties + Read Permissions	ACTRL_DS_LIST | ACTRL_DS_READ_PROP | READ_CONTROL	0x00020014
Write	Write All Properties + All Validated Writes	ACTRL_DS_WRITE_PROP | ACTRL_DS_SELF	0x00000028
	List Contents	ACTRL_DS_LIST	0x00000004
	Read All Properties	ACTRL_DS_READ_PROP	0x00000010
	Write All Properties	ACTRL_DS_WRITE_PROP	0x00000020
	Delete	DELETE	0x00010000
	Delete Subtree	ACTRL_DS_DELETE_TREE	0x00000040
	Read Permissions	READ_CONTROL	0x00020000
	Modify Permissions	WRITE_DAC	0x00040000
	Modify Owner	WRITE_OWNER	0x00080000

	All Validated Writes	ACTRL_DS_SELF	0x00000008
	All Extended Rights	ACTRL_DS_CONTROL_ACCESS	0x00000100
Create All Child Objects	Create All Child Objects	ACTRL_DS_CREATE_CHILD	0x00000001
Delete All Child Objects	Delete All Child Objects	ACTRL_DS_DELETE_CHILD	0x00000002
		ACTRL_DS_LIST_OBJECT	0x00000080

Extended rights are custom rights specified by individual applications. They are specified in the ACL. However, they are meaningless to Active Directory. The specific application enforces any extended rights. Examples of Exchange extended rights are "Create public folder" or "Create named properties in the information store."

Note:

For information about permissions that are set during a Microsoft Exchange Server 2003 installation, see Working with Active Directory Permissions in Exchange Server 2003. For information about permissions that are set during a Microsoft Exchange Server 2007 installation, see Exchange 2007 Setup Permissions Reference.

Prepare Legacy Exchange Permissions

The permissions tables in this section show the permissions set when you execute the `setup /PrepareLegacyExchangePermissions` command.

Distinguished name of the object: DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/ Applies to
Exchange Enterprise Servers	Allow ACE	All	Write Property	Exchange Information
Authenticated Users	Allow ACE	All	Read Property	Exchange Information

Distinguished name of the object: CN=AdminSDHolder,CN=System,DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/ Applies to
Exchange Enterprise Servers	Allow ACE	All	Read Property Write Property	Exchange Information

Distinguished name of the object: CN=<organization>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/ Applies to
Exchange Domain Servers	Allow ACE	All	Write Property	Exchange Information

Prepare Active Directory Permissions

The permissions tables in this section show the permissions set when you execute the `Setup /PrepareAD` command.

Microsoft Exchange Container Permissions

The following table shows the permissions that are set on the Microsoft Exchange container within the configuration partition.

Distinguished name of the object: CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
Installation Account	Allow ACE	All	Full Control		This is the account that is used to run /PrepareAD.
Organization Management	Allow ACE	All	Full Control		
Exchange Trusted Subsystem	Allow ACE	All	Full Control		
Exchange Servers	Allow ACE	All	Read		
Authenticated Users	Allow ACE	None	Read Property List Contents		
Public Folder Management	Allow ACE	All	Read Permissions List Contents Read Property List Object		
Delegated Setup	Allow ACE	All	Read Permissions List Contents Read Property List Object		

Microsoft Exchange Autodiscover Container Permissions

The following table shows the permissions set on the Microsoft Exchange Autodiscover container within the configuration partition.

Distinguished name of the object: CN=Microsoft Exchange Autodiscover,CN=Services,CN=Configuration,DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/

				Applies to
Exchange Servers	Allow ACE	All	Read	

Microsoft Exchange Organization Container Permissions

The permissions tables in this section show the permissions set on the Microsoft Exchange Organization and sub-containers within the configuration partition.

Distinguished name of the object: CN=<organization>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<domain>

Account(s)	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
Enterprise Admins Root Domain Admins Installation Account Organization Management	Deny ACE	All	Send As Receive As		Windows administrators aren't allowed to open mailboxes.

Server Role Installation

During installation of the Client Access, Hub Transport, Unified Messaging, and Mailbox server roles, Setup adds the Organization Management USG to the administrator security group on the local computer so that members of the management role group named Organization Management can manage the server.

The following permissions table shows the permissions set when you install the Client Access, Hub Transport, Unified Messaging, or Mailbox server roles.

Distinguished name of the object: CN=<server>,CN=Servers,CN=<admin group>,CN=Administrative Groups,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
MACHINE$	Allow ACE	All	Read		
MACHINE$	Allow ACE	None	Write Property	msExchServerSite msExchEdgeSyncCredential	
Exchange Servers	Allow ACE	All	Store Transport Access Store Constrained Delegation Store Read Only Access Store Read and Write Access		Extended rights
NT AUTHORITY \NETWORK	Allow ACE	All	Exchange Web Services Token Serialization		Extended right Only granted on Client

					Access server role objects.
NT AUTHORITY\NETWORK	Allow ACE	All	Read		Only granted on Hub Transport server role objects.
Delegated Setup	Allow ACE	All	Full Control		
Delegated Setup	Allow ACE	All	Read		
Delegated Setup	Deny ACE	All	Create Child Delete Child	/msExchPublicMDB	
Authenticated Users	Allow ACE	All	Read Property		
Delegated Setup	Deny ACE	All	Receive As Send As		Extended right

Database Availability Groups

The permissions tables in this section show the permissions set with regards to the database availability groups and its members.

Distinguished name of the object: CN=<DAGName>,CN=Database Availability Groups,CN=<admin group>,CN=Administrative Groups,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to
Authenticated Users	Allow ACE	None	Read Properties	

Distinguished name of the object: CN=<DAGName>,CN=Computers,DC=<domain>

Account	ACE type	Inheritance	Permissions	On property/ Applies to
Mailbox Server Computer Account$	Allow ACE	None	Delete Read Permissions List Contents Read Property Delete Tree List Object	
Mailbox Server Computer	Allow ACE	None	Write Property	Logon Information

Account$				
Mailbox Server Computer Account$	Allow ACE	None	Write Property	description
Mailbox Server Computer Account$	Allow ACE	None	Write Property	displayName
Mailbox Server Computer Account$	Allow ACE	None	Write Property	sAMAccountName
Mailbox Server Computer Account$	Allow ACE	None	Write Property	Account Restrictions
Mailbox Server Computer Account$	Allow ACE	None	Write Property	Validated write to DNS host name
Mailbox Server Computer Account$	Allow ACE	None	Write Property	Validated write to service principal name

Edge Transport

If you install an Edge Transport server and establish an Edge Subscription with the Exchange organization, the permissions in the following permissions table are set when the Edge Transport server is instantiated into the organization.

Distinguished name of the object: CN=<server>,CN=Servers,CN=<admin group>,CN=Administrative Groups,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
Exchange Servers	Allow ACE	All	Write Property		
Authenticated Users	Allow ACE	None	Read Properties		ACE is defined in schema for msExchExchangeServer class objects defaultSecurityDescriptor.

Client Access Server Installation

During installation of the first Client Access server, the following container is created. The following permissions table shows the permissions that are applied.

Distinguished name of the object: CN=Availability Configuration,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
Exchange	Allow ACE	Desc	Read Property	msExchAvail	Extended right

Servers				abilityUser Password / msExchAvail abilityAddr essSpaceObj ects	

Hub Transport Server Installation

During installation of each Hub transport server, the following permissions are set.

Distinguished name of the object: CN=Default <Server>,CN=SMTP Receive Connectors,CN=Protocols,CN=<Server>,CN=Servers,CN=<admin group>,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
ExchangeLegacyInterop	Deny ACE	All	Accept Forest Headers

Authenticated Users	Allow ACE	All	Submit Messages to Server	

SMTP Send Connector Creation

The following table shows the permissions set when you create Send connectors.

Distinguished name of the object: CN=<Connector Name>,CN=Connections,CN=<routing group>,CN=Routing Groups,CN=<admin group>,CN=<organization>

Account	ACE type	Inheritance	Permissions	On property/ Applies to	Comments
S-1-9-1419165041-1139599005-3936102811-1022490595-21	Allow ACE	All	Send Organization Headers		This is the well-known SID for Hub Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-22	Allow ACE	All	Send Organization Headers		This is the well-known SID for Edge Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-21	Allow ACE	All	Send Forest Headers		This is the well-known SID for Hub Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-22	Allow ACE	All	Send Forest Headers		This is the well-known SID for Edge Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-21	Allow ACE	All	Send XShadow		This is the well-known SID for Hub Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-22	Allow ACE	All	Send XShadow		This is the well-known SID for Edge Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-10	Allow ACE	All	Send Routing Headers		This is the well-known SID for partner servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-21	Allow ACE	All	Send Routing Headers		This is the well-known SID for Hub Transport servers.
S-1-9-1419165041-	Allow ACE	All	Send Routing Headers		This is the well-known

1139599005-3936102811-1022490595-22					SID for Edge Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-23	Allow ACE	All	Send Routing Headers		This is the well-known SID for externally secured servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-24	Allow ACE	All	Send Routing Headers		This is the well-known SID for Legacy Exchange servers.
NT AUTHORITY\ANONYMOUS LOGON	Allow ACE	All	Send Routing Headers		
S-1-9-1419165041-1139599005-3936102811-1022490595-21	Allow ACE	All	Send Exch50		This is the well-known SID for Hub Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-22	Allow ACE	All	Send Exch50		This is the well-known SID for Edge Transport servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-23	Allow ACE	All	Send Exch50		This is the well-known SID for externally secured servers.
S-1-9-1419165041-1139599005-3936102811-1022490595-24	Allow ACE	All	Send Exch50		This is the well-known SID for Legacy Exchange servers.

1.2.1.13 Default Authentication Settings for Exchange-related Virtual Directories

Default Authentication Settings for Exchange-related Virtual Directories

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-08*

Microsoft Exchange Server 2010 automatically configures multiple Internet Information Services (IIS) virtual directories during installation. This topic contains information about the default IIS authentication settings and default Secure Sockets Layer (SSL) settings for the Client Access and Mailbox server roles.

Client Access Server Role

The following table lists the default settings on a stand-alone Exchange 2010 Client Access server.

Default Client Access server IIS authentication and SSL settings

Virtual directory	Authentication method	SSL settings	Management method
Default Web site	• Anonymous	• Required	IIS ,management console
aspnet_client	• Anonymous authentication	• SSL required • Requires 128-bit encryption	IIS management console
Autodiscover	• Anonymous authentication • Basic authentication • Windows authentication	• SSL required • Require 128-bit encryption	Exchange Management Shell (Shell)
ecp	• Anonymous authentication • Basic authentication	• SSL required • Requires 128-bit encryption	Exchange Management Console (EMC) or Shell
EWS	• Anonymous authentication • Windows authentication	• SSL required • Requires 128-bit encryption	Shell
Microsoft-Server-ActiveSync	• Basic authentication	• SSL required • Requires 128-bit encryption	EMC or Shell
OAB	• Windows authentication	• Not required	EMC or Shell
owa	• Basic	• SSL required • Requires 128-bit encryption	EMC or Shell
Powershell	• Anonymous authentication	• Not required	Shell
Rpc	• Basic authentication • Windows authentication	• SSL required • Requires 128-bit encryption	Shell
RpcWithCert	By default, all authentication methods are disabled	• Required	

Mailbox Server Role

The following table lists the default settings on a stand-alone Exchange 2010 mailbox server.

Default Mailbox server IIS authentication and SSL settings

Virtual directory	Authentication method	SSL settings	Management method
Default Web site	• Anonymous authentication	• SSL required • Requires 128-bit encryption	This virtual directory isn't configurable by the user.
PowerShell	• Anonymous authentication	• Not required	Shell.

1.2.1.14 Exchange Server Supportability Matrix

Exchange Server Supportability Matrix

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-02-26*

The Exchange Server Supportability Matrix provides a central source for Microsoft Exchange administrators to easily locate information about the level of support available for any configuration or required component for all versions of Microsoft Exchange.

Support Lifecycle

For more information about the support lifecycle for a specific version of Exchange, or of the Microsoft Windows server or client operating systems, see the Microsoft Support Lifecycle page. For more information about the Microsoft Support Lifecycle, see the Microsoft Support Lifecycle Policy FAQ.

Release Model

The following table identifies the release model used for updates and hotfixes for each version of Exchange. With Exchange, each update rollup package is cumulative with regard to the whole product. Therefore, if you apply an update rollup package to Microsoft Exchange Server 2010, you apply all the fixes contained in that update rollup package. This includes all the fixes contained in each earlier update rollup package. For more information, see Exchange 2010 Servicing.

When an update or a hotfix for earlier versions of Exchange is created, one or more of the binary files included in the update or included in the hotfix are cumulative. They are cumulative with regard to the contents of the files. However, they aren't cumulative with regard to the whole Exchange product. The release model used by a product is identified by an X character.

Servicing release model	Exchange 2013	Exchange 2010	Exchange 2007	Exchange 2003

Cumulative Updates	X			
Update rollups		X	X	
Hotfixes				X
Security Hotfixes Delivered Separately	X			X

Important:
Update rollups for Exchange 2010 and Exchange 2007 are a cumulative set of the hotfixes. Cumulative Updates (CU's) for Exchange 2013 are released as a full refresh of Exchange 2013, similar to a product upgrade or a service pack release.

Supported Operating System Platforms

The following table identifies the operating system platforms on which each version of Exchange can run. Supported platforms are identified by an X character.

Operating system platform	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Windows 2000 Server SP4					X
Windows XP Professional SP2				X*	X**
Windows XP Professional SP3				X*	X**
Windows Vista SP1				X*	X***
Windows Vista SP2		X*	X*	X*	X***
Windows Server 2003 SP2				X	X
Windows Server 2003 R2 SP2				X	X
Windows Server 2008				X	
Windows Server 2008 SP2		X	X	X	
Windows Server 2008 R2		X	X	X	

Windows Server 2008 R2 SP1	X	X	X	X	
Windows 7	X*	X*	X*	X*	
Windows 8	X*	X*			
Windows Server 2012	X	X			

*Only for Exchange management tools

**Only for Exchange 2003 or Exchange 2000 System Manager

***Only together with Exchange 2003 System Manager for Windows Vista

Supported Active Directory Environments

The following table identifies the Active Directory environments with which each version of Exchange can communicate. Supported environments are identified by an X character. An Active Directory server refers both to global catalog servers and to domain controllers.

Operating system environment	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Windows 2000 Server SP4 Active Directory servers					X
Windows Server 2003 SP1 Active Directory servers				X	X
Windows Server 2003 SP2 Active Directory servers	X	X	X	X	X
Windows Server 2008 Active Directory servers	X	X	X	X	X
Windows Server 2008 SP2 Active Directory servers	X	X	X	X	X
Windows Server 2008 R2 Active	X	X	X	X	X

Directory servers					
Windows Server 2008 R2 SP1 Active Directory servers	X	X	X	X	X
Windows Server 2008 read-only Active Directory servers					
Windows Server 2008 R2 read-only Active Directory servers					
Windows Server 2012 Active Directory servers	X	X	X	X	
Windows Server 2012 read-only Active Directory servers					

Domain and forest functional level	**Exchange 2013**	**Exchange 2010 SP3**	**Exchange 2010 SP2**	**Exchange 2007 SP3**	**Exchange 2003 SP2**
Windows 2000 Server mixed domain functional level					X
Windows 2000 Server native functional level				X	X
Windows Server 2003 interim domain functional level					X
Windows	X	X	X	X	X

Server 2003 domain functional level					
Windows Server 2008 domain functional level	X	X	X	X	X
Windows Server 2008 R2 domain functional level	X	X	X	X	X
Windows Server 2012 domain functional level	X	X	X	X	
Windows 2000 Server forest functional level				X	X
Windows Server 2003 interim forest functional level					X
Windows Server 2003 forest functional level	X	X	X	X	X
Windows Server 2008 forest functional level	X	X	X	X	X
Windows Server 2008 R2 forest functional level	X	X	X	X	X
Windows Server 2012 forest functional level	X	X	X	X	

Web Browsers Supported for Use with the Premium Version of Outlook Web App or Outlook Web Access

The following table identifies the Web browsers supported for use together with the premium version of Microsoft Office Outlook Web App for Microsoft Exchange Server 2010, Office Outlook Web Access for Exchange 2007 or Exchange 2003, or Outlook Web Access for Exchange 2000. Supported browsers are identified by an X character.

Browser	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Internet Explorer 10	X	X			
Internet Explorer 9	X	X	X	X	
Internet Explorer 8	X	X	X	X	X**
Internet Explorer 7		X	X	X	X***
Internet Explorer 6				X	X
Firefox 3.0.1 or later		X	X		
Firefox 12 or later	X	X	X		
Safari 3.1 or later		X	X		
Safari 5.0 or later	X	X	X		
Chrome 3.0.195 or later		X	X		
Chrome 18 or later	X	X	X		

Support is added by Exchange 2010 SP2 RU5.

**Requires the hotfix described in Microsoft Knowledge Base article 963664, Error message when you click the flag icon of a message in the message list view in Outlook Web Access 2003 when you are using Internet Explorer 8: "'firstchild.firstchild' is null or not an object".

***Requires the hotfix described in Microsoft Knowledge Base article 911829, You receive an error message when you try to perform any editing tasks, or you must click to enable the compose frame in Outlook Web Access.

Web Browsers Supported for Use with the Basic Version of Outlook Web App or Outlook Web Access

The following table identifies the Web browsers that are supported for use together with the light (basic) version of Outlook Web App for Exchange 2010 or Microsoft Outlook Web Access for Microsoft Exchange Server 2007, for Microsoft Exchange Server 2003, or for Microsoft Exchange 2000. Supported browsers are identified by an X character.

Note:

Outlook Web App Basic (Outlook Web App Light) is supported for use in mobile browsers. However, if rendering or authentication issues occur in a mobile browser, determine whether the issue can be reproduced by using Outlook Web App Light in the full client of a supported browser. For example, test the use of Outlook Web App Light in Safari, Chrome, or Internet Explorer. If the issue can't be reproduced in the full client, we recommend that you contact the mobile device vendor for help. In these cases, we collaborate with the vendor as appropriate.

Browser	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Internet Explorer 10	X	X			
Internet Explorer 9	X	X*	X*	X	
Internet Explorer 8	X	X	X	X	X**
Internet Explorer 7	X	X	X	X	X***
Internet Explorer 6		X	X	X	X
Safari	X	X	X	X	X****
Firefox	X	X	X	X	X****
Netscape				X	X****
Opera	X	X	X	X	X****

*Requires Exchange 2010 SP2 RU5-v2, described in Microsoft Knowledge Base article 2785908, Description of Update Rollup 5 version 2 for Exchange Server 2010 Service Pack 2.

**Requires the hotfix described in Microsoft Knowledge Base article 963664, Error message when you click the flag icon of a message in the message list view in Outlook Web Access 2003 when you are using Internet Explorer 8: "'firstchild.firstchild' is null or not an object".

***Requires the hotfix described in Microsoft Knowledge Base article 911829, You receive an error message when you try to perform any editing tasks, or you must click to enable the compose frame in Outlook Web Access.

****Browser should support HTML 3.2, European Computer Manufacturers Association (ECMA) script standards, and JavaScript.

Web Browsers Supported for the Use of S/MIME with Outlook Web App or Outlook Web Access

The following table identifies the Web browsers that are supported for the use of S/MIME together with Outlook Web App for Exchange 2010 or Outlook Web Access for Exchange 2007, Exchange 2003, or Exchange 2000. Supported browsers are identified by an X character.

Browser	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Internet Explorer 10		X			
Internet Explorer 9		X	X	X	
Internet Explorer 8		X	X	X	X*
Internet Explorer 7		X	X	X	X***
Internet Explorer 6					X

**Requires Update Rollup 8 for Exchange Server 2007 Service Pack 1 (SP1) or later versions. For more information, see Description of Update Rollup 8 for Exchange Server 2007 Service Pack 1.

***Requires the hotfix described in Microsoft Knowledge Base article 924334, The Compose Message form stops responding after you install Internet Explorer 7.0 and the S/MIME control on an Outlook Web Access client in Exchange Server 2003.

Clients

The following table identifies the mailbox clients that are supported for use together with each version of Exchange. Supported clients are identified by an X character.

Client	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Outlook 2002					X
Outlook 2003		X	X	X	X
Outlook 2007	X**	X	X	X	X
Outlook 2010	X***	X	X	X	X
Windows Mobile 5.0	X	X	X	X	X

Windows Mobile 6.0	X	X	X	X	X
Windows Mobile 6.1	X	X	X	X	X
Windows Mobile 6.5	X	X	X	X	X
Windows Phone 7	X	X	X	X	X
Windows Phone 7.5	X	X	X	X	X
Entourage X				X*	X
Entourage 2004 (DAV)				X**	X
Entourage 2008 (DAV)				X**	X
Entourage 2008 (EWS)	X****	X****	X****	X	

*WebDav: Contacts, Events, IMAP: Mail

**Requires Outlook 2007 Service Pack 3 and the November 2012 Public Update or later.

***Requires Outlook 2010 Service Pack 1 and the November 2012 Public Update or later.

****EWS only. There is no DAV support for Exchange 2010.

Tools

The following table identifies the version of Microsoft Exchange that can be used together with the Microsoft Exchange Inter-Organization Replication tool (Exscfg.exe; Exssrv.exe). The tool is used to replicate public folder information (including free/busy information) between Exchange organizations. For more information, see Microsoft Exchange Server Inter-Organization Replication. Supported versions are identified by an X character.

Note:

You must run the Inter-Organization Replication tool on a 32-bit operating system that has Exchange 2003 Management Tools installed.

Important:

If you want to use the Inter-Organization Replication tool, one of the Exchange replication endpoints must be an Exchange 2003 server.

Tool	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Inter-Organization Replication tool		X	X	X	X

Microsoft .NET Framework

The following table identifies the version of the Microsoft .NET Framework that can be used together with each version of Exchange. Supported versions are identified by an X character.

.NET Framework	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
.NET Framework 1.0 SP1					X
.NET Framework 1.1 SP1					X
.NET Framework 2.0					
.NET Framework 2.0 SP1				X	
.NET Framework 3.0				X	
.NET Framework 3.5		X*****		X***	
.NET Framework 3.5 SP1		X	X	X	
.NET Framework 4.0		X*****	X****	X***	
.NET Framework 4.5	X	X*****	X****		

***Supported versions of the .NET Framework are included in the .NET Framework 3.5 and in the .NET Framework 3.5 SP1.

****Applies only when upgrading the system from the .NET Framework 3.5 and the .NET Framework 3.5 SP1. Uninstalling the .NET Framework 3.5 and the .NET Framework 3.5 SP1 isn't supported.

***** If you are using Windows Server 2012, the .NET Framework 3.5 must be installed before you can use Exchange 2010 SP3.

Windows PowerShell

The following table identifies the version of the Windows PowerShell command-line interface that can be used together with each version of Exchange. Supported versions

are identified by an X character.

PowerShell	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
PowerShell 1.0				X	
PowerShell 2.0		X	X	X	
PowerShell 3.0	X				

Microsoft Management Console

The following table identifies the version of Microsoft Management Console (MMC) that can be used together with each version of Exchange. Supported versions are identified by an X character.

MMC	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
MMC 2.0					X
MMC 3.0	X	X	X	X	

Windows Installer

The following table identifies the version of Windows Installer that is used together with each version of Exchange. Supported versions are identified by an X character.

Windows Installer	Exchange 2013	Exchange 2010 SP3	Exchange 2010 SP2	Exchange 2007 SP3	Exchange 2003 SP2
Windows Installer 3.0					
Windows Installer 3.1 v1					
Windows Installer 3.1 v2					
Windows Installer 4.0					
Windows Installer 4.5	X	X	X	X	
Windows Installer 5.0	X				

1.2.1.15 Exchange 2010 Solution Accelerator

Exchange 2010 Solution Accelerator

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-24*

The Infrastructure Planning and Design (IPD) Guide for Exchange Server 2010 with Service Pack 1 (SP1) provides the IT architect with a step-by-step process for successfully designing an Exchange Server 2010 infrastructure. Exchange 2010 supports a variety of infrastructure topologies that enable IT departments to deploy the messaging architecture that best suits their business needs. The guide helps organizations make informed decisions about the design of fault tolerance and scalability so that their overall requirements are met.

For more information about the IPD guide, see Infrastructure Planning and Design - Exchange Server 2010.

1.2.2 Deploying Exchange 2010

Deploying Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-08*

The deployment phase is the period during which you install Microsoft Exchange Server 2010 into your production environment. Before you begin the deployment phase, you should plan your Exchange organization. For more information, see Planning for Exchange 2010.

Use the following links to access the information you need to help you with deploying Exchange 2010. Also, see Exchange Server Deployment Assistant for information about a Web-based tool that can help you with your deployment.

Understanding Deployment of Exchange 2010

This section includes topics related to understanding your Exchange 2010 deployment, including important information about prerequisites and security. Also, start here to get insight into upgrading from previous versions of Microsoft Exchange.

Understanding a New Installation of Exchange 2010

This section discusses the scenario in which you install Exchange 2010 into a new Exchange organization.

Understanding Upgrade from Exchange 2003 to Exchange 2010

See this section for information that will help you upgrade from Microsoft Exchange Server 2003 to Exchange 2010.

Understanding Upgrade from Exchange 2007 to Exchange 2010

See this section for information that will help you upgrade from Microsoft Exchange Server 2007 to Exchange 2010.

Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010

See this section for information that will help you upgrade from a mixed environment of Exchange 2003 and Exchange 2007 to Exchange 2010.

Understanding Unified Messaging Deployments

See this section for information that will help you understand deploying Exchange 2010 Unified Messaging, whether a new deployment or an upgrade.

Managing Deployment of Exchange 2010

In this section you'll find the procedures that will help you prepare your organization and install Exchange 2010 server roles or upgrade existing server roles. This section also contains information that will help you move your mailboxes from one version of Exchange to another.

Deploy Multiple Forest Topologies

This section includes information to help you deploy Exchange 2010 in a resource forest or cross-forest topology.

Exchange 2010 Post-Installation Tasks

See this section for mandatory and optional post-installation tasks to complete your Exchange 2010 installation.

Modify an Exchange 2010 Installation

See this section for procedures to help you remove or modify your Exchange 2010 installation.

Installation Guide Templates

This section provides document templates you can use to create customized installation guides for your organization's Exchange 2010 server role installations.

Exchange 2010 Servicing

This section provides guidance about how to deploy fixes for Exchange 2010 and provides information about how to apply the appropriate updates.

1.2.2.1 Understanding Deployment of Exchange 2010

Understanding Deployment of Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-13*

Before you begin the deployment phase, you should plan your Microsoft Exchange Server 2010 organization. For more information, see Planning for Exchange 2010.

This section includes the following topics:

Exchange 2010 Prerequisites

Understanding Exchange 2010 Setup

Overview of Services Installed by Exchange Setup

Deployment Security Checklist

Exchange Management Console Interoperability

Understanding Upgrade to Exchange 2010

1.2.2.1.1 Exchange 2010 Prerequisites

Exchange 2010 Prerequisites

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-02-26*

This topic provides the steps for installing the necessary Windows Server 2008 Service Pack 2 (SP2) or later, Windows Server 2008 R2 or later, and Windows Server 2012 operating system prerequisites for all Microsoft Exchange Server 2010 server roles. It also includes the steps for installing the Windows 8, Windows 7, and Windows Vista operating system prerequisites for the Exchange management tools.

Prerequisites

- Make sure that the functional level of your forest is at least Windows Server 2003, and that the schema master is running Windows Server 2003 with Service Pack 1 (SP1) or later. For more information about the Windows functional level, see Managing Domains and Forests.
- The full installation option of Windows Server 2008 with SP2 or later, Windows Server 2008 R2 RTM or later, or Windows Server 2012 must be used for all servers running Exchange 2010 server roles or management tools.
- For all server roles other than the Edge Transport server role, you must first join the computer to the appropriate internal Active Directory forest and domain.

Note:
If you're installing the Mailbox server role and you intend the server to be a member of a database availability group (DAG), you must be running the Enterprise Edition of Windows Server 2008 or Windows Server 2008 R2. The Standard Edition doesn't support the features needed for DAGs. You can't upgrade Windows when Exchange is installed on the server. This does not apply to Windows Server 2012 because Windows Server 2012 Standard and Windows Server 2012 Datacenter both support failover clustering.

Note:
If you're installing the Mailbox server role, the Task Scheduler and Windows Firewall must be enabled and running. In addition, if the Mailbox server will be a member of a DAG and host replicated databases, it's required that the script is scheduled and run automatically. For more information about the script, see "CheckDatabaseRedundancy.ps1 Script" in the Monitoring High Availability and Site Resilience topic.

Install the Exchange 2010 Hotfixes for Windows Server 2008 SP2

The following hotfixes are required for Windows Server 2008 SP2:

- Install the update described in Microsoft Knowledge Base article 977624, AD RMS clients do not authenticate federated identity providers in Windows Server 2008 or in Windows Vista. Without this update, Active Directory Rights Management Services (AD RMS) features may stop working.

- Install the update described in Knowledge Base article 979744, A .NET Framework 2.0-based Multi-AppDomain application stops responding when you run the application.
- Install the update described in Knowledge Base article 979917, Two issues occur when you deploy an ASP.NET 2.0-based application on a server that is running IIS 7.0 or IIS 7.5 in Integrated mode. For more information, see these MSDN Code Gallery pages:
  - For additional background information, see KB979917 - QFE for Sharepoint issues - Perf Counter fix & User Impersonation.
  - For the available downloads, see KB979917 - QFE for Sharepoint issues - Perf Counter fix & User Impersonation.
- Install the update described in Knowledge Base article 973136, FIX: ArgumentNullException exception error message when a .NET Framework 2.0 SP2-based application tries to process a response with zero-length content to an asynchronous ASP.NET Web service request: "Value cannot be null".
- Install the update described in Knowledge Base article 977592, RPC over HTTP clients cannot connect to the Windows Server 2008 RPC over HTTP servers that have RPC load balancing enabled.

Install the Exchange 2010 Hotfixes for Windows Server 2008 R2

Warning:
The following hotfixes only apply to Windows Server 2008 R2 RTM. If you're installing Exchange on Windows Server 2008 R2 SP1, you don't need to apply these hotfixes.

The following hotfixes are required for the Client Access server for Windows Server 2008 R2 RTM:

- Install the update described in Knowledge Base article 979099, An update is available to remove the application manifest expiry feature from AD RMS clients. Without this update, the AD RMS features may stop working.
- Install the update described in Knowledge Base article 979744, A .NET Framework 2.0-based Multi-AppDomain application stops responding when you run the application.
- Install the update described in Knowledge Base article 983440, An ASP.NET 2.0 hotfix rollup package is available for Windows 7 and for Windows Server 2008 R2. For more information, see these MSDN Code Gallery pages:
  - For additional background information, see KB983440 - Win7 rollup package (PR for QFE 810219).
  - For the available downloads, see KB983440 - Win7 rollup package (PR for QFE 810219).
- Install the update described in Knowledge Base article 977020, FIX: An application that is based on the Microsoft .NET Framework 2.0 Service Pack 2 and that invokes a Web service call asynchronously throws an exception on a computer that is running Windows 7.

The following hotfix is required for Hub Transport and Mailbox servers for Windows Server 2008 R2:

- Install the update described in Knowledge Base article 979099, An update is available to remove the application manifest expiry feature from AD RMS clients. Without this update, the AD RMS features may stop working.

The following hotfix is strongly recommended for Mailbox servers running Windows Server 2008 R2 that are members of a database availability group (DAG):

- Install the update described in Knowledge Base article 2550886, A transient communication failure causes a Windows Server 2008 R2 failover cluster to stop working. Without this update, the underlying cluster for a DAG could

experience a race condition that causes a loss of quorum in the cluster and a loss of functionality in the DAG.

Install the Exchange 2010 Hotfixes for Windows 7 and Windows Vista

The following hotfixes are required for Windows 7 and Windows Vista:

- Install the update described in Knowledge Base article 977020, FIX: An application that is based on the Microsoft .NET Framework 2.0 Service Pack 2 and that invokes a Web service call asynchronously throws an exception on a computer that is running Windows 7.
- Install the update described in Knowledge Base article 983440, An ASP.NET 2.0 hotfix rollup package is available for Windows 7 and for Windows Server 2008 R2. For more information, see these MSDN Code Gallery pages:
  - For additional background information, see KB983440 - Win7 rollup package (PR for QFE 810219).
  - For the available downloads, see KB983440 - Win7 rollup package (PR for QFE 810219).

Install the Windows Server 2008 SP2 operating system prerequisites

1. Install Microsoft .NET Framework 3.5 Service Pack 1 (SP1). For details, see Microsoft .NET Framework 3.5 Service Pack 1.
2. Install the Microsoft .NET Framework 3.5 Family Update for Windows Vista x64 and Windows Server 2008 x64 updates. For details, see Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 and Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available.
3. Install Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu). For details, see Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
4. On servers that will host the Hub Transport or Mailbox server role, install the Microsoft Filter Pack. For Exchange 2010 release to manufacturing (RTM), see 2007 Office System Converter: Microsoft Filter Pack. For Exchange 2010 SP1, see Microsoft Office 2010 Filter Packs. For more information about registering the Filter Pack, see Register Filter Pack IFilters with Exchange 2010.

   Note:
   On Exchange 2010 RTM, you can meet the prerequisite by installing 2007 Office System Converter: Microsoft Filter Pack. However, we recommend that you upgrade to the Microsoft Office 2010 Filter Packs.

5. Open an elevated command prompt, navigate to the \Scripts folder on the Exchange 2010 installation media, and then use one of the following commands to install the necessary operating system components:
   - This example is for a server that will have the typical installation of the Client Access, Hub Transport, and Mailbox server roles.

     ```
     sc config NetTcpPortSharing start= auto
     ServerManagerCmd -ip Exchange-Typical.xml -Restart
     ```

   - This example is for a server that will host the Client Access, Hub Transport, Mailbox, and Unified Messaging server roles.

     ```
     sc config NetTcpPortSharing start= auto
     ServerManagerCmd -i Desktop-Experience
     ServerManagerCmd -ip Exchange-Typical.xml -Restart
     ```

- This example is for a server that will host the Client Access and Hub Transport server roles.

```
sc config NetTcpPortSharing start= auto
ServerManagerCmd -ip Exchange-Typical.xml -Restart
```

- This example is for a server that will host the Hub Transport and Mailbox server roles.

```
ServerManagerCmd -ip Exchange-Typical.xml -Restart
```

- This example is for a server that will host the Client Access and Mailbox server roles.

```
sc config NetTcpPortSharing start= auto
ServerManagerCmd -ip Exchange-Typical.xml -Restart
```

- This example is for a server that will host only the Client Access server role.

```
sc config NetTcpPortSharing start= auto
ServerManagerCmd -ip Exchange-CAS.xml -Restart
```

- This example is for a server that will host only the Hub Transport server role.

```
ServerManagerCmd -ip Exchange-Hub.xml -Restart
```

- This example is for a server that will host only the Mailbox server role.

```
ServerManagerCmd -ip Exchange-MBX.xml -Restart
```

- This example is for a server that will host only the Unified Messaging server role.

```
ServerManagerCmd -ip Exchange-UM.xml -Restart
```

- This example is for a server that will host the Edge Transport server role.

```
ServerManagerCmd -ip Exchange-Edge.xml -Restart
```

Install the Exchange 2010 Hotfixes for Windows Server 2008 SP2

The following hotfix is required for Windows Server 2008 SP2 and must be installed after the operating system prerequisites have been installed:

- Install the hotfix described in Knowledge Base article 982867, WCF services that are hosted by computers together with a NLB fail in .NET Framework 3.5 SP1. For more information, see these MSDN Code Gallery pages:
  - For additional background information, see KB982867 - WCF: Enable WebHeader settings on the RST/SCT.
  - For the available downloads, see KB982867 - WCF: Enable WebHeader settings on the RST/SCT.

After installing the preceding prerequisites and hotfix, and before installing Exchange 2010, we recommend that you install any critical or recommended updates from Microsoft Update.

Install the Windows Server 2008 R2 operating system prerequisites

1. On servers that will host the Hub Transport or Mailbox server role, install the Microsoft Filter Pack. For Exchange 2010 RTM, see 2007 Office System Converter: Microsoft Filter Pack. For Exchange 2010 SP1, see Microsoft Office 2010 Filter Packs. For more information about registering the Filter Pack, see Register Filter Pack IFilters with Exchange 2010.

   Note:

   On Exchange 2010 RTM, you can meet the prerequisite by installing 2007 Office System Converter: Microsoft Filter Pack. However, we recommend that you upgrade to the Microsoft Office 2010 Filter Packs.

2. On the Start menu, navigate to **All Programs** > **Accessories** > **Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following command.

   ```
   Import-Module ServerManager
   ```

3. Use the **Add-WindowsFeature** cmdlet to install the necessary operating system components:
   - This example is for a server that will have the typical installation of the Client Access, Hub Transport, and Mailbox server roles.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host the Client Access, Hub Transport, Mailbox, and Unified Messaging server roles.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host the Client Access and Hub Transport server roles.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host the Hub Transport and Mailbox server roles.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host the Client Access and Mailbox server roles.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host only the Client Access server role.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host the Hub Transport or the Mailbox server role.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

   - This example is for a server that will host only the Unified Messaging server role.

     ```
     Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Ba
     ```

- This example is for a server that will host the Edge Transport server role.

```
Add-WindowsFeature NET-Framework,RSAT-ADDS,ADLDS -Restart
```

Install the Exchange 2010 Hotfixes for Windows Server 2008 R2

The following hotfix is required for Windows Server 2008 R2 and must be installed after the operating system prerequisites have been installed:

- Install the hotfix described in Knowledge Base article 982867, WCF services that are hosted by computers together with a NLB fail in .NET Framework 3.5 SP1. For more information, see these MSDN Code Gallery pages:
  - For additional background information, see KB982867 - WCF: Enable WebHeader settings on the RST/SCT.
  - For the available downloads, see KB982867 - WCF: Enable WebHeader settings on the RST/SCT.

After installing the preceding prerequisites and hotfix, and before installing Exchange 2010, we recommend that you install any critical or recommended updates from Microsoft Update.

Install the Windows Server 2012 operating system prerequisites

Follow the instructions in this section to install the Service Pack 3 (SP3) for Exchange Server 2010 prerequisites on your Windows Server 2012 computer. The prerequisites that are required to install Exchange 2010 SP3 on a Windows Server 2012 computer depend on which Exchange roles you want to install.

1. On the Start screen, right-click **Windows PowerShell** and then click **Run as administrator**. Then, run the following command.

```
Import-Module ServerManager
```

2. Use the **Add-WindowsFeature** cmdlet to install the necessary operating system components for the Exchange 2010 SP3 roles you want to install. Following are examples of installations:
   - This example is for a server that will have the typical installation of the Client Access, Hub Transport, and Mailbox server roles.

```
Add-WindowsFeature NET-Framework-Features,NET-HTTP-Activatic
```

   - This example is for a server that will host the Client Access, Hub Transport, Mailbox, and Unified Messaging server roles.

```
Add-WindowsFeature NET-Framework-Features,Desktop-Experience
```

   - This example is for a server that will host the Client Access and Hub Transport server roles.

```
Add-WindowsFeature NET-Framework-Features,NET-HTTP-Activatic
```

   - This example is for a server that will host the Hub Transport and Mailbox server roles.

```
Add-WindowsFeature NET-Framework-Features,RSAT-Clustering,WA
```

   - This example is for a server that will host the Client Access and Mailbox server roles.

```
Add-WindowsFeature NET-Framework-Features,NET-HTTP-Activatic
```

- This example is for a server that will host only the Client Access server role.

```
Add-WindowsFeature NET-Framework-Features,NET-HTTP-Activatic
```

- This example is for a server that will host only the Hub Transport server role.

```
Add-WindowsFeature NET-Framework-Features,Web-Mgmt-Console,W
```

- This example is for a server that will host only the Mailbox server role.

```
Add-WindowsFeature NET-Framework-Features,RSAT-Clustering,We
```

- This example is for a server that will host only the Unified Messaging server role.

```
Add-WindowsFeature NET-Framework-Features,Desktop-Experience
```

- This example is for a server that will host the Edge Transport server role.

```
Add-WindowsFeature ADLDS,NET-Framework-Features -Restart
```

After you have installed the operating system roles and features, install the following software components in the order presented:

1. Client Access and Unified Messaging servers
   1.a. Microsoft Unified Communications Managed API 4.0, Core Runtime 64-bit
2. Mailbox and Hub Transport servers
   2.a. Microsoft Office 2010 Filter Pack 64 bit
   2.b. Microsoft Office 2010 Filter Pack SP1 64 bit

Install the Windows Vista SP2 operating system prerequisites for the Exchange management tools

1. Install Microsoft .NET Framework 3.5 SP1. For details, see Microsoft .NET Framework 3.5 Service Pack 1.
2. Install the Microsoft .NET Framework 3.5 Family Update for Windows Vista x64 and Windows Server 2008 x64 updates. For details, see Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 and Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available.
3. Install Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu). For details, see Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).
4. Install the necessary operating system components:
   4.a. Open Control Panel, and then select **Programs**.
   4.b. Click **Turn Windows features on or off**.
   4.c. Navigate to **Internet Information Services** > **Web Management Tools** > **IIS 6 Management Compatibility**.
   4.d. Select the check box for **IIS 6 Management Console**, and then click **OK**.

Install the Windows 7 operating system prerequisites for the Exchange management tools

1. Open Control Panel, and then select **Programs**.
2. Click **Turn Windows features on or off**.
3. Select **Microsoft .NET Framework 3.5.1**.
4. Navigate to **Internet Information Services** > **Web Management Tools** > **IIS 6 Management Compatibility**.
5. Select the check box for **IIS 6 Management Console**, and then click **OK**.

Install the Windows 8 operating system prerequisites for the Exchange management tools

Note:
To install the Exchange Management Tools on Windows 8, you must install Exchange 2010 SP3 or later.

The Exchange management tools can be installed on a domain-joined computer with a default install of Windows 8 64-bit.

1.2.2.1.2 Understanding IPv6 Support in Exchange 2010

Understanding IPv6 Support in Exchange 2010

Planning and Deployment > Deploying Exchange 2010 > Understanding Deployment of Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-11*

Internet Protocol version 6 (IPv6) is the most recent version of the Internet Protocol (IP). IPv6 is intended to correct many of the shortcomings of IPv4, which was the previous version of the IP. In Microsoft Exchange Server 2010, IPv6 is supported only when IPv4 is also used; a pure IPv6 environment isn't supported. Using IPv6 addresses and IP address ranges is supported only when both IPv6 and IPv4 are enabled on the computer running Exchange 2010, and the network supports both IP address versions. If Exchange 2010 is deployed in this configuration, all server roles can send data to and receive data from devices, servers, and clients that use IPv6 addresses.

This topic discusses IPv6 addressing in Exchange 2010. For additional background information about IPv6, see IPv6 and IPv6 Support in Exchange 2007 SP1 and SP2.

Contents

Disable or Enable IPv6

Looking for management tasks related to deploying Exchange 2010? See Managing Deployment of Exchange 2010.

IPv6 Addresses

An IPv6 address is 128-bits long. The address is described by using colon-hexadecimal notation. Colon-hexadecimal notation describes the 128-bit address by using eight 16-bit, 4-digit hexadecimal numbers separated by the colon character (:). An example of an IPv6 address in colon-hexadecimal notation is 2001:0DB8:0000:0000:02AA:00FF:C0A8:640A.

You can express an IPv6 address by using the following methods:

- **Suppress leading zeros** You can omit the leading zeros in any of the eight 4-digit hexadecimal numbers in an IPv6 address.
- **Double-colon compression** You can use two colons (::) to represent contiguous 16-bit hexadecimal digits that contain all zeros. These all-zero digits may exist at the beginning, middle, or end of the IPv6 address. You can only use double-colon compression one time in an IPv6 address.
- **Trailing dotted-decimal notation** You may express the last 32 bits at the end of an IPv6 address in dotted-decimal notation by separating the 8-bit digits with a period (.). Trailing dotted-decimal notation is frequently used with IPv4-compatible addresses.

The following table provides examples of the IPv6 address notation and the equivalent IPv6 address syntax.

IPv6 address notation and syntax

IPv6 address notation	IPv6 address syntax
Full IPv6 address	2001:0DB8:0000:0000:02AA:00FF:C0A8:640A
IPv6 address that uses suppressed leading zeros	2001:DB8:0:0:2AA:FF:C0A8:640A
IPv6 address that uses double-colon compression	2001:DB8::2AA:FF:C0A8:640A
IPv6 address that uses trailing dotted-decimal notation	2001:DB8::2AA:FF:192.168.100.10

IPv6 addresses are categorized into the following types:

- **Unicast address** A packet is delivered to one interface.
- **Multicast address** A packet is delivered to multiple interfaces.
- **Anycast address** A packet is delivered to the nearest of multiple interfaces. The distance between interfaces is defined by the routing cost.

IPv6 unicast addresses have the following possible scopes:

- **Link local** The scope of the IPv6 address is the local subnet. IPv6 link local addresses are comparable to IPv4 link local addresses used in Automatic Private IP Addressing (APIPA).
- **Site local** The scope of the IPv6 address is the local organization. Site local addresses were deprecated by RFC 3879 and replaced by unique local addresses as defined in RFC 4193. IPv6 site local addresses and IPv6 unique local addresses are comparable to IPv4 private IP addresses.

- **Global** The scope of the IPv6 address is the whole world. IPv6 global addresses are comparable to IPv4 public IP addresses.

The following table provides a comparison of IPv4 elements and IPv6 elements.

IPv4 vs. IPv6 elements

Item	IPv4	IPv6
Private IP address	10.0.0.0/8 172.16.0.0/12 192.168.0.0/16	FD00::/8
Link local address	169.254.0.0/16	FE80::/64
Loopback address	127.0.0.1	::1
Unspecified address	0.0.0.0	::
Address resolution	Address Resolution Protocol (ARP)	Neighbor Discovery (ND)
Domain Name System (DNS) host name resolution	Address record (A record)	AAAA record or A6 record

For more information about IPv6 addressing, see IPv6 Address Types.

Supported IPv6 Address Input Formats

The following types of IPv6 address input formats are supported in Exchange 2010:

- A single IPv6 address
- An IPv6 address range
- An IPv6 address together with a subnet mask
- An IPv6 address together with a subnet mask that uses Classless Interdomain Routing (CIDR) notation

The following table provides examples of the acceptable IPv6 address input formats in Exchange 2010 on Windows Server 2008.

IPv6 address examples

Type	Example of an IPv6 address
Single address	2001:DB8::2AA:FF:C0A8:640A
Address range	2001:DB8::2AA:FF:C0A8:640A- 2001:DB8::2AA:FF:C0A8:6414
Address together with subnet mask	2001:DB8::2AA:FF:C0A8:640A (FFFF:FFFF:FFFF:FFFF::)
Address together with subnet mask that uses CIDR notation	2001:DB8::2AA:FF:C0A8:640A/64

In Exchange 2010 on Windows Server 2008, the following input formats are supported:

- Suppression of leading zeros
- Double-colon compression
- Trailing dotted-decimal notation

Return to top

IPv6 Support in Exchange 2010 Components

The following table describes the components in Exchange 2010 affected by IPv6.

Exchange 2010 components and IPv6

Server role on the source computer	Feature	IPv6 supported	Comments
Transport	IP Allow list and IP Block list	Yes	For more information about the IP Allow list, see Enable or Disable Connection Filtering and Understanding Connection Filtering.
Transport	IP Allow List providers and IP Block List providers	No	Currently, there is no widely accepted industry standard protocol for looking up IPv6 addresses. Most IP Block List providers don't support IPv6 addresses. If you allow anonymous connections from unknown IPv6 addresses on a Receive connector, you increase the risk that spammers will bypass IP Block List providers and successfully deliver spam into your organization. For more information about IP Block list providers, see "IP Block List Providers" in Understanding Connection Filtering.
Transport	Sender reputation	No	The Protocol Analysis agent doesn't compute the sender reputation level (SRL) for messages that originate from IPv6 senders. For more information about sender reputation, see Understanding Sender Reputation.
Transport	Sender ID	Yes	For more information, see Understanding Sender ID.
Transport	Receive connectors	Yes	IPv6 addresses are accepted for the following components: • Local IP address bindings • Remote IP addresses • IP address ranges We strongly recommend against configuring Receive connectors to accept anonymous

			connections from unknown IPv6 addresses. If your organization must receive mail from senders who use IPv6 addresses, create a dedicated Receive connector that restricts the remote IP addresses to the specific IPv6 addresses that those senders use. For more information, see Understanding Receive Connectors.
Transport	Send connectors	Yes	IPv6 addresses are accepted for the following components: • Smart host IP addresses • The *SourceIPAddress* parameter for Send connectors configured on Edge Transport servers **Note:** If you want to specify an IPv6 address for the *SourceIPAddress* parameter, make sure that the appropriate DNS AAAA and mail exchange (MX) records are configured correctly. This helps ensure message delivery if a remote messaging server tries any kind of reverse lookup test on the specified IPv6 address. For more information, see Understanding Send Connectors.
Transport	Incoming message rate limits	Partial	Incoming message rate limits that you can set on a Receive connector, such as the *MaxInboundConnectionPercentagePerSource* parameter, the *MaxInboundConnectionPerSource* parameter, and the *TarpitInterval* parameter, only apply to a global IPv6 address. Link local IPv6 addresses and site local IPv6 addresses aren't affected by any specified incoming message rate limits. For more information about incoming message rate limits, see Understanding Message Throttling.

Unified Messaging	All features	No	Unified Messaging doesn't support IPv6 in any version of Exchange 2010. For more information about Unified Messaging, see Unified Messaging.
Mailbox (Database availability group member)	IPv6 addresses	Yes	Static IPv6 addresses are supported by Windows Server 2008 and the Cluster service. However, using static IPv6 addresses goes against best practices. Exchange 2010 on Windows Server 2008 doesn't support the configuration of static IPv6 addresses during setup. Failover clusters support Intra-site Automatic Tunnel Addressing Protocol (ISATAP). They support only IPv6 addresses that allow for dynamic registration in DNS. Link local addresses can't be used in a cluster. For more information, see New High Availability and Site Resilience Functionality.

Return to top

Disable IPv6

Exchange servers fully support IPv6 networks. Therefore, you do not have to disable IPv6 on your Exchange servers. To learn more about IPv6 support in Microsoft Windows, see IPv6 for Microsoft Windows: Frequently Asked Questions.

1.2.2.1.3 Understanding Exchange 2010 Setup

Understanding Exchange 2010 Setup

Planning and Deployment > Deploying Exchange 2010 > Understanding Deployment of Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

This topic provides an overview of Microsoft Exchange Server 2010 Setup. You can use different types and modes of Exchange 2010 Setup to install and maintain the various editions and versions of Exchange 2010. Improvements have also been made to Setup in Exchange Server 2010 Service Pack 1 (SP1) to enhance the Setup log and the scenario of

a failed installation.

For a list of the various services installed by Exchange Setup, see Overview of Services Installed by Exchange Setup.

Exchange Editions and Versions

Exchange Server 2010 is available in two server editions: Standard Edition and Enterprise Edition. These are licensing editions that are defined by a product key. The release to manufacturing (RTM) and service pack 1 (SP1) versions of Exchange Server 2010 are now available. For more information, see Exchange 2010: Editions and Versions.

Types of Exchange Setup

You have the following options for Exchange 2010 Setup:

Exchange Setup UI Setup.exe is an interactive experience where you are guided by the Exchange 2010 Setup wizard.

Exchange Unattended Setup Setup.com is an unattended experience where you provide command-line switches interactively or through a script. Setup.com is available from the Exchange 2010 DVD or the downloaded source files.

Modes of Exchange Setup

Setup for Exchange 2010 includes several installation modes:

Install Use this mode when you're installing a new server role or adding a server role to an existing installation (maintenance mode). You can use this mode from both the Exchange Setup wizard and the unattended install.

Uninstall Use this mode when you're removing the Exchange installation or removing a single server role from an existing installation (maintenance). You can use this mode from both the Exchange Setup wizard and the unattended install.

Upgrade Select this mode used when you have an existing installation of Exchange and you're installing the new version. This mode is used for a Service Pack installation. You can use this mode from both the Exchange Setup wizard and the unattended install.

RecoverServer Use this mode when there has been a catastrophic failure of a server, and you need to recover data. You must install a server using the same fully qualified domain name (FQDN) as the failed server, and then run Setup with the **/m:RecoverServer** switch. Don't specify the roles to restore. Setup detects the Exchange Server object in Active Directory and installs the corresponding files and configuration automatically. After you recover the server, you can restore databases and reconfigure any additional settings. To run in RecoverServer mode, you can't have Exchange installed on the server. The Exchange server object must exist in Active Directory. You can only use this mode during an unattended installation.

Note:

You must complete one mode of Setup before you can use another mode.

Exchange 2010 SP1 Setup Improvements

There have been several improvements to Setup in Exchange 2010 SP1:

- **Failed Installations** Unlike Exchange 2010 RTM, Setup in Exchange 2010 SP1

now supports resuming a failed installation. (In Exchange 2010, if you have a failed installation, you can't use the Uninstall mode to correct it.) A watermark in the registry identifies where Setup failed. You will not have to answer the Exchange 2010 Setup wizard questions again when you resume a failed Setup. You can resume the failed install, and let it succeed.

- **Exchange Setup Log** Exchange SP1 improves the Exchange Setup Log by reducing the amount of non-essential information and correctly noting errors. The Setup Log is divided into discrete sections so it's easy to see where Setup failed. For more information, see Verify an Exchange 2010 Installation.
- **Windows Roles and Features** Exchange 2010 SP1 adds the ability to install Windows roles and features that are required for your server roles.

For more information about these improvements, see New Deployment Functionality in Exchange 2010 SP1.

1.2.2.1.4 Overview of Services Installed by Exchange Setup

Overview of Services Installed by Exchange Setup

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-06-21*

During the installation of Microsoft Exchange Server 2010, Setup runs a set of tasks that install new services. A service is a background process that can be launched during operating system startup by the Service Control Manager in Microsoft Windows. Services are executable files designed to operate independently and without administrative intervention. A service can run using either a graphical user interface (GUI) mode or a console mode.

Services aren't new to Exchange 2010. All previous versions of Exchange included components implemented as services. Each server role includes services that are part of, or may be needed by, the server role to perform its functions. Although Setup installs all services whether they're immediately needed or not, some services only become active when specific features are used.

The following table lists by name and by short name the various services installed by Exchange 2010. Also included is a description of each service, the server role that installs the service, and whether the service is required or optional. In the table, *optional* means that the service is installed by Setup, but you can disable it if you determine that the function provided by the service isn't needed by your organization.

Services installed by Exchange Setup

Service name	Service short name	Security context	Description and dependencies	Default startup type	Server roles	Required (R) or optional (O)
Microsoft Exchange Active Directory Topology	MSExchangeADTopology	Local System	Provides Active Directory topology information to Exchange	Automatic	Mailbox, Hub Transport, Client Access, Unified	R

			services. If this service is stopped, most Exchange services are unable to start. This service has no dependencies.		Messaging	
Microsoft Exchange ADAM	ADAM_MSExchange	Network Service	Stores configuration data and recipient data on the Edge Transport server. This service represents the named instance of Active Directory Lightweight Directory Service (AD LDS) that's automatically created by Setup during Edge Transport server installation. This service is dependent upon the COM+ Event System service.	Automatic	Edge Transport	R
Microsoft Exchange Address Book	MSExchangeAB	Local System	Manages client address book connections. This service is dependent upon the Microsoft Exchange Active Directory	Automatic	Client Access	R

			Topology service.			
Microsoft Exchange Anti-spam Update	MSExchangeAntispamUpdate	Local System	Provides the Microsoft Forefront Protection 2010 for Exchange Server anti-spam update service. On Hub Transport servers, this service is dependent upon the Microsoft Exchange Active Directory Topology service. On Edge Transport servers, this service is dependent upon the Microsoft Exchange ADAM service.	Automatic	Hub Transport, Edge Transport	O
Microsoft Exchange Credential Service	MSExchangeEdgeCredential	Local System	Monitors credential changes in AD LDS and installs the changes on the Edge Transport server. This service is dependent upon the Microsoft Exchange ADAM service.	Automatic	Edge Transport	R
Microsoft Exchange EdgeSync	MSExchangeEdgeSync	Local System	Connects to an AD LDS instance on subscribed Edge Transport	Automatic	Hub Transport	O

			servers over a secure LDAP channel to synchronize data between a Hub Transport server and an Edge Transport server. This service is dependent upon the Microsoft Exchange Active Directory Topology service. If Edge Subscription isn't configured, this service can be disabled.			
Microsoft Exchange File Distribution	MSExchangeFDS	Local System	Distributes offline address book (OAB) and custom Unified Messaging prompts. This service is dependent upon the Microsoft Exchange Active Directory Topology and Workstation services.	Automatic	Client Access, Unified Messaging	R
Microsoft Exchange Forms-Based Authentication	MSExchangeFBA	Local System	Provides forms-based authentication to Microsoft Office Outlook Web App	Automatic	Client Access	R

			and the Exchange Control Panel. If this service is stopped, Outlook Web App and the Exchange Control Panel won't authenticate users. This service has no dependencies.			
Microsoft Exchange IMAP4	MSExchangeIMAP4	Network Service	Provides IMAP4 service to clients. If this service is stopped, clients won't be able to connect to this computer using the IMAP4 protocol. This service is dependent upon the Microsoft Exchange Active Directory Topology service.	Manual	Client Access	O
Microsoft Exchange Information Store	MSExchangeIS	Local System	Manages the Exchange Information Store. This includes mailbox databases and public folder databases. If this service is stopped, mailbox	Automatic	Mailbox	R

			databases and public folder databases on this computer are unavailable. If this service is disabled, any services that explicitly depend on it will fail to start. This service is dependent on the RPC, Server, Windows Event Log, and Workstation services.			
Microsoft Exchange Mail Submission Service	MSExchangeMailSubmission	Local System	Submits messages from the Mailbox server to Exchange 2010 Hub Transport servers. This service is dependent upon the Microsoft Exchange Active Directory Topology service.	Automatic	Mailbox	R
Microsoft Exchange Mailbox Assistants	MSExchangeMailboxAssistants	Local System	Performs background processing of mailboxes in the Exchange store. This service is dependent upon the Microsoft Exchange	Automatic	Mailbox	R

			Active Directory Topology service.			
Microsoft Exchange Mailbox Replication Service	MSExchange MailboxRepli cation	Local System	Processes mailbox moves and move requests. This service is dependent upon the Microsoft Exchange Active Directory Topology and Net.Tcp Port Sharing service.	Automatic	Client Access	O
Microsoft Exchange Monitoring	MSExchange Monitoring	Local System	Allows applications to call the Exchange diagnostic cmdlets. This service has no dependenci es.	Manual	All	O
Microsoft Exchange POP3	MSExchange POP3	Network Service	Provides POP3 service to clients. If this service is stopped, clients can't connect to this computer using the POP3 protocol. This service is dependent upon the Microsoft Exchange Active Directory Topology service.	Manual	Client Access	O
Microsoft Exchange	MSExchange ProtectedSe	Local System	Provides a host for	Automatic	Hub Transport,	R

Protected Service Host	rviceHost		several Exchange services that must be protected from other services. This service is dependent upon the Microsoft Exchange Active Directory Topology service.		Client Access	
Microsoft Exchange Replication Service	MSExchangeRepl	Local System	Provides replication functionality for mailbox databases on Mailbox servers in a database availability group (DAG) and database mount functionality for all Mailbox servers. This service is dependent upon the Microsoft Exchange Active Directory Topology service.	Automatic	Mailbox	R
Microsoft Exchange RPC Client Access	MSExchangeRPC	Network Service	Manages client RPC connections for Exchange. This service is dependent upon the Microsoft Exchange Active	Automatic	Mailbox, Client Access	O (Mailbox), R (Client Access)

			Directory Topology service.			
Microsoft Exchange Search Indexer	MSExchange Search	Local System	Drives indexing of mailbox content, which improves the performance of content search. This service is dependent upon the Microsoft Exchange Active Directory Topology and Microsoft Search (Exchange Server) services.	Automatic	Mailbox	O
Microsoft Exchange Server Extension for Windows Server Backup	WSBExchange	Local System	Enables Windows Server Backup users to back up and recover application data for Microsoft Exchange. This service has no dependencies.	Manual	Mailbox	O
Microsoft Exchange Service Host	MSExchange ServiceHost	Local System	Provides a host for several Exchange services. On internal server roles, this service is dependent upon the Microsoft Exchange Active	Automatic	All	R

			Directory Topology service. On Edge Transport servers, this service is dependent upon the Microsoft Exchange ADAM service.			
Microsoft Exchange Speech Engine	MSSpeechService	Network Service	Provides speech processing services for Unified Messaging. This service is dependent upon the Windows Management Instrumentation (WMI) service.	Automatic	Unified Messaging	R
Microsoft Exchange System Attendant	MSExchangeSA	Local System	Forwards directory lookups to a global catalog server for legacy Outlook clients, generates e-mail addresses and OABs, updates free/busy information for legacy clients, and maintains permissions and group memberships for the server. If this service is disabled, any services that	Automatic	Mailbox	R

			explicitly depend on it will fail to start. This service is dependent on the RPC, Server, Windows Event Log, and Workstation services.			
Microsoft Exchange Throttling	MSExchange Throttling	Network Service	Limits the rate of user operations. This service is dependent upon the Microsoft Exchange Active Directory Topology service.	Automatic	Mailbox	R
Microsoft Exchange Transport	MSExchange Transport	Network Service	Provides SMTP server and transport stack. On Hub Transport servers, this service is dependent upon the Microsoft Exchange Active Directory Topology service. On Edge Transport servers, this service is dependent upon the Microsoft Exchange ADAM service.	Automatic	Hub Transport, Edge Transport	R
Microsoft Exchange Transport	MSExchange TransportLogSearch	Local System	Provides remote search	Automatic	Hub Transport, Mailbox,	O

Log Search			capability for Microsoft Exchange Transport log files. On Hub Transport servers, this service is dependent upon the Microsoft Exchange Active Directory Topology service. On Edge Transport servers, this service is dependent upon the Microsoft Exchange ADAM service.		Edge Transport	
Microsoft Exchange Unified Messaging	MSExchangeUM	Local System	Enables Microsoft Exchange Unified Messaging features. This allows voice and fax messages to be stored in Exchange and gives users telephone access to e-mail, voice mail, calendar, contacts, or an auto attendant. If this service is stopped, Unified Messaging isn't available. This service is	Automatic	Unified Messaging	R

			dependent upon the Microsoft Exchange Active Directory Topology and the Microsoft Exchange Speech Engine service.			
Microsoft Search (Exchange Server)	msftesql-Exchange	Local System	This is a Microsoft Exchange-customized version of Microsoft Search. This service is dependent on the RPC service.	Manual	Hub Transport, Mailbox	O

1.2.2.1.5 Deployment Security Checklist

Deployment Security Checklist

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-11*

Microsoft Exchange Server 2010 features are designed to help improve the security of your messaging environment. Generally, for Exchange 2010, the following conditions are true:

- Accounts that are used by Exchange 2010 have the minimum rights that are required to perform the given task sets.
- By default, services are started only when they are required.
- Access control list (ACL) rights for Exchange objects are minimized.
- Administrative permissions are set according to the scope of change on the object that a given modification requires.
- By default, all internal default message paths are encrypted.

This topic lists steps that we recommend you take to harden the messaging environment before you install Microsoft Exchange. We recommend that you refer to this checklist every time that you install a new Exchange server role.

Before installing Exchange 2010, perform the following procedures.

Procedure	Done?
Run Microsoft Update.	

Run the Microsoft Windows Malicious Software Removal Tool. The Malicious Software Removal Tool is included with Microsoft Update. More information about the tool can be found at Malicious Software Removal Tool.	
Run the Microsoft Baseline Security Analyzer.	

1.2.2.1.6 Exchange Management Console Interoperability

Exchange Management Console Interoperability

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

The Exchange Management Console (EMC) is a Microsoft Management Console-(MMC) based tool that provides Exchange administrators with a GUI to manage the configuration of Exchange organizations. You can also add the Exchange Management Console snap-in to custom MMC-based tools. This topic discusses interoperability between the EMC in Microsoft Exchange Server 2010 and earlier versions of Exchange, specifically Exchange Server 2003 and Exchange Server 2007.

For more information about the improvements to the Exchange Management Console, see New Administrative Functionality in the Exchange Management Console.

Interoperability with Exchange 2003

You can't manage Exchange 2010 objects using the Exchange Server 2003 System Manager. You can use the EMC in Exchange 2010 to view certain properties and objects, like the routing group connector in Exchange Server 2003. You can't perform message tracking configuration tasks between Exchange 2010 and Exchange 2003. You must use Exchange 2003 messaging tracking tools within your Exchange 2003 organization, and Exchange 2010 messaging tracking tools within your Exchange 2010.

Interoperability with Exchange 2007

The Exchange Management Console (EMC) is available in both Exchange Server 2010 and Exchange Server 2007. The following lists the tasks and actions that can be performed using the EMC in either Exchange 2010 or Exchange 2007:

- Actions that create objects, such as new mailboxes or a new offline address book (OAB), can only be performed on a version of the EMC that's the same as the target object. For example, creating a mailbox on an Exchange 2007 Mailbox server must be performed with the EMC in Exchange 2007. The following applies:
  - Exchange 2007 Mailbox databases can't be managed from the EMC in Exchange 2010, although these databases can be viewed.
  - The EMC in Exchange 2010 can't enable or disable Exchange 2007 Unified Messaging mailboxes.
  - The EMC in Exchange 2010 can't manage Exchange 2007 mobile devices.
- Actions that require viewing of objects can be performed from any version of

the EMC to any version of Exchange objects, with a few exceptions:

- Exchange 2010 and Exchange 2007 transport rule objects can only be viewed from their corresponding version of the EMC.
- Exchange 2010 and Exchange 2007 servers can only be viewed from their corresponding version of the EMC.
- The Queue Viewer tool in the EMC in Exchange 2010 can't connect to an Exchange 2007 server to view queues or messages.

Note:
If an Exchange 2007 object (such as a storage group) is no longer present in Exchange 2010, there's no interoperability expected or provided because Exchange 2010 isn't aware of the feature.

- You can't use message tracking configuration tasks between Exchange 2010 and Exchange 2007. You must use Exchange 2007 messaging tracking tools within your Exchange 2007 servers, and Exchange 2010 messaging tracking tools within your Exchange 2010 servers.

The following is a list of Exchange 2010-only and Exchange 2007-only objects. These objects are available for viewing, managing, and creating only in the corresponding version of the EMC.

Note:
Be aware that managing an object in the Exchange 2010 Exchange Control Panel can upgrade the object. As a result, it can't be managed by the Exchange 2007 management tools (EMC, Shell) that created the object.

Exchange 2007 objects no longer present in Exchange 2010:

- Storage groups
- Exchange Administrators
- WebDAV

Exchange 2010 Management Console-only objects:

- Database availability group
- Certificate creation
- Database copies
- Federation trust
- Sharing relationships
- Sharing policies
- Microsoft Office Outlook Web App mailbox policies
- Customer Experience Program properties

Side-by-Side Management Console

To use the side-by-side EMC feature, the Exchange 2007 EMC must first be installed on a non-Exchange administrative machine. After the Exchange 2007 EMC is installed, you can then install the Exchange 2010 EMC to run in a side-by-side scenario.

Note:
Exchange 2010 EMC can only be administered from a 64-bit machine. Therefore, for side-by-side management, the Exchange 2007 EMC must be installed on a 64-bit machine. Side-by-side management for Exchange Server 2003 and Exchange 2010 management tools isn't supported, because Exchange Server 2003 management tools can only be run on 32-bit machines. However, you can use 32-bit Windows PowerShell 2.0 and remotely access your Exchange 2010 environment.

For more information, see Install the Exchange 2010 Management Tools.

Understanding Upgrade to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 can be deployed in an Active Directory forest that has an existing messaging system. You have a coexistence scenario if the following conditions are true:

- Exchange Server 2010 is deployed in an existing Exchange organization.
- More than one version of Microsoft Exchange provides messaging services to the organization.

You can't upgrade an existing Exchange 2000 organization directly to Exchange 2010. You must first upgrade the Exchange 2000 organization to either an Exchange 2003 or Exchange 2007 organization, and then you can upgrade the Exchange 2003 or Exchange 2007 organization to Exchange 2010. We recommend that you upgrade your organization from Exchange 2000 to Exchange 2003, and then upgrade from Exchange 2003 to Exchange 2010. For more information about upgrading from Exchange 2000, see Planning an Upgrade from Exchange 2000 and Upgrading to Exchange 2007.

When an organization gradually transitions a messaging system from Exchange Server 2003 or Exchange Server 2007 to Exchange 2010, the organization will probably have to maintain more than one version of Exchange during that time.

The following table lists the scenarios in which coexistence between Exchange 2010 and earlier versions of Exchange are supported.

Coexistence of Exchange 2010 and earlier versions of Exchange Server

Exchange version	Exchange organization coexistence
Exchange 2000 Server	Not supported
Exchange Server 2003	Supported
Exchange 2007	Supported
Mixed Exchange 2007 and Exchange Server 2003 organization	Supported

The following topics provide information about upgrading your organization to Exchange 2010:

Understanding Upgrade from Exchange 2003 to Exchange 2010

Understanding Upgrade from Exchange 2007 to Exchange 2010

Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010

Also, see Exchange Server Deployment Assistant for information about a Web-based tool that can help you with your deployment.

1.2.2.2 Understanding a New Installation of Exchange 2010

Understanding a New Installation of Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

The following topics provide information about deploying a new installation of Microsoft Exchange 2010 in your organization:

Checklist: Perform a New Installation of Exchange 2010

Managing Deployment of Exchange 2010

Deploy a New Exchange 2010 RTM UM Environment

Install or Upgrade to Exchange 2010 SP2 Unified Messaging

In addition, see Understanding Deployment of Exchange 2010 for information about prerequisites to installation of Exchange 2010 and see Exchange Server Deployment Assistant for information about a Web-based tool that can help you with your deployment.

1.2.2.2.1 Checklist: Perform a New Installation of Exchange 2010

Checklist: Perform a New Installation of Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-28*

Use this checklist to deploy Microsoft Exchange Server 2010. Before you start working with this checklist, make sure you're familiar with the concepts discussed in:

- Planning for Exchange 2010
- Understanding Exchange 2010 Setup
- Planning Roadmap for New Deployments
- Deployment Security Checklist
- Deployment Checklist for Multi-Tenancy

This checklist is generic in that it provides guidance for a typical scenario. For more customized step-by-step guidance about how to deploy Exchange 2010, see the Exchange Server Deployment Assistant.

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Checklist for a New Installation of Exchange 2010

Done?	Task	Topic
	1. Verify system requirements	Exchange 2010 System Requirements
	2. Confirm prerequisite steps are done	Exchange 2010 Prerequisites
	3. Configure disjoint namespace **Note:** This step is optional. It's only necessary if your organization is running a disjoint namespace.	Configure the DNS Suffix Search List for a Disjoint Namespace
	4. Install the Client Access server role	Install Exchange Server 2010
	5. Add digital certificates on the Client Access server	Create a New Exchange Certificate
	6. Enable Outlook Anywhere **Note:** This step is optional. It's only necessary if you want to use the Outlook Anywhere component of Exchange 2010.	Enable Outlook Anywhere
	7. Configure settings on virtual directories, including OAB, Web Services, ECP, Outlook Web App, and Exchange ActiveSync virtual directories **Note:** This step is necessary if you want to use Exchange Web Services, Outlook Anywhere, or the offline address book. It also may be required if you need to change any of the default settings for ECP, Outlook Web App, or Exchange ActiveSync.	Create an Offline Address Book Virtual Directory Configure ECP Virtual Directory Properties View or Configure Outlook Web App Virtual Directories View or Configure Exchange ActiveSync Virtual Directory Properties
	8. Install the Hub Transport server role	Install Exchange Server 2010
	9. Install the Mailbox server role	Install Exchange Server 2010

	10. Use public folders	Configure Public Folder Replication
	11. Install the Edge Transport server role **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Install Exchange Server 2010
	12. Subscribe the Edge Transport server **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Create an Edge Subscription File on an Edge Transport Server Import an Edge Subscription File to an Active Directory Site
	13. Install the Unified Messaging server role **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Install Exchange Server 2010
	14. Configure Unified Messaging **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Deploy a New Exchange 2010 RTM UM Environment
	15. Post-installation tasks	Exchange 2010 Post-Installation Tasks

1.2.2.3 Understanding Upgrade from Exchange 2003 to Exchange 2010

Understanding Upgrade from Exchange 2003 to Exchange 2010

Exchange Server 2010 > Planning and Deployment > Deploying Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When you're upgrading your existing Microsoft Exchange Server 2003 organization to Exchange Server 2010, there's a period of time when both Exchange 2003 and Exchange 2010 will coexist within your organization. This section discusses key points about both the upgrade process and coexistence as they apply to the Client Access, Transport, and Mailbox server roles.

You can only deploy Exchange 2010 in an Exchange 2003 organization that operates in

native mode. Use Exchange System Manager to change the Exchange organization to native mode on an Exchange 2003 server, as follows:

1. Start Exchange System Manager. Click **Start** > **Programs** > **Microsoft Exchange** > **System Manager**.
2. Right-click the organization, and then click **Properties**.
3. Click the **General** tab, and then, under **Change Operations Mode**, click **Change Mode**. Click **Yes** if you are sure that you want to permanently switch the organization's mode to native mode.

For more information, see the following topics:

Checklist: Upgrading from Exchange 2003

Upgrade from Exchange 2003 Client Access

Upgrade from Exchange 2003 Transport

Upgrade from Exchange 2003 Mailbox

For more information about the Exchange 2003 to Exchange 2010 planning and upgrade process, see the following topics:

Exchange 2003 - Planning Roadmap for Upgrade and Coexistence

Understanding Upgrade to Exchange 2010

Managing Deployment of Exchange 2010

Exchange Server Deployment Assistant

1.2.2.3.1 Checklist: Upgrading from Exchange 2003

Checklist: Upgrading from Exchange 2003

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-29*

Use this checklist to upgrade from Microsoft Exchange Server 2003 to Exchange Server 2010. Before you start working with this checklist, make sure you're familiar with the concepts discussed in:

- Planning for Exchange 2010
- Deployment Security Checklist
- Exchange 2003 - Planning Roadmap for Upgrade and Coexistence

This checklist is generic in that it provides guidance for a typical upgrade scenario. For more customized step-by-step guidance about how to upgrade your Exchange 2003 organization, see the Exchange Server Deployment Assistant.

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment.

ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Checklist for Upgrading from Exchange 2003 to Exchange 2010

Done?	Task	Topic
	1. Verify system requirements	Exchange 2010 System Requirements
	2. Confirm prerequisite steps are done	Exchange 2010 Prerequisites
	3. Configure disjoint namespace **Note:** This step is optional. It's only necessary if your organization is running a disjoint namespace.	Configure the DNS Suffix Search List for a Disjoint Namespace
	4. Install the Client Access server role	Install Exchange 2010 in an Existing Exchange 2003 Organization
	5. Add digital certificates on the Client Access server	Create a New Exchange Certificate
	6. Enable Outlook Anywhere **Note:** This step is optional. It's only necessary if you want to use the Outlook Anywhere component of Exchange 2010.	Enable Outlook Anywhere
	7. Configure OAB and Web Services virtual directories **Note:** This step is necessary if you want to use Exchange Web Services, Outlook Anywhere, or the offline address book. It also may be required if you need to change any of the default settings for Exchange Control Panel, Microsoft Office Outlook Web App, or Exchange ActiveSync.	Create an Offline Address Book Virtual Directory Configure ECP Virtual Directory Properties View or Configure Outlook Web App Virtual Directories View or Configure Exchange ActiveSync Virtual Directory Properties
	8. Install the Hub Transport server role	Install Exchange Server 2010
	9. Configure a legacy host	Upgrade from Exchange

	name	2003 Client Access
	10. Configure Exchange ActiveSync authentication	Configure Authentication for Exchange ActiveSync
	11. Install the Unified Messaging server role **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Install Exchange Server 2010
	12. Configure Unified Messaging **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Install Exchange Server 2010 Checklist: Deploy a New Exchange 2010 RTM UM Environment
	13. Install the Mailbox server role	Install Exchange Server 2010
	14. Change the offline address book (OAB) generation server	Move the Offline Address Book Generation Process to Another Server
	15. Install the Edge Transport server role **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Install Exchange Server 2010 Upgrade from Exchange 2003 Transport
	16. Move Internet mail flow from Exchange 2003 to Exchange 2010	Move Internet Mail Flow from Exchange 2003 to Exchange 2010
	17. Move mailboxes from Exchange 2003 to Exchange 2010	Create a Local Move Request
	18. Move public folder data from Exchange 2003 to Exchange 2010	Move Public Folder Content from One Public Folder Database to Another Public Folder Database
	19. Post-installation tasks	Exchange 2010 Post-Installation Tasks

Return to top

Upgrade from Exchange 2003 Client Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you're upgrading your existing Microsoft Exchange Server 2003 organization to Exchange Server 2010, there's a period of time when both Exchange 2003 and Exchange 2010 will coexist within your organization. This topic describes the various steps you must take to upgrade an Exchange 2003 organization to Exchange 2010.

Important:

When you upgrade your organization to the RTM version of Exchange 2010, your clients running Outlook 2003 don't use RPC encryption, and RPC Client Access requires it by default. This can cause connection issues between Exchange 2010 and Outlook 2003. In Exchange 2010 SP2, RPC Client Access doesn't require RPC encryption by default. If you have Outlook 2003 clients within your organization, we recommend that you install Exchange 2010 SP2 to avoid connection issues between Exchange 2010 RTM and Outlook 2003. For more information, see Understanding RPC Client Access.

Overview of the Upgrade Process

The upgrade process includes the following steps:

1. Installing Exchange 2010 within your organization on new hardware.
2. Configuring Exchange 2010 Client Access.
3. Creating a set of legacy host names and associating those host names with your Exchange 2003 infrastructure.

   Note:

   Your legacy host name should be in the format "legacy.contoso.com", where contoso.com matches your current host name.

   Note:

   Configuring a legacy host name is necessary only if you'll need Exchange 2003 and Exchange 2010 to coexist in the same organization. If you have a small number of mailboxes and can move all your mailboxes from Exchange 2003 to Exchange 2010 during the downtime you've scheduled for the upgrade, this step isn't necessary.
4. Obtaining a digital certificate with the names you'll be using during the coexistence period and installing it on your Exchange 2010 Client Access server.
5. Associating the host name you currently use for your Exchange 2003 infrastructure with your newly installed Exchange 2010 infrastructure.
6. Moving mailboxes from Exchange 2003 to Exchange 2010.
7. Decommissioning your Exchange 2003 infrastructure.

Note:

Throughout this topic, mail.contoso.com will be used as the primary namespace and legacy.contoso.com will be used as the legacy namespace. When you perform your upgrade you'll substitute the names of your own primary and legacy namespaces.

Understanding Legacy Host Names

An important part of the upgrade process is configuring a legacy host name and associating that host name with your Exchange 2003 infrastructure. This is a necessary step if your organization has a significant number of mailboxes that can't all be moved from Exchange 2003 to Exchange 2010 during the downtime scheduled for the upgrade

and if your organization supports Outlook Web Access for Internet users.

If your organization has a small number of mailboxes, and you're able to schedule downtime over an evening or a weekend, you can skip the step of configuring a legacy host name and move all mailboxes during this downtime. Doing this eliminates the need for Exchange 2003 and Exchange 2010 to coexist.

You'll have to configure a legacy host name to be published to the Internet and associated with the virtual directories of the various services you have on Exchange 2003, such as Microsoft Exchange ActiveSync, Microsoft Outlook Web Access, POP3, and IMAP4 if:

- You have a significant number of mailboxes to move from Exchange 2003 to Exchange 2010
  or
- You don't want to move all mailboxes at once
  and
- You have users who access Outlook Web Access from the Internet.

After a legacy host name has been configured and associated with your Exchange 2003 infrastructure, and your current host name has been associated with your Exchange 2010 infrastructure, users will experience a seamless transition. Exchange 2010 will redirect users from the Exchange 2010 Client Access server to the Exchange 2003 front-end server. Users won't have to learn a new URL to access Outlook Web Access (called Outlook Web App in Exchange 2010) or reconfigure their Exchange ActiveSync devices. POP3, IMAP4, and Outlook Anywhere users can also continue to access their mailboxes without interruption.

How to create a legacy host name

The steps to perform this task will vary for each organization. That's because the exact steps depend on your Internet provider and firewall configuration. Example steps for GoDaddy are provided below to give you an idea of how things work. The steps you need to follow may vary. But, in general, you need to:

1. Create a DNS host (A) record in your internal and external DNS servers that points to the IP address of your legacy Internet-facing Exchange server (for example, your Exchange 2007 Client Access server or Exchange 2003 front-end server) in internal DNS or the public IP address on your reverse proxy or firewall solution (external DNS). The host name should be in the format of legacy.*domain*.com (for example, legacy.contoso.com).
2. Create a publishing rule for the legacy host name in your reverse proxy or firewall solution to point to your legacy Internet-facing Exchange server. Refer to your proxy/firewall solution's user manual for instructions for how to do this.
3. Configure the existing DNS host (A) record in your internal and external DNS servers for your original host name (for example, mail.contoso.com) to point to your Exchange 2010 organization. For example, point to the IP address of your Client Access server or array (internal DNS) or the public IP address on your reverse proxy or firewall solution (external DNS).
   So, for example, if your provider is GoDaddy.com, you can use the following steps to create a DNS host (A) record and associate it with your legacy Exchange infrastructure:
   3.a. From your GoDaddy account management home page, click **Domain Manager** under the **My Products** heading in the left sidebar.
   3.b. If you're prompted to log in to your account, log in.
   3.c. In the **Total DNS** section of the Domain Manager information screen, click **Total DNS Control**.
   3.d. In the **A (Host)** section of the Total DNS Control screen, click **Add new A record**.
   3.e. Enter the host name, for example legacy.contoso.com and enter the IP address of your legacy Exchange server in the **Points to IP address** box.
   3.f. Choose a **TTL** (time to live) value. If you're performing this step well in

advance of your Exchange 2010 installation, you can choose 1 day or 1 week from the drop-down list. Otherwise, choose the default of 1 hour or 1/2 hour.

3.g.Click **OK** to complete your changes.

How to verify the legacy host name can be accessed from the Internet

From outside your firewall, using your specific domain name instead of contoso, perform the following steps:

1. Navigate to https://mail.contoso.com/owa, and verify that you can access Outlook Web App for a user whose mailbox is on an Exchange 2010 server.
2. Navigate to https://legacy.contoso.com/exchange, and verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.
3. Navigate to https://mail.contoso.com/owa, and verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.

You can also use the Exchange Server Remote Connectivity Analyzer to verify connectivity for the legacy namespace.

You'll find ExRCA at: https://www.testexchangeconnectivity.com.

Certificate Planning for Upgrade

To support coexistence of Exchange 2003 and Exchange 2010, you'll likely have to obtain a new commercial certificate. We recommend that you obtain a certificate that supports Subject Alternative Names. However, a wildcard certificate is also supported. For more information about certificates, see Understanding Digital Certificates and SSL.

Return to top

Installing Exchange 2010

After you've ensured that the prerequisites are met and you've obtained the correct certificates, you can begin your upgrade. Do this using the following steps.

Note:

In the following steps, replace <CAS2010> with the name of your Exchange 2010 Client Access server.

1. Install the Exchange 2010 Client Access server role.
2. During Setup, you can enter the primary external namespace for your virtual directories. This value should be the primary host name that your users use to connect to Exchange services from the Internet, for example: mail.contoso.com.
   - If you're upgrading through the graphical user interface Setup experience, you'll be prompted to configure an external Client Access domain.
   - If you're upgrading from a command prompt, use the setup property /`ExternalCASServerDomain` and specify your domain, for example: mail.contoso.com.
3. If your organization requires Outlook Anywhere access, enable Outlook Anywhere.
   - This can be done using the following command: `Enable-OutlookAnywhere -Server:<CAS2010> -ExternalHostName:mail.contoso.com -SSLOffloading $false`
4. If you didn't configure a primary external namespace during setup, you'll have to run the following commands to configure the virtual directories for the Offline Address Book, Exchange Web Services, Exchange ActiveSync, Outlook Web App, and Exchange Control Panel. You can do that with the following commands:
   - Offline Address Book: `Set-OABVirtualDirectory <CAS2010>\OAB* -ExternalURL https://mail.contoso.com/OAB`

- Web Services: `Set-WebServicesVirtualDirectory <CAS2010>\EWS* -ExternalURL https://mail.contoso.com/ews/exchange.asmx`
- Exchange ActiveSync: `Set-ActiveSyncVirtualDirectory -Identity <CAS2010>\Microsoft-Server-ActiveSync -ExternalURL https://mail.contoso.com`
- Outlook Web App:`Set-OWAVirtualDirectory <CAS2010>\OWA* -ExternalURL https://mail.contoso.com/OWA`
- Exchange Control Panel: `Set-ECPVirtualDirectory <CAS2010>\ECP* -ExternalURL https://mail.contoso.com/ECP`

5. Configure the Exchange 2003 URL property on the /owa virtual directory. This is necessary for Exchange 2003 and Exchange 2010 to coexist. To configure this property, use the following command.
   - `Set-OWAVirtualDirectory <CAS2010>\OWA* -Exchange2003URL https://legacy.contoso.com/exchange`

   Note:
   You must enable forms-based authentication on the Exchange 2003 front-end server to allow your users to access their mailboxes through a single sign-on during the coexistence period.

6. Change the Offline Address Book generation server and enable web distribution on the Exchange 2010 Client Access server using the following steps:
   - Move the Offline Address Book using the following command: `Move-OfflineAddressBook "Default Offline Address List" -Server <MBX2010>`
   - Add the Exchange 2010 Client Access server as a web distribution point using the following commands:
   - `$OABVDir=Get-OABVirtualDirectory -Server <CAS2010>`
   - `$OAB=Get-OfflineAddressBook "Default Offline Address List"`
   - `$OAB.VirtualDirectories += $OABVdir.DistinguishedName`
   - `Set-OfflineAddressBook "Default Offline Address List" -VirtualDirectories $OAB.VirtualDirectories`
7. Enable Integrated Windows authentication on the Microsoft-Server-ActiveSync virtual directory on the Exchange 2003 back-end server. This allows the Exchange 2010 Client Access server and the Exchange 2003 back-end server to communicate using Kerberos authentication.
   - Install the hotfix located here, and then use Exchange System Manager to adjust the authentication settings of the Exchange ActiveSync virtual directory.
   - Or, set the **msExchAuthenticationFlags** attribute to a value of 6 on the **Microsoft-Server-ActiveSync** object within the configuration container on each Exchange 2003 mailbox server. An example script is provided here.

     Important:
     Don't use IIS Manager to change the authentication setting on the ActiveSync virtual directory, because the DS2MB process within the System Attendant will overwrite the settings that are stored in Active Directory.

8. Create a legacy host name in your external DNS infrastructure and associate this host name with your Exchange 2003 front-end server or with your proxy infrastructure.
9. Reconfigure your External DNS settings or the publishing rules for your reverse proxy infrastructure to have your original namespace of mail.contoso.com point to your Exchange 2010 Client Access server or Client Access server array.
10. Test all client connections and re-enable Internet protocol client usage.

Upgrade from Exchange 2003 Transport

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-09*

When upgrading from Microsoft Exchange Server 2003 to Exchange Server 2010, there will be a period of time where both versions coexist in production. You can use the information summarized in the following table to help ensure that message flow isn't negatively affected during this period of coexistence.

Important:

If you deploy Exchange 2010 as a new organization, you can't later install Exchange 2003 in the Exchange 2010 organization. This isn't a supported scenario. If you anticipate requiring Exchange 2003 functionality in your organization in the future, you must first install an Exchange 2003 organization and maintain at least one Exchange 2003 server.

Summary by feature of required and optional actions for upgrading Exchange 2003 Transport to Exchange 2010

Feature	Required actions for coexistence	Optional actions and best practices
Routing Topology Differences When you plan for coexistence between Exchange 2010 and Exchange 2003, you must understand the differences in how each version determines its routing topology. This section provides an overview of the differences between the topologies, including a discussion of: • Routing group connectors • Link state updates in a coexistence environment	• Specify an Exchange 2003 bridgehead server for the first routing group connector that is created during setup of Exchange 2010. • Verify that every Exchange 2003 routing group has at least one connector to another routing group before you introduce the first Exchange 2010 server. • Suppress minor link state updates for each server in the Exchange 2003 organization. • Make sure that the Exchange 2010 routing group isn't the only communication path between Exchange 2003	• Specify more than one source server and more than one target server for the routing group connectors between your Exchange 2010 routing group and Exchange 2003 routing groups to provide redundancy and server availability • Create additional routing group connectors between Exchange 2003 and Exchange 2010 to optimize mail flow if necessary.

	routing groups to ensure that major links state updates continue to occur.	
Send and Receive Connectors Exchange 2003 uses SMTP virtual server interfaces for each protocol to send and receive messages between Exchange servers. The Exchange 2010 Hub Transport servers use an implicit connector called the intra-organization Send connector to route messages between sites.	• None. The default configuration of Send and Receive connectors on Exchange 2010 support coexistence with Exchange 2003.	• Create explicit Send connectors and Receive connectors if you want to create a connector that sends messages to a specific address space or receives messages from a specific address range.
X-EXCH50 Data Exchange 2003 uses the proprietary verb X-EXCH50 to transmit information about messages and recipients that can't be included in the e-mail message. Exchange 2010 supports a mapping between MAPI and MIME and doesn't require Exch50 data to reliably transmit message properties.	• None. The routing group connectors support the propagation of EXCH50 data.	• Make sure that the connector permissions allow the routing of EXCH50 data if you're connecting Exchange 2010 to an Exchange 2003 server in a cross-forest scenario.
Message Tracking Significant difference between the versions in that events logged by Exchange 2010 message tracking don't correspond directly to the message tracking events logged by Exchange 2003.	• None.	• Use the Exchange 2003 message tracking tool to search for messages that are transferred to or received from the Exchange 2003 organization.
Edge Transport Server Coexistence When an Edge Transport server is deployed to support an Exchange organization that hasn't yet deployed Exchange 2010, certain features can't be used.	• Create specific Send and Receive connectors on the Edge Transport server and update the configuration of the Exchange 2003 bridgehead servers if you're deploying an Edge Transport server before introducing Exchange 2010 to your Exchange 2003 organization.	• Deploy Exchange 2010 Hub Transport servers in your Exchange 2003 organization and then use EdgeSync.

Routing Topology Differences

Exchange 2003 use routing groups to define an Exchange-specific routing topology. Typically, routing groups are used to specify a set of well-connected Exchange servers. Servers in the same routing group can communicate with each other without the use of connectors. Ideally, the routing groups defined in your existing environment are based on IP subnets and closely mirror the Active Directory site configuration.

When more than one routing group is defined in an Exchange 2003 organization, you must manually create routing group connectors to enable mail flow between Exchange 2003 servers in different routing groups. The routing group connector must specify a source server and a target server as the connector endpoints. A routing group connector defines a one-way connection, and a reciprocal connector must be created to establish mail flow in both directions. The source and target servers are the bridgehead servers for the routing group. The bridgehead servers relay e-mail to other routing groups on behalf of other servers in their routing group and receive e-mail from other routing groups for delivery to other servers in their routing group.

In Exchange 2010, you don't have to define an Exchange-specific routing configuration. Exchange 2010 uses the existing Active Directory site topology to define its routing topology. However, you can make Exchange-specific configuration changes to Active Directory sites and IP site link costs to control mail flow. E-mail routed to Exchange servers located in different sites must be relayed by Hub Transport servers. Hub Transport servers send e-mail to Hub Transport servers in remote sites by using the intra-organization Send connector. The intra-organization Send connector is an implicit connector computed by using Active Directory site and IP site link information. To learn more about how Exchange 2010 uses Active Directory sites to route messages, see Planning to Use Active Directory Sites for Routing Mail.

Routing Group Connectors

To support coexistence between these two routing topologies, all Exchange 2010 servers are automatically added to a single routing group when Exchange 2010 is installed. The Exchange 2010 routing group is recognized in Exchange System Manager in Exchange 2003 as Exchange Routing Group (DWBGZMFD01QNBJR) within Exchange Administrative Group (FYDIBOHF23SPDLT).

During the installation of the first Exchange 2010 Hub Transport server in an existing Exchange organization, you must specify an Exchange 2003 bridgehead server to which to establish the first routing group connector. We recommend that you select a bridgehead server located in a hub routing group or in a routing group that has many mailboxes. The routing group connector links the routing group where the Exchange 2003 server resides and the Exchange 2010 routing group. The Exchange 2010 routing group includes all Exchange 2010 servers, regardless of the Active Directory site in which they reside.

Caution:

Don't move Exchange 2010 servers out of Exchange Routing Group (DWBGZMFD01QNBJR), and don't rename Exchange Routing Group (DWBGZMFD01QNBJR) by using a low-level directory editor. Neither action is supported. Exchange 2010 must use this routing group for communication with Exchange 2003.

The Hub Transport server that you're installing and the Exchange 2003 bridgehead server that you select are configured as the source and target servers on two reciprocal routing group connectors. The selected bridgehead server is automatically added to the membership of the ExchangeLegacyInterop universal security group and is granted the permissions needed to send e-mail to and receive e-mail from Exchange 2010. This routing group connector creates a single connection point between Exchange 2003 and

Exchange 2010.

You can modify the list of source and target servers by using the **Set-RoutingGroupConnector** cmdlet in the Exchange Management Shell. It's a best practice to specify more than one source server and more than one target server to provide redundancy and server availability.

Important:
Placing Exchange 2010 servers and Exchange 2003 servers in the same routing group isn't supported.

Every Exchange 2003 routing group should have at least one connector to another routing group before you introduce the first Exchange 2010 server. Event ID 5006 is logged for each Microsoft Exchange message database (MDB) located in a routing group that doesn't have a routing group connector path from the Exchange 2010 routing group. For more information about the Exchange 2003 routing topology, see the Exchange Server Transport and Routing Guide.

If your existing Exchange environment includes more than one routing group, you may want to create additional connection points between Exchange 2003 and Exchange 2010 to optimize mail flow. To create additional connection points, follow these steps:

1. Determine how you will upgrade the organization to Exchange 2010. The order in which you decommission routing groups will determine which Exchange 2003 routing groups should connect directly with Exchange 2010.
2. Modify the registry to suppress minor link state updates on all the Exchange 2003 servers. This configuration change prevents connector state messages from being relayed throughout the organization by using link state updates, but doesn't prevent configuration change messages from being relayed. For more information, see Suppress Link State Updates.
3. Use the **New-RoutingGroupConnector** cmdlet in the Shell to create all routing group connectors that specify Exchange 2010 Hub Transport servers as source or target servers. Configure a routing group connector from the Exchange Routing Group (DWBGZMFD01QNBJR) to each Exchange 2003 routing group with which Exchange 2010 will communicate directly, and configure the corresponding reciprocal routing group connectors. You can use the *Bidirectional* parameter with the **New-RoutingGroupConnector** cmdlet to create both connectors in a single operation. These connectors will enable mail flow between Exchange 2003 and Exchange 2010.

   Important:
   When you use the **New-RoutingGroupConnector** cmdlet, the specified legacy Exchange servers are automatically added to the membership of the ExchangeLegacyInterop universal security group, and the permissions required to allow a legacy Exchange server to send mail to and receive mail from an Exchange 2010 Hub Transport server are automatically granted. If you use Exchange System Manager to create a routing group connector between the Exchange 2010 routing group and any Exchange 2003 routing group, this group membership isn't updated and the connector won't work correctly. Therefore, always use the Shell to create or update routing group connectors between Exchange 2010 and Exchange 2003.

For more information, see Create Additional Routing Group Connectors from Exchange 2010 to Exchange 2003.

Link State Updates in a Coexistence Environment

When connecting the Exchange 2010 routing group to the Exchange 2003 organization, you must consider the behavior of link state routing. Exchange 2003 servers maintain a link state routing table that's updated through communication with the routing group master. Each connector that has been created between Exchange 2003 routing groups is

considered a link. Exchange 2003 servers determine how a message is routed inside the organization by using the cost assigned to these links. If a particular routing group is inaccessible by using the lowest cost route, the link state table is updated by the routing group master to show the state of that link as down. This data is communicated to every routing group in the Exchange organization. When the data is received, the link state table is updated, and another route is calculated.

Link state routing isn't used by Exchange 2010 Hub Transport servers. Exchange 2010 can't propagate link state updates, and it doesn't recalculate routes. Hub Transport servers always try to communicate directly with other Hub Transport servers. When a connection to a site is unavailable, Exchange 2010 uses the IP site link costs associated with Active Directory sites to determine the closest site at which to queue the message. This behavior is known as *queue at point of failure*. The message queue generated at the point of failure is put in a retry state.

If multiple paths exist between the Exchange 2010 routing group and any Exchange 2003 routing group, minor link state updates must be suppressed to make sure that message looping doesn't occur when a route is recalculated. We recommend that minor link state updates be suppressed for each server in the Exchange 2003 organization. When link state updates are suppressed, Exchange 2003 servers also queue at point of failure, instead of recalculating the route.

Configuration changes, such as the addition of connectors, are still communicated between Exchange 2003 servers by using link state. However, to ensure that major links state updates continue to occur, you must make sure that the Exchange 2010 routing group isn't the only communication path between Exchange 2003 routing groups. For more information about how to suppress link state updates, see Suppress Link State Updates.

Return to top

Send and Receive Connectors

Exchange 2003 uses SMTP virtual server interfaces for each protocol to send and receive messages between Exchange servers. Configuration is required only when you modify the default values or create connectors specific to another organization.

The Exchange 2010 Hub Transport servers use an implicit connector to route messages between sites. This connector is called the intra-organization Send connector. During installation, explicit Receive connectors are automatically created on each Hub Transport server. One Receive connector is configured to receive SMTP traffic from all sources by listening on port 25. A second Receive connector is configured to receive SMTP traffic from non-MAPI clients by listening on port 587. Explicit Send connectors and Receive connectors are created on Hub Transport servers only when you want to create a connector that sends messages to a specific address space or receives messages from a specific address range. For more information about connectors in Exchange 2010, see Understanding Send Connectors and Understanding Receive Connectors.

Return to top

X-EXCH50 Data

Exchange 2003 uses the proprietary verb X-EXCH50 to transmit information about messages and recipients that can't be included in the e-mail message. The information is transmitted as the Exch50 binary large object. Exch50 contains data such as spam confidence level, address rewriting information, and other MAPI properties that don't have MIME representation. Because X-EXCH50 is a proprietary Extended Simple Mail Transfer Protocol (ESMTP) verb, Exch50 data can't be propagated by a non-Exchange server.

Exchange 2010 supports a mapping between MAPI and MIME and doesn't require Exch50 data to reliably transmit message properties. To correctly coexist with Exchange 2003, Exchange 2010 servers can propagate the Exch50 data to Exchange 2003 servers. On incoming SMTP connections, Exch50-related properties used by Exchange 2010 are promoted to Exchange 2010-equivalent properties. Properties that aren't used by Exchange 2010 but are used by Exchange 2003 are preserved. On outgoing SMTP connections, the Exchange 2010 server can form the Exch50 data by promoting the Exchange 2010 properties and appending them to the preserved Exchange 2003 data.

Routing group connectors between Exchange 2010 and Exchange 2003 are automatically configured to support sending and receiving Exch50 data. If you are connecting Exchange 2010 to an Exchange 2003 server in a cross-forest scenario, make sure that the connector permissions allow the routing of Exch50 data. For more information, see Configure Cross-Forest Connectors.

Return to top

Message Tracking

The message tracking schema in Exchange 2010 is significantly different from the message tracking schema in Exchange 2003. The events logged by Exchange 2010 message tracking don't correspond directly to the message tracking events logged by Exchange 2003. Messages sent and received by Exchange 2010 can only be tracked by Exchange 2010 servers. There is no Microsoft Windows Management Instrumentation (WMI) support in Exchange 2010. Therefore, an Exchange 2003 server can't query for message tracking logs on an Exchange 2010 server. If a message tracking query in Exchange 2010 indicates that the message was transferred to an Exchange 2003 server, you must use the Exchange 2003 message tracking tool to continue to search for the message.

Return to top

Edge Transport Server Coexistence

The Edge Transport server role is designed to provide improved antivirus and anti-spam protection for the Exchange organization. The Edge Transport server also applies policies to messages in transport between organizations. This server role is deployed in the perimeter network and outside the Active Directory forest. The Edge Transport server can be deployed as a smart host and SMTP-relay server for an existing Exchange 2003 organization.

You can add an Edge Transport server to an existing Exchange organization without upgrading the internal Exchange servers or making any organizational changes. Because it deployed outside Active Directory, you don't have to perform any Active Directory preparation steps when you install the Edge Transport server. If you are using the Exchange Intelligent Message Filter in Exchange 2003 to perform anti-spam tasks, you can use the Edge Transport server to provide an additional layer of anti-spam protection.

When an Edge Transport server is deployed to support an Exchange organization that hasn't yet deployed Exchange 2010, certain features can't be used. You can't create an Edge Subscription in this scenario. Therefore, you can't use the Recipient Lookup or safelist aggregation features. For more information about using the Edge Transport server role with an Exchange 2003 organization, see Deploy the Edge Transport Server Role in an Existing Exchange 2003 Organization Before Upgrading to Exchange 2010.

Return to top

1.2.2.3.4 Upgrade from Exchange 2003 Mailbox

Upgrade from Exchange 2003 Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

The Microsoft Exchange Server 2010 Mailbox server role can coexist with Exchange Server 2003 and Exchange 2007. If you're upgrading from an Exchange 2003 organization to Exchange 2010, the first server role you need to upgrade is the Client Access server role.

Then, after Mailbox servers have been deployed, you can move mailboxes from Exchange 2003 to Exchange 2010. To move mailboxes to Exchange 2010, you can use either the move request cmdlets or the Exchange Management Console, depending on your Exchange version. For more information about how to move mailboxes, see the following topics:

Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers

Move Mailboxes from Exchange 2010 Servers to Exchange 2003 Servers

Exchange 2003 and Exchange 2010 Coexistence

The following topics provide more details about Mailbox server role feature coexistence between Exchange 2003 and Exchange 2010:

Understanding Public Folders

Understanding Exchange Search

Understanding E-Mail Address Policies

1.2.2.4.1 Checklist: Upgrading from Exchange 2007

Checklist: Upgrading from Exchange 2007

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-24*

Use this checklist to upgrade from Microsoft Exchange Server 2007 to Exchange Server 2010. Before you start working with this checklist, make sure you're familiar with the concepts discussed in:

- Planning for Exchange 2010
- Deployment Security Checklist
- Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

This checklist is generic in that it provides guidance for a typical upgrade scenario. For more customized step-by-step guidance about how to upgrade your Exchange 2007 organization, see the Exchange Server Deployment Assistant.

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Checklist for Upgrading from Exchange 2007 to Exchange 2010

Done?	Task	Topic
	1. Verify system requirements	Exchange 2010 System Requirements
	2. Confirm prerequisite steps are done	Exchange 2010 Prerequisites
	3. Configure disjoint namespace **Note:** This step is optional. It's only necessary if your organization is running a disjoint namespace.	Configure the DNS Suffix Search List for a Disjoint Namespace
	4. Install the Client Access server role	Upgrade from Exchange 2007 Client Access Install Exchange Server 2010
	5. Add digital certificates on the Client Access server	Create a New Exchange Certificate
	6. Enable Outlook Anywhere **Note:** This step is optional. It's only necessary if you decide to deploy Outlook Anywhere.	Enable Outlook Anywhere
	7. Configure settings on virtual directories, including OAB, Exchange Web Services, ECP, Outlook Web App, and Exchange ActiveSync virtual directories **Note:** This step is necessary if you want to use Exchange Web Services, Outlook Anywhere, or the offline address book. It also may be required if you need to change any of the default settings for the Exchange Control Panel, Outlook Web App, or Exchange ActiveSync.	Create an Offline Address Book Virtual Directory Configure ECP Virtual Directory Properties View or Configure Outlook Web App Virtual Directories View or Configure Exchange ActiveSync Virtual Directory Properties
	8. Install the Hub Transport server role	Upgrade from Exchange 2007 Transport Install Exchange Server 2010

	9. Configure a legacy host name	Upgrade from Exchange 2007 Client Access
	10. Install the Unified Messaging server role **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging Install the Exchange 2010 Unified Messaging Server Role
	11. Configure and transition Unified Messaging **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM
	12. Install the Mailbox server role	Install Exchange Server 2010 Upgrade from Exchange 2007 Mailbox
	13. Move OAB generation to Exchange 2010	Move the Offline Address Book Generation Process to Another Server
	14. Install the Edge Transport server role **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Upgrade from Exchange 2007 Transport Install Exchange Server 2010
	15. Subscribe and transition Edge Transport services **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Create an Edge Subscription File on an Edge Transport Server Import an Edge Subscription File to an Active Directory Site
	16. Move Exchange 2007 mailboxes to Exchange 2010	Create a Local Move Request
	17. Move public folder data to Exchange 2010	Configure Public Folder Replication
	18. Post-installation tasks	Exchange 2010 Post-Installation Tasks

Return to top

1.2.2.4.2 Upgrade from Exchange 2007 Client Access

Upgrade from Exchange 2007 Client Access

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you're upgrading your existing Microsoft Exchange Server 2007 organization to Exchange Server 2010, there's a period of time when both Exchange 2007 and Exchange 2010 will coexist within your organization. This topic describes the various steps you must take to upgrade an Exchange 2007 organization to Exchange 2010.

Note:
The information provided in this topic is applicable regardless of whether you have Exchange Server 2003 mailbox servers within your Exchange 2007 organization. For information about upgrading an organization running only Exchange 2003 to Exchange 2010, see Upgrade from Exchange 2003 Client Access.

Important:
When you upgrade your organization to the RTM version of Exchange 2010, your clients running Outlook 2003 don't use RPC encryption, and RPC Client Access requires it by default. This can cause connection issues between Exchange 2010 and Outlook 2003. In Exchange 2010 SP2, RPC Client Access doesn't require RPC encryption by default. If you have Outlook 2003 clients within your organization, we recommend that you install Exchange 2010 SP2 to avoid connection issues between Exchange 2010 RTM and Outlook 2003. For more information, see Understanding RPC Client Access.

Overview of the Upgrade Process

The upgrade process includes the following steps:

1. Installing Exchange 2010 within your organization on new hardware.
2. Configuring Exchange 2010 Client Access.
3. Creating a set of legacy host names that will be associated with the version of Exchange you're upgrading from.

   Note:
   Your legacy host name should be in the format "legacy.contoso.com", where contoso.com matches your current host name.

   Note:
   Configuring a legacy host name is necessary only if you'll need Exchange 2007 and Exchange 2010 to coexist in the same organization. If you have a small number of mailboxes and can move all your mailboxes from Exchange 2007 to Exchange 2010 during the downtime you've scheduled for the upgrade, this step isn't necessary.
4. Obtaining a digital certificate with the names you'll use during the coexistence period and installing it on your Exchange 2010 Client Access server.
5. Associating your current host names, for example: mail.contoso.com, with your Exchange 2010 infrastructure.
6. Moving mailboxes from Exchange 2007 to Exchange 2010.
7. Decommissioning your Exchange 2007 infrastructure.

Note:
Throughout this topic, mail.contoso.com will be used as the primary namespace and

legacy.contoso.com will be used as the legacy namespace. When you perform your upgrade, you'll substitute the names of your own primary and legal namespaces.

Understanding Legacy Host Names

An important part of the upgrade process is configuring a legacy host name and associating that host name with your Exchange 2007 infrastructure. This is a necessary step if your organization has a significant number of mailboxes that can't all be moved from Exchange 2007 to Exchange 2010 during the downtime scheduled for the upgrade and if your organization supports Outlook Web Access for Internet users.

If your organization has a small number of mailboxes, and you're able to schedule downtime over an evening or a weekend, you can skip the step of configuring a legacy host name and move all mailboxes during this downtime. Doing this eliminates the need for Exchange 2007 and Exchange 2010 to coexist.

You'll have to configure a legacy host name to be published to the Internet and associated with the virtual directories of the various services you have on Exchange 2007, such as Microsoft Exchange ActiveSync, Microsoft Outlook Web Access, POP3, and IMAP4 if:

- You have a significant number of mailboxes to move from Exchange 2007 to Exchange 2010
  or
- You don't want to move all mailboxes at once
  and
- You have users who access Outlook Web Access from the Internet.

After a legacy host name has been configured and associated with your Exchange 2007 infrastructure, and your current host name has been associated with your Exchange 2010 infrastructure, users will experience a seamless transition. Exchange 2010 will redirect users from the Exchange 2010 Client Access server to the Exchange 2007 Client Access server. Users won't have to learn a new URL to access Outlook Web Access (called Outlook Web App in Exchange 2010) or reconfigure their Exchange ActiveSync devices. POP3, IMAP4, and Outlook Anywhere users can also continue to access their mailboxes without interruption.

How to create a legacy host name

The steps to perform this task will vary for each organization. That's because the exact steps depend on your Internet provider and firewall configuration. Example steps for GoDaddy are provided below to give you an idea of how things work. The steps you need to follow may vary. But, in general, you need to:

1. Create a DNS host (A) record in your internal and external DNS servers that points to the IP address of your legacy Internet-facing Exchange server (for example, your Exchange 2007 Client Access server or Exchange 2003 front-end server) in internal DNS or the public IP address on your reverse proxy or firewall solution (external DNS). The host name should be in the format of legacy.*domain*.com (for example, legacy.contoso.com).
2. Create a publishing rule for the legacy host name in your reverse proxy or firewall solution to point to your legacy Internet-facing Exchange server. Refer to your proxy/firewall solution's user manual for instructions for how to do this.
3. Configure the existing DNS host (A) record in your internal and external DNS servers for your original host name (for example, mail.contoso.com) to point to your Exchange 2010 organization. For example, point to the IP address of your Client Access server or array (internal DNS) or the public IP address on your reverse proxy or firewall solution (external DNS).
   So, for example, if your provider is GoDaddy.com, you can use the following steps to create a DNS host (A) record and associate it with your legacy Exchange infrastructure:
   3.a. From your GoDaddy account management home page, click **Domain Manager** under the **My Products** heading in the left sidebar.

3.b.If you're prompted to log in to your account, log in.
3.c.In the **Total DNS** section of the Domain Manager information screen, click **Total DNS Control**.
3.d.In the **A (Host)** section of the Total DNS Control screen, click **Add new A record**.
3.e.Enter the host name, for example legacy.contoso.com and enter the IP address of your legacy Exchange server in the **Points to IP address** box.
3.f.Choose a **TTL** (time to live) value. If you're performing this step well in advance of your Exchange 2010 installation, you can choose 1 day or 1 week from the drop-down list. Otherwise, choose the default of 1 hour or 1/2 hour.
3.g.Click **OK** to complete your changes.

How to verify the legacy host name can be accessed from the Internet
From outside your firewall, using your specific domain name instead of contoso, perform the following steps:

1. Navigate to https://mail.contoso.com/owa, and verify that you can access Outlook Web App for a user whose mailbox is on an Exchange 2010 server.
2. Navigate to https://legacy.contoso.com/exchange, and verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.
3. Navigate to https://mail.contoso.com/owa, and verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.

You can also use the Exchange Server Remote Connectivity Analyzer to verify connectivity for the legacy namespace.

You'll find ExRCA at: https://www.testexchangeconnectivity.com.

Certificate Planning for Upgrade

To support coexistence of Exchange 2003 and Exchange 2010, you'll likely have to obtain a new commercial certificate. We recommend that you obtain a certificate that supports Subject Alternative Names. However, a wildcard certificate is also supported. For more information about certificates, see Understanding Digital Certificates and SSL.

Installing Exchange 2010

After you've ensured that the prerequisites are met and you've obtained the correct certificates, you can begin your upgrade. Do this using the following steps:

Note:
In the following steps, replace <CAS2010> with the name of your Exchange 2010 Client Access server.

1. Install the Exchange 2010 Client Access server role.
2. During Setup, you can enter the primary external namespace for your virtual directories. This value should be the primary host name that your users use to connect to Exchange services from the Internet, for example: mail.contoso.com.
   - If you're upgrading through the graphical user interface Setup, you'll be prompted to configure a Client Access domain.
   - If you're upgrading from a command prompt, use the setup property /`ExternalCASServerDomain` and specify your domain, for example: mail.contoso.com.
3. If your organization requires Outlook Anywhere access, enable Outlook Anywhere.
   - This can be done using the following command: `Enable-OutlookAnywhere -Server:<CAS2010> -ExternalHostName:mail.contoso.com -SSLOffloading $false`
4. If you didn't configure a primary external namespace during setup, you'll have

to run the following commands to configure the virtual directories for the Offline Address Book, Exchange Web Services, Exchange ActiveSync, Outlook Web App, and Exchange Control Panel. You can do that with the following commands:

- Offline Address Book: `Set-OABVirtualDirectory <CAS2010>\OAB* -ExternalURL https://mail.contoso.com/OAB`
- Web Services: `Set-WebServicesVirtualDirectory <CAS2010>\EWS* -ExternalURL https://mail.contoso.com/ews/exchange.asmx`
- Exchange ActiveSync: `Set-ActiveSyncVirtualDirectory -Identity <CAS2010>\Microsoft-Server-ActiveSync -ExternalURL https://mail.contoso.com`
- Outlook Web App:`Set-OWAVirtualDirectory <CAS2010>\OWA* -ExternalURL https://mail.contoso.com/OWA`
- Exchange Control Panel: `Set-ECPVirtualDirectory <CAS2010>\ECP* -ExternalURL https://mail.contoso.com/ECP`

5. Configure your Outlook Web App settings to meet your organization's needs.
   - You can obtain the Outlook Web Access settings from your Exchange 2007 server using the cmdlet `Get-OWAVirtualDirectory`.
   - To configure the Outlook Web App settings in Exchange 2010, use the `Set-OWAVirtualDirectory` cmdlet.
6. Configure your Exchange ActiveSync authentication settings.
   - You can obtain the Exchange ActiveSync settings from your Exchange 2007 server using the `Get-ActiveSyncVirtualDirectory` cmdlet.
   - To configure the Exchange ActiveSync settings in Exchange 2010, use the `Set-ActiveSyncVirtualDirectory` cmdlet.
7. Install the Exchange 2010 Hub Transport server role and the Exchange 2010 Mailbox server role into the Internet-facing Active Directory site. For configuration steps for these server roles, see Upgrade from Exchange 2007 Transport and Upgrade from Exchange 2007 Mailbox.
8. Change the offline address book generation server and enable Web distribution on the Exchange 2010 Client Access server with the following steps:
   - Move the offline address book using the following command: Move-OfflineAddressBook "Default Offline Address List" –Server *<MBX2010>*
   - Add the Exchange 2010 Client Access server as a web distribution point using the following commands:

     ```
     $OABVDir=Get-OABVirtualDirectory –Server <CAS2010>
     $OAB=Get-OfflineAddressBook "Default Offline Address List"
     $OAB.VirtualDirectories += $OABVdir.DistinguishedName
     Set-OfflineAddressBook "Default Offline Address List" –VirtualDirectories $OAB.VirtualDirectories
     ```
9. Create a legacy host name in your external DNS infrastructure. You'll either need to associate this host name with your Exchange 2007 Client Access server or with your proxy infrastructure.
10. If you have Exchange 2003 mailboxes in your organization, enable Integrated Windows authentication on the Microsoft-Server-ActiveSync virtual directory on the Exchange 2003 back-end server. This allows the Exchange 2010 Client Access server and the Exchange 2003 back-end server to communicate using Kerberos authentication.
    - Install the hotfix located here, and then use Exchange System Manager to adjust the authentication settings of the Exchange ActiveSync virtual directory.
    - Or, set the **msExchAuthenticationFlags** attribute to a value of 6 on the **Microsoft-Server-ActiveSync** object within the configuration container on each Exchange 2003 mailbox server. An example script is provided here.

Important:

Don't use IIS Manager to change the authentication setting on the ActiveSync virtual directory, because the DS2MB process within the System Attendant will overwrite the settings that are

stored in Active Directory.

11. Reconfigure your External DNS settings or the publishing rules for your reverse proxy infrastructure to have your original namespace of mail.contoso.com point to your Exchange 2010 Client Access server or Client Access server array.
12. Test all client connections and re-enable Internet protocol client usage.

1.2.2.4.3 Upgrade from Exchange 2007 Transport

Upgrade from Exchange 2007 Transport

Planning and Deployment > Deploying Exchange 2010 > Understanding Upgrade from Exchange 2007 to Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-09-26*

When you upgrade from Microsoft Exchange Server 2007 to Exchange Server 2010, there will be a period of time during which both versions coexist in production. You can plan an upgrade path from Exchange 2007 to Exchange 2010 by using the information in this topic, which includes overview information, technical information about message flow in a coexistence environment, and considerations when operating in a mixed version environment.

Important:

If you deploy Exchange 2010 as a new organization, you can't later install Exchange 2007 in the Exchange 2010 organization. This isn't a supported scenario. If you anticipate requiring Exchange 2007 functionality in your organization in the future, you must first install an Exchange 2007 organization and maintain at least one Exchange 2007 server.

The most important point in an Exchange 2010 and Exchange 2007 coexistence scenario is that every Mailbox server needs a Hub Transport server with a matching Exchange version in the same Active Directory site. Due to the changes made to the Exchange Server Object (XSO) model in Exchange 2010, Exchange 2010 Hub Transport servers can't pick up messages from and deliver messages to Exchange 2007 Mailbox servers. Similarly Exchange 2007 Hub Transport servers can't communicate with Exchange 2010 Mailbox servers. Therefore, you need to maintain your Exchange 2007 Hub Transport servers in a specific Active Directory site until all Exchange 2007 Mailbox servers are removed from that site. For more details about how messages are routed in a coexistence environment, see "Message Routing Across Versions" later in this topic.

Note:

In-place upgrades aren't supported in Exchange 2010. You need to install new Exchange 2010 servers into your environment, and then phase out the Exchange 2007 servers. For the scope of this document, the phrase *upgrade* refers to generally upgrading the version of your Exchange deployment and not a specific server.

Maintaining DSN Settings in a Mixed Environment

Message Tracking Across Versions

Exchange 2010 Transport Features in a Coexistence Scenario

Transport Server Upgrade Path

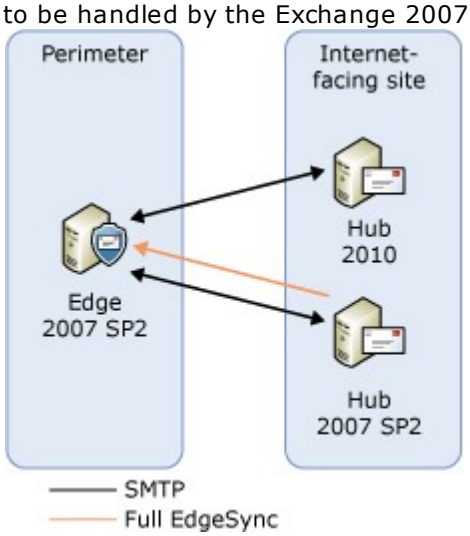
Upgrading your Exchange 2007 Hub Transport and Edge Transport servers should be part of your overall upgrade strategy. The recommended order is to upgrade your transport servers after your Client Access servers and before Unified Messaging and Mailbox servers. The Edge Transport servers need to be upgraded after the Hub Transport servers are upgraded. For more information about planning your upgrade, see Exchange 2007 - Planning Roadmap for Upgrade and Coexistence.

Before you introduce Exchange 2010 Hub Transport or Edge Transport servers, make sure that all of your Exchange 2007 servers in that site are upgraded to Exchange 2007 Service Pack 3 (SP3). Exchange 2007 SP3 is required for Exchange 2010 and Exchange 2007 Hub Transport servers to coexist in a single Active Directory site. Exchange 2007 SP3 is also required so that the Microsoft Exchange EdgeSync service works across versions.

If you have Exchange 2007 deployed in multiple sites, you must upgrade your Internet-facing sites first. The order of upgrade for the remaining sites depends on your particular topology and your organization's priorities.

The following process shows the recommended upgrade path for your transport servers in an Internet-facing site. (It is assumed that you are using Edge Transport servers with EdgeSync. If you are using a third-party smart host, you can omit steps 2-6.) The upgrade process is as follows:

1. Introduce your first Exchange 2010 Hub Transport server to your site. As soon as the Exchange 2010 Hub Transport server is introduced to the site, it will start using the Exchange 2007 Edge Transport server for message delivery to the Internet. The EdgeSync synchronization process will continue to be handled by the Exchange 2007 Hub Transport server.

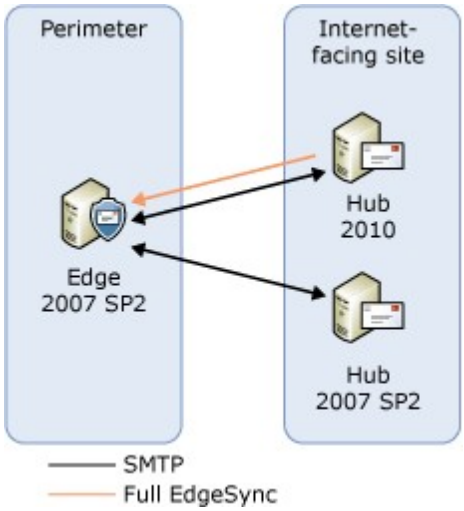


2. Subscribe your Exchange 2007 Edge Transport server to your site again. This action will add your Exchange 2010 Hub Transport server to the Edge Subscription as a source server. Exchange 2010 Hub Transport servers take

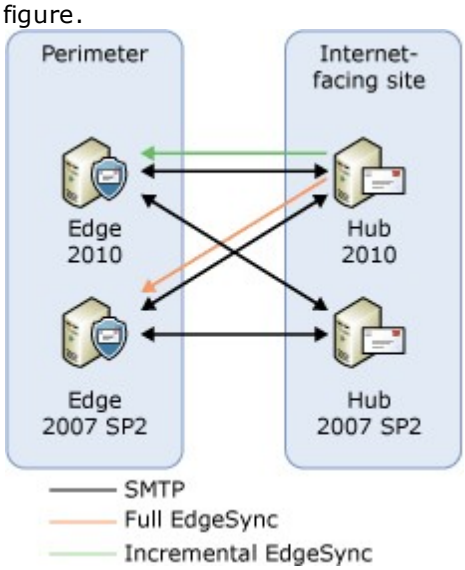
precedence over the Exchange 2007 Hub Transport server for the EdgeSync source server selection. Therefore, the Exchange 2010 Hub Transport server will take over Edge synchronization, as shown in the following figure. However, because the Edge Transport server is still running Exchange 2007 SP3, the Exchange 2010 Hub Transport server will still replicate full EdgeSync data.

Note:

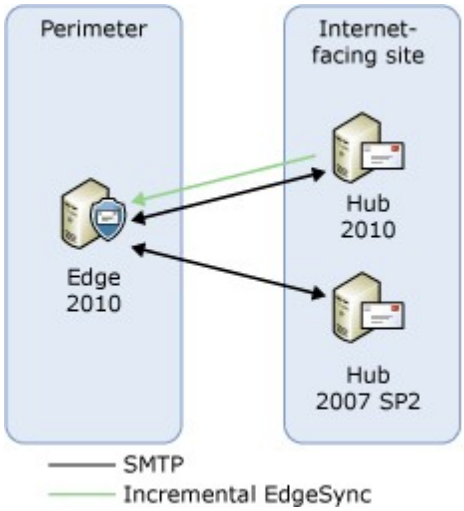
If you plan to add multiple Exchange 2010 Hub Transport servers to your Active Directory site, to save time, you can deploy all the new Hub Transport servers before subscribing your Edge Transport servers.



3. Introduce your first Exchange 2010 Edge Transport server to your perimeter network.
4. Subscribe your Exchange 2010 Edge Transport server to your site. At this point, the Exchange 2010 Hub Transport server will start incremental updates to the Exchange 2010 Edge Transport server, as shown in the following figure.



5. Remove the Exchange 2007 Edge Subscription.
6. Decommission your Exchange 2007 Edge Transport server, as shown in the following figure.

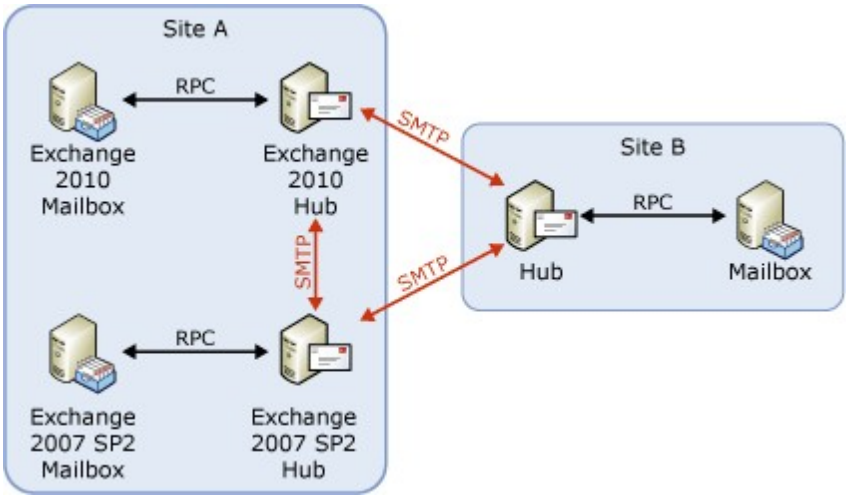


7. After all of your mailboxes are on Exchange 2010 Mailbox servers, decommission your Exchange 2007 Hub Transport servers.

Return to top

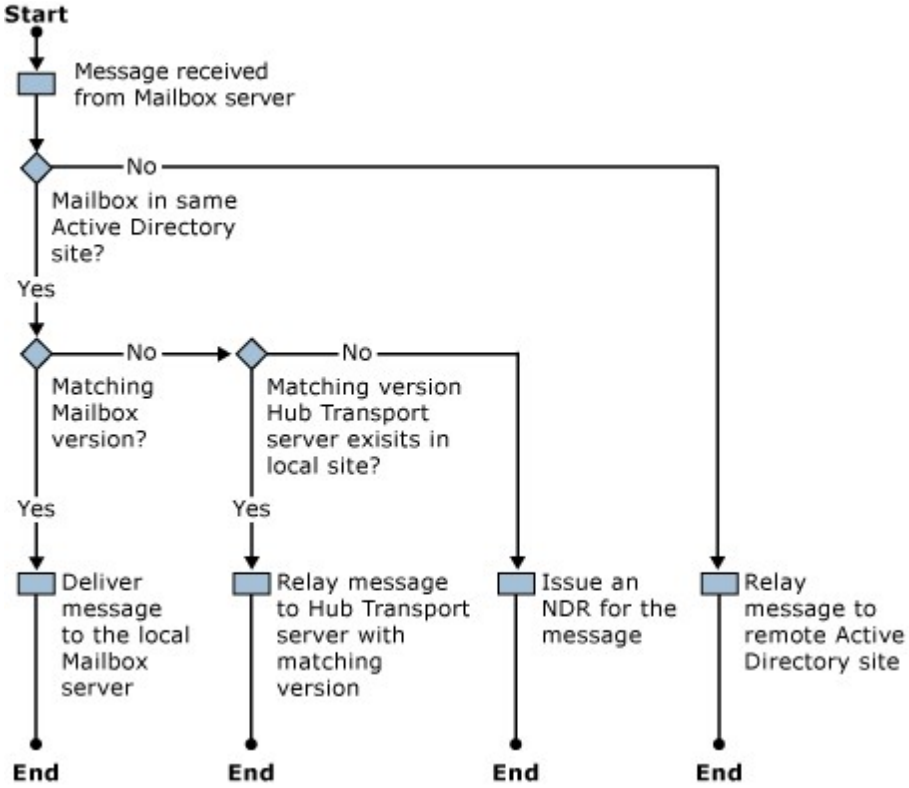
Message Routing Across Versions

Due to changes in the Exchange Server Object (XSO) model in Exchange 2010, Exchange 2010 Hub Transport servers can't pick up messages from and deliver messages to Exchange 2007 Mailbox servers. Similarly Exchange 2007 Hub Transport servers can't communicate with Exchange 2010 Mailbox servers. As a result, to have both Exchange 2010 and Exchange 2007 in the same Active Directory site, you must maintain both versions of Hub Transport servers in that site, as shown in the following figure. The versions of the servers in Site B aren't shown in the figure, because the handling of intersite SMTP traffic is the same as it is in Exchange 2007. The Hub Transport server relays the messages to the Hub Transport server in the remote site for delivery.



To enable message flow across versions, a feature called *versioned routing* is implemented in Exchange 2010. With versioned routing, the routing engine checks the version of a mailbox's home server, along with its Active Directory site. If the version doesn't match, the message is relayed to a Hub Transport server that has a matching version, as shown in the versioned routing workflow in the following figure. Routing is now dependent on

both Active Directory sites and Exchange versions.



When an Exchange 2010 mailbox user sends a message to an Exchange 2007 mailbox user in the same site, the following occurs:

1. The Exchange 2010 Mailbox server notifies the Exchange 2010 Hub Transport server of the new mail.
2. The Exchange 2010 Hub Transport server picks up the message.
3. The routing agent determines that the version of the Mailbox server that's the home server of the destination mailbox doesn't match its own version.
4. The routing agent locates an Exchange 2007 Hub Transport server in the local site.
5. The Exchange 2010 Hub Transport server relays the message to the Exchange 2007 Hub Transport server.
6. The routing agent on the Exchange 2007 Hub Transport server determines that the target mailbox is on an Exchange 2007 Mailbox server in the local site.
7. The Exchange 2007 Hub Transport server delivers the message to the Exchange 2007 Mailbox server.

Any messages sent from Exchange 2007 mailbox users to Exchange 2010 recipients follow a similar path.

Versioned routing was added to Exchange 2007 in SP2. To have both Exchange 2010 and Exchange 2007 coexist in the same Active Directory site, you must first upgrade your existing Exchange 2007 servers to SP3. When you have Exchange 2010 and Exchange 2007 SP3 in the same Active Directory site, each Hub Transport server handles messages for the Mailbox servers with matching versions. Versioned routing doesn't change the way intrasite messages are routed.

Consider the following when you have Exchange 2010 and Exchange 2007 in the same site:

- You can't specify an incompatible Hub Transport server as the submission server override for a Mailbox server.
- For a specific Mailbox server, if you don’t have a matching version Hub Transport server in the local site, any messages sent by users on that Mailbox server will remain on the Mailbox server.
- For a specific Mailbox server, if you don't have a matching version Hub Transport server in the local site, non-delivery reports (NDRs) will be issued for any messages sent to users on that Mailbox server.
- Messages sent to mail-enabled public folders are handled the same way messages sent to mailboxes.

Return to top

EdgeSync Differences

The edge synchronization process has been improved in Exchange 2010. In Exchange 2007, EdgeSync replicated all of the configuration and recipient information in its entirety. Especially in organizations with large number of recipients, this took a long time. Exchange 2010 introduces incremental updates for EdgeSync. When you first subscribe an Exchange 2010 Edge Transport server to a site, all the configuration information and recipient data is synchronized. In all subsequent updates, only the changes are replicated. Therefore, synchronization time and network utilization are substantially reduced.

Although Exchange 2007 Hub Transport servers can participate in EdgeSync with Exchange 2010 Edge Transport servers, incremental updates are only available between Exchange 2010 Hub Transport servers and Exchange 2010 Edge Transport servers. By default, when an Exchange 2010 Edge Transport server is subscribed to an Active Directory site that has Exchange 2010 Hub Transport servers, the Exchange 2010 Hub transport servers take over the EdgeSync process. You can fall back to Exchange 2007 Hub Transport servers by disabling the Microsoft Exchange EdgeSync service on the Exchange 2010 Hub Transport servers. However, when you do that, you go back to replicating all data with each EdgeSync update, instead of incremental updates.

For more information about EdgeSync, see Understanding Edge Subscriptions.

Return to top

Transport Rules and Journaling in a Coexistence Scenario

If you already use transport rules or journaling in your Exchange 2007 organization, make sure that these features continue to function during the coexistence period, regardless of which Hub Transport server processes a specific message.

The following significant changes were made to transport and journaling rules in Exchange 2010, which have an impact when managing these features in a mixed environment:

- **Format changes** Exchange 2010 transport rules support a series of new predicates and actions. To support these new predicates and actions, the format of how transport rules are stored in Active Directory has been modified. Exchange 2007 Hub Transport servers can't process these new predicates and actions. For a complete list of predicates and actions available in Exchange 2010, see Transport Rule Predicates and Transport Rule Actions.
- **Storage location in Active Directory** To prevent the Exchange 2007 Transport Rules agents from loading and attempting to process the rules created in Exchange 2010, the Exchange 2010 rules are stored in a separate

Active Directory container. The same situation applies to journaling rules.

Copying Existing Configuration to Exchange 2010

When installing Exchange 2010, if the Setup program detects the existence of Exchange 2007 transport rules, these legacy rules are automatically exported to a temporary location and subsequently imported to the Exchange 2010 transport rule container in Active Directory. This process happens automatically without any user interaction.

Note:
If there are any existing Exchange 2010 transport rules, Setup won't migrate Exchange 2007 rules because the migration overwrites all existing Exchange 2010 transport rules.

Similarly, all Exchange 2007 journal rules are converted and copied to Exchange 2010 journal rules during setup. For more information, see Export and Import Exchange 2007 Journal Rules.

Maintaining Transport Rules and Journaling in a Mixed Environment

The automatic import of rules to Exchange 2010 is only performed during initial setup. During the initial setup, the set of transport rules and journal rules for Exchange 2010 and Exchange 2007 will be synchronized. Going forward, if you make any changes to an existing rule, or create a rule, the rule will be changed in a single location based on the management tool you use. For example, in Exchange 2010, if you use the Exchange Management Shell to create a rule, only the Exchange 2010 rule container in Active Directory will be updated. Similarly if you use the Exchange Management Console (EMC) on an Exchange 2007 server to change an existing rule, only the Exchange 2007 version of that rule will be modified.

To ensure that your transport and journal rules remain consistent across versions, any changes you make must be made twice; once with Exchange 2010 management tools, and once with Exchange 2007 management tools.

Return to top

Maintaining DSN Settings in a Mixed Environment

In Exchange 2010, the internal and external DSN settings are configured for your entire Exchange organization. In Exchange 2007, these settings were configured on a per-server basis. As a result, these settings are stored in different configuration objects in Active Directory, and just like transport rules, need to be managed separately in a coexistence scenario.

Specifically, the following settings were moved from the **Set-TransportServer** cmdlet to the **Set-TransportConfig** cmdlet in Exchange 2010:

- ExternalDelayDsnEnabled
- ExternalDsnDefaultLanguage
- ExternalDsnLanguageDetectionEnabled
- ExternalDsnMaxMessageAttachSize
- ExternalDsnReportingAuthority
- ExternalDsnSendHtml
- ExternalPostmasterAddress
- InternalDelayDsnEnabled
- InternalDsnDefaultLanguage
- InternalDsnLanguageDetectionEnabled
- InternalDsnMaxMessageAttachSize
- InternalDsnReportingAuthority

- InternalDsnSendHtml

If you need to change any of these settings in your organization, you must make the change once for the organization using the **Set-TransportConfig** cmdlet in the Exchange 2010 Shell and once for each Exchange 2007 Hub Transport server in the organization using the **Set-TransportServer** cmdlet in the Exchange 2007 Shell.

Return to top

Message Tracking Across Versions

Exchange 2010 provides improved message tracking capabilities. End users, as well as administrators, can now track the messages they have sent using the Delivery Reports tool in the Exchange Control Panel.

Delivery Reports enable end-to-end message tracking from a single location, providing detailed delivery information including when a message was marked as read. In Exchange 2010, a new message tracking remote procedure call (RPC) and Web service interface was implemented to support Delivery Reports. These interfaces don't exist in Exchange 2007 and therefore the Delivery Reports feature doesn't extend to the Exchange 2007 infrastructure in a coexistence scenario. However, it's possible to use the message tracking tool in Exchange 2007 to track messages between versions.

The following table shows what to do when tracking messages in a mixed environment.

Tracking messages in a mixed environment

Sent from	Sent to	Tracking Tool
Exchange 2010 mailbox	Exchange 2010 mailbox	Use the Delivery Reports tool in Exchange Control Panel.
Exchange 2010 mailbox	Exchange 2007 mailbox	Use the Delivery Reports tool in Exchange Control Panel. The tool provides message tracking information to the point where the message is transferred to the Exchange 2007 server. No further tracking information will be available for that message. Alternatively, you can use Tracking Log Explorer in Exchange 2010 or message tracking in Exchange 2007.
Exchange 2007 mailbox	Exchange 2007 or Exchange 2010 mailbox	Use Tracking Log Explorer in Exchange 2010 or message tracking in Exchange 2007.

To learn more about message tracking in Exchange 2010, see Understanding Message Tracking.

Exchange 2010 Transport Features in a

Coexistence Scenario

For the most part, new transport features in Exchange 2010 only function within the realm of Exchange 2010. When to start using the new features depends on the needs of your organization. You can wait until the upgrade is complete, or start as soon as you introduce Exchange 2010 to your environment. To decide when to use the new features in a mixed environment, consider the following information.

Moderated Recipients

Exchange 2010 introduces *moderated recipients*, so that messages sent to specific recipients can be subjected to an approval process. If you plan to use moderated recipients in a coexistence scenario, be aware of the following issues, which depend on the type of recipient:

- **Mailboxes** You can only enable mailboxes on Exchange 2010 Mailbox servers for moderation. After you enable a mailbox for moderation, you must make sure that it isn't moved back to an Exchange 2007 Mailbox server.
- **Distribution groups and dynamic distribution groups** The messages to a moderated distribution group go through the approval process only when that distribution group is expanded on an Exchange 2010 Hub Transport server. Because the distribution group can be expanded on any server, we recommend waiting until all your Hub Transport servers are upgraded to Exchange 2010 before using moderated distribution groups.
- **Mail contacts and mail users** Hub Transport servers route messages based on the external e-mail address specified for each mail user or mail contact. Because it isn't possible to force messages for these recipient types to go through an Exchange 2010 Hub Transport server, you may not want to enable these recipient types for moderation in a mixed environment.

If you enable a recipient for moderation, make sure that the designated moderators use a client that can display the "approve" and "reject" options for an approval request. We recommend that all moderators use Microsoft Office Outlook 2010 or Outlook Web App in Exchange 2010. Both of these clients have built-in user interfaces that allow moderators to make decisions on messages.

Note:

If your moderators are using Outlook 2007 or Outlook 2003, the moderation request will show up as voting buttons in the message that they receive. They will still be able to moderate messages using the voting buttons. However, for the best user experience, consider upgrading their clients to Outlook 2010 or later.

To learn more about moderated recipients, see Understanding Moderated Transport.

Shadow Redundancy

Exchange 2010 introduces *shadow redundancy* to provide redundancy for messages for the entire time they are in transit. The solution involves a technique similar to the transport dumpster. With shadow redundancy, the deletion of a message from the transport databases is delayed until the transport server verifies that all of the next hops for that message have completed delivery. If any of the next hops fail before reporting successful delivery, the message is resubmitted for delivery to that next hop.

Shadow redundancy is enabled by default on Exchange 2010, and it ensures that messages are redundant only while being transferred between Exchange 2010 servers. After that message is transferred to an Exchange 2007 server, it's no longer redundant. Therefore, to ensure that a message that originates on an Exchange 2010 server stays redundant until it's delivered, make sure that it doesn't get transferred to an Exchange 2007 server. For example, if you are using a hub site that has Exchange 2007 servers, messages between two spokes won't be redundant even if they both have Exchange 2010 servers.

To learn more about shadow redundancy, see Understanding Shadow Redundancy.

1.2.2.4.4 Upgrade from Exchange 2007 Mailbox

Upgrade from Exchange 2007 Mailbox

Planning and Deployment > Deploying Exchange 2010 > Understanding Upgrade from Exchange 2007 to Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

The Microsoft Exchange Server 2010 Mailbox server role can coexist with Exchange Server 2007. If you're upgrading from an Exchange 2007 organization to Exchange 2010, the first server role you will need to upgrade will be the Client Access server role.

Then, after Mailbox servers have been deployed, you can move mailboxes from Exchange 2007 to Exchange 2010. To move mailboxes to Exchange 2010, you can use either the move request cmdlets or the Exchange Management Console, depending on your Exchange version. For more information about how to move mailboxes, see the following topics:

Move Mailboxes from Exchange 2007 Servers to Exchange 2010 Servers

1.2.2.4.5 Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

Planning and Deployment > Deploying Exchange 2010 > Understanding Upgrade from Exchange

2007 to Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-07*

Unified Messaging (UM) was introduced in Microsoft Exchange Server 2007. In organizations that deployed Exchange 2007 Service Pack 3 (SP3) Unified Messaging and now want to upgrade to Microsoft Exchange Server 2010 Service Pack 1 (SP1) or later Unified Messaging with all its new features, there are tasks the Exchange administrator must perform to successfully upgrade their UM environment.

Note:
Exchange 2007 Service Pack 3 (SP3) contains Unified Messaging features. Versions of Microsoft Exchange earlier than Exchange 2007 can't be upgraded and require you to deploy a new Exchange 2010 Service Pack 1 (SP1) or later organization with all the server roles, including Unified Messaging.

Contents

Overview of Upgrading to Exchange 2010 SP1 or later Unified Messaging

Upgrading is the process of taking an existing Exchange 2007 Service Pack 3 (SP3) Unified Messaging environment, installing Exchange 2010 UM SP1 or later servers, and then removing and uninstalling the Exchange 2007 SP3 UM servers. However, during this process, there's the possibility at any time that an upgraded Exchange 2010 SP1 or later organization would contain both Exchange 2010 SP1 or later and Exchange 2007 SP3 UM servers. Such an organization would also contain both Exchange 2007 SP3 and Exchange 2010 SP1 or later Mailbox, Client Access, and Hub Transport servers. All the Exchange 2007 SP3 servers, including the UM server, must have Exchange Server 2007 SP3 installed. For more information, see Download Exchange Server 2007 Service Pack 3 (SP3).

UM-enabled users who have Exchange 2007 SP3 mailboxes will get the features with Exchange 2007 Service Pack 3 (SP3) Unified Messaging, and UM-enabled users who have Exchange 2010 SP1 or later mailboxes will get all the features included with Exchange 2010 SP1 or later Unified Messaging. The following table summarizes upgrade scenarios and the UM features that are available when Exchange 2007 SP3 and Exchange 2010 SP1 or later Unified Messaging coexist in the same Exchange organization.

Unified Messaging with Exchange 2007 SP 3 and Exchange 2010 SP1 or later mailboxes

	Exchange 2007 SP3 UM server	Exchange 2010 SP1 or later UM server
Exchange 2007 SP3 UM-enabled mailbox	UM-enabled users get the features included with Exchange 2007 SP3.	Incoming calls are redirected to an Exchange 2007 SP3 UM server in the same dial plan.

Exchange 2010 SP1 or later UM-enabled mailbox	Not supported. At least one Exchange 2010 SP1 or later.UM server is required.	UM-enabled users get the features included with Exchange 2010 SP1 or later.

When you install the first Exchange 2010 SP1 or later UM server and add it to an existing Exchange 2007 Service Pack 3 (SP3) organization, you must add the Exchange 2010 SP1 or later UM server to an existing UM dial plan that contains Exchange 2007 SP3 UM servers. Then you must configure each IP gateway or IP PBX to send all incoming calls to the Exchange 2010 SP1 or later UM servers within the same UM dial plan.

When an incoming call is received by an Exchange 2010 SP1 or later UM server, and the UM-enabled user's mailbox is located on an Exchange 2010 SP1 or later Mailbox server, the Exchange 2010 SP1 or later UM server will process the incoming call. If the user's mailbox is located on an Exchange 2007 SP3 Mailbox server, the incoming call will be routed to an Exchange 2007 SP3 UM server within the same UM dial plan, and the incoming call will be processed. If there are multiple Exchange 2007 SP3 UM servers in the same dial plan, the Exchange 2010 SP1 or later UM servers will send the incoming call to the Exchange 2007 SP3 UM servers using a round robin mechanism.

After all UM-enabled users' mailboxes are migrated to an Exchange 2010 SP1 or later Mailbox server, the Exchange 2007 Service Pack 3 (SP3) UM servers can be removed from the UM dial plan.

Upgrade Scenarios

When you're upgrading from Exchange 2007 SP3 Unified Messaging to Exchange 2010 SP1 or later Unified Messaging, there are two basic scenarios:

- **Full Upgrade** In a full upgrade, you replace all the Exchange 2007 SP3 UM servers with Exchange 2010 SP1 or later UM servers, and all existing Exchange 2007 SP3 UM-enabled mailboxes are moved to Exchange 2010 SP1 or later Unified Messaging. During this process, you'll most likely have both Exchange 2007 SP3 and Exchange 2010 SP1 or later UM servers coexisting in the same Exchange organization. At the end of the process, the Exchange 2010 SP1 or later UM server will answer all incoming calls and allow UM-enabled users to access their mailbox when they call in to an Outlook Voice Access number that's configured on a Exchange 2010 SP1 or later UM dial plan.

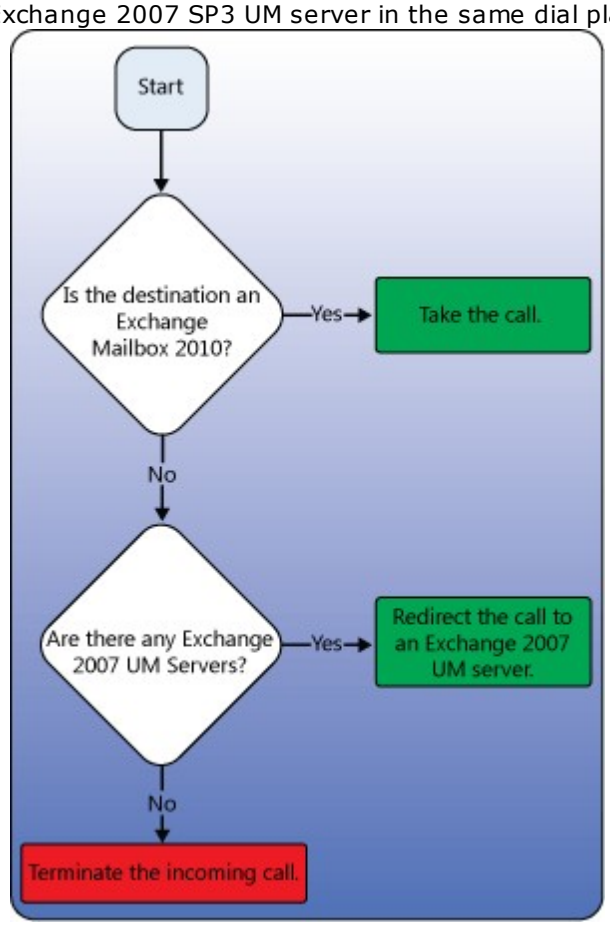
  Important:

  If you're uninstalling the last Exchange 2007 SP3 UM server in the Exchange 2010 SP1 or later organization, run the following command on an Exchange 2010 SP1 or later UM server within the same organization as the Exchange 2007 SP3 UM server: `Set-UMDialPlan -identity MyUMDialPlan -LegacyPromptPublishingPoint $null`. Running this command will force the Exchange 2007 SP3 UM server to unbind from the dial plan. You must run this command before you remove the last Exchange 2007 SP3 server from the Exchange 2010 SP1 or later organization.

- **Partial Upgrade** In a partial upgrade,a portion of the existing Exchange 2007 Service Pack 3 (SP3) UM-enabled mailboxes are moved to Exchange 2010 SP1 or later Unified Messaging. A partial upgrade is a term used to describe upgrading from an Exchange 2007 SP3 organization to an Exchange 2010 SP1 or later organization. In partial upgrades, Exchange 2010 SP1 or later UM servers will only process calls for UM-enabled mailboxes that are on Exchange 2010 SP1 or later Mailbox servers. If you're deploying Exchange 2010 SP1 or later Unified Messaging, and it will coexist with Exchange 2007 SP3 UM, you must keep at least one Exchange 2007 SP3 UM server deployed in your organization and it must be added to the same dial plan as the Exchange 2010 SP1 or later UM server or servers.

When you perform a partial upgrade from Exchange 2007 SP3 Unified Messaging to Exchange 2010 SP1 or later Unified Messaging, incoming calls will be handled differently from the way they're handled after a full upgrade, depending on the type of incoming call and whether UM is integrated with Microsoft Office Communications Server 2007. The following are some ways they're handled differently:

- **Call Answering** In call answering calls, the extension number of the destination mailbox is provided in the SIP INVITE header when the UM server answers the incoming call. Based on the information provided, it verifies the mailbox version, and the Exchange 2010 SP1 or later UM server immediately identifies the location of the destination UM-enabled mailbox. If the recipient mailbox is being hosted on an Exchange 2007 SP3 Mailbox server, the Exchange 2010 SP1 or later UM server will redirect the incoming call to an Exchange 2007 SP3 UM server in the same dial plan.

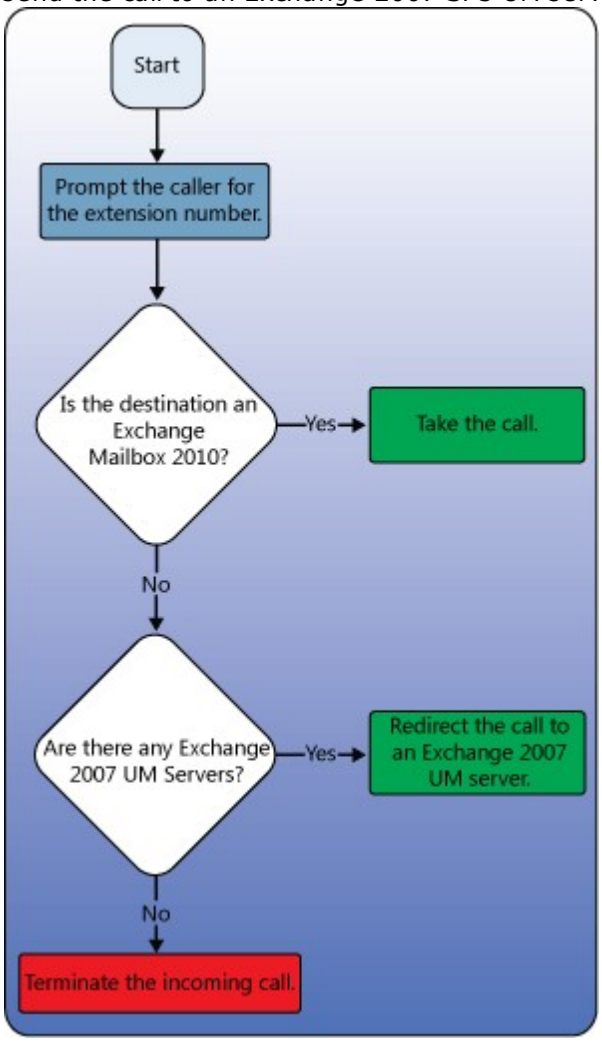


- **Subscriber Access** There are two subscriber access scenarios:

  Scenario 1: When a caller dials in to a subscriber access number configured on a dial plan from a phone number that isn't recognized by a UM server, and the incoming call contains no information about the destination user's mailbox in the SIP INVITE header, the Exchange 2010 SP1 or later UM server will take the call and then prompt the caller to provide the extension number by pressing the corresponding keys on the phone keypad. After the caller has provided the extension number, the Exchange 2010 SP1 or later UM server will identify the user, locate the UM-enabled mailbox, and check the version of the mailbox. If the mailbox is located on an Exchange 2007 SP3 Mailbox server, the Exchange 2010 SP1 or later UM server will do a SIP REFER request and send the call to an Exchange 2007 SP3

UM server.

Scenario 2: When a caller dials in to a subscriber access number configured on a dial plan, and the Exchange 2010 SP1 or later UM server identifies the calling number as an extension for a UM-enabled user with an Exchange 2007 SP3 mailbox, the call will be redirected to an Exchange 2007 SP3 UM server. The Exchange 2010 SP1 or later UM server will make a redirect request and send the call to an Exchange 2007 SP3 UM server.



- **Office Communications Server** If you're running the RTM version of Exchange 2010, Communications Server 2007 without R2 and without Cumulative Update 5 (CU5) or later can't determine the version of the mailbox for a UM-enabled user. So when a call is received by Communications Server 2007, and it redirects the call to another UM server in the same dial plan, either an Exchange 2007 SP3 UM server or an Exchange 2010 SP1 or later UM server might take the call. This causes a problem when you perform a partial upgrade, because the incoming call will fail if it's received by an Exchange 2007 SP3 UM server and the UM-enabled user's mailbox is on an Exchange 2010 SP1 or later Mailbox server. The call will fail because Exchange 2007 SP3 UM servers can't process calls for UM-enabled users who have Exchange 2010 SP1 or later mailboxes.

  The reason the incoming call will fail is that Communications Server 2007 can't tell whether the UM server that it redirected the call to is an Exchange 2007 SP3 UM server or an Exchange 2010 SP1 or later UM server.

If Communications Server 2007 is used as an IP gateway, and there are Exchange 2007 SP3 mailboxes that are enabled for UM, a new SIP URI dial plan will be required. The new SIP URI dial plan must contain only Exchange 2010 SP1 or later UM servers. The new dial plan is required to ensure that incoming calls are redirected only to Exchange 2010 SP1 or later UM servers.
If you're doing a partial upgrade that contains both Exchange 2010 SP1 or later and Exchange 2007 SP3 servers in the same SIP URI dial plan, you must install Communications Server R2 with Cumulative Update 5 (CU5) or later or install Microsoft Lync Server 2010. A separate SIP URI dial plan isn't required when you're running Communications Server R2 with CU5 or later or Lync Server 2010 with Exchange 2010 SP1 or later. The Exchange 2010 SP1 or later and Exchange 2007 SP3 UM servers can coexist in the same SIP URI dial plan. Both Office Communications Server 2007 R2 with CU5 or later and Lync Server 2010 have built-in logic that will direct all incoming calls to an Exchange 2010 SP1 or later UM server and not to an Exchange 2007 SP3 server in the same dial plan.

The following table contains information about the tasks that are required to perform a partial or full upgrade from earlier versions of Microsoft Exchange to Exchange 2010 SP1 or later Unified Messaging.

Upgrading to Exchange 2010 Unified Messaging

Version of Exchange that is currently deployed	Upgrade type	Existing UM dial plans	Actions required
Exchange Server 2003 or earlier versions	Not applicable	Not applicable	• Add Exchange 2010 SP1 or later UM servers to your Exchange 2010 SP1 or later organization. • Create the required UM dial plan(s). • Create the required UM IP gateways and UM hunt groups. • Add the UM servers to the appropriate dial plan. • Copy

			custom prompts to the custom prompts publishing location using the **Import-UMPrompt** cmdlet. • Move the Exchange mailboxes to Exchange 2010 SP1 or later Mailbox servers and UM-enable the mailboxes.
Exchange 2007 SP3	Full upgrade to Exchange 2010 SP1 or later	Telephone Extension, SIP URI and/or E.164	• Add Exchange 2010 SP1 or later UM servers to your Exchange 2010 SP1 or later organization. • Add the Exchange 2010 SP1 or later UM servers to the appropriate dial plan. • Copy custom prompts to the custom prompts publishing location using the **Import-UMPrompt** cmdlet. • From an Exchange

			2010 SP1 or later UM server in the same organization with the Exchange 2007 SP3 UM servers, run the following command: `Set-UMDial` • Move the Exchange 2007 SP3 UM-enabled mailboxes to Exchange 2010 SP1 or later Mailbox servers. • Uninstall the Exchange 2007 SP3 UM servers from the Exchange 2010 SP1 or later organization.
Exchange 2007 SP3	Partial upgrade to Exchange 2010 SP1 or later	Telephone Extension and/or E.164	• Add Exchange 2010 SP1 or later UM servers to the dial plan. • Don't remove the Exchange 2007 SP3 UM servers from the dial plan.

			• Configure the IP gateways or IP PBXs to send calls to an Exchange 2010 SP1 or later UM server. • Copy custom prompts to the custom prompt publishing locations using the **Copy-UMCustomPrompt** and **Import-UMPrompt** cmdlets.
Exchange 2007 SP3	Partial upgrade to Exchange 2010 SP1 or later	SIP URI	• Create a new SIP URI and/or E.164 dial plan. • Add Exchange 2010 SP1 or later servers to the SIP URI dial plan. • Move the Exchange 2007 SP3 UM-enabled mailboxes to Exchange 2010 SP1 or later Mailbox servers. • Create a new UM hunt group for the new SIP URI dial plan. • Disable

			the mailboxes of users who have Exchange 2007 SP3 UM-enabled mailboxes. • Enable the users for Unified Messaging using the new SIP URI dial plan. • Copy custom prompts to the custom prompt publishing locations using the **Copy-UMCustomPrompt** and **Import-UMPrompt** cmdlets.

Upgrading Custom Prompts from Exchange 2007 Unified Messaging

There are many custom greetings used by UM dial plans and auto attendants, including welcome greetings for dial plans and after hours welcome greetings and menus, business hours and non-business hours welcome greetings and menus, and key mappings for UM auto attendants. All these audio files that are used by Unified Messaging are known as custom prompts.

Exchange 2007 Service Pack 3 (SP3) Custom Prompts Overview

In Exchange 2007 SP3, the **Copy-UMCustomPrompt** cmdlet queries the appropriate dial plan object in Active Directory to determine the location of the prompt publishing point. There is only one prompt publishing point for each dial plan, and it's stored as a Windows file share (also known as UNC) path that identifies a file share available for dial plan and auto attendant custom prompts. After the location of the prompt publishing point is determined, the cmdlet validates the content in the custom prompt, and verifies that it's in the correct format and uses a supported audio codec. If the custom prompt passes the validation tests, the cmdlet copies the prompt content to the prompt publishing point.

After the custom prompt is copied to the prompt publishing point, any necessary directory updates are made and the prompt is copied to each UM server in the dial plan. After the custom prompt is added to the appropriate folder on the UM server that's configured as the prompt publishing point, the Microsoft Exchange File Distribution service that runs on

each UM server refers to the prompt publishing point and determines whether the files in the prompt publishing point have changed or additional files have been added. If files have been changed or additional files exist, the other UM servers pull the custom prompts from the prompt publishing point and copy them to the correct location in the *<Server name>*\ExchangeUM folder that exists on a local drive. After the custom prompt is copied to the prompt publishing point using the **Copy-UMCustomPrompt** cmdlet, use the **Set-UMDialPlan** or **Set-UMAutoAttendant** cmdlets to configure the dial plan or auto attendant to use the custom greeting file or prompts.

Exchange 2010 Service Pack 1 or later Custom Prompts

Custom prompts are also available in Exchange 2010 SP1 or later Unified Messaging for dial plans and auto attendants. The prompt publishing point that was available in Exchange 2007 SP3 Unified Messaging doesn't exist in Exchange 2010 SP1 or later. The system mailbox {e0dc1c29-89c3-4034-b678-e6c29d823ed9} is created when you install Exchange 2010 SP1 or later and is used to support features such as Message Approval and Multi-Mailbox Search. This system mailbox is also used in Exchange 2010 SP1 or later Unified Messaging to store dial plan and auto attendant custom prompts. If the system mailbox doesn't exist you can use **Setup /PrepareAD** and one will be created. System mailboxes aren't visible in the Exchange Management Console (EMC) or in Exchange address lists.

By using an Exchange 2010 SP1 or later system mailbox, custom prompts can be backed up and restored along with other mailboxes in a database. This reduces the amount of resources that are needed. Storing custom prompts in a system mailbox removes any possible inconsistencies that may have occurred between Active Directory and the Microsoft Exchange File Distribution service in Exchange 2007 SP3 Unified Messaging. For details about the system mailbox, see Overview of the Mailbox Server Role.

Before you upgrade from Exchange 2007 SP3 Unified Messaging to Exchange 2010 SP1 or later Unified Messaging, you must copy the custom prompts that existed for Exchange 2007 SP3 UM dial plans and auto attendants to a folder on an Exchange 2010 SP1 or later UM server using the **Copy-UMCustomPrompt cmdlet** and then import those custom prompt files to an Exchange 2010 SP1 or later UM server. Custom prompts can be imported to Exchange 2010 UM by using the **Import-UMPrompt** cmdlet. The Exchange 2007 SP3 Unified Messaging cmdlet **Copy-UMCustomPrompt** isn't supported in Exchange 2010 SP1 or later UM for copying custom prompts. For details, see Import and Export Custom Prompts for Unified Messaging.

Use the following syntax to import custom prompts for Exchange 2010 SP1 or later UM dial plans:

```
Import-UMPrompt -PromptFileData <Byte[]> -PromptFileName <String> -UMDialPlan <UM
```

Use the following syntax to import custom prompts for Exchange 2010 UM auto attendants:

```
Import-UMPrompt -PromptFileData <Byte[]> -PromptFileName <String> -UMAutoAttendan
```

The following table contains the steps that are required to ensure that custom prompts are available on the Exchange 2010 SP1 or later and Exchange 2007 SP3 UM servers.

Steps for Custom Prompts

Type of upgrade	Steps for upgrading custom prompts:
Full Upgrade	• Install Exchange 2007 SP3 on all Exchange servers in your organization. • Install the Exchange 2010 SP1 or later Unified Messaging server role and add the UM server to

	the Exchange 2007 SP3 ial plan. • Create the custom prompt if it's a new custom prompt. If the custom prompt was created in Exchange 2007 SP3, manually copy the prompt to a folder on an Exchange 2010 SP1 or later UM server using the **Copy-UMCustomPrompt** cmdlet. • Use the **Import-UMPrompt** cmdlet to import the custom prompt for a UM dial plan or auto attendant to an Exchange 2010 SP1 or later UM server. • From an Exchange 2010 SP1 or later UM server in the same organization with Exchange 2007 SP3 UM servers, run the following command: `Set-UMDialPlan -identity MyUMD` • Decommission your Exchange 2007 SP3 UM servers if there are no Exchange 2007 SP3 UM-enabled mailboxes in your organization.
Partial Upgrade	• Install Exchange 2007 SP3 on all Exchange servers in your organization. • Install the Exchange 2010 SP1 or later Unified Messaging server role and add the UM server to the Exchange 2007 SP3 dial plan. • Create new custom prompts, if needed. If the custom prompt was created in Exchange 2007 SP3, manually copy the prompt to a folder on an Exchange 2010 SP1 or later UM server. • Use the **Import-UMPrompt** cmdlet to import the custom prompt for a UM dial plan or auto attendant to an Exchange 2010 SP1 or later UM server. • If you update or create new custom prompts, you must use the **Import-UMPrompt** cmdlet to import the custom prompt to the Exchange 2010 SP1 or later UM servers and also use the **Copy-UMCustomPrompt** cmdlet to copy the same custom prompt file to the prompt publishing point for your Exchange 2007 SP3 UM servers. **Note:**

	During the upgrade process, Exchange 2007 SP3UM servers and Exchange 2010 SP1 or later UM servers may coexist in the same dial plan and both answer incoming calls. The Exchange 2007 SP3 UM servers will read custom prompts from the Exchange 2007 SP3 custom prompt publishing point and the Exchange 2010 SP1 or later UM servers will read custom prompts from the system mailbox. You must update both custom prompt publishing locations if you're adding or changing custom prompts for a dial plan or auto attendant that's associated with both Exchange 2007 SP3 UM servers and Exchange 2010 SP1 or later UM servers in the same dial plan. If an incoming call is answered by an Exchange 2007 SP3 UM server, the Exchange 2007 SP3 UM servers will play the default greetings if you add a custom prompt for Exchange 2010 SP1 or later UM servers using the **Import-UMPrompt** cmdlet but don't copy the custom prompt using the **Copy-UMCustomPrompt** cmdlet for the Exchange 2007 SP3 UM servers.

Important:

Exchange 2010 SP1 or later UM servers won't answer incoming calls for Exchange 2010 SP1 or later dial plans or auto attendants if the custom prompts are from Exchange 2007 SP3 Unified Messaging and weren't imported using the **Import-UMPrompt** cmdlet.

Autodiscover and Exchange Web Services in Unified Messaging

The Autodiscover service configures client computers running Microsoft Office Outlook 2007 or Outlook 2010 in addition to supported mobile phones. The Autodiscover service provides access to Exchange features for Outlook 2007 or Outlook 2010 clients connected to your Exchange messaging environment. The Autodiscover service must be deployed and configured correctly for these Outlook clients to automatically connect to Exchange features, for example, the offline address book, the Availability service, and Unified Messaging. For details, see Understanding the Autodiscover Service.

In an environment that contains both Exchange 2007 SP3 and Exchange 2010 SP1 or later servers, if the recipient has a mailbox that's hosted on an Exchange 2010 SP1 or later Mailbox server, the Autodiscover request must be directed to an Exchange 2010 SP1 or later Client Access server and not to an Exchange 2007 SP3 Client Access server. If Exchange 2007 SP3 isn't installed on the Exchange 2007 SP3 Client Access server, the Exchange 2007 SP3 Client Access server won't redirect correctly. When the Exchange

2007 SP3 Client Access server tries to generate an Autodiscover response, it isn't aware that there's an Exchange 2010 SP1 or later UM virtual directory and will create an incorrect value for the Unified Messaging URL that's used. You must install Exchange 2007 SP3 to ensure that the Exchange 2007 SP3 Client Access server redirects requests for Exchange 2010 SP1 or later UM-enabled users to the correct UM URL.

Outlook and Microsoft Office Outlook Web App use several URL properties, shown through Autodiscover, to enable UM features such as Play on Phone. When these URL properties are used, the values for the URL are returned but depend on both the version of Outlook and the Mailbox version for the user. The following table shows the versions of Outlook, the version of the user's Exchange mailbox, and which URL will be used.

Versions of Outlook and Exchange mailboxes

	User has an Exchange 2007 SP3 mailbox	**User has an Exchange 2010 SP1 or later mailbox**
Outlook 2007	• Https://<server name>/UnifiedMessaging/service.asmx is the value for the UM virtual directory that's returned to Outlook. • You must make sure that the UM virtual directory is configured correctly using the **Set-UMVirtualDirectory** cmdlet.	• Https://<server name>/EWS/UM2007Legacy.asmx is the value for the UM virtual directory that's returned to Outlook. • You must make sure that the EWS virtual directory is configured correctly using the **Set-WebServicesVirtualDirectory** cmdlet. If it isn't configured correctly, voice mail options and the Play on Phone feature won't work correctly.
Outlook 2010	• https://<server name>/UnifiedMessaging/service.asmx is the value for the UM virtual directory that's returned to Outlook. • You must make sure the UM virtual directory is configured correctly using the **Set-UMVirtualDirectory** cmdlet.	• Exchange Web Services (EWS) URL: https://<servername>/EWS/Exchange.asmx is the value for the EWS virtual directory that's returned to Outlook.You must make sure that the EWS virtual directory is configured correctly using the **Set-WebServicesVirtualDirectory** cmdlet. If it isn't configured correctly, voice mail options and the Play on Phone feature won't work correctly. • Exchange Control Panel (ECP) URL: https://<servername>/ecp/ecp-vdir is the value

		for the ECP virtual directory that's returned to Outlook. You must make sure that the ECP virtual directory is correctly configured using the **Set-WebServicesVirtualDirectory** cmdlet. If it isn't configured correctly, the **Voice Mail** option won't work. • ECP Unified Messaging URL <EcpUrl-um>: ?p=customize/voicemail.aspx&exsvurl=1.This is a hard-coded string, which is used together with the /EcpUrl property to locate the voice mail options page in the ECP. If this isn't configured correctly, the UM-enabled user won't be able to see the voice mail options page.

Service Packs for Exchange 2010

After you upgrade and install the RTM version of Exchange 2010 on UM servers in your organization, you should install Exchange 2010 Service Pack 2 (SP2). For details, see Install or Upgrade to Exchange 2010 SP2 Unified Messaging. If you're upgrading to Exchange 2010 SP2, you must remove all the Exchange 2010 RTM and SP1 UM language packs and install the Exchange 2010 SP2 UM language packs. For details, see:

- Upgrade Exchange 2010 UM Language Packs from RTM or SP1 to Exchange 2010 SP2
- Exchange Server 2010 SP2 UM Language Packs

1.2.2.5 Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010

Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

When you're upgrading your mixed Microsoft Exchange Server 2003 and Exchange Server

2007 organization to Exchange Server 2010, there's a period of time when these earlier versions of Exchange and Exchange 2010 will coexist within your organization. This section discusses key points about both the upgrade process and coexistence as they apply to the Client Access, Transport, and Mailbox server roles.

For more information, see the following topics:

Checklist: Upgrading from Exchange 2003 and Exchange 2007

Upgrade from Exchange 2003 Client Access

Upgrade from Exchange 2003 Transport

Upgrade from Exchange 2003 Mailbox

Upgrade from Exchange 2007 Client Access

Upgrade from Exchange 2007 Transport

Upgrade from Exchange 2007 Mailbox

Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

Managing Deployment of Exchange 2010

For more information about the upgrade process for the mixed Exchange 2003 and Exchange 2007 organization, see the "Exchange 2007 and Exchange 2003 Mixed Mode Coexistence" section in Exchange 2003 - Planning Roadmap for Upgrade and Coexistence.

Also, see Exchange Server Deployment Assistant for information about a Web-based tool that can help you with your deployment.

1.2.2.5.1 Checklist: Upgrading from Exchange 2003 and Exchange 2007

Checklist: Upgrading from Exchange 2003 and Exchange 2007

Planning and Deployment > Deploying Exchange 2010 > Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-30*

Use this checklist to upgrade from an environment in which you're running Microsoft Exchange Server 2003 and Exchange Server 2007 to Exchange Server 2010.

Before you start working with this checklist, make sure you're familiar with the concepts discussed in:

- Planning for Exchange 2010
- Deployment Security Checklist
- Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

This checklist is generic in that it provides guidance for a typical upgrade scenario. For more customized step-by-step guidance about how to upgrade your mixed Exchange

2003 and Exchange 2007 organization, see the Exchange Server Deployment Assistant.

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Checklist for Upgrading from Exchange 2003 and Exchange 2007 to Exchange 2010

Done?	Task	Topic
	1. Verify system requirements	Exchange 2010 System Requirements
	2. Confirm prerequisite steps are done for Exchange 2003 and Exchange 2007	Exchange 2010 Prerequisites
	3. Configure disjoint namespace **Note:** This step is optional. It's only necessary if your organization is running a disjoint namespace.	Configure the DNS Suffix Search List for a Disjoint Namespace
	4. Install the Client Access server role	Install Exchange Server 2010
	5. Add digital certificates on the Client Access server	Create a New Exchange Certificate
	6. Enable Outlook Anywhere **Note:** This step is optional. It's only necessary if you want to use the Outlook Anywhere component of Exchange 2010.	Enable Outlook Anywhere
	7. Configure settings on virtual directories, including OAB, Web Services, ECP, Outlook Web App, and Exchange ActiveSync virtual directories **Note:** This step is necessary if you want to use Exchange Web Services, Outlook Anywhere, or the offline address book. It also may be required if you	Create an Offline Address Book Virtual Directory Configure ECP Virtual Directory Properties View or Configure Outlook Web App Virtual Directories View or Configure Exchange ActiveSync Virtual Directory Properties

	need to change any of the default settings for the Exchange Control Panel, Outlook Web App, or Exchange ActiveSync.	
	8. Install the Hub Transport server role	Install Exchange Server 2010
	9. Configure a legacy host name	Upgrade from Exchange 2007 Client Access
	10. Install the Unified Messaging server role **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM Install the Exchange 2010 Unified Messaging Server Role
	11. Configure Unified Messaging **Note:** This step is optional. It's only necessary if you want to use Unified Messaging in your organization.	Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM
	12. Install the Mailbox server role	Install Exchange Server 2010 Upgrade from Exchange 2007 Mailbox Upgrade from Exchange 2003 Mailbox
	13. Change the offline address book generation server	Move the Offline Address Book Generation Process to Another Server
	14. Install the Edge Transport server role **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Install Exchange Server 2010 Upgrade from Exchange 2007 Transport
	15. Subscribe the Edge Transport server **Note:** This step is optional. It's only necessary if you want to use the Edge server role in your organization.	Create an Edge Subscription File on an Edge Transport Server Import an Edge Subscription File to an Active Directory Site

	16. Move mailboxes from Exchange 2003 or Exchange 2007 to Exchange 2010	Create a Local Move Request
	17. Move public folder data to Exchange 2010	Configure Public Folder Replication
	18. Post-installation tasks	Exchange 2010 Post-Installation Tasks

1.2.2.6 Understanding Unified Messaging Deployments

Understanding Unified Messaging Deployments

Exchange Server 2010 > Planning and Deployment > Deploying Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-28*

Microsoft Exchange Server 2010 Unified Messaging combines voice messaging and e-mail messaging into one store, accessible from a telephone and a computer. Unified Messaging integrates Microsoft Exchange with telephony networks and brings the UM features to the core of Microsoft Exchange. The following topics provide detailed information about deploying Exchange 2010 Unified Messaging:

Deploy a New Exchange 2010 RTM UM Environment

Checklist: Deploy a New Exchange 2010 RTM UM Environment

Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM

Install or Upgrade to Exchange 2010 SP2 Unified Messaging

Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

Deploy and Configure Incoming Faxing

Deploy Unified Messaging and Communications Server 2007 R2

Checklist: Deploy Office Communications Server 2007 R2 and Exchange 2010 Unified Messaging

1.2.2.6.1 Deploy a New Exchange 2010 RTM UM Environment

Deploy a New Exchange 2010 RTM UM Environment

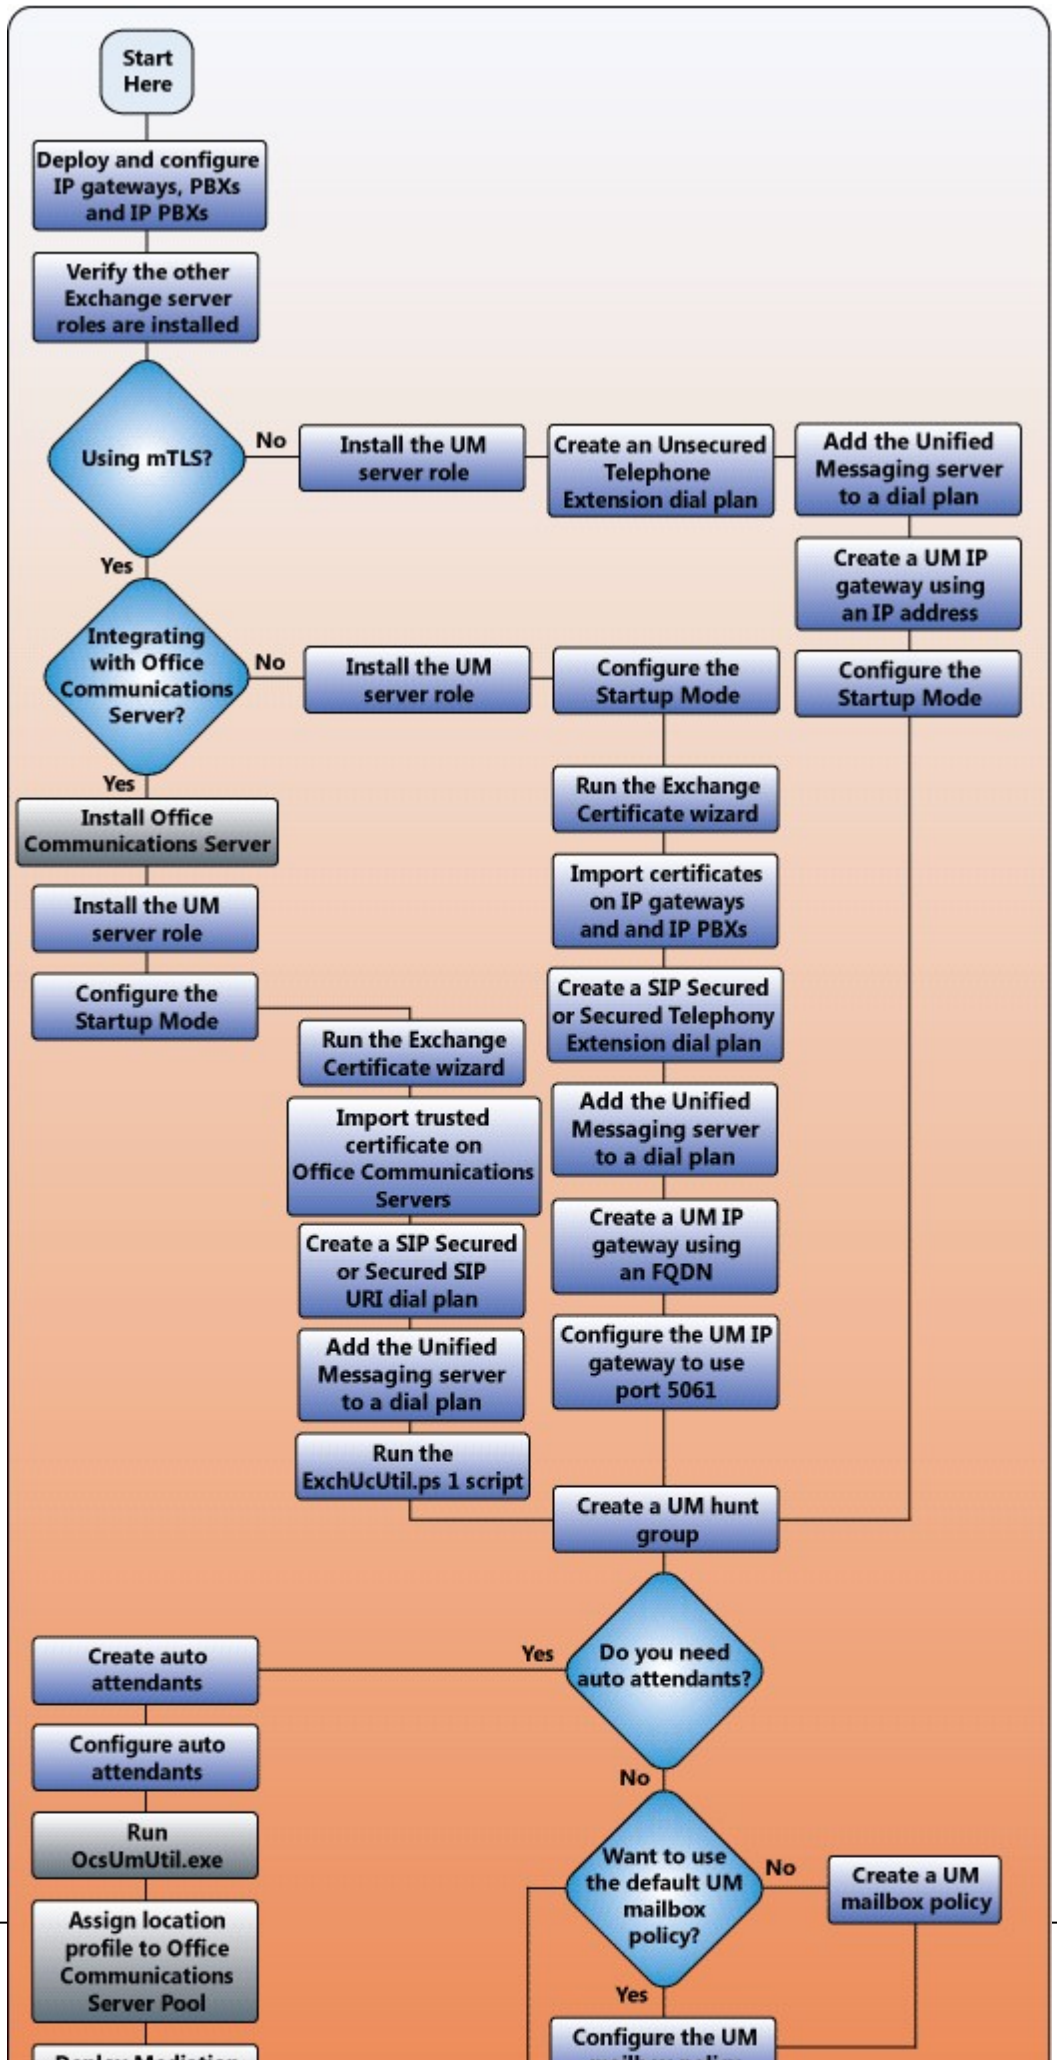
Planning and Deployment > Deploying Exchange 2010 > Understanding Unified Messaging Deployments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Microsoft Exchange Server 2010 Unified Messaging (UM) provides an efficient and simple deployment model that's highly scalable but doesn't increase the complexity of the deployment. There are many deployment models for Unified Messaging in your organization. The recommended deployment model for Unified Messaging centralizes your Unified Messaging servers. Microsoft Exchange Server 2007 and or later versions contain Unified Messaging features. Versions that are earlier than Exchange 2007 can't be upgraded and require you to deploy an Exchange 2010 organization with all the Exchange server roles, including Unified Messaging, and then move the Microsoft Exchange Server 2003 (or earlier) mailboxes to an Exchange 2010 Mailbox server. For details, see Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers.

The following illustration shows the steps that are required to successfully deploy a new Unified Messaging environment.



Start Here
Deploy and configure IP gateways, PBXs and IP PBXs
Verify the other Exchange server roles are installed
Using mTLS?
No
Install the UM server role
Create an Unsecured Telephone Extension dial plan
Add the Unified Messaging server to a dial plan
Create a UM IP gateway using an IP address
Configure the Startup Mode
Yes
Integrating with Office Communications Server?
No
Install the UM server role
Configure the Startup Mode
Run the Exchange Certificate wizard
Import certificates on IP gateways and and IP PBXs
Create a SIP Secured or Secured Telephony Extension dial plan
Add the Unified Messaging server to a dial plan
Create a UM IP gateway using an FQDN
Configure the UM IP gateway to use port 5061
Yes
Install Office Communications Server
Install the UM server role
Configure the Startup Mode
Run the Exchange Certificate wizard
Import trusted certificate on Office Communications Servers
Create a SIP Secured or Secured SIP URI dial plan
Add the Unified Messaging server to a dial plan
Run the ExchUcUtil.ps 1 script
Create a UM hunt group
Do you need auto attendants?
Yes
Create auto attendants
Configure auto attendants
Run OcsUmUtil.exe
Assign location profile to Office Communications Server Pool
No
Want to use the default UM mailbox policy?
No
Create a UM mailbox policy
Yes
Configure the UM

Contents

Before You Deploy

Before you deploy Exchange 2010 Unified Messaging, we recommend that you familiarize yourself with the concepts in the following topics:

- Overview of Unified Messaging
- Understanding Unified Messaging Dial Plans
- Understanding Unified Messaging Mailbox Policies
- Understanding Unified Messaging IP Gateways
- Understanding Unified Messaging Hunt Groups
- Understanding Unified Messaging Auto Attendants
- Understanding Unified Messaging Servers
- Understanding Unified Messaging Users

Return to top

Deploying Unified Messaging

All the available deployment options for Unified Messaging have several steps in common. These steps are required to create a scalable and highly available system to support large numbers of Unified Messaging users. These steps are as follows:

1. Deploy and configure your telephony components for Unified Messaging.
2. Verify that you've correctly installed the Exchange 2010 server roles that are required by Unified Messaging.
3. Install the Unified Messaging server role.
4. Create and configure the required Unified Messaging Active Directory components.
5. Perform post deployment tasks for Unified Messaging.

- If you're looking for a checklist of tasks that must be performed to deploy a new UM environment, see Checklist: Deploy a New Exchange 2010 RTM UM Environment.

Return to top

Deploy and Configure Telephony Components

To successfully deploy an Exchange 2010 Unified Messaging server in an Exchange organization, the Exchange administrator must become knowledgeable about data networking concepts and telephony terminology and concepts and be able to correctly configure the telephony components that are required by Unified Messaging. Performing a new deployment or upgrading a legacy voice mail system requires significant knowledge about PBXs and Exchange 2010 Unified Messaging. For more information, see the Microsoft Exchange Server 2007 Unified Messaging (UM) Specialists Web site.

Generally, there are three tasks that must be completed to successfully configure the telephony components that are required by Unified Messaging:

1. **Provision PBX lines** The first step in deploying a scalable UM solution is to provision PBX lines.
2. **Organize channels** After you provision PBX-based voice channels, you can

organize the channels as hunt groups.

3. **Deploy IP gateways** After you organize your voice channels as hunt groups, you must end these channels at IP gateways. IP gateways are used with a legacy PBX to convert the circuit-switched protocols found on a telephony network to IP-based packet-switched protocols.

When you integrate your organization's telephony and data networks during the deployment of Exchange 2010 Unified Messaging, you must configure the telephony and data networking components correctly. You must also configure the following components or interfaces to successfully deploy Unified Messaging:

- **Configure the connection from the PBXs in your organization to communicate with your IP gateways.** For details, see Configure an IP Gateway to Communicate with a PBX.
- **Configure the connection from the IP gateway interface to the PBX.** For more information about how to configure your PBX interface to communicate with your supported IP gateway, see the product documentation that's specific to your PBX. For details, see Configure an IP Gateway to Communicate with a PBX.
- **Configure the connection from the IP gateway interface to the Exchange Server 2010 Unified Messaging server.** For details, see Configure an IP Gateway or IP PBX for Use with a Unified Messaging Server.
- **Configure the connection from the Unified Messaging server to the IP gateway interface.** For details, see Connect a Unified Messaging Server to a Supported IP Gateway.

For more information about telephony components, see Understanding Telephony Concepts and Components.

Return to top

Verify Installation of the Mailbox, Hub Transport, and Client Access Server Roles

Different deployment paths are available for organizations that plan to deploy Exchange 2010. Although these paths all lead to the same end—a successful deployment of Exchange 2010—each path is slightly different because each customer's needs and starting points are different. However, generally there are common starting points and paths that cover all supported deployment scenarios, including new installations and upgrades. Because Unified Messaging relies on the functionality of other server roles found in Exchange 2010, the Unified Messaging server role will most likely be the last server role that you install in your Exchange 2010 organization. You must follow these steps to install the server roles other than Unified Messaging before you can install the Unified Messaging server role:

1. Verify that your existing infrastructure meets certain prerequisites before you install Exchange 2010. For details, see Exchange 2010 Prerequisites.
2. Verify that you've correctly installed the Exchange 2010 server roles required by Unified Messaging. After you install Exchange 2010, we recommend that you verify the installation and review the server setup logs. For details, see Verify an Exchange 2010 Installation.

Return to top

Install the Unified Messaging Server Role

After you've completed the deployment of your IP gateways or IP PBXs on your network, you must install the Unified Messaging server role on one or more computers in your Exchange environment. Depending on the needs of your business, to provide a highly scalable and available Unified Messaging system, consider installing the Unified Messaging server role on more than one computer. For more information about how to plan and deploy a highly available and scalable Unified Messaging system, see Understanding Unified Messaging Availability or Understanding Unified Messaging Performance and Scalability.

Follow these steps to install the Unified Messaging server role:

1. **Review the Exchange 2010 system requirements before installation.**
   Before you install the Unified Messaging server role, we recommend that you make sure that your network, hardware, software, clients, and other elements meet the requirements for Exchange 2010. For details, see Exchange 2010 System Requirements.
2. **Install the Unified Messaging server role.**
   There's more than one way to install the Unified Messaging server role on a computer that's running Exchange 2010. The Unified Messaging server role can be installed on a single computer that has no other Exchange 2010 server roles installed, or on a computer that's running another Exchange 2010 server role. Before you install the Unified Messaging server role, you must install the Mailbox, Hub Transport, and the Client Access server roles. However, you can install the Mailbox, Hub Transport, Client Access and the Unified Messaging server roles on the same physical computer. For details, see Install the Exchange 2010 Unified Messaging Server Role.
3. **Verify your Exchange 2010 Unified Messaging installation.**
   After you install Exchange 2010, we recommend that you verify the installation and review the server setup logs. If the Setup process fails or errors occur during installation, you can use the setup logs to track down the source of the problem. For details, see Verify an Exchange 2010 Installation.
4. **Download and Install the Unified Messaging Language Packs.**
   After you install Exchange 2010, you may have to download and install the required Unified Messaging Service Pack 1 (SP1) language packs you need on the UM servers in your organization. Make sure to install each UM language pack on each UM server and to set the default language on all dial plans that the UM server is associated with.
   Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange 2007, there have been separate releases for UM language packs, including Exchange 2007 RTM, Exchange 2007 SP1, Exchange 2010 RTM, and Exchange 2010 SP1. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available. It's very important that you install the correct version and platform of the UM language packs on a UM server.
   For more information about how to install a UM language pack, see Install a Unified Messaging Language Pack on a UM Server. To download Unified Messaging language packs, see Exchange Server 2010 UM Language Packs.

Return to top

Create and Configure UM Components

There are several UM components in Active Directory that are required for the deployment and operation of Exchange 2010 Unified Messaging. Unified Messaging components in Active Directory connect the telephony infrastructure with the Unified Messaging Active Directory environment. After you've successfully installed the Unified Messaging server role on at least one computer, follow these steps.

Step 1: Create and configure UM dial plans

UM dial plans are integral to the operation of Exchange 2010 Unified Messaging and are required to successfully deploy Unified Messaging on your network. After you've successfully installed the Unified Messaging server role, a UM dial plan will be the first Active Directory component that you'll create.

By default, UM dial plans and the Unified Messaging servers that are associated with the dial plan send and receive data without using encryption. In Unsecured mode, the VoIP and SIP traffic won't be encrypted. When you create the dial plan or after you've created the dial plan, you can configure the dial plan to encrypt the VoIP and SIP traffic by using Mutual Transport Layer Security (mutual TLS). After you configure the VoIP security setting, you'll then have to configure the startup mode for the UM server. For details, see Configure the Startup Mode on a UM Server.

Perform one of the following procedures to create a new UM dial plan.

Use the EMC to create a UM dial plan
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the action pane, click **New UM Dial Plan**.
3. In the New UM Dial Plan wizard, complete the following fields:
   - **Name** Type the name of the dial plan. A UM dial plan name is required and must be unique. However, the name you type is used only for display purposes in the EMC and the Shell. If you have to change the display name of the dial plan after it's been created, you must first delete the existing UM dial plan and then create another dial plan that has the appropriate name. If your organization uses multiple UM dial plans, we recommend that you use meaningful names for your UM dial plans. The maximum length of a UM dial plan name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.

     Important:
     Although the field for the name of the dial plan can accept 64 characters, the name of the dial plan can't be longer than 49 characters. This is because, when you create a dial plan, a default UM mailbox policy is also created that has the name *<DialPlanName>* Default Policy. The *name* parameter for both the UM dial plan and UM mailbox policy can be 64 characters long.

   - **Number of digits in extension numbers** Enter the number of digits for extension numbers in the dial plan. The number of digits for extension numbers is based on the telephony dial plan created on a Private Branch eXchange (PBX). For example, if a user associated with a telephony dial plan dials a four-digit extension to call another user in the same telephony dial plan, you select 4 as the number of digits in the extension.

     This is a required field that has a value range from 1 through 20. The typical extension length is from 3 through 7. If your existing telephony environment includes extension numbers, you must specify a number of digits that matches the number of digits in those extensions.

     When you create a Session Initiation Protocol (SIP) dial plan or an E.164 dial plan and associate a UM-enabled user with the dial plan, you must still enter an extension number to be used by the user. This number is used by Outlook Voice Access users when they access their Exchange 2010 mailbox.

   - **URI Type** Use this drop-down list to select the URI type for the UM dial plan. A URI is a string of characters that identifies or names a resource. The main purpose of this identification is to enable VoIP devices to communicate with other devices over a network using specific protocols. URIs are defined in schemes that define a specific syntax, format, and the protocols for the call.

     You can select one of the following URI types for the dial plan:
     Telephone extension This is the most common URI type. The calling and called party information from the IP gateway or IP PBX will be listed in one of the following formats: Tel:512345 or 512345@*<IP address>*. This is the default URI type for dial plans.
     SIP URI Use this URI type if you need a SIP URI dial plan when an IP PBX supports SIP routing or if you're integrating Microsoft Office Communications Server 2007 and Exchange Unified Messaging. The calling and called party information from the IP gateway or IP PBX will be listed as a SIP address in the

following format: sip:<*username*>@<*domain* or *IP address*>:Port.
E.164 E.164 is an international numbering plan for public telephone systems in which each assigned number contains a country/region code, a national destination code, and a subscriber number. The calling and called party information sent from the IP gateway is listed in the following format: Tel:+14255550123.

Note:
After you create a dial plan, you will be unable to change the URI type without deleting the dial plan, and then re-creating the dial plan to include the correct URI type.

- **VoIP Security** Use this drop-down list to select the VoIP security setting for the UM dial plan. By default, when you create a UM dial plan, it communicates in unsecured mode. A Unified Messaging server can operate in any mode configured on a dial plan because the Unified Messaging server is configured to listen on TCP port 5060 for unsecured requests and on TCP port 5061 for secured requests at the same time.
  You can select one of the following security settings for the dial plan:
  Unsecured By default, when you create a UM dial plan, it communicates in unsecured mode, and the Unified Messaging servers associated with the UM dial plan send and receive data from IP gateways, IP PBXs, and other Exchange 2010 computers using no encryption. In unsecured mode, both the Realtime Transport Protocol (RTP) media channel and SIP signaling information aren't encrypted.
  SIP secured When you select **SIP secured**, only the SIP signaling traffic is encrypted, and the RTP media channels still use TCP, which isn't encrypted. Mutual Transport Layer Security (TLS) is used to encrypt the SIP signaling traffic.
  Secured When you select **Secured**, both the SIP signaling traffic and the RTP media channels are encrypted. An encrypted signaling media channel that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data.
- **Country/Region code** Use this field to type the country/region code number to be used for outgoing calls. This number will automatically be prepended to the telephone number that's dialed. This field accepts from 1 through 4 digits. For example, in the United States, the country/region code is 1. In the United Kingdom, it's 44.

4. On the **Set UM Servers** page, click **Add** and then on the **Select UM Server** page select the UM server that you want to add to the UM dial plan.
5. On the **Completion** page, confirm whether the dial plan was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM Dial Plan wizard.

Use the Shell to create a UM dial plan
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example creates a new UM dial plan named `MyUMDialPlan` that uses four-digit extension numbers.

```
New-UMDialplan -Name MyUMDialPlan -NumberofDigits 4
```

This example creates a new UM dial plan named MyUMDialPlan that uses five-digit extension numbers and supports SIP URIs:

```
New-UMDialplan -Name MyUMDialPlan -UriType SIPName -NumberofDigits 5
```

For more information about syntax and parameters, see Set-UMDialplan.

Return to top

Step 2: Create and configure your UM IP gateways

A UM IP gateway represents either an IP gateway hardware device or an IP PBX hardware device. The combination of the UM IP gateway object and a UM hunt group object establishes a logical link between an IP gateway or IP PBX and a UM dial plan.

If you've created or enabled VoIP security on a dial plan, the UM IP gateway that you will create by using one of the following procedures in this section will be associated with a UM dial plan that uses VoIP security. In that case, you must use a fully qualified domain name (FQDN) to create the UM IP gateway, and not an IP address. You must also configure the UM IP gateway to listen on TCP port 5061. To configure a UM IP gateway to listen on TCP port 5061, run the following command: **Set-UMIPGateway -identity MyUMIPGateway -Port 5061**. You must also verify that any IP gateways or IP PBXs have also been configured to listen on port 5061 for mutual TLS.

Perform one of the following procedures to create a new UM IP gateway.

Use the EMC to create a UM IP gateway

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the result pane, click the **UM IP Gateways** tab.
3. In the action pane, click **New UM IP Gateway**.
4. In the **New UM IP Gateway** wizard, in the **Name** section, type the name of the UM IP gateway. This is the display name for the UM IP gateway.
5. In the **IP Address** section, type the IP address for the UM IP gateway, and then click **New**.

   Note:

   Alternatively, you can enter an FQDN for the UM IP gateway. If you choose to use an FQDN, you must add the appropriate host records with the correct IP addresses to the DNS zone. If you're configuring a UM IP gateway that will be associated with a dial plan that's operating in Secured mode, you must create the UM IP gateway with an FQDN.

6. On the **New UM IP Gateway** page, click **New**.
7. On the **Completion** page, click **Finish**.

Use the Shell to create a UM IP gateway

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM IP gateways" entry in the Unified Messaging Permissions topic.

This example creates a UM IP gateway named MyUMIPGateway that enables a Unified Messaging server to start accepting calls from an IP gateway that has an IP address of 10.10.10.1.

```
New-UMIPGateway -Name MyUMIPGateway -Address 10.10.10.1
```

This example creates a UM IP gateway named MyUMIPGateway that enables a Unified Messaging server to start accepting calls from an IP gateway that has an FQDN of MyUMIPGateway.contoso.com and listens on port 5061.

```
New-UMIPGateway -Name MyUMIPGateway -Address "MyUMIPGateway.contoso.com" -Port 50
```

For more information about syntax and parameters, see New-UMIPGateway.

Return to top

Step 3: Create and configure your UM hunt groups (optional)

Hunt group is a term that's used to describe a group of PBX or IP PBX resources or extension numbers that are shared by users. Hunt groups are used to efficiently distribute calls into or out of a given business unit.

If you've created a UM IP gateway and associated the UM IP gateway with a UM dial plan, a default UM hunt group is created. You can associate another UM hunt group with the same or a different UM IP gateway, depending on the number of UM IP gateways that you've created.

When you create a UM hunt group, you enable all Unified Messaging servers that are specified within the UM dial plan to communicate with an IP gateway. To learn more about UM hunt groups, see Understanding Unified Messaging Hunt Groups. To create a new UM hunt group, perform one of the following procedures.

Use the EMC to create a UM hunt group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM IP Gateways** tab.
3. In the result pane, select a UM IP gateway.
4. In the action pane, click **New UM Hunt Group**.
5. In the New UM Hunt Group wizard, view or complete the following fields:
   - **Associated UM IP gateway** This display-only field shows the name of the UM IP gateway that will be associated with the UM hunt group.
   - **Name** Use this text box to create the display name for the UM hunt group. A UM hunt group name is required and must be unique, but it's used only for display purposes in the EMC and the Shell. If you have to change the display name of the hunt group after it's been created, you must first delete the existing hunt group and then create another hunt group that has the appropriate name.

     If your organization uses multiple hunt groups, we recommend that you use meaningful names for your hunt groups. The maximum length of a UM hunt group name is 64 characters, and it can include spaces. However, it can't include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Dial plan** Click the **Browse** button to select the dial plan that will be associated with the UM hunt group. Associating a hunt group with a dial plan is required. A UM hunt group can be associated with only one UM IP gateway and one UM dial plan.
   - **Pilot identifier** Use this text box to specify a string that uniquely identifies the pilot identifier or pilot ID configured on the PBX or IP PBX.

     An extension number or a SIP URI can be used in this field. Alphanumeric characters are accepted in this field. For legacy PBXs, a numeric value is used as a pilot identifier. However, some IP PBXs can use SIP URIs.
6. On the **Completion** page, confirm whether the UM hunt group was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

7. Click **Finish** to complete the New UM Hunt Group wizard.

Use the Shell to create a UM hunt group
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM hunt groups" entry in the Unified Messaging Permissions topic.

This example creates a UM hunt group named `MyUMHuntGroup` that has a pilot identifier of 12345.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier 12345  -UMDialplan MyUMDialP
```

This example creates a UM hunt group named `MyUMHuntGroup` that has multiple pilot identifiers.

```
New-UMHuntGroup -Name MyUMHuntGroup -PilotIdentifier 5551234,55555 -UMDialplan My
```

For more information about syntax and parameters, see New-UMHuntGroup.

Return to top

Step 4: Create and configure a UM mailbox policy

UM mailbox policies are required when you enable users for Exchange 2010 Unified Messaging. The mailbox of each UM-enabled user must be linked to a single UM mailbox policy. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of failed sign-in attempts for the UM-enabled users who are associated with the UM mailbox policy.

Every time that you create a UM dial plan, a UM mailbox policy is also created. The UM mailbox policy will be named *<DialPlanName>* Default Policy. However, if you have to create a new UM mailbox policy, perform one of the following procedures.

Use the EMC to create a UM mailbox policy
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Mailbox Policies** tab.
3. In the action pane, click **New UM Mailbox Policy**.
4. In the New UM Mailbox Policy wizard, complete the following fields:
   - **Name** Use this text box to specify a unique name for the UM mailbox policy. If you must change the display name of the UM mailbox policy after it's been created, you must first delete the existing UM mailbox policy, and then create another UM mailbox policy that has the appropriate name. To delete the UM mailbox policy, there must not be any UM-enabled users associated with the UM mailbox policy.
     The UM mailbox policy name is required, but it's used for display purposes only. Because your organization may use multiple UM mailbox policies, we recommend that you use meaningful names for your UM mailbox policies. The maximum length of a UM mailbox policy name is 64 characters, and it can include spaces. However, it cannot include any of the following characters: " / \ [ ] : ; | = , + * ? < >.
   - **Select associated dial plan** Click **Browse** to select the UM dial plan that will be associated with the UM mailbox policy. You must associate a UM mailbox policy with at least one UM dial plan. However, you can also associate multiple UM mailbox policies with a single dial plan.
5. On the **Completion** page, confirm whether the UM mailbox policy was successfully created:

- A status of **Completed** indicates that the wizard completed the task successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

6. Click **Finish** to complete the New UM Mailbox Policy wizard.

Use the Shell to create a UM mailbox policy
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM mailbox policies" entry in the Unified Messaging Permissions topic.

This example creates a UM mailbox policy named `MyUMMailboxPolicy` associated with a UM dial plan named `MyUMDialPlan`.

```
New-UMMailboxPolicy -Name MyUMMailboxPolicy -UMDialPlan MyUMDialPlan
```

For more information about syntax and parameters, see New-UMMailboxPolicy.

Return to top

Step 5: Add a Unified Messaging server to dial plans

After you install the Unified Messaging server role, the UM server can't answer incoming calls until you add it to a UM dial plan. Although the status of the Exchange 2010 Unified Messaging server is set to enabled after installation, there's a parameter that's used to enable or disable the status of the Unified Messaging server.

A Unified Messaging server can be associated with a single or multiple UM dial plans. A single UM server can be added to a multiple dial plans that use mutual TLS (Secured), SIP secured, or TCP (Unsecured). To add a UM server to a dial plan, perform one of the following procedures.

Use the EMC to add a UM server to a dial plan
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

1. In the console tree, click **Server Configuration**.
2. In the result pane, select the Unified Messaging server you want to add to a dial plan.
3. In the action pane, click **Properties**.
4. On the **UM Settings** > **Associated Dial Plans**, click **Add**.
5. In the **Select Dial Plan** window, from the list of available dial plans, select the dial plan you want to add the UM server to, and then click **OK**.

Use the Shell to add a UM server to a dial plan
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM dial plans" entry in the Unified Messaging Permissions topic.

This example adds a Unified Messaging server to a dial plan named `MyUMDialPlan` and prevents the UM server from accepting new calls. It also sets the startup mode to dual mode, which enables the UM server to accept TCP and TLS requests.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlan -Status Disabled -UMSta
```

This example adds the Unified Messaging server named `MyUMServer` to two UM dial plans, named `MyUMDialPlan` and `MyUMDialPlan2`, and also sets the maximum number of incoming voice and fax calls.

```
Set-UMServer -Identity MyUMServer -DialPlans MyUMDialPlan, MyUMDialPlan2 -MaxCall
```

For more information about syntax and parameters, see Set-UMServer.

Return to top

Step 6: Create and configure UM auto attendants (optional)

Exchange 2010 Unified Messaging enables you to create one or more UM auto attendants, depending on the needs of your organization. When you create a UM auto attendant, you create a voice menu system for your organization. Callers from outside or inside your organization can then move through the menu system to locate and place or transfer calls to users or departments in your organization.

Callers can move through the menu system by using dual tone multi-frequency (DTMF), also known as touchtone, or voice inputs. For automatic speech recognition (ASR) to work, so users can use voice inputs, you must speech-enable the UM auto attendant.

Creating and using auto attendants is optional in Exchange 2010 Unified Messaging. However, if you want to create a new UM auto attendant, perform one of the following procedures.

Use EMC to create a UM auto attendant

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Unified Messaging**.
2. In the work pane, click the **UM Auto Attendants** tab.
3. In the action pane, click **New UM Auto Attendant**.
4. In the New UM Auto Attendant wizard, complete the following fields:
   - **Name** Use this text box to create the display name for the UM auto attendant. A UM auto attendant name is required and must be unique. However, it's used only for display purposes in the EMC and the Shell.
     If you have to change the display name of the auto attendant after it's created, you must first delete the existing UM auto attendant and then create another UM auto attendant that has the appropriate name. If your organization uses multiple UM auto attendants, we recommend that you use meaningful names for your UM auto attendants. The maximum length of a UM auto attendant name is 64 characters, and it can include spaces.
   - **Select associated dial plan** Click **Browse** to select the UM dial plan to associate with this UM auto attendant. Selecting and associating a UM dial plan with the auto attendant is required. A UM auto attendant can be associated with only one UM dial plan.
   - **Extension numbers** Use this field to enter the extension number that callers will use to reach the auto attendant. Type an extension number in the box, and then click **Add** to add the number to the list. The number of digits in the extension number that you provide doesn't have to match the number of digits for an extension number configured on the associated UM dial plan. This is because direct calls are allowed to UM auto attendants.
     You can also create a new auto attendant without adding an extension number, because an extension number isn't required. You can edit or remove an existing extension number. To edit an existing extension number, click **Edit**. To remove an existing extension number from the list, click **Remove**.
   - **Create auto attendant as enabled** Select this option to enable the auto attendant to answer incoming calls when you complete the New UM Auto Attendant wizard. By default, a new auto attendant is created as disabled.
     If you decide to create the UM auto attendant as disabled, you can use the EMC or the Shell to enable the auto attendant after you finish the wizard.

- **Create auto attendant as speech-enabled** Select this check box to speech-enable the UM auto attendant. When you speech-enable the auto attendant, callers will be able to respond to the system or custom prompts used by the UM auto attendant using touchtone or voice inputs. By default, the auto attendant won't be speech-enabled when it's created.
  For callers to use a speech-enabled auto attendant, you must install the appropriate Unified Messaging language pack that contains Automatic Speech Recognition (ASR) support and configure the properties of the auto attendant to use this language.

5. On the **Completion** page, confirm whether the UM auto attendant was successfully created:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to complete the New UM Auto Attendant wizard.

Use the Shell to create a new UM auto attendant
You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "UM auto attendants" entry in the Unified Messaging Permissions topic.

This example creates a UM auto attendant named `MyUMAutoAttendant` that can accept incoming calls but isn't speech-enabled.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan MyUMDialPlan -PilotIdenti
```

This example creates a speech-enabled UM auto attendant named `MyUMAutoAttendant`.

```
New-UMAutoAttendant -Name MyUMAutoAttendant -UMDialPlan MyUMDialPlan -PilotIdenti
```

For more information about syntax and parameters, see New-UMAutoAttendant.

After you've created a non-speech-enabled or a speech-enabled auto attendant, you must create and configure key mappings so that the auto attendant can function correctly. If you don't enable key mappings for either business or non-business hours, callers will hear the voice prompts but won't be able to interact with the auto attendant. To create key mappings for an auto attendant, see the following topics:

- Enable Business Hours Key Mappings on a UM Auto Attendant
- Enable Non-Business Hours Key Mappings on a UM Auto Attendant
- Configure Key Mapping Entries on a UM Auto Attendant

Return to top

Post Deployment Tasks for Unified Messaging

After you complete a new installation of the Unified Messaging server role and have successfully deployed Unified Messaging, you should complete the post-installation tasks. The post-deployment tasks will help you enable users for Unified Messaging, secure your UM deployment, and deploy incoming faxing for UM-enabled users.

Enabling Users for Unified Messaging

After you've deployed your IP gateways or IP PBXs, installed the Unified Messaging server role, and created the Active Directory components for Unified Messaging, you must enable your users for Unified Messaging. For details, Enable a User for Unified Messaging.

Secure Your UM Deployment

You can help increase the level of protection for your network if you correctly plan a UM security strategy and then correctly configure the security settings for UM servers and UM-enabled users.

Mutual TLS for UM

To use mutual TLS to encrypt SIP and Real-time Transport Protocol (RTP) traffic that's sent and received by your Unified Messaging servers, perform the following tasks:

- Run the Exchange Certificate wizard. For details, see Create a New Exchange Certificate.
- Associate the certificate with the UM server.
- Import the required certificates on the IP gateways and the IP PBX and Unified Messaging servers in your organization. To import an Exchange certificate, see Import an Exchange Certificate.
- Configure VoIP security on the UM dial plans. For details, see Configure VoIP Security on a UM Dial Plan.
- Configure the startup mode on the Unified Messaging server. For details, see Configure the Startup Mode on a UM Server.
- Configure the UM IP gateways to listen on port 5061. For details, see Configure the TCP Listening Port on a UM IP Gateway.

For more information about VoIP security with Unified Messaging, see Understanding Unified Messaging VoIP Security.

PIN Policies for UM-enabled Users

In Exchange 2010 Unified Messaging, PIN policies are defined and configured on a UM mailbox policy. Multiple UM mailbox policies can be created, depending on your requirements. When you enable a user for Exchange 2010 Unified Messaging, you associate the user with an existing UM mailbox policy. The UM PIN policies that are configured on the UM mailbox policy should be based on the security requirements of your organization. For more information about how to configure PIN settings for UM-enabled users, see Configuring Security for Unified Messaging Users.

Return to top

Deploying Faxing

Exchange 2010 UM forwards incoming fax calls to a dedicated fax partner solution, which then establishes the fax call with the fax sender and receives the fax on behalf of the UM-enabled user. However, to allow UM-enabled users to receive fax messages in their mailbox, you must first deploy Exchange 2010 Unified Messaging, set up and configure the fax partner server, and then configure the UM dial plans, UM mailbox policies, and UM-enabled users to receive faxes. For details, see Deploy and Configure Incoming Faxing.

Return to top

1.2.2.6.2 Checklist: Deploy a New Exchange 2010 RTM UM Environment

Checklist: Deploy a New Exchange 2010 RTM UM Environment

Planning and Deployment > Deploying Exchange 2010 > Understanding Unified Messaging Deployments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-05*

Use this checklist to install and deploy Microsoft Exchange Server 2010 Unified Messaging (UM). Before you start working with this checklist, make sure you're familiar with the concepts in:

- Overview of Unified Messaging
- Deploy a New Exchange 2010 RTM UM Environment

For step-by-step guidance about how to upgrade from Microsoft Exchange Server 2007 to Exchange 2010, see Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM.

Checklist for deploying Exchange 2010 Unified Messaging

Done?	Tasks	Topic
	Deploy and configure the IP gateways, IP PBXs, and PBXs in your organization.	Managing IP Gateways
	Verify that the Exchange server roles other than the Unified Messaging server role have been installed and configured.	Verify an Exchange 2010 Installation
	Install the Unified Messaging server role.	Install the Exchange 2010 Unified Messaging Server Role
	Optional: Install the Unified Messaging language packs you need on the UM servers in your organization.	Install a Unified Messaging Language Pack on a UM Server
	Create the required number of UM dial plans for your organization.	Create a UM Dial Plan
	Configure the UM dial plans in your organization.	View or Configure the Properties of a UM Dial Plan
	Create the required number of UM IP gateways.	Create a UM IP Gateway
	Create the required number of UM hunt groups.	Create a UM Hunt Group
	Add each UM server that has been installed to the appropriate dial plan.	Add a UM Server to a Dial Plan
	Optional: Configuring mutual TLS • Run the Exchange Certificate wizard. • Configure your UM dial plan security setting. • Configure the Startup Mode for each UM server.	• Create a New Exchange Certificate • Configure VoIP Security on a UM Dial Plan • Configure the Startup Mode on a UM Server • Configure a Fully

	• Configure your UM IP gateways to listen on port 5061. • Import your Exchange certificate on each IP gateway or IP PBX.	Qualified Domain Name for a UM IP Gateway • Configure the TCP Listening Port on a UM IP Gateway
	Create the required number of auto attendants.	Create a UM Auto Attendant
	Configure the auto attendants in your organization.	View or Configure the Properties of a UM Auto Attendant
	Create a UM mailbox policy or configure the default UM mailbox policy.	• Create a UM Mailbox Policy • View or Configure the Properties of a UM Mailbox Policy
	Enable users in your organization for Unified Messaging.	Enable a User for Unified Messaging

1.2.2.6.3 Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM

Checklist: Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM UM

Planning and Deployment > Deploying Exchange 2010 > Understanding Unified Messaging Deployments >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-27*

Use this checklist to upgrade an existing Microsoft Exchange Server 2007 Unified Messaging (UM) environment. Before you start working with this checklist, make sure you're familiar with the concepts in:

- Overview of Unified Messaging
- Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

Note:
For more information about how to perform the tasks that must be completed for Microsoft Office Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

Checklist for upgrading to Exchange 2010 Unified Messaging

Done?	Tasks	Topic
	Verify that you have deployed or upgraded	Verify an Exchange 2010 Installation

	the Client Access, Mailbox, and Hub Transport servers in your organization to Exchange Server 2010.	
	Install Exchange 2007 Service Pack 3 (SP3) on all existing Exchange 2007 SP3 servers, including the Unified Messaging servers in your organization.	Download Exchange Server 2007 Service Pack 3 (SP3)
	Install the Exchange 2010 Unified Messaging server role.	Install the Exchange 2010 Unified Messaging Server Role
	Optional: Install the Unified Messaging language packs you need on the UM servers in your organization.	Install a Unified Messaging Language Pack on a UM Server
	Optional: If you're going to have Exchange 2007 SP3 Unified Messaging servers and users with UM-enabled mailboxes on Exchange 2007 SP3 in your Exchange 2010 organization, you'll need to create additional dial plans and UM hunt groups with new pilot numbers. If you're integrating with Communications Server 2007, a new UM SIP URI dial plan is required that has been configured with a new pilot identifier **Note:** You'll need to disable Unified Messaging your users and then re-enable them using the new SIP URI dial plan.	• Create a UM Dial Plan • Create a UM Hunt Group • Managing UM Hunt Groups • Enable a User for Unified Messaging • Disable Unified Messaging for a User
	Add the Exchange 2010 UM servers to the Exchange 2007 SP3 UM dial plan.	Add a UM Server to a Dial Plan
	Import any custom prompts that were created for Exchange 2007 SP3 UM dial plans or auto attendants to	Import-UMPrompt

	Exchange 2010 Unified Messaging.	
	Configure all IP gateways or IP PBXs to send incoming calls to the Exchange 2010 UM servers.	Managing IP Gateways
	Move the Exchange 2007 UM-enabled mailboxes to an Exchange 2010 Mailbox server.	Move Mailboxes from Exchange 2010 Servers to Exchange 2007 Servers
	Remove the Exchange 2007 SP3 Unified Messaging servers from the UM dial plan. **Important:** Only remove the Exchange 2007 SP3 UM servers from the dial plan if there aren't any Exchange 2007 SP3 UM-enabled mailboxes.	Remove a UM Server from a Dial Plan
	Remove the Exchange 2007 SP3 Unified Messaging servers from the Exchange organization. **Important:** Only remove the Exchange 2007 SP3 UM servers from the Exchange organization if there aren't any Exchange 2007 SP3 UM-enabled mailboxes in your organization.	Uninstall the Unified Messaging Server Role in Exchange 2010
	Optional: Deploy and configure incoming faxing.	Deploy and Configure Incoming Faxing

Note:
Exchange 2007 and later versions contain Unified Messaging features. Versions that are earlier than Exchange 2007 SP3 can't be upgraded and require you to deploy an Exchange 2010 organization with all the server roles, including Unified Messaging. For details, see Deploy a New Exchange 2010 RTM UM Environment.

1.2.2.6.4 Install or Upgrade to Exchange 2010 SP2 Unified Messaging

Install or Upgrade to Exchange 2010 SP2 Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-14*

You can deploy Exchange Server 2010 Service Pack 2 (SP2) on your Unified Messaging servers by performing a clean installation of Exchange 2010 SP2, by upgrading from Exchange Server 2007 SP3 to Exchange 2010 SP2, or by upgrading from the RTM or SP1 version of Exchange 2010 to Exchange 2010 SP2.

Upgrading Exchange Unified Messaging Servers to SP2

There are several steps that you must complete to correctly install or upgrade your Exchange Unified Messaging (UM) servers. However, different steps are required depending on the method you're using to deploy Exchange 2010 SP2 on your UM servers. These methods include:

- **A clean installation** You perform a clean installation of the operating system and then install Exchange 2010 SP2 on new hardware. For the steps to perform a clean installation, see Checklist: Install Exchange Server 2010 SP2 on a New UM Server.
- **Upgrading from Exchange 2007 SP3 Unified Messaging** You upgrade an existing Unified Messaging server running Exchange 2007 SP3 to Exchange 2010 SP2. For the steps to upgrade, see Checklist: Upgrade UM from Exchange 2007 SP3 to Exchange 2010 SP2.
- **Upgrading from Exchange 2010 Unified Messaging RTM or SP1** You upgrade an existing Unified Messaging server running the RTM or the SP1 version of Exchange 2010 to Exchange 2010 SP2 Unified Messaging. For the steps to upgrade, see Checklist: Upgrade UM from Exchange 2010 RTM or SP1 to Exchange 2010 SP2.

Performing a Clean Installation of Exchange 2010 SP2

The following steps are required to perform a clean installation of Exchange 2010 SP2 on a new Unified Messaging server.

Step 1: Prerequisites

Starting with Exchange 2010 SP1, the Unified Messaging server role relied on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and speech processing. The UCMA platform, along with its prerequisites, must be installed on the UM server before you install or upgrade UM to Exchange 2010 SP2. If any of the prerequisites are missing from the server, Exchange 2010 SP2 Setup will inform you that the component is missing and provide you with a download link so you can download and install it. Then you can continue by restarting Setup for SP2.

The Unified Messaging server role in Exchange 2010 SP2 relies on the following components and requires that they be installed prior to installing SP2:

- Windows Server 2008 or Windows Server 2008 R2 - Installing Windows Server 2008 R2
- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) - Microsoft .NET Framework 3.5 Service Pack 1
- Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 updates - Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64
- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) - Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0)
- Microsoft Speech Platform - Server Runtime (Version 10.1) (SpeechPlatformRuntime.msi)
- Unified Communications Managed API 2.0, Core Runtime (64-bit) (UcmaRuntimeWebDownloadX64.msi)

Note:
If you've already installed a version of the Unified Communications Managed API v. 2.0 on a Client Access server in your Exchange organization, you must also install a hotfix. For information about how to install the required hotfix, see OCS 2007 R2 Web Service Provider Hotfix KB 981256.

For more information about UCMA, see UCMA 2.0 Core Architecture or Overview of Unified Messaging.

Step 2: Download and Install Exchange 2010 SP2

You can download and install Exchange 2010 SP2 on each server or install SP2 from the Exchange 2010 SP2 DVD. Either way, you use the Microsoft Exchange Server 2010 Service Pack 2 Setup wizard to install Exchange 2010 SP2.

- To download and install Exchange 2010 SP2 from the Web, see Exchange Server 2010 SP2.
- To install Exchange 2010 from the Exchange 2010 SP2 DVD, see Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3.

Step 3: Download and Install the Exchange 2010 SP2 UM Language Packs

Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange 2007, there have been separate releases for UM language packs, including the RTM version of Exchange 2007, Exchange 2007 SP1, SP2, and SP3, the RTM version of Exchange 2010, and Exchange 2010 SP1 and SP2. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available.

It's very important that you install the correct version and platform of the UM language packs on a UM server. Don't install UM language packs on a Unified Messaging server that's running an earlier version of Exchange or that's designed for a 32-bit platform.

The last task to perform when you upgrade is to download and install the required Unified Messaging SP2 language packs that you need on the UM servers in your organization. Make sure to install each UM language pack on each UM server and to set the default language on all dial plans that the UM server is associated with. Setting the default language makes that language available to users. Each UM language pack is bundled in a single .exe file. To download the SP2 UM language packs, see Exchange Server 2010 SP2 UM Language Packs.

Important:
To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don’t install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that's configured on the dial plan, but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won’t work in the language chosen by the user without having both the UM language pack and the Client and Server Language Pack installed. The language pack bundle for Exchange Server 2010 Service Pack 2 (SP2) is integrated into the download for Exchange 2010 SP2. To download SP2 for Exchange 2010, see Microsoft Exchange Server 2010 Service Pack 2 (SP2). However, the language pack bundle for Exchange 2010 SP1 is still available. To download and install the additional Exchange 2010 SP1 client and server language packs on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

Step 4: Add the UM Server to a UM Dial Plan

After you install the Unified Messaging server, it's in an enabled state. However, before the UM server can answer and process incoming calls, you must add the UM server to a UM dial plan. You can add an Exchange 2010 SP2 UM server to one or more UM dial plans that have different security settings at the same time. For more information, see Add a UM

Server to a Dial Plan.

Upgrading Unified Messaging from Exchange 2007 SP3

The following steps are required to perform an upgrade on a Unified Messaging server that has Exchange 2007 SP3 installed to an Exchange 2010 SP2 Unified Messaging server.

Step 1: Verify Installation of Exchange 2010 Servers

Verify that you've deployed or upgraded the Client Access, Mailbox, and Hub Transport servers in your organization to Exchange 2010. For details, see Verify an Exchange 2010 Installation.

Step 2: Disable Call Answering

While you're upgrading the UM server running Exchange 2007 SP3, you don't want it to be able to answering incoming calls. Perform one of the following two tasks to prevent the UM server from answering incoming calls:

- **Disable Unified Messaging** For information about how to do this, see How to Disable Unified Messaging on Exchange 2007.
- **Remove the UM server from a dial plan** For information about how to do this, see How to Remove a Unified Messaging Server from a Dial Plan.

Step 3: Remove Any UM Language Packs

Unified Messaging language packs make it possible for Exchange 2007 and Exchange 2010 UM servers to speak additional languages to callers and recognize languages other than US English (en-US) when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. Several UM language packs are available for Exchange 2010 SP2.

After you install the Unified Messaging sever role, only the en-US UM language pack is available. If you've installed other UM language packs in addition to the en-US language pack on any UM server, you must first remove all Exchange 2007 UM language packs except the en-US language pack (because it can't be removed). You must do this because of the differences between the speech services platform included with Exchange 2007 and the platform used for speech services and SIP signaling in Exchange 2010 SP2. For more information about the new UM language packs that are available, see New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1.

To check which UM language packs are installed, run one of the following commands.

- To see a list of all the language packs that are installed on a specific UM dial plan, run:

```
Get-UMDialPlan identity MyUMDialPlan |FormatList
```

- To see a list of all the UM language packs installed on a single UM server, run:

```
Get-UMServer -identity MyUMServer |FormatList
```

For more information about how to remove a language pack from a UM server, see How to Remove a Unified Messaging Language Pack from a Unified Messaging Server.

After you've removed all the language packs, install the Exchange 2010 SP2 version. For details, see Upgrade Exchange 2010 UM Language Packs from RTM or SP1 to Exchange 2010 SP2.

Important:

If you have multiple UM dial plans in your organization, we recommend that you remove all UM language packs from each of the UM servers that are associated with a single dial plan. After you remove these language packs, you can install the prerequisites and Exchange 2010 SP2 and then install the SP2 UM language packs on each UM server.

Step 4: Prerequisites

Starting with Exchange 2010 SP1, the Unified Messaging server role relied on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and speech processing. The UCMA platform, along with its prerequisites, must be installed on the UM server before you install or upgrade UM to Exchange 2010 SP2. If any prerequisite is missing from the server, Exchange 2010 Setup will inform you that the component is missing and provide you with a link so you can download and install it. Then you can continue by restarting Setup for Exchange 2010 SP2.

The Unified Messaging server role in Exchange 2010 SP2 relies on the following components, and requires that they be installed prior to installing SP2:

- Windows Server 2008 or Windows Server 2008 R2 - Installing Windows Server 2008 R2
- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) - Microsoft .NET Framework 3.5 Service Pack 1
- Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 updates - Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64
- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) - For more information, see Microsoft Knowledge Base article 968930, Windows Management Framework core package (Windows PowerShell 2.0 and WinRM 2.0).
- Microsoft Speech Platform - Server Runtime (Version 10.1) (SpeechPlatformRuntime.msi)
- Unified Communications Managed API 2.0, Core Runtime (64-bit) (UcmaRuntimeWebDownloadX64.msi)

Note:

If you've already installed a version of the Unified Communications Managed API v. 2.0 on a Client Access server in your Exchange organization, you must also install a hotfix. For information about how to install the required hotfix, see OCS 2007 R2 Web Service Provider Hotfix KB 981256.

For more information about UCMA, see UCMA 2.0 Core Architecture or Overview of Unified Messaging.

Step 5: Download and Install Exchange 2010 SP2

After you've removed the Exchange 2010 RTM UM language packs from the UM servers, you can download and install Exchange 2010 SP2 on each UM server. You use the Microsoft Exchange Server 2010 Service Pack 2 Setup wizard to install Exchange 2010 SP2.

- For more information about Exchange 2010 SP2 and to download it, see Exchange Server 2010 SP2.
- For more information about how to install Exchange 2010 SP2, see Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3.

Step 6: Download and Install the SP2 UM Language Packs

Exchange Unified Messaging language packs are version-specific and platform-specific. Since the original release of Exchange 2007, there have been separate releases for UM language packs, including Exchange 2007 RTM, Exchange 2007 SP1, SP2, and SP3, Exchange 2010 RTM, and Exchange 2010 SP1 and SP2. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available.

It's very important that you install the correct version and platform of the UM language packs on a UM server. Don't install UM language packs on a Unified Messaging server that's running an earlier version of Exchange or that's designed for a 32-bit platform.

The last task to perform when you upgrade is to download and install the required Unified Messaging SP2 language packs that you need on the UM servers in your organization.

Make sure to install each UM language pack on each UM server and to set the default language on all dial plans that the UM server is associated with. Setting the default language makes that language available to users. Each UM language pack is bundled in a single .exe file. To download the Exchange 2010 SP2 UM language packs, see Exchange Server 2010 SP2 UM Language Packs.

To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don't install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that's configured on the dial plan but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won't work in the language selected by the user without having both the UM language pack and the Client and Server Language Pack installed. The language pack bundle for Exchange Server 2010 Service Pack 2 (SP2) is integrated into the download for Exchange 2010 SP2. To download SP2 for Exchange 2010, see Microsoft Exchange Server 2010 Service Pack 2 (SP2). However, the language pack bundle for Exchange 2010 SP1 is still available. To download and install the additional Exchange 2010 SP1 client and server language packs on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

Step 7: Add the UM Server to a UM Dial Plan

After you install the Unified Messaging (UM) server, it's in an enabled state. However, before the UM server can answer and process incoming calls, you must add the UM server to a UM dial plan. You can add an Exchange 2010 SP2 UM server to one or more UM dial plans that have different security settings at the same time. For more information, see Add a UM Server to a Dial Plan.

Upgrading from the RTM or SP1 version of Exchange 2010 to SP2

The following steps are required to upgrade a Unified Messaging server running the RTM or SP1 version of Exchange 2010 to Exchange 2010 SP2.

Step 1: Disable Call Answering

While you're upgrading the UM server running Exchange 2010 RTM or SP1, you don't want it to be able to answering incoming calls. Perform one of the following two tasks to prevent the UM server from answering incoming calls:

- **Disable Unified Messaging** For information about how to do this, see Disable Unified Messaging on Exchange 2010.
- **Remove the UM server from a dial plan** For information about how to do this, see Remove a UM Server from a Dial Plan.

Step 2: Prerequisites

Starting with Exchange 2010 SP1, the Unified Messaging server role relied on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and speech processing. The UCMA platform, along with its prerequisites, must be installed on the UM server before you install or upgrade UM to Exchange 2010 SP2. If any prerequisite is missing from the server, Exchange 2010 Setup will inform you that the component is missing and provide you with a link so you can download and install it. Then you can continue by restarting Setup for Exchange 2010 SP2.

The Unified Messaging server role in Exchange 2010 SP2 relies on the following, and requires that they be installed prior to installing SP2:

- Windows Server 2008 or Windows Server 2008 R2 - Installing Windows Server 2008 R2
- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) - Microsoft .NET Framework 3.5 Service Pack 1
- Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 updates - Microsoft .NET Framework 3.5 Family

Update for Windows Vista x64, and Windows Server 2008 x64

- Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) - For more information, see Microsoft Knowledge Base article 968930, Windows Management Framework core package (Windows PowerShell 2.0 and WinRM 2.0).
- Microsoft Speech Platform - Server Runtime (Version 10.1) (SpeechPlatformRuntime.msi)
- Unified Communications Managed API 2.0, Core Runtime (64-bit) (UcmaRuntimeWebDownloadX64.msi)

Note:
If you've already installed a version of the Unified Communications Managed API v. 2.0 on a Client Access server in your Exchange organization, you must also install a hotfix. For information about how to install the required hotfix, see OCS 2007 R2 Web Service Provider Hotfix KB 981256.

For more information about UCMA, see UCMA 2.0 Core Architecture or Overview of Unified Messaging.

Step 3: Remove any RTM or SP1 UM Language Packs

Unified Messaging language packs make it possible for Exchange 2007 and Exchange 2010 UM servers to speak additional languages to callers and recognize languages other than US English (en-US) when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. Several UM language packs are available for Exchange 2010 SP2. For more information about the new UM language packs that are available, see New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1.

After you install the Unified Messaging sever role, only the en-US UM language pack is available. If you've installed other UM language packs in addition to the en-US language pack on any UM server, you must first remove all Exchange 2010 RTM or SP1 UM language packs except the en-US language pack (because it can't be removed). You must do this because of the differences between the speech services platform included with Exchange 2007 SP3 and Exchange 2010 RTM and SP1 and the platform used for speech services and SIP signaling in Exchange 2010 SP2.

To check which UM language packs are installed, run one of the following commands.

- To see a list of all the language packs that are installed on a specific UM dial plan, run:

```
Get-UMDialPlan identity MyUMDialPlan |FormatList
```

- To see a list of all the UM language packs installed on a single UM server, run:

```
Get-UMServer -identity MyUMServer |FormatList
```

For more information about how to remove a language pack from a UM server, see Remove a Unified Messaging Language Pack from a UM Server.

After you've removed all the language packs, install the Exchange 2010 SP2 version. For details, see Upgrade Exchange 2010 UM Language Packs from RTM or SP1 to Exchange 2010 SP2.

Important:
If you have multiple UM dial plans in your organization, we recommend that you remove all UM language packs from each of the UM servers that are associated with a single dial plan. After you remove these language packs, you can install the prerequisites and Exchange 2010 SP2 and then install the SP2 UM language packs on each UM server.

Step 4: Download and Install Service Pack 2

After you've removed the Exchange 2010 RTM UM language packs from the UM servers,

you can download and install Exchange 2010 SP2 on each UM server. You use the Microsoft Exchange Server 2010 Service Pack 2 Setup wizard to install Exchange 2010 SP2.

- For more information about Exchange 2010 SP2 and to download it, see Exchange Server 2010 SP2.
- For more information about how to install Exchange 2010 SP2, see Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3.

Step 5: Download and Install the SP2 UM Language Packs

Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange 2007, there have been separate releases for UM language packs, including Exchange 2007 RTM, Exchange 2007 SP1, SP2, and SP3, Exchange 2010 RTM, and Exchange 2010 SP1 and SP2. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available.

It's very important that you install the correct version and platform of the UM language packs on a UM server. Don't install UM language packs on a Unified Messaging server that's running an earlier version of Exchange or that's designed for a 32-bit platform.

The last task to perform when you upgrade is to download and install the required Unified Messaging SP2 language packs that you need on the UM servers in your organization. Make sure to install each UM language pack on each UM server and to set the default language on all dial plans that the UM server is associated with. Setting the default language makes that language available to users. Each UM language pack is bundled in a single .exe file. To download the Exchange 2010 SP2 UM language packs, see Exchange Server 2010 SP2 UM Language Packs.

Important:

To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don’t install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that’s configured on the dial plan but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won’t work in the language selected by the user without having both the UM language pack and the Client and Server Language Pack installed. The language pack bundle for Service Pack 2 (SP2) is integrated into the download for Exchange Server 2010 SP2. To download SP2 for Exchange 2010, see Microsoft Exchange Server 2010 Service Pack 2 (SP2). However, the language pack bundle for Exchange 2010 SP1 is still available. To download and install the additional Exchange 2010 SP1 client and server language packs on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

Step 6: Add the UM Server to a UM Dial Plan

When you install the Unified Messaging (UM) server, it's left in an enabled state. However, before the UM server can answer and process incoming calls, you must add the UM server to a UM dial plan. You can add a Microsoft Exchange Server 2010 SP2 UM server to one or more UM dial plans with different security settings at the same time. For details, see Add a UM Server to a Dial Plan.

1.2.2.6.4.1 Checklist: Install Exchange Server 2010 SP2 on a New UM Server

Checklist: Install Exchange Server 2010 SP2 on a New UM Server

Deploying Exchange 2010 > Understanding Unified Messaging Deployments > Install or Upgrade to Exchange 2010 SP2 Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

Use this checklist to install Microsoft Exchange Server 2010 Service Pack 2 (SP2) on a new Exchange Unified Messaging (UM) server that you're deploying. Before you start to work with this checklist, make sure you're familiar with the concepts in the following topics:

- What's New in Exchange 2010 SP2
- New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1

Checklist for installing Exchange 2010 SP2 on a new UM server

Done?	Tasks	Topic
	Install Windows Server 2008 or a later version.	• Exchange 2010 Prerequisites • Installing Windows Server 2008 R2
	Prerequisites: • Install Microsoft .NET Framework 3.5 Service Pack 1 (SP1). • Install the Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 updates. • Install Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu). • Install the Microsoft Speech Platform - Server Runtime (Version 10.1) (SpeechPlatformRuntime.msi). • Do one of the following: • If you've installed a version of Communications Managed API 2.0 other than the UCMA Core Runtime on a Client Access server in your Exchange organization, you must also install the OCS 2007 R2 Web Service Provider Hotfix KB 981256. • If you haven't installed a version of Communications	• Microsoft .NET Framework 3.5 Service Pack 1 • Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 • Windows Management Framework Core package (Windows PowerShell 2.0 and WinRm 2.0) • Microsoft Speech Platform - Server Runtime (Version 10.1) • OCS 2007 R2 Web Service Provider Hotfix KB 981256 • Unified Communications Managed API 2.0, Core Runtime (64-bit)

	Managed API 2.0 on a Client Access server in your Exchange organization, you must install the Unified Communications Managed API 2.0, Core Runtime (64-bit).	
	Download Exchange 2010 Service Pack 2 (SP2).	Download SP2 for Exchange Server 2010
	Run Setup.exe to install SP2.	Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3
	Download and install the required Exchange 2010 SP2 Unified Messaging language packs on the UM server.	• Exchange Server 2010 SP2 UM Language Packs • Install a Unified Messaging Language Pack on a UM Server
	Add the Unified Messaging server that's running Exchange 2010 SP2 to a UM dial plan.	Add a UM Server to a Dial Plan

1.2.2.6.4.2 Checklist: Upgrade UM from Exchange 2007 SP3 to Exchange 2010 SP2

Checklist: Upgrade UM from Exchange 2007 SP3 to Exchange 2010 SP2

Deploying Exchange 2010 > Understanding Unified Messaging Deployments > Install or Upgrade to Exchange 2010 SP2 Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-27*

Use this checklist to upgrade an existing Unified Messaging (UM) server running Microsoft Exchange Server 2007 SP3 to Exchange Server 2010 Service Pack 2 (SP2). Before you start to work with this checklist, make sure you're familiar with the concepts in the following topics:

	Add the Unified Messaging server that's running Exchange 2010 SP2 to a UM dial plan.	Add a UM Server to a Dial Plan

1.2.2.6.4.4 Upgrade Exchange 2010 UM Language Packs from RTM or SP1 to Exchange 2010 SP2

Upgrade Exchange 2010 UM Language Packs from RTM or SP1 to Exchange 2010 SP2

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

Unified Messaging (UM) language packs enable the Exchange 2010 UM server to speak additional languages to callers and recognize languages other than US English (en-US) when callers use Automatic Speech Recognition (ASR) or when voice messages are transcribed. For more information, see Client Language Support for Unified Messaging.

Upgrading RTM or SP1 UM Language Packs to SP2

When you upgrade an existing Unified Messaging server to Exchange 2010 SP2, there are specific steps you must follow to replace the Exchange 2010 RTM or SP1 UM language packs that are installed on the server with the Exchange 2010 SP2 version of the UM language packs.

To upgrade the UM servers to use UM language packs for Exchange 2010 SP2, follow these steps:

Step 1 Install the prerequisites on the UM servers that you'll be upgrading to SP1. For more information, see Install or Upgrade to Exchange 2010 SP2 Unified Messaging.

Step 2 Determine which RTM or SP1 UM language packs are installed on each UM server that you'll be upgrading. To see which languages are available or installed, use one of the following commands:

- For a list of all available languages per UM dial plan, run:

```
Get-UMDialPlan identity MyUMDialPlan |FormatList
```

- For a list of all available UM languages installed on a single UM server, run:

```
Get-UMServer -identity MyUMServer |FormatList
```

Step 3 Remove all RTM or SP1 UM language packs from the UM servers that you'll be upgrading. For more information, see Remove a Unified Messaging Language Pack from a UM Server.

Step 4 Download Exchange Server 2010 SP2. For more information, see Download SP2 for Exchange Server 2010.

Step 5 Install Exchange 2010 SP2 on the UM servers that you're upgrading. For more information, see Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3.

Step 6 Download Exchange 2010 SP2 UM language packs that you need. For more information, see Exchange Server 2010 UM Language Packs for SP2. You'll have to download the SP2 version of each RTM or SP1 UM language pack that was installed on the UM servers.

Step 7 Install the Exchange 2010 SP2 UM language packs that you downloaded. For more information, see Install a Unified Messaging Language Pack on a UM Server.

Important:

To ensure that all Unified Messaging features are available in the UM language packs you install, install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don't install the Client and Server Language Pack, some features may not work as expected. Some features, for example, Voice Mail Preview, will work in a specific language when only the UM language pack is installed. However, features such as Outlook Voice Access and user interface text won't work in a specific language without having both the UM language pack and the Client and Server Language Pack installed. The language pack bundle for Exchange Server 2010 Service Pack 2 (SP2) is integrated into the download for Exchange 2010 SP2. To download SP2 for Exchange 2010, see Microsoft Exchange Server 2010 Service Pack 2 (SP2). However, the language pack bundle for Exchange 2010 SP1 is still available. To download and install the additional Exchange 2010 SP1 client and server language packs on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

1.2.2.6.5 Deploy and Configure Incoming Faxing

Deploy and Configure Incoming Faxing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-14*

Microsoft Exchange Server 2010 Unified Messaging (UM) relies on certified fax partner solutions for enhanced fax functionality such as outbound fax or fax routing. By default, when you install the Unified Messaging server role, the server isn't configured to allow incoming fax messages to be delivered to a UM-enabled user. Instead, the UM server redirects incoming fax calls to a certified fax partner solution. The fax partner's server receives the fax data and then sends it to the recipient's mailbox in an e-mail message

with the fax included as a .tif attachment.

The Unified Messaging server ensures that the final message delivered to the user is identical to the fax messages generated by Microsoft Exchange Server 2007 Unified Messaging. However, the fax partner solution must meet a set of requirements to interoperate with Exchange 2010 Unified Messaging. For details about the Fax Partner program, see Fax Advisor for Exchange 2010.

Deploying and Configuring Faxing

Exchange 2010 UM forwards incoming fax calls to a dedicated fax partner solution, which then establishes the fax call with the fax sender and receives the fax on behalf of the UM-enabled user. However, to allow UM-enabled users to receive fax messages in their mailbox, you must first run Exchange 2010 Unified Messaging setup and configure the Fax Partner server, and then configure the UM dial plans, UM mailbox policies, and enable UM-enabled users to receive faxes. For details, see Managing Unified Messaging Components.

Step 1: Deploy Unified Messaging

To correctly deploy faxing, you must first successfully deploy Unified Messaging servers in your organization and configure your supported IP gateways to allow faxing. For details about how to deploy UM, see Deploy a New Exchange 2010 RTM UM Environment. For details about how to deploy IP gateways, see Managing IP Gateways.

Important:

Sending and receiving faxes using T.38 or G.711 isn't supported in an environment where Unified Messaging and Microsoft Office Communications Server 2007 are integrated.

Step 2: Configure Fax Partner Servers

You must next install and configure the Fax Partner server or servers in your organization. There are specific steps that you must take to successfully integrate the fax partner server with Exchange 2010 Unified Messaging. For details, see Fax Advisor for Exchange 2010.

Note:

Microsoft Windows firewall ports on the fax partner server must be configured to allow the SIP signaling traffic using either TCP port 5060 or 5061, and also be configured to allow fax data that uses a UDP port range defined by the manufacturer.

Step 3: Enable Faxing on Unified Messaging

There are three components that must be configured correctly for users to be able to receive faxes by using Exchange 2010 Unified Messaging:

- UM dial plans
- UM mailbox policies
- UM mailboxes

Faxing can be enabled or disabled on UM dial plans, UM mailbox policies, or on the UM-enabled user's mailbox. By default, although the user's mailbox allows incoming faxes, you must first enable inbound faxing on the UM mailbox policy that's associated with the UM-enabled user and then enter the fax partner server's URI.

To enable UM-enabled users to receive faxes, you must do the following:

- Verify that each UM dial plan allows the users who are associated with the dial plan to receive faxes. By default, all users who are associated with a dial plan can receive faxes. For UM-enabled users to receive fax messages in their mailbox, each Unified Messaging server that's associated with the dial plan must be configured to accept incoming fax calls. You must also enable fax messages to be received by users who are associated with the dial plan. For more information about how to enable users associated with a dial plan to receive faxes or to prevent them from doing this, see Enable UM-Enabled Users to Receive Faxes on a UM Dial Plan.

Note:
If you prevent fax messages from being received on a dial plan, no users who are associated with the dial plan will be able to receive fax messages, even if you configure an individual user's properties to allow them to receive fax messages. Enabling or disabling faxing on a UM dial plan takes precedence over the settings for an individual UM-enabled user.

- Configure the UM mailbox policy that's associated with the UM-enabled user. The UM mailbox policy must be configured to allow incoming faxes, including the fax partner's URI and the name of the fax partner's server. The *FaxServerURI* must use the following form: sip:*<fax server URI>*:*<port>*;*<transport>*, where "Fax Server URI" is either an FQDN or an IP address of the fax partner server. The "port" is the port on which the fax server listens for incoming fax calls and "transport" is the transport protocol that's used for the incoming fax (UDP, TCP, or TLS). For example, you might configure fax as follows:

```
Set-UMMailboxPolicy MyUMMailboxPolicy -AllowFax $true -FaxServerURI "si
```

  For details, see Enable or Disable Inbound Faxing on a UM Mailbox Policy.
- Verify that the Exchange 2010 mailbox that's UM-enabled can receive fax messages. By default, all users who are associated with a dial plan can receive faxes. However, there may be situations when a user can't receive faxes because the ability to receive faxes has been disabled on their mailbox. For more information about how to enable a UM-enabled user to receive faxes, see Enable a UM-Enabled User to Receive Faxes.
  You can prevent a single user who's associated with a dial plan from receiving fax messages. To do this, configure the properties for the user by using the Exchange Management Console or by using the **Set-UMMailbox** cmdlet in the Exchange Management Shell. You can also use the **Set-UMMailbox** cmdlet to prevent multiple users from receiving fax messages. For more information about how to prevent a user or users from receiving fax messages, see Prevent a UM-Enabled User from Receiving Faxes.

Step 4: Configuring Authentication

In addition to configuring your UM dial plans, UM mailbox policies, and UM-enabled users, you have to configure authentication between the UM server and the fax partner server. The UM server must be able to authenticate the origin of the messages claiming to be coming from the fax partner's server.

Fax messages sent to a UM server from a fax partner server must be authenticated and any unauthenticated messages claiming to have come from a fax partner server will not be processed by the UM server. To authenticate the connection from the fax partner to a UM server, you can use:

- Mutual TLS
- Sender ID validation
- A dedicated receive connector

A receive connector should be sufficient for authenticating the fax partner servers deployed in your organization together with the UM server. The receive connector will ensure that the Exchange server treats all traffic coming from the fax partner server as authenticated.

The receive connector should be deployed on the Hub Transport server used by the fax partner server to submit SMTP fax messages, and must be configured with the following values:

- *AuthMechanism: ExternalAuthoritative*
- *PermissionGroups: ExchangeServers, PartnersFax*
- *RemoteIPRanges: {the fax server's IP address}*
- *RequireTLS: False*

- *EnableAuthGSSAPI: False*
- *LiveCredentialEnabled: False*

For details, see Managing Connectors.

If the fax partner server sends network traffic to a UM server over a public network, for example, a service-based fax partner server hosted in the cloud, we recommend that you authenticate the fax partner server using a sender ID check. This type of authentication ensures that the IP that the fax message came from is, in fact, authorized to send e-mail message on behalf of the fax partner domain that the message claims to have come from. DNS is used to store the sender ID records (or SPF records) and fax partners must publish their SPF records in the DNS forward lookup zone. Exchange 2010 will validate the IP addresses by querying DNS. However, the sender ID agent must be running on an Exchange 2010 Edge server to be able to perform the DNS query.

You can also use TLS to encrypt the network traffic, or mutual TLS for encryption and authentication between the fax partner server and an Exchange 2010 Unified Messaging server. For details, see Understanding Unified Messaging VoIP Security.

1.2.2.6.6 Deploy Unified Messaging and Communications Server 2007 R2

Deploy Unified Messaging and Communications Server 2007 R2

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-13*

Microsoft Exchange Server 2010 Unified Messaging (UM) and Microsoft Office Communications Server 2007 can be deployed together to provide voice messaging, instant messaging, enhanced user presence, audio/video conferencing, and an integrated e-mail and messaging experience for users in your organization. This topic discusses how to configure Exchange 2010 Unified Messaging and Communications Server 2007 to support these features.

Looking for more information about Communications Server 2007? See the reference and Help documentation for Communications Server 2007 in the Office Communications Server and Client Documentation Rollup.

Contents

Deploying Exchange Unified Messaging and Communications Server 2007

Exchange 2010 Unified Messaging combines voice messaging and e-mail messaging into a single messaging infrastructure. Communications Server 2007 Enterprise Voice takes advantage of the Unified Messaging infrastructure to provide voice mail, subscriber

access, call notification, and auto attendant services.

Before you can implement these services or features, you must do the following:

- Install Communications Server 2007 in the same Active Directory directory service topology as the Unified Messaging servers.
- Deploy the following Exchange 2010 server roles:
  - **Unified Messaging server role** The Unified Messaging server connects Exchange 2010 with Communications Server 2007.
  - **Hub Transport server role** The Hub Transport server routes e-mail messages from the Unified Messaging server to user mailboxes.
  - **Client Access server role** The Client Access server hosts client protocols, such as POP3, IMAP4, HTTPS, Outlook Anywhere (formerly known as RPC over HTTP), the Availability service, and the Autodiscover service. The Client Access server also hosts Exchange Web Services.
  - **Mailbox server role** The Mailbox server hosts user mailboxes.

    For more information about the server roles included in Exchange 2010, see Getting Started With Exchange 2010. For more information about how to install each server role included in Exchange 2010, see Understanding a New Installation of Exchange 2010.
- Install and configure Communications Server 2007 in your organization as follows:
  - Install Communications Server 2007 on servers in your organization.
  - Install a certificate that's valid and signed by a certification authority (CA) on the Communications Server 2007 servers.
  - Make sure that the certificate that you installed on the Communications Server 2007 servers is trusted by the Unified Messaging servers.
  - Confirm that at least one Communications Server 2007 pool object is created during installation.

Certificate Configuration Recommendations

You must have a certificate that's trusted by both the computers running Exchange and Communications Server 2007. In an environment that has Communications Server 2007 and Exchange 2010 Unified Messaging, use the following guidelines for deploying a trusted certificate:

- Import a certificate that's valid and signed by a CA. This should be a trusted third-party commercial certificate or a public key infrastructure (PKI) certificate and should be imported on the Communications Server 2007 computers and the Exchange servers that have the Unified Messaging and Client Access server roles installed.
- The most simple certificate deployment scenario is to import the same third-party commercial or PKI certificate to each Exchange 2010 server that has the following server roles installed: Unified Messaging, Client Access, and Hub Transport. Also, install this trusted certificate on each computer running Communications Server 2007. This will help simplify your certificate deployment and reduce the administrative overhead associated with deploying certificates. However, you must obtain a trusted certificate that supports subject alternative names.

  Note:

  If you use a SIP secured or Secured dial plan, a trusted certificate is required between the Unified Messaging servers and the IP gateways. A trusted certificate is also required if a direct Session Initiation Protocol (SIP) connection is used. If you use a SIP secured or Secured dial plan, you can use the same trusted certificate used between Communications Server 2007 computers and the Unified Messaging, Client Access, and Hub Transport servers.
- Although you can install the Unified Messaging server role and other Exchange 2010 server roles on the same computer, when you deploy Communications

Server 2007, we recommend that you install the Unified Messaging server role on a computer that won't be running other Exchange 2010 server roles. If another server role is installed on the same computer as the Unified Messaging server role, the Microsoft Exchange Unified Messaging service may select the incorrect certificate and be unable to use mutual Transport Layer Security (mutual TLS) to encrypt traffic. This occurs because of limitations with subject alternative names found in certificates.
For example, if you install the Unified Messaging server role first, and then later install the Client Access server role on the same server, the Microsoft Exchange Unified Messaging service will use the certificate created by the Client Access server role instead of the certificate created when the Unified Messaging server role was installed. This is because the Microsoft Exchange Unified Messaging service looks for the certificate in the trusted root store that has the most time left before it will expire.

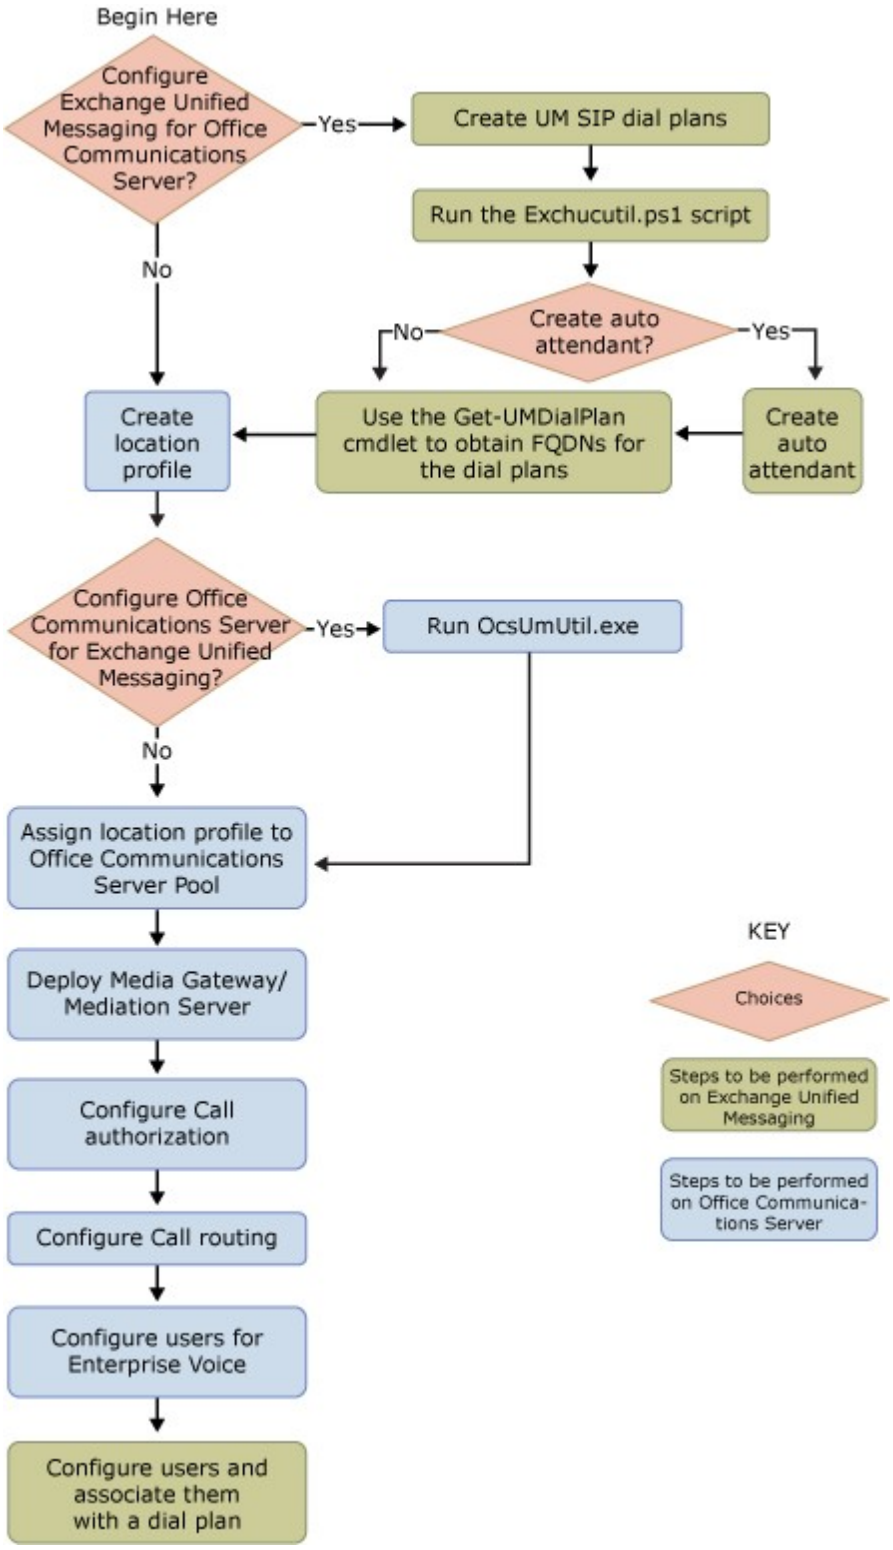
- Because the trusted certificate uses mutual TLS to establish an encrypted channel with Communications Server 2007 and with Client Access, Hub Transport, and Unified Messaging servers, the name on the certificate used during mutual TLS negotiation must match the fully qualified domain name (FQDN) of the server that presents the certificate.

Return to top

Deployment Path

After you install the required server roles in your Exchange 2010 organization, there's a recommended sequence of steps that you must perform on the Exchange Unified Messaging environment and in your Communications Server 2007 environment to correctly deploy Enterprise Voice and Exchange 2010 Unified Messaging. Exchange 2010 Unified Messaging is used to provide call answering, Outlook Voice Access, and auto attendant services. Communications Server 2007 enables more advanced features found in Enterprise Voice services. The following figure illustrates the recommended deployment path for implementing Enterprise Voice services found with Exchange 2010 Unified Messaging and Communications Server 2007.

Deploying Exchange 2010 Unified Messaging and Communications Server 2007



For more information about Communications Server 2007 and to download the reference and Help documentation for Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

There are several steps that you must complete to configure Exchange 2010 Unified Messaging to work with Enterprise Voice in Communications Server 2007. You must do the following:

1. Create one or more Exchange 2010 Unified Messaging SIP Uniform Resource Identifier (URI) dial plans that each map to a corresponding Communications Server 2007 location profile. An Enterprise Voice location profile must be created for each Exchange UM dial plan. You can use the **Get-UMDialPlan** cmdlet to obtain the FQDN of a SIP URI dial plan. For more information about how to create a SIP URI dial plan, see Create a UM Dial Plan.

   Important:
   When you are integrating Exchange Unified Messaging and Office Communications Server, you'll probably find it unnecessary to configure dialing rules or dialing rule groups in Exchange Unified Messaging. Office Communications Server is designed to perform call routing and number translation for users in your organization, and will also do this when the calls are made by Exchange Unified Messaging on behalf of users.

2. Install a certificate on the Unified Messaging servers that's valid and signed by a CA, and then restart the Microsoft Exchange Unified Messaging service on each Unified Messaging server.
3. Encrypt the Voice over IP (VoIP) traffic by configuring the SIP URI dial plan as SIP secured or Secured. For more information about how to configure the security settings on a UM dial plan, see Configure VoIP Security on a UM Dial Plan. For more information about VoIP security and configuring mutual TLS, see Understanding Unified Messaging VoIP Security.
   Although a UM dial plan can be configured as SIP secured or Secured, we recommend that you configure the dial plan as Secured to enable Microsoft Office Communicator 2007 Phone Edition devices to work correctly. This is recommended because of the default encryption level settings configured in Communications Server 2007. A Communicator Phone Edition device will only work if the encryption settings are configured as shown in the following table. This table shows the relationship between the encryption settings for both Communications Server 2007 and UM dial plans.
   Encryption settings for Communicator Phone Edition

Communications Server 2007	UM dial plan
Encryption required (default)	Secured
Encryption optional	SIP secured/secured
No encryption	SIP secured

4. Add the servers running the Unified Messaging server role to the SIP dial plan. To enable the server to answer incoming calls, you must add the Unified Messaging server to a dial plan. For more information about how to add a Unified Messaging server to a dial plan, see Add a UM Server to a Dial Plan.
5. Create a SIP address for the users who will use Enterprise Voice. For more information about how to create a SIP address for a UM-enabled user, see Enable a User for Unified Messaging. Or if you want to change the SIP address for a UM-enabled user, see Modify a SIP Address for a UM-Enabled User.

   Important:
   Users who are associated with a SIP URI dial plan cannot receive incoming faxes. This is because incoming voice and fax calls are routed through a mediation server and faxing isn't supported when using a mediation server.

6. Open the Exchange Management Shell and run the exchucutil.ps1 script located in the <Exchange Installation folder>\Exchange Server\Script folder. The exchucutil.ps1 script does the following:
   - Grants Communications Server 2007 permission to read Exchange UM Active Directory objects, specifically, the SIP URI dial plan objects created in

the previous task. For more information about how to configure permissions on Active Directory objects, see How to Use ADSI Edit to Apply Permissions.

- Creates a UM IP gateway in Active Directory for each Communications Server 2007 pool or for each server running Communications Server 2007 Standard Edition that hosts users who are enabled for Enterprise Voice. For more information about how to create a UM IP gateway, see Create a UM IP Gateway.
- Creates an Exchange UM hunt group for each IP gateway. The hunt group pilot identifier will be the name of the dial plan associated with the corresponding gateway. The hunt group must specify the Exchange 2010 Unified Messaging SIP dial plan used with the UM IP gateway. For more information about how to create a UM hunt group, see Create a UM Hunt Group.

Return to top

You must also complete the following tasks to configure Communications Server 2007 to work with Exchange 2010 Unified Messaging:

- Create location profiles. The location profile name must match the FQDN of the corresponding UM dial plans.
- Assign location profiles to Communications Server 2007 pools.
- Deploy and configure media gateways and mediation servers.
- Define telephone usages, voice policies, and outbound call routes.
- Configure the users for Enterprise Voice services.
- Run the **ocsumutil.exe** command that creates the contact objects for subscriber access and for the auto attendant. It also validates that there's a location profile name that matches the FQDN of the Exchange UM dial plan.

Note:

When you install Communications Server 2007, the **msRTC-SIPLine** attribute is added to Active Directory. If you haven't installed Communications Server 2007 in your environment, this attribute isn't added to Active Directory, and caller ID name resolution across dial plans in a single forest and in cross-forest scenarios won't work correctly unless you configure Unified Messaging proxy addresses for users who aren't UM-enabled.

For more information about how to perform the tasks that must be completed for Communications Server 2007, see Office Communications Server and Client Documentation Rollup.

After you configure the Communications Server 2007 and the Unified Messaging servers, you must enable the user to use Communications Server 2007 and install Communicator on the user's client computer.

Important:

Sending and receiving faxes using T.38 or G.711 isn't supported in an environment when Unified Messaging and Office Communications Server are integrated.

Create Additional Routing Group Connectors from Exchange 2010 to Exchange 2003

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Exchange Management Shell to configure routing group connectors between the default routing group in Microsoft Exchange Server 2010 and Exchange Server 2003 routing groups.

The first routing group connector between Exchange 2010 and Exchange 2003 is created and configured during installation of the first Hub Transport server role in an existing Exchange organization. Perform this procedure if you have planned your routing topology and decided to create additional connectors between Exchange versions.

Important:

You can't use Exchange System Manager in Exchange 2003 to manage the Exchange 2010 routing group or any routing group connectors that include an Exchange 2010 Hub Transport server as either a source server or target server.

To learn more about routing group connectors between Exchange 2010 and Exchange 2003, see Upgrade from Exchange 2003 Transport.

Prerequisites

Suppress minor link state updates on all Exchange 2003 servers. For more information about how to suppress link state updates, see the "Link State Updates in a Coexistence Environment" section in Upgrade from Exchange 2003 Transport.

Use the Shell to create a routing group connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Routing group connectors" entry in the Transport Permissions topic.

Note:
You must use the Shell to create and manage routing group connectors. They aren't shown in the EMC.

This example creates reciprocal routing group connectors between the Exchange 2010 routing group and the routing group associated with the specified Exchange 2003 server, assigns a cost of 10 to that connector, and enables public folder referrals.

```
New-RoutingGroupConnector -Name "Interop RGC" -SourceTransportServers "Ex2010Hub1
```

1.2.2.7.2 Deploy the Edge Transport Server Role in an Existing Exchange 2003 Organization Before Upgrading to Exchange 2010

Deploy the Edge Transport Server Role in an Existing Exchange 2003 Organization Before Upgrading to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Using an Edge Transport server, you can provide anti-spam, antivirus, and transport rules processing for your Exchange organization. You can deploy and configure an Edge Transport server to act as a smart host in the perimeter network of an existing Microsoft Exchange Server 2003 organization before you start upgrading your existing Exchange 2003 servers to Exchange Server 2010. Although it's a better practice to introduce Exchange 2010 into your Exchange 2003 organization and use Edge subscriptions, you may want to start using Edge servers before you start your upgrade. This deployment option may be desirable in the following scenarios:

- You want to start utilizing the benefits of Edge protection before beginning the upgrade of your internal Exchange organization.
- You have multiple sites that won't be upgraded all at the same time, and you want the servers in these sites to send mail directly to the perimeter before they're upgraded.
- You have an Exchange 2010 deployment and your organization merges with or acquires another organization that has Exchange 2003 deployed, and you want to centralize mail flow through your Edge servers.

Note:
In the scenario described in this topic, no computers running Microsoft Exchange Server 2010 have been deployed in the Exchange organization. This limits the available features

on the Edge Transport server because you can't use any of the features that rely on Edge Subscription. The features that rely on Edge Subscription are recipient lookup and safelist aggregation. If you want to create an Edge Subscription, you must deploy at least one Exchange 2010 Hub Transport server in the Exchange organization and configure the organization for coexistence. For more information, see Upgrade from Exchange 2003 Transport.

Looking for other management tasks related to Edge Transport servers? Check out Managing Transport Servers.

Prerequisites

- An Edge Transport server has been deployed in the perimeter network. For detailed steps, see Install Exchange 2010 Using the Custom Installation Type.
- An Edge Transport server has been configured to perform antivirus and anti-spam processing and to apply transport rules. For detailed steps, see Managing Anti-Spam and Antivirus Features and Managing Transport Rules.
- Accepted domains are configured on the Edge Transport server. You need to create an accepted domain entry for each SMTP domain for which the Exchange organization receives e-mail. For detailed steps, see Transport Server Post-Deployment Tasks.
- Verify the configuration of the Domain Name System (DNS) mail exchange (MX) resource record for those domains and make any changes that may be needed so that e-mail to your accepted domains is directed to the Edge Transport server.
- Determine the authentication method that will be used to help secure the connection between the Edge Transport server and the Exchange organization. We recommend that you use Basic authentication over Transport Layer Security (TLS). Alternatively, you can decide to use Externally Secured as your authentication mechanism. This authentication mechanism relies on network security, such as Internet Protocol security (IPsec), to help secure the connection. For more information about the authentication methods that are available, see Securing Transport Servers.

Deploy an Edge Transport server in an Exchange 2003 Organization

For all deployments, you must first create a Send connector from the Edge Transport server to the Internet. Then, configure mail flow as appropriate for your selected authentication method.

Create a Send connector from the Edge Transport server to the Internet

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Use the New Send Connector wizard in the EMC to create a Send connector on the Edge Transport server with the following settings:

- **Introduction page** In **Select the intended use for this Send connector**, select **Internet**.
- **Address space page** Click **Add**, and in the **SMTP Address Space** dialog, type * (an asterisk).

For detailed steps, see Create an SMTP Send Connector.

Alternatively, you can use the **New-SendConnector** cmdlet to create the connector in the Shell. This example creates the Send connector To Internet, which uses DNS to route messages.

```
New-SendConnector -Name "To Internet" -AddressSpaces * -Usage Internet -DNSRoutin
```

If you use a smart host to route messages to the Internet, you need to use different parameters. This example creates the same Send connector but configures it to use the smart host 10.10.1.1 instead of DNS to route messages.

```
New-SendConnector -Name "To Internet" -AddressSpaces * -Usage Internet -DNSRoutin
```

For detailed syntax and parameter information, see New-SendConnector.

Note:

When you install the Edge Transport server role, a default Receive connector is created that's configured to receive mail from the Internet. Therefore, you don't need to create a Receive connector that corresponds to the Send connector you created in this section.

Configure mail flow between the Edge Transport server and the Exchange 2003 organization using Basic authentication over TLS

The procedures in this section help you configure secured mail flow between the Edge Transport server and the Exchange 2003 organization using Basic authentication over TLS.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Configure credentials for authenticated mail flow

1. Create the credentials used by the Edge Transport server to authenticate to the Exchange 2003 server. Create a user account in Active Directory that services the Exchange organization. Add the user account to the Exchange Domain Servers security group.

   Important:

   This account is granted the permissions and rights assigned to Exchange servers. Make sure that you safeguard the account credentials to prevent misuse of the account. You can configure the account to enable logon to specific computers only.

2. On the Edge Transport server, create the credentials used by the Exchange 2003 server to authenticate to the Edge Transport server. Create a user account in the Users folder in the Local Users and Groups container on the Edge Transport server.

Configure Exchange 2003 to accept messages from the Edge Transport server

On the Exchange 2003 server or servers that will receive messages from the Edge Transport server, verify that the SMTP virtual server is configured to enable Basic authentication over TLS.

1. Open Exchange System Manager. Expand the **Servers** node. Expand the

desired server. Expand the **Protocols** node. Expand **SMTP**. Right-click **Default SMTP Virtual Server**, and select **Properties**.
2. Click the **Access** tab, and then click **Authentication**.
3. In the **Authentication** dialog box, select **Basic authentication (password is sent in clear text)** and **Requires TLS encryption**. Click **OK**.
4. Click **OK** to close **Default SMTP Virtual Server Properties**.

Create a Send connector from the Edge Transport server to the Exchange 2003 organization

Use the New Send Connector wizard in the EMC to create a Send connector on the Edge Transport server with the following settings:

- **Introduction page** In **Select the intended use for this Send connector**, select **Internal.**
- **Address Space page** Click Add to open the SMTP Address Space dialog. In this dialog, type – in the Address field. This character is a placeholder that represents all authoritative internal relay domains in your accepted domains configuration. Alternatively, you can list each domain as a separate entry. Leave the remaining fields with their default settings and click OK.
- **Network Settings page** In **Route mail through the following smart hosts**, enter the IP address or the fully qualified domain name (FQDN) of the Exchange 2003 bridgehead server that will receive messages from the Edge Transport server. If you configure more than one bridgehead server as a smart host, the connections from the Edge Transport server will be load-balanced between the smart hosts.
- **Configure smart host authentication settings page** Select **Basic Authentication** and **Basic Authentication over TLS**. In the **User name** and **Password** fields, enter the credentials for the user account that you created in the "Configure credentials for authenticated mail flow" section earlier in this topic.
  For detailed steps, see Create an SMTP Send Connector.

Alternatively, you can use the **New-SendConnector** cmdlet to create the connector in the Shell. This example creates the Send connector To Exchange Organization with the required settings and designates the servers 10.10.1.10 and 10.10.1.11 as the Exchange 2003 bridgehead servers that will receive mail from the Edge Transport server.

```
$mycred = get-credential
```

In the dialog box that appears, enter the credentials for the user account you created the "Configure credentials for authenticated mail flow" section. Use the *domain**user* format or user principal name (UPN) format to enter the user name, and then provide the user's password. Click **OK**.

```
New-SendConnector -Name "To Exchange Organization" -Usage Internal -AddressSpaces
```

For detailed syntax and parameter information, see New-SendConnector.

After you create the Send connector, you must grant the permissions required to enable transmission of XExch50 data from the Edge Transport server to the Exchange 2003 server by running this command in the Shell.

```
Add-AdPermission -Identity "To Exchange Organization" -User "NT Authority\Anonymo
```

Create a Receive connector on the Edge Transport server to accept messages from the Exchange 2003 organization

Use the New Receive Connector wizard in the EMC to create a Receive connector on the Edge Transport server with the following settings:

- **Introduction**page In **Select the intended use for this Receive connector**, select **Internal**.
- **Remote network settings page** Delete all network ranges and add the IP addresses of the Exchange 2003 bridgehead servers that will relay messages

to the Edge Transport server

After you create the connector, modify the authentication method by selecting **Basic Authentication** and **Offer Basic authentication only after starting TLS** on the **Authentication** tab of the connector's properties. For detailed steps, see Create an SMTP Receive Connector and Configure Receive Connector Properties.

Alternatively, you can use the **New-ReceiveConnector** cmdlet to create the connector in the Shell. This example creates the Receive connector From Exchange Organization with the required settings and designates that the servers 10.10.1.10 and 10.10.1.11 are the only ones from which the Receive connector will accept messages.

```
New-ReceiveConnector -Name "From Exchange Organization" -Usage Internal -RemoteIP
```

On the Edge Transport server, run this command in the Shell to grant permissions on the new Receive connector to the local user account you created in the "Configure credentials for authenticated mail flow" section.

```
Add-AdPermission -Identity "Receive Connector Name" -User Edge\Contoso -ExtendedR
```

Important:

This account is granted the permissions that enable it to relay messages through the Edge Transport server. Make sure that you safeguard the account credentials to prevent misuse of the account.

Configure Exchange 2003 to send messages to the Edge Transport server

On the Exchange 2003 server, follow these steps to create an SMTP connector configured to relay all Internet e-mail through the Edge Transport server and use Basic authentication over TLS to help secure the connection:

1. Open Exchange System Manager. Right-click the **Connectors** container that's located in the routing group where the server that will host this connector resides, select **New**, and then select **SMTP Connector**.

   Note:

   If no routing groups are displayed in Exchange System Manager, right-click the Exchange organization container, select **Properties**, and then select the **Display routing groups** check box.

2. Select the **General** tab. In the **Name** field, type a unique name for the connector.
3. Select **Forward all mail through this connector to the following smart hosts**, and type the IP address or FQDN of the Edge Transport server. If you enter an IP address, it must be enclosed in brackets, for example: [192.168.1.1].
4. Click **Add** to add a local bridgehead server. In the **Add Bridgehead** dialog box, select one or more Exchange 2003 servers.
5. Select the **Address Space** tab, and then click **Add** to create an address space. In the **Add Address Space** dialog box, select **SMTP**, and then click **OK**.
6. On the **Internet Address Space Properties** page, enter *, and then click **OK**.
7. Select the **Advanced** tab, and then click **Outbound Security**. In the **Outbound Security** dialog box, select **Basic Authentication**, and then click **Modify**.
8. In the **Outbound Connection Credentials** dialog box, enter the user name for the local user account that you created on the Edge Transport server, enter the password for the account, and then click **OK**.
9. On the **Outbound Security** dialog box, select **TLS encryption**. Click **OK** to close the **Outbound Security** dialog box. Click **OK**.

Configure mail flow between the Edge Transport server and the Exchange 2003

organization using anonymous access

The procedures in this section help you configure unauthenticated mail flow between the Edge Transport server and the Exchange 2003 organization using anonymous access.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Edge Transport server" entry in the Transport Permissions topic.

Configure Exchange 2003 to accept messages from the Edge Transport server

1. On the Exchange 2003 server or servers that will receive messages from the Edge Transport server, verify that the SMTP virtual server is configured to enable Anonymous access:
   a. Open Exchange System Manager. Expand the **Servers** node. Expand the desired server. Expand the **Protocols** node. Expand **SMTP**. Right-click **Default SMTP Virtual Server**, and then select **Properties**.
   b. Click the **Access** tab, and then click **Authentication**.
   c. In the **Authentication** dialog box, select **Anonymous access**. Click **OK**.
2. Configure the relay restriction for the Exchange 2003 server to enable only the Edge Transport server to relay through this virtual server:
   a. On the **Access** tab of **Default SMTP Virtual Server Properties**, click **Relay**.
   b. In the **Relay Restrictions** dialog box, select **Only the list below**, and then click **Add**.
   c. In the **Computer** dialog box, select **Single computer** to specify a single IP address, or select **Group of computers** to specify an IP address range. Click **OK**.
   d. In the **Relay Restrictions** dialog box, verify that the check box **Allow all computers which successfully authenticate to relay, regardless of the list above** is selected. Click **OK**.
   e. Click **OK** to close **Default SMTP Virtual Server Properties**.
3. Follow these steps to modify the registry settings on the Exchange 2003 bridgehead server to enable the Exchange 2003 server to send and receive XExch50 properties anonymously:

   Caution:
   Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

   a. Open Registry Editor.
   b. Locate **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SMTPSVC\XEXCH50**
   c. Right-click **XEXCH50** and select **New | DWORD Value**. Type **SuppressExternal** for the value name. By default, the value data is **0**. This indicates that the XEXCH50 properties are transmitted to the remote server anonymously.
   d. Right-click **XEXCH50** and select **New** | **Key**. Type the number of the SMTP virtual server instance as the key value. For example, the default virtual server instance is **1**, and the second SMTP virtual server created on a server is **2**.
   e. Right-click the key that you just created, point to **New**, and then click **DWORD Value**.
   f. In the details pane, type **Exch50AuthCheckEnabled** for the value name. By default, the value data is **0**. This indicates that the XEXCH50 properties are transmitted when e-mail is sent anonymously.

Create a Send connector from the Edge Transport server to the Exchange 2003 organization

Use the New Send Connector wizard in the EMC to create a Send connector on the Edge Transport server with the following settings:

- **Introduction page** In **Select the intended use for this Send connector**, select **Internal.**
- **Address space**page Type the **--** character, which is a placeholder that represents all authoritative and internal relay domains in your accepted domains configuration. Alternatively, you can list each domain as a separate entry.
- **Network settings**page In **Route mail through the following smart hosts**, enter the IP address or the FQDN of the Exchange 2003 bridgehead server that will receive messages from the Edge Transport server. If you configure more than one bridgehead server as a smart host, the connections from the Edge Transport server will be load-balanced between the smart hosts.
- **Configure smart host authentication settings**page Select **Externally Secured (for example with IPsec)**.
  For detailed steps, see Create an SMTP Send Connector.
  Alternatively, you can use the **New-SendConnector** cmdlet to create the connector in the Shell. This example creates the Send connector To Exchange Organization with the required settings and designates the servers 10.10.1.10 and 10.10.1.11 as the Exchange 2003 bridgehead servers that will receive mail from the Edge Transport server.

```
New-SendConnector -Name "To Exchange Organization" -Usage Internal -Add
```

1. After you create the Send connector, you must grant the permissions required to enable transmission of XExch50 data from the Edge Transport server to the Exchange 2003 server by running this command in the Shell.

```
Add-AdPermission -Identity "To Exchange Organization" -User "NT Author
```

Create a Receive connector on the Edge Transport server to accept messages from the Exchange 2003 organization

Use the New Receive Connector wizard in the EMC to create a Receive connector on the Edge Transport server with the following settings:

- **Introduction**page In **Select the intended use for this Receive connector**, select **Internal.**
- **Remote network settings**page Delete all network ranges and add the IP addresses of the Exchange 2003 bridgehead servers that will relay messages to the Edge Transport server.

After you create the connector, modify the authentication method by selecting **Externally Secured (for example with IPsec)** on the **Authentication** tab of the connector's properties. Clear all other authentication options. For detailed steps, see Create an SMTP Receive Connector and Configure Receive Connector Properties.

Alternatively, you can use the **New-ReceiveConnector** cmdlet to create the connector in the Shell. This example creates the Receive connector From Exchange Organization with the required settings and designates that the servers 10.10.1.10 and 10.10.1.11 are the only ones from which the Receive connector will accept messages.

```
New-ReceiveConnector -Name "From Exchange Organization" -Usage Internal -RemoteIP
```

Important:

If you specify an IP address range instead of specific IP addresses for this Receive connector, it will enable all connections from the specified remote IP address range to relay messages through the Edge Transport server. In this scenario, make sure that a trusted network connection exists between the Edge Transport server and the Exchange

organization.

Configure Exchange 2003 to send messages to the Edge Transport server

On the Exchange 2003 server, follow these steps to create an SMTP connector configured to relay all Internet e-mail through the Edge Transport server:

1. Open Exchange System Manager. Right-click the **Connectors** container located in the routing group where the server that will host this connector resides, select **New**, and then select **SMTP Connector**.

   Note:

   If no routing groups are displayed in Exchange System Manager, right-click the Exchange organization container, select **Properties**, and then select the **Display routing groups** check box.

2. Select the **General** tab. In the **Name** field, type a unique name for the connector.
3. Select **Forward all mail through this connector to the following smart hosts**, and type the IP address or FQDN of the Edge Transport server. If you enter an IP address, it must be enclosed in brackets, for example: [192.168.1.1].
4. Click **Add** to add a local bridgehead server. In the **Add Bridgehead** dialog box, select one or more Exchange 2003 servers.
5. Select the **Address Space** tab, and then click **Add** to create an address space. In the **Add Address Space** dialog box, select **SMTP**, and then click **OK**.
6. On the **Internet Address Space Properties** page, enter *, and then click **OK**.
7. Click **OK** to close the SMTP connector properties page.

1.2.2.7.3 Install Exchange Server 2010

Install Exchange Server 2010

Planning and Deployment > Deploying Exchange 2010 > Managing Deployment of Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-15*

This topic explains how to use the Microsoft Exchange Server 2010 Setup wizard to perform an installation of Exchange 2010. For more information about planning and deploying Exchange 2010, see the following topics:

- Planning for Exchange 2010
- Deploying Exchange 2010

Prerequisite

You must ensure that any server on which you plan to install Exchange 2010 meets the appropriate prerequisites and system requirements before you begin your installation. To understand the prerequisites for all server roles, see Exchange 2010 Prerequisites. For more information about system requirements, see Exchange 2010 System Requirements. For more information about server roles, see Overview of Exchange 2010 Server Roles.

Caution:

After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not

supported.

Install Exchange Server 2010

If you're installing the first Exchange 2010 server in the organization, and the Active Directory preparation steps have not been performed, the account you use must have membership in the Enterprise Administrators group. If you haven't previously prepared the Active Directory schema, the account must also be a member of the Schema Admins group. For more information about preparing Active Directory for Exchange 2010, see Prepare Active Directory and Domains. If you have already performed the schema and Active Directory preparation steps, the account you use must be a member of the Delegated Setup management role group or the Organization Management role group.

On the **Start** page, make sure that you've completed **Steps 1** through **3**. If you haven't already installed the components discussed in those steps, Setup will link you to the appropriate sites where you can download the components. For more information about Windows PowerShell installation, see Install Windows Management Framework.

Important:

If you're installing Exchange 2010 on Windows Server 2008 R2, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.

For information about Exchange language options, see Exchange 2010 Language Support.

1. The **Introduction** page begins the process of installing Exchange into your organization. It will guide you through the installation. Click **Next** to continue.

2. On the License Agreement page, review the software license terms. If you agree to the terms, select "I accept the terms in the license agreement.", and then click **Next**.

3. On the Error Reporting page, select whether you want to enable or disable the Exchange Error Reporting feature, and then click **Next**.

4. On the **Installation Type** page, select whether you want a typical Exchange Server installation or a custom Exchange Server installation. For Exchange 2010 SP1, you can select to automatically install all required Windows roles and features for this server. You can also click **Browse** to change the specified installation path, and then click **Next**. Note that, if you choose the **Typical Exchange Server Installation** option, the Hub Transport, Client Access, and Mailbox server roles plus the Exchange Management Tools will be installed. You will not be able to install the Unified Messaging server role or Edge Transport server role. You can add additional server roles later if you choose not to install them during this installation. For more information about a custom Exchange installation, see Install Exchange 2010 Using the Custom Installation Type.

   Note:

   For e-mail messages to flow correctly, you must install both the Mailbox server role and the Hub Transport server role in the same Active Directory site. You can also install the Mailbox server role, the Hub Transport server role, the Client Access server role, and the Unified Messaging server role on the same computer or on separate computers.

5. On the **Server Role Selection** page, click **Next**. You can add additional server roles later if you choose not to install them during this installation. The Edge Transport server role can't coexist on the same computer with any other

server role. You must deploy the Edge Transport server role in the perimeter network and outside the Active Directory forest. Also, the Exchange management tools aren't installed by default. Therefore, select **Management Tools** to install the Exchange Management Console and the Exchange cmdlets for the Exchange Management Shell. The management tools are installed automatically if you install any other server role.

Note:
You will not see this page if you choose a typical Exchange installation.

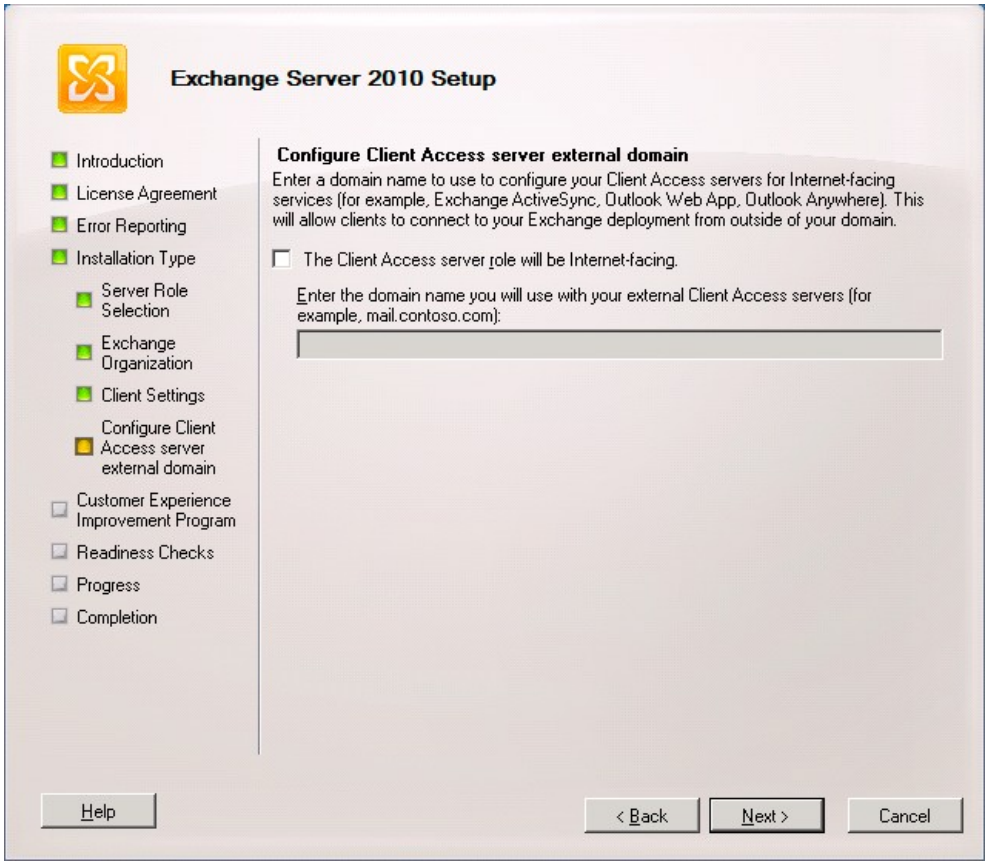
6. If this is the first Exchange server in your organization, on the **Exchange Organization** page, type a name for your Exchange organization. The Exchange organization name can contain only the following characters:
   - A through Z
   - a through z
   - 0 through 9
   - Space (not leading or trailing)
   - Hyphen or dash

   Note:
   The organization name can't contain more than 64 characters. The organization name can't be blank.

7. If this is the first Exchange server in your organization, on the **Client Settings** page, click the option that describes the client computers in your organization that are running Microsoft Office Outlook.
8. On the **Client Settings** page, if you have client computers that are running Outlook 2003 or earlier and you select **Yes**, Exchange 2010 will create a public folder database on the Mailbox server. If all your client computers are running Outlook 2010, public folders are optional in Exchange 2010. If you select **No**, Exchange 2010 will not create a public folder database on the Mailbox server. You can add a public folder database later. For example, if you add client computers that are running Outlook 2003 and you need a public folder database, you can create one on the Exchange 2010 Mailbox server. You must then configure the offline address book for public folder distribution, and then restart the Microsoft Exchange Information Store service before client computers that are running Outlook 2003 and earlier will be able to connect to the server.

9. On the **Configure Client Access Server external domain** page, enter a domain name to use to configure your Client Access servers.

   Note:
   If the Client Access server will not be Internet-facing, you can click **Next** without configuring a domain name. For more information about configuring Client Access servers, see Managing External Client Access. Click **Next**.



10. On the **Customer Experience Improvement** page, choose the appropriate selections for your organization, and then click **Next**.

11. On the Readiness Checks page, view the status to determine if the organization and server role prerequisite checks completed successfully. If they haven't completed successfully, you must resolve any reported errors before you can install Exchange 2010. You don't need to exit Setup when resolving some of the prerequisite errors. After resolving a reported error, click **Retry** to re-run the prerequisite check. Be sure to also review any warnings that are reported. If all readiness checks have completed successfully, click **Install** to install Exchange 2010.

12. On the **Completion** page, click **Finish**.

Important:

If you're installing Exchange 2010 into an existing Exchange 2003 or Exchange 2007 organization, see the "Configure the Client Access server" section in the following topics:
Install Exchange 2010 in an Existing Exchange 2003 Organization
Install Exchange 2010 in an Existing Exchange 2007 Organization
Install Exchange 2010 in a Mixed Exchange 2003 and Exchange 2007 Organization

1.2.2.7.4 Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3

Upgrade Exchange 2010 to Exchange 2010 SP1, SP2 or Exchange 2010 SP3

Planning and Deployment > Deploying Exchange 2010 > Managing Deployment of Exchange 2010

>

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-02-04*

You can use the Microsoft Exchange Server 2010 Service Pack Setup wizard to upgrade your current version of Exchange 2010. If you have the release-to-manufacturing (RTM) version of Exchange 2010 installed, you can upgrade to either Microsoft Exchange Server 2010 Service Pack 3 (SP3), Microsoft Exchange Server 2010 Service Pack 2 (SP2) or to Microsoft Exchange Server 2010 Service Pack 1 (SP1). If you have Exchange 2010 SP1 or Exchange 2010 SP2, installed, we strongly recommend that you upgrade to Exchange 2010 SP3. See Release Notes for Exchange Server 2010 SP3 for more information.

After you install a service pack, you must restart the computer so that changes can be made to the registry and operating system.

Caution:

After you upgrade Exchange 2010 to a newer service pack, you can't uninstall the service pack to revert to the previous version. If you uninstall the service pack, you remove Exchange from the server.

You should upgrade your Exchange 2010 server roles in the following order:

- Client Access
- Hub Transport
- Unified Messaging
- Mailbox

The Edge Transport server role can be upgraded at any time. However, we recommend that you upgrade the Edge Transport server role either before or after you upgrade all other server roles.

Prerequisites

- Make sure that any server on which you plan to install the service pack meets the system requirements. For more information about system requirements, see Exchange 2010 System Requirements.
- Understand the prerequisites for all server roles. For more information about prerequisites, see Exchange 2010 Prerequisites. For more information about server roles, see Overview of Exchange 2010 Server Roles.
- Understand the Unified Messaging server role improvements and new features that were added in Exchange 2010 SP1. These improvements and new features are also included in Exchange 2010 SP2. To use some of these new features, you must correctly deploy Microsoft Office Communications Server 2007 R2 or Microsoft Lync Server 2010 in your environment. For more information, see New Unified Messaging Functionality and Voice Mail Features in Exchange 2010 SP1 and Install or Upgrade to Exchange 2010 SP2 Unified Messaging.

Permissions

To perform the following procedures, the account you use must be a member of the Delegated Setup management role group or the Organization Management management role group.

To apply an Exchange 2010 service pack to an Exchange 2010 server that has the Edge Transport server role installed, the account you use must be a member of the local Administrators group on that computer.

To upgrade a computer that has only the Exchange management tools installed, you must log on by using an account that's a member of the local Administrators group on that computer.

If you haven't yet prepared the schema for Exchange 2010 SP1 or Exchange 2010 SP2, the account you use to upgrade the server must be a member of the Schema Admins group and the Enterprise Admins group. This requirement also applies if you're installing Exchange 2010 SP3, and if you haven't yet prepared the schema for it. For more information, see Prepare Active Directory and Domains.

Upgrade load balanced Client Access array members

If your organization uses a load balanced array of Client Access servers, see the following guidance about how to upgrade your Client Access servers from one version of Exchange 2010 to another, for example, from Exchange 2010 RTM to Exchange 2010 SP1. If you have an array of Client Access servers that you need to upgrade from one version to another, use the following steps.

Note:
Exchange 2010 RTM, Exchange 2010 SP1, Exchange 2010 SP2 and Exchange 2010 SP3 can't coexist within the same load balanced array.

Important:
Do not upgrade any Mailbox server from one version to another until all Client Access servers within the Active Directory site have been upgraded to the target version. The following guidance assumes that the Mailbox and Client Access server roles are not co-located. If your environment deploys multi-role servers, see Exchange Server Team Bog article Patching the Multi-Role Server DAG for the steps to patch the servers.

1. Determine the number of Client Access server array members that can be offline at one time without negatively affecting the service. For example, if you have six Client Access servers in a load balanced array, and you have designed your load-balancing solution to handle three simultaneous failures, you can have three Client Access server array members offline.
2. To continue with the example, disable new connections to the three servers, and let the existing connections terminate. After all connections have been terminated, remove those servers from your load-balancing pool.
3. Upgrade those three servers to the target version. Verify that the upgrade was successful.
4. Restore the upgraded servers to the load-balanced array.
5. Prepare to remove the servers that have not been upgraded from the load balanced array by disabling new connections.
6. Verify that all connections to the servers identified in step 5 have been terminated, and then remove those servers from the load-balanced array.
7. Upgrade the second batch of servers to the target version of the software. Verify that the upgrade was successful.
8. Restore the most recently upgraded servers to the array.

Upgrade database availability group members

When you apply an Exchange 2010 service pack to a database availability group (DAG) member, you need to consider and plan for some specific issues. Before applying an Exchange 2010 service pack to any DAG members, consider the following:

- **Upgrade only passive servers** Before applying the service pack to a DAG member, move all active mailbox database copies off the server to be

upgraded and configure the server to be blocked from activation. If the server to be upgraded currently holds the primary Active Manager role, move the role to another DAG member prior to performing the upgrade. You can determine which DAG member holds the primary Active Manager role by running `Get-DatabaseAvailabilityGroup <DAGName> -Status | Format-List PrimaryActiveManager`.

- **Place server in maintenance mode** Before applying the service pack to any DAG member, you may want to adjust monitoring applications that are in use so that the server doesn't generate alerts or alarms during the upgrade. For example, if you're using Microsoft System Center Operations Manager 2007 to monitor your DAG members, you should put the DAG member to be upgraded in maintenance mode prior to performing the upgrade. If you're not using System Center Operations Manager 2007, you can use `StartDagServerMaintenance.ps1` to put the DAG member in maintenance mode. After the upgrade is complete, you can use `StopDagServerMaintenance.ps1` to take the server out of maintenance mode.
- **Stop any processes that might interfere with the upgrade** Stop any scheduled tasks or other processes running on the DAG member or within that DAG that could adversely affect the DAG member being upgraded or the upgrade process.
- **Verify the DAG is healthy** Before you apply the service pack to any DAG member, we recommend that you verify the health of the DAG and its mailbox database copies. A healthy DAG will pass MAPI connectivity tests to all active databases in the DAG, will have mailbox database copies that have a copy queue length and replay queue length that's very low (if not zero), and will have a copy status and content index state of Healthy.
- **Be aware of other implications of the upgrade** A DAG member running Exchange 2010 RTM can move its active databases to a DAG member running Exchange 2010 SP1 or SP2. After a DAG member has been upgraded to a newer Exchange 2010 service pack, its active database copies cannot be moved to another DAG member that is running Exchange 2010 RTM. If you try to do this, an error will occur.
  When you update a DAG server from Exchange 2010 RTM to Exchange 2010 SP1, Event ID 1185 is recorded in the Application log if there is a database schema update that requires the Exchange mailbox database to change or be updated. If there is no database schema update, this event is not logged.
  When you update from Exchange 2010 SP1 to Exchange 2010 SP2, Event ID 1185 is not recorded in the Application log. This is because a database schema update is not required.

Note:

The database schema update is different from the AD schema update.

Caution:

We recommend that you do not move the active database from a DAG member that is running Exchange 2010 SP2 to a DAG member that is running Exchange 2010 SP1. We make this recommendation even though it is possible to move the database, and the move does not generate an error.

Run the following scripts and commands on the DAG member that is being upgraded in preparation for the service pack.

- Verify the health and status of the DAG by saving the following commands as a Windows PowerShell script (.ps1) file.

```
(Get-DatabaseAvailabilityGroup -Identity (Get-MailboxServer -Identity $
Get-MailboxDatabase | Sort Name | Get-MailboxDatabaseCopyStatus | Forma
function CopyCount
{
$DatabaseList = Get-MailboxDatabase | Sort Name
```

```
$DatabaseList | % {
$Results = $_ | Get-MailboxDatabaseCopyStatus
$Good = $Results | where { ($_.Status -eq "Mounted") -or ($_.Status -eq
$_ | add-member NoteProperty "CopiesTotal" $Results.Count
$_ | add-member NoteProperty "CopiesFailed" ($Results.Count-$Good.Count
}
$DatabaseList | sort copiesfailed -Descending | ft name,copiesTotal,cop
}
CopyCount
```

- Perform a server switchover by running the following command.

```
Move-ActiveMailboxDatabase -Server <DAGMemberName>
```

- Prevent the DAG member from becoming a failover target by running the following command.

```
Set-MailboxServer -DatabaseCopyAutoActivationPolicy:Blocked
```

- If necessary, move the primary Active Manager role to another DAG member by running the following command.

```
Cluster group "cluster group" /move
```

- Install the Exchange 2010 service pack. For details, see "Install the Exchange 2010 service pack" later in this topic.
- Enable the upgraded DAG member to become a failover target by running the following command.

```
Set-MailboxServer -DatabaseCopyAutoActivationPolicy:Value
```

  Where *Value* is either *IntrasiteOnly* or *Unrestricted*.
- Repeat steps 1–6 on each DAG member until the service pack has been applied to every DAG member.

For more information, see the following topics:

- Perform a Server Switchover
- Move-ActiveMailboxDatabase
- Set-MailboxServer
- Understanding Mailbox Database Copies

Install the Exchange 2010 service pack

When installing a new Exchange 2010 service pack on multiple Exchange 2010 servers within an organization, we recommend that you first upgrade your Client Access servers. In an organization that has multiple Active Directory sites that use multiple Client Access servers in a proxy situation, you must upgrade the Internet-facing Client Access servers before upgrading Client Access servers that aren't Internet-facing. Then, we recommend you install the Hub Transport, Unified Messaging, and Mailbox server roles.

The Edge Transport server role can be upgraded at any time. However, we recommend upgrading the Edge Transport server role either before or after all other server roles are upgraded.

1. Insert the Exchange 2010 SP1, SP2 or Exchange 2010 SP3 DVD into the DVD drive. When the **AutoPlay** dialog box appears, click **Run Setup.exe** under **Install or run program**. If the **AutoPlay** dialog box doesn't appear, navigate to the root of the DVD and double-click **Setup.exe**. Alternatively, browse to the location of your Exchange 2010 installation files and double-click **Setup.exe**.
2. On the **Start** page, click **Install Microsoft Exchange Server Upgrade** to

begin the installation.

Important:
Make sure that you've completed all the required steps described on the **Start** page before you begin your installation. If you haven't already installed the components discussed on the **Start** page, Setup provides links to the appropriate sites where you can download the components. For more information about Windows PowerShell installation, see Install Windows Management Framework.

Important:
If you're installing Exchange 2010 on Windows Server 2008 R2, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.

3. The **Introduction** page begins the process of installing Exchange into your organization. It will guide you through the installation. Click **Next** to continue.
4. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
5. On the **Readiness Checks** page, view the status to determine if the organization and server role prerequisite checks completed successfully. If they haven't completed successfully, you must resolve any reported errors before you can install Exchange 2010. You don't need to exit Setup when you resolve some of the prerequisite errors. After you resolve a reported error, click **Retry** to run the prerequisite check. Make sure to also review any reported warnings. If all readiness checks have finished successfully, click **Upgrade** to install the service pack.
6. On the **Completion** page, click **Finish**.

Use unattended setup to install the Exchange 2010 service pack

1. Insert the Exchange 2010 SP1, SP3 or Exchange 2010 SP3 DVD into the DVD drive.
2. At the command prompt, navigate to the DVD drive or to the network location of the Exchange 2010 installation files.
3. At the command prompt, run the following command:

```
Setup.com /M:Upgrade /InstallWindowsComponents
```

For more information, see the following topics:

1. New Deployment Functionality in Exchange 2010 SP1
2. What's New in Exchange 2010 SP2
3. What's New in Exchange 2010 SP3

1.2.2.7.5 Install Exchange 2010 in an Existing Exchange 2003 Organization

Install Exchange 2010 in an Existing Exchange 2003 Organization

>

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-31*

You can use Microsoft Exchange Server 2010 Setup to install the first server running Exchange 2010 in an existing Exchange Server 2003 organization.

You can't perform an in-place upgrade from Exchange 2003 to Exchange 2010. However, you can install an Exchange 2010 server into the existing Exchange organization, and then move the Exchange resources, such as mailboxes, public folders, and connectors to Exchange 2010.

After you perform this procedure, your organization will be running in a coexistence mode. You can maintain this mode for an indefinite period of time, or you can immediately complete the upgrade to Exchange 2010 by moving all resources from Exchange 2003 to Exchange 2010, and then decommissioning the Exchange 2003 servers.

When you install Exchange 2010 in an existing Exchange 2003 organization, Setup performs the following coexistence-specific tasks:

- Creates the Active Directory universal security group ExchangeLegacyInterop. This group is granted the permissions that allow the Exchange 2003 servers to send e-mail messages to the Exchange 2010 servers.
- Creates a two-way routing group connector between Exchange 2010 and a selected Exchange 2003 bridgehead server. Exchange 2010 and Exchange 2003 use different routing topologies. You must configure a routing group connector to enable mail flow between the Exchange versions.

For information about performing a custom installation, see Install Exchange 2010 Using the Custom Installation Type. For information about installing Exchange 2010 in unattended mode, see Install Exchange 2010 in Unattended Mode.

Although it's a better practice to introduce Exchange 2010 into your Exchange 2003 organization and use Edge Subscriptions, you may want to start using Edge Transport servers before you start your upgrade. For more information, see Deploy the Edge Transport Server Role in an Existing Exchange 2003 Organization Before Upgrading to Exchange 2010.

Exchange Server 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Prerequisites

You must ensure that each of the servers meets the appropriate prerequisites and system requirements before you begin your installation. For more information, see the following topics:

- Overview of Exchange 2010 Server Roles
- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements

Warning:
After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Install Exchange 2010

If this is the first instance of Exchange 2010 that you're installing into your existing organization, make sure that you install the Client Access server role first, followed by the Hub Transport server role, followed by the Unified Messaging server role, and last, the Mailbox server role. For more information about the Client Access server role, see "Configure the Client Access server" later in this topic.

To perform the following procedure, the account you use must be delegated membership in the Schema Admins group if you haven't previously prepared the Active Directory schema. If you're installing the first Exchange 2010 server in the organization, the account you use must have membership in the Enterprise Admins group. If you've already prepared the schema and aren't installing the first Exchange 2010 server in the organization, the account you use must be delegated the Delegated Setup role group.

Note:
For information about preparing Active Directory for Exchange 2010, see Prepare Active Directory and Domains. For information about permissions in Exchange 2010, see Understanding Permissions and Understanding Role Based Access Control.

1. Insert the Exchange 2010 DVD into the DVD drive. When the **AutoPlay** dialog box appears, click **Run Setup.exe** under **Install or run program**. If the **AutoPlay** dialog box doesn't appear, navigate to the root of the DVD and double-click **Setup.exe**. Alternatively, browse to the location of your Exchange 2010 installation files and double-click **Setup.exe**.
2. The Exchange Server 2010 Setup welcome screen appears. In the **Plan** section, you can follow the links to read overview information regarding Exchange 2010, deploying languages, and the Exchange 2010 Deployment Assistant. In the **Enhance** section, you can read more information about Forefront Protection 2010, and install Microsoft Forefront Protection 2010. In the **Install** section, the software listed for **Step 1: Install .NET Framework 3.5 SP1** and **Step 2: Install Windows PowerShell v2** was installed with the Exchange 2010 prerequisites. However, if these prerequisites aren't already installed, click the appropriate step to install them.
   For more information about Windows PowerShell installation, see Install Windows Management Framework.

   Important:
   If you're installing Exchange 2010 on the Windows Server 2008 R2 operating system, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.
3. When **Step 1** and **Step 2** are shown as **Installed**, click **Step 3: Choose Exchange language option** to expand the Exchange language options, and then choose the appropriate option:
   - **Install all languages from the language bundle** This option installs all the Exchange 2010 languages from an Exchange 2010 language bundle. You can connect to the Internet to download the latest applicable language bundle or to use a previously downloaded language bundle on a local drive or network share. Internet connectivity is required for Exchange Setup to download the language pack bundle.
   - **Install only languages from the DVD** This option installs only the languages included with the Setup DVD. The installation of additional language support requires installing the languages from the language bundle.

For more information about Exchange language options, see Exchange 2010 Language Support.

4. After language installation is complete, click **Step 4: Install Microsoft Exchange**. This option starts the Exchange Server 2010 Setup wizard.

   Note:
   After your installation is complete, you can return to **Step 5: Get critical updates for Microsoft Exchange**.

5. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
6. On the **Error Reporting** page, click **Yes**, and then click **Next**.
7. On the **Installation Type** page, click **Typical Exchange Server Installation**. If you want to change the path for the Exchange 2010 installation, click **Browse**, locate the appropriate folder in the folder tree, and then click **OK**. Click **Next**.

   Note:
   If you choose the **Typical Exchange Server Installation** option, you won't be able to install the Unified Messaging server role or Edge Transport server role during this installation. You can add additional server roles later if you don't install them during this installation.

8. On the **Configure Client Access Server** external domain page, enter a domain name to use to configure your Client Access servers. Click **Next**. For more information about configuring Client Access servers, see "Configure the Client Access Server" later in this topic.
9. On the **Customer Experience Improvement** page, choose the appropriate selection for your organization, and then click **Next**.
10. On the **Readiness Checks** page, view the status to determine whether the organization and server role prerequisite checks completed successfully. If they completed successfully, click **Install** to install Exchange 2010.
11. On the **Completion** page, click **Finish**.

Configure the Client Access Server

If this is the first Exchange 2010 server you've installed in your Exchange 2003 organization, you need to perform several additional steps to configure your Exchange 2010 Client Access server.

1. If your organization requires Outlook Anywhere access, enable Outlook Anywhere as shown in the following example.

   ```
   Enable-OutlookAnywhere -Server:<CAS2010> -ExternalHostName:mail.contos
   ```

2. If you didn't configure a primary external namespace during setup, configure the virtual directories for the offline address book (OAB), Exchange Web Services, Microsoft Exchange ActiveSync, Microsoft Office Outlook Web App, and Exchange Control Panel (ECP) as shown in the following examples. This example configures the virtual directories for the OAB.

   ```
   Set-OABVirtualDirectory <CAS2010>\OAB* -ExternalUrl "https://mail.cont
   ```

   This example configures the virtual directories for Exchange Web Services.

   ```
   Set-WebServicesVirtualDirectory <CAS2010>\EWS* -ExternalUrl https://ma
   ```

   This example configures the virtual directories for Exchange ActiveSync.

   ```
   Set-ActiveSyncVirtualDirectory -Identity <CAS2010>\Microsoft-Server-Ac
   ```

   This example configures the virtual directories for Outlook Web App.

   ```
   Set-OwaVirtualDirectory <CAS2010>\OWA* -ExternalUrl https://mail.conto
   ```

   This example configures the virtual directories for the ECP.

   ```
   Set-EcpVirtualDirectory <CAS2010>\ECP* -ExternalUrl https://mail.conto
   ```

3. Configure the Exchange 2003 URL property on the /owa virtual directory. This

is necessary for Exchange 2003 and Exchange 2010 to coexist. This example configures this property.

```
Set-OwaVirtualDirectory <CAS2010>\OWA*  -Exchange2003Url https://legac
```

Note:
You must enable forms-based authentication on the Exchange 2003 front-end server to allow your users to access their mailboxes through a single sign-on during the coexistence period.

4. Change the OAB generation server and enable Web distribution on the Exchange 2010 Client Access server using the following steps.
   4.a. Move the OAB as shown in this example.

```
Move-OfflineAddressBook "Default Offline Address List" -Ser
```

   4.b. Add the Exchange 2010 Client Access server as a Web distribution point as shown in these examples.

```
$OABVDir = Get-OABVirtualDirectory -Server
<CAS2010>
$OAB = Get-OfflineAddressBook "Default Offline
Address List"
$OAB.VirtualDirectories and $OABVdir.DistinguishedName =
Set-OfflineAddressBook "Default Offline Address
List" -VirtualDirectories $OAB.VirtualDirectories
```

5. Enable Integrated Windows authentication on the Microsoft-Server-ActiveSync virtual directory on the Exchange 2003 back-end server. This allows the Exchange 2010 Client Access server and the Exchange 2003 back-end server to communicate using Kerberos authentication. Do one of the following:
   5.a. Install a hotfix. To download the hotfix, see Event ID 1036 is logged on an Exchange 2007 server that is running the CAS role when mobile devices connect to the Exchange 2007 server to access mailboxes on an Exchange 2003 back-end server. Use Exchange System Manager to adjust the authentication settings of the Exchange ActiveSync virtual directory.
   5.b. Set the **msExchAuthenticationFlags** attribute to a value of 6 on the **Microsoft-Server-ActiveSync** object within the configuration container on each Exchange 2003 Mailbox server. For an example script, see Server Build DVD Visual Basic Script Examples.

Important:
Don't use IIS Manager to change the authentication setting on the Microsoft ActiveSync virtual directory, because the DS2MB process within the Microsoft Exchange System Attendant will overwrite the settings stored in Active Directory.

6. Create a legacy host name in your external Domain Name System (DNS) infrastructure and associate this host name with your Exchange 2003 front-end server or with your proxy infrastructure. See "Create a Legacy Host Name" later in this topic.
7. Reconfigure your external DNS settings or the publishing rules for your reverse proxy infrastructure to have your original namespace of mail.contoso.com point to your Exchange 2010 Client Access server or Client Access server array.

Create a Legacy Host Name

The exact steps for this procedure depend on your Internet service provider (ISP) and firewall configuration. Example steps for GoDaddy are provided to show you how this works. Your actual steps may vary. In general, you need to perform the following steps.

1. Create a DNS host (A) record in your internal and external DNS servers that points to the IP address of your legacy Internet-facing Exchange server (for example, Exchange Server 2007 Client Access server or Exchange 2003 front-end server) in internal DNS or the public IP address on your reverse proxy or

firewall solution (external DNS). The host name should be in the format of legacy.domain.com (for example, legacy.contoso.com).
2. Create a publishing rule for the legacy host name in your reverse proxy or firewall solution to point to your legacy Internet-facing Exchange server. Refer to your proxy or firewall solution's user manual for instructions about how to do this.
3. Configure the existing DNS host (A) record in your internal and external DNS servers for your original host name (for example, mail.contoso.com) to point to your Exchange 2010 organization, for example, the IP address of your Client Access server or array (internal DNS), or the public IP address on your reverse proxy or firewall solution (external DNS).
   For example, if your provider is GoDaddy.com, you can create a DNS host (A) record and associate it with your legacy Exchange infrastructure.
   3.a. From your GoDaddy account management home page, click **Domain Manager** under the **My Products** heading in the left sidebar.
   3.b. If prompted, log on to your account.
   3.c. In the **Total DNS** section of the **Domain Manager** information screen, click **Total DNS Control**.
   3.d. In the **A (Host)** section of the **Total DNS Control** screen, click **Add new A record**.
   3.e. Enter the host name, for example, legacy.contoso.com, and enter the IP address of your legacy Exchange server in the **Points to IP address** box.
   3.f. Choose a **TTL** (Time to Live) value. If you're performing this step well in advance of your Exchange 2010 installation, you can choose **1 day** or **1 week** from the drop-down list box. Otherwise, choose the default of **1 hour** or **1/2 hour**.
   3.g. Click **OK** to complete your changes.

Verify the legacy host name is accessible from the Internet

From outside your firewall, perform the following steps, using your specific domain name.

1. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on Exchange 2010.
2. Navigate to https://legacy.contoso.com/exchange, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.
3. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.

You can also use the Microsoft Exchange Server Remote Connectivity Analyzer to verify connectivity for the legacy namespace. To use the Remote Connectivity Analyzer, see Microsoft Exchange Remote Connectivity Analyzer.

Verify Installation and View Configuration Objects

To verify that Exchange 2010 installed correctly, see Verify an Exchange 2010 Installation. After installation is complete, you can view the Exchange 2010 configuration objects in the Exchange Management Console (EMC).

Note:

You can only view and manage the Exchange 2010 configuration objects using the EMC in Exchange 2010.

To verify that mail flow is working correctly, you can perform the following procedure:

1. Configure your Hub Transport server. For more information, see Transport Server Post-Deployment Tasks.
2. Create a mailbox on the Exchange 2010 Mailbox server. For more information,

see Create a Mailbox.

3. Send an e-mail message from the Exchange 2010 mailbox to a user who has a mailbox that is located on an Exchange 2007 server. Verify that the e-mail message is received.
4. Send an e-mail message from a user who has a mailbox that is located on an Exchange 2007 server to the new Exchange 2010 mailbox user. Verify that the e-mail message is received.

You can also use the Exchange Remote Connectivity Analyzer to test Exchange connectivity.

Finally, be sure to perform the tasks described in Finalize Deployment Tasks that are required for the server roles that you have installed.

Important:

Exchange 2010 now creates system address lists in a new container. Recipients created or modified using Exchange 2003 or Exchange 2007 management tools won't be stamped with these system address lists. As a result, they won't be seen by the Exchange 2010 **Get-Recipient** cmdlet.
To fix this issue, you must enable Active Directory virtual list view (VLV). After you have completed the upgrade of an existing Exchange 2003 organization to Exchange 2010 and have decommissioned your Exchange 2003 servers, you must enable Active Directory VLV. To enable VLV for Exchange 2010, run the **Enable-AddressListPaging** cmdlet. For more information, see Enable-AddressListPaging.

1.2.2.7.6 Install Exchange 2010 in an Existing Exchange 2007 Organization

Install Exchange 2010 in an Existing Exchange 2007 Organization

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-31*

You can use Microsoft Exchange Server 2010 Setup to install the first server running Exchange 2010 in an existing Exchange Server 2007 organization.

You can't perform an in-place upgrade from Exchange 2007 to Exchange 2010. However, you can install an Exchange 2010 server into the existing Exchange organization, and then move the Exchange resources, such as mailboxes, public folders, and connectors to Exchange 2010. After you perform this procedure, your organization will be running in a coexistence mode. You can maintain this mode for an indefinite period of time, or you can immediately complete the upgrade to Exchange 2010 by moving all resources from Exchange 2007 to Exchange 2010, and then decommissioning the Exchange 2007 servers.

Note:

You can install Exchange 2010 in a native mode Exchange organization. However, if you create a forest in which to install Exchange 2010, you can't later add earlier versions of Exchange.

For more information about performing a custom installation, see Install Exchange 2010 Using the Custom Installation Type. For information about installing Exchange 2010 in unattended mode, see Install Exchange 2010 in Unattended Mode.

Exchange Server 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Prerequisites

You must ensure that each of the servers meets the appropriate prerequisites and system requirements before you begin your installation. For more information, see the following topics:

- Overview of Exchange 2010 Server Roles
- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements

Warning:

After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Install Exchange 2010

If this is the first instance of Exchange 2010 that you're installing into your existing organization, make sure that you install the Client Access server role first, followed by the Hub Transport server role, followed by the Unified Messaging server role, and last, the Mailbox server role. For more information about the Client Access server role, see "Configure the Client Access server" later in this topic.

To perform the following procedure, the account you use must be delegated membership in the Schema Admins group if you haven't previously prepared the Active Directory schema. If you're installing the first Exchange 2010 server in the organization, the account you use must have membership in the Enterprise Admins group. If you've already prepared the schema and aren't installing the first Exchange 2010 server in the organization, the account you use must be delegated the Delegated Setup role group.

Note:

For information about preparing Active Directory for Exchange 2010, see Prepare Active Directory and Domains. For information about permissions in Exchange 2010, see Understanding Permissions and Understanding Role Based Access Control.

1. Insert the Exchange 2010 DVD into the DVD drive. When the **AutoPlay** dialog box appears, click **Run Setup.exe** under **Install or run program**. If the **AutoPlay** dialog box doesn't appear, navigate to the root of the DVD and double-click **Setup.exe**. Alternatively, browse to the location of your Exchange 2010 installation files and double-click **Setup.exe**.
2. The Exchange Server 2010 Setup welcome screen appears. In the **Plan** section, you can follow the links to read overview information regarding Exchange 2010, deploying languages, and the Exchange 2010 Deployment Assistant. In the **Enhance** section, you can read more information about Forefront Protection 2010, and install Microsoft Forefront Protection 2010. In the **Install** section, the software listed for **Step 1: Install .NET Framework 3.5 SP1** and **Step 2: Install Windows PowerShell v2** was installed with the Exchange 2010 prerequisites. However, if these prerequisites aren't already

installed, click the appropriate step to install them.
For more information about Windows PowerShell installation, see Install Windows Management Framework.

Important:
If you're installing Exchange 2010 on the Windows Server 2008 R2 operating system, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.

3. When **Step 1** and **Step 2** are shown as **Installed**, click **Step 3: Choose Exchange language option** to expand the Exchange language options, and then choose the appropriate option:
   - **Install all languages from the language bundle** This option installs all the Exchange 2010 languages from an Exchange 2010 language bundle. You can connect to the Internet to download the latest applicable language bundle or to use a previously downloaded language bundle on a local drive or network share. Internet connectivity is required for Exchange Setup to download the language pack bundle.
   - **Install only languages from the DVD** This option installs only the languages included with the Setup DVD. The installation of additional language support requires installing the languages from the language bundle.

     For more information about Exchange language options, see Exchange 2010 Language Support.
4. After language installation is complete, click **Step 4: Install Microsoft Exchange**. This option starts the Exchange Server 2010 Setup wizard.

Note:
After your installation is complete, you can return to **Step 5: Get critical updates for Microsoft Exchange**.

5. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
6. On the **Error Reporting** page, click **Yes**, and then click **Next**.
7. On the **Installation Type** page, click **Typical Exchange Server Installation**. If you want to change the path for the Exchange 2010 installation, click **Browse**, locate the appropriate folder in the folder tree, and then click **OK**. Click **Next**.

Note:
If you choose the **Typical Exchange Server Installation** option, you won't be able to install the Unified Messaging server role or Edge Transport server role during this installation. You can add additional server roles later if you don't install them during this installation.

8. On the **Configure Client Access Server** external domain page, enter a domain name to use to configure your Client Access servers. Click **Next**. For more information about configuring Client Access servers, see "Configure the Client Access Server" later in this topic.
9. On the **Customer Experience Improvement** page, choose the appropriate selection for your organization, and then click **Next**.
10. On the **Readiness Checks** page, view the status to determine whether the organization and server role prerequisite checks completed successfully. If they completed successfully, click **Install** to install Exchange 2010.
11. On the **Completion** page, click **Finish**.

Configure the Client Access Server

If this is the first Exchange 2010 server you've installed in your Exchange 2007 organization, you need to perform several additional steps to configure your Exchange 2010 Client Access server.

1. If your organization requires Outlook Anywhere access, enable Outlook Anywhere as shown in the following example.

```
Enable-OutlookAnywhere -Server:<CAS2010> -ExternalHostName:mail.contos
```

2. If you didn't configure a primary external namespace during setup, configure the virtual directories for the offline address book (OAB), Exchange Web Services, Microsoft Exchange ActiveSync, Microsoft Office Outlook Web App, and Exchange Control Panel (ECP) as shown in the following examples.
   This example configures the virtual directories for the OAB.

```
Set-OABVirtualDirectory <CAS2010>\OAB* -ExternalUrl "https://mail.cont
```

   This example configures the virtual directories for Exchange Web Services.

```
Set-WebServicesVirtualDirectory <CAS2010>\EWS* -ExternalUrl https://ma
```

   This example configures the virtual directories for Exchange ActiveSync.

```
Set-ActiveSyncVirtualDirectory -Identity <CAS2010>\Microsoft-Server-Ac
```

   This example configures the virtual directories for Outlook Web App.

```
Set-OwaVirtualDirectory <CAS2010>\OWA* -ExternalUrl https://mail.conto
```

   This example configures the virtual directories for the ECP.

```
Set-EcpVirtualDirectory <CAS2010>\ECP* -ExternalUrl https://mail.conto
```

3. Configure your Outlook Web App settings to meet your organization's needs.
   - To obtain the Outlook Web Access settings from your Exchange 2007 server, run the **Get-OwaVirtualDirectory** cmdlet.
   - To configure the Outlook Web App settings in Exchange 2010, run the **Set-OwaVirtualDirectory** cmdlet.
4. Configure your Exchange ActiveSync authentication settings.
   - To obtain the Exchange ActiveSync settings from your Exchange 2007 server, run the **Get-ActiveSyncVirtualDirectory** cmdlet.
   - To configure the Exchange ActiveSync settings in Exchange 2010, run the **Set-ActiveSyncVirtualDirectory** cmdlet.
5. Install the Exchange 2010 Hub Transport server role and the Exchange 2010 Mailbox server role into the Internet-facing Active Directory site. For configuration steps for these server roles, see Upgrade from Exchange 2007 Transport and Upgrade from Exchange 2007 Mailbox.
6. Change the OAB generation server and enable Web distribution on the Exchange 2010 Client Access server using the following steps.
   - Move the OAB as shown in this example.

```
Move-OfflineAddressBook "Default Offline Address List" -Ser
```

   - Add the Exchange 2010 Client Access server as a Web distribution point as shown in these examples.

```
$OABVDir = Get-OABVirtualDirectory -Server <CAS2010>
$OAB = Get-OfflineAddressBook "Default Offline
Address List"
$OAB.VirtualDirectories += $OABVdir.DistinguishedName
```

```
Set-OfflineAddressBook "Default Offline Address List" -Virt
```

7. Create a legacy host name in your external Domain Name System (DNS) infrastructure and associate this host name with your Exchange 2007 Client Access server or with your proxy infrastructure. See "Create a Legacy Host Name" later in this topic.
8. Reconfigure your external DNS settings or the publishing rules for your reverse proxy infrastructure to have your original namespace of mail.contoso.com point to your Exchange 2010 Client Access server or Client Access server array.

Create a Legacy Host Name

The exact steps for this procedure depend on your Internet service provider (ISP) and firewall configuration. Example steps for GoDaddy are provided to show you how this works. Your actual steps may vary. In general, you need to perform the following steps.

1. Create a DNS host (A) record in your internal and external DNS servers that points to the IP address of your legacy Internet-facing Exchange server (for example, Exchange 2007 Client Access server or Exchange 2003 front-end server) in internal DNS or the public IP address on your reverse proxy or firewall solution (external DNS). The host name should be in the format of legacy.domain.com (for example, legacy.contoso.com).
2. Create a publishing rule for the legacy host name in your reverse proxy or firewall solution to point to your legacy Internet-facing Exchange server. Refer to your proxy or firewall solution's user manual for instructions about how to do this.
3. Configure the existing DNS host (A) record in your internal and external DNS servers for your original host name (for example, mail.contoso.com) to point to your Exchange 2010 organization, for example, the IP address of your Client Access server or array (internal DNS), or the public IP address on your reverse proxy or firewall solution (external DNS).
   For example, if your provider is GoDaddy.com, you can create a DNS host (A) record and associate it with your legacy Exchange infrastructure.
   3.a. From your GoDaddy account management home page, click **Domain Manager** under the **My Products** heading in the left sidebar.
   3.b. If prompted, log on to your account.
   3.c. In the **Total DNS** section of the **Domain Manager** information screen, click **Total DNS Control**.
   3.d. In the **A (Host)** section of the **Total DNS Control** screen, click **Add new A record**.
   3.e. Enter the **host name**, for example, legacy.contoso.com, and enter the IP address of your legacy Exchange server in the **Points to IP address** box.
   3.f. Choose a **TTL** (Time to Live) value. If you're performing this step well in advance of your Exchange 2010 installation, you can choose **1 day** or **1 week** from the drop-down list box. Otherwise, choose the default of **1 hour** or **1/2 hour**.
   3.g. Click **OK** to complete your changes.

Verify the legacy host name is accessible from the Internet

From outside your firewall, perform the following steps, using your specific domain name.

1. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on Exchange 2010.
2. Navigate to https://legacy.contoso.com/exchange, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.
3. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.

You can also use the Microsoft Exchange Server Remote Connectivity Analyzer to verify connectivity for the legacy namespace. To use the Remote Connectivity Analyzer, see Microsoft Exchange Remote Connectivity Analyzer.

Verify Installation and View Configuration Objects

To verify that Exchange 2010 installed correctly, see Verify an Exchange 2010 Installation. After installation is complete, you can view the Exchange 2010 configuration objects in the Exchange Management Console (EMC).

Note:
You can only view and manage the Exchange 2010 configuration objects using the EMC in Exchange 2010.

To verify that mail flow is working correctly, you can perform the following procedure:

1. Configure your Hub Transport server. For more information, see Transport Server Post-Deployment Tasks.
2. Create a mailbox on the Exchange 2010 Mailbox server. For more information, see Create a Mailbox.
3. Send an e-mail message from the Exchange 2010 mailbox to a user who has a mailbox that is located on an Exchange 2007 server. Verify that the e-mail message is received.
4. Send an e-mail message from a user who has a mailbox that is located on an Exchange 2007 server to the new Exchange 2010 mailbox user. Verify that the e-mail message is received.

You can also use the Exchange Remote Connectivity Analyzer to test Exchange connectivity.

Finally, be sure to perform the tasks described in Finalize Deployment Tasks that are required for the server roles that you have installed.

Important:
Exchange 2010 now creates system address lists in a new container. Recipients created or modified using Exchange 2003 or Exchange 2007 management tools won't be stamped with these system address lists. As a result, they won't be seen by the Exchange 2010 **Get-Recipient** cmdlet.
To fix this issue, you must enable Active Directory virtual list view (VLV). After you have completed the upgrade of an existing Exchange 2003 organization to Exchange 2010 and have decommissioned your Exchange 2003 servers, you must enable Active Directory VLV. To enable VLV for Exchange 2010, run the **Enable-AddressListPaging** cmdlet. For more information, see Enable-AddressListPaging.

1.2.2.7.7 Install Exchange 2010 in a Mixed Exchange 2003 and Exchange 2007 Organization

Install Exchange 2010 in a Mixed Exchange 2003 and Exchange 2007 Organization

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-31*

You can use Microsoft Exchange Server 2010 Setup to install the first server running Exchange 2010 in an existing Exchange organization where both Exchange Server 2003 and Exchange Server 2007 are present.

You can't perform an in-place upgrade from Exchange 2003 or Exchange 2007 to Exchange 2010. However, you can install an Exchange 2010 server into the existing Exchange organization, and then move the Exchange resources, such as mailboxes, public folders, and connectors to Exchange 2010.

After you perform this procedure, your organization will be running in a coexistence mode. You can maintain this mode for an indefinite period of time, or you can immediately complete the upgrade to Exchange 2010 by moving all resources from Exchange 2003 and Exchange 2007 to Exchange 2010, and then decommissioning the Exchange 2003 and

Exchange 2007 servers. For more information about removing your Exchange 2003 and Exchange 2007 servers, see the following topics:

- How to Remove the Last Legacy Exchange Server from an Organization
- How to Completely Remove Exchange 2007 from a Server

To learn more about upgrading your organization, see the following topics:

- Understanding Upgrade to Exchange 2010
- Exchange 2003 - Planning Roadmap for Upgrade and Coexistence
- Exchange 2007 - Planning Roadmap for Upgrade and Coexistence

For more information about performing a custom installation, see Install Exchange 2010 Using the Custom Installation Type. For information about installing Exchange 2010 in unattended mode, see Install Exchange 2010 in Unattended Mode.

Exchange Server 2010 Deployment Assistant

Exchange Server 2010 introduces the Exchange Server Deployment Assistant, or ExDeploy, a new Web-based tool that can help you with your Exchange deployment. ExDeploy asks you a few questions about your current environment and then generates a custom checklist and procedures that help simplify your deployment.

For more information, see Exchange Server Deployment Assistant.

Prerequisites

You must ensure that each of the servers meets the appropriate prerequisites and system requirements before you begin your installation. For more information, see the following topics:

- Overview of Exchange 2010 Server Roles
- Exchange 2010 Prerequisites
- Exchange 2010 System Requirements

Warning:

After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Install Exchange 2010

If this is the first instance of Exchange 2010 that you're installing into your existing organization, make sure that you install the Client Access server role first, followed by the Hub Transport server role, followed by the Unified Messaging server role, and last, the Mailbox server role. For more information about the Client Access server role, see "Configure the Client Access server" later in this topic.

To perform the following procedure, the account you use must be delegated membership in the Schema Admins group if you haven't previously prepared the Active Directory schema. If you're installing the first Exchange 2010 server in the organization, the account you use must have membership in the Enterprise Admins group. If you've already prepared the schema and aren't installing the first Exchange 2010 server in the organization, the account you use must be delegated the Delegated Setup role group.

Note:

For information about preparing Active Directory for Exchange 2010, see Prepare Active Directory and Domains. For information about permissions in Exchange 2010, see

Understanding Permissions and Understanding Role Based Access Control.

1. Insert the Exchange 2010 DVD into the DVD drive. When the **AutoPlay** dialog box appears, click **Run Setup.exe** under **Install or run program**. If the **AutoPlay** dialog box doesn't appear, navigate to the root of the DVD and double-click **Setup.exe**. Alternatively, browse to the location of your Exchange 2010 installation files and double-click **Setup.exe**.
2. The Exchange Server 2010 Setup welcome screen appears. In the **Plan** section, you can follow the links to read overview information regarding Exchange 2010, deploying languages, and the Exchange 2010 Deployment Assistant. In the **Enhance** section, you can read more information about Forefront Protection 2010, and install Microsoft Forefront Protection 2010. In the **Install** section, the software listed for **Step 1: Install .NET Framework 3.5 SP1** and **Step 2: Install Windows PowerShell v2** was installed with the Exchange 2010 prerequisites. However, if these prerequisites aren't already installed, click the appropriate step to install them.
   For more information about Windows PowerShell installation, see Install Windows Management Framework.

   Important:
   If you're installing Exchange 2010 on the Windows Server 2008 R2 operating system, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.
3. When **Step 1** and **Step 2** are shown as **Installed**, click **Step 3: Choose Exchange language option** to expand the Exchange language options, and then choose the appropriate option:
   - **Install all languages from the language bundle** This option installs all the Exchange 2010 languages from an Exchange 2010 language bundle. You can connect to the Internet to download the latest applicable language bundle or to use a previously downloaded language bundle on a local drive or network share. Internet connectivity is required for Exchange Setup to download the language pack bundle.
   - **Install only languages from the DVD** This option installs only the languages included with the Setup DVD. The installation of additional language support requires installing the languages from the language bundle.

   For more information about Exchange language options, see Exchange 2010 Language Support.
4. After language installation is complete, click **Step 4: Install Microsoft Exchange**. This option starts the Exchange Server 2010 Setup wizard.

   Note:
   After your installation is complete, you can return to **Step 5: Get critical updates for Microsoft Exchange**.
5. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
6. On the **Error Reporting** page, click **Yes**, and then click **Next**.
7. On the **Installation Type** page, click **Typical Exchange Server Installation**. If you want to change the path for the Exchange 2010 installation, click **Browse**, locate the appropriate folder in the folder tree, and then click **OK**. Click **Next**.

   Note:
   If you choose the **Typical Exchange Server Installation** option, you won't be able to install the Unified Messaging server role or Edge Transport server role during this installation. You can add additional server roles later if you don't install them during this installation.
8. On the **Configure Client Access Server** external domain page, enter a domain name to use to configure your Client Access servers. Click **Next**. For

more information about configuring Client Access servers, see "Configure the Client Access Server" later in this topic.

9. On the **Customer Experience Improvement** page, choose the appropriate selection for your organization, and then click **Next**.
10. On the **Readiness Checks** page, view the status to determine whether the organization and server role prerequisite checks completed successfully. If they completed successfully, click **Install** to install Exchange 2010.
11. On the **Completion** page, click **Finish**.

Configure the Client Access Server

If this is the first Exchange 2010 server you've installed in your mixed Exchange 2003 and Exchange 2007 organization, you need to perform several additional steps to configure your Exchange 2010 Client Access server.

1. If your organization requires Outlook Anywhere access, enable Outlook Anywhere as shown in the following example.

```
Enable-OutlookAnywhere -Server:<CAS2010> -ExternalHostName:mail.contos
```

2. If you didn't configure a primary external namespace during setup, configure the virtual directories for the offline address book (OAB), Exchange Web Services, Microsoft Exchange ActiveSync, Microsoft Office Outlook Web App, and Exchange Control Panel (ECP) as shown in the following examples. This example configures the virtual directories for the OAB.

```
Set-OABVirtualDirectory <CAS2010>\OAB* -ExternalUrl "https://mail.cont
```

This example configures the virtual directories for Exchange Web Services.

```
Set-WebServicesVirtualDirectory <CAS2010>\EWS* -ExternalUrl https://ma
```

This example configures the virtual directories for Exchange ActiveSync.

```
Set-ActiveSyncVirtualDirectory -Identity <CAS2010>\Microsoft-Server-Ac
```

This example configures the virtual directories for Outlook Web App.

```
Set-OwaVirtualDirectory <CAS2010>\OWA* -ExternalUrl https://mail.conto
```

This example configures the virtual directories for the ECP.

```
Set-EcpVirtualDirectory <CAS2010>\ECP* -ExternalUrl https://mail.conto
```

3. Configure your Outlook Web App settings to meet your organization's needs.
   - To obtain the Outlook Web Access settings from your Exchange 2007 server, run the **Get-OwaVirtualDirectory** cmdlet.
   - To configure the Outlook Web App settings in Exchange 2010, run the **Set-OwaVirtualDirectory** cmdlet.
4. Configure your Exchange ActiveSync authentication settings.
   - To obtain the Exchange ActiveSync settings from your Exchange 2007 server, run the **Get-ActiveSyncVirtualDirectory** cmdlet.
   - To configure the Exchange ActiveSync settings in Exchange 2010, run the **Set-ActiveSyncVirtualDirectory** cmdlet.
5. Install the Exchange 2010 Hub Transport server role and the Exchange 2010 Mailbox server role into the Internet-facing Active Directory site. For configuration steps for these server roles, see Upgrade from Exchange 2007 Transport and Upgrade from Exchange 2007 Mailbox.
6. Change the OAB generation server and enable Web distribution on the Exchange 2010 Client Access server using the following steps.
   - Move the OAB as shown in this example.

```
Move-OfflineAddressBook "Default Offline Address List" -Ser
```

   - Add the Exchange 2010 Client Access server as a Web distribution point as shown in these examples.

```
$OABVDir = Get-OABVirtualDirectory -Server <CAS2010>
$OAB = Get-OfflineAddressBook "Default Offline
```

```
Address List"
$OAB.VirtualDirectories += $OABVdir.DistinguishedName
Set-OfflineAddressBook "Default Offline Address List" -Virt
```

7. If you have Exchange 2003 mailboxes in your organization, enable Integrated Windows authentication on the Microsoft-Server-ActiveSync virtual directory on the Exchange 2003 back-end server. This allows the Exchange 2010 Client Access server and the Exchange 2003 back-end server to communicate using Kerberos authentication. Do one of the following:
   - Install a hotfix. To download the hotfix, see Event ID 1036 is logged on an Exchange 2007 server that is running the CAS role when mobile devices connect to the Exchange 2007 server to access mailboxes on an Exchange 2003 back-end server. Use Exchange System Manager to adjust the authentication settings of the Exchange ActiveSync virtual directory.
   - Set the **msExchAuthenticationFlags** attribute to a value of 6 on the **Microsoft-Server-ActiveSync** object within the configuration container on each Exchange 2003 Mailbox server. For an example script, see Server Build DVD Visual Basic Script Examples.

   Important:
   Don't use IIS Manager to change the authentication setting on the Microsoft ActiveSync virtual directory, because the DS2MB process within the Microsoft Exchange System Attendant will overwrite the settings stored in Active Directory.
8. Create a legacy host name in your external Domain Name System (DNS) infrastructure and associate this host name with your Exchange 2007 Client Access server or with your proxy infrastructure. See "Create a Legacy Host Name" later in this topic.
9. Reconfigure your external DNS settings or the publishing rules for your reverse proxy infrastructure to have your original namespace of mail.contoso.com point to your Exchange 2010 Client Access server or Client Access server array.

Create a Legacy Host Name

The exact steps for this procedure depend on your Internet service provider (ISP) and firewall configuration. Example steps for GoDaddy are provided to show you how this works. Your actual steps may vary. In general, you need to perform the following steps.

1. Create a DNS host (A) record in your internal and external DNS servers that points to the IP address of your legacy Internet-facing Exchange server (for example, Exchange 2007 Client Access server or Exchange 2003 front-end server) in internal DNS or the public IP address on your reverse proxy or firewall solution (external DNS). The host name should be in the format of legacy.domain.com (for example, legacy.contoso.com).
2. Create a publishing rule for the legacy host name in your reverse proxy or firewall solution to point to your legacy Internet-facing Exchange server. Refer to your proxy or firewall solution's user manual for instructions about how to do this.
3. Configure the existing DNS host (A) record in your internal and external DNS servers for your original host name (for example, mail.contoso.com) to point to your Exchange 2010 organization, for example, the IP address of your Client Access server or array (internal DNS), or the public IP address on your reverse proxy or firewall solution (external DNS).
   For example, if your provider is GoDaddy.com, you can create a DNS host (A) record and associate it with your legacy Exchange infrastructure.
   3.a. From your GoDaddy account management home page, click **Domain Manager** under the **My Products** heading in the left sidebar.
   3.b. If prompted, log on to your account.
   3.c. In the **Total DNS** section of the **Domain Manager** information screen, click **Total DNS Control**.

3.d.In the **A (Host)** section of the **Total DNS Control** screen click **Add new A record**.
3.e.Enter the **host name**, for example, legacy.contoso.com, and enter the IP address of your legacy Exchange server in the **Points to IP address** box.
3.f.Choose a **TTL** (Time to Live) value. If you're performing this step well in advance of your Exchange 2010 installation, you can choose **1 day** or **1 week** from the drop-down list box. Otherwise, choose the default of **1 hour** or **1/2 hour**.
3.g.Click **OK** to complete your changes.

Verify the legacy host name is accessible from the Internet

From outside your firewall, perform the following steps, using your specific domain name.

1. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on Exchange 2010.
2. Navigate to https://legacy.contoso.com/exchange, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.
3. Navigate to https://mail.contoso.com/owa, and then verify that you can access Outlook Web App for a user whose mailbox is on a legacy Exchange server.

You can also use the Microsoft Exchange Server Remote Connectivity Analyzer to verify connectivity for the legacy namespace. To use the Remote Connectivity Analyzer, see Microsoft Exchange Remote Connectivity Analyzer.

Verify Installation and View Configuration Objects

To verify that Exchange 2010 installed correctly, see Verify an Exchange 2010 Installation. After installation is complete, you can view the Exchange 2010 configuration objects in the Exchange Management Console (EMC).

Note:
You can only view and manage the Exchange 2010 configuration objects by using the EMC in Exchange 2010.

To verify that mail flow is working correctly, you can perform the following procedure:

1. Configure your Hub Transport server. For more information, see Transport Server Post-Deployment Tasks.
2. Create a mailbox on the Exchange 2010 Mailbox server. For more information, see Create a Mailbox.
3. Send an e-mail message from the Exchange 2010 mailbox to a user who has a mailbox that is located on an Exchange 2007 server. Verify that the e-mail message is received.
4. Send an e-mail message from a user who has a mailbox that is located on an Exchange 2007 server to the new Exchange 2010 mailbox user. Verify that the e-mail message is received.

You can also use the Exchange Remote Connectivity Analyzer to test Exchange connectivity.

Finally, be sure to perform the tasks described in Finalize Deployment Tasks that are required for the server roles that you have installed.

Important:
Exchange 2010 now creates system address lists in a new container. Recipients created or modified using Exchange 2003 or Exchange 2007 management tools won't be stamped with these system address lists. As a result, they won't be seen by the Exchange 2010

Get-Recipient cmdlet.
To fix this issue, you must enable Active Directory virtual list view (VLV). After you have completed the upgrade of an existing Exchange 2003 organization to Exchange 2010 and have decommissioned your Exchange 2003 servers, you must enable Active Directory VLV. To enable VLV for Exchange 2010, run the **Enable-AddressListPaging** cmdlet. For more information, see Enable-AddressListPaging.

1.2.2.7.8 Install Exchange 2010 in Unattended Mode

Install Exchange 2010 in Unattended Mode

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Setup from a Command Prompt window to install Microsoft Exchange Server 2010 in unattended mode. To perform an unattended setup, you must install Exchange 2010 from the command prompt.

Note:
After you install any server roles on a computer running Exchange 2010, you can't use the Exchange 2010 Setup wizard to add any additional server roles to this computer. If you want to add more server roles to a computer, you must either use Add or Remove Programs from Control Panel or use Setup.com from a Command Prompt window.

For information about tasks to complete after installation, see Exchange 2010 Post-Installation Tasks.

Prerequisites

- You must install both the Mailbox server role and the Hub Transport server role in each Active Directory site for e-mail messages to flow correctly.
- You must install a Client Access server in each Active Directory site that has a Mailbox server role for client access to work correctly.
- You can install the Mailbox server role, the Hub Transport server role, the Client Access server role, and the Unified Messaging (UM) server role on the same computer or on separate computers. You must install the Edge Transport server role on a separate computer in your organization's perimeter network.
- You must ensure that each of the server roles meets the appropriate prerequisites and system requirements before you begin your installation:
  - For more information about server roles, see Overview of Exchange 2010 Server Roles.
  - To understand the prerequisites for all server roles, see Exchange 2010 Prerequisites.
  - For more information about system requirements, see Exchange 2010 System Requirements.
- You must ensure the account you use is delegated membership in the Schema Admins group if you haven't previously prepared the Active Directory schema. If you're installing the first Exchange 2010 server in the organization, the account you use must have membership in the Enterprise Admins group. If you've already prepared the schema and aren't installing the first Exchange 2010 server in the organization, the account you use must be a member of the Exchange 2010 Organization Management role group.
  Administrators who are members of the Delegated Setup role group can

deploy Exchange 2010 servers that have been previously provisioned by a member of the Organization Management role group. For more information about delegated setup, see Provision Exchange 2010 Server and Delegate Setup. For more information about permissions, delegating roles, and the rights that are required to administer Exchange 2010, see Understanding Permissions.

Note:
During Exchange 2010 installation, when preparing Active Directory, system mailboxes are created in the root domain that users and administrators can't log on to. These system mailboxes are created for Exchange 2010 features such as Message Approval and E-discovery.

Warning:
After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Use Setup.com to install Exchange 2010 in unattended mode

1. Log on to the server on which you want to install Exchange 2010.
2. Insert the Exchange 2010 DVD into the DVD drive, and then, at the command prompt, navigate to the DVD drive, or navigate to the network location of the Exchange 2010 installation files.
3. At the command prompt, run the applicable command for your organization.

```
Setup.com [/mode:<setup mode>] [/role:<server roles to install>] [/Ins
```

- *[/mode: <setup mode>*, or */m:<setup mode>]*
  You must use the */mode* parameter to specify the setup mode. If you don't specify a mode, Setup uses the default Install mode. Select one of the following modes:
  Install Use this mode when you're installing a new role or adding a role to an existing installation (maintenance mode). You can use this mode from both the Exchange Setup wizard and the unattended install.
  Uninstall Use this mode when you're removing the Exchange installation or removing a single server role from an existing installation (maintenance). You can use this mode from both the Exchange Setup wizard and the unattended install.
  Upgrade Select this mode used when you have an existing installation of Exchange and you're installing the new version. This mode is used for a Service Pack installation. You can use this mode from both the Exchange Setup wizard and the unattended install.
  RecoverServer Use this mode when there has been a catastrophic failure of a server, and you need to recover data. You must install a server using the same fully qualified domain name (FQDN) as the failed server, and then run Setup with the **/m:RecoverServer** switch. Don't specify the roles to restore. Setup detects the Exchange Server object in Active Directory and installs the corresponding files and configuration automatically. After you recover the server, you can restore databases and reconfigure any additional settings.
  To run in RecoverServer mode, you can't have Exchange installed on the server. The Exchange server object must exist in Active Directory. You can only use this mode during an unattended installation.
- *[/roles: <server roles>*, */role:<server roles>*, or */r:<server roles>]*

You must use the */roles* parameter to specify which server roles to install or uninstall. Select from one or more of the following roles, in a comma-separated list:
ClientAccess (or CA, or C)
EdgeTransport (or ET, or E)

Note:
The Edge Transport server role can't coexist on the same computer with any other server role. You must deploy the Edge Transport server role in the perimeter network and outside the Active Directory forest.

HubTransport (or HT, or H)
Mailbox (or MB, or M)
UnifiedMessaging (or UM, or U)
ManagementTools (or MT, or T)

Note:
If you select ManagementTools, you'll install the EMC and the Exchange cmdlets for the Exchange Management Shell. The management tools will be installed automatically if you install any other server role.

For example, to specify the Client Access and Mailbox server roles, specify the following: **Setup.com /roles:ClientAccess,Mailbox** or alternatively, specify the following: **Setup.com /r:C,M**.

- [*/InstallWindowsComponents*]
  During an Exchange 2010 SP1 installation, you can install the required Windows roles and features for each selected Exchange 2010 SP1 server role. If a reboot is required, Setup will resume where the installation ended. For example, to specify /InstallWindowsComponents, specify the following: **Setup.com /roles:ClientAccess,Mailbox /InstallWindowsComponents**
- [*/OrganizationName:<organization name>*, or */on:<organization name>*]
  Use the */OrganizationName* parameter to specify the name to give the new Exchange organization. This parameter is required if you're installing the first server in an organization, and you haven't run **Setup /PrepareAD**. If you're installing a server in an existing Exchange organization or if you've already run **Setup /PrepareAD**, you can't use this parameter.

  Note:
  In the Exchange 2010 Setup wizard, the default value is **First Organization**. In the command-line version of Setup, there is no default value.

  The Exchange organization name can contain only the following characters:
  A through Z
  a through z
  0 through 9
  Space (not leading or trailing)
  Hyphen or dash
  The organization name can't contain more than 64 characters. The organization name can't be blank. If the organization name contains spaces, you must enclose it in quotation marks (").
- [*/TargetDir:<destination folder>*, or */t:<destination folder>*]
  Use the */TargetDir* parameter to specify the location to install Exchange 2010 files. The default location is Program Files \Microsoft\Exchange Server. You can't install Exchange 2010 to a root directory such as C:\. You can't install Exchange 2010 on

a ROM drive, RAM disk, network drive, removable disk, or unknown drive type. You can't change the installation directory if Exchange is already installed on the server (for example, if you're adding a server role). If the destination folder contains spaces, you must enclose it in quotation marks (").

- [*/SourceDir:<source folder>*, or */s:<source folder>*]
  Use the */SourceDir* parameter to specify the location from which to install Exchange 2010 files when you're adding a server role to an existing Exchange 2010 server and if the source folder isn't the folder from which you're running Setup. The default value is the current directory from which you're running Setup. If the source folder contains spaces, you must enclose it in quotation marks (").
- [*/UpdatesDir:<updates folder>*, or */u:<updates folder>*]
  Use the */UpdatesDir* parameter to specify the directory from which updates will be installed. If the updates folder contains spaces, you must enclose it in quotation marks ("). Files in the Updates directory must be either an Updates.exe file, or one or more *.msp files. Setup will install the updates before installing the Exchange server roles specified.
  By default, Setup uses the Updates folder that's in the root folder of the installation media. If you want Setup to search for updates in a different folder instead of in the default Updates folder, use this parameter. You can specify only one folder for updates.
- [*/DomainController:<FQDN of domain controller>*, or */dc:<FQDN of domain controller>*]
  Use the */DomainController* parameter to specify the domain controller to use to read from and write to Active Directory during setup. You can use NetBIOS or fully qualified domain name (FQDN) format. The domain controller that you specify must be in the same Active Directory site as the server on which you run Setup and must meet the following requirements: Windows Server 2003 Standard Edition with SP1 or later (32-bit or 64-bit), or Windows Server 2003 Enterprise Edition with SP1 or later (32-bit or 64-bit), or Windows Server 2008 Standard or Enterprise (32-bit or 64-bit), or Windows Server 2008 R2 Standard or Enterprise, or Windows Server 2008 Datacenter or R2 Datacenter. If you don't use this parameter, Setup will select a domain controller to use.
  To run **Setup /PrepareSchema** or **Setup /PrepareAD**, or to install the first Exchange 2010 server in an organization if you haven't run **Setup /PrepareAD**, Setup must use the schema master domain controller to read from and write to Active Directory. If you specify a domain controller that isn't the schema master, Setup will stop and return an error message.
- [*/AnswerFile:<filename>*, or */a:<filename>*]
  Use the */AnswerFile* parameter to specify the location of a file that contains parameters for Setup. You can use this file to install Exchange 2010 on multiple computers with the same parameters. You can use the following parameters in the answer file: *EnableLegacyOutlook*, *LegacyRoutingServer*, *OrganizationName*, *DoNotStartTransport*, *UpdatesDir*, *EnableErrorReporting*, *NoSelfSignedCertificates*, *AdamLdapPort*, and *AdamSslPort*.

  Note:
  Don't include the slash mark (/) with the parameters in the answer file.

  The following is an example of the contents in the answer file

AnswerFile01.txt.

```
EnableErrorReporting
UpdatesDir=C:\Exchange2010_Updates
```

The following is an example of the Setup command to use this answer file.

```
Setup.com /Mode:Install /Roles:Mailbox /AnswerFile:C:\Answer
```

- [*/DoNotStartTransport*]
  Use the */DoNotStartTransport* parameter to specify that the Microsoft Exchange Transport service won't start when Setup completes. By default, Setup starts the Microsoft Exchange Transport service after installing either the Hub Transport or Edge Transport server role. If you need to do additional configuration before the Edge Transport or Hub Transport server accepts e-mail messages, for example, configuring anti-spam agents, you should use this parameter. We recommend that you use this parameter when you use the */RecoverServer* parameter to recover a Hub Transport or Edge Transport server so that you can move the queue database from the failed server to the correct location on the new server before starting the Microsoft Exchange Transport service.

  Note:
  The Microsoft Exchange Transport service runs only on the Hub Transport and Edge Transport server roles.

- [*/EnableLegacyOutlook*]
  Use the */EnableLegacyOutlook* parameter to specify that you have client computers that are running Microsoft Outlook 2003 or earlier. Exchange 2010 will create a public folder database on the Mailbox server. If all of your client computers are running Office Outlook 2007, public folders are optional in Exchange 2010. If you don't use this parameter, Exchange 2010 won't create a public folder database on the Mailbox server. You can add a public folder database later.
  You can only use this parameter if you're installing the first Mailbox server in an organization.
  When you install the first Mailbox server in an existing Exchange Server 2003 organization, by default, Setup will create the public folder database on the Exchange 2010 server. You don't need to specify this parameter. Setup won't create a public folder database on subsequent Mailbox server installations in this organization.
- [*/LegacyRoutingServer*]
  Use the */LegacyRoutingServer* parameter to specify an Exchange 2003 bridgehead server that's located in the routing group to which you'll create the initial routing group connector. A routing group connector is required for mail flow between Exchange 2010 and Exchange 2003 when these Exchange server versions coexist in the same organization.
  You can use this parameter only if you're installing the first Hub Transport server in the organization and if you have Exchange 2003 servers in the existing organization. In this scenario, this parameter is required to establish mail flow between Exchange 2010 and Exchange 2003.
- [*/EnableErrorReporting*]
  Use the */EnableErrorReporting* parameter to enable error reporting during Setup. If you decide to enable error reporting,

the Microsoft Error Reporting Service collects information about how you use Exchange 2010 and about any issues you may encounter. This information is used to help Microsoft diagnose problems and provide solutions.
You can use this parameter only if you're running Setup in Install mode.
If you enable error reporting, Setup sets the following registry key to 0:
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\E14\DisableErrorReporting
By default, this registry key is set to 1 and error reporting is disabled.

- [*/NoSelfSignedCertificates*]
  Use the */NoSelfSignedCertificates* parameter if you don't want Setup to create self-signed certificates in the case where no other valid certificate is found for Secure Sockets Layer (SSL) or Transport Layer Security (TLS) sessions. If you don't have a certificate, communication between clients and the Client Access or Unified Messaging server will be unencrypted.
  You can only use this parameter if you're installing either the Client Access server role or the Unified Messaging server role.
- [*/AdamLdapPort:<port>*]
  Use the */AdamLdapPort* parameter to specify the LDAP port to use for the Edge Transport server role Active Directory Lightweight Directory Services (AD LDS) instance. The default value is 50389. Exchange stores the ADAM LDAP port in the following registry key:
  HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v14\EdgeTransportRole\AdamSettings\MSExchangeAdam\LdapPort
  You can use this parameter only if you're installing the Edge Transport server role.
- [*/AdamSslPort:<port>*]
  Use the */AdamSslPort* parameter to specify the SSL port to use for the Edge Transport server role AD LDS instance. You can specify any valid unused port number. The default value is 50636. Exchange stores the Active Directory Lightweight Directory Services (AD LDS) SSL port in the following registry key:
  HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v14\EdgeTransportRole\AdamSettings\MsExchangeAdam\SslPort
  You can use this parameter only if you're installing the Edge Transport server role.
- [*/LanguagePack:<path to language pack bundle> or /lp:<path to language pack bundle>*]
  Use the */LanguagePack* parameter to specify an Exchange language pack that you want to add. For more information, see Exchange 2010 Language Support.
- [*/AddUmLanguagePack:<UM language pack name>*]
  Use the */AddUmLanguagePack* parameter to specify a UM language pack that you want to add. If you add a UM language pack, callers and Outlook Voice Access users can interact with the UM system in another language. For a list of Unified Messaging languages, see Client Language Support for Unified Messaging.
  To install a UM language pack, the Unified Messaging server role must already be installed.
  When you add a language pack, by default, Setup expects the language pack .msi file to be in the ServerRoles

\UnifiedMessaging directory of the installation directory. To specify a different location, use the */SourceDir* parameter.

Note:
Don't include "umlang-" or the .msi extension in the language pack name. For example, the German language pack is umlang-de-DE.msi. To install this language pack, run the following command: **Setup.com /AddUmLanguagePack:de-DE**

Note:
You can't install a language pack by running the language pack .msi file. You must use Setup.com to install the language pack.

- [*/RemoveUmLanguagePack:<UM language pack name>*]
  Use the */RemoveUmLanguagePack* parameter to specify a Unified Messaging language pack that you want to remove.

  Note:
  Don't include "umlang-" or the .msi extension in the language pack name. For example, the German language pack is umlang-de-DE.msi. To remove this language pack, run the following command: **Setup.com /RemoveUmLanguagePack:de-DE**

  Note:
  You can't remove a language pack by running the language pack .msi file. You must use Setup.com to remove the language pack.

- [*/NewProvisionedServer:<server name>*, or */nprs:<server name>*]
  Use the */NewProvisionedServer* parameter to create a placeholder server object in Active Directory so that you can delegate the setup of a server. If you provide permissions to this server object for a user who has Exchange Server Administrators role permissions, that user can install Exchange 2010 on the server. During Setup, additional attributes on this server object will be added. If you don't specify a server name, Setup.com will create a placeholder server object in Active Directory for the local server.
  To run Setup.com with the */NewProvisionedServer* parameter, you must be a member of the Exchange 2010 Organization Management role group, you must have an existing Exchange organization in Active Directory, and you must have at least one Exchange 2010 server installed in the organization. The server that you specify must have a machine account in Active Directory.
  After you provision a server with the */NewProvisionedServer* parameter, you can view the server in the EMC or in the results of the **Get-ExchangeServer** cmdlet.
- [*/RemoveProvisionedServer:<server name>*, or */rprs:<server name>*]
  Use the */RemoveProvisionedServer* parameter to remove a placeholder server object that was created using the *NewProvisionedServer* parameter. You can remove the server object at any time before you install Exchange 2010 on that server. After you install Exchange 2010, you can't use this parameter to remove the server object. You can use this parameter only to remove a provisioned server object. If you run Setup.com with the */RemoveProvisionedServer* parameter on a server that has Exchange 2010 installed, Setup.com will complete successfully, but the server object won't be removed. If you don't specify a server name, Setup.com will remove the placeholder server object in Active Directory that has the same name as the local server.
  To run Setup.com with the */RemoveProvisionedServer* parameter,

you must be a member of the Exchange Organization Management role group.

- [*/ExternalCASServerDomain:<domain>*]
  Use this parameter to specify the external domain for the Client Access server to configure the external URL for the OWA/ ActiveSync/Web Services/OAB virtual directory. For example, to specify the ExternalCASServerDomain, specify the following: **Setup.com /roles:ClientAccess,Mailbox / ExternalCASServerDomain:Mail.Contoso.com**. For more information, see Configure External Client Access Namespaces.
- [*/MdbName:<mailbox database name>*]
  Use this parameter to enter the default database name that is created when installing the Mailbox server role. This name must be unique within the organization. If you don't use this parameter during your Mailbox server role installation, you can create a new database that aligns with your naming conventions, and then move mailboxes if necessary and delete the default database that's created. For example, to specify the MdbName, specify the following: **Setup.com /roles: Mailbox / MdbName: MailboxDatabase01**.
- [*/DbFilePath:<Edb file path>*]
  Use this parameter to enter the full path to the .edb file when installing the Mailbox server role. For example, to specify the Dbfilepath, specify the following: **Setup.com /roles: Mailbox / Dbfilepath:D:\DatabaseFiles\MailboxDatabase01.edb**.
- [*/LogFolderPath:<log folder path>*]
  Use this parameter to enter the folder path to the directory where the database logs should be placed when installing the Mailbox server role. For example, to specify the log folder path, specify the following: **Setup.com /roles: Mailbox / Logfolderpath:D:\DatabaseFiles\LogFolder**.
- [*Upgrade*]
  Use this parameter when you have an existing installation of Exchange and you're installing a new version. This mode is used for service pack installations.
- [*/Hosting*]
  Use this parameter to install and enable hosting functionality and features. For example, to specify hosting mode, specify the following: **Setup.com /roles: Mailbox /Hosting**.
  This parameter is available for multi-tenant deployments. It isn't available for on-premises deployments. For more information about multi-tenant deployments, see Multi-Tenant Support.
- [*/?*]
  Use the */?* parameter to display Help for the Setup.com command.

4. Setup copies the setup files locally to the computer on which you're installing Exchange 2010.
5. Setup checks the prerequisites, including all prerequisites specific to the server roles that you're installing. If you haven't met all the prerequisites, Setup fails and returns an error message that explains the reason for the failure. If you've met all the prerequisites, Setup installs Exchange 2010.
6. Verify that the installation completed successfully. For more information, see Verify an Exchange 2010 Installation.

Examples

The following are examples of using Setup.com:

- **Setup.com /mode:Install /role:Mailbox,HubTransport / TargetDir:"C:\Exchange 2010"**

This command installs the Mailbox server role, the Hub Transport server role, and the management tools to the C:\Exchange 2010 directory.

- **Setup.com /r:M,C,U**
  This command installs the Mailbox server role, Client Access server role, Unified Messaging server role, and the management tools.
- **Setup.com /mode:Uninstall /role:HT**
  This command removes the Hub Transport server role from the server.
- **Setup.com /mode:Uninstall**
  This command completely removes Exchange 2010 from the server and removes this server's Exchange configuration from Active Directory.
- **Setup.com /mode:Install /role:Mailbox,HubTransport /OrganizationName:MyOrg**
  This command creates an Exchange organization in Active Directory called MyOrg and also installs the Mailbox server role, Hub Transport server role, and the management tools.
- **Setup.com /mode:Upgrade**
  This command upgrades an existing version of Exchange. The upgrade parameter is used for service pack installations.
- **Setup.com /PrepareAD /on:"My Org"**
  This command creates an Exchange organization called My Org and prepares Active Directory for Exchange 2010.
- **C:\Exchange2010\bin\Setup.com /m:Install /r:C /SourceDir:d:\amd64**
  This command adds the Client Access server role to an existing Exchange 2010 server using D:\amd64 as the source directory.
- **Setup.com /role:Mailbox,HubTransport /UpdatesDir:"C:\Exchange2010\New Patches"**
  This command updates ExchangeServer.msi with patches from the specified directory, and then installs the Mailbox server role, Hub Transport server role, and the management tools.
- **Setup.com /mode:Install /role:Mailbox,HubTransport /DomainController:DC01**
  This command uses the domain controller DC01 to query and make changes to Active Directory while installing the Mailbox server role, Hub Transport server role, and the management tools.
- **Setup.com /mode:Install /role:Mailbox /AnswerFile:c:\ExchangeConfig.txt**
  This command installs the Mailbox server role by using the settings in the ExchangeConfig.txt file.
- **Setup.com /mode:Install /role:EdgeTranport /DoNotStartTransport**
  This command installs the Edge Transport server role and the management tools. After installation, Exchange doesn't start the Microsoft Exchange Transport service.
- **Setup.com /mode:Install /role:Mailbox,HubTransport /TargetDir:"C:\Exchange2010" /EnableLegacyOutlook**
  This command installs the Mailbox server role, Hub Transport server role, and the management tools into the C:\Exchange2010 directory. This command also creates a public folder database on the Mailbox server.
- **Setup.com /mode:Install /role:Mailbox,HubTransport /TargetDir:"C:\Exchange2010" /LegacyRoutingServer:Ex2003.contoso.com**
  This command installs the Mailbox server role, Hub Transport server role, and the management tools into the C:\Exchange2010 directory. This command also creates a routing group connector from the Hub Transport server to the specified legacy Exchange server, and creates a routing group connector from the legacy Exchange server to the Hub Transport server.
- **Setup.com /mode:Install /role:Mailbox,HubTransport /EnableErrorReporting**
  This command installs the Mailbox server role, Hub Transport server role, and the management tools. This command also enables error reporting.
- **Setup.com /mode:Install /role:ClientAccess /NoSelfSignedCertificates**

This command installs the Client Access server role and the management tools and doesn't create a self-signed certificate.

- **Setup.com /r:ET /AdamLdapPort:50390 /AdamSslPort:50640**
  This command installs the Edge Transport server role and the management tools and configures the Active Directory Lightweight Directory Services (AD LDS) instance to use port 50390 for LDAP and port 50640 for SSL.
- **Setup.com /rprs:Exchange03**
  This command removes the object Exchange03 from Active Directory.
- **Setup.com /mode:Install /languagepack:<"C:ExchangeLanguagePack"> /role:Mailbox,HubTransport**
  This command installs the language pack bundle and the Mailbox and Hub Transport server roles.
- **Setup.com /AddUmLanguagePack:ko-KR**
  This command installs the Korean Unified Messaging language pack from the %ExchangeSourceDir%\ServerRoles\UnifiedMessaging directory.

1.2.2.7.9 Install Exchange 2010 Using the Custom Installation Type

Install Exchange 2010 Using the Custom Installation Type

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-31*

You can install Microsoft Exchange Server 2010 using the **Custom** installation type. A custom installation enables you to select which specific server role or roles you want installed. Custom installation differs from the Exchange 2010 **Typical** installation type in which the Hub Transport, Client Access, and Mailbox server roles plus the Exchange management tools are installed by default. For detailed steps about how to perform an installation of Exchange 2010 with the **Typical** installation type, see Install Exchange Server 2010.

After you've completed a custom installation of Exchange 2010, be aware of the following important points:

- **Potential for simultaneous OAB download requests** After you install the first Exchange 2010 server in an organization, if you create a recipient object (such as a mailbox, contact, distribution list, mailbox agent, or mail-enabled public folder), it will have a LegacyExchangeDN that corresponds to the new administrative group for the Exchange 2010 server. Because of this LegacyExchangeDN, Microsoft Outlook will request a full offline address book (OAB) download from the Exchange 2010 server for each user in this organization that logs on to a mailbox using Outlook and using OAB versions 2 or 3. This could result in many simultaneous OAB download requests, which causes high network utilization.
- **System restart required with the UM server role** After installing the Unified Messaging (UM) server role, you must restart the system to allow the Microsoft Exchange Unified Messaging service to reserve the required TCP ports.

Prerequisites

- Before you can install Exchange 2010, make sure that the server has the necessary prerequisites installed. You must ensure that the appropriate

software and operating system prerequisites are installed on the server before you begin your Exchange 2010 installation. To install the prerequisites for all server roles, see Exchange 2010 Prerequisites. For more information about system requirements, see Exchange 2010 System Requirements.

- For e-mail messages to flow correctly, you must install both the Mailbox server role and the Hub Transport server role in the same Active Directory site.
- You can install the Mailbox server role, Hub Transport server role, Client Access server role, and Unified Messaging server role on the same computer or on separate computers. The Edge Transport server role must always be installed on dedicated hardware; it can't coexist with other server roles.

Warning:

After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Perform a custom installation of Exchange 2010

To perform the following procedure, the account you use must be delegated membership in the Schema Admins group if you haven't previously prepared the Active Directory schema.

If you're installing the first Exchange 2010 server in the organization, the account you use must have membership in the Enterprise Admins group.

If you've already prepared the schema and aren't installing the first Exchange 2010 server in the organization, the account you use must be delegated the Organization Management management role.

Note:

For information about preparing Active Directory for Exchange 2010, see Prepare Active Directory and Domains. For more information about permissions in Exchange 2010, see Understanding Role Based Access Control.

1. Log on to the server on which you want to install Exchange 2010.

   Important:

   Be sure that you've completed the prerequisite tasks discussed both in this topic and the Exchange 2010 Prerequisites topic before you install Exchange 2010.

2. Insert the Exchange 2010 DVD into the DVD drive (or browse to your install location). If Setup.exe doesn't start automatically, navigate to the DVD drive and double-click **Setup.exe**.
3. On the **Start** page, ensure that you've completed Steps 1 and 2. If you haven't already installed these components, Setup will provide you with links to Microsoft Web sites where you can download the necessary prerequisites. For more information about Windows PowerShell installation, see Install Windows Management Framework.

   Important:

   If you're installing Exchange 2010 on Windows Server 2008 R2, don't use the downloadable .NET Framework package. Instead, use Server Manager in Windows Server 2008 R2 or run **ServerManagerCmd -i NET-Framework**.

4. On the **Start** page, click **Step 3: Choose Exchange language option**. The language options will appear below Step 3. Choose either:
   4.a. **Install all languages from the language bundle** If you choose this option, all supported languages in the bundle are installed. Setup can download the necessary language bundles automatically, or you can browse to the location (hard drive or a network share) of previously

downloaded language bundles and install those.

4.b. **Install only languages from the DVD** If you choose this option, only English (U.S.) language support is installed. Language bundles can be installed at a later time to provide support for additional languages if needed.

5. After the language installation is complete, on the **Start** page, click **Step 4: Install Microsoft Exchange**. Setup copies the setup files locally to the computer on which you're installing Exchange 2010.
6. In the Exchange Server 2010 Setup wizard, on the **Introduction** page, click **Next**.
7. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
8. On the **Error Reporting** page, select **Yes**, and then click **Next**.
9. On the **Installation Type** page, click **Custom Exchange Server Installation**. For Exchange Server 2010 Service Pack 1 (SP1), you can select to automatically install all required Windows roles and features for this server. If you want to change the path for the Exchange 2010 installation, click **Browse**, locate the appropriate folder in the folder tree, and then click **OK**. Click **Next**.

10. On the **Server Role Selection** page, select the server roles that you want to install on the computer and click **Next**.

Note:

The Edge Transport server role can't coexist on the same computer with any other server role. You must deploy the Edge Transport server role in a perimeter network and outside your internal Active Directory forest.

11. If you selected **Mailbox Role**, **Client Access Role**, **Hub Transport Role**, and/or **Unified Messaging Role**, and if this is the first Exchange 2010 server in your organization, on the **Exchange Organization** page, type a name for

your Exchange 2010 organization. The Exchange organization name can contain only the following characters:
11.a.A through Z
11.b.a through z
11.c.0 through 9
11.d.Space (not leading or trailing)
11.e.Hyphen or dash

Note:
The organization name can't contain more than 64 characters. The organization name can't be blank. If the organization name contains spaces, you must enclose it in quotation marks.

12. If this is the first Exchange 2010 server in your organization, on the **Client Settings** page, click the appropriate option based on the client computers.
13. On the **Client Settings** page, if you have client computers running Office Outlook 2003 or earlier and you select **Yes**, Exchange 2010 will create a public folder database on the Mailbox server. If all your client computers are running Outlook 2010, public folders are optional in Exchange 2010. If you select **No**, Exchange 2010 won't create a public folder database on the Mailbox server. You can add a public folder database later. For example, if you add client computers running Outlook 2003 and you need a public folder database, you can create one on the Exchange 2010 Mailbox server. You must then configure the OAB for public folder distribution, and then restart the Microsoft Exchange Information Store service before client computers running Outlook 2003 and earlier will be able to connect to the server.
14. On the **Configure Client Access Server external domain** page, enter a domain name to use to configure your Client Access servers.

Note:
If the Client Access server won't be Internet-facing, you can click **Next** without configuring a domain name. For more information about configuring Client Access servers, see Managing External Client Access. Click **Next**.

15. On the **Customer Experience Improvement Program** page, choose the appropriate selection for your organization, and then click **Next**.
16. On the **Readiness Checks** page, view the status to determine if the organization and server role prerequisite checks completed successfully. If they haven't completed successfully, you must resolve any reported errors before you can install Exchange 2010. You don't need to exit Setup when resolving some of the prerequisite errors. After resolving a reported error, click **Retry** to rerun the prerequisite check. Be sure to also review any warnings that are reported. If all readiness checks have completed successfully, click **Install** to install Exchange 2010.
17. On the **Completion** page, click **Finish**.

1.2.2.7.10 Install the Exchange 2010 Management Tools

Install the Exchange 2010 Management Tools

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-21*

With the Microsoft Exchange Server 2010 management tools, you can configure and

manage your Exchange organization remotely. This topic explains how you can either use Setup.exe or unattended setup mode to install the Exchange 2010 management tools.

You can install the Exchange 2010 management tools on the following Windows operating systems:

- Windows 7
- Windows Vista with Service Pack 2 (SP2)
- Windows Server 2008 SP2
- Windows Server 2008 R2

For more information about managing Exchange 2010, see Exchange Management Console and Exchange Management Shell.

Prerequisites

You must ensure that each of your servers meets the appropriate prerequisites and system requirements before you begin your installation. For more information, see Exchange 2010 Prerequisites and Exchange 2010 System Requirements.

Warning:

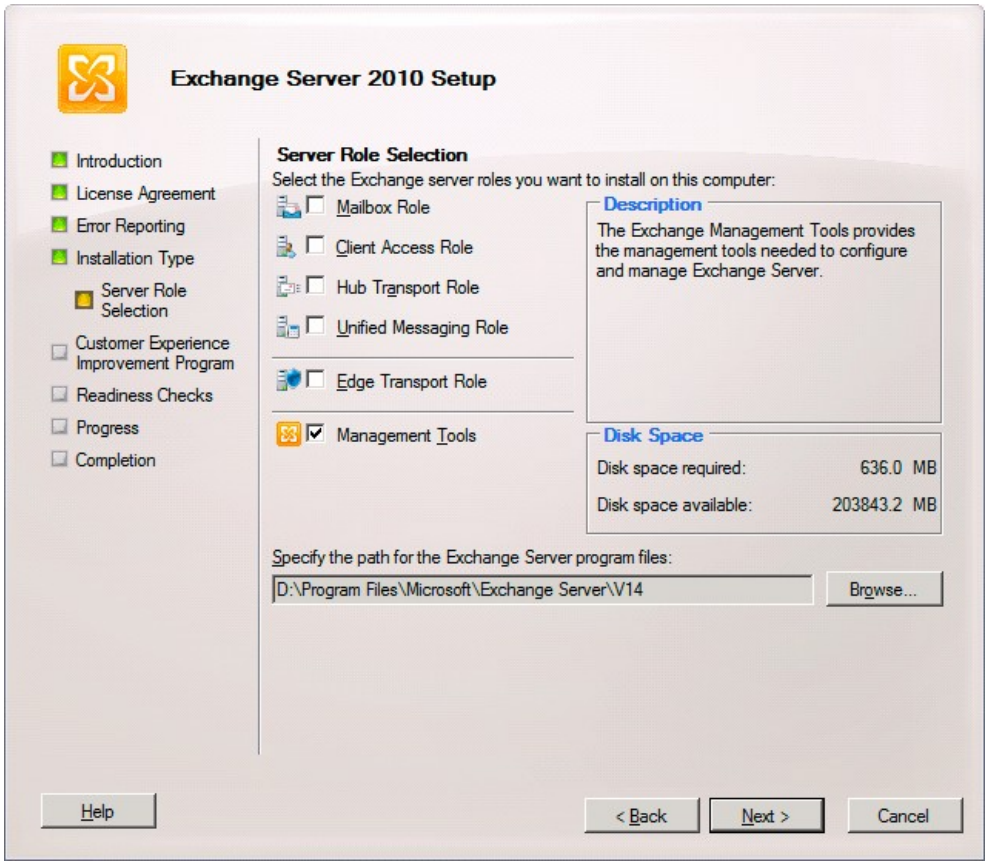
After you install Exchange 2010 on a server, you must not change the server name. Renaming a server after you have installed an Exchange 2010 server role is not supported.

Use Setup to install the Exchange 2010 management tools

1. Log on to the server on which you want to install the Exchange 2010 management tools on, using a domain account that has local administrative privileges.
2. Insert the Exchange 2010 DVD into the DVD drive. When the AutoPlay dialog appears, click **Run Setup.exe** under **Install or run program**. If the AutoPlay dialog doesn't appear, navigate to the root of the DVD and double-click Setup.exe. Alternatively, browse to the location of your Exchange 2010 installation files and double-click Setup.exe.
3. The Exchange Server 2010 Setup welcome screen appears. In the **Install** section, the software listed for **Step 1: Install .NET Framework 3.5 SP1** and **Step 2: Install Windows PowerShell v2** was installed with the Exchange 2010 prerequisites. If these prerequisites aren't already installed, click the appropriate step to install them.
4. When **Step 1**, **Step 2**, and **Step 3** are listed as **Installed**, click **Step 4: Install Microsoft Exchange**.

   Note:

   After your installation is complete, you can return to complete **Step 5: Get critical updates for Microsoft Exchange**.
5. In the Exchange 2010 Setup wizard, on the **Introduction** page, click **Next**.
6. On the **License Agreement** page, select **I accept the terms in the license agreement**, and then click **Next**.
7. On the **Error Reporting** page, select whether you want to enable or disable Exchange Error Reporting feature, and then click **Next**.
8. On the **Installation Type** page, click **Custom Exchange Server Installation**. If you want to change the path for the Exchange 2010 installation, click **Browse**, locate the appropriate folder in the folder tree, and then click **OK**. Click **Next**.
9. On the **Server Role Selection** page, select **Management Tools**.



10. If this is the first Exchange 2010 server in your organization, on the **Exchange Organization** page, type a name for your Exchange organization. The Exchange organization name can contain only the following characters:
    - A through Z
    - a through z
    - 0 through 9
    - Space (not leading or trailing)
    - Hyphen or dash

    Note:
    The organization name can't contain more than 64 characters. The organization name can't be blank. If the organization name contains spaces, you must enclose it in quotation marks.
11. On the **Readiness Checks** page, view the status to determine if the organization and other prerequisite checks completed successfully. If they have not completed successfully, you must resolve any reported errors before you can install Exchange 2010. You don't need to exit Setup when resolving some of the prerequisite errors. After resolving a reported error, click **Retry** to re-run the prerequisite check. Be sure to also review any warnings that are reported. If all readiness checks have completed successfully, click **Install** to install the Exchange 2010 management tools.
12. On the **Completion** page, click **Finish**.

Use unattended Setup mode to install the Exchange 2010 management tools

1. Insert the Exchange 2010 DVD into the DVD drive, and then at the command prompt navigate to the DVD drive, or navigate to the network location of the

Exchange 2010 installation files.
2. At the command prompt, run the following command.

```
Setup.com /R:MT
```

For more information, see Install Exchange 2010 in Unattended Mode.

1.2.2.7.11 Move Internet Mail Flow from Exchange 2003 to Exchange 2010

Move Internet Mail Flow from Exchange 2003 to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you upgrade your organization from Microsoft Exchange Server 2003 to Exchange Server 2010, one of the steps you need to complete is moving the handling of Internet mail from your existing servers to Exchange 2010 servers. In Exchange 2010, the preferred method of handling Internet mail is by using Edge Transport servers subscribed to the Active Directory site where your Hub Transport servers reside. However, you can also configure Internet mail flow through a third-party SMTP host or directly through your Hub Transport servers. This topic provides instructions for both of these approaches to moving Internet mail flow from Exchange 2003 to Exchange 2010 servers:

Move Internet Mail Flow to Exchange 2010 Using Edge Transport Servers

Move Internet Mail Flow to Exchange 2010 without Edge Transport Servers

To learn more about upgrading from Exchange 2003 to Exchange 2010, see the following topics:

- Understanding Upgrade from Exchange 2003 to Exchange 2010
- Understanding Upgrade from Exchange 2003 and Exchange 2007 to Exchange 2010

Prerequisites

- Exchange 2010 Client Access, Hub Transport, and Mailbox servers have been deployed into your existing Exchange organization.
- Mail flow between your existing Exchange organization and Exchange 2010 deployment is functioning correctly.
- Exchange 2010 Edge Transport servers have been deployed in your perimeter network (if you will be using Edge Transport servers for Internet mail).

Move Internet Mail Flow to Exchange 2010 Using Edge Transport Servers

1. Subscribe the Edge Transport servers to your Exchange organization. This will enable Internet message flow through your Exchange 2010 Hub and Edge Transport servers.
   1.a. Create an Edge Subscription File on an Edge Transport Server
   1.b. Import an Edge Subscription File to an Active Directory Site
2. Remove the SMTP connector in Exchange 2003 that is used to handle Internet mail. Your account needs to be a member of the local administrators

group and a member of a group that has had the Exchange Administrators role applied at the administrative group level.
2.a.In Exchange System Manager, expand the **Organization** node, expand **Administrative Groups**, expand *<AdministrativeGroupName>*, expand **Routing Groups**, expand *<RoutingGroupName>*, and then select **Connector**.
2.b.In the right-hand pane, right-click the connector you want to delete and select **Delete**.
2.c.Click **OK** to confirm the deletion.

For more information about Edge subscriptions, see Understanding Edge Subscriptions.

Move Internet Mail Flow to Exchange 2010 without Edge Transport Servers

1. Configure mail flow by using one of the methods listed below depending on the needs of your organization. This will enable Internet message flow through your Exchange 2010 Hub Transport servers.
   - Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway
   - Configure Internet Mail Flow Directly Through a Hub Transport Server
2. Remove the SMTP connector in Exchange 2003 that is used to handle Internet mail. Your account needs to be a member of the local administrators group and a member of a group that has had the Exchange Administrators role applied at the administrative group level.
   - In Exchange System Manager, expand the **Organization** node, expand **Administrative Groups**, expand *<AdministrativeGroupName>*, expand **Routing Groups**, expand *<RoutingGroupName>*, and then select **Connector**.
   - In the right-hand pane, right-click the connector you want to delete and select **Delete**.
   - Click **OK** to confirm the deletion.

1.2.2.7.12 Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers

Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Moving mailboxes from Microsoft Exchange Server 2003 Service Pack 2 (SP2) or later to Exchange Server 2010? Consider the following:

- The move process is performed offline, and end-users won't be able to access their mailboxes during the move.
- Perform the move from a server running Exchange 2010 by using the move request cmdlets in the Exchange Management Shell. You can't use Exchange System Manager on an Exchange 2003 server to move the mailboxes.
- You can't move mailboxes from Exchange 2003 Service Pack 1 (SP1) or earlier.
- Exchange 2003 doesn't have resource mailboxes. Instead, you must use shared mailboxes to represent resources. If you move a shared mailbox from

Exchange 2003 to Exchange 2010, the move request creates the mailbox as a shared Exchange 2010 mailbox. After you move the mailbox to Exchange 2010, you can convert it to a resource mailbox. For more information, see Convert a Mailbox.

For detailed instructions about how to move mailboxes, see Managing Move Requests.

To learn more about moving mailboxes, see Understanding Move Requests.

1.2.2.7.13 Move Mailboxes from Exchange 2007 Servers to Exchange 2010 Servers

Move Mailboxes from Exchange 2007 Servers to Exchange 2010 Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-28*

Moving mailboxes from Microsoft Exchange Server 2007 Service Pack 3 (SP3) to Exchange Server 2010? Consider the following:

- The move process is performed online, and end-users will be able to access their mailboxes during the move.
- You can't move mailboxes from Exchange 2007 SP1 or earlier. The source Mailbox server must be running Exchange 2007 SP3.
- Perform the move from a server running Exchange 2010 by using the Exchange Management Console or the move request cmdlets in the Exchange Management Shell. You can't use the **Move-Mailbox** cmdlets in Exchange 2007 to move mailboxes to Exchange 2010 servers.

For detailed instructions about how to move mailboxes, see Managing Move Requests.

To learn more about moving mailboxes, see Understanding Move Requests.

1.2.2.7.14 Move Mailboxes from Exchange 2010 Servers to Exchange 2003 Servers

Move Mailboxes from Exchange 2010 Servers to Exchange 2003 Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-14*

Moving mailboxes from Microsoft Exchange Server 2010 to Exchange Server 2003? Consider the following:

- The move process is performed offline, and end-users won't be able to access their mailboxes during the move.
- Perform the move from the server running Exchange 2010 by using the move request cmdlets in the Exchange Management Shell. You can't use Exchange System Manager on an Exchange 2003 server to move the mailboxes.

- If you're moving a mailbox that has a personal archive associated with it, you must disable the archive before moving the mailbox. For details, see Disable a Personal (On-Premises) or Cloud-Based Archive for a Mailbox.
- If you're moving a mailbox to Exchange 2003, you must disable single-item recovery and purge the Recoverable Items folder. For details, see Clean Up the Recoverable Items Folder.

For detailed instructions about how to move mailboxes, see Managing Move Requests.

To learn more about moving mailboxes, see Understanding Move Requests.

1.2.2.7.15 Move Mailboxes from Exchange 2010 Servers to Exchange 2007 Servers

Move Mailboxes from Exchange 2010 Servers to Exchange 2007 Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-28*

Moving mailboxes from Microsoft Exchange Server 2010 to Exchange Server 2007? Consider the following:

- The move process is performed offline, and end-users won't be able to access their mailboxes during the move.
- You can't move mailboxes to or from servers running Exchange 2007 Service Pack 1 (SP1) or earlier. The target database must be on a server running Exchange 2007 SP3.
- Perform the move from an Exchange 2010 server by using the move request cmdlets in the Exchange Management Shell. You can't use the **Move-Mailbox** cmdlets in Exchange 2007 to move the mailboxes.
- If the mailbox that you're moving has an archive mailbox associated with it, you must disable the archive before moving the mailbox.
- If you're moving a mailbox to Exchange 2007, you must disable single-item recovery and purge the Recoverable Items folder. For details, see Clean Up the Recoverable Items Folder.

For detailed instructions about how to move mailboxes, see Managing Move Requests.

To learn more about moving mailboxes, see Understanding Move Requests.

1.2.2.7.16 Prepare Legacy Exchange 2003 Permissions

Prepare Legacy Exchange 2003 Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When upgrading from Exchange Server 2003 to Exchange Server 2010, you must first grant specific Exchange permissions in each domain in which you have run Exchange 2003

DomainPrep. To do this, you run the `setup /PrepareLegacyExchangePermissions` command. Granting these permissions is part of preparing Active Directory and your domains for installing Exchange Server 2010. For detailed instructions, see Prepare Active Directory and Domains.

This topic explains why you must run the `setup /PrepareLegacyExchangePermissions` command, when you run it, and what permissions are set by the command in your Exchange Server 2010 organization.

Why Run Setup /PrepareLegacyExchangePermissions

Essentially, you must run the `setup /PrepareLegacyExchangePermissions` command so that the Exchange 2003 Recipient Update Service functions correctly after you update the Active Directory schema for Exchange Server 2010. This section explains the main issue and how running the command resolves this issue.

Issue

In Exchange Server 2003, the Recipient Update Service updates some mailbox attributes, such as the proxy address, on mail-enabled user objects. The Recipient Update Service has permission to modify these attributes because the computer account (named *<ServerName>*) for the server on which the Recipient Update Service runs is in the Exchange Enterprise Servers (EES) group. The EES group is created when you run Exchange Server 2003 DomainPrep. Instead of granting the EES group permissions to each individual mailbox attribute that the Recipient Update Service must modify, the mailbox attributes are grouped together in property sets. When you run Exchange Server 2003 DomainPrep, Exchange provides the EES group with permissions to modify the property sets through access control entries (ACEs) that Exchange sets on the domain container in Active Directory.

Exchange Server 2010 has a management role called Recipient Management. This role contains permissions to manage the e-mail attributes of all users. Exchange administrators who are members of the Exchange Recipient Management role can manage only users' e-mail properties.

To enable this functionality, Exchange Server 2010 must move some e-mail attributes of users into a property set called the "Exchange-Information property set." Exchange does this by redefining the attribute schemas in Active Directory when importing the new Exchange Server 2010 schema. However, the legacy EES group doesn't have permissions to the Exchange-Information property set. Therefore, when you import the new Exchange Server 2010 schema, the Recipient Update Service will no longer have permissions to the users' e-mail attributes and will stop functioning correctly. (For example, it will not be able to set proxy addresses for newly created Exchange Server 2003 users.)

Resolution

Running the `setup /PrepareLegacyExchangePermissions` command enables the legacy Recipient Update Service to function correctly. Before importing the new Exchange Server 2010 schema, Exchange Server 2010 must grant new permissions in each domain in which you have run Exchange Server 2003 DomainPrep. The `setup /PrepareLegacyExchangePermissions` command grants these new permissions. Before you run `setup /PrepareSchema`, you must run `setup /PrepareLegacyExchangePermissions` and allow the permissions to replicate across your Exchange organization.

The server where you run `setup /PrepareLegacyExchangePermissions` contacts the local global catalog to locate the domains in which you have run Exchange Server 2003 DomainPrep by checking for the EES and Exchange Domain Servers (EDS) groups. The

server must be able to communicate with every domain in the forest in which you ran Exchange Server 2003 DomainPrep. Also, the account that you use to run `setup /PrepareLegacyExchangePermissions` must have the permissions assigned to the Enterprise Admins universal security group (USG) so that it can set the ACEs in each domain and in the Exchange organization.

Permissions Set By Setup /PrepareLegacyExchangePermissions

Running `setup /PrepareLegacyExchangePermissions` finds every domain in the forest that has the EES group and the Exchange Domain Servers (EDS) group. For each domain that has these groups, `setup /PrepareLegacyExchangePermissions` does the following:

- Adds an ACE to the domain root access control list (ACL) to provide the EES group with WRITE_PROP permissions on the Exchange-Information property set.
- Adds an ACE to the domain root ACL to provide authenticated users with READ_PROP permissions on the Exchange-Information property set.
- Adds an ACE to the AdminSDHolder container of the domain to provide the EES group with WRITE_PROP and READ_PROP permissions on the Exchange-Information property set.
- Adds an ACE to the Exchange organization container ACL to provide the EDS group with WRITE_PROP permissions on the Exchange-Information property set.

Running Setup /PrepareLegacyExchangePermissions Again

There are some cases in which you will need to run `setup /PrepareLegacyExchangePermissions` again:

- You have a domain that contains Exchange Server 2003 servers, and you have not run DomainPrep.
- In an existing domain, you have mailbox-enabled users who will log on to mailboxes on Exchange Server 2003 servers in domains in which you have not run DomainPrep.

In these cases, you must run `setup /PrepareLegacyExchangePermissions` again after you run Exchange Server 2003 DomainPrep. This allows the Exchange Server 2003 Recipient Update Service to function correctly in this domain.

Exchange 2010 Deployment Permissions Reference

Exchange 2010 needs permissions to deploy and function properly in your organization. These permissions are stamped on the access control lists (ACL) of the objects used by Exchange 2010 during setup. For more information, see Exchange 2010 Deployment Permissions Reference.

Provision Exchange 2010 Server and Delegate Setup

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-06*

This topic explains how to provision a server and delegate the setup and installation of Exchange. After the initial installation of the first instance of Exchange Server, you can provision a server for delegated setup of subsequent installations. This procedure allows a delegated account to install single instances of Exchange in your domain, without being a member of the Organization Management management role group.

However, be aware that you must install the *first* Exchange server in the domain by using an account that *is* a member of the Organization Management role group and local Administrators group. You can then install subsequent instances of Exchange using a member of the Delegated Setup management role group. (You just can't install the first instance of an Exchange server using a member of the Delegated Setup role group.)

Important:

A delegated user can't uninstall an Exchange server. Uninstalling or removing Exchange servers requires an account that is a member of the Organization Management role group and local Administrators group.

For more information about permissions, delegating roles, and the rights that are required to administer Exchange 2010, see Understanding Permissions, Understanding Role Based Access Control, and Delegated Setup.

Note:

Exchange 2010 needs permissions to deploy and function correctly in your organization. These permissions are stamped on the access control lists (ACL) of the objects used by Exchange 2010 during setup. For more information, see Exchange 2010 Deployment Permissions Reference.

You can use **Setup.com /NewProvisionedServer** to provision your server. The **Setup.com /NewProvisionedServer** command performs the following tasks:

- Creates the server object within the configuration partition: **CN=Servers,CN=Exchange Administrative Group (FYDIBOHF23SPDLT),CN=Administrative Groups,CN=<Organization Name>,CN=Microsoft Exchange,CN=Services,CN=Configuration,DC=<Root Domain>**
- Adds the following access control entries (ACE) to the server object within the configuration partition for the Delegated Setup role group:
  - Full Control on the server object and its children
  - Deny access control entry for the Send As extended right
  - Deny access control entry for the Receive As extended right
  - Deny CreateChild and DeleteChild permissions for Exchange Public Folder Store objects

  Note:

  Public folders are administered at an organizational level; therefore, the creation and deletion of public folder stores is restricted to Exchange Organization Administrators.
- Adds the computer account to the Exchange Servers group.
- Adds the server as a provisioned server in the Exchange Management Console.

Provision an Exchange 2010 Server

If Exchange Server is installed on the computer you're provisioning, you can run the Setup.com command with associated arguments from the Run line or a command prompt. If the computer that you are running the Setup.com command from doesn't have Exchange installed, you must insert the Exchange 2010 DVD into the computer, and then run the Setup.com command from the root directory of the DVD.

Provision the local server

To run **Setup.com /NewProvisionedServer**, the account you use must be a member of the Organization Management role group.

To provision the local server, run the following command:

```
Setup.com /NewProvisionedServer
```

Note:
Running this command provisions the local server, but it doesn't delegate a user.

Provision a remote server

To run **Setup.com /NewProvisionedServer**, the account you use must be a member of the Delegated Setup role group.

To provision a remote server, run the following command:

```
Setup.com /NewProvisionedServer:ServerName
```

1.2.2.7.18 Upgrade Custom LDAP Filters to OPATH Filters

Upgrade Custom LDAP Filters to OPATH Filters

Planning and Deployment > Deploying Exchange 2010 > Managing Deployment of Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-21*

In Microsoft Exchange Server 2003 and earlier versions, LDAP filtering syntax is used to create custom address lists, global address lists (GALs), e-mail address policies, and distribution groups. In Exchange Server 2010 and Exchange Server 2007, the OPATH filtering syntax replaces the LDAP filtering syntax. Using the OPATH filtering syntax allows you to create filters directly in Exchange Management Shell commands by using the *-RecipientFilter* parameter.

Note:
LDAP syntax filters are supported in Exchange 2010 and will exist only on objects that have been migrated from Exchange 2003 or earlier versions. If you want to edit the LDAP filter from an Exchange 2010 server, you must upgrade these LDAP filters to the OPATH syntax. For example, if you have Exchange 2003 servers in your organization, you can manage the LDAP syntax filter from an Exchange 2003 server. However, you can't manage or create LDAP syntax filters in Exchange 2010.

For information about how you can use a script to convert your LDAP filters to the OPATH syntax, see the Exchange Server Team blog article Need help converting your LDAP filters to OPATH?

Note:
The content of each blog and its URL are subject to change without notice. The content

within each blog is provided "AS IS" with no warranties, and confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

Important:
In Exchange 2003, you can create custom Active Directory extension attributes. However, in Exchange 2010, you can't use custom extension attributes as a filterable property. If your organization has custom extension attributes, we recommend that you use the 15 custom attributes provided by Exchange 2010 for each recipient. However, if the custom attributes don't meet the needs of your organization, we recommend that you don't upgrade objects that use custom extension attributes.

For more information about creating filters in recipient commands, see Creating Filters in Recipient Commands.

Contents

Determining Which Objects Require Upgrading

Before you upgrade the Exchange objects, you must first determine which objects require upgrading. There are two types of filters that you may need to upgrade:

- **Default objects** Default objects are the default e-mail address policies and address lists created when Exchange is installed.
- **Custom objects** Custom objects are custom LDAP filters created by an Exchange administrator in Exchange 2003 or an earlier version.

To determine which objects require upgrading, you can use the Exchange Management Console or the Exchange Management Shell.

Using the Exchange Management Console

To use the Exchange Management Console to determine which objects require upgrading, you must edit the object by using the Edit wizard for that object.

For example, if you want to determine whether an e-mail address policy has been upgraded, you select the e-mail address policy from the result pane, and then in the action pane, click **Edit** to open the Edit E-Mail Address Policy wizard.

If the e-mail address policy was created in Exchange 2003 and the filtering syntax hasn't yet been upgraded to OPATH, an error is displayed. This error signifies that the filtering syntax of the e-mail address policy was created in Exchange 2003 or an earlier version and may require upgrading. For information about how to upgrade the filtering syntax, see "Upgrading Default Objects" and "Upgrading Custom Objects" later in this topic.

Using the Exchange Management Shell

To use the Exchange Management Shell to determine which objects require upgrading, you can use the associated **Get-** cmdlet and format the list to view the recipient filters and the version of Exchange.

This example determines which e-mail address policies require upgrading.

```
Get-EmailAddressPolicy | Format-List Name, *RecipientFilter*, ExchangeVersion
```

After you run this command, the following information is displayed in the Exchange Management Shell.

In this example, two e-mail address policies were returned by the **Get-EmailAddressPolicy** cmdlet. **Default Policy**, which is highlighted in blue, is an Exchange 2003 object that requires upgrading. **Resource Mailboxes**, which is highlighted in red, was either created in Exchange 2010 or has already been upgraded.

If you can answer "Yes" to any of the following questions, the object hasn't been upgraded:

- Is the *RecipientFilter* attribute empty?
- Does the value of the *RecipientFilterType* attribute equal "Legacy"?
- Does the value of the *ExchangeVersion* attribute equal "0.0 (6.5.6200.0)"?

Return to top

Upgrading Default Objects

When you install Exchange 2003, a default e-mail address policy and multiple default address lists are created. The following list includes the default objects that will need to be upgraded if the filter must be changed in Exchange 2010, or if you need to administer the object in Exchange 2010:

- **E-mail Address Policies:** Default Policy
- **Address Lists:** All Contacts, All Groups, All Rooms, All Users, Default Global Address List, Public Folders

Because default objects have known filters, you can easily upgrade these default objects. For detailed instructions about how to upgrade default objects, see the following topics:

- Upgrade Default Address Lists from LDAP Filters to OPATH Filters
- Upgrade the Default E-Mail Address Policy from LDAP Filters to OPATH Filters

Note:

The *-ForceUpgrade* parameter doesn't construct the replacement recipient filter for the object, nor does it upgrade the object. The *-ForceUpgrade* parameter suppresses the confirmation question so that you can upgrade by using an unattended script.

Return to top

Upgrading Custom Objects

Upgrading custom objects is more difficult because it requires you to determine what the custom LDAP filter is filtering for, and then translate the filter into OPATH syntax. Custom LDAP filters can be created for the following Exchange objects:

- Address lists
- E-mail address policies
- Dynamic distribution groups

There are two methods you can use to upgrade custom objects:

- Use a script provided by the Microsoft Exchange Team. For information about this script, see the Exchange Server Team blog article Need help converting your LDAP filters to OPATH?

  Note:

  The content of each blog and its URL are subject to change without notice. The content within each blog is provided "AS IS" with no warranties, and

confers no rights. Use of included script samples or code is subject to the terms specified in the Microsoft Terms of Use.

- Manually upgrade the LDAP filter to OPATH as described in the following sections.

Step 1: Determine What the Custom LDAP Filter Does

To upgrade an Exchange 2003 LDAP filter to the OPATH syntax, you must first determine what the LDAP filter is filtering. Perform the following steps:

1. Copy an existing filter into a text editing application, such as Notepad.

Important:

Before you begin, document your existing LDAP filter.

This example is an LDAP filter for an e-mail address policy.

```
(&(&(|(&(&(objectCategory=user)(msExchangeHomeServerName=/o=ORG/ou=SIT
```

2. In Notepad, indent the lines of the filter to see the logical flow.
3. Write a statement that explains what the filter does. In this example, the e-mail address policy's filter includes the following objects:
   - All user category objects that have a home server in a particular administrative group
   - All groups or dynamic distribution lists that begin with a specific display name

Step 2: Translate the LDAP Filter into OPATH Syntax

After you determine the function of the LDAP filter, you must translate the LDAP filter into the OPATH syntax.

Note:

The names for many properties have changed. For example, the LDAP property **mailNickname** is called **Alias** in Exchange 2010. To view a complete list of the property names, see Filterable Properties for the -RecipientFilter Parameter.

1. Create the recipient filter based on the statements you recorded in Step 3 of the section "Determine What the Custom LDAP Filter Does" earlier in this topic.

```
(ServerLegacyDN -like "/o=ORG/ou=SITE/cn=Configuration/cn=Servers/cn=*
 ((RecipientType -eq "<group recipient type>" -or RecipientType -eq "D
```

2. Construct the command by using the appropriate **Set** cmdlet, and then run the command in the Exchange Management Shell.

```
Set-EmailAddressPolicy eap1 -RecipientFilter {(ServerLegacyDN -like "/
```

Note:

Many of the properties for the *-RecipientFilter* parameter accept wildcard characters. If you use a wildcard character, don't use the *-eq* operator. Instead, use the *-like* operator. The *-like* operator is used to find pattern matches in strings, whereas the *-eq* operator is used to find an exact match.

Return to top

1.2.2.7.18.1 Upgrade the Default E-Mail Address Policy from LDAP Filters to OPATH Filters

Upgrade the Default E-Mail Address Policy from LDAP Filters to OPATH Filters

Deploying Exchange 2010 > Managing Deployment of Exchange 2010 > Upgrade Custom LDAP Filters to OPATH Filters >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Exchange Server 2003 and earlier versions, LDAP filtering syntax is used when customizing the default e-mail address policy. However, in Exchange Server 2010, the OPATH filtering syntax replaces the LDAP filtering syntax. This topic explains how to use the Exchange Management Shell to upgrade the filtering syntax from LDAP to OPATH for the legacy default e-mail address policy.

There is only one default e-mail address policy (named **Default Policy**) in your organization. The default e-mail address policy can be identified by having the priority value of "lowest".

Note:
LDAP syntax filters are supported in Exchange 2010 and will exist only on objects that have been migrated from Exchange 2003 or earlier versions. You must upgrade these LDAP filters to the OPATH syntax only if you want to edit the filter from an Exchange 2010 server. For example, if you have Exchange 2003 and Exchange 2010 servers in your organization, you can manage the LDAP syntax filter from an Exchange 2003 server. You can't manage or create LDAP syntax filters in Exchange 2010.

For more information about how to determine if the default e-mail address policy requires upgrading, see "Determining Which Objects Require Upgrading" in Upgrade Custom LDAP Filters to OPATH Filters.

Use the Shell to upgrade the default e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to upgrade the default e-mail address policy.

This example upgrades the default e-mail address policy.

```
Set-EmailAddressPolicy "Default Policy" -IncludedRecipients AllRecipients
```

A warning appears asking if you're sure you want to perform this action. Type **Y** to confirm.

For detailed syntax and parameter information, see Set-EmailAddressPolicy.

1.2.2.7.18.2 Upgrade Default Address Lists from LDAP Filters to OPATH Filters

Upgrade Default Address Lists from LDAP Filters to OPATH Filters

Deploying Exchange 2010 > Managing Deployment of Exchange 2010 > Upgrade Custom LDAP Filters to OPATH Filters >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-06-16*

In Microsoft Exchange Server 2003 and earlier versions, LDAP filtering syntax is used when customizing default address lists (which are created during an Exchange installation). However, in Exchange Server 2010, the OPATH filtering syntax replaces the LDAP filtering syntax. This topic explains how to use the Exchange Management Shell to upgrade the filtering syntax for any legacy default address lists from LDAP to OPATH.

Note:
LDAP syntax filters are supported in Exchange 2010 and will exist only on objects that have been migrated from Exchange 2003 or earlier versions. You must upgrade these LDAP filters to the OPATH syntax only if you want to edit the filter from an Exchange 2010 server. For example, if you have Exchange 2003 servers in your organization, you can manage the LDAP syntax filter from an Exchange 2003 server. You can't manage or create LDAP syntax filters in Exchange 2010.

The following default address lists may need to be upgraded:

- All Users
- All Groups
- All Contacts
- Public Folders
- Default Global Address List

Note:
The All Rooms address list is an Exchange 2010 default address list and doesn't require upgrading.

For more information about how to determine if your address lists require upgrading, see "Determining Which Objects Require Upgrading" in Upgrade Custom LDAP Filters to OPATH Filters.

Use the Shell to upgrade default recipient filters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" and "Global address lists" entries in the Mailbox Permissions topic.

Note:
You can't use the EMC to upgrade default recipient filters.

This example upgrades the All Users default address list.

```
Set-AddressList "All Users" -IncludedRecipients MailboxUsers
```

This example upgrades the All Groups default address list.

```
Set-AddressList "All Groups" -IncludedRecipients MailGroups
```

This example upgrades the All Contacts default address list.

```
Set-AddressList "All Contacts" -IncludedRecipients MailContacts
```

This example upgrades the Public Folders default address list.

```
Set-AddressList "Public Folders" -RecipientFilter { RecipientType -eq 'PublicFold
```

This example upgrades the Default Global Address List.

```
Set-GlobalAddressList "Default Global Address List" -RecipientFilter {(Alias -ne
```

A warning appears asking if you're sure you want to perform this action. Type **Y** to confirm.

For detailed syntax and parameter information, see Set-AddressList or Set-GlobalAddressList

1.2.2.7.19 Suppress Link State Updates

Suppress Link State Updates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic explains how to use Registry Editor to suppress propagation of minor link state updates between routing groups in Microsoft Exchange Server 2010 and Exchange Server 2003.

We recommend that you perform this procedure if the following conditions are true:

- You have installed the Exchange 2010 Hub Transport server role in an existing Exchange 2003 organization. For more information about this step, see Install Exchange 2010 in an Existing Exchange 2003 Organization.
- The existing Exchange organization includes more than one Exchange 2003 routing group.
- You will configure more than one routing group connector between Exchange 2003 routing groups and Exchange 2010.

The first routing group connector is created when the first Hub Transport server role is installed on a computer in the Exchange organization. Before you create additional routing group connectors, perform this procedure on every Exchange 2003 server in the organization. When you suppress minor link state updates, the servers running Exchange 2003 don't mark connectors as unavailable. This procedure makes sure that earlier versions of Exchange only use least cost routing and don't try to calculate an alternative route.

The purpose of this procedure is to make sure that routing loops can't occur. Exchange 2010 doesn't use a link state routing table and doesn't support relay of link state information. If you don't suppress minor link state updates, routing loops may occur. For more information about how routing occurs in an Exchange organization that includes Exchange 2010 servers and Exchange 2003 servers, see Upgrade from Exchange 2003 Transport.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

Suppress Link State Updates on Exchange 2003

To perform this procedure, you must log on to the Exchange 2003 server by using an account that is delegated membership in the local Administrators group.

1. Open Registry Editor.
2. Locate **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RESvc\Parameters**.
3. Right-click **Parameters** and select **New | DWORD value**. Name the new DWORD value **SuppressStateChanges**.
4. Double-click **SuppressStateChanges**.
5. In the **Value** data field, enter **1**.
6. Close Registry Editor, and then restart the SMTP service, the Microsoft Exchange Routing Engine service, and the Microsoft Exchange MTA Stacks services for the change to take effect.

1.2.2.8 Deploy Multiple Forest Topologies

Deploy Multiple Forest Topologies

Exchange Server 2010 > Planning and Deployment > Deploying Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-11*

This topic provides an overview of deploying Microsoft Exchange Server 2010 in multiple forest topologies. You'll find information about the following subjects:

- **Supported Multiple Forest Topologies** Exchange 2010 supports two types of multiple forest topologies: cross-forest and resource forest.
- **GAL Synchronization** If you have a cross-forest environment, you need to ensure that the GAL in any given forest contains mail recipients from other forests.
- **Moving Mailboxes Across Forests** The **New-MoveRequest** cmdlet in the Exchange Management Shell can help move mailboxes from one forest to another.
- **Understanding Multiple Forest Administration** Learn about the permissions model to configure and manage the permissions between your forests.

Supported Multiple Forest Topologies

Exchange 2010 supports two types of multiple forest topologies:

- **Cross-forest** A cross-forest topology is one with multiple Exchange forests. Here is an overview of what you need to do to deploy Exchange 2010 in a topology with a multiple forest:
  .1. You must first install Exchange 2010 in each forest. For more information, see Understanding a New Installation of Exchange 2010.
  .2. Next, you must synchronize the recipients in each of the forests, so that the Global Address List (GAL) in each forest contains users from all the synchronized forests. See the "GAL Synchronization" section below for more details.
  .3. Finally, you must configure the Availability service so that users in one forest can view availability data for users in another forest. For more information, see Configure the Availability Service for Cross-Forest Topologies.
  For details about deploying Exchange 2010 in a cross-forest topology, see Deploy Exchange 2010 in a Cross-Forest Topology.
- **Resource forest** A resource forest topology is one with an Exchange forest and one or more user accounts forests. Here is an overview of what you need to do to deploy Exchange 2010 in a topology with a resource forest:
  .1. You must have a forest with Exchange installed. In the Exchange forest, you

must have disabled the user accounts that have Exchange mailboxes.
.2.You must have at least one forest that contains user accounts. This forest should *not* have Exchange installed.
.3.Then, you must associate the disabled user accounts in the Exchange forest with the user accounts in the accounts forest.

For details about deploying Exchange 2010 in a resource forest topology, see Deploy Exchange 2010 in an Exchange Resource Forest Topology.

GAL Synchronization

By default, a GAL contains mail recipients from a single forest. If you have a cross-forest environment, we recommend using Microsoft Identity Lifecycle Manager (ILM) 2007 Feature Pack 1 (FP1) to ensure that the GAL in any given forest contains mail recipients from other forests. ILM 2007 FP1 creates mail users that represent recipients from other forests, thereby allowing users to view them in the GAL and send mail. For example, users in Forest A appear as a mail user in Forest B and vice versa. Users in the target forest can then select the mail user object that represents a recipient in another forest to send mail.

To enable GAL synchronization, you create management agents that import mail-enabled users, contacts, and groups from designated Active Directory services into a centralized metadirectory. In the metadirectory, mail-enabled objects are represented as mail users. Groups are represented as contacts without any associated membership. The management agents then export these mail users to an organizational unit in the specified target forest.

For more information about Microsoft Identity Lifecycle Manager 2007 FP1, see Microsoft Identity Lifecycle Manager 2007 Feature Pack 1 Evaluation Edition.

Moving Mailboxes across Forests

In a cross-forest topology, you may want to move mailboxes from one forest to another. To do this you must use the **New-MoveRequest** cmdlet in the Exchange Management Shell. This is the same command that you use to move mailboxes within a single forest. For more information about moving mailboxes across forests, see the following topics:

- Prepare Mailboxes for Cross-Forest Move Requests
- Create a Remote Move Request That has Exchange 2010 in Both Forests
- Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

Understanding Multiple Forest Administration

Microsoft Exchange Server 2010 uses new permissions functionality to manage your multiple forest environments.

Exchange 2010 uses a Role Based Access Control (RBAC) permissions model. The management role groups that administrators are members of, and the management role assignment policies that end-users are assigned, determine what each administrator and end-user can do. To understand multiple forest permissions, you need to be familiar with RBAC. For more information about RBAC and role groups and role assignment policies in particular, see Understanding Role Based Access Control.

You can use the RBAC permissions model to configure and manage the permissions between your forests. For more information about multiple forest permissions, see the following topics:

- Understanding Multiple-Forest Permissions
- Create Linked Role Groups that Mirror Built-in Role Groups

- Create a Linked Role Group

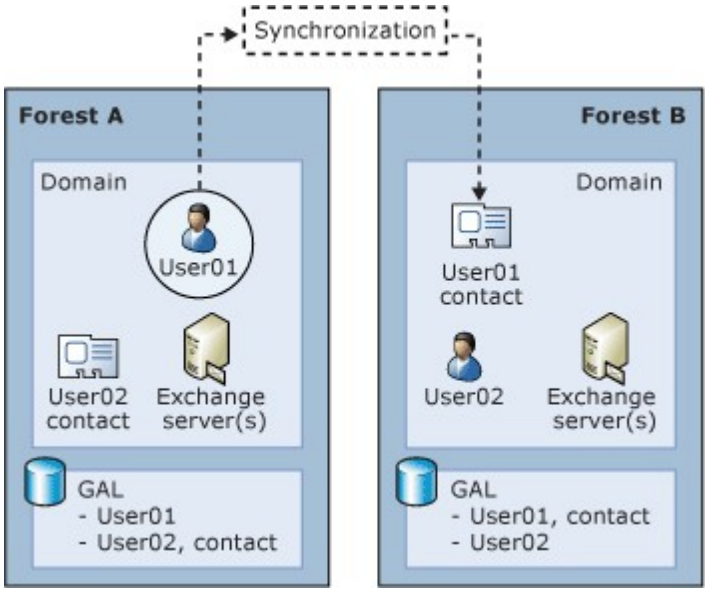
1.2.2.8.1 Deploy Exchange 2010 in a Cross-Forest Topology

Deploy Exchange 2010 in a Cross-Forest Topology

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-27*

This topic explains how to deploy Exchange 2010 in a cross-forest topology using Service Pack 1 (SP1) for ILM 2007 Feature Pack 1 (FP1). To deploy Exchange 2010 in a cross-forest topology, you must first install Exchange 2010 in each forest, and then connect the forests so that users can see address and availability data across the forests.



This topic does not describe how to deploy Exchange 2010 in a dedicated Exchange forest (or resource forest) topology. For more information about how to deploy Exchange 2010 in a resource forest topology, see Deploy Exchange 2010 in an Exchange Resource Forest Topology.

To synchronize the GALs in Exchange 2010, we recommend that you use Service Pack 1 (SP1) for ILM 2007 Feature Pack 1 (FP1). To download the feature pack, see Microsoft Knowledge Base article 977791, Service Pack 1 (build 3.3.1139.2) is available for Identity Lifecycle Manager 2007 Feature Pack 1.

Prerequisites

To perform the following procedure in Exchange 2010, confirm the following:

- You have correctly configured Domain Name System (DNS) for name resolution across forests in your organization. To verify that DNS is configured correctly, use the Ping tool to test connectivity to each forest from the other forests in your organization and from the server on which you will run the GALSync

agent.

- The GALSync management agent (MA) communicates with the Exchange 2010 forest using Windows PowerShell V2.0 RTM. Make sure Windows PowerShell v1.0 isn't installed on this computer by going to Control Panel, and then clicking Programs and Features.
- Ensure that Windows Remote Management has not been installed by Windows Update.
- Install Windows PowerShell and Windows Remote Management. For details, see Microsoft Knowledge Base article 968930, Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0).

Deploy Exchange 2010 in a cross-forest topology with SP1 for ILM 2007 FP1

1. In each forest, install Exchange 2010 separately. To install Exchange 2010, perform the same steps that you would if you were installing Exchange 2010 in a single forest topology. For detailed steps, see one of the following topics:
   - Install Exchange Server 2010
   - Install Exchange 2010 Using the Custom Installation Type

   Note:
   This topic assumes that you don't have an existing Exchange 2007 or Exchange Server 2003 topology. If you do have an existing Exchange topology and you want to upgrade, see Understanding Upgrade to Exchange 2010.
2. In each forest, use Active Directory Users and Computers to create a container in which ILM will create contacts for each mailbox from the other forest. We recommend that you name this container **FromILM**. To create the container, select the domain in which you want to create the container, right-click the domain, select **New**, and then select **Organizational Unit**. In **New Object - Organizational Unit**, type **FromILM**, and then click **OK**.
3. Create a GALSync management agent for each forest by using ILM 2007 Feature Pack 1. This allows you to synchronize the users in each forest and create a common GAL. For detailed steps, see the procedure "Configure a GAL Synchronization management agent with SP1 for ILM 2007 FP1" later in this topic.
4. Enable GALSync. To do this, in the main ILM Identity Manager window, click **Tools**, click **Options**, and then select the **Enable Provisioning Rules Extension** check box. Click **OK**.
5. Create an SMTP Send connector in each of the forests. For detailed steps, see Configure Cross-Forest Connectors.
6. In each forest, enable the Availability service so that users in each forest can view free/busy data about users in the other forest. For more information, see Managing the Availability Service.

   Note:
   The Availability service is supported only for Office Outlook 2007 clients.
7. If you require that mail can be relayed through any forest in your organization, you must configure a domain in that forest as an authoritative domain. For detailed steps, see Configure Exchange 2010 to Accept E-Mail for More Than One Authoritative Domain.
8. Move mailboxes from your existing Exchange 2003 or Exchange 2007 servers to the new Exchange 2010 Mailbox servers in each forest. For detailed steps, see Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010.

Configure a GAL Synchronization management agent with SP1

for ILM 2007 FP1

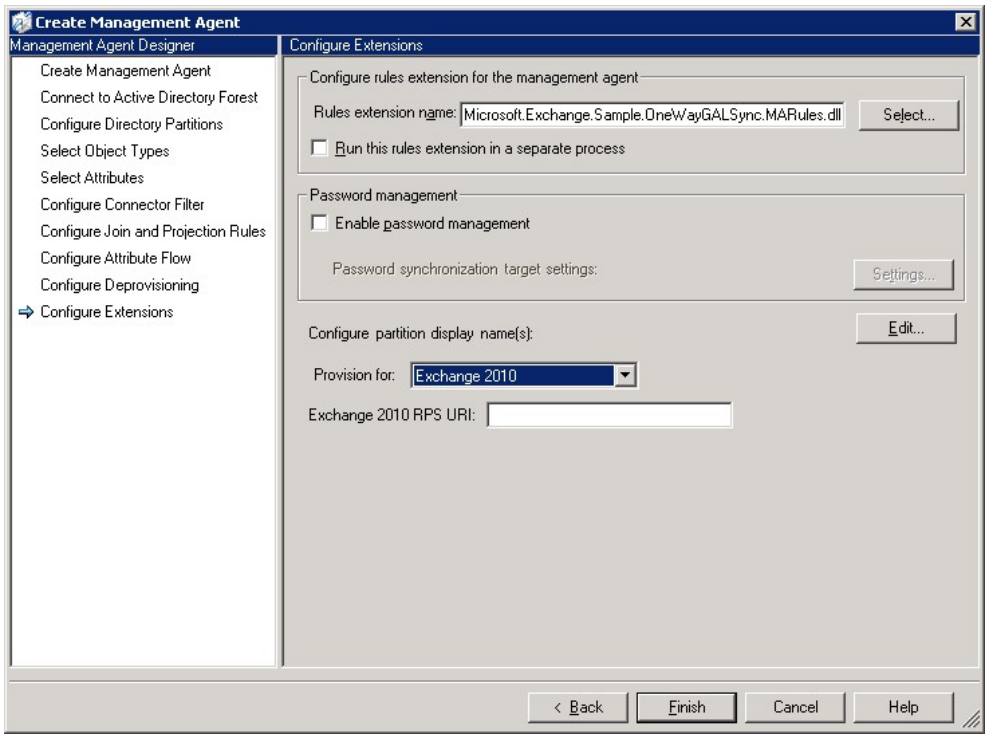
This procedure is necessary for deployment of Exchange 2010 in a cross-forest topology using Service Pack 1 (SP1) for ILM 2007 Feature Pack 1 (FP1). See step 3 in "Deploy Exchange 2010 in a cross-forest topology with SP1 for ILM 2007 FP1" earlier in this topic.

1. In SP1 for ILM 2007 FP1, select **Management Agents** from the toolbar, and then under **Actions**, click **Create**.
2. On the **Create Management Agent** page, under **Management agent for**, select **Active Directory global address list (GAL)**.
3. In the **Name** box, type a name for this management agent. When creating the name, we recommend that you include the name of the source forest from which this management agent will gather recipient information.
4. In the **Description** box, type a description for this management agent, and then click **Next**.
5. On the **Connect to Active Directory Forest** page, complete the following fields:
   - **Forest name** Name of the source forest.
   - **User name** and **Password** User name and password of an account that has permission to read schema information from the source forest.
   - **Domain** Domain for the specified account.

   Note:
   You can also enter the user name as *<user>*@*<domain>* and leave the domain field blank.
6. Click **Next**.
7. On the **Configure Directory Partitions** page, select the directory partitions on the source forest from which you want to project data to a destination forest.
8. On the **Configure Directory Partitions** page, click **Containers**.
9. On the **Select Containers** page, clear the top-level check box for the directory partition, select the containers for which this management agent will gather and store information, and then click **OK**. Be sure to select the container in which ILM will create contacts for each mailbox from the other forest, such as the FromILM container.
10. On the **Configure Directory Partitions** page, click **Next**.
11. On the **Configure GAL** page, click **Target**, and then select the container in which the contacts from other forests will reside in the target forest.
12. On the **Configure GAL** page, click **Source**, and then select the container in which other forests' objects that are synchronized to the target forest will reside.
13. Under **Exchange configuration**, click **Edit** to specify at least one Simple Mail Transfer Protocol (SMTP) e-mail suffix that is managed in the source forest. Click **Next**.
14. On the **Select Object Types** page, click **Next**.
15. On the **Select Attributes** page, click **Next**.
16. On the **Configure Connector Filter** page, click **Next**.
17. On the **Configure Join and Projection Rules** page, click **Next**.
18. On the **Configure Attributes Flow** page, click **Next**.
19. On the **Configure Deprovisioning** page, click **Next**.
20. On the **Configure Extensions** page, under **Configure partition display name(s)**: section, next to **Provision for:**, select **Exchange 2010**. If you select Exchange 2010, you will see the **Exchange 2010 RPS URI** field. Enter the URI of an Exchange 2010 Client Access server to make sure the Remote Powershell connection is functioning. The **Exchange 2010 RPS URI** should be in the following format: http://CAS_Server_FQDN/Powershell. Click **OK**.

    Note:
    Make sure that the administrator credentials used to connect to the Exchange 2010 forest can also make remote PowerShell connections to that forest.

The following figure shows how to select provisioning for Exchange 2010.



Testing Remote PowerShell Connection

This example tests whether you can make a remote PowerShell call to an Exchange 2010 Client Access server to verify that remote PowerShell is functioning correctly. From your ILM 2007 computer, first run this command:

```
$rs = new-pssession -conf microsoft.exchange -conn http://CAS_SERVER_NAME/powersh
```

Then run this command:

```
Invoke-Command $rs {get-recipient -ResultSize 1}
```

1.2.2.8.2 Deploy Exchange 2010 in an Exchange Resource Forest Topology

Deploy Exchange 2010 in an Exchange Resource Forest Topology

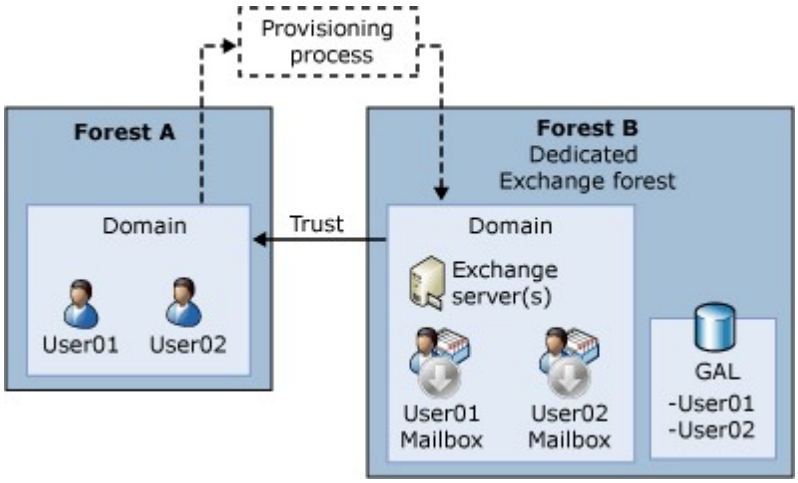
Planning and Deployment > Deploying Exchange 2010 > Deploy Multiple Forest Topologies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic explains how to deploy Microsoft Exchange 2010 in an Exchange resource forest topology. An Exchange resource forest is also called a dedicated Exchange forest. This topic assumes that you don't have an existing Exchange 2010 topology.

The following figure shows an Exchange organization with a resource forest.



Prerequisites

Before you begin, confirm the following:

- You have the following two Active Directory forests:
  - One forest contains the user accounts for your organization. In this procedure, this forest is called the *accounts forest*.
  - One forest does not contain user accounts and does not yet have Exchange installed. In this procedure, this forest is called the *Exchange forest*. You will use the procedure to install Exchange 2010 in this forest.
- You have correctly configured Domain Name System (DNS) for name resolution across forests in your organization. To check that you have DNS configured correctly, ping each forest from the other forest or forests in your organization. For more information about configuring DNS, see the DNS Operations Guide.

Deploy Exchange 2010 in an Exchange resource forest topology

1. From a domain controller in the Exchange forest, create a one-way outgoing trust so that the Exchange forest trusts the accounts forest. For detailed steps, see Create a one-way, outgoing, forest trust for both sides of the trust.

   Note:

   Although we recommend that you create a forest trust, you can create either a forest trust or an external trust. If you create an external trust, when you create linked mailboxes in Step 3, on the **Master Account** page of the New Mailbox wizard, you must specify a user account that can access the domain controller in the trusted forest. You can't use the credentials with which you are currently logged on. If you create linked mailboxes by using the **New-Mailbox** cmdlet, you must specify a user account that can access the domain controller in the trusted forest by using the *LinkedCredential* parameter.

2. In the Exchange forest, install Exchange 2010. Install Exchange the same way that you would in a single forest scenario. For detailed steps about how to install Exchange 2010, see one of the following topics:
   - Install Exchange Server 2010
   - Install Exchange 2010 in Unattended Mode
3. In the Exchange forest, for each user in the accounts forest that will have a mailbox in the Exchange forest, create a mailbox that is associated with an external account. For detailed steps, see Create a Linked Mailbox.

1.2.2.8.3 Configure Cross-Forest Connectors

Configure Cross-Forest Connectors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to configure Send connectors and Receive connectors to enable cross-forest communication. To establish direct mail flow between servers that are running Microsoft Exchange in different Active Directory forests, you must configure Send connectors and Receive connectors.

This topic explains how to configure cross-forest connectors for the following scenarios:

- Exchange Server 2010 to Exchange Server 2010
- Exchange 2010 to Exchange Server 2003

Configure cross-forest connectors between Exchange 2010 forests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

In this scenario, you create the cross-forest connectors between the Hub Transport servers in two Exchange 2010 organizations that are located in separate Active Directory forests. Basic authentication or external authentication mechanisms provide authentication and authorization between the servers in different forests. If you use Basic authentication, you can select from the following two methods to also use Transport Layer Security (TLS):

- Set the smart host authentication method to Basic authentication over TLS. This method provides both confidentiality and authentication of the receiving server. If you select this smart host authentication method, the sending server will validate the certificate of the receiving server as a requirement for mail flow.
- Set the *RequireTLS* parameter to `$true`. This method provides confidentiality, but doesn't authenticate the receiving server.

To configure a cross-forest connector between the Hub Transport servers in two Exchange 2010 organizations, you must meet the following prerequisites:

- Each forest must have an Exchange organization with Exchange 2010 servers.
- If you use Basic authentication, a domain account must exist in each forest to use for Basic authentication. For example, provide a user account that has the user principal name (UPN) FourthCoffee@Contoso.com as the credentials that must be used for authentication by the Exchange servers in the Fourth Coffee domain when mail is sent to the Exchange servers in the Contoso domain.
- If you use Basic authentication over TLS, the target server must be configured to use an X.509 certificate that contains a fully qualified domain name (FQDN) that's the same as the FQDN of the Receive connector.
- If you use external authentication, a trusted network connection must exist between the Hub Transport servers. This connection may be an IPsec

association or VPN. Alternatively, the servers may reside in a trusted physically controlled network.

To establish mail flow between the forests, follow these steps:

1. Create a user account in each forest to use for authentication to the receiving server in the second forest.
2. Create a Send connector.
3. Set permissions on the Send connector.
4. For externally secured connectors, create a new Receive connector.

Note:
If you're using Basic authentication over TLS, you must provide the FQDN of the remote Hub Transport server in the smart host settings. You can't use an IP address.

The following procedures establish cross-forest mail flow between the Exchange 2010 Hub Transport servers in the Contoso.com and FourthCoffee.com forests by using either Basic authentication or external authentication. You must perform the reciprocal procedure in each forest.

Configure cross-forest connectors between Exchange 2010 servers by using Basic authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Step 1: Create a user account in each forest

- Create the user account in each forest and then add the account to the Exchange Servers universal security group. This account is used by the Send connector to authenticate to the receiving server in the second forest.

Important:
This account is granted the permissions that are associated with Exchange servers. Be sure to safeguard the account credentials to prevent misuse of the account. You can configure the account to allow logon to specific computers only.

Step 2: Create a Send connector in the Contoso forest

Use the EMC to create a Send connector

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**, and then in the action pane, click **New Send connector**.
2. On the New SMTP Send connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
3. From the **Select the intended use for this Send connector** drop-down list, select **Internal**, and then click **Next**.
4. On the **Address Space** page, click **Add**. In the **SMTP Address Space** dialog box, type the name of the remote SMTP domain, and then click **Next**.
5. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
6. In the **Add Smart Host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the FQDN of a Hub Transport server in the remote forest, and then click **OK**. To specify more than one Hub Transport server as a smart host, click **Add** and enter additional FQDNs, and then click **Next**.
7. On the Configure **smart host authentication settings** page, select **Basic Authentication** or **Basic Authentication over TLS**, type the user name and password that will be used to authenticate the connection, and then click **Next**.
8. On the **Source Server** page, click **Add**. In the **Select Hub Transport or Subscribed Edge Transport Server** dialog box, select one or more Hub

Transport servers in your organization, click **OK**, and then click **Next**.

9. On the **New Connector** page, click **New**.
10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector

This example creates the Send connector from Contoso.com to FourthCoffee.com and uses Basic authentication over TLS to provide both confidentiality and authentication to the receiving server.

1. This command stores the credentials for use in authentication.

```
$mycred = Get-Credential
```

2. In the dialog box that appears, enter the credentials for the user account in the Fourth Coffee domain. Use the *domain**user* format or UPN format to enter the user name and provide the user's password.
3. Click **OK**.
4. This command creates the Send connector.

```
New-SendConnector -Name "Cross-Forest" -Usage Internal -AddressSpaces
```

This example creates the Send connector from Contoso.com to FourthCoffee.com and uses Basic authentication over TLS to provide only confidentiality.

1. This command stores the credentials for use in authentication.

```
$mycred = Get-Credential
```

2. In the dialog box that appears, enter the credentials for the user account in the Fourth Coffee domain. Use the *domain**user* format or UPN format to enter the user name and provide the user's password.
3. Click **OK**.
4. This command creates the Send connector.

```
New-SendConnector -Name "Cross-Forest" -Usage Internal -AddressSpaces
```

For detailed syntax and parameter information, see New-SendConnector.

Step 3: Use the Shell to set permissions on the Send connector

Note:

You can't use the EMC to set permissions on the Send connector.

This example uses the **Enable-CrossForestConnector.ps1** script in the Shell to set permissions on the Send connector.

```
.\Enable-CrossForestConnector.ps1 -Connector "Cross-Forest" -user "ANONYMOUS LOGO
```

Configure cross-forest connectors between Exchange 2010 servers by using external authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Step 1: Create a Send connector

Use the EMC to create a Send connector

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**, and then in the action pane, click **New Send connector**.
2. On the New SMTP Send connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended**

use for this Send connector drop-down list, select **Internal**, and then click **Next**.

3. On the **Address space** page, click **Add**. In the **SMTP Address Space** dialog box, type the name of the remote SMTP domain, and then click **Next**.
4. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
5. In the **Add Smart Host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of a Hub Transport server in the remote forest, and then click **OK**. To specify more than one Hub Transport server as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
6. On the Configure **smart host authentication settings** page, select **Externally Secured (for example, with IPsec)**, and then click **Next**.
7. On the **Source Server** page, click **Add**. In the **Select Hub Transport or Subscribed Edge Transport Server** dialog box, select one or more Hub Transport servers in your organization, click **OK**, and then click **Next**.
8. On the **New Connector** page, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector

This example creates the Send connector from Contoso.com to FourthCoffee.com.

```
New-SendConnector -Name "Cross-Forest" -Usage Internal -AddressSpaces FourthCoffe
```

For detailed syntax and parameter information, see New-SendConnector.

Step 2: Create a Receive connector

Use the EMC to create a Receive connector

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**, and then in the action pane, click **New Receive Connector**.
2. On the New SMTP Receive Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
3. From the **Select the intended use for this Receive connector** drop-down list, select **Internal**, and then click **Next**.
4. On the **Remote Network settings** page, remove the all network ranges entry, and then click **Add**.
5. In the **Add IP Address(es) of Remote Servers** dialog box, type the IP address of the remote Hub Transport server, click **OK**, and then click **Next**.
6. On the New Connector page, click **New**.
7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Receive connector

This example creates the Receive connector for Contoso.com to receive mail from FourthCoffee.com.

```
New-ReceiveConnector -Name "Cross-Forest" -Server HubA -PermissionGroups Exchange
```

For detailed syntax and parameter information, see New-ReceiveConnector.

Step 3: Modify the authentication method used for this connector

Note:
This step isn't necessary if you used the Shell to create the Receive connector in step 2. It's required if you used the EMC in step 2.

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**.
2. In the result pane, select the Receive connector that you want to modify, and then in the action pane, click **Properties**.
3. Click the **Authentication** tab.
4. Clear the check boxes for **Transport Layer Security (TLS)** and **Exchange Server authentication**, and then select **Externally Secured (for example with IPsec)**.
5. Click **OK**.

Configure cross-forest connectors between Exchange 2010 and Exchange 2003

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

In this scenario, you create the cross-forest connectors between an Active Directory forest with an Exchange organization that's running Exchange 2010 and a second Active Directory forest with an Exchange organization that's running Exchange 2003. You can create the Send connectors and Receive connectors between the Exchange 2010 Edge Transport server and the Exchange 2003 bridgehead server or between the Exchange 2010 Hub Transport server and the Exchange 2003 bridgehead server.

To establish mail flow between the forests, follow these steps:

1. Create user accounts in each forest for authenticating the sending server. This step isn't required if you use external authentication.
2. Create a Send connector and select **Internal** as the usage for this connector on either the Exchange 2010 Edge Transport server or Hub Transport server.
3. Modify the authentication for the new Send connector.
4. Create an SMTP connector on Exchange 2003.
5. If you're using external authentication, modify the registry on the Exchange 2003 server to allow the Exchange 2003 server to send and receive XEXCH50 properties anonymously.

The following procedures establish cross-forest mail flow between the Exchange 2010 transport servers in the Contoso.com forest and the Exchange 2003 bridgehead servers in the FourthCoffee.com forest by using either Basic authentication or external authentication. After you perform one of the following procedures, we recommend that you test mail flow by sending a message between the two organizations. You should also examine the protocol logs to verify that XEXCH50 data is propagated to Exchange 2003.

Configure cross-forest connectors between Exchange 2010 and Exchange 2003 servers in separate forests and use Basic authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Step 1: Create a user account in each forest

In the Exchange 2003 forest, create a user account. Add the user account to the Exchange Domain Servers security group in the domain where the Exchange 2003 server

that will act as smart host for this connector resides.

Important:

This account is granted the permissions that are associated with Exchange servers. Be sure to safeguard the account credentials to prevent misuse of the account. You can configure the account to allow logon to specific computers only.

In the Exchange 2010 forest, create a user account. Add the user account to the ExchangeLegacyInterop security group in the domain where the Exchange 2010 server that will act as the smart host for receiving messages from Exchange 2003 resides.

Step 2: Create a Send connector from Exchange 2010 to Exchange 2003

Use the EMC to create a Send connector

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**, and then in the action pane, click **New Send connector**.
2. On the New SMTP Send connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended use for this Send connector** drop-down list, select **Internal**, and then click **Next**.
3. On the **Address Space** page, click **Add**. In the **SMTP Address Space** dialog box, type the name of the remote SMTP domain, and then click **Next**.
4. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
5. In the **Add Smart Host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of the Exchange 2003 bridgehead server in the remote forest, and then click **OK**. To specify more than one bridgehead server as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
6. On the Configure **smart host authentication settings** page, in either **Basic Authentication** or **Basic Authentication over TLS**, type the user name and password that will be used to authenticate the connection, and then click **Next**.
7. On the **Source Server** page, click **Add**. In the **Select Hub Transport or Subscribed Edge Transport Server** dialog box, select one or more Hub Transport servers in your organization, click **OK**, and then click **Next**.
8. On the **New Connector** page, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector

If the Exchange 2010 Send connector is configured to use Basic authentication over TLS or to use Basic authentication with the *RequiredTLS* parameter set to `$true`, the Exchange 2003 server must advertise the correct certificate before authentication can occur. You can verify that a certificate has been imported to the Exchange 2003 SMTP virtual server by viewing the properties of the virtual server. To view or import a server certificate, select the **Access** tab and click **Certificate**.

1. This command stores the credentials for use in authentication. In the Exchange 2010 forest, open the Shell on the Edge Transport server or the Hub Transport server, and run the following command.

   ```
   $mycred = Get-Credential
   ```

   In the dialog box that appears, enter the credentials for the user account that you created in the Exchange 2003 forest. Use the *domain**user* format or the UPN format to enter the user name and provide the user's password. Click **OK**.
2. In the Shell, use one of the following commands to create the Send

connector.

- This example creates a Send connector to use Basic authentication over TLS to provide both confidentiality and authentication to the receiving server.

```
New-SendConnector -Name "Legacy Forest" -SmartHostAuthMechar
```

- This example creates a Send connector to use Basic authentication with TLS to provide only confidentiality.

```
New-SendConnector -Name "Legacy Forest" -SmartHostAuthMechar
```

For detailed syntax and parameter information, see New-SendConnector.

Step 3: Use the Shell to set permissions on the Send connector

Note:
You can't use the EMC to set permissions on the Send connector.

This example uses the **Enable-CrossForestConnector.ps1** script in the Shell to set permissions on the Send connector.

```
.\Enable-CrossForestConnector.ps1 -Connector "Legacy Forest" -user "ANONYMOUS LOG
```

Step 4: Use Exchange System Manager to create an SMTP connector on an Exchange 2003 bridgehead server in the remote forest

1. In the Exchange 2010 forest, create a user account. Add the user account to the ExchangeLegacyInterop security group.

   Important:
   This account is granted the permissions that are associated with Exchange servers. Be sure to safeguard the account credentials to prevent misuse of the account. You can configure the account to allow logon to specific computers only.

2. In the Exchange 2003 forest, open Exchange System Manager. Right-click the **Connectors** container that's located in the routing group where the server that will host this connector resides, select **New**, and then select **SMTP Connector**.
3. Select the **General** tab. In the **Name** field, type a unique name for the connector.
4. Select **Forward all mail through this connector to the following smart hosts**, and then type the IP address or FQDN of the Exchange 2010 Edge Transport server or Hub Transport server. If you enter an IP address, it must be enclosed in brackets, for example, [192.168.1.1].
5. Click **Add** to add a local bridgehead server. In the **Add Bridgehead** dialog box, select one or more Exchange 2003 servers.
6. Select the **Address Space** tab, and then click **Add** to create an address space. In the **Add Address Space** dialog box, select **SMTP**, and then click **OK**.
7. On the **Internet Address Space Properties** page, enter the SMTP domain name of the Exchange 2010 forest, and then click **OK**.
8. Select the **Advanced** tab, and then click **Outbound Security**. In the **Outbound Security** dialog box, select **Basic Authentication**, and then click **Modify**.
9. In the **Outbound Connection Credentials** dialog box, enter the user name for the account that you created in the Exchange 2010 forest, enter the password for the account, and then click **OK**.
10. Click **OK** to close the **Outbound Security** dialog box. Click **OK**.

Configure cross-forest connectors between Exchange 2010 and Exchange 2003 servers without a trust relationship by using

external authentication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send connectors" and "Receive connectors" entries in the Transport Permissions topic.

Step 1: Create a Send connector

Use the EMC to create a Send connector

1. In the console tree navigate to **Organization Configuration** > **Hub Transport**.
2. In the action pane, click **New Send connector**.
3. On the New SMTP Send connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector. From the **Select the intended use for this Send connector** drop-down list, select **Internal**, and then click **Next**.
4. On the **Address Space** page, click **Add**. In the **SMTP Address Space** dialog box, type the name of the remote SMTP domain, and then click **Next**.
5. On the **Network settings** page, only the **Route mail through the following smart hosts** setting can be selected. Click **Add**.
6. In the **Add Smart Host** dialog box, in the **IP address** or **Fully qualified domain name (FQDN)** field, type the IP address or FQDN of the bridgehead server in the Exchange 2003 forest, and then click **OK**. To specify more than one bridgehead server as a smart host, click **Add** and enter additional IP addresses or FQDNs, and then click **Next**.
7. On the **Configure smart host authentication settings** page, select **Externally Secured (for example with IPsec)**, and then click **Next**.
8. On the **Source Server** page, click **Add**. In the **Select Hub Transport or Subscribed Edge Transport Server** dialog box, select one or more Hub Transport servers in your organization, click **OK**, and then click **Next**.
9. On the **New Connector** page, click **New**.
10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Send connector

This example creates the Send connector from Contoso.com to FourthCoffee.com.

```
New-SendConnector -Name "Legacy Forest" -Usage Internal -AddressSpaces FourthCoff
```

For detailed syntax and parameter information, see New-SendConnector.

Step 2: Create a Receive connector

Use the EMC to create a Receive connector

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**, and then in the action pane, click **New Receive Connector**.
2. On the New SMTP Receive Connector wizard **Introduction** page, in the **Name** field, type a unique name for the connector.
3. From the **Select the intended use for this Receiver connector** drop-down list, select **Internal**, and then click **Next**.
4. On the **Remote Network settings** page, remove the all network ranges entry, and then click **Add**.
5. In the **Add IP address(es) of Remote Servers** dialog box, type the IP address of the bridgehead server in the Exchange 2003 organization, click **OK**, and then click **Next**.
6. On the New Connector page, click **New**.
7. On the **Completion** page, review the following, and then click **Finish** to close

the wizard:

- A status of **Completed** indicates that the wizard completed the task successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a Receive connector

This example creates the Receive connector for Contoso.com to receive mail from FourthCoffee.com.

```
New-ReceiveConnector -Name "Legacy Forest" -Usage Internal -Server HubA -Permissi
```

For detailed syntax and parameter information, see New-ReceiveConnector.

Step 3: Modify the authentication method used for this connector

Note:

This step isn't necessary if you used the Shell to create the Receive connector in step 2. It's required if you used the EMC in step 2.

1. In the console tree, navigate to **Server Configuration** > **Hub Transport**.
2. In the result pane, select the Receive connector that you want to modify, and then in the action pane, click **Properties**.
3. Click the **Authentication** tab.
4. Clear the check boxes for **Transport Layer Security (TLS)** and **Exchange Server authentication**, select **Externally Secured (for example with IPsec)**, and then click **OK**.

Step 4: Modify the registry settings on the Exchange 2003 bridgehead server to allow the Exchange 2003 server to send and receive XEXCH50 properties anonymously

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Open Registry Editor.
2. Locate **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\SMTPSVC\XEXCH50**
3. Right-click **XEXCH50** and select **New | DWORD Value**. Type **SuppressExternal** for the value name. By default, the value data is **0**, which indicates that the XEXCH50 properties are transmitted to the remote server anonymously.
4. Right-click **XEXCH50** and select **New** | **Key**. Type the number of the SMTP virtual server instance as the key value. For example, the default virtual server instance is **1**, and the second SMTP virtual server created on a server is **2**.
5. Right-click the key that you just created, point to **New**, and then click **DWORD Value**.
6. In the details pane, type **Exch50AuthCheckEnabled** for the value name. By default, the value data is **0**, which indicates that the XEXCH50 properties are transmitted when e-mail is sent anonymously.

1.2.2.9 Exchange 2010 Post-Installation Tasks

Exchange 2010 Post-Installation Tasks

Exchange Server 2010 > Planning and Deployment > Deploying Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

After you complete a new installation of Microsoft Exchange Server 2010 or after you add an additional Exchange 2010 server role to an existing Exchange 2010 server, you should complete the post-installation tasks. The post-installation tasks will help you verify the installation and configure the components that you have just installed. Because each server role offers several features that you can configure for your organization, make sure that you complete the post-installation tasks for each server role that you install.

In the Exchange Management Console, when you select the **Microsoft Exchange** node, the result pane displays the **Post-Installation Tasks** tab. From that tab, you can find more information via links to several topics that describe, by server role, the various post-installation tasks:

Finalize Deployment Tasks This topic describes tasks that are required to complete the deployment of your Exchange 2010 organization. The tasks apply to features that are enabled by default but require additional configuration.

End-to-End Scenario Tasks This topic provides a checklist of the recommended actions to take to configure specific end-to-end scenarios. For example, how to configure monitoring for your Exchange servers.

Additional Post-Installation Tasks This topic provides you with information about optional tasks that you may want to perform after you install Exchange Server 2010.

In addition to the preceding topics, the following topics also provide information related to post-installation tasks:

Verify an Exchange 2010 Installation

Enter Product Key

Register Filter Pack IFilters with Exchange 2010

Transport Server Post-Deployment Tasks

And, if you're upgrading from an Exchange 2003 or a mixed Exchange 2003 and Exchange 2007 organization, see Upgrade Custom LDAP Filters to OPATH Filters.

1.2.2.9.1 Finalize Deployment Tasks

Finalize Deployment Tasks

Planning and Deployment > Deploying Exchange 2010 > Exchange 2010 Post-Installation Tasks >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-20*

Use this checklist to help you perform tasks to finalize your deployment after you install Exchange Server 2010. The tasks in this topic are required to complete the deployment of your Exchange organization. The tasks apply to features that are enabled by default but require additional configuration.

For guidance about optional tasks that you may want to perform after installing Exchange 2010, see Additional Post-Installation Tasks and End-to-End Scenario Tasks.

All Server Roles

Done?	Task
	Enter the product key for Exchange 2010. For more information, see Enter Product Key. You can also enter the product key by using the Set-ExchangeServer cmdlet.
	We recommend that you protect your Exchange servers from viruses, worms, and other malicious software. For more information, see Forefront Protection 2010 for Exchange Server.

Mailbox Server Role

Done?	Task
	Configure offline address book (OAB) distribution for Microsoft Office Outlook clients. For more information, see Create an Offline Address Book and Configure Offline Address Book Properties.
	Configure high availability, backup, and disaster recovery. For more information, see High Availability and Site Resilience.

Client Access Server Role

Done?	Task
	Configure secure access for your Client Access server. For more information, see Understanding Client Access Security.
	Configure Microsoft Exchange ActiveSync. By default, when you install the Client Access server role on a computer that is running Exchange 2010, Exchange ActiveSync is enabled. However, we recommend that you configure security, authentication, and policy settings if you plan to use ActiveSync in your environment. For more information, see Managing Exchange ActiveSync.

Hub Transport Server Role

Done?	Task
	Configure domains for which you will accept e-mail messages. For more information, see Transport Server Post-Deployment Tasks.
	Configure Internet mail flow. By default, a Hub Transport server isn't configured for Internet mail flow. If you don't subscribe an Edge Transport server to your Exchange organization, you must use one of the following methods to configure Internet mail flow to and from your Exchange organization: • Deploy an Edge Transport server and manually configure the Send connectors and Receive connectors that are required for Internet mail flow. This method doesn't establish any replication of recipient and configuration information from Active Directory Domain Services to the Edge Transport server. For more information, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync. • Manually configure Internet mail flow between your Exchange 2010 organization and Microsoft Exchange Hosted Services or other external SMTP gateway servers. This method requires you to create the Send connectors and Receive connectors on one or more Hub Transport servers in your organization that are assigned to communicate with Exchange Hosted Services or the external SMTP gateway servers. For more information see Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway. • Configure the Hub Transport server for direct mail flow with the Internet. This method requires you to create the Send connectors and Receive connectors on one or more Hub Transport servers in your organization that are assigned to connect to the Internet. For more information, see Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway.
	Configure an external postmaster recipient to receive e-mail messages. The external postmaster address is used as the sender for system-

	generated messages and notifications that are sent to message senders that exist outside the Exchange 2010 organization. According to RFC 2821, every domain must be able to receive mail that is sent to the postmaster address. By default, no mailbox or other recipient object is configured to receive messages that are sent to the postmaster address for any accepted domains that are defined in the Exchange organization. For more information, see Configure the External Postmaster Address.

Unified Messaging Server Role

Done?	Task
	Configure Unified Messaging (UM). For more information see the following topics: • Create a UM Dial Plan • Create a UM IP Gateway • Add a UM Server to a Dial Plan • Enable a User for Unified Messaging **Note** These tasks are required to configure the first UM server in your organization or the first UM server in a new dial plan. To configure an additional UM server for an existing dial plan, you only need to complete the steps in Add a UM Server to a Dial Plan.
	Configure UM and Office Communications Server integration. For more information, see Deploy Unified Messaging and Communications Server 2007 R2.

Edge Transport Server Role

Done?	Task
	Subscribe the Edge Transport server. For more information, see Configure Internet Mail Flow Through a Subscribed Edge Transport Server. **Note** To subscribe the Edge Transport server manually instead of using the Edge Subscription process, see Configure Mail Flow Between an Edge Transport Server and Hub Transport Servers Without Using EdgeSync.
	Configure an external postmaster recipient to receive e-mail messages. The external postmaster address is used as the sender for system-generated messages and notifications that are sent to message senders that exist outside the Exchange

	2010 organization. According to RFC 2821, every domain must be able to receive mail that is sent to the postmaster address. By default, no mailbox or other recipient object is configured to receive messages that are sent to the postmaster address for any accepted domains that are defined in the Exchange organization. If you haven't subscribed this Edge Transport server to your Exchange organization, the value of the external postmaster address is postmaster@[Edge Transport server FQDN]. After you subscribe the Edge Transport server to the Exchange organization, the value of the external postmaster address is postmaster@[default accepted domain]. If you specify a custom value for the external postmaster address on the Hub Transport servers in your Exchange organization, you must manually configure the external postmaster address on the Edge Transport server. For more information, see Configure the External Postmaster Address.
	Configure Domain Name System (DNS). The Edge Transport server must be configured for internal DNS lookups within the Exchange organization and external DNS lookups for external recipients. Public DNS records must also be configured for this server to send or receive mail from the Internet. For more information, see Configure Edge Transport Server Properties.

1.2.2.9.2 End-to-End Scenario Tasks

End-to-End Scenario Tasks

Planning and Deployment > Deploying Exchange 2010 > Exchange 2010 Post-Installation Tasks >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use this checklist to track your work to configure specific end-to-end scenarios after you install Exchange Server 2010. The tasks in this topic are optional for configuring features.

For information about other optional post-installation configuration tasks that aren't listed in this topic, but are recommended after you install Exchange 2010, see Additional Post-Installation Tasks.

For guidance about required tasks that you must perform after installing Exchange 2010, see Finalize Deployment Tasks.

All Server Roles

Done?	Task
	Configure monitoring for your Exchange servers. For more information, see Performance and Scalability.

Mailbox Server Role

Done?	Task
	Configure messaging records management (MRM). For more information, see Messaging Records Management.

Client Access Server Role

Done?	Task
	Configure Microsoft Outlook Anywhere to provide access to Exchange using Office Outlook 2007 or Outlook 2010 clients from outside the corporate network. For more information, see Managing Outlook Anywhere.
	Verify that AutoDiscover is enabled and configured correctly. For more information, see Managing the Autodiscover Service.

Hub Transport Server Role

Done?	Task
	Replicate safelist aggregation data. For more information, see Configure Safelist Aggregation.

Unified Messaging Server Role

Done?	Task
	Enable outdialing. For more information, see Understanding Outdialing.
	Enable mutual-TLS between IP gateways or IP PBXs and an Exchange Unified Messaging (UM) server. For more information, see Understanding Unified Messaging VoIP Security.
	Create and configure a UM auto attendant. For more information, see Create a UM Auto

	Attendant.

Edge Transport Server Role

Done?	Task
	Configure the list of internal SMTP servers. For more information, see Set-TransportConfig.
	Replicate safelist aggregation data. For more information, see Configure Safelist Aggregation.

1.2.2.9.3 Additional Post-Installation Tasks

Additional Post-Installation Tasks

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-08-21*

Use this checklist to keep track of the tasks you may want to perform after you install Exchange Server 2010. The tasks in this checklist are optional, depending on the features you want to enable in your organization.

For information about other optional post-installation configuration tasks that aren't listed in this topic, but are recommended after you install Exchange 2010, see End-to-End Scenario Tasks.

For guidance about required tasks that you must perform after installing Exchange 2010, see Finalize Deployment Tasks.

All Server Roles

Done?	Task
	Verify your Exchange Server 2010 installation: • Review the setup logs. • Verify the folder structure of Exchange files. • Verify the tools installed. • Verify the required Exchange services are started. For more information, see Verify an Exchange 2010 Installation.

Mailbox Server Role

Done?	Task
	Verify your Mailbox Server role installation. For more information, see Verify an Exchange 2010 Installation.
	Configure permissions using the Exchange administrator roles. For more information, see Permissions to Manage Mailbox Servers.
	Configure your Mailbox server role. For more information, see Configure Mailbox Server Properties.
	Create and manage databases. For more information, see Managing Mailbox Databases.
	Create mailboxes for users in your organization. For more information, see Create a Mailbox Database.
	Move mailboxes from an existing Exchange server. For more information, see Managing Move Requests.
	Configure high availability, backup, and disaster recovery. For more information, see High Availability and Site Resilience.

Client Access Server Role

Done?	Task
	Enable the Client Access server for POP3 and IMAP4 if you plan to let clients use POP3 or IMAP4. For more information, see Enabling POP3 and IMAP4 on a Client Access Server.
	Increase security for communications between clients and the Client Access server and between the Client Access server and other servers. For more information about how to help secure the Client Access server messaging environment, see Understanding Client Access Security.

Hub Transport Server Role

Done?	Task
	Verify your Hub Transport Server role installation. For more information, see Transport Server Post-Deployment Tasks.

Unified Messaging Server Role

Done?	Task
	Add additional Unified Messaging (UM) servers. For more information, see Add a UM Server to a Dial Plan.
	Add additional UM languages to UM servers. For more information, see Install a Unified Messaging Language Pack on a UM Server.
	Enable UM users to receive incoming faxes. For more information, see Fax Advisor for Exchange 2010.
	Configure UM dial plans and auto attendants with customized greetings. For more information, see Enable a Custom Welcome Greeting on a UM Dial Plan or Enable a Custom Business Hours Main Menu Prompt Greeting on a UM Auto Attendant.
	Configure UM auto attendants with key mappings. For more information, see Configure Key Mapping Entries on a UM Auto Attendant.

Edge Transport Server Role

Done?	Task
	Verify your Edge Transport Server role installation. For more information, see Transport Server Post-Deployment Tasks.

1.2.2.9.4 Verify an Exchange 2010 Installation

Verify an Exchange 2010 Installation

Planning and Deployment > Deploying Exchange 2010 > Exchange 2010 Post-Installation Tasks >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

After you install Microsoft Exchange Server 2010, we recommend that you verify the installation by running the **Get-ExchangeServer** cmdlet and by reviewing the setup log file. If the setup process fails or errors occur during installation, you can use the setup log file to track down the source of the problem.

Note:
For information about the Exchange services that are installed and their status after you install Exchange 2010, see Overview of Services Installed by Exchange Setup.

Run Get-ExchangeServer

To verify that Exchange 2010 installed successfully, run the **Get-ExchangeServer** cmdlet in the Exchange Management Shell. A list is displayed of all Exchange 2010 server roles that are installed on the specified server when this cmdlet is run.

Note:

The Edge Transport server role can't share hardware with another Exchange 2010 server role.

For detailed syntax and parameter information, see Get-ExchangeServer.

Review the Setup Log

You can also learn more about the installation and configuration of Exchange 2010 by reviewing the setup log created during the setup process.

During installation, Exchange Setup logs events in the Application log of Event Viewer on computers that are running Windows Server 2008 and Windows Server 2008 R2. Review the Application log, and make sure that there are no warning or error messages related to Exchange setup. These log files contain a history of each action that the system takes during Exchange 2010 setup and any errors that may have occurred. By default, the logging method is set to verbose. Information is available for each installed server role.

You can find the setup log at *<system drive>*\ExchangeSetupLogs\ExchangeSetup.log. The *<system drive>* variable represents the root directory of the drive where the operating system is installed.

The setup log file tracks the progress of every task that is performed during the Exchange 2010 installation and configuration. The file contains information about the status of the prerequisite and system readiness checks that are performed before installation starts, the application installation progress, and the configuration changes that are made to the system. Check this log file to verify that the server roles were installed as expected.

We recommend that you start to review the setup log file by searching for any errors. If you find an entry that indicates that an error occurred, read the associated text to determine the cause of the error.

1.2.2.9.5 Enter Product Key

Enter Product Key

Planning and Deployment > Deploying Exchange 2010 > Exchange 2010 Post-Installation Tasks >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the Enter Product Key wizard to enter a product key for a server running Microsoft Exchange Server 2010 that doesn't already have a product key configured.

When you install Exchange 2010, it's unlicensed. This is also known as a trial edition. The trial edition expires 120 days after the date of installation. A server that is unlicensed functions as an Exchange Standard Edition server, but it isn't eligible for support from Microsoft support services. When you start the Exchange Management Console, if you have Exchange 2010 servers in your organization that are unlicensed, Exchange displays

a list of all unlicensed Exchange 2010 servers and the number of days that are remaining until the trial edition expires. If you have Exchange 2010 servers for which the trial edition has expired, Exchange also displays a separate warning for each expired server.

After you complete the Enter Product Key wizard, you must restart the Microsoft Exchange Information Store service so that the change is applied. Depending on the product key that you enter, Exchange will determine if the server is running the Standard Edition or Enterprise Edition of Exchange 2010 and will update any necessary settings.

What Do You Want to Do?

- Use the EMC to enter the product key
- Use the Shell to enter the product key

Use the EMC to enter the product key

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Product key" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In the console tree, navigate to **Server Configuration**.
2. In the action pane, click **Enter Product Key Group**.
3. On the **Enter Product Key** page, enter the product key, and then click **Enter**.
4. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to enter the product key

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Product key" entry in the Exchange and Shell Infrastructure Permissions topic.

This example uses the **set-ExchangeServer** cmdlet to enter the product key.

```
Set-ExchangeServer -Identity ExServer01 -ProductKey aaaaa-aaaaa-aaaaa-aaaaa-aaaaa
```

For detailed syntax and parameter information, see Set-ExchangeServer.

1.2.2.9.6 Register Filter Pack IFilters with Exchange 2010

Register Filter Pack IFilters with Exchange 2010

Planning and Deployment > Deploying Exchange 2010 > Exchange 2010 Post-Installation Tasks >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

Exchange Search uses IFilters to index text content in different file formats. Microsoft Office 2010 Filter Packs includes filters for Microsoft Office 2010 and Office 2007 file formats. Installation of the Filter Pack is a pre-requisite for Exchange 2010 Mailbox and Hub Transport servers. For details, see Exchange 2010 Prerequisites. The following file

name extensions are supported by the filter pack: .docm, .docx, .one, .pptm, .pptx, .vdx, .vsd, .vss, .vst, .vsx, .vtx, .xlsb, .xlsm, .xlsx, .zip. For more information and to download the Filter Pack, see Microsoft Office 2010 Filter Packs.

After you install the Filter Pack, the included IFilters are registered with Windows Search. To allow Exchange 2010 to index Office 2010 file formats, the IFilters must also be registered with Exchange Search. This is done by modifying the registry.

In Exchange 2010 SP1, Exchange Setup registers the IFilters from Office 2010 Filter Packs with Exchange Search.

In the release to manufacturing (RTM) version of Exchange 2010, you must register the IFilters with Exchange 2010 by modifying the registry. You must perform this step after you have installed Exchange 2010 RTM on the server.

Note:

In Exchange 2010 RTM, you can meet the prerequisite by installing 2007 Office System Converter: Microsoft Filter Pack. We recommend that you upgrade to the Office 2010 version of the Filter Pack.

What Do You Want to Do?

- Register Microsoft Filter Pack IFilters manually
- Register Microsoft Filter Pack IFilters automatically

Register Microsoft Filter Pack IFilters manually

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Start Registry Editor (regedit).
2. Locate the following registry subkey: **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\CLSID**
   Add the subkeys and values that are listed in the following table to this subkey.

Subkey	Value
{5A98B233-3C59-4B31-944C-0E560D85E6C3}	drive:\Program Files\Common Files\Microsoft Shared\Filters\offfiltx.dll
{DDFE337F-4987-4EC8-BDE3-133FA63D5D85}	drive:\Program Files\Common Files\Microsoft Shared\Filters\offfiltx.dll
{F90DFE0C-CBDF-41FF-8598-EDD8F222A2C8}	drive:\Program Files\Common Files\Microsoft Shared\Filters\offfiltx.dll
{20E823C2-62F3-4638-96BD-90F4F6784EBC}	drive:\Program Files\Common Files\Microsoft Shared\Filters\offfiltx.dll
{312AB530-ECC9-496E-AE0E-C9E6C5392499}	drive:\Program Files\Common Files\Microsoft Shared\Filters\offfiltx.dll
{B8D12492-CE0F-40AD-83EA-099A03D493F1}	drive:\Program Files\Common Files\Microsoft Shared\Filters\ONIFilter.dll
{FAEA5B46-761B-400E-B53E-	drive:\Program Files\Common Files

E805A97A543E}	\Microsoft Shared\Filters\VISFilt.DLL

3. In each of the subkeys you created in Step 2, create the following string value.

Value Name	Type	Value Data
ThreadingModel	String (REG_SZ)	Both

4. Locate the following registry subkey:
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\Filters
Add the subkeys and values that are listed in the following table to this subkey.

Subkey	Value
.docm	{5A98B233-3C59-4B31-944C-0E560D85E6C3}
.docx	{5A98B233-3C59-4B31-944C-0E560D85E6C3}
.pptm	{DDFE337F-4987-4EC8-BDE3-133FA63D5D85}
.pptx	{DDFE337F-4987-4EC8-BDE3-133FA63D5D85}
.xlsm	{F90DFE0C-CBDF-41FF-8598-EDD8F222A2C8}
.xlsx	{F90DFE0C-CBDF-41FF-8598-EDD8F222A2C8}
.xlsb	{312AB530-ECC9-496E-AE0E-C9E6C5392499}
.zip	{20E823C2-62F3-4638-96BD-90F4F6784EBC}
.one	{B8D12492-CE0F-40AD-83EA-099A03D493F1}
.vsd	{FAEA5B46-761B-400E-B53E-E805A97A543E}
.vss	{FAEA5B46-761B-400E-B53E-E805A97A543E}
.vst	{FAEA5B46-761B-400E-B53E-E805A97A543E}
.vdx	{FAEA5B46-761B-400E-B53E-E805A97A543E}
.vsx	{FAEA5B46-761B-400E-B53E-E805A97A543E}
.vtx	{FAEA5B46-761B-400E-B53E-E805A97A543E}

5. Restart the **Microsoft Search (Exchange)** service using the Services console or by typing the following command in the Exchange Management Shell.

```
Stop-Service msftesql-Exchange -Force; Start-Service MSExchangeSearch
```

Register Microsoft Filter Pack IFilters automatically

1. Paste the following text into a Notepad file.

```
# Copyright (c) 2009 Microsoft Corporation. All rights reserved.
# THIS CODE IS MADE AVAILABLE AS IS, WITHOUT WARRANTY OF ANY KIND. THE
# This is a filter registration script to configure Exchange Server 20
$DLLPath = $env:CommonProgramFiles + "\Microsoft Shared\Filters"
$CLSIDKey = "HKLM:\SOFTWARE\Microsoft\ExchangeServer\V14\MSSearch\CLSI
$FiltersKey = "HKLM:\SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\Fi
# Filter DLL Locations

2. Name the file RegisterMicrosoftFilterPack.ps1, and then save it.
3. Start Windows PowerShell or the Exchange Management Shell.
4. Run the script RegisterMicrosoftFilterPack.ps1.

Important:

Whether Windows PowerShell or Exchange Management Shell allow you to run scripts is determined by the execution policy. For more details, see Script Security.

5. Restart the **Microsoft Search (Exchange)** service using the Services console or by typing the following command in the Exchange Management Shell.

```
Stop-Service msftesql-Exchange -Force; Start-Service MSExchangeSearch
```

1.2.2.9.7 Transport Server Post-Deployment Tasks

Transport Server Post-Deployment Tasks

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-04*

After you install Hub Transport server and Edge Transport server roles, you need to perform specific, additional tasks to have full message flow functionality. Tasks include configuring accepted domains and configuring Internet mail flow. These tasks, and recommendations for how to accomplish them, are described in this topic.

Configure Accepted Domains

Accepted domains are SMTP namespaces for which an Exchange organization sends and receives e-mail. An Exchange organization is considered authoritative for a specific accepted domain if it handles all mail delivery for recipients in that domain. Typically, the accepted domains that you use in a new installation are all authoritative. However, there are other types of accepted domains, which you may want to use depending on your needs.

To learn more about accepted domains, see Understanding Accepted Domains.

Accepted Domains in the Exchange Organization

By default, one accepted domain exists and is configured as authoritative for the Exchange organization during installation. The default authoritative domain is the fully qualified domain name (FQDN) of your Active Directory forest root domain. In many organizations, the internal domain name differs from the external domain name.

For example, your internal domain name may be contoso.local, and your external domain name may be contoso.com. The public Domain Name System (DNS) MX resource record for your organization will reference contoso.com. To send and receive e-mail across the Internet, you must configure contoso.com as an accepted domain. Also, if your Exchange organization is handling mail for more than one domain, you must specify these additional domains as accepted domains.

Accepted domains need to be configured only once for the Exchange organization after you deploy your first Hub Transport server.

For step-by-step instructions about creating accepted domains, see Create an Accepted Domain.

Note:

If you configure additional accepted domains for your organization, you need to update your e-mail address policies to assign these domain names to your recipients. To learn more about e-mail address policies, see Understanding E-Mail Address Policies.

Accepted Domains on Edge Transport Servers

You need to configure your accepted domains on each Edge Transport server you deploy. However, we recommend that you configure accepted domains only on the Hub Transport

server role, and then create an Edge Subscription for the Edge Transport server. The accepted domain configuration will be replicated to the Edge Transport servers when the Microsoft Exchange EdgeSync service runs. For more information, see Understanding Edge Subscriptions.

Configure Internet Mail Flow

After you install your first Hub Transport server, you must create additional connectors to begin sending and receiving messages from the Internet. The following connectors are created when you install your first Hub Transport server:

- **Intra-organization Send connector** This implicit Send connector isn't visible in the management tools and is computed based on your Active Directory site topology. This Send connector enables your Hub Transport servers to communicate with each other. For more information about internal message routing, see Understanding Message Routing.
- **Receive connector configured to accept messages from all remote IP addresses through port 25** This connector typically accepts connections from all IP address ranges. The usage type for this connector is Internal. This connector only accepts mail from other Exchange servers that are part of the same Exchange organization. By default, this connector doesn't accept anonymous submissions.
- **Receive connector configured to receive messages from all remote IP addresses through port 587** This connector is used to accept SMTP connections from POP3 or IMAP4 clients. This connector typically accepts connections from all IP address ranges. The usage type for this connector is Internal.

When you install an Edge Transport server, only the following connector is created during setup:

- **Receive connector configured to receive messages from all remote IP addresses through port 25** This connector is used for both incoming Internet e-mail and incoming e-mail from the Hub Transport servers. The permissions on the connector are automatically determined by how sessions are authenticated.

To learn more about connectors, see Understanding Send Connectors and Understanding Receive Connectors.

After a default installation:

- Your Hub Transport servers can communicate with each other.
- Your Hub Transport servers can receive message submissions from your Mailbox servers and non-MAPI clients (such as POP3 or IMAP4).
- Your Edge Transport server can receive messages from the Internet and your Hub Transport servers.

To complete deployment, you need to:

- Configure your Hub Transport servers to forward Internet messages to your Edge Transport servers.
- Configure your Edge Transport servers to send Internet messages to the Internet.
- Configure your Edge Transport servers to forward inbound messages to your Hub Transport servers.

You have two options to accomplish the additional tasks. For best results, we recommend that you subscribe your Edge Transport servers to your organization. The options are described in the following topics:

- Configure Internet Mail Flow Through a Subscribed Edge Transport Server
- Configure Mail Flow Between an Edge Transport Server and Hub Transport

Servers Without Using EdgeSync

If you don't use Edge Transport servers in your organization, you have two options for configuring Internet mail flow. Keep in mind that configuring Internet mail flow directly through your Hub Transport servers isn't recommended. The options are described in the following topics:

- Configure Internet Mail Flow Through Exchange Hosted Services or an External SMTP Gateway
- Configure Internet Mail Flow Directly Through a Hub Transport Server

1.2.2.10 Modify an Exchange 2010 Installation

Modify an Exchange 2010 Installation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-20*

The following topics provides information about modifying an installation of Microsoft Exchange Server 2010:

Modify or Remove Exchange 2010

Remove the Last Legacy Exchange Server from an Exchange 2010 Organization

Install an Exchange 2010 Language Pack

1.2.2.10.1 Modify or Remove Exchange 2010

Modify or Remove Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-03*

This topic explains how to use the Exchange Server 2010 Setup wizard to modify or remove Exchange 2010.

Prerequisite

You must ensure that each of the server roles meets the appropriate prerequisites and system requirements before you begin the modification or uninstall process. For more information about server roles, see Overview of Exchange 2010 Server Roles. To understand the prerequisites for all server roles, see Exchange 2010 Prerequisites. For more information about system requirements, see Exchange 2010 System Requirements.

Modify or Remove Exchange Server 2010

You can either run Exchange 2010 Setup.exe or navigate to Control Panel to modify or remove Exchange 2010 (either server roles or an entire installation).

1. The **Maintenance Mode** page of the Exchange Server 2010 Setup wizard begins the process of changing or removing your Exchange installation. Click **Next** to continue.

2. On the **Server Role Selection** page, select the Exchange server roles that you want to add (if you're changing an installation) or remove (if you're removing one or more server roles or an entire installation). Click **Next** to continue.

3. On the **Readiness Checks** page, view the status to determine if the organization and server role prerequisite checks completed successfully. If the prerequisites check doesn't complete successfully, review the **Summary** page to help troubleshoot and fix any issues that are preventing Setup from completing. If the checks have completed successfully, click **Install** if you want to add a server role or **Uninstall** to remove the specified server role(s) or the entire installation of Exchange 2010.

4. On the **Completion** page, click **Finish**.

1.2.2.10.2 Remove the Last Legacy Exchange Server from an Exchange 2010 Organization

Remove the Last Legacy Exchange Server from an Exchange 2010 Organization

Planning and Deployment > Deploying Exchange 2010 > Modify an Exchange 2010 Installation >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove the last computer running Microsoft Exchange Server 2007 or Exchange Server 2003 from an organization that also has Exchange Server 2010 servers. First, you prepare your Exchange organization for removal of the last Exchange 2007 or Exchange 2003 server. Next, you remove the last Exchange 2007 or Exchange 2003 server. To successfully remove the Exchange 2007 or Exchange 2003 server from your organization, you must complete both steps.

Looking for other management tasks related to installing Exchange 2010? Check out Managing Deployment of Exchange 2010.

Remove the last Exchange 2003 server

Removal of the last Exchange 2003 server requires that you satisfy some prerequisites and then complete a two-step process.

Prerequisites for removing the last Exchange 2003 server

- You installed one or more Exchange 2010 servers in the organization.
- If you're removing the last Exchange 2003 server, confirm that you don't plan to use any of the Exchange 2003 features that have been removed in Exchange 2010. The following are some of the features that aren't supported in Exchange 2010:
  - Novell GroupWise connector

- Network News Transfer Protocol (NNTP)
- Routing groups
- Lotus Notes connector

For a complete list of the features discontinued in Exchange 2010, see Discontinued Features.

Step 1: Prepare the Exchange 2003 organization to remove legacy Exchange servers

To perform the following procedure, the account you use must be delegated membership in the Exchange Full Administrator role on Exchange 2003 servers.

1. Move all mailboxes to an Exchange 2010 server in the organization. For more information, see Create a Local Move Request.
2. Move all content from the public folder database on the legacy Exchange 2003 server to a public folder database on an Exchange 2010 server in the organization. For detailed steps, see Move Public Folder Content from One Public Folder Database to Another Public Folder Database.
3. On Exchange 2003 servers, for each offline address book (OAB), move the generation process to an Exchange 2010 server. For detailed steps, see Move the Offline Address Book Generation Process to Another Server.
4. To remove the public folder mailbox and stores on the Exchange 2003 server, see How to Dismount and Delete the Mailbox and Public Folder Stores.
5. Verify that Internet mail flow is configured to route through your Exchange 2010 transport servers. For more information, see the following topics:
   - Configure Internet Mail Flow Directly Through a Hub Transport Server
   - Configure Internet Mail Flow Through a Subscribed Edge Transport Server
6. To verify that all inbound protocol services (Microsoft Exchange ActiveSync, Microsoft Office Outlook Web App, Outlook Anywhere, POP3, IMAP4, Autodiscover service, and any other Exchange Web service) are configured for Exchange 2010, see Managing Client Access Servers.
7. Delete the routing group connectors that connect the Exchange 2003 routing groups. You can do this from Exchange 2003 System Manager, or you can use the Remove-RoutingGroupConnector cmdlet in the Exchange Management Shell.
8. If you have Exchange 2003 recipient policies that are only Mailbox Manager policies and don't define e-mail addresses (they don't have an **E-mail Addresses (Policy)** tab), perform the following steps to delete the policies:
   - In Exchange System Manager, expand **Recipients**, and then select **Recipient Policies**.
   - To verify that a policy is only a Mailbox Manager policy, right-click the policy, and then select **Properties**. The **Properties** page must not have an **E-Mail Addresses (Policy)** tab.
   - To delete the policy, right-click the policy, and then select **Delete**. Click **OK**, and then click **Yes**.
9. If you have Exchange 2003 policies that are both E-mail Addresses and Mailbox Manager policies (they have both the **Mailbox Manager Settings (Policy)** tab and the **E-mail Addresses (Policy)** tab), perform the following steps to remove the mailbox manager portion of the policy:
   - In Exchange System Manager, expand **Recipients**, and then select **Recipient Policies**.
   - Right-click the policy, and then select **Change property pages**.
   - Clear the **Mailbox Manager Settings** check box, and then click **OK**.

Note:

Don't delete any e-mail address recipient policies that have e-mail addresses that you still want defined in your organization. Exchange 2010 will use those policies when provisioning new recipients.

Step 2: Remove the last Exchange 2003 server from an

Exchange 2010 organization

To perform the following procedure, the account you use must be delegated membership in the Exchange Full Administrator role on Exchange 2003 servers.

1. Perform the following steps to delete the domain Recipient Update Service:
   1.a. In Exchange 2003 System Manager, expand **Recipients**, and then select **Recipient Update Service**.
   1.b. Right-click each domain Recipient Update Service, and then select **Delete**.
   1.c. Click **Yes**.
2. You won't be able to delete the Enterprise **Recipient Update Service** by using Exchange 2003 System Manager. Instead, perform the following steps to delete the **Recipient Update Service** by using Active Directory Service Interfaces Editor (ADSI Edit or AdsiEdit.msc). AdsiEdit.msc is included on the Windows Server 2003 CD in Support\Tools. For more information about ADSI Edit, see ADSI Edit (adsiedit.msc).
   2.a. In ADSI Edit, navigate to **Configuration** > **CN=Configuration,CN=**<*domain*> > **CN=Services** > **CN=Microsoft Exchange** > **CN=**<*Exchange organization name*> > **CN=Address Lists Container** > **CN=Recipient Update Services**.
   2.b. In the result pane, right-click **Recipient Update Service (Enterprise Configuration)**, click **Delete**, and then click **Yes** to confirm the deletion.
3. Uninstall Exchange 2003 by using **Add or Remove Programs** from **Control Panel**. For more information, see How to Uninstall Exchange Server 2003.

   Caution:

   Before you remove any Exchange 2003 administrative groups that contained mailboxes, verify that the public folder hierarchy has been moved to another administrative group. Also, verify that the Free/Busy public folder has replicated to the servers in other administrative groups.
   The general process to create public folder replicas on servers in other administrative groups is to update the replica list for each public folder to specify the destination server. After you allow sufficient time for the data to be replicated to the destination server, verify that the public folder database is empty. To do this, use the Exchange System Manager **Public Folder Instances** node or use the **Get-PublicFolderStatistics** cmdlet. If the results are blank, the public folder database is empty. When you remove the public folder database, you may be prompted to select another public folder database to act as the site folder for administrative groups and OABs. You may also be prompted to select another public folder database to act as the default public folder database for some messaging databases. For these prompts, the site folder server represents the public folder database responsible for making sure that administrative group and OAB site folders exist. The site folder server may be any public folder database server in the organization. The site folder server doesn't delete site folders for missing administrative groups. However, the site folder server does remove site folders for missing OABs.

4. After the last Exchange 2003 server has been removed from the Exchange 2010 organization, you can also remove the legacy Exchange Domain Servers and Exchange Enterprise Servers security groups. For more information, see Delete a group.

   Caution:

   Before you delete either of these security groups, verify that each group is empty and isn't being used for any other purpose or process. If one or both of these groups has members, but if all members are shown as security identifiers (SIDs), the groups can be safely removed. If at least one group has members, and if the members are resolved to computer names, you should verify that the computers aren't functioning Exchange servers before you delete the groups.

Remove the last Exchange 2007 server

Removal of the last Exchange 2007 server requires that you satisfy some prerequisites and then complete a two-step process.

Prerequisites for removing the last Exchange 2007 server

- You installed one or more Exchange 2010 servers in the organization.
- If you're removing the last Exchange 2007 server, confirm that you don't plan to use any of the Exchange 2007 features that have been removed in Exchange 2010. The following are some of the features that aren't supported in Exchange 2010:
  - Storage groups
  - DSProxy
  - Cluster continuous replication
  - Single copy cluster

For a complete list of the Exchange 2007 features discontinued in Exchange 2010, see Discontinued Features.

Step 1: Prepare the Exchange 2007 organization to remove legacy Exchange servers

To perform the following procedure, the account you use must be delegated membership in the Exchange Organization Administrator role on Exchange 2007 servers.

1. Move all mailboxes to an Exchange 2010 server in the organization. For more information, see Create a Local Move Request.
2. Move all content from the public folder database on the legacy Exchange 2007 server to a public folder database on an Exchange 2010 server in the organization. For detailed steps, see Move Public Folder Content from One Public Folder Database to Another Public Folder Database.
3. On Exchange 2007 servers, for each offline address book (OAB), move the generation process to an Exchange 2010 server. For detailed steps, see Move the Offline Address Book Generation Process to Another Server.
4. To remove the public folder mailbox and stores on the Exchange 2007 server, see the following topics:
   - How to Remove a Public Folder Database
   - How to Remove a Mailbox Database
5. Verify that Internet mail flow is configured to route through your Exchange 2010 transport servers. For more information, see the following topics:
   - Configure Internet Mail Flow Directly Through a Hub Transport Server
   - Configure Internet Mail Flow Through a Subscribed Edge Transport Server
6. To verify that all inbound protocol services (Microsoft Exchange ActiveSync, Microsoft Office Outlook Web App, Outlook Anywhere, POP3, IMAP4, Autodiscover service, and any other Exchange Web service) are configured for Exchange 2010, see Managing Client Access Servers.

Step 2: Remove the last Exchange 2007 server from an Exchange 2010 organization

Uninstall Exchange 2007 by using **Add or Remove Programs** from **Control Panel**. For more information, see the following topics:

- How to Completely Remove Exchange 2007 from a Server
- How to Remove an Exchange 2007 Organization

Install an Exchange 2010 Language Pack

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-14*

You can use the Microsoft Exchange 2010 Language Pack wizard to install a language pack on your Microsoft Exchange Server 2010 server. An Exchange 2010 language pack contains the necessary resources for a supported Exchange language. Client and server language packs are grouped into a single bundle containing both client and server resource and support files. For more information about language packs, see Exchange 2010 Language Support.

Install the Exchange 2010 language pack

1. Download the language pack. For Exchange 2010 Service Pack 1 (SP1), download the latest language pack from Microsoft Exchange 2010 SP1 Language Pack Bundle.
2. Double-click the language pack file that you downloaded to start language pack setup.
3. On the **License Agreement** page, review the software license terms. If you agree to the terms, select **I accept the terms in the license agreement**, and then click **Next**.
4. On the **Readiness Checks** page, view the status to determine if the prerequisite checks completed successfully. If they haven't completed successfully, you must resolve any reported errors before you can install the language pack. You don't need to exit Setup when resolving some of the prerequisite errors. After resolving a reported error, click **Retry** to run the prerequisite check. Be sure to also review any warnings reported. If all readiness checks have completed successfully, click **Install** to install the language pack.
5. On the **Completion** page, click **Finish**.

Use unattended setup to install the Exchange 2010 language pack

1. Download the language pack. For Exchange 2010 SP1, download the latest language pack from Microsoft Exchange 2010 SP1 Language Pack Bundle.
2. Insert the Exchange 2010 SP1 DVD into the DVD drive. At the command prompt, navigate to the DVD drive or navigate to the network location of the Exchange 2010 installation files.
3. At a command prompt, run the following command. Include the path to the location where you saved the language pack and the filename of the language pack. For example, C:\Exchange\LanguagePackBundle.exe.

```
Setup.com /LanguagePack:<path to language pack bundle>
```

1.2.2.11 Installation Guide Templates

Installation Guide Templates

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-02*

This section provides the following document templates you can use to create customized installation guides for your organization's Microsoft Exchange Server 2010 server role installations:

Installation Guide Template - Client Access Server

Installation Guide Template - Hub Transport Server

Installation Guide Template - Mailbox Server

Installation Guide Template - DAG Member

You can use the Exchange 2010 templates as a starting point for formalizing your server build procedures. These guides are generic, so you'll need to modify them to meet the specific needs of your organization. Also, you can download these templates as a download package in .zip file format at Microsoft Exchange Server 2010 Install Guide Templates (http://go.microsoft.com/fwlink/?LinkID=187961).

We recommend that every procedure described in the guides that you perform be tested and validated in a lab environment before you use the procedure in a production environment.

1.2.2.11.1 Installation Guide Template - Client Access Server

Installation Guide Template - Client Access Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-21*

This topic provides you with an installation guide template that you can use as a starting point for formally documenting your organization's server build procedures for Microsoft Exchange Server 2010 servers that will have the Client Access server role installed.

The template includes the following key sections:

- Executive Summary
- Server Configuration
- Load Balancing Configuration
- Verification Steps
- Exchange Server Role Installation
- Exchange Server Role Configuration

For purposes of providing an example, the template uses the fictitious company name of Contoso. Also, you can download this template, along with templates for other server roles, as a download package in .zip file format at Microsoft Exchange Server 2010 Install

Guide Templates (http://go.microsoft.com/fwlink/?LinkID=187961).

Executive Summary

The purpose of this document is to explain the installation and configurations necessary to install the Exchange 2010 Client Access server role on the Windows Server 2008 platform.

Business Justification

By having an installation guide, Contoso will be able to ensure standardization across the enterprise, reducing total cost of ownership (TCO), and easing troubleshooting steps.

Scope

The scope of this document is limited to installation of an Exchange 2010 Client Access server for Contoso on the x64 version of the Windows Server 2008 (SP2 or R2) operating system.

Prerequisites

The administrator should have working knowledge of Windows Server 2008 concepts, Exchange 2010 concepts, the Exchange Management Console and Exchange Management Shell, the command line, and various system utilities. This document does not elaborate on the details of any system utility except as necessary to complete the tasks within.

In addition, before implementing the server role, the administrator should review the Understanding Client Access topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187352).

Assumptions

This document assumes that Windows Server 2008 x64 Edition is installed on the intended Client Access server per company baseline regulations which include the latest approved service pack and hotfixes. In addition, the following system prerequisites have been installed:

- Microsoft .NET Framework 3.5 SP1 and the update for .NET Framework 3.5 SP1 For more information, see Microsoft Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available (http://go.microsoft.com/fwlink/?linkid=3052&kbid=959209).
- Windows Management Framework (Windows Remote Management 2.0 and Windows PowerShell 2.0).

This document assumes that forest and domain preparation steps have been performed as described in the Prepare Active Directory and Domains topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187262).

This document assumes that the account you will be using for the Exchange tasks has been delegated the Server Management management role, as described in the Server Management topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187265).

This document also assumes that both Exchange 2010 Windows Server 2008 and Windows Server 2008 will be secured following the best practices found in the Windows Server 2008 Security Guide (http://go.microsoft.com/fwlink/?LinkId=122593).

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Server Configuration

The following media are required for this section:

- Windows Server 2008 installation files

The following procedures are in this section:

1. Additional Software Verification
2. Network Interfaces Configuration
3. Drive Configuration
4. Windows Server 2008 Hotfix Installation
5. Domain Membership Configuration
6. Local Administrators Verification
7. Local Administrator Account Password Reset
8. Debugging Tools Installation
9. Page File Modifications
10. Drive Permissions
11. Windows Network Load Balancing Installation and Configuration
12. DNS Entry Creation

Additional Software Verification

1. Verify that Remote Desktop is enabled.
2. As an optional process, install Microsoft Network Monitor (http://go.microsoft.com/fwlink/?LinkId=86611).

Network Interfaces Configuration

1. Log on to the server with an account that has been delegated at least local administrative access.
2. Click **Start > Control Panel**, and then double-click **Network and Sharing Center**.
3. Click **Manage Network Connections**.
4. Locate the connection for the internal network and rename it according to your organization's naming standards.
5. Right-click the connection and then select **Properties**.
6. For Internet Protocol Version 4 (TCP/IPv4), add the following:
   6.a. **Static IP Address**, **Subnet Mask**, and **Gateway**
   6.b. DNS Server IP Addresses
   6.c. Select the check box to **Append parent suffixes of the primary DNS suffix**.
   6.d. WINS IP Addresses (if using WINS)
7. If you are using Internet Protocol Version 6 (TCP/IPv6), configure the IPv6 settings according to your organization's network standards.

Drive Configuration

1. Connect to the server through Remote Desktop and then log on with an account that has been delegated local administrative access.
2. Click **Start > Administrative Tools**, and then select **Computer Management**.
3. Expand **Storage** and then click **Disk Management**.
4. Using the Disk Management snap-in of the Microsoft Management Console (MMC), format, rename, and assign the appropriate **Drive Letters** so that the volumes and DVD drive match the appropriate server configuration.

Drive configuration

LUN	Drive letter	Usage
1	C	Operating system and Exchange binaries
2	Z	DVD drive

Windows Server 2008 Hotfix Installation

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Obtain the latest hotfixes approved by your company for your version of Windows Server 2008 x64 (SP2 or R2) and copy them to the server.
3. Launch the hotfix setup via one of two ways:
   3.a. Double-click the file and follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
<hotfix>.msu /quiet /norestart
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

> **Note:**
> These dialog boxes will not appear in environments that have not deployed the Windows Security templates.

5. Wait for all file copies to complete, and then restart the server. You can use the **Processes** tab in Windows Task Manager to monitor the hotfix installation progress. When the wusa.exe process has exited, the hotfix installation is complete.

Domain Membership Configuration

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start,** right-click **My Computer**, and then select **Properties**.
3. Under the **Computer Name, domain, and workgroup** settings, click **Change Settings**.
4. Click **Change**.
5. Choose the **Domain** option button, and then enter the appropriate domain name.
6. Enter the appropriate credentials.
7. Click **OK** and **OK**.
8. Click **OK** to close **System Properties**.
9. Restart the server.

Local Administrators Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Verify (or add if not already there) that the Domain Admins account and the user account that will perform the Exchange installation are members of the local Administrators group on this server.
3. Verify that your user account is a member of a group which is a member of the local Administrators group on the Windows Server 2008 server. If it is not, use an account that is a member of the local Administrators group before continuing.

Local Administrator Account Password Reset

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Manage**.
3. Expand the nodes to find **Configuration\Local Users and Groups\Users**.
4. Right-click **Administrator**, and then select **Set Password**. Change the password so that it meets strong complexity requirements.

Debugging Tools Installation

This section describes several useful tools that aid administrators in Exchange administration and in troubleshooting support issues.

Debugging Tools for Windows allow administrators to debug processes that are affecting service and determine root cause.

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Download and install the latest 64-bit Debugging Tools from Install Debugging Tools for Windows 64-bit Version (http://go.microsoft.com/fwlink/?LinkID=123594).

Page File Modifications

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Startup and Recovery**, click **Settings**.
   4.a. Under **Write Debugging Information**, select **Kernel Memory Dump** from the memory dump drop-down list.
   4.b. Click **OK**.
5. Under **Performance**, click **Settings**.
6. Click the **Advanced** tab.
7. Under **Virtual Memory**, click **Change**.
8. On servers that have a dedicated page file drive, follow these steps:
   8.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   8.b. For the C: drive, set the **Initial Size (MB)** value to a minimum of 200 MB. (Windows requires between 150 MB and 2 GB page file space, depending on server load and the amount of physical RAM that is available for page file space on the boot volume when Windows is configured for a kernel memory dump. Therefore, you may be required to increase the size.)
   8.c. For the C: drive, set the **Maximum Size (MB)** value to that of the **Initial Size**.
   8.d. In the **Drive** list, select the page file drive (for example, the P: drive), and then click **Custom size**.
   8.e. In the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   8.f. In the **Maximum Size (MB)** box, type the same amount that you typed in the **Initial Size** box.
   8.g. Delete all other page files.
   8.h. Click **OK**.
9. On servers that do not have a dedicated page file drive, follow these steps:
   9.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   9.b. For the C: drive, in the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   9.c. Delete all other page files.
   9.d. Click **OK**.
10. Click **OK** two times to close the **System Properties** dialog box.
11. Click **No** if prompted to restart the system.

Note:

For more information about page file recommendations, see the following Microsoft Knowledge Base articles: How to determine the appropriate page file size for 64-bit versions of Windows Server 2003 or Windows XP (http://go.microsoft.com/fwlink/?linkid=3052&kbid=889654); and Overview of

memory dump file options for Windows Vista, Windows Server 2008 R2, Windows Server 2008, Windows Server 2003, Windows XP, and Windows 2000 (http://go.microsoft.com/fwlink/?linkid=3052&kbid=254649).

Drive Permissions

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, and then select **Computer**.
3. Right-click **D Drive**, and then select **Properties**.
4. Click the **Security** tab.
5. Click **Edit**.
6. Click **Add**, and then select the local server from **Locations**.
7. Grant the following rights as outlined in the following table.

Drive permissions

Account	Permissions
Administrators	Full Control
SYSTEM	Full Control
Authenticated Users	Read and Execute, List, Read
CREATOR OWNER	Full Control

8. Click the **Advanced** button.
9. Select the **CREATOR OWNER** permission entry, and then click **View/Edit**.
10. Select **Subfolders and Files Only** from the drop-down list.
11. Click **OK** two times.
12. Click **OK** to close the drive properties.
13. Repeat steps 3-12 for each additional drive (other than the C drive).

Load Balancing Configuration

Procedures in this section only need to be performed on Client Access servers that will be used in a load-balanced array. In particular, this section focuses on Windows Network Load Balancing (NLB). For more information about NLB, see Network Load Balancing (http://go.microsoft.com/fwlink/?LinkId=187482) and Network Load Balancing Clusters (http://go.microsoft.com/fwlink/?LinkId=49315) and Implementing a Network Load Balancing Cluster (http://go.microsoft.com/fwlink/?LinkId=187483).

If you are deploying a hardware load balancing array, review your vendor's documentation and follow their guidance for configuration.

For more information about load balancing in Exchange 2010, see the topics Understanding Load Balancing in Exchange 2010 (http://go.microsoft.com/fwlink/?LinkId=196447) and Load Balancing Requirements of Exchange Protocols (http://go.microsoft.com/fwlink/?LinkId=196448) in the Exchange Server 2010 Library.

Windows Network Load Balancing Installation and Configuration

The values used in NLB must be the same across all nodes in the NLB cluster. The values specified in the following table will ensure that the Windows Network Load Balancing array can load-balance the appropriate protocols (HTTPS, IMAP4, POP3, RPC Endpoint Mapper, the Address Book service, and the RPC Client Access service). For more information, see Understanding Load Balancing in Exchange 2010.

Load-balanced protocols and ports

Protocol	TCP port numbers
HTTPS	443

IMAP4	143 and 993
POP3	110 and 995
RPC Endpoint Mapper	135
Address Book service	59595
RPC Client Access service	59596

Note:
This document uses TCP59595 for the Address Book service and TCP59596 for the RPC Client Access service, but you can use any TCP high ports that are available within the environment between ports 59530 and 60554.

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Install Network Load Balancing for your operating system:
   2.a. **Windows Server 2008 SP2** Open an administrative command prompt window and run the following command:

```
ServerManagerCmd.exe -i NLB
```

   2.b. **Windows Server 2008 R2** Open an elevated Windows PowerShell console, and run the following commands:

```
Import-Module ServerManager
Add-WindowsFeature NLB
```

3. Click **Start > Administrative Tools**, and then right-click **Network Load Balancing Manager**.
4. Click **Cluster-New**.
5. In the **New Cluster wizard**, enter the local server's computer name, click **Connect** and then select the appropriate network connection.
6. Click **Next**.
7. In the **Host Parameters** section, verify the host's IP address and subnet mask.
8. Click **Next**.
9. In the **Cluster IP Address** section, click **Add** and enter:
   9.a. **IP Address**
   9.b. **Subnet Mask**
10. Click **Next**.
11. In the **Cluster Parameters** section, enter in the **Full Internet Name** (for example, mail.contoso.com) that will be used by the cluster and make sure **Unicast** is selected.
12. Click **Next**.
13. In the **Port Rules** section, select the default rule and click **Edit**.
14. Under **Port Range**, change the **From** value to **80** and the **To** value to **80**.
15. Under **Protocols**, select **TCP**.
16. Click **OK**.
17. Click **Add** to create a new port rule.
    17.a. Under **Port Range**, change the **From** value to **443** and the **To** value to **443**.
    17.b. Under Protocols, select **TCP**.
    17.c. Click **OK**.

Note:
If you are using IMAP or POP in the environment, be sure to create the appropriate rules.

18. Click **Add** to create a new port rule.
    18.a. Under **Port Range**, change the **From** value to **143** and the **To** value to

143.
18.b.Under **Protocols**, select **TCP**.
18.c.Click **OK**.
19.Click **Add** to create a new port rule.
19.a.Under **Port Range**, change the **From** value to **110** and the **To** value to **110**.
19.b.Under **Protocols**, select **TCP**.
19.c.Click **OK**.
20.Click **Add** to create a new port rule.
20.a.Under **Port Range**, change the **From** value to **993** and the **To** value to **993**.
20.b.Under **Protocols**, select **TCP**.
20.c.Click **OK**.
21.Click **Add** to create a new port rule.
21.a.Under **Port Range**, change the **From** value to **500** and the **To** value to **500**.
21.b.Under **Protocols**, select **UDP**.
21.c.Click **OK**.

Note:
The above rule for UDP 500 should be created if you are using IPSec in the environment.

22.Click **Add** to create a new port rule.
22.a.Under **Port Range**, change the **From** value to **995** and the **To** value to **995**.
22.b.Under **Protocols**, select **TCP**.
22.c.Click **OK**.
23.Click **Add** to create a new port rule.
23.a.Under **Port Range**, change the **From** value to **135** and the **To** value to **135**.
23.b.Under **Protocols**, select **TCP**.
23.c.Click **OK**.
24.Click **Add** to create a new port rule.
24.a.Under **Port Range**, change the **From** value to **59595** and the **To** value to **59596**.
24.b.Under **Protocols**, select **TCP**.
24.c.Click **OK**.
25.Click **OK**.
26.Click **OK** to acknowledge the resulting dialog box.
27.While still in the internal network connection properties, click **Internet Protocol (TCP/IP)** and select **Properties**.
28.Click **Advanced**.
29.Under **IP Addresses**, click **Add**.
29.a.Enter the **virtual IP Address** and **Subnet Mask** and click **OK**.
29.b.Click **OK**.
30.Click **Finish** to complete the New Cluster wizard.

DNS Entry Creation

Submit a change request to the appropriate operations group to have the domain name that was specified in the previous "Network Load Balancing Installation and Configuration" section for the NLB cluster (for example, mail.contoso.com) created as a host record associated to the NLB cluster's IP address.

Verification Steps

The following procedures are in this section:

1.Organizational Unit Verification
2.Active Directory Site Verification
3.Domain Controller Diagnostics Verification

4. Exchange Best Practices Analyzer Verification

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Organizational Unit Verification

Submit a change request to the appropriate operations group and have the computer object moved to the appropriate organizational unit (OU).

Active Directory Site Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window.
3. Verify that the server is in the correct domain and Active Directory site. At the command line, type the following:

```
NLTEST /server:%COMPUTERNAME% /dsgetsite
```

4. The name of the Active Directory site to which the server belongs will be displayed. If the server is not in the correct Active Directory site, submit a change request to the appropriate operations group and have the server moved to the appropriate Active Directory site.

Domain Controller Diagnostics Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window, and then change paths to the C drive.
3. Run the following command:

```
dcdiag /s:<Domain Controller> /f:c:\dcdiag.log
```

Note:
Change **<domain Controller>** to a domain controller contained within the same Active Directory site as the Exchange server.

4. Review the output of **C:\dcdiag.log** file, and verify that there are no connectivity issues with the local domain controller.
5. Repeat steps 3 and 4 for each domain controller in the local Active Directory site.

Note:
Domain Controller Diagnostics (DCDiag) is a Windows support tool that tests network connectivity and DNS resolution for domain controllers. If the account being used does not have administrative privileges, several tests under the **Doing primary tests** heading may not pass. These tests can be ignored if the connectivity tests pass. In addition, the log file may report that some service validation tests did not pass. These messages can be ignored if the services do not exist on the domain controller.

Exchange Best Practices Analyzer Verification

The Microsoft Exchange Analyzers help administrators troubleshoot various operational support issues. Connect to a server in the environment that either has the Exchange 2010 SP1 (or later) Management tools installed through Remote Desktop and log on with an account that has local administrative access.

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010** and then select **Exchange Management Console**.
2. Open the **Toolbox** node.
3. Double-click **Best Practices Analyzer**.
4. Check and apply any updates for the Best Practices Analyzer engine.
5. Provide the appropriate information to connect to Active Directory and then click **Connect to the Active Directory server**.
6. In **Start a New Best Practices Scan**, select **Health Check**, and then click

Start Scanning.

7. Review the report, and take action on any errors or warnings that are reported by following the resolution articles that are provided within the Best Practices Analyzer.

Exchange Server Role Installation

The following media are required for this section:

- Microsoft Exchange Server 2010 installation files

The following procedures are in this section:

1. Exchange 2010 Prerequisites Installation for:
   - Windows Server 2008 SP2

     -or-
   - Windows Server 2008 R2
2. Exchange 2010 Installation
3. Exchange 2010 Update Rollup Installation
4. Product Key Configuration
5. System Performance Verification

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Exchange 2010 Prerequisites Installation for Windows Server 2008 SP2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open an elevated command prompt, navigate to the \Setup\ServerRoles \Common folder on the Exchange 2010 installation media, and then use the following commands to configure the Net.Tcp Port Sharing Service for automatic startup and to install the necessary operating system components:

```
sc config NetTcpPortSharing start= auto
ServerManagerCmd -ip Exchange-CAS.xml -Restart
```

Exchange 2010 Prerequisites Installation for Windows Server 2008 R2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. On the Start Menu, navigate to **All Programs** > **Accessories** > **Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following commands:

```
Import-Module ServerManager
Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Basic-Auth,W
```

3. After the system has restarted, log on as an administrator, open an elevated Windows PowerShell console, and configure the Net.Tcp Port Sharing Service for automatic startup by running the following command:

```
Set-Service NetTcpPortSharing -StartupType Automatic
```

Exchange 2010 Installation

This document uses the command-line method for installing the Exchange 2010 server roles; however, you can also use a GUI called the Setup Wizard. For more information about how to use the Setup Wizard to install an Exchange 2010 server role, see the Perform a Custom Exchange 2010 Installation topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187220).

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access. If the Exchange server

has been provisioned for delegated setup, the account must be delegated the Delegated Setup management role (or higher).
2. Follow the procedure detailed in the Install Exchange 2010 in Unattended Mode topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187229). For example, this command installs the Client Access server role:

```
setup.com /r:C
```

3. If this is the first Exchange 2010 server role being installed into an environment that does not contain any version of Microsoft Exchange, you must also specify the */OrganizationName* setup parameter. Do not restart the server, even if required.
4. To prevent the use of the server role before it is fully configured, open an administrative command prompt and stop the IIS services by running the following command:

```
net stop iisadmin /y
```

Exchange Server 2010 Update Rollup Installation

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Obtain the latest company approved rollup, and then copy it to the server.
3. Launch the Windows Installer patch (the MSP file) setup via one of two ways:
   3.a. Double-click the MSP file, and then follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
msiexec /i <Path and filename of MSP file> /q
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

Note:
These dialog boxes will appear only in environments that have deployed the Windows Security templates.

Product Key Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Follow the procedure documented in the Enter Product Key topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187234).

System Performance Verification

By default, Exchange 2010 optimizes the server's processor scheduling management for background services.

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Performance**, click **Settings**.
   4.a. Click the **Advanced** tab.
   4.b. Verify that **Processor Scheduling** is set to **Background Services**.
5. Click **OK**.

Exchange Server Role Configuration

The following procedures are in this section:

1. Commercial Certificate Configuration
2. RPC Client Access Array Configuration
3. RPC Client Access and Address Book Services Configuration

4. Autodiscover Configuration
5. Outlook Anywhere Configuration
6. Offline Address Book Configuration
7. IMAP4 Configuration
8. POP3 Configuration
9. Outlook Web App Configuration (Internet Scenario) or Outlook Web App Configuration (Proxy Scenario)
10. Legacy ActiveSync Configuration
11. Handoff Test

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Commercial Certificate Configuration

A commercial certificate is only needed if the Client Access server will service client requests from the Internet, or if you need to facilitate un-trusted cross-forest communication between Client Access servers.

Note:

For more information about using the certificate tasks, see the Understanding TLS Certificates topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187237).

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

   Note:

   If generating a certificate that will use Subject Alternative Names, be sure that the certificate's principal name will be the one that the clients will use to connect (for example, mail.contoso.com). Do not list the Autodiscover namespace as the principal name in the certificate.

2. Generate the certificate request by using the following Exchange Management Shell command. The *DomainName* parameter includes the principal URL and the Autodiscover FQDN; be sure to define other FQDNs that clients may utilize. The *FriendlyName* parameter matches the principal URL that is used by Microsoft Office Outlook Web App and Outlook Anywhere.

   ```
   $Data = New-ExchangeCertificate -GenerateRequest -SubjectName [Full Su
   Set-Content -Path "c:\cert.req" -Value $Data.FileData -Encoding Byte
   ```

   An example of [Full Subject Path] is "c=US, o=Company, cn=CAS01.contoso.com".

   Note:

   The Windows RPC/HTTP client-side component in Windows Vista requires that the Subject Name (Common Name) on the certificate match the "Certificate Principal Name" configured for the Outlook Anywhere connection in the Outlook profile. This behavior was changed in Windows Vista Service Pack 1 (SP1). Therefore, as a best practice, make sure that mail.contoso.com is listed as the Subject Name in your certificate unless you plan to change the configuration. You can use the **Set-OutlookProvider** cmdlet to change the configuration. For more information about how to change the configuration, see the Exchange Team Blog article, When, if and how do you modify Outlook Providers? (http://go.microsoft.com/fwlink/?LinkId=160947)

3. Submit the request file to the Certificate Authority (CA) and have the CA generate the certificate.
4. After receiving the certificate, import and enable the certificate by running the following Exchange Management Shell command where [services] can be POP, IMAP, IIS, or a combination:

   ```
   Import-ExchangeCertificate -FileData ([Byte[]]$(Get-Content -Path C:\N
   ```

5. To mandate SSL on the default Web site, do the following:
   5.a. Open **Internet Information Services (IIS) Manager**.

5.b.Expand the **Server Node** object and the **Sites** node.
5.c.Click the **Default Web Site**.
5.d.In the middle pane, double-click **SSL Settings**.
5.e.Verify **Require secure channel (SSL)** is enabled.

Note:
If you require 128-bit encryption, also verify that **Require 128-bit encryption** is enabled.

RPC Client Access Array Configuration

If this is the first Client Access server being installed in the Active Directory site, and the Client Access server infrastructure will participate in a load-balanced array, then you also need to create the RPC Client Access array object. The fully-qualified domain name (FQDN) you specify for the RPC Client Access array should map to the FQDN or virtual IP address that is used for the load-balanced array that was previously created.

Note:
If the RPC Client Access array object already exists for this Active Directory site, you can skip this section.

- Launch the Exchange Management Shell with an account that has been delegated the Server Management role and then run the following command:

```
New-ClientAccessArray -Fqdn <FQDN of CAS load balanced array> -Site <Ac
```

RPC Client Access and Address Book Services Configuration

If the Client Access server is configured to participate in a load-balanced array, follow these steps to configure the RPC Client Access and Address Book services to use a specific TCP port for client connections. The procedure uses TCP59595 and TCP59596, but you can utilize any TCP high ports that are available within the environment between ports 59531 and 60554 (adjust load-balanced array rules accordingly).

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Start Registry Editor.

Important:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

2.a.Navigate to **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\MSExchangeRPC**
2.b.Right-click **MSExchangeRPC**, point to **New**, and then click **Key**.
2.c.Type **ParametersSystem** to name the new key.
2.d.Right-click **ParametersSystem**, point to **New**, and then click **DWORD (32-bit) Value**.
2.e.Type **TCP/IP Port** to name the new value.
2.f.Double-click **TCP/IP Port**.
2.g.In the **Value data** box, type **59595**, and then click **OK**.

Configure a static port for the Microsoft Exchange Address Book service by performing the steps below for your version of Exchange 2010.

In the Release to Manufacturing (RTM) version of Exchange 2010:

1. Navigate to *<Exchange Install Path>*\bin.
2. Open the MicrosoftExchange.AddressBook.Service.exe.config file in Notepad and add the following entry to the <appSettings> section of the file:

```
<add key="RpcTcpPort" value="59596" />
```

3. Close and save the file.

In Exchange 2010 Service Pack 1 (SP1):

1. Start Registry Editor.

Important:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

   1.a. Navigate to **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\MSExchangeAB**
   1.b. Right-click **MSExchangeAB**, point to **New**, and then click **Key**.
   1.c. Type **Parameters** to name the new key.
   1.d. Right-click **Parameters**, point to **New**, and then click **String Value**.
   1.e. Type **RpcTcpPort** to name the new value.
   1.f. Double-click **RpcTcpPort**.
   1.g. In the **Value data** box, type **59596**, and then click **OK**.
2. Close Registry Editor and then restart the Microsoft Exchange Address Book service.

Autodiscover Configuration

Exchange 2010 includes a service named the Autodiscover service. The Autodiscover service makes it easier to configure Outlook 2007 or Outlook 2010 and some mobile phones. For more information, see the Understanding the Autodiscover Service topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=194169).

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Configure the internal Autodiscover URL by running the following command within the Exchange Management Shell. In the following example, CAS01 is the name of the Client Access server and internal.domain.fqdn is the internal namespace used for Autodiscover:

```
Set-ClientAccessServer -Identity CAS01 -AutoDiscoverServiceInternalUri
```

3. Optional: Follow the procedure outlined in the Configure the Exchange Services for the Autodiscover Service topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187243) to configure the Autodiscover service for use by Internet clients. This will enable Outlook Anywhere and set the offline address book (OAB), Web Services, and Unified Messaging virtual directories external URL parameter.
4. Optional: Follow the procedure outlined in the Configure Exchange ActiveSync Autodiscover Settings topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187244) for usage by mobile clients.
5. Optional: Enable site affinity by following the procedure outlined in the Configure the Autodiscover Service to Use Site Affinity topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187245).
6. Verify that Autodiscover functions correctly by following the procedure outlined in the Test Outlook Autodiscover Connectivity topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187247).

Outlook Anywhere Configuration

If you completed step 3 from the previous "Autodiscover Configuration" section, you can skip this section. Otherwise, complete this procedure.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. To enable Outlook Anywhere, follow the procedure outlined in the Enable Outlook Anywhere topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187249).
3. If the server will be servicing Outlook Anywhere clients on the Internet, follow the procedure outlined in the Configure an External Host Name for Outlook Anywhere topic in the Exchange Server 2010 Library (http://go.microsoft.com/

fwlink/?LinkId=187253).

Offline Address Book Configuration

If the Client Access server will not be a distribution point for the OAB, you can skip this section.

By default, the OAB virtual directory does not require SSL. By default, Client Access servers use self-signed certificates for providing HTTP and RPC encryption. Clients that use the BITS service to download files (such as OAB) cannot use self-signed certificates. If a commercial certificate is going to be used and ISA 2006 is not going to be used to enforce SSL, you should enable SSL on the OAB virtual directory.

Note:

To use OAB Web distribution, the OAB must be generated on an Exchange 2010 Mailbox server. If the OAB is not generated on an Exchange 2010 Mailbox server, you can skip step 1.

1. Launch the Exchange Management Shell with an account that has been delegated the Organization Management role and then run the following commands. In the following example, CAS01 is the name of the Client Access server and mail.contoso.com is the name of the external URL.

```
$a=get-oabvirtualdirectory -Server CAS01
Set-oabvirtualdirectory $a -ExternalURL https://mail.contoso.com/OAB
Set-OfflineAddressBook "default offline address book" -VirtualDirector
iisreset /noforce
```

2. If the server has a commercial certificate and will be servicing requests from the Internet and either Microsoft Internet Security and Acceleration (ISA) Server 2006, Microsoft Forefront Unified Access Gateway (UAG) or Microsoft Forefront Threat Management Gateway (TMG) 2010 will not be in use to enforce SSL for Internet requests, follow the procedure outlined in the Require SSL for Offline Address Book Distribution topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187254).

IMAP4 Configuration

If the Client Access server will not allow IMAP4 connections, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
   1.a. To configure the IMAP4 bindings, run the following command. In the following example, CAS01 is the Client Access server and 0.0.0.0 implies any IP address.

```
Set-ImapSettings -server CAS01 -UnencryptedOrTLSBindings "(
```

   1.b. To disable plain text authentication and enable custom calendar item retrieval option for IMAP4, run the following command. In the following example, mail.contoso.com is the certificate name and external URL.

```
Set-ImapSettings -server CAS01 -X509CertificateName "mail.c
```

   1.c. To enable the Exchange IMAP4 service for automatic startup, run the following command:

```
Set-Service MSExchangeIMAP4 -ComputerName CAS01 -StartupTyp
```

POP3 Configuration

If the Client Access server will not allow POP3 connections, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
   1.a. To configure the POP3 bindings, run the following command. In the

following example, CAS01 is the Client Access server and 0.0.0.0 implies any IP address.

```
Set-PopSettings -server CAS01 -UnencryptedOrTLSBindings "0.
```

1.b.To disable plain text authentication and enable custom calendar item retrieval option for POP3, run the following command. In the following example, mail.contoso.com is the certificate name and external URL.

```
Set-PopSettings -server CAS01 -X509CertificateName "mail.co
```

1.c.To enable the Exchange POP3 service for automatic startup, run the following command:

```
Set-Service MSExchangePOP3 -ComputerName CAS01 -StartupType
```

Outlook Web App Configuration (Internet Scenario)

Follow the steps in this section only if the Client Access server will service directly from the Internet and either ISA 2006 or UAG or TMG pre-authentication mechanisms are not in use. If either is not true, then skip this section and follow the steps outlined in the Outlook Web App Configuration (Proxy Scenario) section below.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. By default, when the Client Access server role is installed, forms-based authentication is enabled. Ensure that forms-based authentication is enabled by following the procedure outlined in the Configure Forms-based Authentication for Outlook Web App topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187486).
3. Configure the public and private cookie timeouts by following the procedures outlined in the Set the Forms-Based Authentication Public Computer Cookie Time-Out Value topic (http://go.microsoft.com/fwlink/?LinkId=187334) and the Set the Forms-Based Authentication Private Computer Cookie Time-Out Value topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187336).
4. Optional: Configure GZip compression by following the procedure outlined in the Configure Gzip Compression Settings topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187343).
5. Configure WebReady Document Viewing by following the procedure outlined in the Configure WebReady Document Viewing topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187344).
6. Configure private and public computer file access by following the procedure outlined in Configure Public and Private Computer File Access topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187346).
7. Optional: If redirection is to be used, run the following command from the Exchange Management Shell. In the following example, CAS01 is the name of the Client Access server and mail.contoso.com is the name of the external URL.

```
Set-OwaVirtualDirectory -identity "CAS01\owa (Default Web Site)" -Exte
Set-OwaVirtualDirectory -identity "CAS01\ecp (Default Web Site)" -Exte
```

8. Optional: To simplify the Outlook Web App URL and redirect users to HTTPS, follow the procedure outlined in the Simplify the Outlook Web App URL topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187347).
9. Restart the Client Access server.

Outlook Web App Configuration (Proxy Scenario)

Follow the steps in this section only if the Client Access server will not service requests

directly from the Internet, but it will receive requests from other Client Access servers that are located in other Active Directory sites, or the Client Access server will be using ISA or UAG or TMG to pre-authenticate Internet requests.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Configure Windows Integrated Authentication by following the procedure outlined in the Configure Forms-based Authentication for Outlook Web App topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187486).
3. Optional: Configure GZip compression by following the procedure outlined in the Configure Gzip Compression Settings topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187343).
4. Configure WebReady Document Viewing by following the procedure outlined in the Configure WebReady Document Viewing topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187344).
5. Configure private and public computer file access by following the procedure outlined in Configure Public and Private Computer File Access topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187346).
6. Optional: To simplify the Outlook Web App URL and redirect users to HTTPS, follow the procedure outlined in the Simplify the Outlook Web App URL topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187347).
7. Restart the Client Access server.

Legacy ActiveSync Configuration

In order for mobile devices to synchronize using Client Access servers when the mailbox resides on Exchange Server 2003, the Microsoft-Server-ActiveSync virtual directory must be configured to use Windows Integrated Authentication.

If there are no legacy Exchange Mailbox servers or no legacy mailboxes that are accessed via Exchange ActiveSync, you can skip this section.

Note:

You can manually configure the Microsoft-Server-ActiveSync virtual directory to use Windows Integrated Authentication by installing the hotfix described in Microsoft Knowledge Base article 937031 on a workstation running the Exchange 2003 System Manager (http://go.microsoft.com/fwlink/?linkid=3052&kbid=937031).

1. Connect to the server via Remote Desktop and log on with an account that has been delegated both local administrative access and the Exchange Full Administrator role within the Exchange 2003 environment.
2. Create the legacyEAS.vbs script by copying the code from the Server Build DVD Visual Basic Script Examples topic in the Exchange Server 2007 Library (http://go.microsoft.com/fwlink/?LinkId=167205).
3. Open a command prompt and navigate to the directory containing the script file and run the following command:

```
legacyEAS.vbs -d:DomainController -a:AdminGroup
```

Note:

Replace `Domain Controller` with a domain controller that is in the same Active Directory site as the Exchange server (optional parameter).

The output will be similar to the following if successful:

```
Z:\E2010-Scripts\CAS>legacyeas.vbs -d:W2K3-DC-01 -a:NorthAmerica
Microsoft (R) Windows Script Host Version 5.1 for Windows
Copyright (C) Microsoft Corporation 1996-1999. All rights reserved.
Exchange Server Container - cn=Microsoft-Server-Activesync,cn=1,cn=HTTP,cn=Protoc
Attribute Name & Value - msExchAuthenticationFlags: 6
Attribute Set!!
```

Handoff Test

Before you can complete the diagnostic tasks in this section, you must have already created test mailboxes in your environment by using the New-TestCasConnectivityUser.ps1 script.

Create Test Mailboxes

1. Connect to the Exchange 2010 Mailbox server through Remote Desktop and log on with an account that has local administrative access and was delegated the Server Management role.
2. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010**, and then select **Exchange Management Shell**.
3. Change the directory path to **<***Exchange Server Install Path***>\Scripts**.
4. Type **New-TestCasConnectivityUser.ps1** and press **Enter**.
5. Enter a temporary password and follow the prompts to create the test mailboxes.

Perform Handoff Test

1. If the server has not been restarted as a result of a previous section's instructions, restart the server.
2. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
3. To test Exchange ActiveSync connectivity, run the following command where *<Server>* is the name of the Client Access server:

```
Test-ActiveSyncConnectivity -ClientAccessServer <Server>
```

4. To test Autodiscover connectivity, run the following command where *<EmailAddress>* is the e-mail address of a mailbox:

```
Add-TargetAddress <EmailAddress>
```

5. To test Exchange Web Services functionality, run the following command:

```
Test-WebServicesConnectivity -ClientAccessServer <Server> -AllowUnsecu
```

6. To test Outlook Web App connectivity, run the following command where *<Server>* is the name of the Client Access server:

```
Test-OwaConnectivity -ClientAccessServer:<Server> -AllowUnsecureAccess
```

If this server will be responding to Internet client requests, consider using the Exchange Remote Connectivity Analyzer (https://www.testexchangeconnectivity.com/) to verify your configuration, as well.

1.2.2.11.2 Installation Guide Template - Hub Transport Server

Installation Guide Template - Hub Transport Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-21*

This topic provides you with an installation guide template that you can use as a starting point for formally documenting your organization's server build procedures for Microsoft Exchange Server 2010 servers that will have the Hub Transport server role installed.

The template includes the following key sections:

- Executive Summary
- Server Configuration
- Verification Steps

- Exchange Server Role Installation
- Exchange Server Role Configuration

For purposes of providing an example, the template uses the fictitious company name of Contoso. Also, you can download this template, along with templates for other server roles, as a download package in .zip file format at Microsoft Exchange Server 2010 Install Guide Templates (http://go.microsoft.com/fwlink/?LinkID=187961).

Executive Summary

The purpose of this document is to explain the installation and configurations necessary to install the Exchange 2010 Hub Transport server role on the Windows Server 2008 platform.

Business Justification

By having an installation guide, Contoso will be able to ensure standardization across the enterprise, reducing total cost of ownership (TCO), and easing troubleshooting steps.

Scope

The scope of this document is limited to installation of an Exchange 2010 Hub Transport server for Contoso on the x64 version of the Windows Server 2008 (SP2 or R2) operating system.

Prerequisites

The administrator should have working knowledge of Windows Server 2008 concepts, Exchange 2010 concepts, the Exchange Management Console and Exchange Management Shell, the command line, and various system utilities. This document does not elaborate on the details of any system utility except as necessary to complete the tasks within.

In addition, before implementing the server role, the administrator should review the Understanding Transport topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187524).

Assumptions

This document assumes that Windows Server 2008 x64 Edition is installed on the intended Client Access server per company baseline regulations which include the latest approved service pack and hotfixes. In addition, the following system prerequisites have been installed:

- Microsoft .NET Framework 3.5 SP1 and the update for .NET Framework 3.5 SP1 For more information, see Microsoft Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available (http://go.microsoft.com/fwlink/?linkid=3052&kbid=959209).
- Windows Management Framework (Windows Remote Management 2.0 and Windows PowerShell 2.0).

This document assumes that forest and domain preparation steps have been performed as described in the Prepare Active Directory and Domains topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187262).

This document assumes that the account you will be using for the Exchange tasks has been delegated the Server Management management role, as described in the Server Management topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187265).

This document also assumes that both Exchange 2010 Windows Server 2008 and Windows Server 2008 will be secured following the best practices found in the Windows Server 2008 Security Guide (http://go.microsoft.com/fwlink/?LinkId=122593).

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Server Configuration

The following media are required for this section.

- Windows Server 2008 installation files

The following procedures are in this section:

1. Additional Software Verification
2. Network Interfaces Configuration
3. Drive Configuration
4. Windows Server 2008 Hotfix Installation
5. Domain Membership Configuration
6. Local Administrators Verification
7. Local Administrator Account Password Reset
8. Debugging Tools Installation
9. Page File Modifications
10. Drive Permissions

Additional Software Verification

1. Verify that Remote Desktop is enabled.
2. As an optional process, install Microsoft Network Monitor (http://go.microsoft.com/fwlink/?LinkId=86611).

Network Interfaces Configuration

1. Log on to the server with an account that has been delegated at least local administrative access.
2. Click **Start > Control Panel**, and then double-click **Network and Sharing Center**.
3. Click **Manage Network Connections**.
4. Locate the connection for the internal network and rename it according to your organization's naming standards.
5. Right-click the connection and then select **Properties**.
6. For Internet Protocol Version 4 (TCP/IPv4), add the following:
   6.a. **Static IP Address**, **Subnet Mask**, and **Gateway**
   6.b. DNS Server IP Addresses
   6.c. Select the check box to **Append parent suffixes of the primary DNS suffix**.
   6.d. WINS IP Addresses (if using WINS)
7. If you are using Internet Protocol Version 6 (TCP/IPv6), configure the IPv6 settings according to your organization's network standards.

Drive Configuration

1. Connect to the server through Remote Desktop and then log on with an account that has been delegated local administrative access.
2. Click **Start > Administrative Tools**, and then select **Computer Management**.
3. Expand **Storage** and then click **Disk Management**.
4. Open the Disk Management Microsoft Management Console (MMC) and then format, rename, and assign the appropriate **Drive Letters** so that the volumes and DVD drive match the appropriate server configuration.

Drive configuration

LUN	Drive letter	Usage
1	C	Operating system and Exchange binaries

2	D	Mail.que database
3	E	Exchange transaction logs, tracking logs
4	Z	DVD drive

Windows Server 2008 Hotfix Installation

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Obtain the latest hotfixes approved by your company for your version of Windows Server 2008 x64 (SP2 or R2) and copy them to the server.
3. Launch the hotfix setup via one of two ways:
   3.a. Double-click the file and follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
<hotfix>.msu /quiet /norestart
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

> **Note:**
> These dialog boxes will not appear in environments that have not deployed the Windows Security templates.

5. Wait for all file copies to complete, and then restart the server. You can use the **Processes** tab in Windows Task Manager to monitor the hotfix installation progress. When the wusa.exe process has exited, the hotfix installation is complete.

Domain Membership Configuration

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start,** right-click **My Computer**, and then select **Properties**.
3. Under the **Computer Name, domain, and workgroup** settings, click **Change Settings**.
4. Click **Change**.
5. Choose the **Domain** option button, and then enter the appropriate domain name.
6. Enter the appropriate credentials.
7. Click **OK** and **OK**.
8. Click **OK** to close **System Properties**.
9. Restart the server.

Local Administrators Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Verify (or add if not already there) that the Domain Admins account and the user account that will perform the Exchange installation are members of the local Administrators group on this server.
3. Verify that your user account is a member of a group which is a member of the local Administrators group on the Windows Server 2008 server. If it is not, use an account that is a member of the local Administrators group before continuing.

Local Administrator Account Password Reset

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Manage**.
3. Expand the nodes to find **Configuration\Local Users and Groups\Users**.

4. Right-click **Administrator**, and then select **Set Password**. Change the password so that it meets strong complexity requirements.

Debugging Tools Installation

This section describes several useful tools that aid administrators in Exchange administration and in troubleshooting support issues.

Debugging Tools for Windows allow administrators to debug processes that are affecting service and determine root cause.

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Download and install the latest 64-bit Debugging Tools from Install Debugging Tools for Windows 64-bit Version (http://go.microsoft.com/fwlink/?LinkID=123594).

Page File Modifications

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Startup and Recovery**, click **Settings**.
   4.a. Under **Write Debugging Information**, select **Kernel Memory Dump** from the memory dump drop-down list.
   4.b. Click **OK**.
5. Under **Performance**, click **Settings**.
6. Click the **Advanced** tab.
7. Under **Virtual Memory**, click **Change**.
8. On servers that have a dedicated page file drive, follow these steps:
   8.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   8.b. For the C: drive, set the **Initial Size (MB)** value to a minimum of 200 MB. (Windows requires between 150 MB and 2 GB page file space, depending on server load and the amount of physical RAM that is available for page file space on the boot volume when Windows is configured for a kernel memory dump. Therefore, you may be required to increase the size.)
   8.c. For the C: drive, set the **Maximum Size (MB)** value to that of the **Initial Size**.
   8.d. In the **Drive** list, select the page file drive (for example, the P: drive), and then click **Custom size**.
   8.e. In the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   8.f. In the **Maximum Size (MB)** box, type the same amount that you typed in the **Initial Size** box.
   8.g. Delete all other page files.
   8.h. Click **OK**.
9. On servers that do not have a dedicated page file drive, follow these steps:
   9.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   9.b. For the C: drive, in the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   9.c. Delete all other page files.
   9.d. Click **OK**.
10. Click **OK** two times to close the **System Properties** dialog box.
11. Click **No** if prompted to restart the system.

Note:
For more information about page file recommendations, see the following Microsoft Knowledge Base articles: How to determine the appropriate page file size for 64-bit versions of Windows Server 2003 or Windows XP (http://go.microsoft.com/fwlink/?linkid=3052&kbid=889654); and Overview of memory dump file options for Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP, and Windows 2000 (http://go.microsoft.com/fwlink/?linkid=3052&kbid=254649).

Drive Permissions

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, and then select **Computer**.
3. Right-click **D Drive**, and then select **Properties**.
4. Click the **Security** tab.
5. Click **Edit**.
6. Click **Add**, and then select the local server from **Locations**.
7. Grant the following permissions as outlined in the following table.

Drive permissions

Account	Permissions
Administrators	Full Control
SYSTEM	Full Control
Authenticated Users	Read and Execute, List, Read
CREATOR OWNER	Full Control

8. Click the **Advanced** button.
9. Select the **CREATOR OWNER** permission entry, and then click **View/Edit**.
10. Select **Subfolders and Files Only** from the drop-down list.
11. Click **OK** two times.
12. Click **OK** to close the drive properties.
13. Repeat steps 3-12 for each additional drive (other than the C drive).

Verification Steps

The following procedures are in this section:

1. Organizational Unit Verification
2. Active Directory Site Verification
3. Domain Controller Diagnostics Verification
4. Exchange Best Practices Analyzer Verification

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Organizational Unit Verification

Submit a change request to the appropriate operations group and have the computer object moved to the appropriate organizational unit (OU).

Active Directory Site Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window.
3. Verify that the server is in the correct domain and Active Directory site. At the command line, type the following:

```
NLTEST /server:%COMPUTERNAME% /dsgetsite
```

4. The name of the Active Directory site to which the server belongs will be displayed. If the server is not in the correct Active Directory site, submit a

change request to the appropriate operations group and have the server moved to the appropriate Active Directory site.

Domain Controller Diagnostics Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window, and then change paths to the C drive.
3. Run the following command:

```
dcdiag /s:<Domain Controller> /f:c:\dcdiag.log
```

Note:

Change **<domain Controller>** to a domain controller contained within the same Active Directory site as the Exchange server.

4. Review the output of **C:\dcdiag.log** file, and verify that there are no connectivity issues with the local domain controller.
5. Repeat steps 3 and 4 for each domain controller in the local Active Directory site.

Note:

Domain Controller Diagnostics (DCDiag) is a Windows support tool that tests network connectivity and DNS resolution for domain controllers. If the account being used does not have administrative privileges, several tests under the **Doing primary tests** heading may not pass. These tests can be ignored if the connectivity tests pass. In addition, the log file may report that some service validation tests did not pass. These messages can be ignored if the services do not exist on the domain controller.

Exchange Best Practices Analyzer Verification

The Microsoft Exchange Analyzers help administrators troubleshoot various operational support issues. Connect to a server in the environment that either has the Exchange 2010 SP1 (or later) Management tools installed through Remote Desktop and log on with an account that has local administrative access.

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010**, and then select **Exchange Management Console**.
2. Open the **Toolbox** node.
3. Double-click **Best Practices Analyzer**.
4. Check and apply any updates for the Best Practices Analyzer engine.
5. Provide the appropriate information to connect to Active Directory and then click **Connect to the Active Directory server**.
6. In the **Start a New Best Practices Scan**, select **Health Check**, and then click **Start Scanning**.
7. Review the report, and take action on any errors or warnings that are reported by following the resolution articles that are provided within the Best Practices Analyzer.

Exchange Server Role Installation

The following media are required for this section.

- Microsoft Exchange Server 2010 installation files

The following procedures are in this section:

1. Exchange 2010 Prerequisites Installation for:
   - Windows Server 2008 SP2

     -or-
   - Windows Server 2008 R2
2. Exchange 2010 Installation
3. Exchange 2010 Update Rollup Installation
4. Product Key Configuration
5. Exchange Search Configuration

6. System Performance Verification

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Exchange 2010 Prerequisites Installation for Windows Server 2008 SP2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open an administrative command prompt window.
3. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
4. Open an elevated command prompt, navigate to the Setup\ServerRoles\Common folder on the Exchange 2010 installation media and then use the following command to install the necessary operating system components:

```
ServerManagerCmd -ip Exchange-Hub.xml -Restart
```

Exchange 2010 Prerequisites Installation for Windows Server 2008 R2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
3. On the Start Menu, navigate to **All Programs** > **Accessories > Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following command:

```
Import-Module ServerManager
```

4. Use the **Add-WindowsFeature** cmdlet to install the necessary operating system components:

```
Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Basic-Auth,W
```

Exchange 2010 Installation

This document uses the command-line method for installing the Exchange 2010 server roles; however, you can also use a GUI called the Setup Wizard. For more information about how to use the Setup Wizard to install an Exchange 2010 server role, see the Perform a Custom Exchange 2010 Installation topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187220).

1. Connect to the server via Remote Desktop, and then log on with an account that has local administrative access and has been delegated the Delegated Setup management role (or higher) if the server has been pre-created.
2. Follow the procedure detailed in the Install Exchange 2010 in Unattended Mode topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187229). For example, this command installs the Hub Transport server role and prevents the service from starting:

```
setup.com /r:HT /DoNotStartTransport
```

Do not restart the server, even if required.

Exchange 2010 Update Rollup Installation

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Obtain the latest company approved rollup, and then copy it to the server.
3. Launch the Windows Installer patch (the MSP file) setup via one of two ways:
   3.a. Double-click the MSP file, and then follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an

administrative command prompt:

```
msiexec /i <Path and filename of MSP file> /q
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

Note:
These dialog boxes will appear only in environments that have deployed the Windows Security templates.

Product Key Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Follow the procedure documented in the Enter Product Key topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187234).

Exchange Search Configuration

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Follow the procedure documented in the Register Filter Pack IFilters with Exchange 2010 topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187516).
3. Optional: If you want the ability to search PDF files, install the Adobe PDF iFilter (http://www.adobe.com/support/downloads/detail.jsp?ftpID=4025) and follow the Configuring PDF iFilter for MS Exchange Server 2007 (http://www.adobe.com/special/acrobat/configuring_pdf_ifilter_for_ms_exchange_server_2007.pdf) documentation.

Note:
The third-party Web site information in this topic is provided to help you find the technical information you need. The URLs are subject to change without notice.

System Performance Verification

By default, Exchange 2010 optimizes the server's processor scheduling management for background services.

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Performance**, click **Settings**.
   4.a. Click the **Advanced** tab.
   4.b. Verify that **Processor Scheduling** is set to **Background Services**.
5. Click **OK**.

Exchange Server Role Configuration

The following procedures are in this section:

1. Default Receive Connector Configuration
2. Transport Server Configuration
3. Transaction Log Location
4. Transport Logs Location
5. Temporary Storage Path
6. Handoff Test

Default Receive Connector Configuration

By default, the default Receive connector will accept various authentication mechanisms and allow users as well as Exchange servers to connect. The following steps modify this behavior by restricting the type of authentication that can occur and ensuring only Exchange servers can connect and transmit messages to this Receive connector. Also, in

addition to the default Receive connector, each Hub Transport server has a client Receive connector that listens on TCP 587.

For more information, see the Understanding Receive Connectors topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=183419).

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Modify the default Receive connector's permissions and authentication mechanisms using the following command:

```
Set-ReceiveConnector "<ServerName>\Default <ServerName>" -PermissionGr
```

Transport Server Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Modify various settings on the default Receive connector by running the following command:

```
Set-TransportServer <ServerName> -MessageTrackingLogMaxAge <MaxAge> -M
```

You can use the following table for information you need for the command.

Important:
The values in the following table are example values only, not recommended values. Revise these values to reflect the actual values required for your organization.

Parameter values for Hub Transport server configuration

Parameter	Default value	Contoso value
ActiveUserStatisticsLogMaxAge	30.00:00:00	30.00:00:00
ActiveUserStatisticsLogMaxDirectorySize	250 MB	250 MB
ActiveUserStatisticsLogMaxFileSize	10 MB	10 MB
ExternalDsnReportingAuthority	[None]	SMTP namespace
ExternalPostmasterAddress	[None]	postmaster@smtpnamespace
MaxPerDomainOutboundConnections	20	50
MessageTrackingLogEnabled	True	True
MessageTrackingLogMaxAge	30.00:00:00	10.00:00:00
MessageTrackingLogMaxDirectorySize	1000 MB	150 GB
MessageTrackingLogMaxFileSize	10 MB	10 MB
MessageTrackingLogSubject LoggingEnabled	True	True
ReceiveProtocolLogMaxAge	30.00:00:00	10.00:00:00
ReceiveProtocolLogMaxDirectorySize	250 MB	15 GB
ReceiveProtocolLogMaxFil	10 MB	10 MB

eSize		
SendProtocolLogMaxAge	30.00:00:00	10.00:00:00
SendProtocolLogMaxDirectorySize	250 MB	15 GB
SendProtocolLogMaxFileSize	10 MB	10 MB
ServerStatisticsLogMaxAge	30.00:00:00	30.00:00:00
ServerStatisticsLogMaxFileSize	250 MB	250 MB
ServerStatisticsLogPath	10 MB	10 MB

Transaction Log Location

1. Connect to an Exchange 2010 server via Remote Desktop, and then log on with an account that has local administrative access and that has been delegated the Server Management role (or higher).
2. Verify that the MSExchangeTransport service is stopped. If it is not stopped, stop the service.
3. Create the folder E:\Exchange\QueueLogs.
4. Move the TRNxxxx.LOG and *.JRS files from <*Exchange Install Path*>\TransportRoles\Data\Queue to E:\Exchange\QueueLogs.
5. Navigate to <*Exchange Install Path*>\bin.
6. Open the EdgeTransport.exe.config file in Notepad and edit the following entry:

```
<add key="QueueDatabaseLoggingPath" value="E:\Exchange\QueueLogs" />
```

7. Save the file.

Transport Logs Location

1. Connect to an Exchange 2010 server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Verify that the MSExchangeTransport service is stopped. If it is not stopped, stop the service.
3. Create the E:\Exchange\Logs folder.
4. Move the folders that reside in <*Exchange Install Path*>\TransportRoles\Logs to the E:\Exchange\Logs folder.
5. Launch the Exchange Management Shell with an account that has been delegated the Server Management role and then run the following command:

```
Set-TransportServer <ServerName> -ConnectivityLogPath "E:\Exchange\Log
```

6. Open a command prompt and start the Transport service by running the following command:

```
net start MSExchangeTransport
```

Temporary Storage Path

1. Connect to an Exchange 2010 server via Remote Desktop, and then log on by using an account that has been delegated local administrative access and that has been delegated the Server Management role (or higher).
2. Verify that the MSExchangeTransport service is stopped. If it is not stopped, stop the service.
3. Move to the <*Exchange Install Path*>\bin directory.
4. Open the EdgeTransport.exe.config file in Notepad, and then change the TemporaryStoragePath entry to point to the mail.que drive. By default, this path is "C:\Program Files\Microsoft\Exchange Server\V14\TransportRoles\data\Temp."

```
<add key="TemporaryStoragePath" value="<path of mail queue>" />
```

5. Save the file.
6. Restart the server.

Handoff Test

Before you can complete the diagnostic tasks in this section, you must have already created test mailboxes in your environment by using the New-TestCasConnectivityUser.ps1 script.

Create Test Mailboxes

1. Connect to the Exchange 2010 Mailbox server through Remote Desktop and log on with an account that has local administrative access and was delegated the Server Management role.
2. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010**, and then select **Exchange Management Shell**.
3. Change the directory path to *<Exchange Server Install Path>*\Scripts.
4. Type **New-TestCasConnectivityUser.ps1** and press **Enter**.
5. Enter a temporary password and follow the prompts to create the test mailboxes.

Perform Handoff Test

1. If the server had not been restarted as a result of a previous section's instructions, then restart the server.
2. Using a test mailbox, send sample messages to various mailboxes and verify that mail is successfully delivered.
3. Send sample messages from Internet mailboxes to various internal test mailboxes, and verify that the mail is successfully delivered.
4. Review the event logs and tracking logs and ensure that the Hub Transport server is operating correctly.

Consider using the Exchange Remote Connectivity Analyzer (https://www.testexchangeconnectivity.com/) to verify your configuration, as well.

1.2.2.11.3 Installation Guide Template - Mailbox Server

Installation Guide Template - Mailbox Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-21*

This topic provides you with an installation guide template that you can use as a starting point for formally documenting your organization's server build procedures for Microsoft Exchange Server 2010 servers that will have the Mailbox server role installed.

The template includes the following key sections:

- Executive Summary
- Server Configuration
- Verification Steps
- Exchange Server Role Installation
- Exchange Server Role Configuration
- Appendix: Server Configuration

For purposes of providing an example, the template uses the fictitious company name of

Contoso. Also, you can download this template, along with templates for other server roles, as a download package in .zip file format at Microsoft Exchange Server 2010 Install Guide Templates (http://go.microsoft.com/fwlink/?LinkID=187961).

Executive Summary

The purpose of this document is to explain the installation and configurations necessary to install the Exchange 2010 Mailbox server role on the Windows Server 2008 platform.

Business Justification

By having an installation guide, Contoso will be able to ensure standardization across the enterprise, reducing total cost of ownership (TCO), and easing troubleshooting steps.

Scope

The scope of this document is limited to installation of an Exchange 2010 Mailbox server for Contoso on the x64 version of the Windows Server 2008 (SP2 or R2) operating system.

Prerequisites

The administrator should have working knowledge of Windows Server 2008 concepts, Exchange 2010 concepts, the Exchange Management Console and Exchange Management Shell, the command line, and various system utilities. This document does not elaborate on the details of any system utility except as necessary to complete the tasks within.

In addition, before implementing the server role, the administrator should review the Overview of the Mailbox Server Role topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187526).

Assumptions

This document assumes that Windows Server 2008 x64 Edition is installed on the intended Client Access server per company baseline regulations which include the latest approved service pack and hotfixes. In addition, the following system prerequisites have been installed:

- Microsoft .NET Framework 3.5 SP1 and the update for .NET Framework 3.5 SP1 For more information, see Microsoft Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available (http://go.microsoft.com/fwlink/?linkid=3052&kbid=959209).
- Windows Management Framework (Windows Remote Management 2.0 and Windows PowerShell 2.0).

This document assumes that forest and domain preparation steps have been performed as described in the Prepare Active Directory and Domains topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187262).

This document assumes that the account you will be using for the Exchange tasks has been delegated the Server Management management role, as described in the Server Management topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187265).

This document also assumes that both Exchange 2010 Windows Server 2008 and Windows Server 2008 will be secured following the best practices found in the Windows Server 2008 Security Guide (http://go.microsoft.com/fwlink/?LinkId=122593).

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Server Configuration

The following media are required for this section.

- Windows Server 2008 installation files

The following procedures are in this section:

1. Additional Software Verification
2. Network Interfaces Configuration
3. Drive Configuration
4. Windows Server 2008 Hotfix Installation
5. Domain Membership Configuration
6. Local Administrators Verification
7. Local Administrator Account Password Reset
8. Debugging Tools Installation
9. Page File Modifications
10. Drive Permissions

Additional Software Verification

1. Verify that Remote Desktop is enabled.
2. As an optional process, install Microsoft Network Monitor (http://go.microsoft.com/fwlink/?LinkId=86611).

Network Interfaces Configuration

1. Log on to the server with an account that has been delegated at least local administrative access.
2. Click **Start > Control Panel**, and then double-click **Network and Sharing Center**.
3. Click **Manage Network Connections**.
4. Locate the connection for the internal network and rename it according to your organization's naming standards.
5. Right-click the connection and then select **Properties**.
6. For Internet Protocol Version 4 (TCP/IPv4), add the following:
   6.a. **Static IP Address**, **Subnet Mask**, and **Gateway**
   6.b. DNS Server IP Addresses
   6.c. Select the check box to **Append parent suffixes of the primary DNS suffix**.
   6.d. WINS IP Addresses (if using WINS)
7. If you are using Internet Protocol Version 6 (TCP/IPv6), configure the IPv6 settings according to your organization's network standards.

Drive Configuration

1. Connect to the server through Remote Desktop and log on with an account that has local administrative access.
2. Click **Start, Administrative Tools**, and select **Computer Management**.
3. Expand Storage and click on **Disk Management**.
4. Using the Disk Management snap-in of the Microsoft Management Console (MMC), format, rename, and assign the appropriate **Drive Letters** so that the volumes and DVD drive match the appropriate server configuration. Refer to the Database Log LUN appendix at the end of this document for the actual drive configuration that should be used.

Drive configuration

LUN	Drive letter	Usage
1	C	Operating system, Exchange binaries, and tracking logs
2	E	Exchange databases

4	L	Exchange transaction logs
5-x	--	Additional drives for databases and logs
6	Z	DVD drive

Windows Server 2008 Hotfix Installation

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Obtain the latest hotfixes approved by your company for your version of Windows Server 2008 x64 (SP2 or R2) and copy them to the server.
3. Launch the hotfix setup via one of two ways:
   3.a. Double-click the file and follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
<hotfix>.msu /quiet /norestart
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

> **Note:**
> These dialog boxes will not appear in environments that have not deployed the Windows Security templates.

5. Wait for all file copies to complete, and then restart the server. You can use the **Processes** tab in Windows Task Manager to monitor the hotfix installation progress. When the wusa.exe process has exited, the hotfix installation is complete.

Domain Membership Configuration

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start,** right-click **My Computer**, and then select **Properties**.
3. Under the **Computer Name, domain, and workgroup** settings, click **Change Settings**.
4. Click **Change**.
5. Choose the **Domain** option button, and then enter the appropriate domain name.
6. Enter the appropriate credentials.
7. Click **OK** and **OK**.
8. Click **OK** to close **System Properties**.
9. Restart the server.

Local Administrators Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Verify (or add if not already there) that the Domain Admins account and the user account that will perform the Exchange installation are members of the local Administrators group on this server.
3. Verify that your user account is a member of a group which is a member of the local Administrators group on the Windows Server 2008 server. If it is not, use an account that is a member of the local Administrators group before continuing.

Local Administrator Account Password Reset

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Manage**.

3. Expand the nodes to find **Configuration\Local Users and Groups\Users**.
4. Right-click **Administrator**, and then select **Set Password**. Change the password so that it meets strong complexity requirements.

Debugging Tools Installation

This section describes several useful tools that aid administrators in Exchange administration and in troubleshooting support issues.

Debugging Tools for Windows allow administrators to debug processes that are affecting service and determine root cause.

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Download and install the latest 64-bit Debugging Tools from Install Debugging Tools for Windows 64-bit Version (http://go.microsoft.com/fwlink/?LinkID=123594).

Page File Modifications

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Startup and Recovery**, click **Settings**.
   4.a. Under **Write Debugging Information**, select **Kernel Memory Dump** from the memory dump drop-down list.
   4.b. Click **OK**.
5. Under **Performance**, click **Settings**.
6. Click the **Advanced** tab.
7. Under **Virtual Memory**, click **Change**.
8. On servers that have a dedicated page file drive, follow these steps:
   8.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   8.b. For the C: drive, set the **Initial Size (MB)** value to a minimum of 200 MB. (Windows requires between 150 MB and 2 GB page file space, depending on server load and the amount of physical RAM that is available for page file space on the boot volume when Windows is configured for a kernel memory dump. Therefore, you may be required to increase the size.)
   8.c. For the C: drive, set the **Maximum Size (MB)** value to that of the **Initial Size**.
   8.d. In the **Drive** list, select the page file drive (for example, the P: drive), and then click **Custom size**.
   8.e. In the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   8.f. In the **Maximum Size (MB)** box, type the same amount that you typed in the **Initial Size** box.
   8.g. Delete all other page files.
   8.h. Click **OK**.
9. On servers that do not have a dedicated page file drive, follow these steps:
   9.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   9.b. For the C: drive, in the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   9.c. Delete all other page files.
   9.d. Click **OK**.
10. Click **OK** two times to close the **System Properties** dialog box.

11. Click **No** if prompted to restart the system.

> **Note:**
> For more information about page file recommendations, see the following Microsoft Knowledge Base articles: How to determine the appropriate page file size for 64-bit versions of Windows Server 2003 or Windows XP (http://go.microsoft.com/fwlink/?linkid=3052&kbid=889654); and Overview of memory dump file options for Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP, and Windows 2000 (http://go.microsoft.com/fwlink/?linkid=3052&kbid=254649).

Drive Permissions

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, and then select **Computer**.
3. Right-click **D Drive**, and then select **Properties**.
4. Click the **Security** tab.
5. Click **Edit**.
6. Click **Add**, and then select the local server from **Locations**.
7. Grant the following rights as outlined in the following table.

Drive permissions

Account	Permissions
Administrators	Full Control
SYSTEM	Full Control
Authenticated Users	Read and Execute, List, Read
CREATOR OWNER	Full Control

8. Click the **Advanced** button.
9. Select the **CREATOR OWNER** permission entry, and then click **View/Edit**.
10. Select **Subfolders and Files Only** from the drop-down list.
11. Click **OK** two times.
12. Click **OK** to close the drive properties.
13. Repeat steps 3-12 for each additional drive (other than the C drive).

Verification Steps

The following procedures are in this section:

1. Organizational Unit Verification
2. Active Directory Site Verification
3. Domain Controller Diagnostics Verification
4. Exchange Best Practices Analyzer Verification

> **Important:**
> The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Organizational Unit Verification

Submit a change request to the appropriate operations group and have the computer object moved to the appropriate organizational unit (OU).

Active Directory Site Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window.
3. Verify that the server is in the correct domain and Active Directory site. At the command line, type the following:

```
NLTEST /server:%COMPUTERNAME% /dsgetsite
```

4. The name of the Active Directory site to which the server belongs will be

displayed. If the server is not in the correct Active Directory site, submit a change request to the appropriate operations group and have the server moved to the appropriate Active Directory site.

Domain Controller Diagnostics Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window, and then change paths to the C drive.
3. Run the following command:

```
dcdiag /s:<Domain Controller> /f:c:\dcdiag.log
```

Note:

Change **<domain Controller>** to a domain controller contained within the same Active Directory site as the Exchange server.

4. Review the output of **C:\dcdiag.log** file, and verify that there are no connectivity issues with the local domain controller.
5. Repeat steps 3 and 4 for each domain controller in the local Active Directory site.

Note:

Domain Controller Diagnostics (DCDiag) is a Windows support tool that tests network connectivity and DNS resolution for domain controllers. If the account being used does not have administrative privileges, several tests under the **Doing primary tests** heading may not pass. These tests can be ignored if the connectivity tests pass. In addition, the log file may report that some service validation tests did not pass. These messages can be ignored if the services do not exist on the domain controller.

Exchange Best Practices Analyzer Verification

The Microsoft Exchange Analyzers help administrators troubleshoot various operational support issues. Connect to a server in the environment that either has the Exchange 2010 SP1 (or later) Management tools installed through Remote Desktop and log on with an account that has local administrative access.

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010**, and then select **Exchange Management Console**.
2. Open the **Toolbox** node.
3. Double-click **Best Practices Analyzer**.
4. Check and apply any updates for the Best Practices Analyzer engine.
5. Provide the appropriate information to connect to Active Directory and then click **Connect to the Active Directory server**.
6. In the **Start a New Best Practices Scan**, select **Health Check**, and then click **Start Scanning**.
7. Review the report, and take action on any errors or warnings that are reported by following the resolution articles that are provided within the Best Practices Analyzer.

Exchange Server Role Installation

The following media are required for this section.

- Microsoft Exchange Server 2010 installation files

The following procedures are in this section:

1. Exchange 2010 Prerequisites Installation for:
   - Windows Server 2008 SP2

     -or-
   - Windows Server 2008 R2
2. Exchange 2010 Installation
3. Exchange 2010 Update Rollup Installation
4. Product Key Configuration

5. System Performance Verification
6. Test Mailbox Creation

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Exchange 2010 Prerequisites Installation for Windows Server 2008 SP2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open an administrative command prompt window.
3. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
4. Open an elevated command prompt, navigate to the \Setup\ServerRoles\Common folder on the Exchange 2010 installation media and use the following command to install the necessary operating system components:

```
ServerManagerCmd -ip Exchange-MBX.xml -Restart
```

Exchange 2010 Prerequisites Installation for Windows Server 2008 R2

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
3. On the Start Menu, navigate to **All Programs** > **Accessories > Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following command:

```
Import-Module ServerManager
```

4. Use the **Add-WindowsFeature** cmdlet to install the necessary operating system components:

```
Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Basic-Auth,W
```

Exchange 2010 Installation

This document uses the command-line method for installing the Exchange 2010 server roles; however, you can also use a GUI called the Setup Wizard. For more information about how to use the Setup Wizard to install an Exchange 2010 server role, see the Perform a Custom Exchange 2010 Installation topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187220).

Important:
If this is the first Mailbox server role being installed into an organization that does not contain any version of Microsoft Exchange, and you have client computers running Microsoft Office Outlook 2003, you must also specify the optional */EnableLegacyOutlook* setup parameter. In addition, if this is the first Exchange 2010 server role being installed into an environment that does not contain any version of Microsoft Exchange, you must also specify the */OrganizationName* setup parameter.

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access. If the Exchange server has been provisioned for delegated setup, the account must be delegated the Server Management or the Delegated Setup role (or higher).
2. Follow the procedure detailed in the Install Exchange 2010 in Unattended Mode topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187229). For example, the following command installs the Mailbox server role, provides a custom database name, database path, and transaction log file location.

```
setup.com /r:M /mdbName "<Server Name> MBX DB1" /dbfilepath e:\MBXDB1\
```

3. Do not restart the server, even if required.

Exchange 2010 Update Rollup Installation

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Obtain the latest company approved rollup, and then copy it to the server.
3. Launch the Windows Installer patch (the MSP file) setup via one of two ways:
   3.a. Double-click the MSP file, and then follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
msiexec /i <Path and filename of MSP file> /q
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

Note:
These dialog boxes will appear only in environments that have deployed the Windows Security templates.

Product Key Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Follow the procedure documented in the Enter Product Key topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187234).

Exchange Search Configuration

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Follow the procedure documented in the Register Filter Pack IFilters with Exchange 2010 topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187516).
3. Optional: If you want the ability to search PDF files, install the Adobe PDF iFilter (http://www.adobe.com/support/downloads/detail.jsp?ftpID=4025) and follow the Configuring PDF iFilter for MS Exchange Server 2007 (http://www.adobe.com/special/acrobat/configuring_pdf_ifilter_for_ms_exchange_server_2007.pdf) documentation.

Note:
The third-party Web site information in this topic is provided to help you find the technical information you need. The URLs are subject to change without notice.

System Performance Verification

By default, Exchange 2010 optimizes the server's processor scheduling management for background services.

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Performance**, click **Settings**.
   4.a. Click the **Advanced** tab.
   4.b. Verify that **Processor Scheduling** is set to **Background Services**.
5. Click **OK**.

Test Mailbox Creation

Several of the diagnostics tasks used to monitor Exchange require that you create test mailboxes on the mailbox servers.

1. Connect to the Exchange 2010 Mailbox server through Remote Desktop, and

then log on with an account that has been delegated local administrative access and was also delegated the Server Management role (or higher).
2. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010** and then select **Exchange Management Shell**.
3. Change the directory path to *<Exchange Server Install Path>*\Scripts.
4. Type **New-TestCasConnectivityUser.ps1** and press **Enter**.
5. Enter a temporary password, and then follow the prompts to create the test mailboxes.

Exchange Server Role Configuration

The following procedures are in this section:

1. First Database Configuration
2. Second Database Configuration
3. Records Management Configuration
4. Message Tracking Server Configuration
5. Additional Databases

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

First Database Configuration

If you provided the */mdbname*, */dbfilepath*, and */logfolderpath* parameters when you installed the mailbox server, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

   Important:

   The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

   ### First database configuration at Contoso

Database parameter	Old	New example
Name	Mailbox Database *<GUID>*	*<ServerName>* MBX DB 1
Log Path	%ProgramFiles% \Microsoft\Exchange Server\v14\Mailbox \Mailbox Database <GUID>	L:\LOG01
Database Filename and Path	%ProgramFiles% \Microsoft\Exchange Server\v14\Mailbox \Mailbox Database <GUID>\Mailbox database <GUID>.edb	E:\MBXDB1\Priv01.edb

2. To dismount the database, run the following command:

   ```
   Dismount-Database "Mailbox Database <GUID>"
   ```

3. To change the mailbox database name, run the following command:

   ```
   Set-MailboxDatabase "<Old DB Name>" -Name "<New DB Name>"
   ```

4. To change the location of the database's transaction logs and the location of the database file, run the following command:

   ```
   Move-DatabasePath "<Database Name>" -LogFolderPath "<New Log Location>
   ```

5. To mount the database, run the following command:

   ```
   Mount-Database "<New DB Name>"
   ```

Second Database Configuration

If a public folder database was created during the installation of the Mailbox server role, the public folder database will be placed in the default location. If there is no public folder database, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

Important:
The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Public folder database configuration at Contoso

Database parameter	Old	New example
Name	Public Folder Database <*GUID*>	<*ServerName*> PUB Store 2
Log Path	%ProgramFiles% \Microsoft\Exchange Server\Mailbox\Public Folder Database <GUID>	L:\LOG02
Database Filename and Path	%ProgramFiles% \Microsoft\Exchange Server\Mailbox\Public Folder Database <GUID> \Public Folder database <GUID>.edb	E:\MBXDB2\Pub02.edb

2. To dismount the database, run the following command:

```
Dismount-Database "Public Folder Database <GUID>"
```

3. To change the public folder database name, run the following command:

```
Set-PublicFolderDatabase "<Old DB Name>" -Name "<New DB Name>"
```

4. To change the location of the database's transaction logs and the location of the database file, run the following command:

```
Move-DatabasePath "<Database Name>" -LogFolderPath "<New Log Location>
```

5. To mount the database, run the following command:

```
Mount-Database "<New DB Name>"
```

Records Management Configuration

You can skip this section if the default schedule for the Managed Folder Assistant to apply messaging records management (MRM) settings does not need to be changed.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. To enable the Managed Folder Assistant, run the following command:

```
Set-MailboxServer <MailboxServerName> -ManagedFolderAssistantSchedule
```

Note:
Refer to the "Records management configuration for Contoso" table in the Server Configuration Appendix at the end of this document for the information that you need for the commands.

Message Tracking Server Configuration

You can skip this section if the default message tracking parameters are appropriate for the environment.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

2. To configure message tracking settings, run the following command:

```
Set-MailboxServer <MailboxServerName> -MessageTrackingLogPath <LogPath
```

Note:
Refer to the "Message tracking configuration for Contoso" table in the Server Configuration Appendix at the end of this document for the information that you need for the commands.

Additional Databases

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Use the appropriate tables in Database / Log LUN Appendix and Database Configuration Appendix at the end of this document for information that you need for the commands.
3. To create the database, run the following command:

```
New-MailboxDatabase -Name "<DB Name>" -LogFolderPath <Transaction Log
```

4. To mount the database, run the following command:

```
Mount-Database "<Database Name>"
```

5. Repeat steps 3 and 4 for each database that needs to be created.

Appendix: Server Configuration

The following information is included in this section:

- Records Management Configuration
- Message Tracking Configuration
- Database / Log LUN Appendix
- Database Configuration Appendix

Records Management Configuration

The following table is an example configuration that can be applied to the Mailbox server, depending on requirements.

Important:
The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Records management configuration for Contoso

Parameter	Default value	Contoso value
Server Name	*<ServerName>*	*<ServerName>*
Managed Folder Assistant Schedule	Sun.1:00 AM-Sun.9:00 AM, Mon.1:00 AM-Mon.9:00 AM, Tue.1:00 AM-Tue.9:00 AM, Wed.1:00 AM-Wed.9:00 AM, Thu.1:00 AM-Thu.9:00 AM, Fri.1:00 AM-Fri. 9:00 AM, Sat.1:00 AM-Sat.9:00 AM	"Sun.6:00 PM-Sun.7:45 PM", "Mon.6:00 PM-Mon.7:45 PM", "Tue.6:00 PM-Tue.7:45 PM", "Wed.6:00 PM-Wed.7:45 PM", "Thu.6:00 PM-Thu.7:45 PM", "Fri.6:00 PM-Fri.7:45 PM", "Sat.6:00 PM-Sat.7:45 PM"

Message Tracking Configuration

The following table is an example configuration that can be applied to the Mailbox server, depending on requirements.

Important:
The values in the following table are example values, not recommended values. Revise

these values to reflect the actual values for your organization.

Message tracking configuration for Contoso

Parameter	Default value	Contoso value
Server Name	*<ServerName>*	*<ServerName>*
Message Tracking Log Path	*<Exchange Install Path>* \TransportRoles\Logs \MessageTracking	L:\exchsrvr\MessageTracking
Message Tracking Log Enabled	True	True
Message Tracking Log Max Age	30.00:00:00	45.00:00:00
Message Tracking Log Max Directory Size	1 GB	20 GB
Message Tracking Log Max File Size	10 MB	10 MB
Message Tracking Log Subject Logging Enabled	True	True

Database / Log LUN Appendix

With mailbox resiliency, you do not have to perform daily full backups because the mailbox database copies and other features provide the first line of defense against physical corruption and data loss. Therefore, there are two approaches to how backups can be performed in an environment enabled for mailbox resiliency:

- Use an Exchange -aware, Volume ShadowCopy Service (VSS)-based application to perform backups and restores, as needed.
- Use Exchange Native Data Protection features as your backup methodology. For more information about Exchange Native Data Protection, see the Understanding Backup, Restore and Disaster Recovery topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187541).

As a result of the backup methodology selected, the LUN layout has to be altered.

Exchange 2010 supports the following LUN layout architectures:

- **One LUN per database** A single LUN per database architecture means that both the database and its corresponding log files are placed on the same LUN. To deploy this architecture, you must have two or more copies of your databases, and you must not be using a hardware-based VSS solution.
- **Two LUNs per database** With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend upon your backup strategy. If your recovery time objective (RTO) is small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. This approach will exceed the number of available drive letters; therefore, volume mount points must be used.
- **Two LUNs per backup set** A backup set is the number of databases fully backed up in a night. A solution that performs a full backup on 1/7th of the databases nightly (for example, using a weekly or bimonthly full backup with daily incremental or differential backups) can reduce complexity by placing all of the databases to be backed up on the same log and database LUN. This approach can reduce the number of LUNs on the server.

Two LUNs per Database / LUN Layout

Exchange 2010 uses VSS included in Windows Server 2008 to take volume shadow copies of Exchange 2010 databases and transaction log files. For basic information about VSS, including both clone and snapshot techniques, review the white paper, Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003 (http://go.microsoft.com/fwlink/?LinkId=122556).

Exchange 2010 enables you to make software-based VSS snapshots of both the active and passive database copies. Taking a VSS snapshot of the passive copy offloads the disk I/O from the active LUN during both the checksum integrity (ESEUTIL), and subsequent copy to tape or disk.

Creating two LUNs (log and database) for a database was the standard best practice for Exchange 2003. With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend on your backup strategy. If your recovery time objective (RTO) is very small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. Depending on the number of LUNs required, volume mount points may need to be used.

Some benefits of this strategy include the following:

- Enables hardware-based VSS at a database level, providing single database backup and restore.
- Flexibility to isolate the performance between databases when not sharing spindles between LUNs.
- Increased reliability: A capacity or corruption problem on a single LUN will only affect one database.
- This is also the recommended strategy for databases that do not participate in mailbox resiliency.

Some concerns with this strategy include the following:

- 100 databases using mailbox resiliency could require 400 LUNs which would exceed some storage array maximums. 100 databases without mailbox resiliency could require 200 LUNs which would exceed some storage array maximums.
- A separate LUN for each database causes more LUNs per server increasing the administrative costs and complexity.

Note:
In the following table, the reference to MP stands for Mount Point. X and Y refer to unique databases.

LUN design approach: Two LUNs per database

Database	Database name	Database location	Database file name	Transaction log location
Anchor LUN	--	E:\	--	L:\
DBx	<DAGName> MBX DB x	MP:\MDB0x	Priv0x.edb	MP:\LOG0x
DBy	<DAGName> MBX DB y	MP:\MDB0y	Priv0y.edb	MP:\LOG0y
…	…	…	…	…

One LUN per Database / LUN Layout

Single LUN per database architecture means that both the database and its corresponding log files are placed on the same LUN. To deploy this architecture, you must have two or more copies, and you must not be using a hardware-based VSS solution.

Some of the benefits of this strategy include:

- Simplifies storage administration with fewer LUNs to manage.
- Reduces (potentially) the number of backup jobs.
- Provides flexibility to isolate the performance between databases when not sharing spindles between LUNs.

A concern with this strategy is that it limits the ability to perform hardware-based VSS backup and restore procedures (for example, clone snapshots). For VSS details, review the white paper, Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003 (http://go.microsoft.com/fwlink/?LinkId=122556).

Note:
In the following table, the reference to MP stands for Mount Point. X and Y refer to unique databases.

LUN design approach: One LUN per database

DB	Database name	Database location	Database file name
Anchor LUN	--	E:\	--
DBx	<DAGName> MBX Store X	MP:\ \MDBx \LOGx	PrivX.edb
DBy	<DAGName> MBX Store Y	MP:\ \MDBy \LOGy	PrivY.edb
…	…	…	…

Database / LUN Layout

Exchange 2010 uses VSS included in Windows Server 2008 to take volume shadow copies of Exchange 2010 databases and transaction log files. For basic information about VSS, including both clone and snapshot techniques, review the white paper, Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003 (http://go.microsoft.com/fwlink/?LinkId=122556).

Exchange 2010 enables you to make software-based VSS snapshots of both the active and passive database copies. Taking a VSS snapshot of the passive copy offloads the disk I/O from the active LUN during both the checksum integrity (ESEUTIL), and subsequent copy to tape or disk.

Creating two LUNs (log and database) for a database is the standard best practice for Exchange 2003. With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend on your backup strategy. If your recovery time objective (RTO) is very small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. Depending on the number of LUNs required, volume mount points may need to be used.

Some benefits of this strategy include the following:

- Enables hardware-based VSS at a database level, providing single database backup and restore.
- Flexibility to isolate the performance between databases when not sharing spindles between LUNs.
- Increased reliability: A capacity or corruption problem on a single LUN will only affect one database.
- This is also the recommended strategy for databases that do not participate in

mailbox resiliency.

Some concerns with this strategy include the following:

- 100 databases using mailbox resiliency could require 400 LUNs which would exceed the maximum capacity of some storage arrays. 100 databases without mailbox resiliency could require 200 LUNs which could also exceed the maximum capacity of some storage arrays.
- A separate LUN for each database causes more LUNs per server increasing the administrative costs and complexity.

Note:
In the following table, the reference to MP stands for Mount Point.
DB2 may contain either a mailbox database or a public folder database, depending on the configuration.

VSS approach LUN design for Contoso

Database	Database name	Database location	Database file name	Transaction log location
Anchor LUN	--	E:\	--	L:\
DB1	<ServerName> MBX DB 1	MP:\MBXDB1	Priv01.edb	MP:\LOG1
DB2	<ServerName> MBX DB 2	MP:\MBXDB2	Priv02.edb	MP:\LOG2
PF2	<ServerName> PUB DB 2	MP:\PFMDB2	Pub02.edb	MP:\PFLOG2
DB3	<ServerName> MBX DB 3	MP:\MBXDB3	Priv03.edb	MP:\LOG3
DB4	<ServerName> MBX DB 4	MP:\MBXDB4	Priv04.edb	MP:\LOG4
DB5	<ServerName> MBX DB 5	MP:\MBXDB5	Priv05.edb	MP:\LOG5
DB6	<ServerName> MBX DB 6	MP:\MBXDB6	Priv06.edb	MP:\LOG6
DB7	<ServerName> MBX DB 7	MP:\MBXDB7	Priv07.edb	MP:\LOG7
DB8	<ServerName> MBX DB 8	MP:\MBXDB8	Priv08.edb	MP:\LOG8
DB9	<ServerName> MBX DB 9	MP:\MBXDB9	Priv09.edb	MP:\LOG9
DB10	<ServerName> MBX DB 10	MP:\MBXDB10	Priv10.edb	MP:\LOG10
DB11	<ServerName> MBX DB 11	MP:\MBXDB11	Priv11.edb	MP:\LOG11
DB12	<ServerName> MBX DB 12	MP:\MBXDB12	Priv12.edb	MP:\LOG12
DB13	<ServerName> MBX DB 13	MP:\MBXDB13	Priv13.edb	MP:\LOG13

DB14	<ServerName> MBX DB 14	MP:\MBXDB14	Priv14.edb	MP:\LOG14
DB15	<ServerName> MBX DB 15	MP:\MBXDB15	Priv15.edb	MP:\LOG15
DB16	<ServerName> MBX DB 16	MP:\MBXDB16	Priv16.edb	MP:\LOG16
DB17	<ServerName> MBX DB 17	MP:\MBXDB17	Priv17.edb	MP:\LOG17
DB18	<ServerName> MBX DB 18	MP:\MBXDB18	Priv18.edb	MP:\LOG18
DB19	<ServerName> MBX DB 19	MP:\MBXDB19	Priv19.edb	MP:\LOG19
DB20	<ServerName> MBX DB 20	MP:\MBXDB20	Priv20.edb	MP:\LOG20
DB21	<ServerName> MBX DB 21	MP:\MBXDB21	Priv21.edb	MP:\LOG21
DB22	<ServerName> MBX DB 22	MP:\MBXDB22	Priv22.edb	MP:\LOG22
DB23	<ServerName> MBX DB 23	MP:\MBXDB23	Priv23.edb	MP:\LOG23
DB24	<ServerName> MBX DB 24	MP:\MBXDB24	Priv24.edb	MP:\LOG24
DB25	<ServerName> MBX DB 25	MP:\MBXDB25	Priv25.edb	MP:\LOG25
DB26	<ServerName> MBX DB 26	MP:\MBXDB26	Priv26.edb	MP:\LOG26
DB27	<ServerName> MBX DB 27	MP:\MBXDB27	Priv27.edb	MP:\LOG27
DB28	<ServerName> MBX DB 28	MP:\MBXDB28	Priv28.edb	MP:\LOG28
DB29	<ServerName> MBX DB 29	MP:\MBXDB29	Priv29.edb	MP:\LOG29
DB30	<ServerName> MBX DB 30	MP:\MBXDB30	Priv30.edb	MP:\LOG30
DB31	<ServerName> MBX DB 31	MP:\MBXDB31	Priv31.edb	MP:\LOG31
DB32	<ServerName> MBX DB 32	MP:\MBXDB32	Priv32.edb	MP:\LOG32
DB33	<ServerName> MBX DB 33	MP:\MBXDB33	Priv33.edb	MP:\LOG33
DB34	<ServerName> MBX DB 34	MP:\MBXDB34	Priv34.edb	MP:\LOG34

DB35	<ServerName> MBX DB 35	MP:\MBXDB35	Priv35.edb	MP:\LOG35
DB36	<ServerName> MBX DB 36	MP:\MBXDB36	Priv36.edb	MP:\LOG36
DB37	<ServerName> MBX DB 37	MP:\MBXDB37	Priv37.edb	MP:\LOG37
DB38	<ServerName> MBX DB 38	MP:\MBXDB38	Priv38.edb	MP:\LOG38
DB39	<ServerName> MBX DB 39	MP:\MBXDB39	Priv39.edb	MP:\LOG39
DB40	<ServerName> MBX DB 40	MP:\MBXDB40	Priv40.edb	MP:\LOG40
DB41	<ServerName> MBX DB 41	MP:\MBXDB41	Priv41.edb	MP:\LOG41
DB42	<ServerName> MBX DB 42	MP:\MBXDB42	Priv42.edb	MP:\LOG42
DB43	<ServerName> MBX DB 43	MP:\MBXDB43	Priv43.edb	MP:\LOG43
DB44	<ServerName> MBX DB 44	MP:\MBXDB44	Priv44.edb	MP:\LOG44
DB45	<ServerName> MBX DB 45	MP:\MBXDB45	Priv45.edb	MP:\LOG45
DB46	<ServerName> MBX DB 46	MP:\MBXDB46	Priv46.edb	MP:\LOG46
DB47	<ServerName> MBX DB 47	MP:\MBXDB47	Priv47.edb	MP:\LOG47
DB48	<ServerName> MBX DB 48	MP:\MBXDB48	Priv48.edb	MP:\LOG48
DB49	<ServerName> MBX DB 49	MP:\MBXDB49	Priv49.edb	MP:\LOG49
DB50	<ServerName> MBX DB 50	MP:\MBXDB50	Priv50.edb	MP:\LOG50

Database Configuration Appendix

The following table is an example configuration that can be applied to each database that is created or customized for each database on the server, depending on requirements.

Important:

The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Database configuration for Contoso

Parameter	Default value	Contoso value
Database Name	<ServerName> MBX DB xx	<ServerName> MBX DB xx

Offline Address Book	[None]	Default Offline Address List
Public Folder Database	<ServerName> PUB DB xx	<ServerName> PUB DB xx
Warning Quota	1991680 KB	1700000 KB
Send Quota	2097152 KB	1900000 KB
Send Receive Quota	2411520 KB	2090000 KB
Maintenance Schedule	Sun.1:00 AM-Sun.5:00 AM, Mon.1:00 AM-Mon.5:00 AM, Tue.1:00 AM-Tue.5:00 AM, Wed.1:00 AM-Wed.5:00 AM, Thu.1:00 AM-Thu.5:00 AM, Fri.1:00 AM-Fri.5:00 AM, Sat.1:00 AM-Sat.5:00 AM	"Sun.12:00 AM-Sun.4:00 AM", "Mon.12:00 AM-Mon.4:00 AM", "Tue.12:00 AM-Tue.4:00 AM", "Wed.12:00 AM-Wed.4:00 AM", "Thu.12:00 AM-Thu.4:00 AM", "Fri.12:00 AM-Fri.4:00 AM", "Sat.12:00 AM-Sat.4:00 AM"
Quota Notification Schedule	Sun.1:00 AM-Sun.1:15 AM, Mon.1:00 AM-Mon.1:15 AM, Tue.1:00 AM-Tue.1:15 AM, Wed.1:00 AM-Wed.1:15 AM, Thu.1:00 AM-Thu.1:15 AM, Fri.1:00 AM-Fri.1:15 AM, Sat.1:00 AM-Sat.1:15 AM	"Sun.12:00 AM-Sun.12:15 AM", "Mon.12:00 AM-Mon.12:15 AM", "Tue.12:00 AM-Tue.12:15 AM", "Wed.12:00 AM-Wed.12: 15 AM", "Thu.12:00 AM-Thu.12:15 AM", "Fri.12:00 AM-Fri.12:15 AM", "Sat.12:00 AM-Sat.12:15 AM"
Mailbox Retention	30.00:00:00	30.00:00:00
Deleted Item Retention	14.00:00:00	14.00:00:00
Keep Deleted Items Until Backup	False	True

1.2.2.11.4 Installation Guide Template - DAG Member

Installation Guide Template - DAG Member

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-06*

This topic provides you with an installation guide template that you can use as a starting point for formally documenting your organization's server build procedures for Microsoft Exchange Server 2010 servers that will have the Mailbox server role installed in a database availability group (DAG) configuration.

The template includes the following key sections:

- Executive Summary
- Server Configuration
- Verification Steps
- Exchange Server Role Installation
- Exchange Server Role Configuration
- Appendix: Server Configuration

For purposes of providing an example, the template uses the fictitious company name of Contoso. Also, you can download this template, along with templates for other server roles, as a download package in .zip file format at Microsoft Exchange Server 2010 Install Guide Templates (http://go.microsoft.com/fwlink/?LinkID=187961).

Executive Summary

The purpose of this document is to explain the installation and configurations necessary to install the Exchange 2010 Mailbox server role and create a database availability group (DAG) on the Windows Server 2008 platform.

Business Justification

By having an installation guide, Contoso will be able to ensure standardization across the enterprise, reducing total cost of ownership (TCO), and easing troubleshooting steps.

Scope

The scope of this document is limited to installation of an Exchange 2010 Mailbox server and creation of a database availability group (DAG) for Contoso on the x64 version of the Windows Server 2008 (SP2 or R2) operating system.

Prerequisites

The administrator should have working knowledge of Windows Server 2008 concepts, Exchange 2010 concepts, the Exchange Management Console and Exchange Management Shell, the command line, and various system utilities. This document does not elaborate on the details of any system utility except as necessary to complete the tasks within.

In addition, before implementing the server role, the administrator should review the Overview of the Mailbox Server Role topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187526).

Assumptions

This document assumes that Windows Server 2008 x64 Edition is installed on the intended Client Access server per company baseline regulations which include the latest approved service pack and hotfixes. In addition, the following system prerequisites have been installed:

- Microsoft .NET Framework 3.5 SP1 and the update for .NET Framework 3.5 SP1 For more information, see Microsoft Knowledge Base article 959209, An update for the .NET Framework 3.5 Service Pack 1 is available (http://go.microsoft.com/fwlink/?linkid=3052&kbid=959209).
- Windows Management Framework (Windows Remote Management 2.0 and Windows PowerShell 2.0).

This document assumes that forest and domain preparation steps have been performed as described in the Prepare Active Directory and Domains topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187262).

This document assumes that the account you will be using for the Exchange tasks has been delegated the Server Management management role, as described in the Server Management topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187265).

This document also assumes that both Exchange 2010 Windows Server 2008 and Windows Server 2008 will be secured following the best practices found in the Windows Server 2008 Security Guide (http://go.microsoft.com/fwlink/?LinkId=122593).

Important:

The procedures within this document should be followed sequentially. If changes are

made out of sequence, unexpected results may occur.

Server Configuration

The following media are required for this section.

- Windows Server 2008 installation files

The following procedures are in this section:

1. Additional Software Verification
2. Network Interfaces Configuration - MAPI Network
3. Network Interfaces Configuration - Replication Network
4. Drive Configuration
5. Windows Server 2008 Hotfix Installation
6. Domain Membership Configuration
7. Local Administrators Verification
8. Local Administrator Account Password Reset
9. Debugging Tools Installation
10. Page File Modifications
11. Drive Permissions

Additional Software Verification

1. Verify that Remote Desktop is enabled.
2. As an optional process, install Microsoft Network Monitor (http://go.microsoft.com/fwlink/?LinkId=86611).

Network Interfaces Configuration - MAPI Network

Make sure that the IP address scheme for the MAPI network is not using the same subnet or network as any replication network adapters. The MAPI network must use the subnet or network that is used to route network traffic within your intranet.

Teaming can be used on the MAPI network in redundancy mode, but it cannot be used in load balancing mode. However, even when using teaming, this does not prevent the network itself from being a single point of failure. In addition, if problems or issues occur that are related to teaming, Microsoft Customer Support Services may require you to disable teaming. If this resolves the issue, you must seek assistance from the hardware manufacturer. For more information about teaming, see Microsoft Knowledge Base article 254101, Network adapter teaming and server clustering (http://go.microsoft.com/fwlink/?linkid=3052&kbid=254101).

1. Connect to what will become the first member of the DAG through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start** > **Control Panel**, and then double-click **Network and Sharing Center**.
3. Click **Manage network connections**.
4. Locate the connection for the MAPI network, and then rename the connection with an appropriate name.
5. Right-click the connection and then select **Properties**.
6. In the network connection's properties on the **General** tab, make sure that the **Client for Microsoft Networks**, **Internet Protocol Version 4 (TCP/IPv4)** and **File and Printer Sharing for Microsoft Networks** check boxes are selected in the **This connection uses the following items** area.
7. Click **Internet Protocol Version 4 (TCP/IPv4)**, and then click **Properties**.
8. In **Internet Protocol Version 4 (TCP/IPv4) Properties**, click **Advanced**.
9. In **Advanced TCP/IP Settings**, verify the following information on the **DNS** tab:
   9.a. Make sure that all the required addresses are listed in the **DNS server addresses, in order of use** area.
   9.b. Make sure that the correct suffixes are listed in the **Append these DNS suffixes (in order)** area.

10. On the **WINS** tab, make sure that **Disable NetBIOS over TCP/IP** is not selected.
11. Click **OK** two times to save the changes, and then click **Close** to exit **Properties**.
12. If you are using Internet Protocol Version 6 (TCP/IPv6), configure the IPv6 settings according to your organization's network standards.

Network Interfaces Configuration - Replication Network

For any optional replication networks, make sure that the IP address scheme is not using the same subnet or network as the MAPI network or any other replication network adapters.

1. Connect to what will become the first member of the DAG through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start** > **Control Panel**, and then double-click **Network and Sharing Center**.
3. Click **Manage network connections**.
4. Locate the connection for the replication network, and then rename the connection with an appropriate name.
5. Right-click the connection, and then click **Properties**.
6. In the network connection properties, on the **General** tab, verify that the **Internet Protocol Version 4 (TCP/IPv4)** check box is selected and that **File and Printer Sharing for Microsoft Networks** and **Client for Microsoft Networks** are not selected in the **This connection uses the following items** area.
7. Click **Internet Protocol Version 4 (TCP/IPv4)**, and then click **Properties**.
8. In **Internet Protocol Version 4 (TCP/IPv4) Properties**, click **Advanced**.
9. On the **DNS** tab, verify the following information in **Advanced TCP/IP Settings**:
   9.a. Make sure that addresses are not listed in the **DNS server addresses, in order of use** area if this is a private network.
   9.b. Make sure that the **Register this connection's addresses in DNS** check box is cleared.
10. On the **WINS** tab, make sure that **Disable NetBIOS over TCP/IP** is not selected.
11. Click **OK** two times to save the changes, and then click **Close** to exit **Properties**.
12. If you are using Internet Protocol Version 6 (TCP/IPv6), configure the IPv6 settings according to your organization's network standards.

Drive Configuration

1. Connect to the server through Remote Desktop and log on with an account that has local administrative access.
2. Click **Start** > **Administrative Tools**, and select **Computer Management**.
3. Expand Storage and click **Disk Management**.
4. Open the Disk Management Microsoft Management Console (MMC) and format, rename, and assign the appropriate **Drive Letters** so that the volumes and DVD drive match the appropriate server configuration. Refer to the Database Log/LUN Appendix at the end of this document for the actual drive configuration that should be used.

Drive configuration

LUN	Drive letter	Usage
1	C	Operating system, Exchange binaries, and tracking logs
2	E	Exchange databases
4	L	Exchange transaction

		logs
5-x	--	Additional drives for databases and logs
6	Z	DVD drive

Windows Server 2008 Hotfix Installation

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Obtain the latest hotfixes approved by your company for your version of Windows Server 2008 x64 (SP2 or R2) and copy them to the server. Microsoft strongly recommends the hotfix documented in Microsoft Knowledge Base article 2550886 - A transient communication failure causes a Windows Server 2008 R2 failover cluster to stop working. This hotfix resolves a potential race condition and cluster database deadlock issue that can occur when a Windows Failover cluster encounters a transient communication failure. If this situation occurs, it causes the cluster database to hang, resulting in quorum loss in the failover cluster and the dismounting of all databases within the DAG.
3. Launch the hotfix setup via one of two ways:
   3.a.Double-click the file and follow the GUI instructions.
   3.b.Perform a silent installation using the following command from an administrative command prompt:

```
<hotfix>.msu /quiet /norestart
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

> **Note:**
> These dialog boxes will not appear in environments that have not deployed the Windows Security templates.

5. Wait for all file copies to complete, and then restart the server. You can use the **Processes** tab in Windows Task Manager to monitor the hotfix installation progress. When the wusa.exe process has exited, the hotfix installation is complete.

Domain Membership Configuration

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start,** right-click **My Computer**, and then select **Properties**.
3. Under the **Computer Name, domain, and workgroup** settings, click **Change Settings**.
4. Click **Change**.
5. Choose the **Domain** option button, and then enter the appropriate domain name.
6. Enter the appropriate credentials.
7. Click **OK** and **OK**.
8. Click **OK** to close **System Properties**.
9. Restart the server.

Local Administrators Verification

1. Connect to the server through Remote Desktop and then log on with an account that has been delegated local administrative access.
2. Verify (or add if not already there) that the Domain Admins account and the user account that will perform the Exchange installation are members of the local Administrators group on this server.
3. Verify that your user account is a member of a group which is a member of the local Administrators group on the Windows Server 2008 server. If it is not, use an account that is a member of the local Administrators group before

continuing.

Local Administrator Account Password Reset

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Manage**.
3. Expand the nodes to find **Configuration\Local Users and Groups\Users**.
4. Right-click **Administrator**, and then select **Set Password**. Change the password so that it meets strong complexity requirements.

Debugging Tools Installation

This section describes several useful tools that aid administrators in Exchange administration and in troubleshooting support issues.

Debugging Tools for Windows allow administrators to debug processes that are affecting service and determine root cause.

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Download and install the latest 64-bit Debugging Tools from Install Debugging Tools for Windows 64-bit Version (http://go.microsoft.com/fwlink/?LinkID=123594).

Page File Modifications

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Startup and Recovery**, click **Settings**.
   4.a. Under **Write Debugging Information**, select **Kernel Memory Dump** from the memory dump drop-down list.
   4.b. Click **OK**.
5. Under **Performance**, click **Settings**.
6. Click the **Advanced** tab.
7. Under **Virtual Memory**, click **Change**.
8. On servers that have a dedicated page file drive, follow these steps:
   8.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   8.b. For the C: drive, set the **Initial Size (MB)** value to a minimum of 200 MB. (Windows requires between 150 MB and 2 GB page file space, depending on server load and the amount of physical RAM that is available for page file space on the boot volume when Windows is configured for a kernel memory dump. Therefore, you may be required to increase the size.)
   8.c. For the C: drive, set the **Maximum Size (MB)** value to that of the **Initial Size**.
   8.d. In the **Drive** list, select the page file drive (for example, the P: drive), and then click **Custom size**.
   8.e. In the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of RAM times 1.5.
      If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.
   8.f. In the **Maximum Size (MB)** box, type the same amount that you typed in the **Initial Size** box.
   8.g. Delete all other page files.
   8.h. Click **OK**.
9. On servers that do not have a dedicated page file drive, follow these steps:
   9.a. In the **Drive** list, click **C:**, and then click **Custom size**.
   9.b. For the C: drive, in the **Initial Size (MB)** box, type the result of one of the following calculations:
      If the server has less than 8 GB of RAM, multiply the amount of

RAM times 1.5.
If the server has 8 GB of RAM or more, add the amount of RAM plus 10 MB.

9.c.Delete all other page files.
9.d.Click **OK**.
10.Click **OK** two times to close the **System Properties** dialog box.
11.Click **No** if prompted to restart the system.

Note:
For more information about page file recommendations, see the following Microsoft Knowledge Base articles: How to determine the appropriate page file size for 64-bit versions of Windows Server 2003 or Windows XP (http://go.microsoft.com/fwlink/?linkid=3052&kbid=889654); and Overview of memory dump file options for Windows Vista, Windows Server 2008, Windows Server 2003, Windows XP, and Windows 2000 (http://go.microsoft.com/fwlink/?linkid=3052&kbid=254649).

Drive Permissions

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Click **Start** and select **Computer**.
3. Right-click **D Drive** and select **Properties**.
4. Click the **Security** tab.
5. Click **Edit**.
6. Click **Add**, and then select the local server from **Locations**.
7. Grant the following rights as outlined in the following table.

Drive permissions

Account	Permissions
Administrators	Full Control
SYSTEM	Full Control
Authenticated Users	Read and Execute, List, Read
CREATOR OWNER	Full Control

8. Click the **Advanced** button.
9. Select the **CREATOR OWNER** permission entry, and then click **View/Edit**.
10. Select **Subfolders and Files Only** from the drop-down list.
11. Click **OK** two times.
12. Click **OK** to close the drive properties.
13. Repeat steps 3-12 for each additional drive (other than the C drive).

Verification Steps

The following procedures are in this section:

1. Organizational Unit Verification
2. Active Directory Site Verification
3. Domain Controller Diagnostics Verification
4. Exchange Best Practices Analyzer Verification

Important:
The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Organizational Unit Verification

Submit a change request to the appropriate operations group and have the computer object moved to the appropriate organizational unit (OU).

Active Directory Site Verification

1. Connect to the server through Remote Desktop, and then log on with an

account that has been delegated local administrative access.
2. Open a Command Prompt window.
3. Verify that the server is in the correct domain and Active Directory site. At the command line, type the following:

```
NLTEST /server:%COMPUTERNAME% /dsgetsite
```

4. The name of the Active Directory site to which the server belongs will be displayed. If the server is not in the correct Active Directory site, submit a change request to the appropriate operations group and have the server moved to the appropriate Active Directory site.

Domain Controller Diagnostics Verification

1. Connect to the server through Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open a Command Prompt window, and then change paths to the C drive.
3. Run the following command:

```
dcdiag /s:<Domain Controller> /f:c:\dcdiag.log
```

Note:
Change **<domain Controller>** to a domain controller contained within the same Active Directory site as the Exchange server.

4. Review the output of **C:\dcdiag.log** file, and verify that there are no connectivity issues with the local domain controller.
5. Repeat steps 3 and 4 for each domain controller in the local Active Directory site.

Note:
Domain Controller Diagnostics (DCDiag) is a Windows support tool that tests network connectivity and DNS resolution for domain controllers. If the account being used does not have administrative privileges, several tests under the **Doing primary tests** heading may not pass. These tests can be ignored if the connectivity tests pass. In addition, the log file may report that some service validation tests did not pass. These messages can be ignored if the services do not exist on the domain controller.

Exchange Best Practices Analyzer Verification

The Microsoft Exchange Analyzers help administrators troubleshoot various operational support issues. Connect to a server in the environment that either has the Exchange 2010 SP1 (or later) Management tools installed through Remote Desktop and log on with an account that has local administrative access.

1. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010**, and then select **Exchange Management Console**.
2. Open the **Toolbox** node.
3. Double-click **Best Practices Analyzer**.
4. Check and apply any updates for the Best Practices Analyzer engine.
5. Provide the appropriate information to connect to Active Directory, and then click **Connect to the Active Directory server**.
6. In the **Start a New Best Practices Scan**, select **Health Check**, and then click **Start Scanning**.
7. Review the report, and take action on any errors or warnings that are reported by following the resolution articles that are provided within the Best Practices Analyzer.

Exchange Server Role Installation

The following media are required for this section.

- Microsoft Exchange Server 2010 installation files

The following procedures are in this section:

1. Exchange 2010 Prerequisites Installation for:
   - Windows Server 2008 SP2

   -or-

   - Windows Server 2008 R2
2. Exchange 2010 Installation
3. Exchange 2010 Update Rollup Installation
4. Product Key Configuration
5. Exchange Search Configuration
6. System Performance Verification
7. Test Mailbox Creation

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Exchange 2010 Prerequisites Installation for Windows Server 2008 SP2

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Open an administrative command prompt window.
3. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
4. Open an elevated command prompt, navigate to the \Setup\ServerRoles\Common folder on the Exchange 2010 installation media and use the following command to install the necessary operating system components:

```
ServerManagerCmd -ip Exchange-MBX.xml -Restart
```

Exchange 2010 Prerequisites Installation for Windows Server 2008 R2

1. Connect to the server via Remote Desktop and log on with an account that has local administrative access.
2. Install the Microsoft Filter Pack. For details, see 2007 Office System Converter: Microsoft Filter Pack (http://go.microsoft.com/fwlink/?linkid=137042).
3. On the Start Menu, navigate to **All Programs** > **Accessories > Windows PowerShell**. Open an elevated Windows PowerShell console, and run the following command:

```
Import-Module ServerManager
```

4. Use the **Add-WindowsFeature** cmdlet to install the necessary operating system components:

```
Add-WindowsFeature NET-Framework,RSAT-ADDS,Web-Server,Web-Basic-Auth,W
```

Exchange 2010 Installation

This document uses the command-line method for installing the Exchange 2010 server roles; however, you can also use a GUI called the Setup Wizard. For more information about how to use the Setup Wizard to install an Exchange 2010 server role, see the Perform a Custom Exchange 2010 Installation topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187220).

Important:

If this is the first Mailbox server role being installed into an organization that does not contain any version of Microsoft Exchange, and you have client computers running Microsoft Office Outlook 2003, you must also specify the optional */EnableLegacyOutlook* setup parameter. In addition, if this is the first Exchange 2010 server role being installed into an environment that does not contain any version of Microsoft Exchange, you must also specify the */OrganizationName* setup parameter.

1. Connect to the server through Remote Desktop and log on with an account

that has local administrative access and was delegated the Server Management or Delegated Setup role if the server was pre-created.

2. Follow the procedure detailed in the Install Exchange 2010 in Unattended Mode topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187229). For example, the following command installs the Mailbox server role , provides a custom database name, database path, and transaction log file location.

```
setup.com /r:MB /mdbName "<DAGName> MBX Store 1" /dbfilepath e:\mdb1\p
```

3. Do not restart the server, even if required.

Exchange Server 2010 Update Rollup Installation

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Obtain the latest company approved rollup, and then copy it to the server.
3. Launch the Windows Installer patch (the MSP file) setup via one of two ways:
   3.a. Double-click the MSP file, and then follow the GUI instructions.
   3.b. Perform a silent installation using the following command from an administrative command prompt:

```
msiexec /i <Path and filename of MSP file> /q
```

4. Click **Yes** for any **Digital Signature not Found** dialog boxes that may appear.

Note:
These dialog boxes will appear only in environments that have deployed the Windows Security templates.

Product Key Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Follow the procedure documented in the Enter Product Key topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187234).

Exchange Search Configuration

1. Connect to the server via Remote Desktop, and then log on with an account that has been delegated local administrative access.
2. Follow the procedure documented in the Register Filter Pack IFilters with Exchange 2010 topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187516).
3. Optional: If you want the ability to search PDF files, install the Adobe PDF iFilter (http://www.adobe.com/support/downloads/detail.jsp?ftpID=4025) and follow the Configuring PDF iFilter for MS Exchange Server 2007 (http://www.adobe.com/special/acrobat/configuring_pdf_ifilter_for_ms_exchange_server_2007.pdf) documentation.

Note:
The third-party Web site information in this topic is provided to help you find the technical information you need. The URLs are subject to change without notice.

System Performance Verification

By default, Exchange 2010 optimizes the server's processor scheduling management for background services.

1. Connect to the server through Remote Desktop, and then log on with an account that has local administrative access.
2. Click **Start**, right-click **Computer**, and then select **Properties**.
3. Select the **Advanced System Settings**.
4. Under **Performance**, click **Settings**.
   4.a. Click the **Advanced** tab.
   4.b. Verify that **Processor Scheduling** is set to **Background Services**.

5. Click **OK**.

Test Mailbox Creation

Several of the diagnostics tasks used to monitor Exchange require that you create test mailboxes on the mailbox servers.

1. Connect to the Exchange 2010 Mailbox server through Remote Desktop, and then log on with an account that has been delegated local administrative access and was also delegated the Server Management role (or higher).
2. Click **Start** > **All Programs** > **Microsoft Exchange Server 2010** and then select **Exchange Management Shell**.
3. Change the directory path to **<***Exchange Server Install Path***>\Scripts**.
4. Type **New-TestCasConnectivityUser.ps1** and press **Enter**.
5. Enter a temporary password, and then follow the prompts to create the test mailboxes.

Exchange Server Role Configuration

The following procedures are in this section:

1. Database Availability Group Creation
2. Database Availability Group Member Server Addition
3. Database Availability Group Network Configuration
4. First Database Configuration
5. Public Folder Database Configuration
6. Mailbox Database Copy Addition
7. Records Management Configuration
8. Message Tracking Server Configuration
9. Additional Databases

Important:

The procedures within this document should be followed sequentially. If changes are made out of sequence, unexpected results may occur.

Database Availability Group Creation

If the DAG has been created, you can skip this section.

1. Make sure that there are no pending reboots for the server before adding it to a DAG.
2. Launch the Exchange Management Shell with an account that has been delegated the Organization Management role.
3. In environments where computer account creation is restricted or where computer accounts are created in a container other than the default computers container, you must pre-stage the cluster network object (CNO) and then provision the CNO by assigning permissions to it. Follow the procedures documented in the Pre-stage the Cluster Network Object for a Database Availability Group topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187665).
4. Create a database availability group by following the procedures documented in the Create a Database Availability Group topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187666).
5. Configure the database availability group properties such as the witness settings, replication port, compression, and encryption by following the procedures documented in the Configure Database Availability Group Properties topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187667).

Database Availability Group Member Server Addition

1. Launch the Exchange Management Shell with an account that has been delegated the Organization Management role.
2. Add the mailbox server to the database availability group by following the procedures documented in the Manage Database Availability Group Membership topic in the Exchange Server 2010 Library (http://

go.microsoft.com/fwlink/?LinkId=187669).

Database Availability Group Network Configuration

1. Launch the Exchange Management Shell with an account that has been delegated the Organization Management role.
2. When the Windows Failover Cluster is formed it will create a cluster-managed network for each subnet detected within the failover cluster. When the DAG is formed, the initial DAG network configuration is based on the enumeration of the cluster networks. If the DAG will span subnets, the recommendation is to collapse the DAG networks into a single MAPI network and a single replication network. You can do this by adding the additional subnets to the appropriate DAG networks and deleting unused networks. For example, consider the following environment:

   Sites
   - Two Active Directory sites: Exchange-1 and Exchange-2

   DAG Members
   - DAG members MBX-1 and MBX-2 located in Exchange-1
   - DAG members MBX-3 and MBX-4 located in Exchange-2

   MAPI Networks
   - MBX-1 and MBX-2 have MAPI networks on 192.168.0.0/24
   - MBX-3 and MBX-4 have MAPI networks on 192.168.1.0/24

   Replication Networks
   - MBX-1 and MBX-2 have replication networks on 10.0.0.0/24
   - MBX-3 and MBX-4 have replication networks on 10.0.1.0/24

   The database availability group networks are configured as follows:

Network	Subnets
DAGNetwork01	192.168.0.0/24
DAGNetwork02	10.0.0.0/24
DAGNetwork03	192.168.1.0/24
DAGNetwork04	10.0.1.0/24

3. To collapse these networks, run the following commands.

```
Set-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork01 -Subnets 1
Set-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork02 -Subnets 1
Remove-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork03
Remove-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork04
```

4. To rename the networks according to their behavior, run the following commands.

```
Set-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork01 -Name MAPI
Set-DatabaseAvailabilityGroupNetwork <DAGName>\DAGNetwork02 -Name Repl
```

5. If both MAPI and replication networks are deployed, run the following command to enable replication and seeding traffic on the replication network (unless it is unavailable).

```
Set-DatabaseAvailabilityGroupNetwork <DAGName\MAPINetworkName> -Replic
```

First Database Configuration

If you provided the */mdbname*, */dbfilepath*, and */logfolderpath* parameters when you installed the mailbox server, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

Important:

The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

First database configuration at Contoso

Database parameter	Old	New example
Name	Mailbox Database <GUID>	<DAGName> MBX Store 1
Log Path	%Program Files% \Microsoft\Exchange Server\v14\Mailbox \Mailbox Database <GUID>	E:\LOG01
Path and Filename	%Program Files% \Microsoft\Exchange Server\v14\Mailbox \Mailbox Database <GUID>\Mailbox database <GUID>.edb	E:\MDB01\Priv01.edb

2. To dismount the database, run the following command:

```
Dismount-Database "Mailbox Database <GUID>"
```

3. To change the mailbox database name from "Mailbox Database <GUID>" to "<DAGName> MBX Store 1", run the following command:

```
Set-MailboxDatabase "<Old DB Name>" -Name "<New DB Name>"
```

4. To change the location of the database's transaction logs and the location of the database file, run the following command:

```
Move-DatabasePath "<Database Name>" -LogFolderPath:<New Log Location>
```

5. To mount the database, run the following command:

```
Mount-Database "<New DB Name>"
```

6. To add a database copy for a specific mailbox database, follow the procedures documented in the Add a Mailbox Database Copy topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187673).

Public Folder Database Configuration

If a public folder database was created during the installation of the Mailbox server role, the public folder database will be placed in the default location. If there is no public folder database, you can skip this section.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.

Important:

The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Public folder database configuration at Contoso

Database parameter	Old	New example
Name	Public Folder Database <GUID>	<DAGName> PUB Store 2
Log Path	%Program Files% \Microsoft\Exchange Server\Mailbox\Public Folder Database <GUID>	E:\LOG02
Path and Filename	%Program Files% \Microsoft\Exchange Server\Mailbox\Public Folder Database <GUID> \ Public Folder database <GUID>.edb	E:\MDB02\Pub02.edb

2. To dismount the database, run the following command:

```
Dismount-Database "Public Folder Database <GUID>"
```

3. To change the mailbox database name from "Mailbox Database <GUID>" to "<ServerName> MBX Store 1", run the following command:

```
Set-PublicFolderDatabase "<Old DB Name>" -Name "<New DB Name>"
```

4. To change the location of the database's transaction logs and the location of the database file, run the following command:

```
Move-DatabasePath "<Database Name>" -LogFolderPath:<New Log Location>
```

5. To mount the database, run the following command:

```
Mount-Database "<New DB Name>"
```

Mailbox Database Copy Addition

If mailbox databases already exist within the DAG, follow these steps to add mailbox database copies to the mailbox server.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Make sure that the directory and path structure exists on the target server for the database in question. Then, to add a database copy for a specific mailbox database, follow the Exchange Management Shell procedures outlined in the Add a Mailbox Database Copy topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187673).

Records Management Configuration

You can skip this section if the default schedule for the Managed Folder Assistant to apply messaging records management (MRM) settings does not need to be changed.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. To enable the Managed Folder Assistant, run the following command:

```
Set-MailboxServer <MailboxServerName> -ManagedFolderAssistantSchedule
```

Note:

Refer to the "Records management configuration for Contoso" table in the Server Configuration Appendix at the end of this document for the information that you need for the commands.

Message Tracking Server Configuration

You can skip this section if the default message tracking parameters are appropriate for the environment.

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. To configure message tracking settings, run the following command:

```
Set-MailboxServer <MailboxServerName> -MessageTrackingLogPath <LogPath
```

Note:

Refer to the "Message tracking configuration for Contoso" table in the Server Configuration Appendix at the end of this document for the information that you need for the commands.

Additional Databases

1. Launch the Exchange Management Shell with an account that has been delegated the Server Management role.
2. Use the appropriate table in the Database/Log LUN Appendix and Database Configuration Appendix at the end of this document for information that you need for the commands.
3. To create the database, run the following command:

```
New-MailboxDatabase -Name "<DB Name>" -LogFolderPath <Transaction Log
```

4. To mount the database, run the following command:

```
Mount-Database "<Database Name>"
```

5. To add replicas for this mailbox database, follow the procedures outlined in the Add a Mailbox Database Copy topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187673) after ensuring that the directory and path structure exists on the target server for the database in question.
6. Repeat steps 3, 4, and 5 for each database that needs to be created.

Appendix: Server Configuration

The following information is included in this section:

- Records Management Configuration
- Message Tracking Configuration
- Database Log LUN Appendix
- Two LUNs per Database/LUN Layout
- One LUN per Database/LUN Layout
- Database Configuration Appendix

Records Management Configuration

The following table is an example configuration that can be applied to the Mailbox server, depending on requirements.

Important:
The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Records management configuration for Contoso

Parameter	Default value	Contoso value
Server Name	<ServerName>	<ServerName>
Managed Folder Assistant Schedule	Sun.1:00 AM-Sun.9:00 AM, Mon.1:00 AM-Mon.9:00 AM, Tue.1:00 AM-Tue.9:00 AM, Wed.1:00 AM-Wed.9:00 AM, Thu.1:00 AM-Thu.9:00 AM, Fri.1:00 AM-Fri. 9:00 AM, Sat.1:00 AM-Sat.9:00 AM	"Sun.6:00 PM-Sun.7:45 PM", "Mon.6:00 PM-Mon.7:45 PM", "Tue.6:00 PM-Tue.7:45 PM", "Wed.6:00 PM-Wed.7:45 PM", "Thu.6:00 PM-Thu.7:45 PM", "Fri.6:00 PM-Fri.7:45 PM", "Sat.6:00 PM-Sat.7:45 PM"

Message Tracking Configuration

The following table is an example configuration that can be applied to the Mailbox server, depending on requirements.

Important:
The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Message tracking configuration for Contoso

Parameter	Default value	Example value
Server Name	<ServerName>	<ServerName>
Message Tracking Log Path	<Exchange Install Path>	L:\exchsrvr\MessageTracking

	\TransportRoles\Logs \MessageTracking	
Message Tracking Log Enabled	True	True
Message Tracking Log Max Age	30.00:00:00	45.00:00:00
Message Tracking Log Max Directory Size	1 GB	20 GB
Message Tracking Log Max File Size	10 MB	10 MB
Message Tracking Log Subject Logging Enabled	True	True

Database / Log LUN Appendix

With mailbox resiliency, you do not have to perform daily full backups as the mailbox database copy provides the first line of defense against corruption and data loss. Therefore, there are two approaches to how backups can be performed in an environment enabled for mailbox resiliency.

- Use an Exchange-aware, Volume ShadowCopy Service (VSS) application to perform backups.
- Use Exchange Native Data Protection features as your backup methodology. For more information about Exchange Native Data Protection, see the Understanding Backup, Restore and Disaster Recovery topic in the Exchange Server 2010 Library (http://go.microsoft.com/fwlink/?LinkId=187541).

As a result of the backup methodology selected, the LUN layout has to be altered. Exchange 2010 supports the following LUN layout architectures:

- **One LUN per database** A single LUN per database architecture means that both the database and its corresponding log files are placed on the same LUN. To deploy this architecture, you must have two or more copies of your databases, and you must not be using a hardware-based VSS solution.
- **Two LUNs per database** With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend upon your backup strategy. If your recovery time objective (RTO) is small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. This approach will exceed the number of available drive letters; therefore, volume mount points must be used.
- **Two LUNs per backup set** A backup set is the number of databases fully backed up in a night. A solution that performs a full backup on 1/7th of the databases nightly (for example, using a weekly or bimonthly full backup with daily incremental or differential backups) can reduce complexity by placing all of the databases to be backed up on the same log and database LUN. This approach can reduce the number of LUNs on the server.

Two LUNs per Database / LUN Layout

Exchange 2010 uses VSS included in Windows Server 2008 to take volume shadow copies of Exchange 2010 databases and transaction log files. For basic information about VSS, including both clone and snapshot techniques, review the white paper, Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003 (http://go.microsoft.com/fwlink/?LinkId=122556).

Exchange 2010 enables you to make software-based VSS snapshots of both the active and passive database copies. Taking a VSS snapshot of the passive copy offloads the disk I/O from the active LUN during both the checksum integrity (ESEUTIL), and subsequent copy to tape or disk.

Creating two LUNs (log and database) for a database was the standard best practice for Exchange 2003. With Exchange 2010, in the maximum case of 100 databases, the number of LUNs you provision will depend on your backup strategy. If your recovery time objective (RTO) is very small, or if you use VSS clones for fast recovery, it may be best to place each database on its own transaction log LUN and database LUN. Depending on the number of LUNs required, volume mount points may need to be used.

Some benefits of this strategy include the following:

- Enables hardware-based VSS at a database level, providing single database backup and restore.
- Flexibility to isolate the performance between databases when not sharing spindles between LUNs.
- Increased reliability: A capacity or corruption problem on a single LUN will only affect one database.
- This is also the recommended strategy for databases that do not participate in mailbox resiliency.

Some concerns with this strategy include the following:

- 100 databases using mailbox resiliency could require 400 LUNs which would exceed some storage array maximums. 100 databases without mailbox resiliency could require 200 LUNs which would exceed some storage array maximums.
- A separate LUN for each database causes more LUNs per server increasing the administrative costs and complexity.

Note:

In the following table, the reference to MP stands for Mount Point. X and Y may refer to unique databases.

LUN design approach: Two LUNs per database

DB	Database name	Database location	Database file name	Transaction log location
Anchor LUN	--	E:\	--	L:\
DBx	<DAGName> MBX DB x	MP:\MDB0x	Priv0x.edb	MP:\LOG0x
DBy	<DAGName> MBX DB y	MP:\MDB0y	Priv0y.edb	MP:\LOG0y
…	…	…	…	…

One LUN per Database / LUN Layout

Single LUN per database architecture means that both the database and its corresponding log files are placed on the same LUN. To deploy this architecture, you must have two or more copies, and you must not be using a hardware-based VSS solution.

Some of the benefits of this strategy include:

- Simplifies storage administration with fewer LUNs to manage.
- Reduces (potentially) the number of backup jobs.
- Provides flexibility to isolate the performance between databases when not sharing spindles between LUNs.

A concern with this strategy is that it limits the ability to perform hardware-based VSS backup and restore procedures (for example, clone snapshots). For VSS details, review the white paper, Best Practices for Using Volume Shadow Copy Service with Exchange Server 2003 (http://go.microsoft.com/fwlink/?LinkId=122556).

Note:
In the following table, the reference to MP stands for Mount Point. X and Y refer to unique databases.

LUN design approach: One LUN per database

DB	Database name	Database location	Database file name
Anchor LUN	--	E:\	--
DBx	<DAGName> MBX Store X	MP:\ \MDBx \LOGx	PrivX.edb
DBy	<DAGName> MBX Store Y	MP:\ \MDBy \LOGy	PrivY.edb
…	…	…	…

Database Configuration Appendix

The following table is an example configuration that can either be applied to each database that is created or customized for each database on the server depending on requirements.

Important:
The values in the following table are example values, not recommended values. Revise these values to reflect the actual values for your organization.

Database configuration for Contoso

Parameter	Default value	Contoso value
Database Name	Mailbox Database <GUID>	<DAGName> MBX DB xx
Offline Address Book	[None]	Default Offline Address List
Public Folder Database	Public Folder Database <GUID>	<ServerName> PUB DB xx
Warning Quota	1991680 KB	1700000 KB
Send Quota	2097152 KB	1900000 KB
Send Receive Quota	2411520 KB	2090000 KB
Maintenance Schedule	Sun.1:00 AM-Sun.5:00 AM, Mon.1:00 AM-Mon.5:00 AM, Tue.1:00 AM-Tue.5:00 AM, Wed.1:00 AM-Wed.5:00 AM, Thu.1:00 AM-Thu.5:00 AM, Fri.1:00 AM-Fri.5:00 AM, Sat.1:00 AM-Sat.5:00 AM	"Sun.12:00 AM-Sun.4:00 AM", "Mon.12:00 AM-Mon.4:00 AM", "Tue.12:00 AM-Tue.4:00 AM", "Wed.12:00 AM-Wed.4:00 AM", "Thu.12:00 AM-Thu.4:00 AM", "Fri.12:00 AM-Fri.4:00 AM", "Sat.12:00 AM-Sat.4:00 AM"
Quota Notification Schedule	Sun.1:00 AM-Sun.1:15 AM, Mon.1:00 AM-Mon.1:15 AM,	"Sun.12:00 AM-Sun.12:15 AM", "Mon.12:00 AM-

	Tue.1:00 AM-Tue.1:15 AM, Wed.1:00 AM-Wed.1:15 AM, Thu.1:00 AM-Thu.1:15 AM, Fri.1:00 AM-Fri.1:15 AM, Sat.1:00 AM-Sat.1:15 AM	Mon.12:15 AM", "Tue.12:00 AM-Tue.12:15 AM", "Wed.12:00 AM-Wed.12: 15 AM", "Thu.12:00 AM-Thu.12:15 AM", "Fri.12:00 AM-Fri.12:15 AM", "Sat.12:00 AM-Sat.12:15 AM"
Mailbox Retention	30.00:00:00	30.00:00:00
Deleted Item Retention	14.00:00:00	14.00:00:00
Keep Deleted Items Until Backup	False	True

1.2.2.12 Exchange 2010 Servicing

Exchange 2010 Servicing

Exchange Server 2010 > Planning and Deployment > Deploying Exchange 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-04-06*

This topic describes the servicing strategy for Microsoft Exchange Server 2010, discusses the release schedule and distribution methods related to updates, provides guidance about how to deploy fixes for Exchange 2010, provides information about interim updates and how they interact with update rollups, and provides guidance related to Microsoft Exchange and daylight saving time and time zone changes.

Several improvements have been made in servicing for Exchange 2010, including:

- An integrated automated test product that is built together with the shipping product. Therefore, we can perform better integrated, end-to-end system testing than was possible with previous versions of Microsoft Exchange.
- Windows Installer is used instead of the Update.exe installation program.
- Update rollup packages are cumulative. For example, if you apply Update Rollup 4 on a computer that is running Exchange 2010, you receive all the fixes in that specific update package together with all the fixes that were released in all earlier update rollup packages. That is, in Update Rollup 4, you receive all the updates that were released in the previous Update Rollup 1 through Update Rollup 3 packages plus the updates in Update Rollup 4.

Note:
This approach to updating doesn't replace service packs for the product. Additional product fixes and features are released in separately available service packs for Exchange 2010.

For more information about Exchange 2010 servicing, see Install the Latest Update Rollup for Exchange 2010. For information about build numbers and release dates for various versions of Microsoft Exchange, see Exchange Server Build Numbers and Release Dates.

Release Schedule and Distribution Methods

Microsoft releases update rollup packages approximately every six to eight weeks. The

rollup packages are available via Microsoft Update and the Microsoft Download Center. In the Search box on the Microsoft Download Center, type "**Exchange 2010 update rollup**" to find links to the rollup packages.

Deployment Order of Update Rollups

Exchange update rollups work across multiple server roles. Because the update rollups aren't segmented for different Exchange server roles or for specific file configurations, apply each update rollup package to all Exchange 2010 servers in your environment.

For Exchange 2010 configurations, the recommended order in which to apply the update rollup is as follows: Client Access server, Hub Transport server, Mailbox server, and Unified Messaging server.

If you have multiple Active Directory sites and have deployed a Client Access server in the proxy sites that aren't Internet-facing, apply the update rollup to the Internet-facing Client Access servers before you apply the update rollup to the non-Internet-facing Client Access servers. For more information about Client Access to Client Access server proxying, see Understanding Proxying and Redirection.

Interim Updates

The critical fix process for Exchange 2010 is similar to the critical fix process for earlier versions of Exchange.

After working with a Customer Support Specialist or with Escalation Services personnel to troubleshoot an issue, Microsoft Support personnel may escalate a request to the Exchange Customer Experience team. The Customer Experience team may fix the specific problem and give you an interim update to resolve the issue. The interim update is intended to support your Exchange installation until the next scheduled update rollup package is released. The interim updates benefit from much of the same testing that the cumulative updates experience. However, interim update testing isn't as comprehensive as update rollup testing.

Interim updates for Exchange 2010 are update rollup-specific. For example, an interim update that is created to fix a problem on a server that is running the release to manufacturing version of Exchange 2010 doesn't function correctly on an Exchange 2010 server that has Update Rollup 2 installed. If you receive an error message when you install an interim update, check for one of the following issues:

- You have another interim update installed.
- You're installing an interim update that was targeted for a different update rollup baseline.

We deliver the interim update to you under your existing service level agreement. However, you must agree to remove the interim update and install the official update rollup package that resolves your problem when it becomes available. This process ensures that your Exchange 2010 configuration returns to a known, quantifiable state.

If you have an interim update installed on an Exchange 2010 server, you must remove the update before you install the next update rollup package. If the interim update isn't removed, you may receive an error message when you try to install the next update rollup package.

Note:

You will also receive an error message if you try to install an earlier update rollup package over a later update rollup package.

Exchange Server and Daylight Saving Time

For information related to daylight saving time and time zones, see Update Your Exchange Organization When Daylight Saving Time or the Time Zone Changes.

1.2.2.12.1 Install the Latest Update Rollup for Exchange 2010

Install the Latest Update Rollup for Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic describes how to deploy the latest update rollup for Microsoft Exchange Server 2010. Service packs and update rollups are part of the servicing strategy for Exchange 2010. They provide an effective and easy-to-use method to distribute Exchange 2010 fixes and modifications. We recommend that you install the latest service pack and update rollup to keep the product up-to-date.

Update rollups for the release to manufacture (RTM) version of Exchange Server 2010, also known as Exchange Server 2010 Service Pack 0, will continue to be released as long as Exchange 2010 is supported as per the support timeline that is described on the Microsoft Support Lifecycle Web site. For more information about which versions and service packs are supported, see the Support Lifecycle Index.

Note:
The latest update rollup in the series includes the fixes that were released in previous update rollups for the same series. For example, if you install Update Rollup 3 for Exchange 2010 RTM, it includes the fixes that were released in Update Rollup 1 for Exchange 2010 RTM and Update Rollup 2 for Exchange 2010 RTM.

Important Considerations Prior to Installing an Exchange 2010 Update Rollup

The following sections discuss important issues to consider before you deploy an Exchange 2010 update rollup package.

Certificate Revocation List

When you install an update rollup package, Exchange tries to connect to the certificate revocation list (CRL) Web site. Exchange examines the CRL list to verify the code signing certificate. (To download and view the CRL list, see CodeSignPCA.crl.) If Exchange can't connect to the CRL Web site, the following symptoms may occur:

- The installation takes a long time to complete.
- You receive the following message during the installation: **Creating native images for .Net assemblies**

When Exchange isn't connected to the Internet, each CRL request must complete before the installation can continue.

To work around this issue and to reduce installation times, turn off the **Check for publisher's certificate revocation** option on the server that is being upgraded. Use the following steps:

1. Start Internet Explorer.
2. On the **Tools** menu, click **Internet Options**.
3. Click the **Advanced** tab, and then locate the **Security** section.
4. Clear the **Check for publisher's certificate revocation** check box, and then click **OK**.
5. After the update rollup installation is complete, select the **Check for publisher's certificate revocation** option.

Note:

The **Check for publisher's certificate revocation** option is set on a per-account basis.

For more information, see Microsoft Knowledge Base article 971445, Generating NGEN images takes longer than expected.

Outlook Web App Customizations

When you apply an update rollup package, the update process may update the Logon.aspx file. If you have modified the Logon.aspx file, the file can't be updated successfully. Therefore, Microsoft Office Outlook Web App may not be updated correctly. In this scenario, after the update process is finished, Outlook Web App may display a blank page.

To work around this issue, rename the Logon.aspx file before you apply the update rollup, and then, after you apply the update, re-create the Outlook Web App customizations in the Logon.aspx file.

We recommend that you make a backup copy of any customized Outlook Web App files before you apply an update rollup. For more information about Outlook Web App customization details, see Customize the Outlook Web App Sign-In and Sign-Out Pages.

Proxying between Client Access Servers

If you have deployed Client Access server to Client Access server proxying, you must apply the update rollup to the Internet-facing Client Access servers before you apply the update rollup to non-Internet-facing Client Access servers. For other Exchange 2010 configurations, the recommended order in which to apply the update rollup is as follows: Client Access server, Hub Transport server, and Mailbox server.

For more information about Client Access to Client Access server proxying, see Understanding Proxying and Redirection.

Backup Recommendations

We strongly recommend that you create the following backups before you install an update rollup package:

- A full backup of all Exchange databases on the server.
- A system state backup of the server.

Exchange and Internet Services Considerations

When you install an update rollup, the Setup program automatically stops the appropriate Exchange services and Internet Information Services (IIS)-related services. Therefore, during the installation process, the server may be unable to service user requests. We recommend that you install an update rollup during a period of scheduled maintenance or during a period of low business impact.

Slipstream Update Rollup Installations

Exchange 2010 doesn't support the slipstream installation of an update rollup during the installation of a service pack.

The Exchange installation folder includes an Updates folder. The Updates folder supports a new installation of Exchange. When you perform a new Exchange installation, you can copy an update rollup to the Updates folder. In this scenario, the update rollup package is applied during the installation of Exchange.

To perform a supported new installation, follow these example steps:

1. Copy the Exchange 2010 RTM files to a local directory on the server or to a network share.
2. Place the appropriate update rollup package in the **Updates** subdirectory.
3. Install Exchange. The update rollup is automatically applied during the installation of Exchange.

The Updates folder isn't supported for use during a service pack installation. Therefore, you can't include (that is, slipstream) an update rollup along with the installation of a service pack. The slipstream installation of an update rollup during a service pack installing hasn't been tested. Therefore, you may experience unintended results.

To perform a supported upgrade installation, follow these example steps:

1. Install Exchange 2010 Service Pack 1 (SP1) on a computer that is running Exchange 2010 RTM together with Exchange 2010 Update Rollup 1.
2. Install Exchange 2010 SP1 Update Rollup 2.

Note:

You can't use the Updates folder in combination with running the **Setup /m:upgrade** unattended install.

Antivirus Services Considerations

Before you install an update rollup package or a service pack, make sure that all antivirus services are stopped.

Pre-Installation Checklist for an Exchange 2010 Update Rollup

Before you install an Exchange 2010 update rollup, we recommend that you review Exchange 2010 Servicing. That topic contains more information about the updates that are included in an update rollup and the methodology behind the Exchange update process.

Applying update rollups to Mailbox servers that are part of a database availability group (DAG) requires specific planning and application steps. For more information about how to apply update rollups to Exchange 2010 DAG member servers, see Installing Update Rollups on Database Availability Group Members.

You can use the following pre-installation checklist to help you install an Exchange 2010 update rollup:

1. **Determine which update rollup packages are installed on your Exchange server roles**
   Installed update rollup packages are shown in the **Programs and Features** dialog box in Control Panel. To see the list of installed updates, click **View installed updates**. Update rollup packages appear as "Update Rollup N for Exchange Server 2010 KBNNNNNN." You can use this information to help determine whether any update rollup packages are installed on the computer.
2. **Determine whether any interim updates are installed**
   Out-of-band fixes for certain Exchange issues are known as *interim updates*. The issue or issues that an interim update resolves may be fixed in a later update rollup package. Before you install an update rollup package, you must remove any interim updates from the computer. Interim updates appear in

the **Programs and Features** dialog box in Control Panel. These updates appear as "Interim Update for Exchange Server 2010 KBNNNNNN."

Note:
You can remove the interim updates on a per-computer basis. You don't have to remove all the interim updates from all the computers in the organization before you install an update rollup.

3. **Review interim updates**
   Examine any interim updates to determine whether they are resolved in the update rollup that you plan to install. To do this, read the Microsoft Knowledge Base article that corresponds to the interim update. If the Knowledge Base article mentions that the issue is resolved in the update rollup package that you plan to install or in an earlier update rollup package, you can remove the interim update and then install the update rollup without the risk of experiencing the specific issue that the interim update resolves. In this scenario, you don't have to obtain a replacement interim update. However, if the Knowledge Base article doesn't mention that the issue is resolved in the update rollup package that you plan to install, you must obtain a replacement interim update from Microsoft Customer Support Services (CSS). In this scenario, you must remove the interim update, install the specific update rollup package, and then install an interim update that is appropriate for the update rollup level of the computer.

   Important:
   Interim updates are created for a specific Exchange build. Therefore, an interim update that is suitable for Exchange 2010 Update Rollup 1 is not suitable for Exchange 2010 Update Rollup 2. You must contact CSS to obtain an interim update that is appropriate for the specific Exchange build that you're running. As previously mentioned, if the issue that the interim update resolves is fixed in the specific update rollup that you install, you don't have to obtain and install a replacement interim update.

4. **Obtain the latest update rollup package**
   The update rollup packages are available via Microsoft Update and the Microsoft Download Center. In the Search box on the Microsoft Download Center, type "**Exchange 2010 update rollup**" to find links to the rollup packages. We strongly recommend that you install the most recent update rollup package that is available. Microsoft releases update rollup packages approximately every six to eight weeks. This step makes sure that you benefit from the latest fixes for Exchange 2010.

Install an Exchange 2010 Update Rollup

Microsoft releases update rollup packages approximately every six to eight weeks. The rollup packages are available via Microsoft Update and the Microsoft Download Center. In the Search box on the Microsoft Download Center, type "**Exchange 2010 update rollup**" to find links to the rollup packages.

Note:
If you use Microsoft Update to install an update rollup package or if you install an update rollup package in silent mode, some Exchange services may be disabled. This issue occurs if the update rollup package must update a file that is being used.

1. Ensure that you have downloaded the appropriate rollup to a local drive on your Exchange servers, or on a remote network share.
2. Run the Windows Installer *.msp Setup file that you downloaded in step 1.

Post-Installation of an Exchange 2010 Update Rollup

When the installation is finished, complete the following tasks:

- Start the Services MMC snap-in, and then verify that all the Exchange-related services are started successfully.
- Log on to Outlook Web App to verify that it's running correctly.
- Restore Outlook Web App customizations, and then check Outlook Web App for correct functionality.
- After the update rollup installation is complete, select the **Check for publisher's certificate revocation** option in Internet Explorer. See "Certificate Revocation List" earlier in this topic.

View the Exchange 2010 Version Number

After you install an update rollup for Exchange 2010, the version of Exchange Server isn't updated to show that the update rollup is installed. This issue occurs because the version number that is displayed by the Exchange Management Console or by other administrative mechanisms is obtained from the Exchange Server Object in Active Directory.

For more information about Exchange 2010 version information, see Exchange 2010: Editions and Versions.

View Installed Update Rollups

The account must be a member of the local administrators group in Active Directory to view the installed update rollups.

1. Click **Start**, click **Control Panel**, and then click **Programs and Features**.
2. In the **Tasks** list, click **View installed updates**.
3. In the **Name** column, locate the Exchange Update Rollups that are installed on the computer.

Remove an Update Rollup

If you need to remove a specific update rollup, use the following procedure.

1. Click **Start**, and then click **Control Panel**.
2. Select **Installed Updates**, and in the Name column, select the update that you want to remove, and then click **Uninstall**.

Exchange Server Build Numbers and Release Dates

For information about build numbers and release dates for each version of Microsoft Exchange, see Exchange Server Build Numbers and Release Dates.

1.2.2.12.2 Update Your Exchange Organization When Daylight Saving Time or the Time Zone Changes

Update Your Exchange Organization When Daylight Saving Time or the Time Zone Changes

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2011-11-01*

If the country or region where your organization or some of your users reside has changed their policy of recognizing Daylight Saving Time (DST), or changed the local time offset from Coordinated Universal Time (UTC), you need may need to update Microsoft Windows, Microsoft Exchange, Microsoft Outlook, or other programs to accommodate these changes.

For more information about DST changes around the world, including links, see the Microsoft Daylight Saving Time Help and Support Center. To find out if there are current DST or time zone issues, see the Office 365 release notes. Also visit the support Web

sites of your other software suppliers to see if they require any additional updates.

Even if your time zone hasn't changed, if you interact with other computers or users globally, your computer needs to be able to perform accurate date and time calculations for events elsewhere in the world.

Installing time zone updates as soon as possible minimizes the number of meetings or appointments that are scheduled during the transition from the old time and date to the new one.

Step 1: Install the Windows DST update on all client and desktop computers

Because the Office 365 authentication system is updated when DST or a time zone changes, all Office 365 client computers need to be updated or they may experience connectivity issues.

- Make sure all client and desktop computers have installed the Windows DST update. For more information, see How to configure daylight saving time for Microsoft Windows operating systems.

Step 2: Install the Windows DST update on all servers

1. Update all your on-premises servers with the Windows DST update.
2. If you're running Office 365, update any servers that interact with the Office 365 authentication system, such as DirSync or AD FS servers. These servers must be updated to ensure uptime.

Note If you're updating server clusters, make sure you follow the usual process for updating clusters. You update the passive server first, fail over to the passive server (which becomes active), and then update the formerly active (now passive) server. For more information about how to update server clusters and high-availability server clusters, see Update Exchange Server Clusters and High Availability Servers.

Step 3: Update Exchange 2003 SP2 and Exchange 2007 SP3 servers with the latest updates

1. Install the latest DST update on your Exchange servers. For more information, see CDO time zone tables.

Note If you're updating server clusters, make sure you follow the usual process for updating clusters. You update the passive server first, fail over to the passive server (which becomes active), and then update the formerly active (now passive) server. For more information about how to update server clusters and high-availability server clusters, see Update Exchange Server Clusters and High Availability Servers.

Step 4: Update Exchange and Outlook on all client and desktop computers

1. Determine which of your users need to run the Exchange or Outlook time

zone tools, and which tool to run, using the table following this procedure.
2. Send a message to your users who need to update their computers, giving them a link to the appropriate tool.

The following table shows when users should run the Exchange Calendar Update Tool or the Time Zone Data Update Tool for Microsoft Office Outlook. Find which version your organization's servers are running, and then determine which client programs your users are running.

	Client Version		
Organization version	**Outlook 2003**	**Outlook 2007**	**Outlook 2010**
Exchange 2003 on premises	Exchange Calendar Tool or Time Zone Data Update Tool for Microsoft Office Outlook	Exchange Calendar Tool or Time Zone Data Update Tool for Microsoft Office Outlook	No action required
Exchange 2007 on premises	Exchange Calendar Tool or Time Zone Data Update Tool for Microsoft Office Outlook	Exchange Calendar Tool or Time Zone Data Update Tool for Microsoft Office Outlook	No action required
Exchange 2010 on premises	Time Zone Data Update Tool for Microsoft Office Outlook	Time Zone Data Update Tool for Microsoft Office Outlook	No action required
BPOS-S (Exchange 2007)	Time Zone Data Update Tool for Microsoft Office Outlook	Time Zone Data Update Tool for Microsoft Office Outlook	No action required
BPOS-D (Exchange 2010)	Time Zone Data Update Tool for Microsoft Office Outlook	Time Zone Data Update Tool for Microsoft Office Outlook	No action required
Office 365 (Exchange 2010)	Not supported	Time Zone Data Update Tool for Microsoft Office Outlook	No action required

1.2.2.12.2.1 Update Exchange Server Clusters and High Availability Servers

Update Exchange Server Clusters and High Availability Servers

Deploying Exchange 2010 > Exchange 2010 Servicing > Update Your Exchange Organization When Daylight Saving Time or the Time Zone Changes >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2011-11-09*

If you need to update clustered or high availability servers, the instructions are different depending on which version of Microsoft Exchange is running on your on-premises servers.

Choose from the following instructions:

- **Exchange 2003** See How to apply Exchange service packs and hotfixes.
- **Exchange 2007** See How to Install Update Rollups in a CCR Environment.
- **Exchange 2010** See Installing Update Rollups on Database Availability Group Members.
- **Windows updates (Windows 2003, Windows 2008 and Windows 2008 R2)** See How to install service packs in a cluster.

Understanding Permissions

Learn about the permissions models that are used by Microsoft Exchange Server 2010.

Feature Permissions

This topic provides access to information about the permissions required to perform operations in each area of Exchange 2010, such as Transport and Unified Messaging.

Managing Permissions

This topic is a collection of links that provide information about managing permissions in your organization.

1.3.1 Understanding Permissions

Understanding Permissions

Exchange Server 2010 > Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 includes a large set of predefined permissions, based on the Role Based Access Control (RBAC) permissions model, which you can use right away to easily grant permissions to your administrators and users. You can use the permissions features in Exchange 2010 so that you can get your new organization up and running quickly.

RBAC grants permissions to manage the Mailbox, Hub Transport, Client Access, and Unified Messaging server roles. For information about permissions on the Edge Transport server role, see Edge Transport Permissions later in this topic.

Note:

Several RBAC features and concepts aren't discussed in this topic because they're

advanced features. If the functionality discussed in this topic doesn't meet your needs, and you want to further customize your permissions model, see Understanding Role Based Access Control.

Looking for management tasks related to permissions? See Managing Permissions.

Role-Based Permissions

In Exchange 2010, the permissions that you grant to administrators and users are based on management roles. A role defines the set of tasks that an administrator or user can perform. For example, a management role called `Mail Recipients` defines the tasks that someone can perform on a set of mailboxes, contacts, and distribution groups. When a role is assigned to an administrator or user, that person is granted the permissions provided by the role.

There are two types of roles, administrative roles and end-user roles:

- **Administrative roles** These roles contain permissions that can be assigned to administrators or specialist users using role groups that manage a part of the Exchange organization, such as recipients, servers, or databases.
- **End-user roles** These roles, assigned using role assignment policies, enable users to manage aspects of their own mailbox and distribution groups that they own. End-user roles begin with the prefix `My`.

Roles give permissions to perform tasks to administrators and users by making cmdlets available to those who are assigned the roles. Because the Exchange Management Console (EMC), Exchange Control Panel (ECP), and Exchange Management Shell use cmdlets to manage Exchange, granting access to a cmdlet gives the administrator or user permission to perform the task in each of the Exchange management interfaces.

Exchange 2010 includes approximately 60 roles that can be used to grant permissions. For a list of roles included with Exchange 2010, see Built-in Management Roles.

Role Groups and Role Assignment Policies

Roles grant permissions to perform tasks in Exchange 2010, but you need an easy way to assign them to administrators and users. Exchange 2010 provides you with the following to help you do that:

- **Role groups** Role groups enable you to grant permissions to administrators and specialist users.
- **Role assignment policies** Role assignment policies enable you to grant permissions to end users to change settings on their own mailbox or distribution groups that they own.

For more information about role groups and role assignment policies, see the following sections.

Role Groups

Every administrator that manages Exchange 2010 must be assigned at least one or more roles. Administrators might have more than one role because they may perform job functions that span multiple areas in Exchange. For example, one administrator might manage both recipients and Exchange servers. In this case, that administrator might be assigned both the `Mail Recipients` and `Exchange Servers` roles.

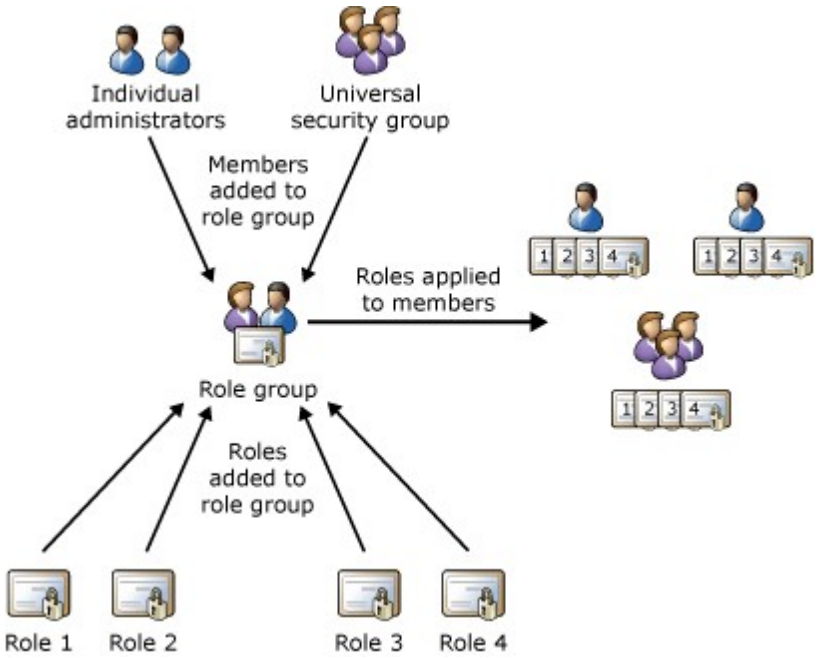
To make it easier to assign multiple roles to an administrator, Exchange 2010 includes role groups. Role groups are special universal security groups (USGs) used by Exchange 2010 that can contain Active Directory users, USGs, and other role groups. When a role is assigned to a role group, the permissions granted by the role are granted to all the members of the role group. This enables you to assign many roles to many role group

members at once. Role groups typically encompass broader management areas, such as recipient management. They're used only with administrative roles, and not end-user roles.

Note:

It's possible to assign a role directly to a user or USG without using a role group. However, that method of role assignment is an advanced procedure and isn't covered in this topic. We recommend that you use role groups to manage permissions.

The following figure shows the relationship between users, role groups, and roles.



Exchange 2010 includes several built-in role groups, each one providing permissions to manage specific areas in Exchange 2010. Some role groups may overlap with others. The following table lists each role group with a description of its use. If you want to see the roles assigned to each role group, click the name of the role group in the table, and then open the "Management Roles Assigned to This Role Group" section.

Built-in role groups

Role group	Description
Organization Management	Administrators who are members of the Organization Management role group have administrative access to the entire Exchange 2010 organization and can perform almost any task against any Exchange 2010 object, with some exceptions, such as the `Discovery Management` role. **Important:** Because the Organization Management role group is a powerful role, only users or USGs that perform organizational-level administrative tasks that can potentially impact the entire Exchange organization should be members of this role group.

View-Only Organization Management	Administrators who are members of the View Only Organization Management role group can view the properties of any object in the Exchange organization.
Recipient Management	Administrators who are members of the Recipient Management role group have administrative access to create or modify Exchange 2010 recipients within the Exchange 2010 organization.
UM Management	Administrators who are members of the UM Management role group can manage features in the Exchange organization such as Unified Messaging (UM) server configuration, UM properties on mailboxes, UM prompts, and UM auto attendant configuration.
Help Desk	The Help Desk role group, by default, enables members to view and modify the Microsoft Office Outlook Web App options of any user in the organization. These options might include modifying the user's display name, address, and phone number. They don't include options that aren't available in Outlook Web App options, such as modifying the size of a mailbox or configuring the mailbox database on which a mailbox is located.
Hygiene Management	Administrators who are members of the Hygiene Management role group can configure the antivirus and anti-spam features of Exchange 2010. Third-party programs that integrate with Exchange 2010 can add service accounts to this role group to grant those programs access to the cmdlets required to retrieve and configure the Exchange configuration.
Records Management	Users who are members of the Records Management role group can configure compliance features, such as retention policy tags, message classifications, and transport rules.
Discovery Management	Administrators or users who are members of the Discovery Management role group can perform searches of mailboxes in the Exchange organization for data that meets specific criteria and can also configure legal holds on mailboxes. For more information, see Discovery and Understanding Litigation Hold.
Public Folder Management	Administrators who are members of the Public Folder Management role group can manage public folders and databases on servers running Exchange 2010.

Server Management	Administrators who are members of the Server Management role group can configure server-specific configuration of transport, Unified Messaging, client access, and mailbox features such as database copies, certificates, transport queues and Send connectors, virtual directories, and client access protocols.
Delegated Setup	Administrators who are members of the Delegated Setup role group can deploy servers running Exchange 2010 that have been previously provisioned by a member of the Organization Management role group. For more information about delegated setup, see Provision Exchange 2010 Server and Delegate Setup.

If you work in a small organization that has only a few administrators, you might need to add those administrators to the Organization Management role group only, and you may never need to use the other role groups. If you work in a larger organization, you might have administrators who perform specific tasks administering Exchange, such as recipient or server management. In those cases, you might add one administrator to the Recipient Management role group, and another administrator to the Server Management role group. Those administrators can then manage their specific areas of Exchange 2010 but won't have permissions to manage areas they're not responsible for.

If the built-in role groups in Exchange 2010 don't match the job function of your administrators, you can create role groups and add roles to them. For more information, see Work with Role Groups later in this topic.

Role Assignment Policies

Exchange 2010 provides role assignment policies so that you can control what settings your users can configure on their own mailboxes and on distribution groups they own. These settings include their display name, contact information, voice mail settings, and distribution group membership.

Your Exchange 2010 organization can have multiple role assignment policies that provide different levels of permissions for the different types of users in your organizations. Some users can be allowed to change their address or create distribution groups, while others can't, depending on the role assignment policy associated with their mailbox. Role assignment policies are added directly to mailboxes, and each mailbox can only be associated with one role assignment policy at a time.

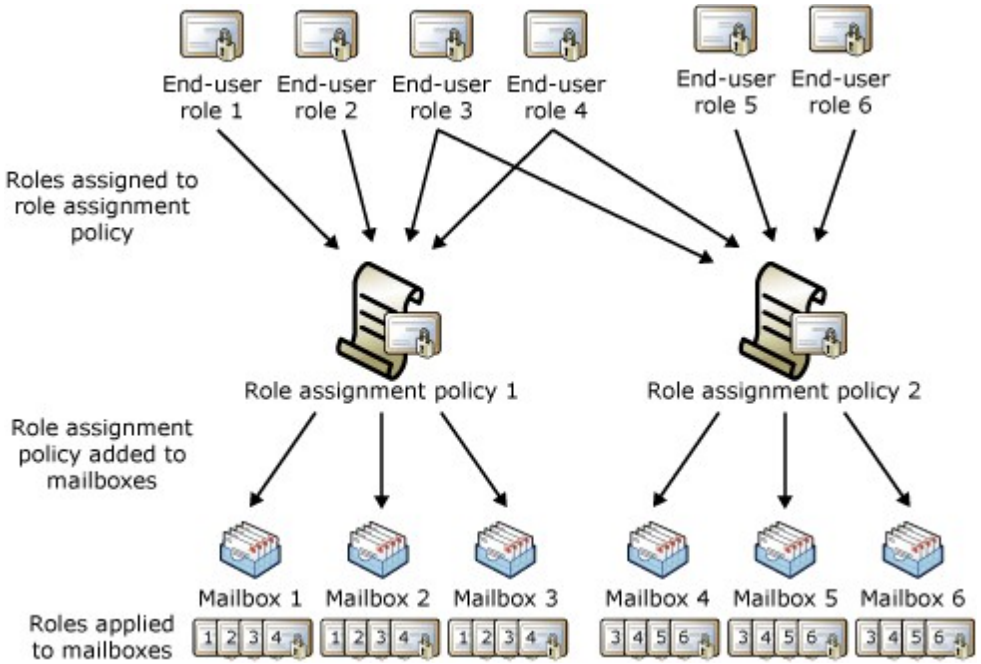
Of the role assignment policies in your organization, one is marked as default. The default role assignment policy is associated with new mailboxes that aren't explicitly assigned a specific role assignment policy when they're created. The default role assignment policy should contain the permissions that should be applied to the majority of your mailboxes.

Permissions are added to role assignment policies using end-user roles. End-user roles begin with My and grant permissions for users to manage only their mailbox or distribution groups they own. They can't be used to manage any other mailbox. Only end-user roles can be assigned to role assignment policies.

When an end-user role is assigned to a role assignment policy, all of the mailboxes associated with that role assignment policy receive the permissions granted by the role. This enables you to add or remove permissions to sets of users without having to configure individual mailboxes. The following figure shows:

- End-user roles are assigned to role assignment policies. Role assignment

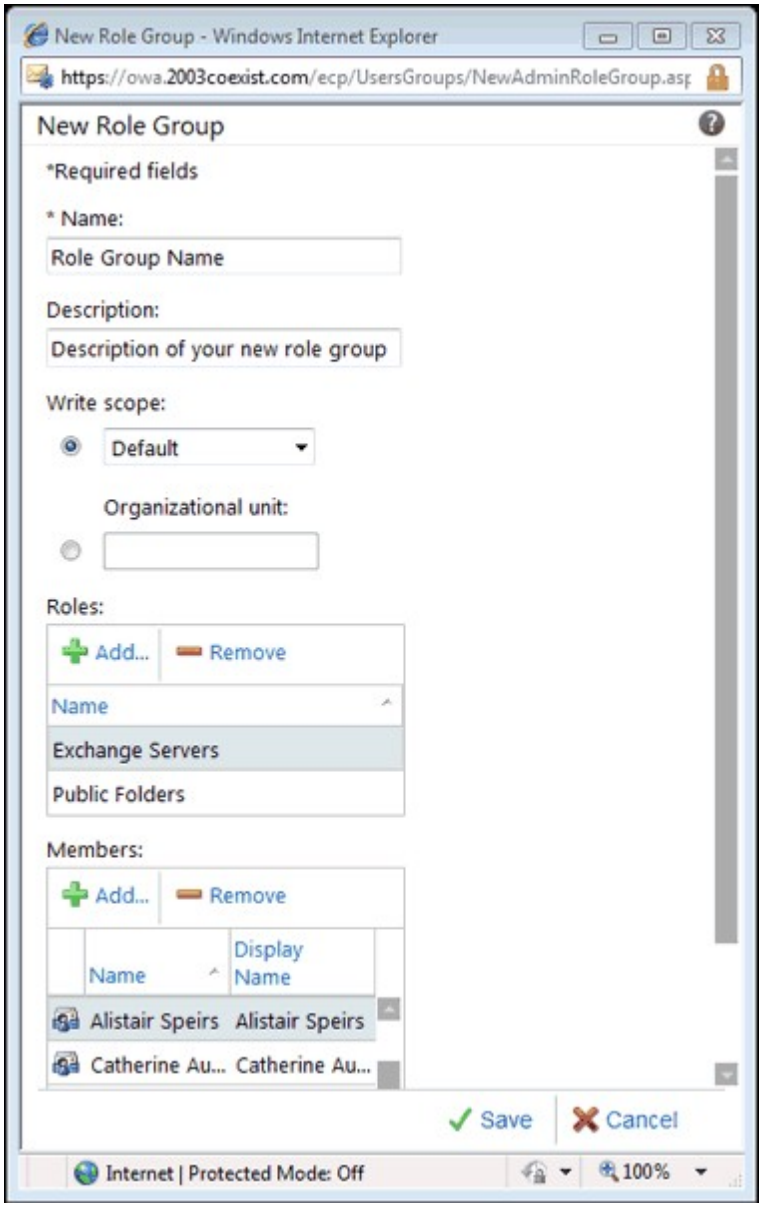
policies can share the same end-user roles.
- Role assignment policies are associated with mailboxes. Each mailbox can only be associated with one role assignment policy.
- After a mailbox is associated with a role assignment policy, the end-user roles are applied to that mailbox. The permissions granted by the roles are granted to the user of the mailbox.



The Default Role Assignment Policy role assignment policy is included with Exchange 2010. As the name implies, it's the default role assignment policy. If you want to change the permissions provided by this role assignment policy, or if you want to create role assignment policies, see Work with Role Assignment Policies later in this topic.

Work with Role Groups

To manage your permissions using role groups in Exchange 2010 Service Pack 1 (SP1), we recommend that you use the ECP. When you use the ECP to manage role groups, you can add and remove roles and members, create role groups, and copy role groups with a few clicks of your mouse. The ECP provides simple dialog boxes, such as the **New Role Group** dialog box, shown in the following figure, to perform these tasks.



As mentioned earlier in this topic, Exchange 2010 includes several role groups that separate permissions into specific administrative areas. If these existing role groups provide the permissions your administrators need to manage your Exchange 2010 organization, you need only add your administrators as members of the appropriate role groups. After you add administrators to a role group, they can administer the features that relate to that role group. To add or remove members to or from a role group, open the role group in the ECP, and then add or remove members from the membership list. For a list of built-in role groups, see Built-in Role Groups.

Important:

If an administrator is a member of more than one role group, Exchange 2010 grants the administrator all of the permissions provided by the role groups he or she is a member of.

If none of the role groups included with Exchange 2010 have the permissions you need, you can use the ECP to create a role group and add the roles that have the permissions you need. For your new role group, you will:

1. Choose a name for your role group.

2. Select the roles you want to add to the role group.
3. Add members to the role group.
4. Save the role group.

After you create the role group, you manage it like any other role group.

If there's an existing role group that has some, but not all of the permissions you need, you can copy it and then make changes to create a role group. You can copy an existing role group and make changes to it, without affecting the original role group. As part of copying the role group, you can add a new name and description, add and remove roles to and from the new role group, and add new members. When you create or copy a role group, you use the same dialog box that's shown in the preceding figure.

Existing role groups can also be modified. You can add and remove roles from existing role groups, and add and remove members from it at the same time, using an ECP dialog box similar to the one in the preceding figure. By adding and removing roles to and from role groups, you turn on and off administrative features for members of that role group. For a list of roles you can add to a role group, see Built-in Management Roles.

Note:

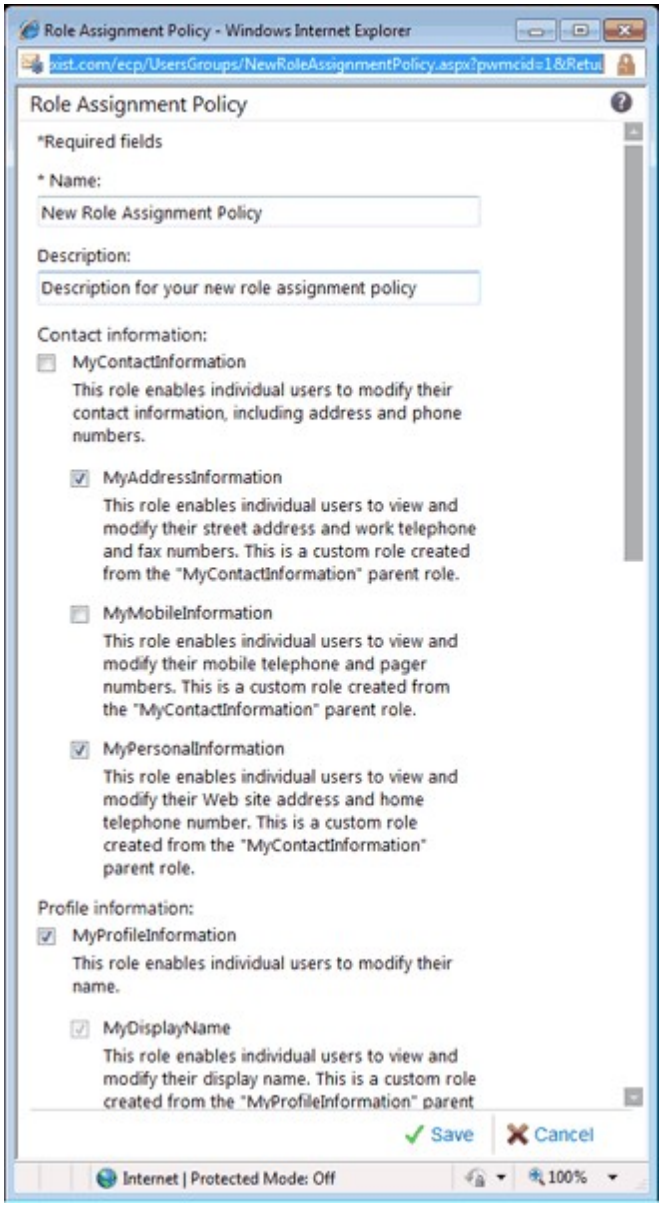
Although you can change which roles are assigned to built-in role groups, we recommend that you copy built-in role groups, modify the role group copy, and then add members to the role group copy.

For detailed steps about how to create or copy role groups, or make changes to existing role group roles and membership, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group
- Create a Role Group
- Copy a Role Group
- Remove a Role Group
- Add a Role to a Role Group
- Remove a Role from a Role Group

Work with Role Assignment Policies

To manage the permissions that you grant end users to manage their own mailbox in Exchange 2010 SP1, we recommend that you use the ECP. When you use the ECP to manage end-user permissions, you can add roles, remove roles, and create role assignment policies with a few clicks of your mouse. The ECP provides simple dialog boxes, such as the **Role Assignment Policy** dialog box, shown in the following figure, to perform these tasks. To apply a role assignment policy to a mailbox, you can use either the EMC or the ECP.



Exchange 2010 includes a role assignment policy named Default Role Assignment Policy. This role assignment policy enables users whose mailboxes are associated with it to do the following:

- Join or leave distribution groups that allow members to manage their own membership.
- View and modify basic mailbox settings on their own mailbox, such as Inbox rules, spelling behavior, junk mail settings, and Microsoft ActiveSync devices.
- Modify their contact information, such as address and phone number.
- Create, modify, or view text message settings.
- View or modify voice mail settings.

If you want to add or remove permissions from the Default Role Assignment Policy or any other role assignment policy, you can use the ECP. The dialog box you use is similar to the one in the preceding figure. When you open the role assignment policy in the ECP, select the check box next to the roles you want to assign to it or clear the check box next to the roles you want to remove. The change you make to the role assignment policy is applied

to every mailbox associated with it.

If you want to assign different end-user permissions to the various types of users in your organization, you can create role assignment policies. When you create a role assignment policy, you see a dialog box similar to the one in the preceding figure. You can specify a new name for the role assignment policy, and then select the roles you want to assign to the role assignment policy. After you create a role assignment policy, you can associate it with mailboxes using the EMC or the ECP.

If you want to change which role assignment policy is the default, you must use the Shell. When you change the default role assignment policy, any mailboxes that are created will be associated with the new default role assignment policy if one wasn't explicitly specified. The role assignment policy associated with existing mailboxes doesn't change when you select a new default role assignment policy.

Note:

If you select a check box for a role that has child roles, the check boxes for the child roles are also selected. If you clear the check box for a role with child roles, the check boxes for the child roles are also cleared.

For detailed steps about how to create role assignment policies or make changes to existing role assignment policies, see the following topics:

- Add an Assignment Policy
- Remove an Assignment Policy
- Add a Role to an Assignment Policy
- Remove a Role from an Assignment Policy
- Change the Assignment Policy on a Mailbox
- Change the Default Assignment Policy

Edge Transport Permissions

The Edge Transport server role is deployed in an organization's perimeter network, which is also known as the boundary network or screened subnet. An Edge Transport server can be deployed as a stand-alone server or as a member of a perimeter Active Directory domain.

On Edge Transport servers, RBAC isn't used to control permissions. The local Administrators group is used to control who can configure Exchange features on the local server. If you have multiple Edge Transport servers, you need to add the user you want to manage those servers to the local Administrators group on each server.

For more information about permissions on Edge Transport servers, see Setting Administrator Permissions for the Edge Transport Server Role.

Feature Permissions

1.3.1.1 Understanding Role Based Access Control

Understanding Role Based Access Control

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Role Based Access Control (RBAC) is the new permissions model in Microsoft Exchange Server 2010. With RBAC, you don't need to modify and manage access control lists (ACLs), which was done in Exchange Server 2007. ACLs created several challenges in Exchange 2007, such as modifying ACLs without causing unintended consequences, maintaining ACL modifications through upgrades, and troubleshooting problems that occurred due to using ACLs in a nonstandard way.

RBAC enables you to control, at both broad and granular levels, what administrators and end-users can do. RBAC also enables you to more closely align the roles you assign users and administrators to the actual roles they hold within your organization. In Exchange 2007, the server permissions model applied only to the administrators who managed the Exchange 2007 infrastructure. In Exchange 2010, RBAC now controls both the administrative tasks that can be performed and the extent to which users can now administer their own mailbox and distribution groups.

RBAC has two primary ways of assigning permissions to users in your organization, depending on whether the user is an administrator or specialist user, or an end-user: management role groups and management role assignment policies. Each method associates users with the permissions they need to perform their jobs. A third, more advanced method, direct user role assignment, can also be used. The following sections in this topic explain RBAC and provide examples of its use.

Note:

This topic focuses on advanced RBAC functionality. If you want to manage basic Exchange 2010 permissions, such as using the Exchange Control Panel (ECP) to add and remove members to and from role groups, create and modify role groups, or create and modify role assignment policies, see Understanding Permissions.

Contents

Management Role Groups

Management role groups associate management roles to a group of administrators or specialist users. Administrators manage a broad Exchange organization or recipient configuration. Specialist users manage the specific features of Exchange, such as compliance. Or they may have limited management abilities, such as Help desk members, but aren't given broad administrative rights. Role groups typically associate administrative

management roles that enable administrators and specialist users to manage the configuration of their organization and recipients. For example, whether administrators can manage recipients or use mailbox discovery features is controlled using role groups.

Adding or removing users to or from role groups is how you most often assign permissions to administrators or specialist users. For more information, see Understanding Management Role Groups.

Role groups consist of the following components that define what administrators and specialist users can do:

- **Management role group** The *management role group* is a special universal security group (USG) that contains mailboxes, users, USGs, and other role groups that are members of the role group. This is where you add and remove members, and it's also what management roles are assigned to. The combination of all the roles on a role group defines everything that users added to a role group can manage in the Exchange organization.
- **Management role** A *management role* is a container for a grouping of management role entries. Roles are used to define the specific tasks that can be performed by the members of a role group that's assigned the role. A *management role entry* is a cmdlet, script, or special permission that enables each specific task in a role to be performed. For more information, see Understanding Management Roles.
- **Management role assignment** A *management role assignment* links a role and a role group. Assigning a role to a role group grants members of the role group the ability to use the cmdlets and parameters defined in the role. Role assignments can use management scopes to control where the assignment can be used. For more information, see Understanding Management Role Assignments.
- **Management role scope** A *management role scope* is the scope of influence or impact on a role assignment. When a role is assigned with a scope to a role group, the management scope targets specifically what objects that assignment is allowed to manage. The assignment, and its scope, are then given to the members of the role group, and restrict what those members can manage. A scope can consist of a list of servers or databases, organizational units (OUs), or filters on server, database or recipient objects. For more information, see Understanding Management Role Scopes.

When you add a user to a role group, the user is given all of the roles assigned to the role group. If scopes are applied to any of the role assignments between the role group and the roles, those scopes control what server configuration or recipients the user can manage.

If you want to change what roles are assigned to role groups, you need to change the role assignments that link the role groups to roles. Unless the assignments built into Exchange 2010 don't suit your needs, you won't have to change these assignments. For more information, see Understanding Management Role Assignments.

For more information about role groups, see Understanding Management Role Groups.

Return to top

Management Role Assignment Policies

Management role assignment policies associate end-user management roles to users. Role assignment policies consist of roles that control what a user can do with his or her mailbox or distribution groups. These roles don't allow management of features that aren't directly associated with the user. When you create a role assignment policy, you define everything a user can do with his or her mailbox. For example, a role assignment policy may allow a user to set the display name, set up voice mail, and configure Inbox

rules. Another role assignment policy might allow a user to change the address, use text messaging, and set up distribution groups. Every user with an Exchange 2010 mailbox, including administrators, is given a role assignment policy by default. You can decide which role assignment policy should be assigned by default, choose what the default role assignment policy should include, override the default for certain mailboxes, or not assign role assignment policies by default at all.

Assigning a user to an assignment policy is how you most often manage permissions for users to manage their own mailbox and distribution group options. For more information, see Understanding Management Role Assignment Policies.

Role assignment policies consist of the following components that define what users can do with their own mailboxes. Notice that some of the same components also apply to role groups. When used with role assignment policies, these components are limited to enable users to manage only their own mailbox:

- **Management role assignment policy** The *management role assignment policy* is a special object in Exchange 2010. Users are associated with the role assignment policy when their mailboxes are created or if you change the role assignment policy on a mailbox. This is also what you assign end-user management roles to. The combination of all the roles on a role assignment policy defines everything that the user can manage on his or her mailbox or distribution groups.
- **Management role** A *management role* is a container for a grouping of management role entries. Roles are used to define the specific tasks that a user can do with his or her mailbox or distribution groups. A *management role entry* is a cmdlet, script or special permission that enables each specific task in a management role to be performed. You can only use end-user roles with role assignment policies. For more information, see Understanding Management Roles.
- **Management role assignment** A *management role assignment* is the link between a role and a role assignment policy. Assigning a role to a role assignment policy grants the ability to use the cmdlets and parameters defined in the role. When you create a role assignment between a role assignment policy and a role, you can't specify any scope. The scope applied by the assignment is either `Self` or `MyGAL`. All role assignments are scoped to the user's mailbox or distribution groups. For more information, see Understanding Management Role Assignments.

If you want to change what roles are assigned to role assignment policies, you need to change the role assignments that link the role assignment policies to roles. Unless the assignments built into Exchange 2010 don't suit your needs, you won't have to change these assignments. For more information, see Understanding Management Role Assignments.

For more information, see Understanding Management Role Assignment Policies.

Return to top

Direct User Role Assignment

Direct role assignment is an advanced method for assigning management roles directly to a user or USG without using a role group or role assignment policy. Direct role assignments can be useful when you need to provide a granular set of permissions to a specific user and no others. However, using direct role assignments can significantly increase the complexity of your permissions model. If a user changes jobs or leaves the company, you need to manually remove the assignments and add them to the new employee. We recommend that you use role groups to assign permissions to administrators and specialist users, and role assignment policies to assign permissions to users.

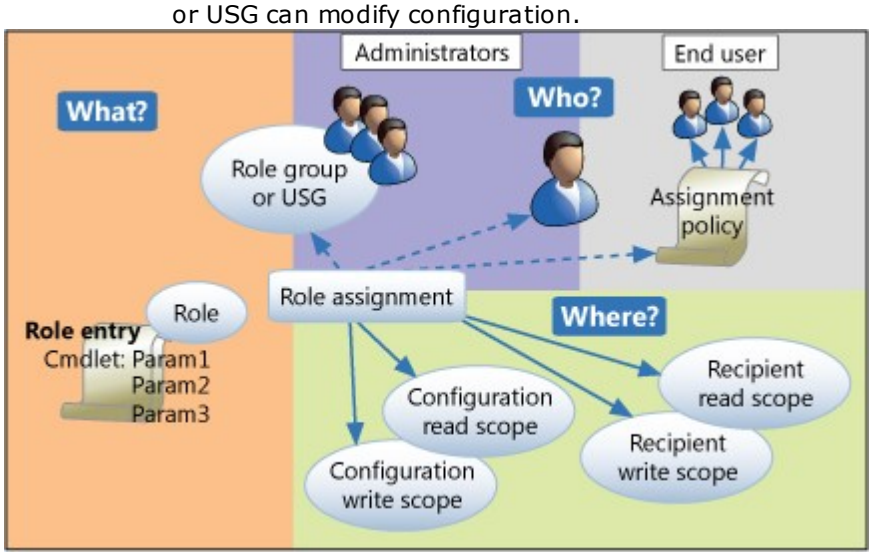
For more information about direct user assignment, see Understanding Management Role Assignments.

Return to top

Summary and Examples

The following figure shows the components in RBAC and how they fit together:

- Role groups:
  - One or more administrators can be members of a role group. They can also be members of more than one role group.
  - The role group is assigned one or more role assignments. These link the role group with one or more administrative roles that define what tasks can be performed.
  - The role assignments can contain management scopes that define where the users of the role group can perform actions. The scopes determine where the users of the role group can modify configuration.
- Role assignment policies:
  - One or more users can be associated with a role assignment policy.
  - The role assignment policy is assigned one or more role assignments. These link the role assignment policy with one or more end-user roles. The end-user roles define what the user can configure on his or her mailbox.
  - The role assignments between role assignment policies and roles have built-in scopes that restrict the scope of assignments to the user's own mailbox or distribution groups.
- Direct role assignment (advanced):
  - A role assignment can be created directly between a user or USG and one or more roles. The role defines what tasks the user or USG can perform.
  - The role assignments can contain management scopes that define where the user or USG can perform actions. The scopes determine where the user or USG can modify configuration.



As shown in the preceding figure, many components in RBAC are related to each other. It's how each component is put together that defines the permissions applied to each administrator or user. The following examples provide some additional context about how role groups and role assignment policies are used in an organization.

Jane the Administrator

Jane is an administrator for the medium-size company, Contoso. She's responsible for

managing the company's recipients in their Vancouver office. When the permissions model for Contoso was created, Jane was made a member of the Recipient Management - Vancouver custom role group. The Recipient Management - Vancouver custom role group most closely matches her job's duties, which include creating and removing recipients, such as mailboxes and contacts, managing distribution group membership and mailbox properties, and similar tasks.

In addition to the Recipient Management - Vancouver custom role group, Jane also needs a role assignment policy to manage her own mailbox's configuration settings. The organization administrators have decided that all users, except for senior management, receive the same permissions when they manage their own mailboxes. They can configure their voice mail, set up retention policies and change their address information. The default role assignment policy provided with Exchange 2010 now reflects these requirements.

Note:

You may have noticed that because Jane is a member of the Recipient Management - Vancouver custom role group, that should give her permissions to manage her own mailbox. This is true; however, the role group doesn't provide her all of the permissions necessary to manage all of the features of her mailbox. The permissions needed to manage voice mail and retention policy settings aren't included in her role group. Those are provided only by the default role assignment policy assigned to her.

To allow for this, consider the role group, which provides Jane's administrative permissions over the recipients in Vancouver:

1. A custom role group called Recipient Management - Vancouver was created. When it was created, the following occurred:
   a. The role group was assigned all of the same management roles that are also assigned to the Recipient Management built-in role group. This gives users added to the Recipient Management - Vancouver custom role group the same permissions as those users added to the Recipient Management role group. However, the following steps limit where they can use those permissions.
   b. The Vancouver Recipients custom management scope was created, which matches only recipients who are located in Vancouver. This was done by creating a scope that filters on a user's city or other unique information.
   c. The role group was created with the Vancouver Recipients custom management scope. This means while administrators added to the Recipient Management - Vancouver custom role group have full recipient management permissions, they can only use those permissions against recipients based in Vancouver.
2. Jane is then added as a member of the Recipient Management - Vancouver custom role group.
   For more information about creating a custom role group, see the following topics:
   a. Create a Role Group
   b. Add a Role to a Role Group
   c. Change the Scope of Role Assignments to a Role Group
   d. Add Members to a Role Group
   To give Jane the ability to manage her own mailbox settings, a role assignment policy needs to be configured with the required permissions.
3. The default role assignment policy is used to provide users with the permissions they need to configure their own mailbox. The following is done to provide these permissions:
   a. All end-user roles are removed from the default role assignment policy, except for: `MyBaseOptions`, `MyContactInformation`, `MyVoicemail` and `MyRetentionPolicies`. `MyBaseOptions` is included because this management role provides the basic user functionality in Microsoft Office Outlook Web App, such as Inbox rules, calendar configuration, and other tasks.

Nothing else needs to be done because Jane is already assigned the default role assignment policy. This means that the changes made to that role assignment policy are immediately applied to her mailbox, and any other mailboxes also assigned to the default role assignment policy.

For more information about customizing the default role assignment policy, see Change the Default Assignment Policy.

Joe the Specialist

Joe works for Contoso, the same company that Jane works for. He's responsible for performing legal discovery, setting the retention policies, and configuring transport rules and journaling for the whole organization. As with Jane, when the permissions model for Contoso was created, Joe was added to the role groups that match his job duties. The Records Management role group provides Joe with the permissions to configure retention policies, journaling, and transport rules. The Discovery Management role group provides him with the ability to perform mailbox searches.

As with Jane, Joe also needs permissions to manage his own mailbox. He is also given the same permissions as Jane: He can set up his voice mail and retention policies, and change his address information.

To give Joe the permissions to perform his job duties, Joe is added to the Records Management and Discovery Management role groups. The role groups don't need to be changed in any way because they already provide him with the permissions he needs, and the management scopes applied to them encompass the entire organization.

For more information about adding a user to a role group, see Add Members to a Role Group.

Joe's mailbox is also assigned the same default role assignment policy that's applied to Jane's mailbox. This gives him all the permissions he needs to manage the features of his mailbox that he's allowed to manage.

Isabel the Vice President

Isabel is the Vice President of Marketing at Contoso. Isabel, as part of the senior leadership team of Contoso, is given more permissions than the average user. This includes the permissions she's provided to manage her mailbox, with one exception: Isabel isn't allowed to manage her own retention policies for legal compliance reasons. Isabel can configure her voice mail, change her contact information, change her profile information, create and manage her own distribution groups, and add or remove herself from existing distribution groups owned by others.

So Isabel is given different permissions on her own mailbox. Most users at Contoso are assigned to the default role assignment policy. Senior leadership, however, is assigned to the Senior Leadership role assignment policy. The following is done to create the custom role assignment policy:

1. A custom role assignment policy called Senior Leadership is created. The role assignment policy is assigned the `MyBaseOptions`, `MyContactInformation`, `MyVoicemail`, `MyProfileInformation`, `MyDistributionGroupMembership`, and `MyDistributionGroups` roles. `MyBaseOptions` is included because this role provides the basic user functionality in Outlook Web App, such as Inbox rules, calendar configuration, and other tasks.
2. Isabel is then manually assigned the Senior Leadership role assignment policy.

Isabel's mailbox now has the permissions provided by the Senior Leadership role assignment policy. Any changes made to this role assignment policy are automatically applied to her mailbox, and any other mailboxes also assigned to the same role

assignment policy.

1.3.1.1.1 Understanding Management Role Groups

Understanding Management Role Groups

Permissions > Understanding Permissions > Understanding Role Based Access Control >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-16*

A *management role group* is a universal security group (USG) used in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. A management role group simplifies the assignment of management roles to a group of users. All members of a role group are assigned the same set of roles. Role groups are assigned administrator and specialist roles that define major administrative tasks in Exchange 2010 such as organization management, recipient management, and other tasks. Role groups enable you to more easily assign a broader set of permissions to a group of administrators or specialist users.

Note:

This topic focuses on advanced RBAC functionality. If you want to manage basic Exchange 2010 permissions, such as using the Exchange Control Panel (ECP) to add and remove members to and from role groups, create and modify role groups, or create and modify role assignment policies, see Understanding Permissions.

Contents

Note:

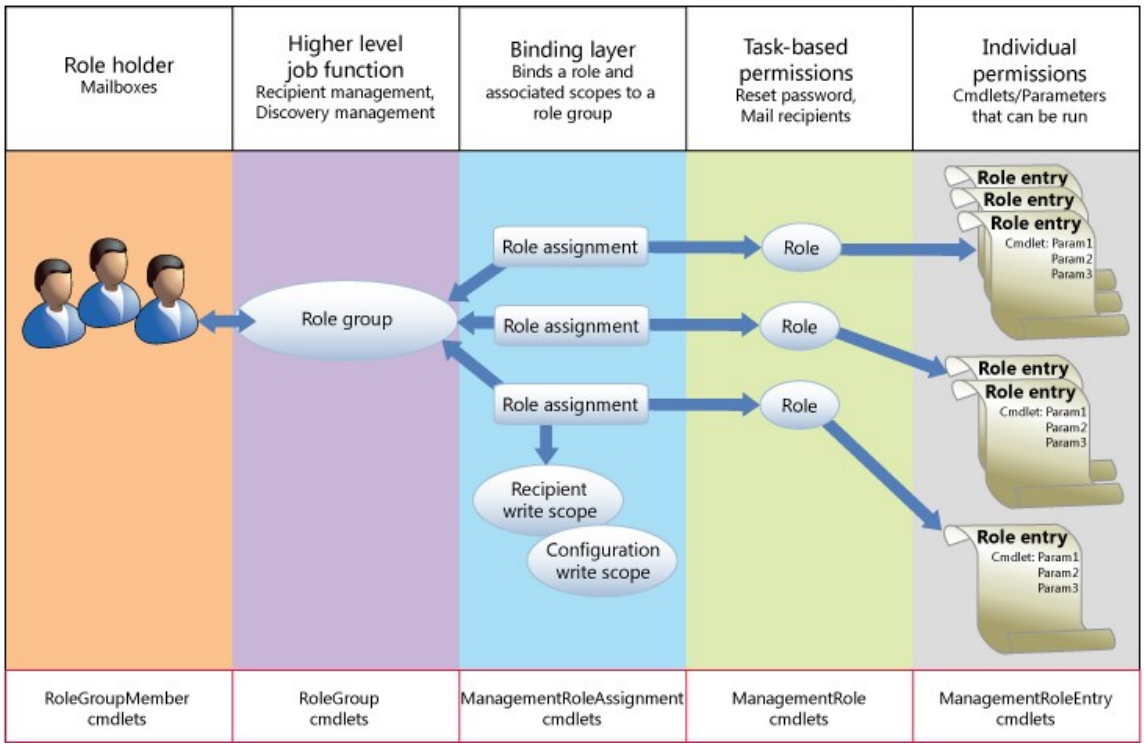
If you want to assign permissions to users to manage their own mailbox or distribution groups, see Understanding Management Role Assignment Policies.

Role Group Layers

The following are the layers that make up the role group model:

- **Role holder** A *role holder* is a mailbox that can be added as a member of a role group. When a mailbox is added as a member of a role group, the assignments that have been made between management roles and a role group are applied to the mailbox. This grants the mailbox all of the permissions provided by the management roles.
- **Management role group** The *management role group* is a special USG that contains mailboxes that are members of the role group. This is where you add and remove members, and it's also what management roles are assigned to. The combination of all the roles on a role group defines everything that users added to a role group can manage in the Exchange organization.
- **Management role assignment** A *management role assignment* links a management role and a role group. Assigning a management role to a role group grants members of the role group the ability to use the cmdlets and parameters defined in the management role. Role assignments can use management scopes to control where the assignment can be used. For more information, see Understanding Management Role Assignments.
- **Management role scope** A *management role scope* is the scope of influence or impact on a role assignment. When a role is assigned with a scope to a role group, the management scope targets specifically what objects that assignment is allowed to manage. The assignment, and its scope, are then given to the members of the role group, which restricts what those members can manage. A scope can be made up of lists of servers or databases, organizational units, or filters on server, database or recipient objects. For more information, see Understanding Management Role Scopes.
- **Management role** A *management role* is a container for a grouping of management role entries. Roles are used to define the specific tasks that can be performed by the members of a role group assigned the role. For more information, see Understanding Management Roles.
- **Management role entries** *Management role entries* are the individual entries on a management role that provide access to cmdlets, scripts, and other special permissions that enable access to perform a specific task. Most often, role entries consist of a single cmdlet and the parameters that can be accessed by the management role, and therefore the role group to which the role is assigned.

The following figure shows each of the role group layers in the preceding list and how each of the layers relates to the other.



For more information about RBAC, see Understanding Role Based Access Control.

Return to top

Role Group Management

When you create a role group, you create the USG that holds the members of the role group, and you create the assignments between the role group and the management roles you specify. Optionally, you can also specify a management scope to apply to the role assignments, and you can add any mailboxes that you want to be members of the new role group.

After you create a role group, each layer becomes an independent object. The role group continues to be the central point at which all of the layers are joined together, however, each layer is managed individually. For example, to modify the management scope that you applied to the role group when it was created, you need to change the scope on each individual role assignment after the role group is created. The management of the role group model is performed using the cmdlets that manage the individual layers of the role group model.

The following table lists the role group layer and the procedural topics that you can use to manage each layer.

Role group management topics

Role group model layer	Management topic
Role holder	Add Members to a Role Group Remove Members from a Role Group
Role group	Create a Role Group

	Change a Linked Foreign USG on a Linked Role Group Add or Remove a Role Group Delegate Remove a Role Group
Management roles and assignments	Add a Role to a Role Group Remove a Role from a Role Group Change the Scope of Role Assignments to a Role Group
Management role entries	Add a Role Entry to a Role Change a Role Entry Remove a Role Entry from a Role **Note:** Changing the management role entries in management roles in a role group is an advanced task and is generally not required in most cases. You may, instead, be able to use a preexisting management role that suits your requirements. For more information, see Built-in Role Groups.

Return to top

Built-in Role Groups

Built-in roles groups are roles shipped with Exchange 2010. They provide you with a set of role groups that you can use to provide varying levels of administrative permissions to groups of users. You can add or remove users to or from any built-in role group. You can also add or remove role assignments to or from most role groups. The only exceptions are the following:

- You can't remove any delegating role assignments from the Organization Management role group.
- You can't remove the Role Management role from the Organization Management role group.

The following table lists all of the built-in role groups included with Exchange 2010. For more information about built-in role groups, see Built-in Role Groups.

Built-in role groups

Role group	Description
Organization Management	Administrators who are members of the Organization Management role group have administrative access to the entire Exchange 2010 organization and can perform almost any task against any Exchange 2010 object.
View-Only Organization Management	Administrators who are members of the View Only Organization Management role

	group can view the properties of any object in the Exchange organization.
Recipient Management	Administrators who are members of the Recipient Management role group have administrative access to create or modify Exchange 2010 recipients within the Exchange 2010 organization.
UM Management	Administrators who are members of the UM Management role group can manage the Unified Messaging (UM) features in the Exchange organization such as Unified Messaging server configuration, UM properties on mailboxes, UM prompts, and UM auto attendant configuration.
Discovery Management	Administrators or users who are members of the Discovery Management role group can perform searches of mailboxes in the Exchange organization for data that meets specific criteria.
Records Management	Users who are members of the Records Management role group can configure compliance features, such as retention policy tags, message classifications, transport rules, and more.
Server Management	Administrators who are members of the Server Management role group have administrative access to Exchange 2010 server configuration. They don't have access to administer Exchange 2010 recipient configuration.
Help Desk	Users who are members of the Help Desk role group can perform limited recipient management of Exchange 2010 recipients.
Hygiene Management	Administrators who are members of the Hygiene Management role group can configure the antivirus and anti-spam features of Exchange 2010. Third-party programs that integrate with Exchange 2010 can add service accounts to this role group to grant those programs access to the cmdlets required to retrieve and configure the Exchange configuration.
Public Folder Management	Administrators who are members of the Public Folder Management role group can manage public folders and databases on Exchange 2010 servers.
Delegated Setup	Administrators who are members of the Delegated Setup role group can deploy previously provisioned Exchange 2010 servers.

Return to top

Linked Role Groups

Linked role groups are used in organizations that install Exchange 2010 in a dedicated resource forest and place users in other, trusted foreign forests. Linked role groups, as the name implies, create a link between a role group in the Exchange forest and a USG in a foreign forest. This is useful when the Active Directory Domain Services (AD DS) user accounts of the administrators you want to administer Exchange don't reside in the same resource forest as Exchange. Linked role groups can only be associated with one foreign USG. Additionally, you don't need to create a two-way trust between the Exchange forest and the foreign forest. The Exchange forest needs to trust the foreign forest but the foreign forest doesn't need to trust the Exchange forest.

For more information about permissions in multiple-forest topologies, see Understanding Multiple-Forest Permissions.

A linked role group consists of two parts:

- **Linked role group** The linked role group is a container object that associates the foreign USG with the management role assignments assigned to the role group.
- **Foreign USG** The foreign USG contains the members that should be granted the permissions provided by the linked role group.

When you create a linked role group, you provide a domain controller in the foreign forest that contains the users you want to manage the Exchange forest and the USG that contains those users as members, the foreign USG name, and the credentials required to access the foreign forest. Exchange adds the security identifier (SID) of the foreign USG to the linked role group. Because the USG SID is the only identification of the foreign USG, we strongly recommend that you specify the foreign forest in the name of the role group if you have multiple foreign forests.

A linked role group doesn't contain any members. All of the members of that role group are managed using the foreign USG. This means you can't use the **Update-RoleGroupMember**, **Add-RoleGroupMember**, or **Remove-RoleGroupMember** cmdlets to add or remove role group members. When you add members to the foreign USG, they are given the permissions provided by the linked role group.

You can't change a standard role group, which contains its own members, to a linked role group and vice versa. If you want to change a role group from a standard role group to a linked role group, you must create a new linked role group and replicate the management role assignments that are present on the standard role group on the linked role group. This is also the case for built-in role groups because they're standard role groups. If you want to perform all of the management of your Exchange forest from a foreign forest, you need to create new linked role groups and add the management roles that exist on the built-in role groups to the new linked role groups. For more information about how to accomplish this, see Create Linked Role Groups that Mirror Built-in Role Groups.

For more information about deploying Exchange in a resource forest, see Deploy Exchange 2010 in an Exchange Resource Forest Topology.

Return to top

Role Group Delegation

By default, members of the Organization Management role group can add and remove members to and from role groups. However, you might want to enable users who aren't

members of the Organization Management role group to add and remove role group members. If so, you can use role group delegation.

Role group delegation is controlled by the **ManagedBy** property on each role group. The **ManagedBy** property contains a list of users who can add and remove members to and from that role group or change the configuration of a role group. The users aren't assigned any permissions given by the role group unless they're also members of the role group.

If the **ManagedBy** property is set on a role group, only those users who are listed as role group managers on that property can modify a role group or the membership of a role group by default. However, an optional parameter on cmdlets that modify role groups or role group membership can override that restriction. The *BypassSecurityGroupManagerCheck* switch can be used by users who are members of the Organization Management role or are assigned, either directly or indirectly, the Role Management management role. When this switch is used, the **ManagedBy** property is ignored and the user can modify the role group or role group membership.

If the **ManagedBy** property isn't set on a role group, only users who are members of the Organization Management role or are assigned, either directly or indirectly, the Role Management management role can modify a role group or role group membership.

Note:

Roles assigned to a role group may be assigned using delegating role assignments. With delegating role assignments, members of a role group that's assigned a delegated role can assign that role to another role group, assignment policy, user, or USG. Members of the role group can assign only that role and can't delegate the role group, unless they're also added to the **ManagedBy** property. For more information about delegated role assignments, see Understanding Management Role Assignments.

For more information about how to manage role group delegation, see Add or Remove a Role Group Delegate.

Return to top

Role Group Membership

When a user is made a member of a role group, the management roles assigned to the role group are assigned to the user. If a user is a member of multiple role groups, the management roles from each role group are aggregated and assigned to the user. Users, USGs, and other role groups can be members of role groups.

Only users who are members of the Organization Management or Role Management role groups and users who have been delegated the ability to add and remove users to or from role groups can manage role group membership.

For more information about how to manage role group membership, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group
- View the Members of a Role Group

Role Group Creation Workflow

As mentioned previously, a role group is made up of several layers. To help you understand what happens when a role group is created, consider the following example, which creates a new role group.

```
New-RoleGroup -Name "Seattle Recipient Management" -Roles "Mail Recipients", "Dis
```

When the preceding command is run, the following happens:

1. A new role group object, which is a special USG, called Seattle Recipient Management is created.
2. The mailboxes for Ray, Jens, Maria, Chris, Maira, Carter, Jesse, Lukas, Isabel, Rick, and Katie are added as members of the role group. These users receive the permissions provided by this role group.
3. The users Brian and David are added to the **ManagedBy** property of the role group. These users can add and remove members to and from the role group but won't be given any permissions provided by the role group because they're not members. Katie is also added to the **ManagedBy** property of the role group. Because she's added to the **ManagedBy** property, and she's a member of the role group, she can add or remove members to and from the role group, and she also receives the permissions provided by the role group.
4. The following management role assignments are created. The role assignments assign each management role specified in the command to the role group. The management scope Seattle Users is added to each role assignment. The name of each role assignment is a combination of the management role being assigned and the role group name.
   4.a. `Mail Recipients_Seattle Recipient Management`
   4.b. `Distribution Groups_Seattle Recipient Management`
   4.c. `Move Mailboxes_Seattle Recipient Management`
   4.d. `UM Mailboxes_Seattle Recipient Management`

If you compare the results of this command to the Management role group layers figure earlier in this topic, you can see where each step correlates to the role group layers. You can then refer to the Management role group management topics shown in "Role Group Management" earlier in this topic to manage each role group layer.

Return to top

1.3.1.1.2 Understanding Management Role Assignment Policies

Understanding Management Role Assignment Policies

Permissions > Understanding Permissions > Understanding Role Based Access Control >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-16*

A *management role assignment policy* is a collection of one or more end-user management roles that enables end users to manage their own Microsoft Exchange Server 2010 mailbox and distribution group configuration. Role assignment policies, which are part of the Role Based Access Control (RBAC) permissions model in Exchange 2010, enable you to control what specific mailbox and distribution group configuration settings your end users can modify. Different groups of users can have role assignment policies specialized to them.

Note:

This topic focuses on advanced RBAC functionality. If you want to manage basic Exchange 2010 permissions, such as using the Exchange Control Panel (ECP) to add and remove members to and from role groups, create and modify role groups, or create and modify role assignment policies, see Understanding Permissions.

For more information about RBAC, see Understanding Role Based Access Control.

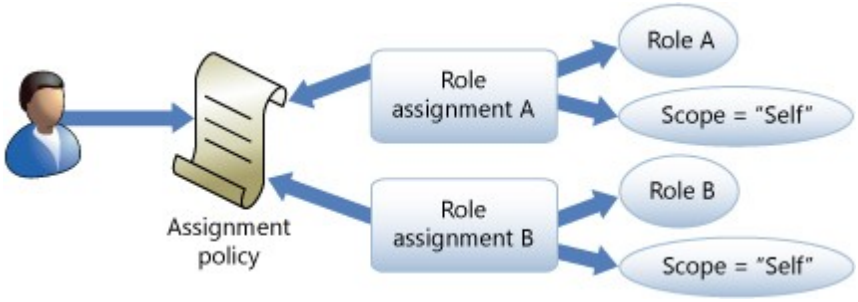
Contents

Role Assignment Policy Layers

The following are the various layers that make up the role assignment policy model:

- **Mailbox** Mailboxes are assigned a single role assignment policy. When a mailbox is assigned a role assignment policy, the assignments between management roles and a role assignment policy are applied to the mailbox. This grants the mailbox all of the permissions provided by the management roles.
- **Management role assignment policy** The *management role assignment policy* is a special object in Exchange 2010. Users are associated with a role assignment policy when their mailboxes are created, or if you change the role assignment policy on a mailbox. This is also what you assign end-user management roles to. The combination of all the roles on a role assignment policy defines everything that the user can manage on his or her mailbox or distribution groups.
- **Management role assignment** A *management role assignment* is the link between a management role and a role assignment policy. Assigning a management role to a role assignment policy grants the ability to use the cmdlets and parameters defined in the management role. When you create a role assignment between a role assignment policy and a management role, you can't specify any scope. The scope applied by the assignment is based on the management role and is either `Self` or `MyGAL`. For more information, see Understanding Management Role Assignments.
- **Management role** A *management role* is a container for a grouping of management role entries. Roles are used to define the specific tasks that a user can do with his or her mailbox or distribution groups. A *management role entry* is a cmdlet, script, or special permission that enables each specific task in a management role to be performed. You can only use end-user management roles with role assignment policies. For more information, see Understanding Management Roles.
- **Management role entry** Management role entries are the individual entries on a management role that determine what cmdlets and parameters are available to the management role and the role group. Each role entry consists of a single cmdlet and the parameters that can be accessed by the management role.

The following figure shows each of the role assignment policy layers in the preceding list and how each of the layers relates to the other.



For more information about management roles, role assignments, and scopes, see Understanding Role Based Access Control.

Return to top

Default and Explicit Role Assignment Policies

The following sections describe the two types of role assignment policies in Exchange 2010.

Default Role Assignment Policy

A default role assignment policy is one assigned to a mailbox when the mailbox is created or moved to a server running Exchange 2010, and a role assignment policy wasn't provided using the *RoleAssignmentPolicy* parameter on the **New-Mailbox** or **Enable-Mailbox** cmdlets.

Exchange 2010 includes a default role assignment policy that provides end users with the permissions most commonly used. You can change the default permissions on the default role assignment policy by adding or removing management roles to or from it.

If you want to replace the built-in default role assignment policy with your own default role assignment policy, you can use the **Set-RoleAssignmentPolicy** cmdlet to select a new default. When you do this, any new mailboxes are assigned the role assignment policy you specified by default if you don't explicitly specify a role assignment policy.

When you change the default role assignment policy, mailboxes assigned the default role assignment policy aren't automatically assigned the new default role assignment policy. If you want to update previously created mailboxes to use the role assignment policy you've set as default, you must use the **Set-Mailbox** cmdlet to do so.

Explicit Role Assignment Policy

An explicit role assignment policy is a policy that you assign to a mailbox manually using the *RoleAssignmentPolicy* parameter on the **New-Mailbox**, **Set-Mailbox**, or **Enable-Mailbox** cmdlets. When you assign an explicit role assignment policy, the new policy takes effect immediately and replaces the previously assigned explicit role assignment policy.

Return to top

Using Role Assignment Policies

Role assignment policies enable you to tailor permissions based on what your business needs your users to be able to configure. If the default role assignment policy meets your needs, you don't need to do any customization. However, if you have many different user groups with specialized needs, you can create role assignment policies for each of them.

The default role assignment policy you use should contain the permissions that apply to your broadest set of users. Then, create role assignment policies for each of your specialized user groups and tailor those role assignment policies to grant more or less restrictive permissions to them. When you organize your role assignment policies this way, you reduce complexity by only explicitly assigning role assignment policies to your specialized users while the majority of your users receive the more common permissions provided by the default role assignment policy.

A mailbox can have only one role assignment policy. All users, including administrators and specialist users, are assigned one role assignment policy. If you want a user to have a different set of permissions, you must assign that user's mailbox another role assignment policy with the required permissions.

Return to top

Role Assignment Policy Management

To add a new role assignment policy, you first create one and decide whether it should be the default role assignment policy. After you create a role assignment policy, you assign management roles to the role assignment policy, and then assign the role assignment policy to mailboxes. You can later choose to add or remove management roles or choose a different role assignment policy to be the default.

The following table lists the role assignment policy layer and the procedural topics that you can use to manage each layer.

Role assignment policy management topics

Role assignment policy model layer	Management topics
Mailbox	Create a Mailbox Change the Assignment Policy on a Mailbox
Role assignment policy	Add an Assignment Policy Remove an Assignment Policy Change the Default Assignment Policy
Management roles and assignments	Add a Role to an Assignment Policy Remove a Role from an Assignment Policy
Management role entries	Add a Role Entry to a Role Change a Role Entry Remove a Role Entry from a Role **Note:** Changing the management role entries in management roles in a role assignment policy is an advanced task and is generally not required in most cases. You may, instead, be able to use a preexisting management role that suits your requirements. For more information, see Built-in Role Groups.

Return to top

1.3.1.1.3 Understanding Management Roles

Understanding Management Roles

Permissions > Understanding Permissions > Understanding Role Based Access Control >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-25*

Management roles are part of the Role Based Access Control (RBAC) permissions model used in Microsoft Exchange Server 2010. Roles act as a logical grouping of cmdlets that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. Management roles can be further combined into larger groupings called management role groups and management role assignment policies, which enable management of feature areas and recipient configuration. Role groups and role assignment policies assign permissions to administrators and end users, respectively. For more information about management role groups and management role assignment policies, see Understanding Role Based Access Control.

Note:

This topic focuses on advanced RBAC functionality. If you want to manage basic Exchange 2010 permissions, such as using the Exchange Control Panel (ECP) to add and remove members to and from role groups, create and modify role groups, or create and modify role assignment policies, see Understanding Permissions.

Contents

Management role scopes and management role assignments are important components for the operation of management roles. For more information about these components, see the following topics:

- Understanding Management Role Scopes
- Understanding Management Role Assignments

Looking for management tasks related to management roles? See Managing Permissions.

Built-in Management Roles

Exchange 2010 provides many built-in management roles that you can use to administer your organization. Each role includes the cmdlets and parameters necessary for users to manage specific Exchange components. The following are examples of some built-in management roles:

- **Mail Recipients** Enables administrators to manage mailboxes, contacts, and mail users.
- **Transport Rules** Enables administrators or specialist users assigned the role to manage the transport rules feature.
- **Distribution Groups** Enables administrators or specialist users assigned the role to manage distribution groups and distribution group members.
- **MyPersonalInformation** Enables end users to modify their own home phone number and Web site address.

For a complete list of the management roles included with Exchange 2010, see Built-in Management Roles.

You can take the built-in roles provided with Exchange 2010 and combine them in any way to create a permissions model that works with your business. For example, if you want members of a role group to manage recipients and public folders, you assign both the Mail Recipients and Public Folders roles to the role group. Most often, you assign roles to role groups or role assignment policies. You can also assign management roles directly to users if you want to control permissions at a granular level. We recommend that you use role groups and role assignment policies rather than direct user role assignment to simplify your permissions model.

Note:
You can only assign end-user management roles to role assignment policies.

Built-in management roles can't be changed. You can, however, create management roles based on the built-in management roles, and then assign those new roles to role groups or role assignment policies. You can then change the new management roles to suit your needs. Doing so is an advanced task that you should rarely, if ever, need to do.

For more information about creating custom roles based on the built-in Exchange roles, see Custom Management Roles later in this topic.

You need to assign management roles for them to take effect. Most often, you assign management roles to role groups and role assignment policies. In certain circumstances, you might also assign roles directly to users, although this is an advanced task that you should rarely, if ever, need to do.

For more information about assigning management roles, see the following topics:

- Add a Role to a Role Group
- Add a Role to an Assignment Policy
- Add a Role to a User or USG

For more information about management role assignments, see Understanding Management Role Assignments.

Return to top

Unscoped Top-Level Management Roles

Unscoped top-level management roles are a special type of management role that enables you to grant access to custom scripts and non-Exchange cmdlets to users using RBAC. Regular management roles provide access only to Exchange cmdlets. If you need to provide access to non-Exchange cmdlets that run on an Exchange server, or if you need to publish a script that can be run by your users, you need to add them to an unscoped role. They're called a top-level role because if an unscoped role is created without deriving

it from a parent role, it has no parent and is a peer of the built-in management roles provided with Exchange 2010. To indicate that you want to create an unscoped top-level role entry, you need to use the *UnscopedTopLevel* switch with the **New-ManagementRole** cmdlet.

Unscoped roles are named as such because, unlike regular management roles, they can't be scoped to a specific target. Unscoped roles are always organization wide. This means that someone assigned an unscoped role can modify any object in the Exchange 2010 organization. For this reason, care must be taken to make sure that scripts and cmdlets made available through an unscoped role are thoroughly tested so that you know what they will modify, and that you carefully assign unscoped roles.

Unscoped roles can be assigned to role assignees such as role groups, management roles, users, and universal security groups (USGs). They can't be assigned to management role assignment policies.

Although Exchange cmdlets can't be added as a management role entry on an unscoped role, they can be included in scripts added as role entries. This enables you to create custom scripts that perform Exchange tasks that you can then assign to users. A useful scenario is where a user must perform a highly privileged task that's normally outside his or her administrative level and where crafting a new management role or role group would be problematic. You can create a script that performs this specific function, add it to an unscoped role, and then assign the unscoped role to the user. The user can then perform only the specific function provided by the script.

The role entries that you add to an unscoped role must also be designated as an unscoped top-level role entry. For more information about unscoped top-level role entries, see Unscoped Top-Level Role Entries later in this topic.

The Organization Management role group doesn't, by default, have permissions to create or manage unscoped role groups. This is to prevent unscoped role groups from mistakenly being created or modified. The Organization Management role group can delegate the Unscoped Role Management management role to itself and other role assignees. For more information about how to create an unscoped top-level management role, see Create an Unscoped Role.

Return to top

Custom Management Roles

You can create custom management roles based on built-in Exchange roles when the built-in management roles don't match the needs of your users. When you create a custom management role, the new child role inherits all of the management role entries of the parent role. You can then choose which management role entries you want to keep in the custom management role and remove all of the entries you don't want.

Custom roles become children of the role used to create the new role. You can only use management role entries in the new child role that exist in the parent role. For more information, see the following sections later in this topic:

- Management Role Hierarchy
- Management Role Entries

Creating custom management roles requires multiple steps and is an advanced task that you should rarely, if ever, need to perform. Before you create a custom management role, make sure one of the existing built-in management roles doesn't provide the permissions you need. For more information about the built-in management roles, or if you want to create custom management roles, see the following topics:

- Built-in Management Roles
- Managing Advanced Permissions

For more information about how to create a management role, see Create a Role.

Return to top

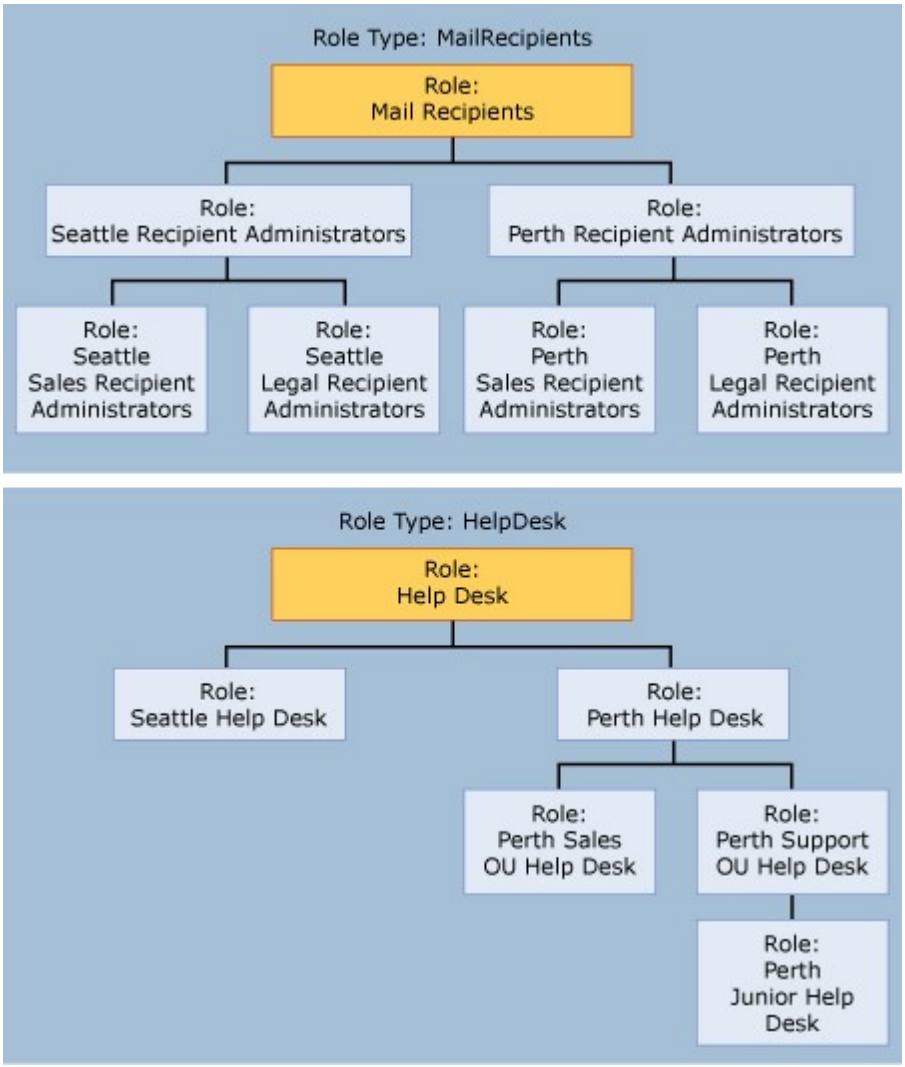
Management Role Hierarchy

Management roles exist in a parent and child hierarchy. At the top of the hierarchy are the built-in management roles provided in Exchange 2010 by default. When you create a role, a copy of a parent role is made. The new role is a child of the role you copied from. You can then customize the new role to suit the needs of the administrators or users you want to assign it to.

Customized roles can be used to create roles. When you create a role from an existing customized role, the existing customized role remains a child of its parent role, but also becomes the parent for the new role. Each time a role is copied, the new child role can contain only the role entries that exist in the immediate parent role.

Each management role is given a role type that can't be changed. The role type defines the base context of use for the role. The role type is copied from the parent role when the child role is created.

Management role hierarchy



The preceding figure illustrates the hierarchical relationship of several management roles. The Mail Recipients and Help Desk roles are built-in roles. All of the child roles derived from these roles inherit the role type of each built-in role. For example, all child roles derived either directly or indirectly from the Mail Recipients role inherit the `MailRecipients` role type.

The Seattle Recipient Administrators custom role is a child of the Mail Recipients built-in role but it's also the parent of the Seattle Sales Recipient Administrators custom role and the Seattle Legal Recipient Administrators custom role. The Seattle Recipient Administrators custom role contains only a subset of cmdlets that are available in the Mail Recipients role. The child roles of the Seattle Recipient Administrators custom role can only contain cmdlets that also exist in that role. For example, if a cmdlet exists in the Mail Recipients role, but the cmdlet doesn't exist in the Seattle Recipient Administrators custom role, the cmdlet can't be added to the Seattle Sales Recipient Administrators custom role.

All of the custom roles follow the same pattern as the roles discussed previously. For more information about how access to cmdlets is controlled on management roles, see Management Role Entries next in this topic.

Return to top

Management Role Entries

Every management role, whether it's a custom Exchange role or an unscoped role, must have at least one management role entry. An entry consists of a single cmdlet and its parameters, a script, or a special permission that you want to make available. If a cmdlet or script doesn't appear as an entry on a management role, that cmdlet or script isn't accessible via that role. Likewise, if a parameter doesn't exist in an entry, the parameter on that cmdlet or script isn't accessible via that role.

Exchange 2010 enables you to manage role entries based on built-in Exchange management top-level roles and role entries based on unscoped top-level management roles. Roles based on built-in Exchange top-level roles can only contain role entries that are Exchange 2010 cmdlets. To add custom scripts or non-Exchange cmdlets so that your users can use them, you need to add them as unscoped role entries to an unscoped top-level role. For more information about unscoped role entries, see Unscoped Top-Level Role Entries later in this topic.

All role entries, regardless of whether the role entry is an Exchange cmdlet-based role entry or an unscoped role entry, adhere to the same principles explained in the following sections.

For more information about managing role entries, see Management Roles and Role Entries.

Parent and Child Management Role Relationship

As mentioned previously, a management role entry, including the cmdlet and its parameters, must exist in the immediate parent role to add the entry to the child role. For example, if the parent role doesn't have an entry for **New-Mailbox**, the child role can't be assigned that cmdlet. Additionally, if **Set-Mailbox** is on the parent role but the *Database* parameter has been removed from the entry, the *Database* parameter on the **Set-Mailbox** cmdlet can't be added to the entry on the child role.

Because you can't add management role entries to child roles if the entries don't appear in parent roles, and because the role is based on a specific role type, you must carefully choose the parent role to copy when you want to create a customized role.

Return to top

Management Role Entry Names

Management role entry names are a combination of the management role that they're associated with, and the name of the cmdlet or script. The role name and the cmdlet or script are separated by a backslash character (\). For example, the role entry name for the **Set-Mailbox** cmdlet on the Mail Recipients role is `Mail Recipients\Set-Mailbox`. If the name of a role entry contains spaces, enclose the entire name in quotation marks (").

The wildcard character (*) can be used in the role entry name to return all of the role entries that match the input you provide. The wildcard character can be used on either side of the backslash character. The following table contains a few variations on how you can use the wildcard character in a role entry name.

Management role entry name with wildcard characters

Example	Description
`*\*`	Returns a list of all role entries for all roles.
`*\Set-Mailbox`	Returns a list of all role entries that contain the **Set-Mailbox** cmdlet.

`Mail Recipients\*`	Returns a list of all role entries on the Mail Recipients role.
`Mail Recipients\*Mailbox`	Returns a list of all role entries on the Mail Recipients role that contain cmdlets that end in Mailbox.
`My*\*Group*`	Returns a list of all role entries that contain the string Group in the cmdlet name for all roles that begin with My.

Unscoped Top-Level Role Entries

Unscoped top-level role entries are used with unscoped top-level management roles to create roles based on custom scripts or non-Exchange cmdlets. Each unscoped role entry is associated with a single custom script or a non-Exchange cmdlet. To indicate that you want to create an unscoped role entry on an unscoped role, you need to specify the *UnscopedTopLevel* parameter on the **Add-ManagementRoleEntry** cmdlet.

When you add the unscoped role entry, you need to specify all of the parameters that can be used with the script or non-Exchange cmdlet. Exchange attempts to verify the parameters that you provide when you add the role entry. Only the parameters that you add to the role entry when it's created will be available to the users assigned to the unscoped role. If you add parameters to the script or non-Exchange cmdlet, or if a parameter is renamed, you must update the role entry manually. Exchange doesn't check whether existing parameters on an unscoped role entry have changed. If a parameter on a role entry changes in a script and you try to use that parameter, the command fails.

Scripts that you add to an unscoped role entry must reside in the Exchange 2010 scripts directory on every server where administrators and users connect using the Exchange Management Shell. If you try to add an unscoped role entry based on a script that doesn't exist in the Exchange 2010 scripts directory on the server you're using to add the role entry, an error occurs. The default installation location of the Exchange 2010 scripts directory is C:\Program Files\Microsoft\Exchange Server\V14\Scripts.

Non-Exchange cmdlets that you add to an unscoped role entry must be installed on every Exchange 2010 server where administrators and users connect using the Shell and want to use the cmdlets. If you try to add an unscoped role entry based on a non-Exchange cmdlet that isn't installed on the Exchange 2010 server you're using to add the role entry, an error occurs. When you add a non-Exchange cmdlet, you must specify the Windows PowerShell snap-in name that contains the non-Exchange cmdlet.

For more information about how to add an unscoped management role entry, see Add a Role Entry to a Role.

Return to top

Management Role Types

Management role types are the foundation of all management roles. Types define the implicit scopes defined on all management roles of a specified role type and also act as a logical grouping of related roles. All management roles derived from the parent built-in management role have the same role type. Refer to the Management role hierarchy figure earlier in this topic for an illustration of this relationship. Management role types also represent the maximum set of cmdlets and their parameters that can be added to a role associated with a role type.

Management role types are split into the following categories:

- **Administrative or specialist** Roles associated with an administrative or specialist role type have a broader scope of impact in the Exchange organization. Roles of this role type enable tasks such as server or recipient management, organization configuration, compliance administration, auditing, and more.
- **User-focused** Roles associated with a user-focused role type have a scope of impact closely tied with an individual user. Roles of this role type enable tasks such as user profile configuration and self management, management of user-owned distribution groups, and more.
  The names of roles associated with user-focused role types and user-focused role type names begin with My.
- **Specialty** Roles associated with specialty role types enable tasks that aren't administrative or user-focused role types. Roles of this role type enable tasks such as application impersonation and the use of non-Exchange cmdlets or scripts.

The following table lists all of the administrative management role types in Exchange 2010 and whether the configuration that's permitted by the role type is applied across the whole Exchange organization or only to an individual server. For more information about each of the management roles associated with these role types, including a description of each role, who may benefit from being assigned the role, and other information, see Built-in Management Roles.

Administrative role types

Management role type	Built-in management role	Description	Organization or server
ActiveDirectoryPermissions	Active Directory Permissions Role	This role type is associated with roles that enable administrators to configure Active Directory permissions in an organization. Some features that use Active Directory permissions or an access control list (ACL) include transport Receive and Send connectors, and Send As and send on behalf permissions for mailboxes. **Note:** Permissions set directly on Active Directory objects may not be enforced through RBAC.	Organization
AddressLists	Address Lists Role	This role type is associated with roles that enable administrators to manage address lists, the global address list (GAL), and offline address lists in an organization.	Organization
ApplicationImpersonation	ApplicationImpersonation Role	This role type is associated with roles that enable applications to impersonate users in an organization to perform tasks on behalf of the user.	Organization
AuditLogs	Audit Logs Role	This role type is associated with roles that enable administrators to manage the administrator audit logging configuration in an	Organization

		organization.	
CmdletExtensionAgents	Cmdlet Extension Agents Role	This role type is associated with roles that enable administrators to manage cmdlet extension agents in an organization.	Organization
DatabaseAvailabilityGroups	Database Availability Groups Role	This role type is associated with roles that enable administrators to manage database availability groups (DAGs) in an organization. Administrators assigned this role either directly or indirectly are the highest level administrators responsible for the high availability configuration in an organization.	Organization
DatabaseCopies	Database Copies Role	This role type is associated with roles that enable administrators to manage database copies on individual servers.	Server
Databases	Databases Role	This role type is associated with roles that enable administrators to create, manage, mount, and dismount mailbox and public folder databases on individual servers.	Server
DisasterRecovery	Disaster Recovery Role	This role type is associated with roles that enable administrators to restore mailboxes and DAGs in an organization.	Organization
DistributionGroups	Distribution Groups Role	This role type is associated with roles that enable administrators to create and manage distribution groups and distribution group members in an organization.	Organization
EdgeSubscriptions	Edge Subscriptions Role	This role type is associated with roles that enable administrators to manage edge synchronization and subscription configuration between Edge Transport servers and Hub Transport servers in an organization.	Organization
EmailAddressPolicies	E-Mail Address Policies Role	This role type is associated with roles that enable administrators to manage e-mail address policies in an organization.	Organization
ExchangeConnectors	Exchange Connectors Role	This role type is associated with roles that enable administrators to manage connectors that aren't Send and Receive connectors in an organization.	Organization

		These connectors include routing group connectors and delivery agent connectors.	
ExchangeServerCertificates	Exchange Server Certificates Role	This role type is associated with roles that enable administrators to create, import, export, and manage Exchange server certificates on individual servers.	Server
ExchangeServers	Exchange Servers Role	This role type is associated with roles that enable administrators to manage Exchange server configuration on individual servers.	Server
ExchangeVirtualDirectories	Exchange Virtual Directories Role	This role type is associated with roles that enable administrators to manage Microsoft Office Outlook Web App, Microsoft ActiveSync, offline address book (OAB), Autodiscover, Windows PowerShell, and Web administration interface virtual directories on individual servers.	Server
FederatedSharing	Federated Sharing Role	This role type is associated with roles that enable administrators to manage cross-forest and cross-organization sharing in an organization.	Organization
InformationRightsManagement	Information Rights Management Role	This role type is associated with roles that enable administrators to manage the Information Rights Management (IRM) features of Exchange in an organization.	Organization
Journaling	Journaling Role	This role type is associated with roles that enable administrators to manage journaling configuration in an organization.	Organization
LegalHold	Legal Hold Role	This role type is associated with roles that enable administrators to configure whether data within a mailbox should be retained for litigation purposes in an organization.	Organization
MailboxImportExport	Mailbox Import Export Role	This role type is associated with roles that enable administrators to import and export mailbox content and to purge unwanted content from a mailbox.	Organization
MailboxSearch	Mailbox Search Role	This role type is associated with roles that enable administrators to search the content of one or	Organization

		more mailboxes in an organization.	
MailEnabledPublicFolders	Mail Enabled Public Folders Role	This role type is associated with roles that enable administrators to configure whether individual public folders are mail-enabled or mail-disabled in an organization. This role type enables you to manage the e-mail properties of public folders only. It doesn't enable you to manage properties of public folders that aren't e-mail properties. To manage properties of public folders that aren't e-mail properties, you need to be assigned a role associated with the PublicFolders role type.	Organization
MailRecipientCreation	Mail Recipient Creation Role	This role type is associated with roles that enable administrators to create mailboxes, mail users, mail contacts, distribution groups, and dynamic distribution groups in an organization. Roles associated with this role type can be combined with roles associated with the MailRecipients role type to enable the creation and management of recipients. This role type doesn't enable you to mail-enable public folders. To mail-enable public folders, you must be assigned a role associated with the MailEnabledPublicFolders role type. If your organization maintains a split permissions model where recipient creation is performed by a different group from the group that performs recipient management, assign the MailRecipientCreation role to the group that performs recipient creation, and the MailRecipients role to the group that performs recipient management.	Organization
MailRecipients	Mail Recipients Role	This role type is associated with roles that enable administrators to manage existing mailboxes, mail users, mail contacts,	Organization

		distribution groups, and dynamic distribution groups in an organization. Roles associated with this role type can't create these recipients but can be combined with roles associated with the MailRecipientCreation role type to enable the creation and management of recipients. This role type doesn't enable you to manage mail-enabled public folders or distribution groups. To manage mail-enabled public folders, you must be assigned a role associated with the MailEnabledPublicFolders role type. To manage distribution groups, you must be assigned a role associated with the DistributionGroups role type. If your organization maintains a split permissions model where recipient creation is performed by a different group from the group that performs recipient management, assign the MailRecipientCreation role to the group that performs recipient creation, and the MailRecipients role to the group that performs recipient management.	
MailTips	Mail Tips Role	This role type is associated with roles that enable administrators to manage MailTips in an organization.	Organization
MessageTracking	Message Tracking Role	This role type is associated with roles that enable administrators to track messages in an organization.	Organization
Migration	Migration Role	This role type is associated with roles that enable administrators to migrate mailboxes and mailbox content into or out of a server.	Server
Monitoring	Monitoring Role	This role type is associated with roles that enable administrators to monitor the Microsoft Exchange services and component availability in an organization. In addition to	Organization

		administrators, roles associated with this role type can be used with the service account used by monitoring applications to collect information about the state of Exchange servers.	
MoveMailboxes	Move Mailboxes Role	This role type is associated with roles that enable administrators to move mailboxes between servers in an organization and between servers in the local organization and another organization.	Organization
OrganizationClientAccess	Organization Client Access Role	This role type is associated with roles that enable administrators to manage Client Access server settings in an organization.	Organization
OrganizationConfiguration	Organization Configuration Role	This role type is associated with roles that enable administrators to manage organization-wide settings in an organization. Organization configuration that can be controlled with this role type include the following and more: • Whether MailTips are enabled or disabled for the organization. • The URL for the managed folder home page. • The Microsoft Exchange recipient SMTP address and alternate e-mail addresses. • The resource mailbox property schema configuration. • The Help URLs for the Exchange Management Console and Outlook Web App. This role type doesn't include the permissions included in the OrganizationClientAccess or OrganizationTransportSettings role types.	Organization
OrganizationTransportSettings	Organization Transport Settings Role	This role type is associated with roles that enable administrators to manage organization-wide	Organization

		transport settings, such as system messages, site configuration, and other organization-wide transport settings in an organization. This role doesn't enable you to create or manage transport Receive or Send connectors, queues, hygiene, agents, remote and accepted domains, or rules. To create or manage each of the transport features, you must be assigned roles associated with the following role types: • **Receive connectors** ReceiveConnectors • **Send connectors** SendConnectors • **Transport queues** TransportQueues • **Transport hygiene** TransportHygiene • **Transport agents** TransportAgents • **Remote and accepted domains** RemoteAndAcceptedDomains • **Transport rules** TransportRules	
POP3AndIMAP4Protocols	POP3 and IMAP4 Protocols Role	This role type is associated with roles that enable administrators to manage POP3 and IMAP4 configuration, such as authentication and connection settings, on individual servers.	Server
PublicFolderReplication	Public Folder Replication Role	This role type is associated with roles that enable administrators to start and stop public folder replication in an organization.	Organization
PublicFolders	Public Folders Role	This role type is associated with roles that enable administrators to manage public folders in an organization. This role type doesn't enable you to manage whether public folders are mail-enabled or manage public folder replication. To mail-enable or disable a public folder, you must be assigned a role associated with the	Organization

		MailEnabledPublicFolders role type. To configure public folder replication, you must be assigned a role associated with the PublicFolderReplication role type.	
ReceiveConnectors	Receive Connectors Role	This role type is associated with roles that enable administrators to manage transport Receive connector configuration, such as size limits on an individual server.	Server
RecipientPolicies	Recipient Policies Role	This role type is associated with roles that enable administrators to manage recipient policies, such as provisioning policies, in an organization.	Organization
RemoteAndAcceptedDomains	Remote and Accepted Domains Role	This role type is associated with roles that enable administrators to manage remote and accepted domains in an organization.	Organization
RetentionManagement	Retention Management Role	This role type is associated with roles that enable administrators to manage retention policies in an organization.	Organization
RoleManagement	Role Management Role	This role type is associated with roles that enable administrators to manage management role groups, role assignment policies, management roles, role entries, assignments, and scopes in an organization. Users assigned roles associated with this role type can override the **role group managed by** property, configure any role group, and add or remove members to or from any role group.	Organization
SecurityGroupCreationAndMembership	Security Group Creation and Membership Role	This role type is associated with roles that enable administrators to create and manage USGs and their memberships in an organization. If your organization maintains a split permissions model where USG creation and management is performed by a different group from the group that manages Exchange servers,	Organization

		assign roles associated with this role type to that group.	
SendConnectors	Send Connectors Role	This role type is associated with roles that enable administrators to manage transport Send connectors in an organization.	Organization
SupportDiagnostics	Support Diagnostics Role	This role type is associated with roles that enable administrators to perform advanced diagnostics under the direction of Microsoft support services in an organization. **Caution:** Roles associated with this role type grant permissions to cmdlets and scripts that should only be used under the direction of Microsoft Customer Service and Support.	Organization
TransportAgents	Transport Agents Role	This role type is associated with roles that enable administrators to manage transport agents in an organization.	Organization
TransportHygiene	Transport Hygiene Role	This role type is associated with roles that enable administrators to manage antivirus and anti-spam features in an organization.	Organization
TransportQueues	Transport Queues Role	This role type is associated with roles that enable administrators to manage transport queues on an individual server.	Server
TransportRules	Transport Rules Role	This role type is associated with roles that enable administrators to manage transport rules in an organization.	Organization
UMMailboxes	UM Mailboxes Role	This role type is associated with roles that enable administrators to manage the Unified Messaging (UM) configuration of mailboxes and other recipients in an organization.	Organization
UMPrompts	UM Prompts Role	This role type is associated with roles that enable administrators to create and manage custom UM voice prompts in an organization.	Organization
UnifiedMessaging	Unified Messaging Role	This role type is associated with roles that enable administrators to manage Unified Messaging servers in an organization.	Organization

		This role doesn't enable you to manage UM-specific mailbox configuration or UM prompts. To manage UM-specific mailbox configuration, use roles associated with the UMMailboxes role type. To manage UM prompts, use the roles associated with the UMPrompts role type.	
UnScopedRoleManagement	Unscoped Role Management Role	This role type is associated with roles that enable administrators to create and manage unscoped top-level management roles in an organization.	Organization
UserOptions	User Options Role	This role type is associated with roles that enable administrators to view the Outlook Web App options of a user in an organization. Roles associated with this role type can be used to help a user with diagnosing problems with his or her configuration.	Organization
ViewOnlyAuditLogs	View-Only Audit Logs Role	This role type is associated with roles that enable administrators to search the administrator audit log in an organization.	Organization
ViewOnlyConfiguration	View-Only Configuration Role	This role type is associated with roles that enable administrators to view all of the non-recipient Exchange configuration settings in an organization. Examples of configuration that are viewable are server configuration, transport configuration, database configuration, and organization-wide configuration. Roles associated with this role type can be combined with roles associated with the ViewOnlyRecipients role type to create a role that can view every object in an organization.	Organization
ViewOnlyRecipients	View-Only Recipients Role	This role type is associated with roles that enable administrators to view the configuration of recipients, such as mailboxes, mail users, mail contacts, distribution groups, and dynamic distribution groups.	Organization

		Roles associated with this role type can be combined with roles associated with the `ViewOnlyConfiguration` role type to create a role that can view every object in the organization.	

The following table lists all of the user-focused management role types and their associated built-in management roles in Exchange 2010.

User-focused role types

Management role type	Built-in user-focused roles	Description
`MyBaseOptions`	MyBaseOptions Role	This role type is associated with roles that enable individual users to view and modify the basic configuration of their own mailbox and associated settings.
`MyContactInformation`	MyAddressInformation Role MyContactInformation Role MyMobileInformation Role MyPersonalInformation Role	This role type is associated with roles that enable individual users to modify their contact information. This information includes their address and phone numbers.
`MyDistributionGroupMembership`	MyDistributionGroupMembership Role	This role type is associated with roles that enable individual users to view and modify their membership in distribution groups in an organization, provided that those distribution groups allow manipulation of group membership.
`MyDistributionGroups`	MyDistributionGroups Role	This role type is associated with roles that enable individual users to create, modify, and view distribution groups and modify, view, remove, and add members to distribution groups they own.
`MyProfileInformation`	MyDisplayName Role MyName Role MyProfileInformation Role	This role type is associated with roles that enable individual users to modify their name.
`MyRetentionPolicies`	MyRetentionPolicies Role	This role type is associated with roles that enable individual users to view their retention tags and view and modify their retention tag

		settings and defaults.
MyTextMessaging	MyTextMessaging Role	This role type is associated with roles that enable individual users to create, view, and modify their text messaging settings.
MyVoiceMail	MyVoiceMail Role	This role type is associated with roles that enable individual users to view and modify their voice mail settings.

1.3.1.1.4 Understanding Management Role Scopes

Understanding Management Role Scopes

Permissions > Understanding Permissions > Understanding Role Based Access Control >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-05*

Management role scopes enable you to define the specific scope of impact or influence of a management role when a management role assignment is created. When you apply a scope, the role assignee assigned to the role can only modify the objects contained within that scope. A role assignee can be a management role group, management role, management role assignment policy, user, or universal security group (USG). For more information about management roles, see Understanding Role Based Access Control.

Every management role, whether built-in or custom, has management scopes. Management scopes can be either of the following:

- **Regular** A *regular scope* isn't exclusive. It determines where, in Active Directory, objects can be viewed or modified by users assigned the management role. In general, a management role indicates what you can create or modify, and a management role scope indicates where you can create or modify. Regular scopes can be either implicit or explicit scopes, both

of which are discussed later in this topic.

- **Exclusive** An *exclusive scope* behaves almost the same as a regular scope. The key difference is that it enables you to deny users access to objects contained within the exclusive scope if those users aren't assigned a role associated with the exclusive scope. All exclusive scopes are explicit scopes, which are discussed later in this topic.
  For more information about exclusive scopes, see Understanding Exclusive Scopes.

Scopes can be inherited from the management role, specified as a predefined relative scope on a management role assignment, or created using custom filters and added to a management role assignment. Scopes inherited from management roles are called *implicit scopes* while predefined and custom scopes are called *explicit scopes*. The following sections describe each type of scope:

- Implicit Scopes
- Explicit Scopes
- Predefined Relative Scopes
- Custom Scopes
  - Recipient Filter Scopes
  - Configuration Scopes

Each role can have the following types of scopes:

- **Recipient read scope** The implicit recipient read scope determines what recipient objects the user assigned the management role is allowed to read from Active Directory.
- **Recipient write scope** The implicit recipient write scope determines what recipient objects the user assigned the management role is allowed to modify in Active Directory.
- **Configuration read scope** The implicit configuration read scope determines what configuration objects the user assigned the management role is allowed to read from Active Directory.
- **Configuration write scope** The implicit configuration write scope determines what organizational, database, and server objects the user assigned the management role is allowed to modify in Active Directory.

Recipient objects include mailboxes, distribution groups, mail enabled users, and other objects. Configuration objects include servers running Microsoft Exchange Server 2010, and databases located on servers running Exchange. Each type of scope can be either an implicit scope or explicit scope.

Implicit Scopes

Implicit scopes are the default scopes that apply to a management role type. Because implicit scopes are associated with a management role type, all of the parent and child management roles with the same role type also have the same implicit scopes. Implicit scopes apply to both built-in management roles and also to custom management roles. For more information about management roles and management role types, see Understanding Management Roles.

The following tables list all of the implicit scopes that can be defined on management roles.

Implicit scopes defined on management roles

Implicit scopes	Description
`Organization`	If `Organization` is present in the role's recipient write scope, the role can create or modify recipient objects across the Exchange organization.

	If Organization is present in the role's recipient read scope, roles can view any recipient object across the Exchange organization. This scope is used only with recipient read and write scopes.
MyGAL	If MyGAL is present in the role's recipient write scope, the role can view the properties of any recipient within the current user's global address list (GAL). If MyGAL is present in the role's recipient read scope, the role can view the properties of any recipient within the current GAL. This scope is used only with recipient read scopes.
Self	If Self is present in the role's recipient write scope, the role can modify only the properties of the current user's mailbox. If Self is present in the role's recipient read scope, the role can view only the properties of the current user's mailbox. This scope is used only with recipient read and write scopes.
MyDistributionGroups	If MyDistributionGroups is present in the role's recipient write scope, the role can create or modify distribution list objects owned by the current user. If MyDistributionGroups is present in the role's recipient read scope, the role can view distribution list objects owned by the current user. This scope is used only with recipient read and write scopes.
OrganizationConfig	If OrganizationConfig is present in the role's configuration write scope, the role can create or modify any server or database configuration object across the Exchange organization. If OrganizationConfig is present in the role's configuration read scope, the role can view any server or database configuration object across the Exchange organization. This scope is used only with configuration read and write scopes.

None	If None is in a scope, that scope isn't available to the role. For example, a role that has None in the recipient write scope can't modify recipient objects in the Exchange organization.

If a role is assigned to a role assignee and no predefined or custom scopes are specified, the implicit scopes defined on the role are used to control the recipient or organization objects the user can view or modify.

The implicit write scope of a role is always equal to, or less than, the implicit read scope. This means that a role can never modify objects that can't be seen by the scope.

You can't change the implicit scopes defined on management roles. You can, however, override the implicit write scope and configuration scope on a management role. When a predefined relative scope or custom scope is used on a role assignment, the implicit write scope of the role is overridden, and the new scope takes precedence. The implicit read scope of a role can't be overridden and always applies. For more information, see Predefined Relative Scopes and Custom Scopes.

Expand the following table to see a list of all the built-in management roles and their implicit scopes. For more information about each built-in role, see Built-in Management Roles.

Explicit Scopes

Explicit scopes are scopes that you set yourself to control which objects a management role can modify. Although implicit scopes are defined on a management role, explicit scopes are defined on a management role assignment. This enables the implicit scopes to be applied consistently across all management roles unless you choose to use an overriding explicit scope. For more information about management role assignments, see Understanding Management Role Assignments.

Explicit scopes override the implicit write and configuration scopes of a management role. They don't override the implicit read scope of a management role. The implicit read scope continues to define what objects the management role can read.

Explicit scopes are useful when the implicit write scope of a management role doesn't meet the needs of your business. You can add an explicit scope to include nearly anything you want as long as the new scope doesn't exceed the bounds of the implicit read scope. The cmdlets that are part of a management role must be able to read information about the objects or containers that contain objects for the cmdlets to create or modify objects. For example, if the implicit read scope on a management role is set to `Self`, you can't add an explicit write scope of `Organization` because the explicit write scope exceeds the bounds of the implicit read scope.

For more information, see the following sections:

- Predefined Relative Scopes
- Custom Scopes

Predefined Relative Scopes

Exchange 2010 provides several predefined relative write scopes that you can use to modify scope of a management role. Predefined relative scopes provide an easy way for you to more closely match the needs of your business without having to create custom scopes manually. They're called relative scopes because they're relative to the role assignee to which the associated role assignment is assigned. For example, the `Self` predefined relative scope restricts that write scope to the current user only. The `MyDistributionGroups` predefined relative scope restricts the write scope to the distribution group the current user owns only. Predefined relative scopes can only be used to scope recipient objects. Predefined relative scopes can't be used to scope configuration objects. The following table lists the predefined relative scopes that you can use.

Predefined relative scopes

Implicit scopes	Description
`Organization`	If `Organization` is present in the role's recipient write scope, the role can create or modify recipient objects across the Exchange organization. If `Organization` is present in the role's recipient read scope, roles can view any recipient object across the Exchange organization. This scope is used only with recipient read and write scopes.
`Self`	If `Self` is present in the role's recipient write scope, the role can modify only the properties of the current user's mailbox. If `Self` is present in the role's recipient read scope, the role can view only the properties of the current user's mailbox. This scope is used only with recipient read and write scopes.

MyDistributionGroups	If MyDistributionGroups is present in the role's recipient write scope, the role can create or modify distribution list objects owned by the current user. If MyDistributionGroups is present in the role's recipient read scope, the role can view distribution list objects owned by the current user. This scope is used only with recipient read and write scopes.

Predefined relative scopes are applied when you create a new management role assignment. During the creation of the role assignment, using the **New-ManagementRoleAssignment** cmdlet, you can specify a predefined relative scope using the *RecipientRelativeWriteScope* parameter. When the new role assignment is created, the new predefined role overrides the implicit write scope of the management role. You can't specify a custom recipient scope when you create a role assignment with a predefined relative scope. You can, however, specify a custom configuration scope if needed.

For more information about how to add a management role assignment with a predefined relative scope, see Add a Role to a User or USG.

Custom Scopes

Custom scopes are needed when neither the implicit write scope nor the predefined relative scopes meets the needs of your business. Custom scopes enable you to define at a granular level, the scope to which your management role will be applied. For example, you might want to target a specific organizational unit (OU), a specific type of recipient, or both. Or, you might only want to allow a group of administrators to be able to manage a specific set of mailbox databases.

As with predefined relative scopes, custom scopes override the implicit write and organization configuration scopes defined on management roles. The implicit read scope on management roles continue to apply and the resulting custom scope must not exceed the boundaries of the implicit read scope. You can create the following three types of custom scopes:

- **OU scope** An OU scope, which is the simplest custom scope, is created using the *RecipientOrganizationalUnitScope* parameter on the **New-ManagementRoleAssignment** cmdlet. By specifying an OU scope when a role is assigned, the role assignee assigned the role can modify only recipient objects within that OU. For more information about how to add a management role assignment with an OU scope, see Add a Role to a User or USG.
- **Recipient filter scope** Recipient filter scopes use filters to target specific recipients based on recipient type or other recipient properties such as department, manager, location, and more. For more information, see the Recipient Filter Scopes section.
- **Configuration scope** Configuration scopes use filters or lists to target specific servers based on server lists or filterable properties that can be defined on servers, such as an Active Directory site or a server role. In Exchange 2010 Service Pack 1 (SP1), configuration scopes can also use database scopes to target specific databases based on database lists or filterable database properties. For more information, see the Configuration Scopes section.

Simple and broad or complex and granular recipient and configuration custom scopes can be created by using the **New-ManagementScope** cmdlet. When you create either a recipient or configuration scope, only the recipient, server, or database objects that match

their respective scopes are returned. When these scopes are applied to a role assignment using the **New-ManagementRoleAssignment** or **Set-ManagementRoleAssignment** cmdlets, only the objects that match the scopes can be modified by the role assignees who are assigned the role. After a custom scope has been created, you can't change the scope type. A recipient scope is always a recipient scope and a configuration scope is always a configuration scope.

By default, a custom scope enables a role assignee to access a set of objects that match the scopes you define. However, they don't actively exclude access to other role assignees who aren't also assigned the same or equivalent scope. Any custom scope can access the same objects if the lists or filters on those scopes match the same objects. There might be objects where this behavior isn't wanted, such as in the case of important personnel, such as executives. For these objects, you can define exclusive scopes. Exclusive scopes use filters or lists in the same way as regular scopes but unlike regular scopes, deny access to objects included in the scope to anyone who isn't part of the same or equivalent exclusive scope. For more information about exclusive scopes, see Understanding Exclusive Scopes.

Recipient Filter Scopes

Recipient filter scopes enable you to control which recipient objects role assignees can manage by evaluating one or more properties on a recipient object against a value that you specify in a filter statement. Recipients included in recipient scopes are mailboxes, mail-enabled users, distribution groups and mail contacts. Only the recipients that match the filter you specify can be managed by the role assignees assigned that role assignment. An example of a filter statement is `{ Name -Eq "David" }` where **Name** is the property on the recipient object that's being evaluated and **David** is the value you want to evaluate against the property. The **-Eq** comparison operator indicates that the value stored in the property must be equal to the value that was specified for the filter to be true. If the filter is true, that recipient is included in scope.

Recipient filter scopes are created by specifying the recipient filter to use with the *RecipientRestrictionFilter* parameter on the **New-ManagementScope** cmdlet. By default, the **New-ManagementScope** cmdlet creates regular scopes. If you want to create an exclusive scope, include the *Exclusive* switch along with the *RecipientRestrictionFilter* parameter.

When you create a recipient restriction filter, Exchange evaluates the filter you provided against every recipient object in the organization by default. If you want to limit which recipients the scope evaluates, you can use the *RecipientRoot* parameter along with the *RecipientRestrictionFilter* parameter. The *RecipientRoot* parameter accepts an OU. When you use the *RecipientRoot* parameter, Exchange evaluates only the recipients included in the specified OU against the filter you provided.

When you add a recipient filter scope to a role assignment, specify the name of the recipient scope in the *CustomRecipientWriteScope* parameter on the **New-ManagementRoleAssignment** if you're creating a new role assignment, or the **Set-ManagementRoleAssignment** cmdlet if you're updating an existing role assignment. Each role assignment can have one recipient scope, including predefined relative scopes. You can add one configuration scope to the same role assignment you added a recipient scope to.

For more information about filter syntax and for a full list of filterable recipient properties on recipients, see Understanding Management Role Scope Filters.

Configuration Scopes

The following are the two types of configuration scopes offered in Exchange 2010:

- **Server scopes** There are two types of server scopes, server filter scopes and server list scopes. Server configuration that can be managed if a server object is included in a server scope include Receive connectors, transport queues,

server certificates, virtual directories, and so on.

- **Server filter scopes** Server filter scopes enable you to control which server objects role assignees can manage by evaluating one or more properties on a server object against a value that you specify in a filter statement. To create a server filter scope, use the *ServerRestrictionFilter* parameter on the **New-ManagementScope** cmdlet.
- **Server list scopes** Server list scopes enable you to control which server objects role assignees can manage by defining a list of servers that a role assignee can access. To create a server list scope, use the *ServerList* parameter on the **New-ManagementScope** cmdlet.

- **Database scopes** There are two types of database scopes, database filter scopes and database list scopes. Database configuration that can be managed if a database object is included in a database scope include database quota limits, database maintenance, public folder replication, whether a database is mounted, and so on. In addition to database configuration, database scopes can also be used to control which databases recipients can be created in. Database scopes are available only in Exchange 2010 SP1.
  - **Database filter scopes** Database filter scopes enable you to control which database objects role assignees can manage by evaluating one or more properties on a database object against a value that you specify in a filter statement. To create a database filter scope, use the *DatabaseRestrictionFilter* parameter on the **New-ManagementScope** cmdlet.
  - **Database list scopes** Database list scopes enable you to control which database objects role assignees can manage by defining a list of databases that a role assignee can access. To create a database list scope, use the *DatabaseList* parameter on the **New-ManagementScope** cmdlet.

For more information about filter syntax and for a full list of filterable server and database properties, see Understanding Management Role Scope Filters.

Server and database lists can be defined by specifying each server and database you want to include in their respective scopes. Multiple servers or databases can be specified in their respective scopes by separating the server and database names with commas.

When you add a server or database configuration scope to a role assignment, specify the name of the server or database configuration scope in the *CustomConfigWriteScope* parameter on the **New-ManagementRoleAssignment** cmdlet if you're creating a new role assignment, or the **Set-ManagementRoleAssignment** cmdlet if you're updating an existing role assignment. Each role assignment can only have one configuration scope.

In addition to controlling which databases role assignees can manage, database scopes also enable you to control which databases role assignees can create mailboxes on. This is separate from controlling which recipients a role assignee can manage. If a role assignee has permissions to create a new mailbox, mail-enable an existing user, or move mailboxes, you can further refine their permissions by using database scopes to control the database on which the mailbox is created, or which database a mailbox is moved to. Controlling which recipients a role assignee can manage is done using a recipient scope specified in the *CustomRecipientWriteScope* parameter on the **New-ManagementRoleAssignment** or **Set-ManagementRoleAssignment** cmdlet. Controlling which databases a mailbox can be created on or moved to is controlled using a database scope specified in the *CustomConfigurationWriteScope* parameter on the same cmdlets.

Note:

Automatic mailbox distribution can be controlled using database scopes. For more information, see Understanding Automatic Mailbox Distribution.

Exchange 2010 SP1 features may require either server scopes, database scopes, or both, to be managed. If a feature requires both server and database scopes to be managed, two role assignments must be created and assigned to the role assignee that should

have access to manage the feature. One role assignment should be associated with the server scope, and one role assignment should be associated with the database scope.

Some cmdlets may use configuration scopes that aren't immediately obvious. The following table includes a list of cmdlets and the configuration scopes that you can use to control their usage. For cmdlets included in the recipients feature area, configuration scopes enable you to control on which databases recipients can be created. They don't control which recipients can be managed. The **Required scopes** column can contain the following:

- **Database** To run the cmdlet, the role assignee must be assigned a role assignment with a database scope that includes the database to be managed or the role's implicit configuration write scope must include the database to be managed.
- **Server** To run the cmdlet, the role assignee must be assigned a role assignment with a server scope that includes the server to be managed or the role's implicit configuration write scope must include the server to be managed.
- **Server or database** To run the cmdlet, the role assignee must be assigned a role assignment where either a database scope includes the database being managed, or where a server scope includes the server where the database is located. Or, the role's implicit configuration write scope must contain the database to be managed, or contain the server where the database is located, and the role assignment can't have a custom write scope.
- **Server and database** To run this cmdlet, the role assignee must be assigned two role assignments. The first role assignment must include a database scope that includes the database to be managed. The second role assignment must include a server scope that includes the server where the database is located. The role assignments can have custom configuration scopes defined, or the role assignments can inherit the implicit configuration write scope from the role. To inherit the implicit write scope from the role, the role assignment can't have a custom write scope.

Feature areas and applicable database and server scopes

Feature area	Cmdlet	Required scopes
Databases	**Clean-MailboxDatabase**	Database
Databases	**Dismount-Database**	Database
Databases	**Mount-Database**	Database
Databases	**Move-DatabasePath**	Server and database
Databases	**Remove-MailboxDatabase**	Server or database
Databases	**Remove-PublicFolderDatabase**	Server or database
Databases	**Set-MailboxDatabase**	Database
Databases	**Set-PublicFolderDatabase**	Database
High availability	**Add-DatabaseAvailabilityGroupServer**	Server
High availability	**Add-MailboxDatabaseCopy**	Server
High availability	**Move-ActiveMailboxDatabase**	Server

High availability	**New-DatabaseAvailabilityGroup**	Server
High availability	**Remove-DatabaseAvailabilityGroup**	Server
High availability	**Remove-DatabaseAvailabilityGroupServer**	Server
High availability	**Remove-MailboxDatabaseCopy**	Server or database
High availability	**Resume-MailboxDatabaseCopy**	Server or database
High availability	**Set-DatabaseAvailabilityGroup**	Server
High availability	**Set-MailboxDatabaseCopy**	Server or database
High availability	**Start-DatabaseAvailabilityGroup**	Server
High availability	**Stop-DatabaseAvailabilityGroup**	Server
High availability	**Suspend-MailboxDatabaseCopy**	Server or database
High availability	**Update-MailboxDatabaseCopy**	Server or database
Recipients	**Connect-Mailbox**	Database
Recipients	**Enable-Mailbox**	Database
Recipients	**New-Mailbox**	Database
Recipients	**New-MoveRequest**	Database
Troubleshooting	**Test-MapiConnectivity**	Database

Database scopes and pre-Exchange 2010 SP1 installations

Database scopes are new in Exchange 2010 SP1. The release to manufacturing (RTM) version of Exchange 2010 supports only recipient scopes and server configuration scopes. When you create a new database scope on an Exchange 2010 SP1 server, you'll receive the following warning:

```
WARNING: Database management scopes will only apply when connected to a server ru
Exchange 2010 RTM servers will not apply any roles from a role assignment linked
management scopes will also not be visible to reporting cmdlets (Get-ManagementSc
2010 RTM server.
```

When you create a database scope, it's only applied to users who connect to servers running Exchange 2010 SP1. Users who connect to servers running Exchange 2010 RTM won't have any role assignments associated with database scopes applied to them. This means that any permissions provided by these role assignments won't be granted to users when they connect to Exchange 2010 RTM servers. Database scopes can't be created, removed, modified, or viewed from Exchange 2010 RTM servers.

A database scope can include any database in your Exchange organization. This includes Exchange Server 2007 and Exchange 2010 RTM. This enables you to control which databases, regardless of Exchange version, that users can manage. As with other

database scopes, role assignments associated with database scopes that contain Exchange 2007 and Exchange 2010 RTM databases are only applied to users when they connect to an Exchange 2010 SP1 server.

Users who connect to an Exchange 2010 RTM server can view and modify role assignments associated with database scopes. This includes changing the configuration scope on an existing role assignment to a server scope if it's currently associated with a database scope. However, if the configuration scope on a role assignment is changed to a server scope and a user later wants to change it back to a database scope, or if the user wants to change the configuration scope to another database scope, the user must make the change while connected to an Exchange 2010 SP1 server. Users can only specify server scopes when they change the configuration scope on a role assignment if they're connected to an Exchange 2010 RTM server.

1.3.1.1.4.1 Understanding Management Role Scope Filters

Understanding Management Role Scope Filters

Understanding Permissions > Understanding Role Based Access Control > Understanding Management Role Scopes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Management role scope filters can be used to define management scopes that are highly customizable. Using scope filters, you can create a scope that matches how you segment your recipients, databases, and servers so that administrators can manage only those objects they should have access to. Scope filters can use nearly any recipient, database, or server object property.

To use management role scope filters, you must be familiar with management role scopes. For more information about management role scopes, see Understanding Management Role Scopes.

Filtered custom scopes in Microsoft Exchange Server 2010 are created by using the **New-ManagementScope** cmdlet. The two types of filtered scopes, recipient and configuration (which consists of server and database scopes), are divided into regular scopes and exclusive scopes. The following list shows which parameter on the **New-ManagementScope** cmdlet to use to create each type of filtered scope:

- **Recipient regular filtered scope** To create this type of filtered scope, use the *RecipientRestrictionFilter* parameter.
- **Recipient exclusive filtered scope** To create this type of filtered scope, use the *RecipientRestrictionFilter* parameter along with the *Exclusive* switch.
- **Server-based configuration regular filtered scope** To create this type of filtered scope, use the *ServerRestrictionFilter* parameter.
- **Server-based configuration exclusive filtered scope** To create this type of filtered scope, use the *ServerRestrictionFilter* parameter along with the *Exclusive* switch.
- **Database-based configuration regular filtered scope** To create this type of filtered scope, use the *DatabaseRestrictionFilter* parameter.
- **Database-based configuration exclusive filtered scope** To create this type of filtered scope, use the *DatabaseRestrictionFilter* parameter along with the *Exclusive* switch.

When you create a filtered custom scope, the scope attempts to match the filter with any objects accessible within the implicit read scope of the management role. If an object is

found, it's included in the results returned by the filter, and the object is made available to the management role by the custom scope. A filter can't return results that are outside of the implicit read scope of the management role.

If you specify a recipient filter using the *RecipientRestrictionFilter* parameter, you can use the *RecipientRoot* parameter to specify an organizational unit (OU) to restrict the filter to. When you specify an OU in the *RecipientRoot* parameter, the recipient filter attempts to match recipients that reside in that OU only, rather than within the entire implicit read scope.

To create a management scope using the filterable properties included in this topic, see Create a Regular or Exclusive Scope.

Filter Syntax

Both recipient and configuration filters use the same syntax to create a filter query. All filter queries must have, at minimum, the following components:

- **Opening bracket** The opening brace ({) indicates the start of the filter query.
- **Property to examine** The property is the value on an object that you want to test. For example, this can be the city or department on a recipient object, an Active Directory site name or server name on a server configuration object, or a database name on a database configuration object.
- **Comparison operator** The comparison operator directs how the query should evaluate the value that you specify against the value that's stored in the property. For example, comparison operators can be **Eq**, which means equal to; **Ne**, which means not equal to; **Like**, which means similar to, and so on. For a full list of operators that you can use in the Exchange Management Shell, see Comparison Operators.
- **Value to compare** The value you specify in the filter query will be compared to the value that's stored in the property you specified. The value you specify must be enclosed in quotation marks ("). If you want to specify a partial string, you can enclose the string you provide in wildcard characters (*) and use a comparison operator that supports wildcard characters, such as **Like**. Any string that contains the partial string will match the filter query.
- **Closing bracket** The closing brace (}) indicates the end of the filter query.

The following components are optional and enable you to create more complex filter queries:

- **Parentheses** As in mathematics, parentheses, ( ), in a filter query enable you to force the order in which an operation occurs. Innermost parentheses are evaluated first and the filter query works outward to the outermost parentheses.
- **Logical operators** Logical operators tie together one or more comparison operations and require the filter query to evaluate the entire statement. For example, logical operators include **And**, **Or**, and **Not**.

When put together, a simple query looks like `{ City -Eq "Vancouver" }`. This filter matches any recipient where the value in the property **City** equals the string "Vancouver".

Another, more complex, query is `{ ((City -Eq "Vancouver") -And (Department -Eq "Sales")) -Or (Title -Like "*Manager*") }`. The filter query is evaluated in the following order:

1. The properties **City** and **Department** are evaluated. Each is set to either `True` or `False`, depending on the values stored in each property.
2. The results of the **City** and **Department** statements are then evaluated. If both are `True`, the entire **And** statement becomes `True`. If one or both are `False`, the entire **And** statement becomes `False`. The following applies:
   - If the **And** statement evaluates as `True`, the entire filter query becomes

`True` because the **Or** operator indicates that one side of the query, or the other, must be `True`. The object is exposed to the role assignment.
- If the **And** statement is `False`, the filter query continues on to evaluate the **Title** property.

3. The **Title** property is then evaluated. It's set to `True` or `False`, depending on the value that's stored in the **Title** property. The following applies:
   - If the **Title** property evaluates as `True`, the entire filter query becomes `True` because the **Or** operator indicates that one side of the query, or the other, must be `True`. The object is exposed to the role assignment.
   - If the **Title** property evaluates as `False`, the entire filter query evaluates as `False`, and the object isn't exposed to the role assignment.

The following table shows an example with values, which indicates when the complex query would evaluate as `True`, and when it would evaluate as `False`.

Complex query

City	Department	Title	Result
Vancouver (True)	Sales (True)	CEO (False)	True because both **City** and **Department** evaluated as True. **Title** isn't evaluated because the filter query conditions are already satisfied.
Seattle (False)	Sales (True)	IT Manager (True)	True because **Title** evaluated as True. The results of the **City** and **Department** comparison are discarded because **Title** evaluated as True, which satisfied the filter query conditions. **Note:** IT Manager matches the filter query because the **Like** comparison operator was used, which matches partial strings when wildcard characters (*) are used in the filter query.
Vancouver (True)	Marketing (False)	Writer (False)	False because **City** and **Department** didn't both evaluate as True, and **Title** also didn't evaluate as True.

Filterable Recipient Properties

You can use almost any property on a recipient object when you create a recipient filter. For a list of filterable recipient properties, see Filterable Properties for the -Filter

Parameter. Although this topic discusses the properties that can be used with the *Filter* parameter on other cmdlets, most of these properties also work with the *RecipientRestrictionFilter* parameter on the **New-ManagementScope** cmdlet.

Filterable Server Properties

You can use the following server properties when you create a management scope with the *ServerRestrictionFilter* parameter:

- **CurrentServerRole**
- **CustomerFeedbackEnabled**
- **DataPath**
- **DistinguishedName**
- **ExchangeLegacyDN**
- **ExchangeLegacyServerRole**
- **ExchangeVersion**
- **Fqdn**
- **Guid**
- **InternetWebProxy**
- **Name**
- **NetworkAddress**
- **ObjectCategory**
- **ObjectClass**
- **ProductID**
- **ServerRole**
- **ServerSite**
- **WhenChanged**
- **WhenChangedUTC**
- **WhenCreated**
- **WhenCreatedUTC**

Filterable Database Properties

You can use the following database properties when you create a management scope with the *DatabaseRestrictionFilter* parameter:

- **AdminDisplayName**
- **AllowFileRestore**
- **BackgroundDatabaseMaintenance**
- **CircularLoggingEnabled**
- **DatabaseCreated**
- **DeletedItemRetention**
- **Description**
- **DistinguishedName**
- **EdbFilePath**
- **EventHistoryRetentionPeriod**
- **ExchangeLegacyDN**
- **ExchangeVersion**
- **Guid**
- **IssueWarningQuota**
- **LogFilePrefix**
- **LogFileSize**
- **LogFolderPath**
- **MasterServerOrAvailabilityGroup**
- **MountAtStartup**
- **Name**
- **ObjectCategory**
- **ObjectClass**

- **PublicFolderDatabase**
- **RetainDeletedItemsUntilBackup**
- **Server**
- **WhenChanged**
- **WhenChangedUTC**
- **WhenCreated**
- **WhenCreatedUTC**

1.3.1.1.4.2 Understanding Exclusive Scopes

Understanding Exclusive Scopes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-25*

Exclusive scopes are a special type of explicit management scope that can be associated with management role assignments. Exclusive scopes are designed to enable situations where you have a group of highly valuable objects, such as a CEO mailbox, and you want to tightly control who has access to manage those objects.

A role assignment that has an exclusive scope is called an *exclusive role assignment*.

When you create an exclusive scope, only those who are assigned that exclusive scope, or an equivalent exclusive scope, can modify the objects that match the scope. Role assignees who aren't assigned that exclusive scope, or an equivalent, can't modify the objects that match the scope, even if their own roles have scopes that would otherwise include the objects. Exclusive scopes override any other regular scope that isn't exclusive. This behavior is similar to how a deny access control entry (ACE) on an Active Directory access control list (ACL) functions.

An *equivalent exclusive scope* refers to another exclusive scope that matches some of the same objects as another exclusive scope. The scopes don't have to match the same complete set of objects. Both scopes may be able to modify some, or all, of the objects that match them.

Creating Exclusive Scopes

Exclusive scopes can be created like any other explicit scope. You can specify a prebuilt relative scope; a recipient, database, or server filter; or a database or server list. Unlike regular scopes, which don't take effect until you associate a scope to a management role assignment, the deny aspect of an exclusive scope takes effect immediately. This means that as soon as an exclusive scope is created, the objects contained within that scope are immediately no longer accessible by any user until the role assignment has been created.

After the assignment has been created, the exclusive scope provides access to those assigned the management role and scope. If another equivalent exclusive scope matches the same objects, the role assignment associated with that exclusive scope is still able to access the objects.

For more information about management scope filters, see Understanding Management Role Scope Filters.

Important:
Active Directory replication times should be taken into account when making changes to any management role components, including exclusive scopes.

If you have objects contained within more than one exclusive scope, being assigned to any one of the exclusive scopes provides access to the objects. For more information, see Exclusive and Regular Scope Interaction later in this topic.

Exclusive scopes control only the explicit recipient or configuration write scope of a role assignment. The implicit recipient or configuration read scope of the role assigned to a user or group still applies. This means that the following applies:

- Those assigned a role continue to see objects that match the role's implicit read scope.
- Those assigned other roles may be able to see objects contained within an exclusive scope, if the read scopes of the other roles include the objects. However, the objects can only be modified by those who are assigned a role associated with the exclusive scope.

Exclusive scopes can only be used with administrative or specialist roles and can't be used with end-user roles. For more information about roles, see Understanding Management Roles.

Exclusive and Regular Scope Interaction

The figure at the end of this section illustrates how exclusive scopes interact with each other, and with regular scopes. The users in the figure all have the following attributes associated with them.

User	City	Title	Department
Terry	Vancouver	Accountant	Accounting
David	Vancouver	Writer	Marketing
Walter	Vancouver	Manager	Marketing
Bob	Vancouver	CEO	Board
Christine	Vancouver	President	Board
Fred	Vancouver	CFO	Executives
Martin	Vancouver	CIO	Executives
Kim	Vancouver	Vice President, Operations	Executives
Jennifer	Vancouver	Vice President, Technology	Executives

The following three management role assignments in the figure manage the users in the preceding table. Each has an associated scope, some of which are exclusive scopes.

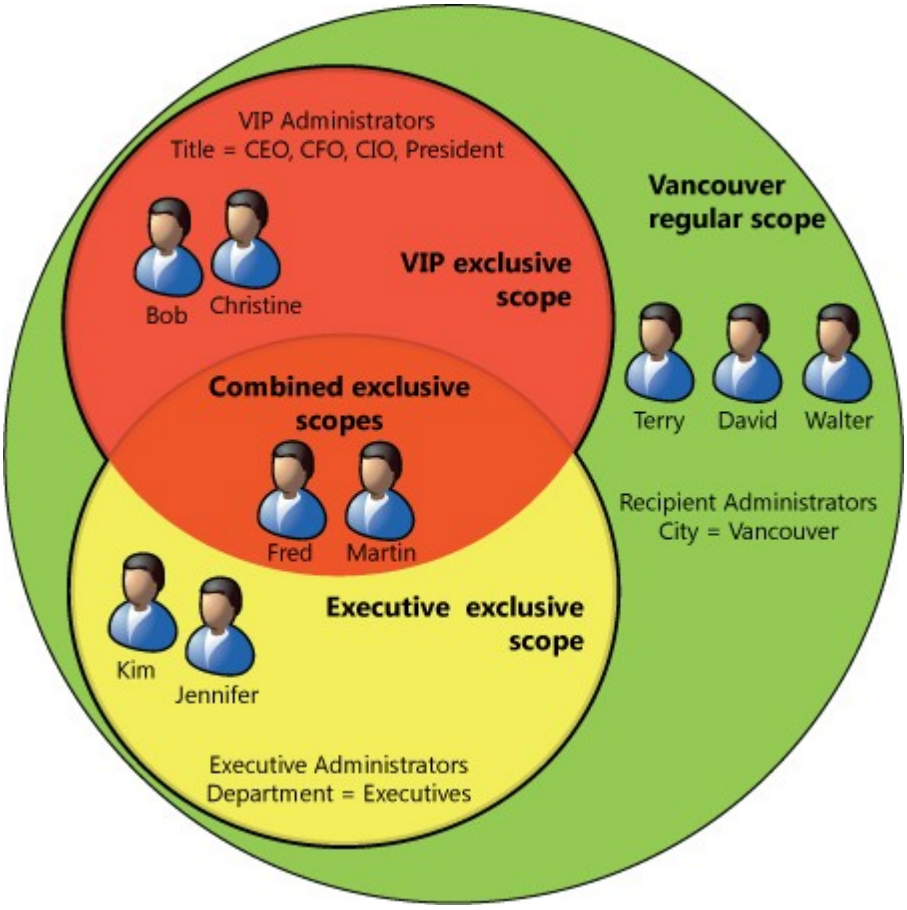
Role assignment	Scope filter	Exclusive or regular
Recipient Administrators	City = Vancouver	Regular
VIP Administrators	Title = CEO or CFO or CIO or President	Exclusive
Executive Administrators	Department = Executives	Exclusive

The Recipient Administrators role assignment has a scope that matches all of the users because every user is located in Vancouver. Without any exclusive scopes, this would mean that the Recipient Administrators role assignment could manage any of the users. However, this organization has created two exclusive scopes: VIP Administrators and Executive Administrators. These exclusive scopes restrict who can manage the users that match their respective scope filters. The VIP Administrators role assignment has a scope filter that matches any user who has a title of CEO, CFO, CIO, or President. The Executive Administrators role assignment has a scope filter that matches any user who is in the Executives department.

When the regular and exclusive scopes are evaluated, the following is the result:

- The Recipient Administrators role assignment can manage the users Terry, David, and Walter. This role assignment can't manage any of the other users because they match the exclusive scope filters of the VIP Administrators and Executive Administrators role assignments.
- The VIP Administrators role assignment can manage the users Bob, Christine, Fred, and Martin. This is because the exclusive scope filter associated with this role assignment matches the attributes on these objects. This role assignment can't manage the users Kim and Jennifer because their attributes don't match this exclusive scope.
- The Executive Administrators role assignment can manage the users Kim, Jennifer, Fred, and Martin. This is because the exclusive scope filter associated with this role assignment matches the attributes on these objects. This role assignment can't manage the users Bob and Christine because their attributes don't match this exclusive scope.

Notice that Fred and Martin are accessible by both exclusive scopes. This is because the attributes on these users match the filters of both exclusive scopes.



For more information about management scopes, see Understanding Management Role Scopes.

1.3.1.1.5 Understanding Management Role Assignments

Understanding Management Role Assignments

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-12-16*

A *management role assignment*, which is part of the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010, is the link between a management role and a role assignee. A *role assignee* is a role group, role assignment policy, user, or universal security group (USG). A role must be assigned to a role assignee for it to take effect. For more information about RBAC, see Understanding Role Based Access Control.

Note:

This topic focuses on advanced RBAC functionality. If you want to manage basic Exchange 2010 permissions, such as using the Exchange Control Panel (ECP) to add and remove members to and from role groups, create and modify role groups, or create and modify role assignment policies, see Understanding Permissions.

This topic discusses the assignment of roles to role groups and role assignment policies and direct role assignment to users and USGs. It doesn't talk about assignment of role groups or role assignment policies to users. For more information about role groups and role assignment policies, which are the recommended way to assign permissions to users, see the following topics:

- Understanding Management Role Groups
- Understanding Management Role Assignment Policies

You can create the following types of role assignments, which are explained in detail later in this topic:

- Regular and delegating role assignments
- Exclusive role assignments

Managing Role Assignments

When you change role assignments, the changes you make will probably be between role groups and role assignment policies. By adding, removing, or modifying role assignments to or from these role assignees, you can control what permissions are given to your administrators and users, in effect turning on and off management of related features.

You might also want to assign roles directly to users or USGs. This is a more advanced task that enables you to define at a granular level what permissions your users are given. Although this provides you with flexibility, it also increases the complexity of your permissions model. For example, if the user changes jobs, you might need to manually reassign the roles assigned to that user to another user. This is why we recommend that you use role groups and role assignment policies to give permissions to your users. You can assign the roles to a role group or role assignment policy, and then just add or remove members of the role group, or change role assignment policies as needed.

You can add, remove, and enable role assignments, modify the management scope on an existing role assignment, and move role assignments to other role assignees. The process of assigning roles to role groups, role assignment policies, users, and USGs is largely the same for each role assignee. The following are the only exceptions:

- Role assignment policies can only be assigned end-user management roles.
- Role assignment policies can't be assigned delegating role assignments.
- You can't specify a management scope when creating a role assignment to role assignment policies.

For more information about managing role assignments, see the following topics:

- Role groups:
  - Add a Role to a Role Group
  - Remove a Role from a Role Group
  - Change a Role Assignment
  - Change the Scope of Role Assignments to a Role Group
  - Delegate Role Assignments
- Role assignment policies:
  - Add a Role to an Assignment Policy
  - Remove a Role from an Assignment Policy
  - Change a Role Assignment
- Users and USGs:
  - Add a Role to a User or USG
  - Remove a Role from a User or USG
  - Change a Role Assignment
  - Change a Role Scope
  - Delegate Role Assignments

Regular and Delegating Role Assignments

Regular role assignments enable the role assignee to access the management role entries made available by the associated management role. If multiple management roles are assigned to a role assignee, the management role entries from each management role are aggregated and applied. This means that if a role assignee is assigned the Transport Rules and Journaling roles, the roles are combined, and all the associated management role entries are given to the role assignee. If the role assignee is a role group or role assignment policy, the permissions provided by the roles are then given to the users assigned to the role group or role assignment policy. For more information about management roles and role entries, see Understanding Management Roles.

Delegating role assignments doesn't give access to manage features. Delegating role assignments gives a role assignee the ability to assign the specified role to other role assignees. If the role assignee is a role group, any member of the role group can assign the role to another role assignee. By default, only the Organization Management role group has the ability to assign roles to other role assignees. Only the user that installed Exchange 2010 is a member of the Organization Management role group by default. You can, however, add other users to this role group as needed, or create other role groups and assign delegating role assignments to those groups.

Note:

Delegating role assignments enables role assignees to delegate management roles to other role assignees. This doesn't enable users to delegate role groups. For more information about role group delegation, see Understanding Management Role Groups.

If you want a user to be able to manage a feature and assign the role that gives permissions to use the feature to other users, assign the following:

1. A regular role assignment for each management role that grants access to the features that need to be managed.
2. A delegating role assignment for each management role that you allow to be assigned to other role assignees.

The regular and delegating role assignments for a role assignee don't need to be identical. For example, a user is a member of a role group assigned the Transport Rules role using a regular role assignment. This enables the user to manage the Transport Rules feature. However the user isn't assigned a delegating role assignment for the Transport Rules role so the user can't assign this role to other users. However, the user is a member of a role group assigned the Journaling management role using a delegating role assignment. The role group the user is a member of doesn't have a regular role assignment for the Journaling role but because it has a delegating role assignment, the user can assign the role to other role assignees.

Management Scopes

When you create either a regular or delegating management role assignment, you have the option of creating the assignment with a management scope to limit the objects that the user can manipulate. You can create recipient scopes or configuration scopes. Recipient scopes enable you to control who can manipulate mailboxes, mail users, distribution groups, and so on. Configuration scopes enable you to control who can manipulate servers and databases.

Recipient and configuration scopes enable you to segment the management of server, database or recipient objects in your organization. For example, a recipient scope can be added to a role assignment so that administrators in Vancouver can only manage recipients in the same office. A server configuration scope could be added to a different role assignment so that administrators in Sydney can only manage servers in their Active Directory site.

Scopes enable permissions to be assigned to groups of users and enable you to direct

where those administrators can perform their administration. This enables you to create a permissions model that maps to your geographic or organizational boundaries.

You can create an assignment with a predefined scope, or you can add a custom scope to the assignment. Predefined scopes, such as limiting a user to only his or her mailbox or distribution groups, can be applied using options available on the assignment itself. Alternatively, you can create a custom recipient or configuration scope, and then add that scope to the role assignment. Custom scopes give you more granularity over which objects are included in the scope.

You can't specify predefined and custom scopes on the same assignment. You also can't mix exclusive and regular scopes on the same assignment.

Each role assignment can only have one recipient scope and one configuration scope. If you want to apply more than one recipient scope, or one configuration scope, to a role assignee for the same management role, you must create multiple role assignments.

With neither a custom or predefined scope, role assignments are limited to the recipient and configuration scopes that are defined on the role itself. These scopes are called implicit scopes. Any role assignment that doesn't have a predefined or custom scope inherits the implicit scopes from the role it's associated with.

For more information about scopes, see Understanding Management Role Scopes.

Exclusive Role Assignments

Exclusive role assignments are created when you associate an exclusive scope with a role assignment. Exclusive scopes work like regular scopes and enable role assignees to manage recipients that match the exclusive scope. However, unlike regular scopes, all other role assignees are denied the ability to manage the recipient, even if the recipient matches scopes applied to their role assignments. This can be useful when you want to limit who can manage a recipient to a few administrators. Only those specific administrators can manage the recipient, and all other administrators are denied access.

For example, consider the following:

- John is an executive at Contoso. His mailbox matches an exclusive scope called VIP Users, which is associated with the VIP Restricted exclusive assignment.
- John's mailbox is also included in a regular scope called Redmond Users, which is associated with the Redmond Administration regular assignment.
- Bill is an administrator who is associated with the VIP Restricted exclusive assignment.
- Chris is an administrator who is associated with the Redmond Administration regular assignment.

Because John's mailbox matches the VIP Users exclusive scope, only Bill can manage his mailbox. Even though John's mailbox also matches the Redmond Users regular scope, Chris isn't associated with the VIP Restricted exclusive assignment. Therefore, Exchange denies Chris the ability to manage John's mailbox. For Chris to manage John's mailbox, Chris needs to be assigned an exclusive assignment that has an exclusive scope that matches John's mailbox.

For more information, see Understanding Management Role Scopes.

1.3.1.1.6 Built-in Role Groups

Built-in Role Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-09*

Microsoft Exchange Server 2010 includes several management role groups by default. The following built-in role groups provide you with a preconfigured set of roles that you can assign to various administrator and specialist users in your organization.

Note:

Role groups don't control access to end-user mailbox features. To control access to end-user mailbox features, see Understanding Management Role Assignment Policies.

- Organization Management
- View-Only Organization Management
- Recipient Management
- UM Management
- Help Desk
- Hygiene Management
- Records Management
- Discovery Management
- Public Folder Management
- Server Management
- Delegated Setup

For more information about role groups, see Understanding Management Role Groups.

1.3.1.1.6.1 Organization Management

Organization Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Organization Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators that are members of the Organization Management role group have administrative access to the entire Microsoft Exchange Server 2010 organization and can perform almost any task against any Exchange 2010 object, with some exceptions. By default, members of this role group can't perform mailbox searches and management of unscoped top-level management roles. For more information, see the "Delegating Only Role Assignments" section later in this topic.

Important:

The Organization Management role group is a very powerful role and as such, only users or universal security groups (USGs) that perform organizational-level administrative tasks

that can potentially impact the entire Exchange organization should be members of this role group.

This role group is equivalent to the Exchange Organization Administrators role in Exchange Server 2007.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

By default, the account that's used to install Exchange 2010 in the organization is added as a member of the Organization Management role group. This account can then add other members to the role group as needed.

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or USGs that are members of this role group.

```
Get-RoleGroupMember "Organization Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group

- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

The following are some ways you might want to customize this role:

- **Permissions owner** If the permissions in your organization are controlled by a specific group other than the Exchange administrators, you can create a role group and move the regular and delegating role assignments for the Role Management role to the new role group. Doing so prevents members of the Organization Management role group from managing any RBAC permissions.
- **Active Directory split permissions** If the creation of security principals in your organization, such as user accounts, is controlled by a specific group other than the Exchange administrators, you can create a role group and move the regular and delegating role assignments for the Mail Recipient Creation role and the Security Group Creation and Membership role to the new role group. Doing so prevents members of the Organization Management role group from creating Active Directory objects. They can, however, continue to mail-enable the new Active Directory objects. For more information about split permissions, see Understanding Split Permissions.

Customization Limitations

Any role can be added to or removed from this role group, with the following limitations:

- Every role must have at least one delegating role assignment to a role group or USG before the delegating role assignment can be removed from this role group.
- The Role Management role must have at least one regular role assignment to a role group or USG before the regular role assignment can be removed from this role group.

These limitations are intended to help prevent you from inadvertently locking yourself out of the system. By requiring that at least one delegating role assignment exists between every role and one or more role groups or USGs, you will always be able to assign roles to role assignees. By requiring that at least one regular role assignment exists between the Role Management role and one or more role groups or USGs, you will always be able to configure role groups and role assignments.

Important:

These limitations require that role groups or USGs be the targets of the delegating and regular role assignments. You can't remove a delegating role assignment or the regular assignment for the Role Management role if the last assignment is to a user.

Delegating Only Role Assignments

Some role assignments between the Organization Management role group and management roles, such as Mailbox Search and Unscoped Role Management, are delegating only role assignments. These roles allow access to sensitive or personal information, such as the contents of mailboxes, or enable the creation of powerful unscoped management roles.

Delegating only role assignments enable members of the Organization Management role group only to assign the associated roles to other role groups, management role assignment policies, users, or USGs. Members of the Organization Management role group aren't given, by default, any permissions that the roles provide. This helps avoid accidental exposure to personal information or accidental elevation of privileges.

Members of the Organization Management role group can, however, assign themselves any role, in effect enabling them to perform any task. For example, a member of the Organization Management role group can assign the Mailbox Search role to the

Organization Management role group. After this role assignment is made, members of the Organization Management role group can perform tasks enabled by the Mailbox Search role.

For more information about delegating role assignments, see Understanding Management Role Assignments.

Additional Permissions

The permissions granted to members of the Organization Management role group are primarily determined by the management roles assigned to the role group. However, not all tasks that you need to perform are covered by management roles. Some tasks occur outside of the Exchange management tools, and therefore the RBAC permissions model doesn't apply. For these tasks, permissions are provided by adding the Organization Management role group to the access control lists (ACLs) of certain Active Directory objects.

The following tasks are granted permissions by way of ACLs on Active Directory objects and not by management roles assigned to the Organization Management role group:

- Running DomainPrep and ForestPrep using Setup.exe
- Deploying additional servers in the organization
- Provisioning servers using delegated setup
- Creating, managing, and deleting top level public folders
- Managing permissions of top level public folders

To see all permissions granted to the Organization Management role group by way of ACLs, see Exchange 2010 Deployment Permissions Reference.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

1.3.1.1.6.2 View-Only Organization Management

View-Only Organization Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The View-Only Organization Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of the View-Only Organization Management role group can view the properties of any object in the Exchange organization.

This role is equivalent to the Exchange View-Only Administrators role in Microsoft Exchange Server 2007.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "View-Only Organization Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to

perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Monitoring Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig

View-Only Configuration Role	X		Organization	None	OrganizationConfig	None
View-Only Recipients Role	X		Organization	None	OrganizationConfig	None

1.3.1.1.6.3 Recipient Management

Recipient Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Recipient Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of the Recipient Management role group have administrative access to create or modify Microsoft Exchange Server 2010 recipients within the Exchange 2010 organization.

This role group is equivalent to the Exchange Recipient Administrators role in Exchange Server 2007.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Recipient Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are

listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

If the creation of security principals in your organization, such as user accounts, is controlled by a specific group other than the Exchange administrators, you can create a role group and move the Mail Recipient Creation role and the Security Group Creation and Membership role to the new role group. Doing so prevents members of the Recipient Management role group from creating Active Directory objects. They can, however, continue to mail-enable the new Active Directory objects. For more information about split permissions, see Understanding Split Permissions.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following

topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

1.3.1.1.6.4 UM Management

UM Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The UM Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of the UM Management role group can manage features in the Exchange organization such as Unified Messaging (UM) server configuration, UM

properties on mailboxes, UM prompts, and UM auto attendant configuration.

For more information about Unified Messaging, see Unified Messaging.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "UM Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
UM Mailboxes Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
UM Prompts Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Unified Messaging Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig

1.3.1.1.6.5 Help Desk

Help Desk

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Help Desk management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more

information about role groups, see Understanding Management Role Groups.

Users who are members of the Help Desk role group can perform limited recipient management of Microsoft Exchange Server 2010 recipients.

The Help Desk role group, by default, enables members to view and modify the Outlook Web App options of any user in the organization. These options might include modifying the user's display name, address, phone number, and so on. They don't include options that aren't available in Outlook Web App options, such as modifying the size of a mailbox or configuring the mailbox database on which a mailbox is located.

The members of this role group can only modify the Outlook Web App options that the user can modify. This means that if a user can modify his or her display name, a member of the Help Desk role group can also modify that user's display name. However, if another user isn't allowed to modify his or her display name, a member of the Help Desk role group can't modify that user's display name.

Caution:

The limitations on which Outlook Web App options a member of the Help Desk role group can modify are enforced by the Exchange Web interface. If a member of the Help Desk role group has access to the Exchange Management Shell, he or she can modify any Outlook Web App option for any user. You should carefully consider who you make a member of the Help Desk role group and whether they should also be given access to the Shell.

The Help Desk role group doesn't enable any other tasks because there are so many different types of organizations. Instead, you can add management roles to this role group to create a Help Desk role group that matches the needs of your organization. For example, if you want members of the Help Desk role group to be able to manage mailboxes, mail contacts, and mail-enabled users, assign the Mail Recipients management role to this role group. For more information about how to add management roles to this role group, see the "Role Group Customization" section later in this topic.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Help Desk"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or

remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope

User Options Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
View-Only Recipients Role	X		Organization	None	OrganizationConfig	None

1.3.1.1.6.6 Hygiene Management

Hygiene Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Hygiene Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Users who are members of the Hygiene Management role group can configure the antivirus and anti-spam features of Exchange Server 2010. Third-party programs that integrate with Exchange 2010 can add service accounts to this role group to grant those programs access to the cmdlets required to retrieve and configure the Exchange configuration.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Hygiene Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or

remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

1.3.1.1.6.7 Records Management

Records Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Records Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Users who are members of the Records Management role group can configure compliance features, such as retention policy tags, message classifications, and transport rules.

For more information about compliance features, see Messaging Policy and Compliance. For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups

(USGs) that are members of this role group.

```
Get-RoleGroupMember "Records Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server

objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Audit Logs Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Journaling Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Retention Management Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Transport Rules Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig

1.3.1.1.6.8 Discovery Management

Discovery Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Discovery Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators or users who are members of the Discovery Management role group can perform searches of mailboxes in the Exchange organization for data that meets specific criteria and can also configure legal holds on mailboxes. For more information, see Discovery and Understanding Litigation Hold.

Important:

The Organization Management role group doesn't, by default, enable the discovery search feature for users or universal security groups (USGs) that are members of that role group. Members of the Organization Management role group must either be made members of this role group, or the Mailbox Search role listed later in this topic must be manually assigned to the Organization Management role group. For information about how to assign a role to a role group, see Add a Role to a Role Group.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or USGs that are members of this role group.

```
Get-RoleGroupMember "Discovery Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role

Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Legal Hold Role	X		Organization	Organization	OrganizationConfig	None
Mailbox Search Role	X		Organization	Organization	None	None

1.3.1.1.6.9 Public Folder Management

Public Folder Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Public Folder Management management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of the Public Folder Management role group can manage public folders and databases on servers running Exchange 2010.

For more information about public folders, see Understanding Public Folders. For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Public Folder Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Additional Permissions

The permissions granted to members of the Public Folder Management role group are primarily determined by the management roles assigned to the role group. However, not all tasks that you need to perform are covered by management roles. This is because some tasks occur outside of the Exchange management tools and therefore the RBAC

permissions model doesn't apply. For these tasks, permissions are provided by adding the Public Folder Management role group to the access control lists (ACLs) of certain Active Directory objects.

The following tasks are granted permissions by way of ACLs on Active Directory objects and not by management roles assigned to the Public Folder Management role group:

- Creation, management, and deletion of top level public folders
- Permissions management of top level public folders

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Mail Enabled Public Folders Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Public Folders Role	X		Organization	Organization	OrganizationConfig	OrganizationConfig

1.3.1.1.6.10 Server Management

Server Management

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Server Management management role group is one of several built-in role groups

that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of this role group can configure server-specific configuration of transport, Unified Messaging, client access, and mailbox features such as database copies, certificates, transport queues and Send connectors, virtual directories, and client access protocols.

This role group is similar to the Exchange Server Administrators role in Microsoft Exchange Server 2007. It grants access to manage the configuration of physical servers. However, unlike the Exchange Server Administrators role in Exchange 2007, which provided access only to a local server running Exchange 2007, the Server Management role group enables access to view and configure all Exchange Server 2010 servers in the organization.

If you want to allow administrators to manage only specific servers in your organization, you can change the management scopes that are applied to this role group. Alternatively, you can create a role group, based on the Server Management role group, and customize the management scopes on the new role group. For more information, see the "Role Group Customization" section later in this topic.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Server Management"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

Management role	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope

1.3.1.1.6.11 Delegated Setup

Delegated Setup

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Delegated Setup management role group is one of several built-in role groups that make up the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Role groups are assigned one or more management roles that contain the permissions required to perform a given set of tasks. The members of a role group are granted access to the management roles assigned to the role group. For more information about role groups, see Understanding Management Role Groups.

Administrators who are members of the Delegated Setup role group can deploy servers running Exchange 2010 that have been previously provisioned by a member of the Organization Management role group. For more information about delegated setup, see Provision Exchange 2010 Server and Delegate Setup.

Members of the Delegated Setup role group can only deploy Exchange 2010 servers. They can't manage the server after it's been deployed. To manage a server after it's been deployed, a user must be a member of the Server Management role group.

For more information about RBAC, see Understanding Role Based Access Control.

Role Group Membership

If you want to add or remove members to or from this role group, see the following topics:

- Add Members to a Role Group
- Remove Members from a Role Group

By default, only members of the Organization Management role group can add or remove members from this role group. For more information about how to add additional role group delegates, see Add or Remove a Role Group Delegate.

You can use the following command to view a list of users or universal security groups (USGs) that are members of this role group.

```
Get-RoleGroupMember "Delegated Setup"
```

For more information about the members of a role group, see View the Members of a Role Group.

Role Group Customization

This role group is assigned management roles by default. The roles that are included are listed in the "Management Roles Assigned to this Role Group" section. You can add or remove role assignments to or from this role group to match the needs of your organization.

The role groups provided with Exchange 2010 are designed to match more granular tasks. By assigning roles to a role group, you enable the members of that role group to perform the tasks associated with the role. For example, the Journaling role enables the management of the Journaling agent and journaling rules. For more information about how roles are assigned to role groups, see Understanding Management Role Assignments.

The roles assigned to this role group are given default management scopes. Management scopes determine what Exchange objects can be viewed or modified by the members of a role group. You can change the scopes associated with assignments between roles and role groups. For example, you might want to do this if you only want members of a role group to be able to change recipients that are under a specific organizational unit or in a specific location. For more information about management scopes, see Understanding Management Role Scopes.

For more information about how to customize this role group, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add Members to a Role Group
- Remove Members from a Role Group
- Change the Scope of Role Assignments to a Role Group

If you want to create a role group and assign some of the roles that are assigned to this role group to the new role group, see Create a Role Group.

Additional Permissions

The permissions granted to members of the Delegated Setup role group are primarily determined by the management roles assigned to the role group. However, not all tasks that you need to perform are covered by management roles. This is because some tasks occur outside of the Exchange management tools and therefore the RBAC permissions

model doesn't apply. For these tasks, permissions are provided by adding the Delegated Setup role group to the access control lists (ACLs) of certain Active Directory objects.

The following task is granted permissions by way of ACLs on Active Directory objects and not by management roles assigned to the Delegated Setup role group:

- Deployment of servers that have been previously provisioned by a member of the Organization Management role group.

To see all permission granted to the Delegated Setup role group by way of ACLs on Active Directory objects, see Exchange 2010 Deployment Permissions Reference.

Management Roles Assigned to This Role Group

The following table lists all the management roles that are assigned to this role group and the following attributes of each role assignment:

- **Regular assignment** Enables members of the role group to access the management role entries made available by the associated management role.
- **Delegating assignment** Gives members of the role group the ability to assign the specified role to other role groups, role assignment policies, users, or USGs.
- **Recipient read scope** Determines what recipient objects members of the role group are allowed to read from Active Directory.
- **Recipient write scope** Determines what recipient objects members of the role group are allowed to modify in Active Directory.
- **Configuration read scope** Determines what configuration and server objects members of the role group are allowed to read from Active Directory.
- **Configuration write scope** Determines what organizational and server objects members of the role group are allowed to modify in Active Directory.

For more information about role assignments and management scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

Management roles assigned to this role group

View-Only Configuration Role	X		Organization	None	OrganizationConfig	None

1.3.1.1.7 Built-in Management Roles

Built-in Management Roles

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-15*

Microsoft Exchange Server 2010 includes many management roles by default. The

following roles are assigned to management role groups or management role assignment policies in various combinations that grant permissions to manage and use the features provided by Exchange 2010. For more information about roles, see Understanding Management Roles.

Active Directory Permissions Role

Address Lists Role

ApplicationImpersonation Role

Audit Logs Role

Cmdlet Extension Agents Role

Database Availability Groups Role

Database Copies Role

Databases Role

Disaster Recovery Role

Distribution Groups Role

Edge Subscriptions Role

E-Mail Address Policies Role

Exchange Connectors Role

Exchange Server Certificates Role

Exchange Servers Role

Exchange Virtual Directories Role

Federated Sharing Role

Information Rights Management Role

Journaling Role

Legal Hold Role

Mail Enabled Public Folders Role

Mail Recipient Creation Role

Mail Recipients Role

Mail Tips Role

Mailbox Import Export Role

Mailbox Search Role

Message Tracking Role

Support Diagnostics Role

Transport Agents Role

Transport Hygiene Role

Transport Queues Role

Transport Rules Role

UM Mailboxes Role

UM Prompts Role

Unified Messaging Role

Unscoped Role Management Role

User Options Role

View-Only Audit Logs Role

View-Only Configuration Role

View-Only Recipients Role

1.3.1.1.7.1 Active Directory Permissions Role

Active Directory Permissions Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Active Directory Permissions` management role enables administrators to configure Active Directory permissions in an organization. Some features that use Active Directory permissions or an access control list (ACL) include transport Receive and Send connectors, and Send As and Send on behalf of permissions for mailboxes.

Note:

Permissions set directly on Active Directory objects may not be enforced through Role Based Access Control (RBAC).

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.2 Address Lists Role

Address Lists Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Address Lists` management role enables administrators to create, modify, view, and remove address lists, global address lists (GALs), and offline address lists (OABs) in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment

should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.3 ApplicationImpersonation Role

ApplicationImpersonation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `ApplicationImpersonation` management role enables applications to impersonate users in an organization to perform tasks on behalf of the user.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a

cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:
There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in

Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Hygiene Management	X		Organization	Organization	None	None
Organization Management		X	Organization	Organization	None	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group

- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.4 Audit Logs Role

Audit Logs Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Audit Logs` management role enables administrators to configure the administrator audit log in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a

Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Records Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.5 Cmdlet Extension Agents Role

Cmdlet Extension Agents Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Cmdlet Extension Agents` management role enables administrators to enable, disable, and set the priority of cmdlet extension agents in an organization.

This management role is one of several built-in roles in the Role Based Access Control

(RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.

- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.6 Database Availability Groups Role

Database Availability Groups Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Database Availability Groups` management role enables administrators to manage database availability groups in an organization. Administrators assigned this role either directly or indirectly are the highest level administrators responsible for the high availability configuration in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.7 Database Copies Role

Database Copies Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Database Copies` management role enables administrators to add, remove, suspend, resume, view, and update database copies on individual servers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which

are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and

USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

The **Set-MailboxDatabaseCopy** and **Remove-MailboxDatabaseCopy** cmdlets, which are included with this role, require that the database you want to configure or remove must be within the database scope and the database must reside on a server that's within the server scope. For more information about scopes, see Understanding Management Role Scopes.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the

following topics:
- Change a Role Entry
- Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.8 Databases Role

Databases Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Databases management role enables administrators to create, manage, mount, and dismount mailbox and public folder databases on individual servers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the

combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what

objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

The **Move-DatabasePath** cmdlet, which is included with this role, requires that the database you want to configure must be within the database scope and the database must reside on a server that's within the server scope.

Also, the **Remove-MailboxDatabase** and **Remove-PublicFolderDatabase** cmdlets, which are also included with this role, require that the database you want to remove must either be within the database scope or the database must reside on a server that's within the server scope. This means you control who can remove mailbox or public folder databases using either database or server scopes.

For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Automatic Mailbox Distribution

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in

Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group

- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.9 Disaster Recovery Role

Disaster Recovery Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Disaster Recovery` management role enables administrators to restore mailboxes and database availability groups, create mailbox databases, and start and stop database availability groups in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a

Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:
The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.10 Distribution Groups Role

Distribution Groups Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Distribution Groups` management role enables administrators to create, modify, view, and remove distribution groups, and add or remove distribution group members in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or

scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment.

This limitation helps prevent you from locking yourself out of the system.

Important:
There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.

- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X	Not applicable	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following

topics:

- Add a Role to a Role Group
- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.11 Edge Subscriptions Role

Edge Subscriptions Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Edge Subscriptions` management role enables administrators to manage edge synchronization and subscription configuration between Edge Transport servers and Hub Transport servers in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.

- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.12 E-Mail Address Policies Role

E-Mail Address Policies Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `E-Mail Address Policies` management role enables administrators to manage e-mail address policies in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which

are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and

USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what

configuration and server objects the role assignee is allowed to read from Active Directory.

- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group

- Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.13 Exchange Connectors Role

Exchange Connectors Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Exchange Connectors management role enables administrators to create, modify, view, and remove routing group connectors and delivery agent connectors.

This role can't be used to manage Send and Receive connectors. To manage Send and Receive connectors, use the Send Connectors and Receive Connectors roles. For more information, see:

- Send Connectors Role
- Receive Connectors Role

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions

granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope

- Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of

this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.14 Exchange Server Certificates Role

Exchange Server Certificates Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Exchange Server Certificates` management role enables administrators to create, import, export, and manage Exchange server certificates on individual servers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee

the ability to assign this role to role groups, users, or USGs.

- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role

3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.15 Exchange Servers Role

Exchange Servers Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Exchange Servers management role enables administrators to do the following on individual servers:

- Add and remove database availability groups
- Enable and disable Unified Messaging servers
- Enable and disable Microsoft Outlook Anywhere on Client Access servers
- Modify Mailbox, Hub Transport, Client Access, and Unified Messaging server configuration
- Modify Outlook Anywhere configuration on Client Access servers
- Modify content filtering configuration on Hub Transport servers
- Modify general Exchange server configuration
- View the configuration for each server role

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organizatio	X	X	Organizat	Organizat	Organizat	Organizat

n Management			ion	ion	ionConfig	ionConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.16 Exchange Virtual Directories Role

Exchange Virtual Directories Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Exchange Virtual Directories` management role enables administrators to manage Microsoft Office Outlook Web App, Microsoft ActiveSync, offline address books (OABs), Autodiscover, Windows PowerShell, and Web administration interface virtual directories on individual servers.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Server Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.17 Federated Sharing Role

Federated Sharing Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Federated Sharing` management role enables administrators to manage cross-forest and cross-organization sharing in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are

included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to

add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.18 Information Rights Management Role

Information Rights Management Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Information Rights Management` management role enables administrators to manage the Information Rights Management (IRM) features of Exchange in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the

following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your

permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.19 Journaling Role

Journaling Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Journaling` management role enables administrators to create, modify, enable, disable, view, and remove journal rules in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries,

see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this

role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Records Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the

role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.20 Legal Hold Role

Legal Hold Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Legal Hold` management role enables administrators to configure whether data within a mailbox should be retained for litigation purposes in an organization.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the

following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

In addition to recipient scopes, the **Enable-Mailbox** cmdlet, which is included with this role, is also scoped using database configuration scopes. Database configuration scopes control which databases the cmdlet can create new mailboxes on. The database where you want to create a mailbox must be within the database scope. This applies both when you specify a database using the *Database* parameter on the **Enable-Mailbox** cmdlet, or if you allow automatic mailbox distribution to select the database for you. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Automatic Mailbox Distribution

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Discovery Management	X		Organization	Organization	OrganizationConfig	None
Organization Management	X	X	Organization	Organization	OrganizationConfig	None

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.21 Mail Enabled Public Folders Role

Mail Enabled Public Folders Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Mail Enabled Public Folders` management role enables administrators to configure whether individual public folders are mail-enabled or mail-disabled in an organization.

This role enables you to manage only the e-mail properties of public folders. It doesn't enable you to manage public folder properties that aren't related to e-mail. To manage public folder properties that aren't related to e-mail, use the `Public Folders` role. For more information, see Public Folders Role.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role

assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Public Folder Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your

permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:
If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.22 Mail Recipient Creation Role

Mail Recipient Creation Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Mail Recipient Creation` management role enables administrators to create mailboxes, mail users, mail contacts, distribution groups, and dynamic distribution groups in an organization. This role can be combined with the `Mail Recipients` role to enable the creation and management of recipients. For more information, see Mail Recipients Role.

This role doesn't enable you to mail-enable public folders. To mail-enable public folders, the `Mail Enabled Public Folders` role must be used. For more information, see Mail Enabled Public Folders Role.

If your organization maintains a Role Based Access Control (RBAC) split permissions model where recipient creation is performed by a different group than those who perform

recipient management, assign the `Mail Recipient Creation` role to the management role group that performs recipient creation, and the `Mail Recipients` role to the role group that performs recipient management.

If your organization has enabled Active Directory split permissions, all non-delegating management role assignments to this management role were removed. When Active Directory split permissions is enabled, only Active Directory administrators using Active Directory management tools can create new security principals such as users and security groups.

For more information about RBAC and Active Directory split permissions, see Understanding Split Permissions.

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role

assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

In addition to recipient scopes, the **New-Mailbox** cmdlet, which is included with this role, is also scoped using database configuration scopes. Database configuration scopes control which databases the cmdlet can create new mailboxes on. The database where you want to create a mailbox must be within the database scope. This condition applies when you specify a database using the *Database* parameter on the **New-Mailbox** cmdlet or if you allow automatic mailbox distribution to select the database for you. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Automatic Mailbox Distribution

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.23 Mail Recipients Role

Mail Recipients Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The `Mail Recipients` management role enables administrators to manage existing mailboxes, mail users, and mail contacts in an organization. This role can't create these recipients. Use the `Mail Recipient Creation` role to create them.

This role type doesn't enable you to manage mail-enabled public folders or distribution groups. Use the following roles to manage these objects:

- Mail Enabled Public Folders Role
- Distribution Groups Role

If your organization has a split permissions model where recipient creation and management are performed by different groups, assign the `Mail Recipient Creation` role to the group that performs recipient creation and the `Mail Recipients` role to the group that performs recipient management. For more information, see the following topics:

- Mail Recipient Creation Role
- Mail Recipients Role
- Understanding Split Permissions

This management role is one of several built-in roles in the Role Based Access Control (RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign

the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Additional Scope Considerations

In addition to recipient scopes, the **Connect-Mailbox** and **Enable-Mailbox** cmdlets, which are included with this role, are also scoped using database configuration scopes. Database configuration scopes control which databases the cmdlets can create new mailboxes on. The database where you want to create a mailbox must be within the database scope. This condition applies when you specify a database using the *Database* parameter on either cmdlet or if you allow automatic mailbox distribution to select the database for you. For more information, see the following topics:

- Understanding Management Role Scopes
- Understanding Automatic Mailbox Distribution

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:

- **Regular assignment** Regular role assignments enable the role assignee to access the permissions provided by the management role entries on this role.
- **Delegating assignment** Delegating role assignments give the role assignee the ability to assign this role to role groups, users, or USGs.
- **Recipient read scope** The recipient read scope determines what recipient objects the role assignee is allowed to read from Active Directory.
- **Recipient write scope** The recipient write scope determines what recipient objects the role assignee is allowed to modify in Active Directory.
- **Configuration read scope** The configuration read scope determines what configuration and server objects the role assignee is allowed to read from Active Directory.
- **Configuration write scope** The configuration write scope determines what organizational and server objects the role assignee is allowed to modify in Active Directory.

Default management role assignments for this role

Role group	Regular assignment	Delegating assignment	Recipient read scope	Recipient write scope	Configuration read scope	Configuration write scope
Organization Management	X	X	Organization	Organization	OrganizationConfig	OrganizationConfig
Recipient Management	X		Organization	Organization	OrganizationConfig	OrganizationConfig

Management Role Customization

This role has been configured to provide a role assignee with all of the necessary cmdlets, and their parameters, to manage the features and components listed in the beginning of this topic. Other roles have also been provided to enable management of other features. By adding and removing roles to and from role groups, you can create a customized permissions model without the need to customize individual management roles. For a complete list of roles, see Built-in Management Roles. For more information about customizing role groups, see the following topics:

- Add a Role to a Role Group

- Remove a Role from a Role Group

If you decide that you need to create a customized version of this role, you must create a role as a child of this role, and customize the new role.

Caution:

The following information enables you to perform advanced management of permissions. Customizing management roles can significantly increase the complexity of your permissions model. You could cause certain features to stop functioning if you replace a built-in management role with an incorrectly configured custom role.

The following are the most common steps to create a customized role and assign it to a role assignee:

1. Create a copy of this role using the **New-ManagementRole** cmdlet. For more information, see Create a Role.
2. Change or remove the role entries on the new role using the **Set-ManagementRoleEntry** and **Remove-ManagementRoleEntry** cmdlets. You can't add additional role entries to the new role because it can only contain the role entries on the parent built-in role. For more information, see the following topics:
   - Change a Role Entry
   - Remove a Role Entry from a Role
3. If you want to replace the built-in role with this new customized role, remove any role assignments associated with the built-in role using the **Remove-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Remove a Role from a Role Group
   - Remove a Role from a User or USG
4. Add the new customized role to the required role assignees using the **New-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
   - Add a Role to a Role Group
   - Add a Role to a User or USG

Important:

If you want other users, in addition to the user that created the role, to be able to assign the new customized role, be sure to add a delegating role assignment to at least one role assignee. For more information, see Delegate Role Assignments.

1.3.1.1.7.24 Mail Tips Role

Mail Tips Role

Understanding Permissions > Understanding Role Based Access Control > Built-in Management Roles >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Mail Tips management role enables administrators to manage mail tips in an organization.

This management role is one of several built-in roles in the Role Based Access Control

(RBAC) permissions model in Microsoft Exchange Server 2010. Management roles, which are assigned to one or more management role groups, management role assignment policies, users, or universal security groups (USG), act as a logical grouping of cmdlets or scripts that are combined to provide access to view or modify the configuration of Exchange 2010 components, such as mailboxes, transport rules, and recipients. If a cmdlet or script and its parameters, together called a management role entry, are included on a role, that cmdlet or script and its parameters can be run by those assigned the role. For more information about management roles and management role entries, see Understanding Management Roles.

For more information about management roles, management role groups, and other RBAC components, see Understanding Role Based Access Control.

Management Role Assignments

For this role to grant permissions, it must be assigned to a role assignee, which can be a role group, user, or universal security group (USG). This assignment is done using management role assignments. Role assignments link role assignees and roles together. If more than one role is assigned to a role assignee, the role assignee is granted the combination of all the permissions granted by all the assigned roles.

In addition to linking role assignees to roles, role assignments can also apply custom or built-in management scopes. Management scopes control which recipient, server and database objects can be modified by role assignees. If this role is assigned to a role assignee, but a management scope allows the role assignee only to manage certain objects based on a defined scope, the role assignee can only use the permissions granted by this role on those specific objects. The permissions provided by this role can't be applied to objects outside the scope defined on the role assignment. For more information about role assignments and scopes, see the following topics:

- Understanding Management Role Assignments
- Understanding Management Role Scopes

This role is assigned to one or more role groups by default. For more information, see the "Default Management Role Assignments" section later in this topic.

If you want to view a list of role groups, users, or USGs assigned to this role, use the following command.

```
Get-ManagementRoleAssignment -Role "<role name>"
```

Regular and Delegating Role Assignments

This role can be assigned to role assignees using either regular or delegating role assignments. Regular role assignments grant the permissions provided by the role to the role assignee. Delegating role assignments grant the role assignee the ability to assign the role to other role assignees. For more information about regular and delegating role assignments, see Understanding Management Role Assignments.

Adding or Removing Role Assignments

You can change which role assignees are assigned this role. By changing which role assignee is assigned this role, you change who is granted its permissions. You can assign this role to other built-in role groups, or you can create role groups and assign this role to them. You can also assign this role to users or USGs. However, we recommend that you limit assignment of roles to users and USGs because such assignments can greatly increase the complexity of your permissions model.

To assign this role to role assignees, the role must be assigned to a role group you're a member of, directly to you, or to a USG you're a member of, using a delegating role assignment. For more information about delegating role assignments, see the "Regular and Delegating Role Assignments" section.

You can also remove this role from built-in role groups, role groups you create, users, and USGs. However, there must always be at least one delegating role assignment between this role and a role group or USG. You can't delete the last delegating role assignment. This limitation helps prevent you from locking yourself out of the system.

Important:

There must be at least one delegating role assignment between this role and a role group or USG. You can't remove the last delegating role assignment associated with this role if the last assignment is to a user.

For more information about how to add or remove assignments between this role and role groups, users, and USGs, see the following topics:

- Add a Role to a Role Group
- Remove a Role from a Role Group
- Add a Role to a User or USG
- Remove a Role from a User or USG

Changing the Management Scopes on Role Assignments

You can also change the management scopes on existing role assignments between this role and role assignees. By changing the scopes on role assignments, you control what objects can be managed using the permissions provided by this role. You have several choices when changing the scope on a role assignment. You can do one of the following:

- Add a new custom scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see the following topics:
  - Create a Regular or Exclusive Scope
  - Change a Role Assignment
- Add or change an organizational unit scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Add or change a predefined scope using the **Set-ManagementRoleAssignment** cmdlet. For more information, see Change a Role Assignment.
- Change the recipient, server, or database scope on a custom scope associated with a role assignment using the **Set-ManagementScope** cmdlet. For more information, see Change a Role Scope.

Enabling or Disabling Role Assignments

By enabling or disabling a role assignment, you control whether that role assignment should be in effect. If a role assignment is disabled, the permissions granted by the associated role aren't applied to the role assignee. This is convenient if you want to temporarily remove permissions without deleting a role assignment. For more information, see Change a Role Assignment.

Default Management Role Assignments

This role has role assignments to one or more role assignees. The following table indicates whether the role assignment is regular or delegating, and also indicates the management scopes applied to each assignment. The following list describes each column:
