   5.b. Select **Equals** from the comparison operator drop-down list.
   5.c. Select **Retry** from the value drop-down list.
6. Click **Apply Filter**. All queues that currently have a retry status are displayed.
7. Select one or more queues from the list. Right-click, and then select **Retry Queue**. If the connection attempt is successful, the queue status changes to

Active. If no connection can be made, the queue remains in a status of Retry and the next retry time is updated.

Use the Shell to retry a queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

This example retries all queues with the status of Retry.

```
Retry-Queue -Filter {status -eq "retry"}
```

This example retries the queue Server\Queue.

```
Retry-Queue -Identity Server\Queue
```

For detailed syntax and parameter information, see Retry-Queue.

1.7.2.18.8 Suspend Queues

Suspend Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can suspend a queue that's present on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed. By suspending a queue, you prevent messages from leaving the queue, but you don't change the status of messages in the queue. Messages that are in delivery through SMTP-send will finish operations. You can suspend a queue to stop mail flow, and then suspend one or more messages in the queue. When you resume the queue, the messages that were suspended won't leave the queue.

You can suspend a queue that has a status of Active or Retry. You can also suspend the Unreachable queue and the Submission queue.

If you suspend the Unreachable queue, items won't be resubmitted to the categorizer when configuration updates are received by the transport server until the queue is resumed. If you suspend the Submission queue, messages won't be picked up by the categorizer until the queue is resumed.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to suspend a queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed. You can create a filter to display only queues that meet specific criteria.
5. Select one or more queues, right-click, and then select **Suspend**.

Use the Shell to suspend a queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

To suspend a queue, use the following syntax.

```
Suspend-Queue -Filter {property -operator "value"}
```

This example suspends all queues that have a message count equal to or greater than 1,000 and that have a status of Retry.

```
Suspend-Queue -Filter {MessageCount -ge 1000 -and Status -eq "Retry"}
```

For detailed syntax and parameter information, see Suspend-Queue.

1.7.2.18.9 Configure Message Retry, Resubmit, and Expiration Intervals

Configure Message Retry, Resubmit, and Expiration Intervals

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure message retry, resubmit, and expiration intervals on a server running Microsoft Exchange Server 2010 that has the Hub Transport server role or the Edge Transport server role installed.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Configure the queue glitch retry count

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The queue glitch retry count specifies the number of connection attempts that are immediately tried when a transport server has trouble connecting with the destination server. The default queue glitch retry count is 4. The valid input range for this parameter is from 0 through 15. Typically, you don't have to modify this parameter unless the network is unreliable and continues to experience many accidentally dropped connections. If you set the queue glitch retry count to 0, the server doesn't immediately attempt to retry an unsuccessful connection, and the next connection attempt is controlled by the *transient failure retry attempts*.

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section.

   ```
   <add key="QueueGlitchRetryCount" value="<Integer>" />
   ```

   This example changes the queue glitch retry count to 6.

   ```
   <add key="QueueGlitchRetryCount" value="6" />
   ```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

Configure the queue glitch retry interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The queue glitch retry interval specifies the interval between each connection attempt specified by the *QueueGlitchRetryCount* parameter. The default queue glitch retry interval is 1 minute. To specify an age value, enter the value as a time span, as follows: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds. Typically, you don't have to modify this parameter unless the network is unreliable and continues to experience many accidentally dropped connections.

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section.

```
<add key="QueueGlitchRetryInterval" value="<hh:mm:ss>" />
```

   This example changes the queue glitch retry interval to 30 seconds,

```
<add key="QueueGlitchRetryInterval" value="00:00:30" />
```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

Configure the number of transient failure retry attempts

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The number of transient failure retry attempts specifies the number of connection attempts that are tried after the connection attempts controlled by the *QueueGlitchRetryCount* and *QueueGlitchRetryInterval* parameters have failed. The default number of transient failure retry attempts is 6. The valid input range for this parameter is from 0 through 15. If you set the number of transient failure retry attempts to 0, the next connection attempt is controlled by the outbound connection failure retry interval.

Use the EMC to configure the number of transient failure retry attempts

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, in the console tree, select **Edge Transport**, and then click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and then select **Hub Transport**. In the result pane, select a server. In the action pane, click the **Properties** link that's directly under the server name.
2. Click the **Limits** tab.
3. Enter an integer next to **Transient failure retry attempts**.
4. Click **Apply** to save your changes and remain in the **Properties** page, or click **OK** to save your changes and exit the **Properties** page.

Use the Shell to configure the number of transient failure retry attempts

This example changes the number of transient failure retry attempts to 8 on the Edge Transport server Exchange01.

```
Set-TransportServer Exchange01 - TransientFailureRetryCount 8
```

For detailed syntax and configuration information, see Set-TransportServer.

Configure the transient failure retry interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The transient failure retry interval specifies the interval between each connection attempt that's specified by the number of transient failure retry attempts. On a Hub Transport server, the default transient failure retry interval is 5 minutes. On an Edge Transport server, the default transient failure retry interval is 10 minutes.

Use the EMC to configure the transient failure retry interval

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, in the console tree, select **Edge Transport**, and then click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and then select **Hub Transport**. In the result pane, select a server. In the action pane, click the **Properties** link that's directly under the server name.
2. Click the **Limits** tab.
3. Enter a value in seconds next to **Transient failure retry interval (seconds)**. In the EMC, the valid input range is from 1 second through 43200 seconds (12 hours).
4. Click **Apply** to save your changes and remain in the **Properties** page, or click **OK** to save your changes and exit the **Properties** page.

Use the Shell to configure the transient failure retry interval

To configure the transient failure retry interval, use the following syntax.

```
Set-TransportServer <Identity> -TransientFailureRetryInterval <Age>
```

This example changes the transient failure retry interval to 1 minute on the Exchange 2010 Hub Transport server Exchange01.

```
Set-TransportServer Exchange01 - TransientFailureRetryInterval 00:01:00
```

To specify an age value, enter the value as a time span, as follows: *hh:mm:ss*, where *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:01 through 12:00:00.

For detailed syntax and configuration information, see Set-TransportServer.

Configure the outbound connection failure retry interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The outbound connection failure retry interval specifies the retry interval for outgoing

connection attempts that have previously failed. The previously failed connection attempts are controlled by the transient failure retry attempts and the transient failure retry interval. The default value for the outbound connection failure retry interval on a Hub Transport server is 10 minutes. The default value on an Edge Transport server is 30 minutes.

Use the EMC to configure the outbound connection failure retry interval

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, in the console tree, select **Edge Transport**, and then click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and then select **Hub Transport**. In the result pane, select a server. In the action pane, click the **Properties** link that's directly under the server name.
2. Click the **Limits** tab.
3. Enter a value in minutes next to **Outbound connection failure retry interval (minutes)**. In the EMC, the valid input range is from 1 minute through 28800 minutes (20 days).
4. Click **Apply** to save your changes and remain in the **Properties** page, or click **OK** to save your changes and exit the **Properties** page.

Use the Shell to configure the outbound connection failure retry interval

This example changes the outbound connection failure retry interval to 45 minutes on the Exchange 2010 Edge Transport server Exchange01.

```
Set-TransportServer Exchange01 - OutboundConnectionFailureRetryInterval 00:45:00
```

To specify an age value, enter the value as a time span, as follows: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:01 through 20.00:00:00.

For detailed syntax and configuration information, see Set-TransportServer.

Configure the mailbox delivery queue retry interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The mailbox delivery queue retry interval specifies how frequently the mailbox delivery queues on a Hub Transport server try to connect to a Mailbox server destination that can't be successfully reached. By default, the mailbox delivery queue retry interval is 5 minutes. The mailbox delivery queue retry interval is controlled by the *MailboxDeliveryQueueRetryInterval* parameter in the EdgeTransport.exe.config application configuration file located in the C:\Program Files\Microsoft\Exchange Server\V14\Bin directory. Changes that are saved to the EdgeTransport.exe.config file take effect after the Microsoft Exchange Transport service is restarted.

1. Open the following file by using Notepad: C:\Program Files\Microsoft\Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section:

   ```
   <add key="MailboxDeliveryQueueRetryInterval" value="<hh:mm:ss>" />
   ```

   This example sets the mailbox delivery queue retry interval to 3 minutes.

```
<add key="MailboxDeliveryQueueRetryInterval" value="00:03:00" />
```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

To specify an age value, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:01 through 1.00:00:00.

Configure the message retry interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

The message retry interval specifies how frequently a Hub Transport server or an Edge Transport server resends a message that has a status of Retry. By default, the message retry interval is 1 minute. We recommend that you don't modify the default value unless Microsoft Customer Service and Support advises you to do this.

This example changes the message retry interval to 2 minutes on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageRetryInterval 00:02:00
```

To specify an age value, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:01 through 1.00:00:00.

For detailed syntax and configuration information, see Set-TransportServer.

Configure the delay DSN message notification time-out interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

By default, the delay DSN message notification time-out interval is 4 hours. If the message isn't successfully delivered before the notification time-out interval has passed, a delay DSN message is delivered to the sender.

The value of the *DelayNotificationTimeout* parameter should always be greater than the value of the *TransientFailureRetryCount* parameter multiplied by the value of the *TransientFailureRetryInterval* parameter.

Use the EMC to configure the delay DSN message notification time-out interval

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, in the console tree, select **Edge Transport**, and then click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and then select **Hub**

Transport. In the result pane, select a server. In the action pane, click the **Properties** link that's directly under the server name.
2. Click the **Limits** tab.
3. Enter a value in hours next to **Notify sender when message is delayed more than (hours)**. In the EMC, the valid input range is from 1 hour through 720 hours (30 days).
4. Click **Apply** to save your changes and remain in the **Properties** page, or click **OK** to save your changes and exit the **Properties** page.

Use the Shell to configure the delay DSN message notification time-out interval

This example changes the delay DSN message notification time-out interval to 6 hours on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -DelayNotificationTimeout 06:00:00
```

To specify an age value, enter the value as a time span, as follows: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:01 through 30.00:00:00.

For detailed syntax and configuration information, see Set-TransportServer.

Enable or disable the sending of delay DSN notifications to external message senders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

By default, delay DSN notification messages can be sent to message senders who are outside the Exchange organization.

This example prevents the sending of delay DSN notification messages to external senders on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -ExternalDelayDSNEnabled $false
```

For detailed syntax and configuration information, see Set-TransportServer.

Enable or disable the sending of delay DSN notifications to internal message senders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

By default, delay DSN notification messages can be sent to message senders who are inside the Exchange organization.

This example prevents the sending of delay DSN notification messages to internal senders on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -InternalDelayDSNEnabled $false
```

For detailed syntax and configuration information, see Set-TransportServer.

Configure the message resubmit interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

Undelivered messages are automatically resubmitted if the mailbox delivery queue or remote delivery queue is in the status of Retry for a specified amount of time, and the messages aren't in the Suspended state. That amount of time is controlled by the *MaxIdleTimeBeforeResubmit* parameter in the EdgeTransport.exe.config application configuration file. By default, the value of the *MaxIdleTimeBeforeResubmit* parameter is 12 hours.

1. Open the following file by using Notepad: C:\Program Files\Microsoft \Exchange Server\V14\Bin\EdgeTransport.exe.config.
2. Modify the following line in the <appSettings> section:

   ```
   <add key="MaxIdleTimeBeforeResubmit" value="<hh:mm:ss>" />
   ```

   This example changes the message resubmit interval to 6 hours.

   ```
   <add key="MaxIdleTimeBeforeResubmit" value="6:00:00" />
   ```

3. Save and close the EdgeTransport.exe.config file.
4. Restart the Microsoft Exchange Transport service.

Configure the message expiration time-out interval

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" and "Edge Transport server" entries in the Transport Permissions topic.

The message expiration time-out interval specifies the maximum length of time that an Edge Transport server or a Hub Transport server tries to deliver a failed message. If the message can't be successfully delivered before the message expiration time-out interval has passed, a non-delivery report (NDR) that contains the original message or the message headers is delivered to the sender, and the original message is removed from the queue.

By default, the message expiration time-out interval is 2 days.

Use the EMC to configure the message expiration time-out interval

1. Perform one of the following steps:
   - On a computer that has the Edge Transport server role installed, in the console tree, select **Edge Transport**, and then click the **Properties** link that's directly under the server name.
   - On a computer that has the Hub Transport server role installed, in the console tree, expand **Server Configuration**, and then select **Hub**

Transport. In the result pane, select a server. In the action pane, click the **Properties** link that's directly under the server name.
2. Click the **Limits** tab.
3. Enter a value in days next to **Maximum time since submission (days)**. In the EMC, the valid input range is from 1 day through 90 days.
4. Click **Apply** to save your changes and remain in the **Properties** page, or click **OK** to save your changes and exit the **Properties** page.

Use the Shell to configure the message expiration time-out interval

To configure the message expiration time-out interval, use the following syntax.

```
Set-TransportServer <Identity> -MessageExpirationTimeout <Age>
```

This example changes the message expiration time-out interval to 4 days on the Exchange 2010 computer Exchange01.

```
Set-TransportServer Exchange01 -MessageExpirationTimeout 4.00:00:00
```

To specify an age value, enter the value as a time span: *dd.hh:mm:ss*, where *d* = days, *h* = hours, *m* = minutes, and *s* = seconds. The valid input range for this parameter is from 00:00:05 through 90.00:00:00.

For detailed syntax and configuration information, see Set-TransportServer.

1.7.2.18.10 Filter Messages in Queues

Filter Messages in Queues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Queue Viewer or the Exchange Management Shell to filter messages in the queues on a computer that has the Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed. The list of messages can be lengthy, depending on current mail flow. The list of messages changes when messages enter and leave the server.

When you filter messages by message properties, you can adjust your search to specific criteria and locate messages that may be causing a mail flow problem or are suspected spam. You can then perform operations that modify the status of those messages.

To learn more about filtering messages, see "Message Filtering Scenarios" in Understanding Transport Queues.

Looking for other management tasks related to queues? Check out Managing Transport Queues.

Use Queue Viewer to filter messages in queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. Open the EMC.

2. In the console tree, click **Toolbox**.
3. In the result pane, click **Exchange Queue Viewer**.
4. In the action pane, click **Open Tool**.
5. In Queue Viewer, click the **Messages** tab. A list of all messages in all queues on the server to which you are connected is displayed. To limit the view to a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server\Queue* tab that appears.
6. Click **Create Filter**, and enter your filter expression as follows:
   6.a. Select a message property from the message property drop-down list.
   6.b. Select a comparison operator from the comparison operator drop-down list.
   6.c. Enter the value from the value drop-down list. If the property has fixed values, select a value from the drop-down list. If the property requires a date/time expression, change the current date/time values or click the drop-down list to select a date from the calendar interface.
7. (Optional) Click **Add Expression** to specify additional filter criteria. Only messages that meet all filter criteria will be displayed.
8. Click **Apply Filter**. The results of messages that meet the filter criteria are displayed.

Use the Shell to filter messages in queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

To filter messages in queues, use the following syntax.

```
Get-Message -Filter {property -operator "value"}
```

This example uses the **Get-Message** cmdlet to view all messages that have a spam confidence level (SCL) value equal to or greater than 6 and that were sent from any sender in the Contoso.com domain.

```
Get-Message -Filter {SCL -ge 6 -and FromAddress -eq "*Contoso.com"}
```

For detailed syntax and parameter information, see Get-Message.

1.7.2.18.11 View Queued Message Properties

View Queued Message Properties

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-07-21*

This topic explains how to use either the Exchange Queue Viewer in the EMC or the Shell to view the properties of a message that is queued for delivery.

What Do You Want to Do?

- Use Queue Viewer in the EMC to view the properties of a message
- Use the Shell to view the properties of a message

Use Queue Viewer in the EMC to view the

properties of a message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, select **Toolbox** to display a list of available tools in Exchange Server 2010.
2. Under Performance **tools**, double-click **Queue Viewer** to open the tool in a new window.
3. Select the **Messages** tab to see the list of messages that are currently queued for delivery in your organization.
4. Right-click the message whose properties you want to view and then select **Properties**.

5. The **General** tab displays the following detailed information about the message:
   - **Identity** This field shows the integer that represents a particular message. The message identity is assigned by the queuing database when the message is received for processing. You can include an optional server and queue identity to identify a unique instance of the message.
   - **Subject** This field shows the subject of a message and is expressed as a text string. The value is taken from the `Subject:` header field.
   - **Internet Message ID** This field shows the value of the `MessageID:` header field. The value of this property is expressed as a GUID followed by the SMTP address of the sending server, as in this example: 67D754D6103DC4FB3BA6BC7205DACABA61231@exchange.contoso.com
   - **From Address** This field shows the SMTP address of the sender of the message. This value is taken from MAIL FROM: in the message envelope.
   - **Status** This field shows the current message status. A message can have one of the following status values:
     ? **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.
     ? **Pending Remove** The message was deleted by the administrator but was already in delivery. The message will be deleted if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     ? **Pending Suspend** The message was suspended by the administrator but was already in delivery. The message will be suspended if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     ? **Ready** The message is waiting in the queue and is ready to be processed.
     ? **Retry** The last connection attempt failed for the queue in which this message is located. The message is waiting for the next queue retry.
     ? **Suspended** The message was suspended by the administrator.
   - **Size (KB)** This field shows the size of the message rounded up to the nearest kilobyte (KB).
   - **Message Source Name** This field shows the name of the component that submitted this message to the queue.
   - **Source IP** This field shows the IP address of the external server that submitted the message to the Exchange organization.
   - **SCL** This field shows the spam confidence Level (SCL) rating of the message. Valid SCL entries are integers 0 through 9. An empty SCL entry indicates that the message hasn't been processed by the Content Filter

agent.

- **Date Received** This field shows the date-time when the message was received by the server that holds the queue in which the message is located.
- **Expiration Time** This field shows the date-time when the message will expire and will be deleted from the queue if the message can't be delivered.
- **Last Error** This field shows the last error that was recorded for a message.
- **Queue ID** This field shows the identity of the queue that holds the message. The queue identity is expressed in the form *Server\destination*, where destination is a remote domain, mailbox server, persistent queue name, or the queue database identifier. The queue database identifier is represented as an integer and can be determined by viewing the message properties.
- **Recipients** This field shows the list of recipients to which the message is addressed.
- **Retry Count** This field shows the number of times that delivery of a message to a destination was tried.

6. The **Recipient Information** tab displays the following information about the message recipients:
   - **Address** This field shows the SMTP address of the recipient of the message. This value is taken from RCPT TO: in the message envelope.
   - **Status** This field shows the current message status. A message can have one of the following status values:
     ? **Active** If the message is in a delivery queue, the message is being delivered to its destination. If the message is in the Submission queue, the message is being processed by the categorizer.
     ? **Pending Remove** The message has been deleted by the administrator but was already in delivery. The message will be deleted if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     ? **Pending Suspend** The message has been suspended by the administrator but was already in delivery. The message will be suspended if the delivery ends in an error that causes the message to re-enter the queue. Otherwise, delivery will continue.
     ? **Ready** The message is waiting in the queue and is ready to be processed.
     ? **Retry** The last connection attempt failed for the queue in which this message is located. The message is waiting for the next queue retry.
     ? **Suspended** The message has been suspended by the administrator.
   - **Last Error** This field shows the last error that was recorded for a message.

Use the Shell to view the properties of a message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

You can use the **Get-Message** cmdlet to view the properties of a message that is currently queued for delivery. The following example tabulates the sender address, recipients, subject, and received date information for all messages that are currently in

retry state:

```
Get-Message -IncludeRecipientInfo -Filter {Status -eq "Retry"} | FT FromAddress,R
```

For detailed syntax and parameter information, see Get-Message.

1.7.2.18.12 Resume Messages

Resume Messages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can resume a message that's in a queue on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed.

You can resume a message that currently has a status of Suspended. By resuming a message, you enable delivery of the message. If you resume a message located in the poison message queue, the message will be sent to the categorizer for processing. A message being sent to multiple recipients might be located in multiple queues. To resume a message in more than one queue in a single operation, you must use a filter.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to resume a message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're connected is displayed. To adjust the action to focus on a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server\Queue* tab that appears.
5. Click **Create Filter**, and enter your filter expression as follows:
   5.a.Select **Status** from the message property drop-down list.
   5.b.Select **Equals** from the comparison operator drop-down list.
   5.c.Select **Suspended** from the value drop-down list.
6. Click **Apply Filter**. All messages that have a status of Suspended are displayed.
7. Select one or more messages from the list, right-click, and select **Resume**.

Use the Shell to resume a message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

This example resumes all messages being sent from any sender in the Contoso.com domain.

```
Resume-Message -Filter {FromAddress -eq "*contoso.com"}
```

This example resumes the message with the message ID 3 in the unreachable queue on server Hub01.

```
Resume-Message -Identity Hub01\Unreachable\3
```

For detailed syntax and parameter information, see Resume-Message.

1.7.2.18.13 Suspend Messages

Suspend Messages

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can suspend one or more messages in the queues on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed.

By suspending a message, you prevent delivery of the message. A message that appears in the queue but is already in delivery won't be suspended. Delivery will continue, and the message status will be PendingSuspend. If the delivery fails, the message will re-enter the queue, and the message will then be suspended. You can't suspend a message in the Submission queue or in the poison message queue.

A message being sent to multiple recipients might be located in multiple queues. To suspend a message in more than one queue in a single operation, you must use a filter.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to suspend messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're connected is displayed. To limit the view to a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server\Queue* tab that appears.
5. Select one or more messages, right-click, and then select **Suspend**.

Use the Shell to suspend messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

This example suspends all messages in the queues that are from any sender in the domain Contoso.com.

```
Suspend-Message -Filter {FromAddress -eq "*contoso.com"}
```

This example suspends the message with the message ID 3 in the unreachable queue on

server Hub01:

```
Suspend-Message -Identity Hub01\Unreachable\3
```

For detailed syntax and parameter information, see Suspend-Message.

1.7.2.18.14 Remove Messages from Queues

Remove Messages from Queues

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove one or more messages that are in a queue on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed. A message that's being sent to multiple recipients might be located in more than one queue. To remove a message from more than one queue in a single operation, you must use a filter.

You can select whether to send a non-delivery report (NDR) when you remove messages from a queue. You can't remove a message from the Submission queue.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the EMC to remove messages from queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Messages** tab. A list of all messages on the server to which you're connected is displayed. To adjust the action to a single queue, click the **Queues** tab, double-click the queue name, and then click the *Server\Queue* tab that appears.
5. Select one or more messages from the list, right-click, and then select **Remove Messages (with NDR)** or **Remove Messages (without NDR)**. A dialog box appears that confirms the selected action and displays, **Do you want to continue?** Click **Yes**.
6. To remove all messages from a particular queue, click the **Queues** tab. Select a queue, right-click, and then select **Remove Messages (with NDR)** or **Remove Messages (without NDR)**. A dialog box appears that confirms the selected action and displays, **Do you want to continue?** Click **Yes**.

Note:

If you're working with a filtered list, the displayed page may not include all items in the filter. In this case, a prompt appears that displays: **This action will affect all items on this page. To expand the scope of this action to include all items in this filter, check the following box before you click OK.**

Use the Shell to remove messages from queues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

To remove messages from queues, use the following syntax.

```
Remove-Message -Filter {property -operator "value"} -WithNDR <$true | $false>
```

This example removes messages in the queues that have a subject of "Win Big." This example doesn't send an NDR.

```
Remove-Message -Filter {Subject -eq "Win Big"} -WithNDR $false
```

For detailed syntax and parameter information, see Remove-Message.

1.7.2.18.15 Export Messages from Queues

Export Messages from Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-30*

You can use the Shell to export messages from a queue on a computer that has the Microsoft Exchange Server 2010 Hub Transport server role or the Edge Transport server role installed to a specified file path. You can't use Queue Viewer to perform this task. However, you can use Queue Viewer to locate, identify, and suspend the messages before you perform this task.

When you export a message from a queue to a file, the message isn't removed from the queue. A copy of the message is made in the specified location as a plain text file. The resulting file can be viewed in an application, such as a text editor or an e-mail client application, or the message file can be resubmitted by using the Replay directory on any other Hub Transport server or Edge Transport server inside or outside the Exchange organization.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Prerequisites

Before you export a message from a queue, you must follow these steps:

1. Verify the following information about the target directory location:
   - The target directory must exist before you export any messages. The directory won't be created for you. If an absolute path isn't specified, the current Shell working directory is used.
   - The path may be local to the Exchange 2010 computer, or it may be a Universal Naming Convention (UNC) path to a share on a remote server.
   - Your account must have the Write permission to the target directory.
2. Locate and identify the messages to be exported. For information about how to view messages, see View Queued Message Properties.
3. Suspend the messages to be exported to prevent their delivery during the

export process. The messages must be in a suspended state for the export process to be successful. You can export messages from remote delivery queues, mailbox delivery queues, the Unreachable queue, or the poison message queue. Messages in the poison message queue are already in a suspended state. You can't suspend or export messages that are in the Submission queue. For information about how to suspend messages, see Suspend Messages.

4. When you specify a file name, make sure that you include the .eml file name extension so that the file can be opened easily by e-mail client applications or processed correctly by the Replay directory.

Use the Shell to export a specific message from a specific queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

This example exports a copy of a message that has an **InternalMessageID** of 1234 that's located in the remote delivery queue for the domain Contoso.com on the server Exchange01 to the path C:\Contoso Export\export.eml.

```
Export-Message -Identity ExchSrv1\contoso.com\1234 | AssembleMessage -Path "c:\ex
```

For detailed syntax and parameter information, see Export-Message.

Use the Shell to export all messages from a specific queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

This example exports a copy of all the messages from the Contoso.com remote delivery queue on the server Exchange01 to the directory C:\Contoso Export on the local computer using the Internet Message IDs of each message as the file name. To accomplish this, the command does the following:

- Retrieves all messages in a specific queue using the **Get-Message** cmdlet.
- Pipelines the result into the **ForEach-Object** cmdlet, which executes the following actions for each message:
  - Prepares a file name including full path using the temporary variable `$Temp` that consists of the Internet Message ID with .eml extension. The Internet Message ID field contains angled brackets (> and <), which need to be removed because they're invalid file names. This is done using the **Replace** method of the temporary variable.
  - Exports the message using the file name prepared.

```
Get-Message -Queue "Exchange01\Contoso.com" | ForEach-Object {$Temp="C:\Contoso E
```

For detailed syntax and parameter information, see the Get-Message and Export-Message topics.

Use the Shell to export specific messages from all the queues on a server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

This example exports a copy of all the messages from senders in the Contoso.com domain from all queues on the server Exchange01 to the directory C:\Contoso Export on the local computer using the Internet Message IDs of each message as the file name. To accomplish this, the command does the following:

- Retrieves all messages that match the criteria using the **Get-Message** cmdlet with a filter.
- Pipelines the result into the **ForEach-Object** cmdlet, which executes the following actions for each message:
  - Prepares a file name including full path using the temporary variable `$Temp` that consists of the Internet Message ID with .eml extension. The Internet Message ID field contains angled brackets (> and <), which need to be removed because they're invalid file names. This is done using the **Replace** method of the temporary variable.
  - Exports the message using the file name prepared.

```
Get-Message -Filter {FromAddress -like "@Contoso.com"} -Server "Exchange01" | For
```

For detailed syntax and parameter information, see the Get-Message and Export-Message topics.

1.7.2.18.16 Resubmit Messages in Queues

Resubmit Messages in Queues

Transport > Managing Transport Servers > Managing Transport Queues >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can manually resubmit messages to the Submission queue for the categorizer to reprocess. You can manually resubmit messages that have the following status on a computer running Microsoft Exchange Server 2010 and that has the Hub Transport server role or the Edge Transport server role installed:

- Mailbox delivery queues or remote delivery queues that have the status of Retry. The messages in the queues must not be in the Suspended state.
- Messages in the Unreachable queue that aren't in the Suspended state.
- Messages in the poison message queue.

You can use the following methods to manually resubmit messages:

- Use the **Retry-Queue** cmdlet with the *Resubmit* parameter.
- Export the messages to .eml message files and resubmit them by using the Replay directory. For more information about this resubmission method, see Export Messages from Queues.
- Use Queue Viewer or the **Resume-Message** cmdlet to resubmit the messages in the poison message queue. The poison message queue can't be

resubmitted by using the **Retry-Queue** cmdlet with the *Resubmit* parameter. For more information, see Resume Messages.

By using the **Retry-Queue** cmdlet with the *Resubmit* parameter, you can force messages to be resubmitted back through the categorization process for a new attempt at delivery.

Using the **Retry-Queue** cmdlet without the *Resubmit* parameter forces the delivery queue to try to connect to the next hop immediately. The messages aren't resubmitted back through the categorization process. For information about how to retry the connection of a delivery queue, see Retry Queues.

Looking for other management tasks related to managing transport queues? Check out Managing Transport Queues.

Use the Shell to resubmit all messages located in a specific mailbox delivery queue or remote delivery queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

To resubmit all messages located in a specific mailbox delivery queue or remote delivery queue, use the following syntax.

```
Retry-Queue -Identity "<ServerName>\<Destination>" -Resubmit $true
```

This example resubmits all messages located in the remote delivery queue Contoso.com on the server Exchange01.

```
Retry-Queue -Identity "Exchange01\Contoso.com" -Resubmit $true
```

For detailed syntax and parameter information, see Retry-Queue.

Use the Shell to resubmit all messages located in all mailbox delivery queues or remote delivery queues that have the status of Retry

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

To resubmit all messages located in all mailbox delivery queues or remote delivery queues that have the status of Retry, use the following syntax.

```
Retry-Queue -Filter {Status -eq "Retry"} -Server "<ServerName>" -Resubmit $true
```

This example resubmits all messages located in any remote delivery queues with the status of Retry on the server Exchange01.

```
Retry-Queue -Filter {Status -eq "Retry"} -Server "Exchange01" -Resubmit $true
```

For detailed syntax and parameter information, see Retry-Queue.

Use the Shell to resubmit all messages located in the Unreachable queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Note:

You can't use the EMC to perform this task.

To resubmit all messages located in the Unreachable queue, use the following syntax.

```
Retry-Queue -Identity "<ServerName>\Unreachable" -Resubmit $true
```

This example resubmits all messages located in the Unreachable queue on the server Exchange01.

```
Retry-Queue -Identity "Exchange01\Unreachable" -Resubmit $true
```

For detailed syntax and parameter information, see Retry-Queue.

Resubmit messages located in the poison message queue

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Queues" entry in the Transport Permissions topic.

Messages that are located in the poison message queue must be resubmitted by resuming the message. The poison message queue can't be resubmitted by using the **Retry-Queue** cmdlet with the *Resubmit* parameter. To resume a message from the poison message queue, you can use Queue Viewer or the **Resume-Message** cmdlet.

Note:

The poison message queue contains messages that are determined to be harmful to the Exchange 2010 system after a server failure. The messages may be genuinely harmful in their content or format. Alternatively, they may be victims of a poorly written agent that crashed the Exchange server while it was processing the supposedly bad messages. If you're unsure of the safety of the messages in the poison message queue, you should export them to files so that you can examine them. The poison message queue is only visible in Queue Viewer when there are messages in the poison message queue.

Use the EMC to resume messages in the poison message queue

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Queue Viewer**.
3. In the action pane, click **Open Tool**.
4. In Queue Viewer, click the **Queues** tab. A list of all queues on the server to which you're connected is displayed.
5. Click the poison message queue. In the action pane, select **View Messages**.
6. Select one or more messages from the list, right-click, and select **Resume**.

Use the Shell to resume messages in the poison message queue

1. Before you can resume a message from the poison message queue, you must first determine the Identity of the message. This example determines

the Identity of all messages in the poison message queue.

```
Get-Message -Queue "Poison" | Format-Table Identity
```

2. To resume a message from the poison message queue, use the Identity of the message from the previous step and use the following syntax.

```
Resume-Message <IdentityofPoisonMessage>
```

This example resumes a message from the poison message queue that has the message Identity value of 222.

```
Resume-Message 222
```

For detailed syntax and parameter information, see Resume-Message or Get-Message.

1.7.3 Securing Transport Servers

Securing Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-08-25*

The security of your Transport servers is crucial to maintaining a robust and secure Exchange environment. This topic provides links to security-related topics that can help you understand the security model for Edge and Hub Transport servers in Microsoft Exchange Server 2010.

TLS Protection

All SMTP communications between Transport servers are protected by Transport Layer Security (TLS) encryption. For more information about TLS encryption in Exchange 2010, see the following topics:

- Understanding TLS Certificates
- TLS Functionality and Related Terminology in Exchange 2010
- Certificates

Exchange 2010 allows you to disable TLS encryption in certain scenarios. For example, if you're using WAN Optimization Controller (WOC) devices, the TLS-encrypted traffic may prevent the compression of SMTP communications over your WAN link. In such scenarios, you can disable TLS encryption. However, we recommend that you only disable TLS encryption on specific links and allow all other communications to continue to be protected by TLS. To learn more, see Disabling TLS Between Active Directory Sites to Support WAN Optimization.

Domain Security

Exchange 2010 provides a feature set called Domain Security that provides administrators a way to manage secure message paths with business partners over the Internet. The following topics provide information about Domain Security:

- Understanding Domain Security
- Using PKI on the Edge Transport Server for Domain Security
- Using Domain Security: Configuring Mutual TLS
- Test PKI and Proxy Configuration

Transport Permissions

Exchange 2010 uses Role Based Access Control (RBAC) for assigning permissions to users. With RBAC, you can control what resources administrators can configure and what features users can access. To learn more about RBAC, see Understanding Permissions.

For specific information about permissions required for managing Transport servers, see Transport Permissions.

1.7.4 Troubleshooting Reference for Transport Servers

Troubleshooting Reference for Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-09-02*

After the Transport server role is installed on a computer that is running Microsoft Exchange Server 2010, you may want to test the functionality of the server or solve problems related to message flow. The following topics can help you make sure that your Transport server is configured correctly.

Can't Remove an Arbitration Mailbox that Is Associated with an Existing Approval Workflow

Troubleshooting Certificate Validation Errors

Use Telnet to Test SMTP Communication

1.7.4.1 Can't Remove an Arbitration Mailbox that Is Associated with an Existing Approval Workflow

Can't Remove an Arbitration Mailbox that Is Associated with an Existing Approval Workflow

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2008-10-13*

You may receive the following error when you attempt to remove an arbitration mailbox:

> Can't remove the arbitration mailbox "{0}", because it is being used for the approval workflow for existing recipients that either membership restrictions or moderation enabled. Please either disable the approval features on those recipients or specify a different arbitration mailbox for those recipients before removing this arbitration mailbox.

An arbitration mailbox can be used to handle the approval workflow for moderated recipients and distribution group membership approvals. If you receive this error, you need to do the following:

1. Determine which recipients use this arbitration mailbox for handling approval workflow using the **Get-Recipient** cmdlet.

For example, if you want to find all recipients that use the arbitration mailbox AMBX1 for approval features, you can run the following command:

```
Get-Recipient -RecipientPreviewFilter {ArbitrationMailbox -eq "CN=AMBX
```

If you don't want to type in the entire distinguished name, you can use variables instead. The following three commands accomplish the same goal as the one above without having to type the distinguished name for the arbitration mailbox. The first command stores the arbitration mailbox in the variable *$ArbitrationMailbox*, and the second command stores the distinguished name in the *$ArbitrationMailboxDN* variable. Finally, the third command returns all recipients that use AMBX1 as the arbitration mailbox.

```
$ArbitrationMailbox = Get-Mailbox -Identity "AMBX1" -Arbitration
$ArbitrationMailboxDN = $ArbitrationMailbox.DistinguishedName
Get-Recipient -RecipientPreviewFilter {ArbitrationMailbox -eq $Arbitra
```

2. Either specify a different arbitration mailbox using the *ArbitrationMailbox* parameter or disable that feature.
   For example, assume that the distribution group All Employees uses the arbitration mailbox AMBX1 for moderation. You can run the following command to specify a different arbitration mailbox:

```
Set-DistributionGroup -Identity "All Employees" -ArbitrationMailbox "A
```

Alternatively, you can run the following command to disable moderation:

```
Set-DistributionGroup -Identity "All Employees" -ModerationEnabled $fa
```

After you reconfigure all recipients that use the arbitration mailbox for approval features, you will be able to delete the arbitration mailbox.

For More Information

Understanding Moderated Transport

Configure a Moderated Recipient

1.7.4.2 Troubleshooting Certificate Validation Errors

Troubleshooting Certificate Validation Errors

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to resolve certificate validation errors or refers to documentation that may help you resolve the errors.

For more information about how the Microsoft Exchange Transport service selects certificates for Transport Layer Security (TLS), see the following topics:

- Selection of Inbound Anonymous TLS Certificates
- Selection of Inbound STARTTLS Certificates
- Selection of Outbound Anonymous TLS Certificates

Certificate Validation Errors or Status Messages

The certificate is valid but it is selfsigned.

This error is an informational status message. By default, the certificate that installed with Exchange Server 2010 is self-signed. It's generally a best practice to use certificates from trusted third-party certification authorities (CA).

For more information, see Using PKI on the Edge Transport Server for Domain Security.

Certificate subject does not match the passed value.

This status message indicates that the domain name in either the subject name or subject alternative name fields of the certificate does not match the fully qualified domain name (FQDN) of the sender or receiver domain name. To correct this error, a new certificate that matches the FQDN of the Send connector or Receive connector that tried to validate this certificate must be created.

For more information, see Understanding TLS Certificates.

The signature of the certificate cannot be verified.

This status message indicates that the Microsoft Exchange Transport service was unable to validate the certificate chain, or that the public key that was used to validate the certificate signature is not the correct key.

A certificate chain processed, but ended in a root certificate which is not trusted by the trust provider.

This status message indicates that the certificate that was used for this operation is not trusted by the computer certificate store. To trust this certificate, the root certification authority for the given certificate must be present in the certificate store for this computer.

For more information about how to manually add certificates to the local certificate store, see the Help file for the Certificate Manager snap-in in the Microsoft Management Console (MMC).

The certificate is not valid for the requested usage.

This status message indicates that you must enable the certificate for use in the current application. For example, if you're trying to use this certificate for Domain Security, the certificate must be enabled for SMTP.

For more information about how to enable certificates, see Enable-ExchangeCertificate.

Alternatively, this status message may indicate that the certificate that you're using doesn't have the correct data in the Enhanced Key Usage field. All certificates that are used for TLS must contain a Server Authentication object identifier (also known as OID). If you're trying to use a certificate for TLS that doesn't contain a Server Authentication OID in the Enhanced Key Usage Field, you must create a new certificate.

For more information, see Understanding TLS Certificates.

A required certificate is not within its validity period when verifying against the current system clock or the timestamp in the signed file.

This status message indicates that the system time is incorrect, the certificate has expired, or the time of the system that signed the file is incorrect. Verify that the following conditions are true:

- The local computer clock is accurate.
- The certificate has not expired.
- The sending system clock is accurate.

If the certificate has expired, you must generate a new certificate.

For more information, see Understanding TLS Certificates.

The validity periods of the certification chain do not nest correctly.

This status message indicates that the certificate chain is corrupted or otherwise unreliable. Generate a new certificate by using New-ExchangeCertificate cmdlet, or contact your certification authority to validate the certificate chain that was used for this certificate.

A certificate that can only be used as an end entity is being used as a CA or visa versa.

This status message indicates that the certificate is invalid because it was issued by an end-entity certificate and not a certification authority. An end-entity certificate is a certificate that has been created for specific application cryptographic usage. Generate a new certificate by using the New-ExchangeCertificate cmdlet, or contact your certification authority to validate the certificate.

The certificate or signature has been revoked.

Contact your certification authority to resolve this issue.

A certificate was explicitly revoked by its issuer.

Contact your certification authority to resolve this issue.

The revocation function was unable to check revocation because the revocation server was offline.

This status message indicates that the revocation server for the certificate could not be reached. In some cases, this is a temporary error because the revocation server is malfunctioning. Otherwise, make sure that this computer can access the revocation server. If there is a firewall or proxy server in between this computer and the revocation server, make sure that your computer is configured to traverse the obstacle.

For more information, see Using PKI on the Edge Transport Server for Domain Security.

The revocation process could not continue. The certificates could not be checked.

This status message indicates that the revocation process was interrupted by a general network failure. If there is a firewall or proxy server in between this computer and the revocation server, make sure that your computer is configured to traverse the obstacle.

For more information, see Using PKI on the Edge Transport Server for Domain Security.

1.7.4.3 Use Telnet to Test SMTP Communication

Use Telnet to Test SMTP Communication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use Telnet to test Simple Mail Transfer Protocol (SMTP) communication between messaging servers. By default, SMTP listens on port 25. If you use Telnet on port 25, you can enter the SMTP commands that are used to connect to an SMTP server and send a message exactly as if your Telnet session was an SMTP messaging server. You can see the success or failure of each step in the connection and

message submission process.

Here are the scenarios where you may want to use Telnet to test SMTP communication to or from the transport servers that exist in your Microsoft Exchange Server organization:

- Connect to your organization's Edge Transport server from a host that is located outside your perimeter network and send a test message.
- Connect to a remote messaging server from your organization's Edge Transport server and send a test message.

The procedure in this topic shows you how to use Telnet Client, which is a component that is included with Microsoft Windows. Third-party Telnet clients may require a syntax that is different from that of the Windows Telnet component.

Prerequisites

- **Configure a Receive connector to allow anonymous access or Basic authentication** Because the message transfers that normally occur between Hub Transport servers are encrypted and authenticated, the internal Hub Transport server should have a Receive connector that is configured to allow anonymous access or Basic authentication to receive messages when using Telnet on port 25 to test communication. Anonymous access is required for Internet-facing servers

  Note:
  When you send a message to a Receive connector that accepts Basic authentication, you must have a utility to convert the text strings that are used for the username and password into the Base64 format. Because the user name and password are easily discernable when Basic authentication is used, we don't recommend Basic authentication without encryption.

- **Connect to a remote messaging server** You may also want to connect to a remote messaging server from your organization's Edge Transport server. This will help to avoid rejection of the test message by Internet-facing SMTP servers that are configured to validate the source IP address, the corresponding domain name system (DNS) domain name, and the reverse lookup IP address of any Internet host that tries to send a message to the server.
- **Install and/or enable the Telnet Client** You may need to perform one or more of the following tasks before you use Telnet to test SMTP communication between messaging servers:
  - Install Telnet Client if you haven't already done so. See Install Telnet Client for details about how to install Telnet Client on Windows Vista or Windows Server 2008.
  - Enable Telnet Client on Windows Server 2008. See the procedure later in this topic.
- **Find the FQDN or IP address of an SMTP server**. If you don't know the FQDN or IP address, you can use Nslookup to find the FQDN or IP address of an SMTP server. See the procedure later in this topic.

Enable Telnet Client in Windows Server 2008

Membership in the Windows Server 2008 local Administrators group, or equivalent, is the minimum required to complete this procedure.

In Windows Server 2008, Telnet Client is disabled by default. To enable it, complete the following steps:

1. Open **Server Manager.**
2. Click **Action,** and then select **Add Features.**
3. Select **Telnet Client**, and then click **Next.**
4. Click **Install,** and then click **Close** to complete the installation of Telnet Client.

Use Nslookup to find the FQDN or IP address of an SMTP server

To connect to a destination SMTP server by using Telnet on port 25, you must use the fully qualified domain name (FQDN) or the IP address of the SMTP server. If the FQDN or IP address is unknown, the easiest way to find this information is to use the Nslookup command-line tool to find the MX record for the destination domain.

1. At a command prompt, type **nslookup**, and then press ENTER. This command opens the Nslookup session.
2. Type **set type=mx** and then press ENTER.
3. Type **set timeout=20** and then press ENTER. By default, Windows DNS servers have a 15-second recursive DNS query time-out limit.
4. Type the name of the domain for which you want to find the MX record. For example, to find the MX record for the fabrikam.com domain, type **fabrikam.com.**, and then press ENTER.

   Note:

   The trailing period (**.**) indicates a FQDN. The use of the trailing period prevents any default DNS suffixes that are configured for your network from being unintentionally added to the domain name.

   The output of the command will resemble the following:

   ```
   fabrikam.com mx preference=10, mail exchanger = mail1.fabrikam.com
   fabrikam.com mx preference=20, mail exchanger = mail2.fabrikam.com
   mail1.fabrikam.com internet address = 192.168.1.10
   mail2 fabrikam.com internet address = 192.168.1.20
   ```

   You can use any of the host names or IP addresses that are associated with the MX records as the destination SMTP server. A lower value of preference indicates a preferred SMTP server. You can use multiple MX records and different values of preference for load balancing and fault tolerance.
5. When you're ready to end the Nslookup session, type **exit**, and then press ENTER.

Note:

Firewall or Internet proxy restrictions that are imposed on your organization's internal network may prevent you from using the Nslookup tool to query public DNS servers on the Internet.
MX records are not strictly required for internal message flow inside an Exchange organization. If you have to find the FQDN of any Hub Transport server or subscribed Edge Transport server in your organization, you can use the following command in the Exchange Management Shell: `Get-ExchangeServer | where {$_.isHubTransportServer -eq $true -or $_.isEdgeServer -eq $true} | Format-List Fqdn,ServerRole`
For more information, see Get-ExchangeServer and Pipelining.

Use Telnet on Port 25 to test SMTP communication

For purposes of providing an example, the following procedure uses the values that are described in the following list:

- **Destination SMTP server** mail1.fabrikam.com
- **Source domain** contoso.com
- **Sender's e-mail address** chris@contoso.com
- **Recipient's e-mail address** kate@fabrikam.com
- **Message subject** Test from Contoso
- **Message body** This is a test message

Note:

You should always use a valid sender e-mail address so that any non-delivery report (NDR) messages that are generated by the destination SMTP server

are delivered to the sender of the message.

The commands in Telnet Client are not case-sensitive. The SMTP command verbs are capitalized for clarity.

1. At a command prompt, type **telnet**, and then press ENTER. This command opens the Telnet session.
2. Type **set localecho** and then press ENTER. This optional command lets you view the characters as you type them. This setting may be required for some SMTP servers.
3. Type **set logfile** *<filename>*. This optional command enables logging of the Telnet session to the specified log file. If you only specify a file name, the location of the log file is the current working directory. If you specify a path and a file name, the path must be local to the computer. Both the path and the file name that you specify must be entered in the Microsoft DOS 8.3 format. The path that you specify must already exist. If you specify a log file that doesn't exist, it will be created for you.
4. Type **open mail1.fabrikam.com 25** and then press ENTER.

   Note:
   You can't use the backspace key after you have connected to the destination SMTP server within the Telnet session. If you make a mistake as you type an SMTP command, you must press ENTER and then type the command again. Unrecognized SMTP commands or syntax errors result in an error message that resembles the following:

   ```
   500 5.3.3 Unrecognized command
   ```

5. Type **EHLO contoso.com** and then press ENTER.
6. Type **MAIL FROM:chris@contoso.com** and then press ENTER.
7. Type **RCPT TO:kate@fabrikam.com NOTIFY=success,failure** and then press ENTER. The optional NOTIFY command defines the particular delivery status notification (DSN) messages that the destination SMTP server must provide to the sender. DSN messages are defined in RFC 1891. In this case, you're requesting a DSN message for successful or failed message delivery.
8. Type **DATA** and then press ENTER. You will receive a response that resembles the following:

   ```
   354 Start mail input; end with <CLRF>.<CLRF>
   ```

9. Type **Subject: Test from Contoso** and then press ENTER.
10. Press ENTER. RFC 2822 requires a blank line between the `Subject:` header field and the message body.
11. Type **This is a test message** and then press ENTER.
12. Press ENTER, type a period (**.**) and then press ENTER. You will receive a response that resembles the following:

    ```
    250 2.6.0 <GUID> Queued mail for delivery
    ```

13. To disconnect from the destination SMTP server, type **QUIT** and then press ENTER. You will receive a response that resembles the following:

    ```
    221 2.0.0 Service closing transmission channel
    ```

14. To close the Telnet session, type **quit** and then press ENTER.

Evaluate the Results of a Telnet Session

This section provides information about responses that may be provided to the following commands, which were used in the previous example:

- Open mail1.fabrikam.com 25
- EHLO contoso.com
- MAIL FROM:chris@contoso.com
- RCPT TO:kate@fabrikam.com NOTIFY=success,failure

Note:
The 3-digit SMTP response codes that are defined in RFC 2821 are the same for all SMTP messaging servers. The text descriptions may differ slightly for some SMTP messaging servers. In the previous example, the destination computer is running Exchange Server 2010.

Open mail1.fabrikam.com 25

Successful Response `220 mail1.fabrikam.com Microsoft ESMTP MAIL Service ready at <day-date-time>`

Failure Response `Connecting to mail1.fabrikam.com...Could not open connection to the host, on port 25: Connect failed`

Possible Reasons for Failure

- The destination SMTP service is unavailable.
- There are restrictions on the destination firewall.
- There are restrictions on the source firewall.
- An incorrect FQDN or IP address for the destination SMTP server was specified.
- An incorrect port number was specified.

EHLO contoso.com

Successful Response `250 mail1.fabrikam.com Hello [<sourceIPaddress>]`

Failure Response `501 5.5.4 Invalid domain name`

Possible Reasons for Failure There are invalid characters in the domain name. Alternatively, there are connection restrictions on the destination SMTP server.

Note:
EHLO is the Extended Simple Message Transfer Protocol (ESMTP) verb that is defined in RFC 2821. ESMTP servers can advertise their capabilities during the initial connection. These capabilities include their maximum accepted message size and their supported authentication methods. HELO is the older SMTP verb that is defined in RFC 821. Most SMTP messaging servers support ESMTP and EHLO.

MAIL FROM:chris@contoso.com

Successful Response `250 2.1.0 Sender OK`

Failure Response `550 5.1.7 Invalid address`

Possible Reasons for Failure There is a syntax error in the sender's e-mail address.

Failure Response `530 5.7.1 Client was not authenticated`

Possible Reasons for Failure The destination server does not accept anonymous message submissions. You receive this error if you try to use Telnet to submit a message directly to a Hub Transport server.

RCPT TO:kate@fabrikam.com NOTIFY=success,failure

Successful Response `250 2.1.5 Recipient OK`

Failure Response `550 5.1.1 User unknown`

Possible Reasons for Failure The specified recipient does not exist in the organization.

1.7.5 Performance Counter Reference for Transport Servers

Performance Counter Reference for Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Ensuring that servers running Microsoft Exchange Server 2010 are operating reliably is a key objective for messaging operations. An important part of Exchange 2010 operations is monitoring the Exchange components to understand the health state of servers and server roles. For more information about Transport performance counters, see the following topics:

- Transport Server Counters
- Performance and Scalability Counters and Thresholds

1.7.6 Error and Event Reference for Transport Servers

Error and Event Reference for Transport Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-01*

Microsoft Exchange Server 2010 Transport components, features, and services generate Error events to let you effectively troubleshoot and monitor Hub Transport and Edge Transport servers.

Event Viewer is a Microsoft Management Console (MMC) snap-in that enables you to browse and manage event logs. You can also gather information about hardware and software problems, and monitor Microsoft Windows security events. Although Event Viewer isn't a Microsoft Exchange component, Event Viewer is useful when you troubleshoot problems with Exchange 2010 server roles. For more information, see Event Viewer. For more information about Exchange 2010 event logs, look for "MSExchange" event logs in the Event Viewer on your Exchange 2010 server.

Transport Errors and Events

The following Transport errors and events are grouped according to the Transport feature areas.

- Antispam Errors and Events
- Antispam Update Errors and Events
- EdgeSync Errors and Events
- Extensibility Errors and Events
- Mail Submission Errors and Events
- Messaging Policies Errors and Events
- Message Security Errors and Events
- Store Driver Errors and Events
- Transport Errors and Events
- TransportLogSearch Errors and Events

1.7.6.1 Antispam Errors and Events

Antispam Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Antispam events in Event Viewer so that you can troubleshoot and verify the Antispam features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Antispam Errors and Events

The following table provides a list of the Antispam events.

Event ID	Category	Event type	Value or description
MSExchange Antispam 100	General	Warning	Protocol Analysis Background agent warning. The queue this agent uses is full. This does not affect SRL calculations. Open proxy, reverse DNS, and sender blocking are affected.
MSExchange Antispam 101	General	Error	Protocol Analysis: DNS is not configured. Most likely, no DNS servers found. Sender Reputation calculations are disabled.
MSExchange Antispam 200	General	Warning	Protocol Analysis warning. No DNS entries were found for this server's authoritative domains. Open proxy detection is not available.
MSExchange Antispam 301	General	Error	Unable to initialize the Content Filter agent: %1
MSExchange	General	Warning	Unable to quarantine

Antispam 302			message because the spam quarantine mailbox is invalid. Please configure the quarantine mailbox.
MSExchange Antispam 303	General	Error	Microsoft Exchange was unable to initialize the Content Filter agent. Check the access control lists (ACLs) on the files under '%1' and make sure the Microsoft Exchange Transport service can access them. Details: %2
MSExchange Antispam 304	General	Warning	Microsoft Exchange was unable to initialize the Content Filter agent. Files under %1 may be corrupted. Details: %2
MSExchange Antispam 305	General	Error	Microsoft Exchange was unable to initialize the Content Filter agent. Notification of the file system change could not be initialized. Try restarting the Microsoft Exchange Transport service. Details: %1
MSExchange Antispam 306	General	Error	Microsoft Exchange was unable to initialize the Content Filter agent. It could not allocate sufficient memory for an internal buffer. Increase the available memory and restart the Microsoft Exchange Transport service. Details: %1
MSExchange Antispam 307	General	Error	The Content Filter wrapper process is not responding. Unable to scan the message.
MSExchange Antispam 308	General	Error	Content Filter wrapper process is

			now being restarted.
MSExchange Antispam 310	General	Error	Content Filter wrapper process could not be restarted in a timely manner. Restarting Microsoft Exchange Transport Service may solve the problem.
MSExchange Antispam 311	General	Error	An error occurred while sending the shutdown message to the Content Filter wrapper process. Details: %1
MSExchange Antispam 312	General	Warning	Content Filter wrapper did not timely respond to the last %1 messages.
MSExchange Antispam 313	General	Warning	A message could not be sent to the Content Filter wrapper because of an error. The message is being rejected. Details: %1
MSExchange Antispam 314	General	Warning	Microsoft Exchange couldn't initialize the Content Filter agent because ExSMime.dll couldn't be initialized. Verify that ExSMime.dll is properly registered by using Regsrv32.exe. Details: %1
MSExchange Antispam 315	General	Error	An unexpected failure occurred while trying to scan the message with ID %1. This message has not been assigned a spam confidence level (SCL) value. Details: %2
MSExchange Antispam 316	General	Error	Failed to read the current Microsoft Anti-spam Update service mode. Therefore, any recent change in the mode may not have taken effect. To solve the problem, try

			restarting the Microsoft Exchange Transport service. Details: %1
MSExchange Antispam 318	General	Error	Microsoft Exchange couldn't initialize the Content Filter agent because a required file could not be found on your system. Please run the Reset-AntispamUpdates script from the Exchange Management Shell and restart Microsoft Exchange Transport service to solve the problem. Details: %1
MSExchange Antispam 400	General	Error	Update agent warning. Microsoft Exchange couldn't load the IP reputation data file.
MSExchange Antispam 500	General	Error	A notification of a configuration change has been received for %1 but the new configuration could not be read. Please check network connectivity between this server and the Active Directory directory service. The agent will continue to run with the old configuration.
MSExchange Antispam 600	General	Error	Connection Filter agent: DNS is not configured. IP Allow List and Block List providers will be skipped
MSExchange Antispam 700	General	Error	Sender ID agent: DNS is not configured. Messages will be handled as if DNS requests have failed temporarily.

1.7.6.2 Antispam Update Errors and Events

Antispam Update Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-08-10*

Microsoft Exchange Server 2010 generates Anti-spam Update events in Event Viewer so that you can troubleshoot and verify the Anti-spam Update features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Anti-spam Update Errors and Events

The following table provides a list of the Antispam Update errors and events.

Event ID	Category	Event type	Value or description
MSExchange Anti-spam Update 1009	Update Service	Error	The download of update %1 failed with error %2
MSExchange Anti-spam Update 1012	Update Service	Error	The installation of update %1 failed with error %2
MSExchange Anti-spam Update 1015	Update Service	Error	Microsoft Exchange couldn't determine the version of the Microsoft Update agent, or the Microsoft Update agent is not current. Please see Microsoft Update, and then update your client. Anti-spam updates will not be downloaded until this problem is fixed.
MSExchange Anti-spam Update 1016	Update Service	Error	Microsoft Exchange couldn't complete the opt-in process for Microsoft Update: %1. Please see Microsoft Update, and then update your client manually. Anti-spam updates will not be downloaded until this problem is fixed.
MSExchange Anti-spam Update 1017	Update Service	Error	Microsoft Exchange couldn't successfully use the Microsoft

			Update agent: %1. Please see Microsoft Update, and then update your client manually. Antispam updates will not be downloaded until this problem is fixed.
MSExchange Anti-spam Update 1002	Update Service	Error	Unable to start the Microsoft Exchange Anti-spam Update service: %1
MSExchange Anti-spam Update 1003	Update Service	Error	Unable to stop the Microsoft Exchange Anti-spam Update service: %1
MSExchange Anti-spam Update 1000	Update Service	Information	The Microsoft Exchange Anti-spam Update service has started successfully.

1.7.6.3 EdgeSync Errors and Events

EdgeSync Errors and Events

Exchange Server 2010 > Transport > Error and Event Reference for Transport Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates EdgeSync events in Event Viewer so that you can troubleshoot and verify the EdgeSync features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

EdgeSync Errors and Events

The following table provides a list of the EdgeSync errors and events.

Event ID	Category	Event type	Value or description
MSExchange EdgeSync 1004	Synchronization	Error	EdgeSync failed to confirm the credentials for replication account %1 for subscription server %2. The start date is %3. The password hash is %4. Please make sure Microsoft Exchange Credential service

			(MSExchangeEdgeCredential) is running properly on the subscription server.
MSExchange EdgeSync 10104	Synchronization	Warning	Microsoft Exchange couldn't match certificate when contacting %1. The connection was stopped.
MSExchange EdgeSync 1013	Synchronization	Warning	Synchronization failed because it could not read replication data from the Active Directory server %1, port %2 with exception: %3. Check network connectivity, and test the health of the domain controller.
MSExchange EdgeSync 1024	Topology	Warning	Failed to connect to the Edge Transport server ADAM instance with exception %1. This could be caused by a failure to resolve the Edge Transport server name %2 in DNS, a failure trying to connect to port %3 on %2, network connectivity issues, an invalid certificate, or an expired subscription. Verify your network and server configuration.
MSExchange EdgeSync 1025	Topology	Warning	Topology load generated exception %1. EdgeSync must be able to acquire current Exchange topology data from the Active Directory directory service to properly operate. Check network connectivity and test the health of the domain controller.
MSExchange EdgeSync 1032	Topology	Warning	Microsoft Exchange EdgeSync can't find the replication credential on %1 to synchronize with

			Edge server %2. This may happen if %1 joined the current Active Directory site after subscription for %2 was established. To have this Hub Transport server participate in EdgeSync, re-subscribe %2 to the current Active Directory site.
MSExchange EdgeSync 1033	Topology	Error	EdgeSync failed to decrypt the credential for Edge Transport server %1 using the private key of the default Exchange certificate with exception %2. The certificate's thumbprint is %3 and its subject is %4. Use either Enable-ExchangeCertificate or New-ExchangeCertificate to set the proper Exchange default certificate and re-subscribe the Edge Transport server %1 again.
MSExchange EdgeSync 1034	Synchronization	Error	EdgeSync failed to synchronize the following address %1 to MSERV with permanent error %2. EdgeSync could not retry this item.
MSExchange EdgeSync 1104	Synchronization	Warning	Failed to sync entry "%1" to EHF. Failure details: %2
MSExchange EdgeSync 1045	Initialization	Error	Initialization failed with exception: %1. If this warning frequently occurs, contact Microsoft Product Support.
MSExchange EdgeSync 1059	Initialization	Information	EdgeSync is starting

1.7.6.4 Extensibility Errors and Events

Extensibility Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Extensibility events in Event Viewer so that you can troubleshoot and verify the Extensibility features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Extensibility Errors and Events

The following table provides a list of Extensibility errors and events.

Event ID	Category	Event type	Value or description
MSExchange Extensibility 1050	MExRuntime	Warning	The execution time of agent '%1' exceeded %2 milliseconds while handling event '%3' for message with InternetMessageId: '%4'. This is an unusual amount of time for an agent to process a single event. However, Transport will continue processing this message.
MSExchange Extensibility 1051	MExRuntime	Warning	Agent '%1' caused an unhandled exception '%2: %3' while handling event '%4'
MSExchange Extensibility 1053	MExRuntime	Error	Agent '%1' failed to create an agent instance with error '%2'.

1.7.6.5 Mail Submission Errors and Events

Mail Submission Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Mail Submission events in Event Viewer so

that you can troubleshoot and verify the MSExchangeMailSubmission features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchangeMailSubmission Errors and Events

The following table provides a list of the MSExchangeMailSubmission errors and events.

Event ID	Category	Event type	Value or description
MSExchangeMailSubmission 1002	MSExchangeMailSubmission	Error	Unable to start the Microsoft Exchange Mail Submission service: %1
MSExchangeMailSubmission 1010	MSExchangeMailSubmission	Error	The hub server %1 is currently processing %2 submissions, which is the maximum allowed.
MSExchangeMailSubmission 1004	MSExchangeMailSubmission	Error	Unable to load the Microsoft Exchange Mail Submission service performance counters: %1

1.7.6.6 Messaging Policies Errors and Events

Messaging Policies Errors and Events

Exchange Server 2010 > Transport > Error and Event Reference for Transport Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Messaging Policies events in Event Viewer so that you can troubleshoot and verify the Messaging Policies features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Messaging Policies Errors and Events

The following table provides a list of the Messaging Policies errors and events.

Event ID	Category	Event type	Value or description
MSExchange Messaging Policies	AttachFilter	Warning	An error occurred while loading the

2001			configuration for the Attachment Filter agent, the configuration may be corrupt, or Active Directory Application Mode (ADAM) may be unreachable. The Attachment Filter agent will use the last known "good" configuration.
MSExchange Messaging Policies 3001	AddressRewrite	Error	An error occurred while loading the configuration for the Address Rewriting Inbound agent and Address Rewriting Outbound agent. The configuration may be corrupt, or Active Directory Application Mode (ADAM) may be unreachable. The Address Rewriting Inbound agent and Address Rewriting Outbound agent will use the last known "good" configuration.
MSExchange Messaging Policies 6007	PolicyApplication	Error	Encryption Agent failed to get a delegation token for %1 for the target %2. Error is %3.
MSExchange Messaging Policies 6008	PolicyApplication	Warning	Federation is not enabled, but the %1 agent encountered a message that needs to be %2 %3
MSExchange Messaging Policies 6009	PolicyApplication	Warning	Failed to find certificate to decrypt the token. Please make sure that the organization private certificate is installed on this server and enabled for SMTP. The OrgPrivCertificate thumbprint is available from the get-federationtrust task. Messages that need to be decrypted will be temporarily rejected.

MSExchange Messaging Policies 6017	PolicyApplication	Warning	Failed to load federated delivery configuration when encrypting message '%1'. MSExchange Encryption agent will send an NDR for this message. The error is: '%2'
MSExchange Messaging Policies 4002	Rules	Information	'%1' rule collection was loaded successfully.

1.7.6.7 Message Security Errors and Events

Message Security Errors and Events

Exchange Server 2010 > Transport > Error and Event Reference for Transport Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates Message Security events in Event Viewer so that you can troubleshoot and verify the Message Security features and services. Event Viewer tracks the following kinds of events in the given order based on importance:

- Error events
- Warning events
- Informational events

Message Security Errors and Events

The following table provides a list of Message Security errors and events.

Event ID	Category	Event type	Value or description
MSExchange Message Security 1003	EdgeCredentialService	Error	No valid Transport Layer Security (TLS) certificate was found. Microsoft Exchange can't update the Active Directory Application Mode (ADAM) credentials.
MSExchange Message Security 1005	EdgeCredentialService	Error	Could not decrypt EdgeSync credential %1 using Edge default certificate with thumbprint %2, The exception is %3. Please unsubscribe and resubscribe your Edge Transort server.
MSExchange Message Security	EdgeCredentialService	Error	Microsoft Exchange couldn't read the

1001			server configuration. The service will be stopped.
MSExchange Message Security 1000	EdgeCredentialService	Error	Microsoft Exchange couldn't read the server configuration because the directory is unavailable. The service will be stopped.
MSExchange Message Security 1004	EdgeCredentialService	Error	The local server couldn't be found. Microsoft Exchange can't update the Active Directory Lightweight Directory Services (AD LDS) credentials. Exception is %1. Make sure that the service account used by the Microsoft Exchange Edge Credential service has permission to access the local Exchange server object in the Active Directory service. Also make sure that the FQDN of the computer matches the FQDN attribute of the server object in Active Directory.
MSExchange Message Security 1007	EdgeCredentialService	Error	Microsoft Exchange couldn't read the registry information about the Secure Sockets Layer (SSL) port that is used by Active Directory Application Mode (ADAM), exception % 1. Using the default value for the SSL port that is used by ADAM: 50636.
MSExchange Message Security 1006	EdgeCredentialService	Error	Failed to update EdgeSync credential %1 in ADAM. The exception is: %2. Please make sure ADAM service is running.

1.7.6.8 Store Driver Errors and Events

Store Driver Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates MSExchange Store Driver events in Event Viewer so that you can troubleshoot and verify the Store Driver features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Store Driver Errors and Events

The following table provides a list of Store Driver errors and events.

Event ID	Category	Event type	Value or description
MSExchange Store Driver 1012	MSExchangeStoreDriver	Error	The store driver failed to submit event %1 mailbox %2 MDB %3 and couldn't generate an NDR due to exception %4.
MSExchange Store Driver 1018	MeetingMessageProcessing	Warning	An error occurred processing the meeting message with subject %1 in mailbox %2. Error: %3.
MSExchange Store Driver 1016	MSExchangeStoreDriver	Warning	The sender for event %1 mailbox %2 MDB %3 is invalid. The event will be ignored.
MSExchange Store Driver 1004	MSExchangeStoreDriver	Error	Unable to load the store driver performance counters: %1.
MSExchange Store Driver 1009	MSExchangeStoreDriver	Warning	The store driver encountered a poison message during message submission. The submission will be stopped for event %1 on mailbox %2 MDB %3. Exception is: %4.
MSExchange Store Driver 1011	MSExchangeStoreDriver	Warning	The store driver encountered a poison message during

			message submission. The submission will be stopped for event %1 on mailbox %2 Mdb %3.
MSExchange Store Driver 1017	MSExchangeStoreDriver	Warning	There are too many mail submission threads. The number of submission threads is currently limited to %1.

1.7.6.9 Transport Errors and Events

Transport Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates MSExchangeTransport events in Event Viewer so that you can troubleshoot and verify the Exchange Transport features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchange Transport Errors and Events

The following table provides a list of Certificate Deployment errors and events.

Event ID	Category	Event type	Value or description
MSExchangeTransport 10001	PoisonMessage	Warning	%1 messages have reached or exceeded the configured poison threshold of %2. After the Microsoft Exchange Transport service restarted, these messages were moved to the poison message queue.
MSExchangeTransport 10003	PoisonMessage	Error	The transport process failed during message processing with the following call stack: %1.
MSExchangeTransport 10005	PoisonMessage	Error	The transport process couldn't load poison message information from the registry.

			Access to the registry failed with the following error: %1.
MSExchangeTransport 10004	PoisonMessage	Warning	The processing of Pickup file %1 caused the transport process to fail. Pickup file %1 will be renamed.
MSExchangeTransport 10006	PoisonMessage	Error	The transport process couldn't save poison message information to the registry. Access to the registry failed with the following error: %1.
MSExchangeTransport 10007	PoisonMessage	Error	The transport process couldn't remove poison message information from the registry. Access to the registry failed with the following error: %1.
MSExchangeTransport 1003	SmtpReceive	Error	The configuration of one of the SMTP Receive connectors is invalid. The configuration change will be ignored. The description of the configuration error is: %1.
MSExchangeTransport 1012	SmtpReceive	Warning	Receive connector %1: Authentication failures have exceeded the maximum of %2 for the connection from %3. Disconnecting.
MSExchangeTransport 1018	SmtpReceive	Warning	The account '%1' provided valid credentials, but it does not have submit permissions on SMTP Receive connector '%2'; failing authentication.
MSExchangeTransport 1020	SmtpReceive	Warning	The account '%1' provided valid credentials, but is not authorized to use the server; failing authentication.

MSExchangeTransport 1021	SmtpReceive	Warning	Receive connector %1 rejected an incoming connection from IP address %3. The maximum number of connections per source (%2) for this connector has been reached by this source IP address.
MSExchangeTransport 1022	SmtpReceive	Warning	Anti-spam agents are enabled, but the list of internal SMTP servers is empty. If there are any MTAs between this server and the Internet, populate this list by using the Set-TransportConfig cmdlet in the Exchange Management Shell.
MSExchangeTransport 1025	SmtpReceive	Error	SMTP rejected a (%4) mail from '%1' with '%2' connector and the user authenticated as '%3'. The Active Directory lookup for the sender address returned validation errors. %5
MSExchangeTransport 1028	SmtpReceive	Error	SMTP rejected a mail from '%1', sender '%4' on '%2' connector, and user authenticated as '%3'. The Active Directory directory service lookup for the FROM address returned the following error: %5
MSExchangeTransport 1034	SmtpReceive	Error	Initialization of inbound authentication failed with error %1 for Receive connector %2. The authentication mechanism is %3. The source IP address of the client who tried to authenticate to us is [%4].
MSExchangeTranspo	SmtpReceive	Error	Inbound direct trust

rt 1036			authentication failed for certificate %1. The source IP address of the server that tried to authenticate to Microsoft Exchange is [%2]. Make sure EdgeSync is running properly.
MSExchangeTransport 11005	MessageSecurity	Error	Unable to validate the TLS certificate of the smart host for the connector %1. The certificate validation error for the certificate is %2. If the problem persists, contact the administrator of the smart host to resolve the problem.
MSExchangeTransport 11011	MessageSecurity	Error	A secure connection from domain-secured domain '%1' on connector '%2' failed to authenticate because validation of the Transport Layer Security (TLS) certificate failed with status '%3'. Contact the administrator of %1 to resolve the problem, or remove the domain from the domain-secured list.
MSExchangeTransport 11012	MessageSecurity	Error	A message from domain-secured domain '%1' on connector '%2' could not be authenticated because the server did not use Transport Layer Security (TLS). Contact the administrator for %1 to resolve the problem, or remove the domain from the domain-secured list.
MSExchangeTransport 11013	MessageSecurity	Error	The connection to secure domain '%1' on connector '%2' failed because Transport Layer Security (TLS)

			negotiation was unsuccessful. Error: '%3'. Please contact the administrator of %1 to resolve the problem.
MSExchangeTransport 11014	MessageSecurity	Error	A secure connection to domain secure domain '%1' on connector '%2' could not be established because TLS was not offered. Contact the administrator for %1 to resolve the problem or remove the domain from the domain-secured list.
MSExchangeTransport 11015	MessageSecurity	Error	A secure connection to domain secure domain '%1' on connector '%2' could not be established because TLS was not offered. Contact the administrator for %1 to resolve the problem or remove the domain from the domain-secured list.
MSExchangeTransport 11016	MessageSecurity	Error	Authentication of the connection to secure domain %1 failed because the Transport Layer Security (TLS) server certificate didn't contain the name of that domain. Either contact the administrator for domain %1 to resolve the problem with their certificate or remove the domain from the domain-secured list.
MSExchangeTransport 11017	MessageSecurity	Error	A message from domain-secured domain '%1' on connector '%2' failed to authenticate because no Transport Layer Security (TLS) certificate was supplied. Contact the administrator for %1

			to resolve the problem, or remove the domain from the domain-secured list.
MSExchangeTransport 11018	MessageSecurity	Error	The message could not be received from domain-secured domain %1 because of a configuration error on Receive connector %2. You must set Transport Layer Security (TLS) as the authentication mechanism on the connector to receive messages from domain-secured domains.
MSExchangeTransport 11019	MessageSecurity	Error	The connection to secure domain '%1' on Send connector '%2' failed because Transport Layer Security (TLS) negotiation failed with response '%3'. Contact the administrator of secure domain '%1' to resolve the problem or remove the domain from the domain-secured list.
MSExchangeTransport 11020	MessageSecurity	Error	A secure connection to domain-secured domain '%1' on connector '%2' could not be established because the validation of the Transport Layer Security (TLS) certificate for %1 failed with status '%3. Contact the administrator of %1 to resolve the problem, or remove the domain from the domain-secured list.
MSExchangeTransport 12008	TransportService	Error	Microsoft Exchange couldn't read the Receive connector configuration. The service will be

			stopped.
MSExchangeTransport 12010	TransportService	Error	Microsoft Exchange couldn't load the Active Directory recipient cache performance counters %1.
MSExchangeTransport 12011	TransportService	Error	Microsoft Exchange couldn't register the service principal name %1: %2
MSExchangeTransport 12012	TransportService	Error	The internal transport certificate that is used for SMTP authentication by Microsoft Exchange could not be read from Active Directory. The certificate may be missing. If an existing certificate that matches the fully qualified domain name (FQDN) of the server is already installed, run the Enable-ExchangeCertificate cmdlet to publish this certificate to Active Directory. If a certificate for the FQDN of the server is not installed, create a certificate by running the New-ExchangeCertificate cmdlet for the FQDN of the server.
MSExchangeTransport 12013	TransportService	Error	Microsoft Exchange could not load the certificate with thumbprint of %1 from the personal store on the local computer. This certificate was configured for authentication with other Exchange servers. Mail flow to other Exchange servers could be affected by this error. If the certificate with this thumbprint still

			exists in the personal store, run Enable-ExchangeCertificate %1 -Services SMTP to resolve the issue. If the certificate does not exist in the personal store, restore it from backup by using the Import-ExchangeCertificate cmdlet, or create a new certificate for the FQDN or the server enabled for SMTP by running the following command: New-ExchangeCertificate -DomainName serverfqdn -Services SMTP.
MSExchangeTransport 12014	TransportService	Error	Microsoft Exchange could not find a certificate that contains the domain name %1 in the personal store on the local computer. Therefore, it is unable to support the STARTTLS SMTP verb for the connector %2 with a FQDN parameter of %1. If the connector's FQDN is not specified, the computer's FQDN is used. Verify the connector configuration and the installed certificates to make sure that there is a certificate with a domain name for that FQDN. If this certificate exists, run Enable-ExchangeCertificate -Services SMTP to make sure that the Microsoft Exchange Transport service has access to the certificate key.
MSExchangeTransport 12016	TransportService	Error	There is no valid SMTP Transport Layer Security (TLS)

			certificate for the FQDN of %1. The existing certificate for that FQDN has expired. The continued use of that FQDN will cause mail flow problems. A new certificate that contains the FQDN of %1 should be installed on this server as soon as possible. You can create a new certificate by using the New-ExchangeCertificate task.
MSExchangeTransport 12018	TransportService	Warning	The STARTTLS certificate will expire soon: subject: %1, thumbprint: %2, hours remaining: %3. Run the New-ExchangeCertificate cmdlet to create a new certificate.
MSExchangeTransport 12020	TransportService	Error	A secure connection to the domain %1 could not be established because the Transport Layer Security (TLS) certificate for the domain has expired. Contact the administrator for %1 to resolve the problem.
MSExchangeTransport 12021	TransportService	Warning	Microsoft Exchange detected a configuration change but couldn't read the updated Receive connector configuration. The configuration change will be ignored.
MSExchangeTransport 14001	Process	Error	The worker process with process ID %1 is not responding and will be forced to shut down.
MSExchangeTranspo	Process	Error	The worker process

rt 14004			has failed to load application configuration file: %1.
MSExchangeTransport 15006	ResourceManager	Warning	Microsoft Exchange Transport is rejecting message submissions because the available disk space has dropped below the configured threshold. %1
MSExchangeTransport 15007	ResourceManager	Warning	The Microsoft Exchange Transport service is rejecting message submissions because the service continues to consume more memory than the configured threshold.%1.
MSExchangeTransport 16011	Configuration	Warning	MessageTrackingLog is enabled, but MessageTrackingLogPath is null. MessageTrackingLog will be disabled.
MSExchangeTransport 16013	Configuration	Warning	The SendProtocolLogPath parameter is set to $null. Setting the value of this parameter to $null disables protocol logging for all Send connectors on the server. No send protocol log is written.
MSExchangeTransport 16014	Configuration	Warning	The path to the protocol logging location for Receive connectors has not been set. Use the existing path.
MSExchangeTransport 16015	Configuration	Warning	The SendProtocolLogPath parameter is set to $null. Microsoft Exchange will continue to use the old location for protocol log storage.
MSExchangeTranspo	Configuration	Error	There is no default

rt 16016			authoritative domain or the domain name is empty.
MSExchangeTranspo rt 16017	Configuration	Error	Microsoft Exchange couldn't activate transport components because of the unexpected exception: %1.
MSExchangeTranspo rt 16018	Configuration	Warning	A configuration update occurred but the internal %1 cache failed to load. Microsoft Exchange will retain the existing configuration. %2
MSExchangeTranspo rt 16021	Configuration	Error	An accepted domain entry was damaged in Active Directory. Exchange is rejecting the configuration.
MSExchangeTranspo rt 16023	Configuration	Error	Microsoft Exchange couldn't start transport agents. The Microsoft Exchange Transport service will be stopped. Exception details: %1 : %2.
MSExchangeTranspo rt 16024	Configuration	Error	The data for an accepted domain entry included invalid data. Skipping record for %1.
MSExchangeTranspo rt 16025	Configuration	Warning	No DNS servers could be retrieved from network adapter %1. Check if the computer is connected to a network and Get-NetworkConnectionIn fo returns any results.
MSExchangeTranspo rt 17001	Storage	Error	Column %3 in Extensible Storage Engine (ESE) table % 2 from database %1 should contain data type %4, but instead it contains data type %5. The module that contains the database schema may have been

			updated and could be trying to open an older database. The old database must be removed before starting the Microsoft Exchange Transport service.
MSExchangeTransport 17002	Storage	Error	The non-nullable column %3 on the Extensible Storage Engine (ESE) table %2 from database %1 is part of the database schema but cannot be found in the actual database table. The module containing the database schema may have been updated and could be attempting to open an older database. The old database must be removed before starting the Exchange Server Transport service in Microsoft Exchange Server 2010.
MSExchangeTransport 17003	Storage	Error	%1: An operation has encountered a fatal error. The database may be corrupted. The Microsoft Exchange Transport service is shutting down. Manual database recovery or repair may be required. Exception details: %2
MSExchangeTransport 17004	Storage	Error	%1: An operation has encountered a fatal error. There wasn't enough disk space to complete the operation. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17005	Storage	Error	%1: The database could not be opened because a log file is

			missing or corrupted. The Microsoft Exchange Transport service is shutting down. Manual database recovery or repair may be required. The exception is %2.
MSExchangeTransport 17006	Storage	Error	%1: The database could not be opened because the log file path that was supplied is invalid. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17007	Storage	Error	%1: The database could not be opened because the database file does not match the log files. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17011	Storage	Error	%1: The database could not be opened because the checkpoint file (.chk) is missing or corrupted. The Microsoft Exchange Transport service is shutting down. Manual database recovery or repair may be required. The exception is %2.
MSExchangeTransport 17101	Storage	Error	%1: MSExchangeTransport has detected a critical storage error but will not take any recovery actions. Manual actions should be taken to resolve issues encountered with this database (%2) and associated transaction logs (%3).
MSExchangeTranspo	Storage	Error	%1:

rt 17102			MSExchangeTransport has detected a critical storage error and has taken an automated recovery action. This recovery action will not be repeated until the target folders are renamed or deleted. %2.
MSExchangeTransport 17104	Storage	Error	%1: MSExchangeTransport has detected a critical storage error but failed to complete the desired recovery action on %2 due to error %3.
MSExchangeTransport 17105	Storage	Warning	%1: MSExchangeTransport has detected a critical storage error and will now stop. The service attempted to update the registry key (%2) used to initiate automated recovery but failed with the following error: %3. Please make sure Network Service has Full Control to this registry key.
MSExchangeTransport 2000	SmtpSend	Warning	Send connector %1: A DNS failure occurred with the following diagnostic information %2.
MSExchangeTransport 2002	SmtpSend	Error	Send connector %1: an error occurred while connecting to %2.
MSExchangeTransport 2003	SmtpSend	Warning	Send connector %1 has failed to authenticate with %2. The response from the remote site is %3.
MSExchangeTransport 2006	SmtpSend	Warning	Send connector %1: the connection to %2 was disconnected by the remote server.
MSExchangeTransport 2011	SmtpSend	Error	A secure connection with Exchange server

			%1 could not be established because the protocol negotiation did not find a mutually supported hash algorithm. Modify the configuration of either %1 or this server so that one hash algorithm is supported by both servers.
MSExchangeTransport 2014	SmtpSend	Error	Failed to bind to SourceIPAddress '%1' configured on send connector '%2'.
MSExchangeTransport 2015	SmtpSend	Error	Send connector %1 couldn't connect to remote domain %2. The send connector requires Transport Layer Security (TLS) authentication, but is unable to establish TLS with the receiving server for the remote domain. Check this connector's authentication setting and the EHLO response from the remote server %3.
MSExchangeTransport 2016	SmtpSend	Error	An authentication credential initialization error %1 occurred with Send connector %2. The authentication mechanism used was %3. The name of the server that we were trying to authenticate to was %4. This server was using the name %5. Try reentering the credential. If the problem persists, contact Microsoft Support Services.
MSExchangeTransport 2017	SmtpSend	Error	Outbound authentication failed with error %1 for Send connector %2. The authentication

			mechanism is %3. The target is %4.
MSExchangeTransport 2018	SmtpSend	Error	Outbound direct trust authentication failed for certificate %1. The target IP address of the Exchange server that Microsoft Exchange tried to authenticate to is [%2]. Make sure EdgeSync is running properly.
MSExchangeTransport 2019	SmtpSend	Warning	Unable to transmit ORAR information to remote server '%1' over send connector '%2'. Message '%3' will not be delivered to recipient '%4'.
MSExchangeTransport 3004	Dsn	Error	The generation of the quarantine message may fail because of an error reading the spam quarantine mailbox configuration from the directory. The configuration data may be corrupt or the Active Directory directory service may be unreachable.
MSExchangeTransport 3005	Dsn	Error	An error caused by reading the SystemMessage configuration from the directory indicates that generation of delivery status notifications (DSNs) and storage quota is using out-of-date or incomplete message customizations. The configuration data may be corrupt, or the Active Directory directory service may be unreachable. The error was '%1'.
MSExchangeTransport 5001	Routing	Error	Microsoft Exchange couldn't load the routing performance counters: %1.

MSExchangeTransport 5002	Routing	Error	Microsoft Exchange couldn't load routing tables because the Active Directory directory service is unavailable. Microsoft Exchange will continue to use the existing routing table if one is available.
MSExchangeTransport 5003	Routing	Error	Microsoft Exchange couldn't load configuration information for routing. The process will block and retry the operation in %1 seconds.
MSExchangeTransport 5004	Routing	Error	Microsoft Exchange cannot obtain the fully qualified domain name (FQDN) of Exchange server %1 in routing tables with timestamp %2. Recipients will not be routed to this server.
MSExchangeTransport 5005	Routing	Error	The Active Directory site for Exchange server %1 was not determined in routing tables with timestamp %2. Recipients will not be routed to this server.
MSExchangeTransport 5006	Routing	Error	Cannot find route to Mailbox Server %1 for store %2 in routing tables with timestamp %3. Recipients will not be routed to this store.
MSExchangeTransport 5007	Routing	Error	The topology doesn't contain a route to Active Directory site %1 in routing tables with the timestamp %2. Recipients will not be routed to servers in this Active Directory site. Hub Transport server %3 is unreachable.
MSExchangeTranspo	Routing	Error	The topology does

rt 5008			not contain any route to server %1 in Active Directory site %2 in routing tables with timestamp %3. Recipients will not be routed to this server.
MSExchangeTranspo rt 5009	Routing	Warning	Microsoft Exchange cannot find the route to mailbox database %1 for public folder hierarchy %2 in routing tables with timestamp %3.
MSExchangeTranspo rt 5010	Routing	Warning	No route has been created for public folder hierarchy %1 in routing tables with timestamp %2. Recipients will not be routed to this public folder. Check the routing logs for further information.
MSExchangeTranspo rt 5011	Routing	Error	Source routing group %1 was not found for routing group connector %2 in routing tables with timestamp %3. Microsoft Exchange is skipping the connector.
MSExchangeTranspo rt 5012	Routing	Error	Target routing group %1 was not found for routing group connector %2 in routing tables with timestamp %3; skipping the connector.
MSExchangeTranspo rt 5013	Routing	Error	The routing group for Exchange server %1 was not determined in routing tables with timestamp %2. Recipients will not be routed to this server.
MSExchangeTranspo rt 5014	Routing	Error	No source transport servers or home MTA server have been set for connector %1 in routing tables with timestamp %2.

			Ignoring the connector.
MSExchangeTransport 5015	Routing	Error	Microsoft Exchange cannot find a route to the source transport server or home MTA server %1 for connector %2 in routing tables with timestamp %3. Microsoft Exchange is ignoring the source transport server.
MSExchangeTransport 5016	Routing	Error	The Active Directory topology service could not discover any route to connector %1 in the routing tables with the timestamp %2. This connector will not be used.
MSExchangeTransport 5017	Routing	Error	Microsoft Exchange cannot find target bridgehead server %1 for routing group connector %2 in routing tables with timestamp %3. Microsoft Exchange is ignoring the target bridgehead server.
MSExchangeTransport 5018	Routing	Error	No target bridgehead servers were found for routing group connector %1 in routing tables with timestamp %2. Ignoring the routing group connector.
MSExchangeTransport 5019	Routing	Error	MSExchangeTransport found invalid smart hosts string %1 on SMTP connector %2 in routing tables with timestamp %3. MSExchangeTransport is ignoring the SMTP connector.
MSExchangeTransport 5020	Routing	Warning	The topology doesn't contain a route to Exchange 2000 Server or Exchange Server 2003 %1 in Routing Group %2 in

			routing tables with the timestamp %3.
MSExchangeTransport 5021	Routing	Error	The Exchange 2000 or Exchange 2003 server %1 was found in Exchange 2007 routing group %2 in routing tables with timestamp %3.
MSExchangeTransport 5023	Routing	Error	A transient configuration error was detected while the routing configuration was loading. Exception details: %1 : %2.
MSExchangeTransport 5024	Routing	Error	The maximum number of retries to load routing configuration data has been reached. The service will be stopped.
MSExchangeTransport 5025	Routing	Error	Non-SMTP address space '%1' was detected on the DNS SMTP connector '%2' in routing tables with timestamp %3. The address space is ignored on the connector because a non-delivery report (NDR) will be sent for the message or because the message will go to another connector. Exchange Server 2007 or Exchange 2010 tasks block this configuration. However, the connector may have been set up by Exchange Server 2003.
MSExchangeTransport 5026	Routing	Warning	Source servers belonging to different Active Directory sites were detected for connector '%1' in routing tables with timestamp %2. Only the closest site will be used and load-

			balancing will be affected.
MSExchangeTransport 5027	Routing	Error	Source routing group %1 was not found for the connector with connected routing groups %2 in routing tables with timestamp %3. Microsoft Exchange Transport is skipping the connector.
MSExchangeTransport 5028	Routing	Error	Source routing group %1 is the local routing group for a connector with connected routing groups %2 in routing tables with timestamp %3. Connectors with connected routing groups are only supported in routing groups with Exchange 2000 or Exchange 2003 servers.
MSExchangeTransport 5029	Routing	Error	Connected routing group %1 was not found for connector %2 in routing tables with timestamp %3.
MSExchangeTransport 5030	Routing	Error	Microsoft Exchange couldn't create routing table log file or directory %1. Exception details: %2 : %3.
MSExchangeTransport 5031	Routing	Error	Microsoft Exchange couldn't delete routing table log file %1. Exception details: %2 : %3.
MSExchangeTransport 5500	Logging	Warning	Transport pipeline tracing is active. This may degrade system performance.
MSExchangeTransport 7002	Components	Error	Database %1 is already in use. The service will be stopped. Exception details: %2
MSExchangeTranspo	RemoteDelivery	Error	A non-SMTP gateway

rt 8004			connection failure occurred on connector %1. When writing to the drop directory %2, an I/O exception %3 occurred.
MSExchangeTransport 8005	RemoteDelivery	Error	A non-SMTP gateway connection failure occurred on connector %1. The drop directory quota limit of %2(MB) has been exceeded.
MSExchangeTransport 8007	RemoteDelivery	Error	Non-SMTP Gateway Connection Failure on Connector %1. The drop directory filename %2 exceeds the system-defined maximum length.
MSExchangeTransport 8008	RemoteDelivery	Error	A connection failure occurred on the foreign connector %1. The Drop directory %2 does not exist.
MSExchangeTransport 8009	RemoteDelivery	Error	Non-SMTP connector %1 failed because the Drop directory %2 does not have the correct access permissions. Change the access permissions for directory %2 or use another directory.
MSExchangeTransport 8010	RemoteDelivery	Error	A message with the Internal Message ID %1 was rejected by the remote server. This message will be deferred and retried because it was marked for retry if rejected. Other messages may also have encountered this error.
MSExchangeTransport 9002	Pickup	Error	The Pickup directory doesn't have the necessary Read permissions and Delete Subfolders and Files permissions for Pickup directory %1.

MSExchangeTransport 9003	Pickup	Warning	Read-only files have been found in the directory %1. Read-only files cannot be processed by the Pickup directory or the Replay directory. Please remove the read-only attributes or remove the read-only files.
MSExchangeTransport 9004	Pickup	Error	File(s) cannot be deleted from %1 by the Pickup directory. This may cause duplicate mail. Please verify that the Network Service account has "Delete Subfolders and Files" permission for this directory.
MSExchangeTransport 9005	Pickup	Error	The Pickup directory cannot submit the message because of database problems.
MSExchangeTransport 9006	Pickup	Error	The Microsoft Exchange Transport service failed to create the Pickup directory: %1. Pickup will not function until the directory is created. The detailed error is %2.
MSExchangeTransport 9007	Pickup	Error	File(s) cannot be opened or renamed in %1 by the Pickup directory. Some mail may not be processed by the Pickup directory. Please verify that the Network Service account has "Create Files" permission for this directory, and that files in the directory do not deny read access to the Network Service account.
MSExchangeTransport 9009	Pickup	Error	The Pickup directory doesn't have permissions to write

			the pickup location to registry (%1). Please make sure Network Service has Full Control to the registry location. The error was %2.
MSExchangeTransport 9010	Pickup	Error	At least one file in %1 can't be processed. These files have .bad extensions. Please look for .bad files, and make sure that their content is valid.
MSExchangeTransport 9201	Categorizer	Error	Transport agent (%1) running on the OnSubmittedMessage event did not handle a catchable exception: (%2).
MSExchangeTransport 9202	Categorizer	Error	Transport agent (%1) running on the OnRoutedMessage event did not handle a catchable exception: (%2).
MSExchangeTransport 9212	Categorizer	Error	Microsoft Exchange couldn't load the resolver performance counters: %1.
MSExchangeTransport 9213	Categorizer	Warning	A non-expirable message with the Internal Message ID %1 could not be categorized. This message may be a journal report or other system message. The message will remain in the queue until administrative action is taken to resolve the error. Other messages may also have encountered this error. To further diagnose the error, use the Queue Viewer or the Exchange Mail Flow Troubleshooter.
MSExchangeTransport 1009	SmtpReceive	Warning	Receive connector %1 rejected an incoming

			connection. The maximum number of connections (%2) for this connector has been reached.
MSExchangeTransport 18001	Agents	Error	Agent '%1' did not close the MIME stream after handling the %2 event for message with ID '%3'. The message has been rejected. Please report this problem to the agent vendor.
MSExchangeTransport 7007	Components	Information	Online defragmentation has completed for database %1. The database has %2 free bytes.
MSExchangeTransport 7006	Components	Information	Scheduled online defragmentation will start for database %1. The database has %2 free bytes.
MSExchangeTransport 7005	Components	Information	A new database file %1 has been created.
MSExchangeTransport 7004	Components	Information	The activation of all modules took longer than expected to complete. Total Load Time: %1 Total Start Time: %2 Load Time Breakdown: %3 Start Time Breakdown: %4.
MSExchangeTransport 2021	SmtpSend	Information	Unable to transmit RDST (Routing Destination) to remote server '%1' over send connector '%2'. Message '%3' will not be delivered to recipient '%4'.
MSExchangeTransport 2020	SmtpSend	Information	Unable to transmit long ORAR address '%1' to remote server '%2' over send connector '%3'. Message '%4' will not be delivered to recipient '%5'.
MSExchangeTranspo	SmtpSend	Information	Send connector %1

rt 2007			has initiated a new session to %2.
MSExchangeTransport 2005	SmtpSend	Information	Send connector %1: Errors occurred with the connection to %2. The connection was acknowledged with SMTP response %3.
MSExchangeTransport 2004	SmtpSend	Information	Send connector %1: Message delivery was not successful. The message with message ID %2 was acknowledged with SMTP response %3.
MSExchangeTransport 10002	PoisonMessage	Information	PoisonCount for the message with the record ID %1 has been incremented. The new value is %2.
MSExchangeTransport 1002	SmtpReceive	Information	The connectors have been configured.
MSExchangeTransport 1010	SmtpReceive	Error	Receive connector %1 rejected a message at SMTP end of data with %2.
MSExchangeTransport 1023	SmtpReceive	Error	SMTP rejected a message from '%1' with '%2' connector. The authenticated user '%3' doesn't have permission to submit e-mail messages to this server.
MSExchangeTransport 1024	SmtpReceive	Error	SMTP rejected a (%4) mail from '%1' with '%2' connector and user authenticated as '%3'. There was a transient Active Directory directory service exception thrown with the following information. %5.
MSExchangeTransport 1026	SmtpReceive	Error	SMTP rejected a (%4) mail from '%1' with '%2' connector. The user '%3' does not have permissions to send as this address.

MSExchangeTransport 1027	SmtpReceive	Error	SMTP rejected a mail from '%1', sender '%4' with '%2' connector and user authenticated as '%3'. The Active Directory lookup for the FROM address threw a transient Active Directory exception with the following information. %5
MSExchangeTransport 1029	SmtpReceive	Information	SMTP rejected a mail from '%1', sender '%4' with '%2' connector and user authenticated as '%3'. The sender does not have permissions to send on behalf of the FROM address.
MSExchangeTransport 1031	SmtpReceive	Error	The connection for user [%1] with IP address [%2] is being dropped. The rate of message submissions from this connection has exceeded the throttling policy of %3 per minute.
MSExchangeTransport 1033	SmtpReceive	Error	An exception was thrown while processing data from client IP address %1. The exception is %2.
MSExchangeTransport 1035	SmtpReceive	Error	Inbound authentication failed with error %1 for Receive connector %2. The authentication mechanism is %3. The source IP address of the client who tried to authenticate to Microsoft Exchange is [%4].
MSExchangeTransport 1037	SmtpReceive	Error	Failure occurred while trying to determine the Mailbox server for mailbox database [%1]. Message submission quota for user [%2] with IP address [%3] will not

			be enforced. Exception details: %4
MSExchangeTransport 1039	SmtpReceive	Error	SMTP rejected a message from '%1' on '%2' connector. The user was authenticated as '%3'. The Active Directory lookup returned the following error: %4.
MSExchangeTransport 11021	MessageSecurity	Warning	A secure connection to domain-secured domain '%1' on connector '%2' could not be established because the DomainSecureEnabled flag on the connector was not set. Set the DomainSecureEnabled flag or remove the domain '%1' from the domain-secured list.
MSExchangeTransport 11022	MessageSecurity	Error	Failed to confirm domain capabilities '%1' on connector '%2' because validation of the Transport Layer Security (TLS) certificate failed with status '%3'. Contact the administrator of '%4' to resolve the problem, or remove the domain from the TlsDomainCapabilities list of the Receive connector.
MSExchangeTransport 11023	MessageSecurity	Error	Connection to remote endpoint '%1 (%2)' for send connector '%3' is dropped because the server did not advertise the XOORG (Originator Organization) ESMTP protocol extension.
MSExchangeTransport 11024	MessageSecurity	Warning	Remote certificate with thumbprint '%1' contains '%2' subject alternative names and exceeds the limit of %3. Subject

			alternative names of this certificate will be ignored. The limit can be changed by adding/modifying the SubjectAlternativeNameLimit parameter in the EdgeTransport.exe.config file.
MSExchangeTransport 12002	TransportService	Information	A configuration update occurred.
MSExchangeTransport 12003	TransportService	Information	The configured server role is invalid for this process.
MSExchangeTransport 12009	TransportService	Error	Microsoft Exchange couldn't read the Receive connector configuration because the directory is unavailable. The service will be stopped.
MSExchangeTransport 12015	TransportService	Information	An internal transport certificate expired. Thumbprint:%1
MSExchangeTransport 12017	TransportService	Information	An internal transport certificate will expire soon. Thumbprint:%1, hours remaining: %2.
MSExchangeTransport 12019	TransportService	Information	The remote internal transport certificate expired. Certificate subject: %1.
MSExchangeTransport 12023	TransportService	Information	Microsoft Exchange could not load the certificate with thumbprint of %1 from the personal store on the local computer. This certificate was configured for authentication with other Exchange servers. Mail flow to other Exchange servers could be affected by this error. If the certificate with this thumbprint still exists in the personal store, run Enable-

			ExchangeCertificate %1 -Services SMTP to resolve the issue. If the certificate does not exist in the personal store, restore it from backup by using the Import-ExchangeCertificate cmdlet, or create a new certificate for the FQDN or the server enabled for SMTP by running the following command: New-ExchangeCertificate -DomainName serverfqdn -Services SMTP. Meanwhile, the certificate with thumbprint %2 is being used.
MSExchangeTransport 12024	TransportService	Information	Microsoft Exchange could not load the certificate with thumbprint of %1 from the personal store on the local computer. This certificate was configured for authentication with other Exchange servers. Mail flow to other Exchange servers could be affected by this error. If the certificate with this thumbprint still exists in the personal store, run Enable-ExchangeCertificate %1 -services SMTP to resolve the issue. If the certificate does not exist in the personal store, restore it from backup by using the Import-ExchangeCertificate cmdlet, or create a new certificate for the FQDN or the server enabled for SMTP by running the following command: New-ExchangeCertificate -DomainName

			serverfqdn -Services SMTP. Meanwhile, an ephemeral, self-signed certificate with thumbprint %2 is being used.
MSExchangeTransport 12025	TransportService	Warning	Transport service is disconnecting performance counters with process lifetime from their old process.
MSExchangeTransport 12026	TransportService	Error	Transport service failed to disconnect performance counters with process lifetime in category : %1 from their old process.
MSExchangeTransport 12028	TransportService	Warning	The process with processId %1 is holding the performance counter %2 from instance %3 and category %4 while running processes are: %5.

MSExchangeTransport 15005	ResourceManager	Information	The resource pressure decreased from %1 to %2.%3.
MSExchangeTransport 16012	Configuration	Warning	The path to the protocol logging location for Receive connectors has not been set. No protocol log for Receive connectors was written. The default location is C:\Program Files\Microsoft Exchange \TransportRoles\Logs \ProtocolLog \SmtpReceive.
MSExchangeTransport 16019	Configuration	Error	Active Directory directory service encountered an error

			for %1. Microsoft Exchange will retain the existing configuration, if available. Exception details: %2.
MSExchangeTransport 16022	Configuration	Information	A configuration update for %1 has successfully completed.
MSExchangeTransport 16026	Configuration	Information	Microsoft Exchange failed to query a network adapter to obtain the IP addresses assigned to it. Microsoft Exchange will continue to use previously loaded IP address information if available. The Microsoft Exchange Transport service will be stopped if this error occurred during service startup. Exception details: %1.
MSExchangeTransport 16027	Configuration	Information	The configuration for %1 has had to be forcibly loaded %2 time(s). There might be a problem with AD notifications.
MSExchangeTransport 16028	Configuration	Information	A forced configuration update for %1 has successfully completed. Object details from last notification based reload: %2. New details: %3.
MSExchangeTransport 17008	Storage	Information	The Microsoft Exchange Transport service has started the background scan of the queue database. All messages that have not yet been delivered will be loaded.
MSExchangeTransport 17009	Storage	Information	The background scan of the transport

			queue database has been stopped. %1 message(s) found so far. There may be other messages left in the database that have not yet been loaded.
MSExchangeTransport 17010	Storage	Information	The background scan of the transport queue database has completed. %1 message(s) were found.
MSExchangeTransport 17012	Storage	Error	%1: The database could not allocate memory. Please close some applications to make sure you have enough memory for Exchange Server. The exception is %2.
MSExchangeTransport 17013	Storage	Error	%1: The database could not be opened because there is another process using it. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17014	Storage	Error	%1: The database could not be opened because there is no such database found. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17015	Storage	Error	%1: The database could not be opened because it does not belong with the current set of log files. The Microsoft Exchange Transport service is shutting down. The exception is %2.
MSExchangeTransport 17016	Storage	Error	%1: An operation has encountered a fatal error. The database may be fragmented

			and manual offline defragmentation using ESEUTIL may be required. The Microsoft Exchange Transport service is shutting down. Exception details: %2
MSExchangeTransport 17017	Storage	Error	%1: Quota was exceeded while performing a database operation. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17018	Storage	Error	%1: There are insufficient resources to perform a database operation. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17019	Storage	Error	%1: A database operation has encountered an I/O error. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17020	Storage	Error	%1: A database operation has encountered a fatal error. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17021	Storage	Error	%1: Exchange couldn't open the database because it can't find a table. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17022	Storage	Error	%1: Exchange couldn't open the database because it

			can't find a file. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17023	Storage	Error	%1: The database could not be started because a critical database file has the read-only attribute set. The Microsoft Exchange Transport service is shutting down. Exception details: %2.
MSExchangeTransport 17103	Storage	Error	%1: MSExchangeTransport has detected a critical storage error and has taken an automated recovery action. %2.
MSExchangeTransport 17106	Storage	Information	%1: MSExchangeTransport has detected a critical storage error, updated the registry key (%2) and as a result, will attempt self-healing after process restart.
MSExchangeTransport 12022	TransportService	Information	The internal transport certificate that is used for SMTP authentication by Microsoft Exchange could not be read from Active Directory. The certificate may be corrupted. If an existing certificate that matches the fully qualified domain name (FQDN) of the server is already installed, run the Enable-ExchangeCertificate cmdlet to publish this certificate to Active Directory. If a certificate for the FQDN of the server is not installed, create an internal transport certificate by running

			the New-ExchangeCertificate cmdlet for the FQDN of the server.

1.7.6.10 TransportLogSearch Errors and Events

TransportLogSearch Errors and Events

Exchange Server 2010 > Transport > Error and Event Reference for Transport Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates TransportLogSearch events in Event Viewer so that you can troubleshoot and verify the TransportLogSearch features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

TransportLogSearch Errors and Events

The following table provides a list of TransportLogSearch errors and events.

Event ID	Category	Event type	Value or description
MSExchangeTransportLogSearch 7004	General	Error	The Microsoft Exchange Transport Log Search service could not be stopped.
MSExchangeTransportLogSearch 7005	General	Error	Microsoft Exchange couldn't read the configuration from the Active Directory directory service because of error: %1.
MSExchangeTransportLogSearch 7009	General	Warning	The Microsoft Exchange Transport Log Search service failed to access %1 because of insufficient access permissions. The exception message is: %2.
MSExchangeTransportLogSearch 7010	General	Error	The Microsoft Exchange Transport Log Search Service

			failed to access %1 due to I/O error. The exception message is: %2.
MSExchangeTransportLogSearch 7012	General	Error	The following message tracking log file is corrupted: '%1'. The corrupted record won't be included in the search results.
MSExchangeTransportLogSearch 7011	General	Error	The Microsoft Exchange Transport Log Search service failed because the parameter that sets the location of the message tracking logs was set to an invalid value.
MSExchangeTransportLogSearch 7013	General	Error	The Microsoft Exchange Transport Log Search service failed to start because of an Log Session Manager startup error.
MSExchangeTransportLogSearch 7014	General	Error	The Microsoft Exchange Transport Log Search service failed to start because of a message tracking log error.
MSExchangeTransportLogSearch 7015	General	Error	The Microsoft Exchange Transport Log Search service started but it is not functional because of an RPC server startup error.
MSExchangeTransportLogSearch 7016	General	Error	The Microsoft Exchange Transport Log Search service failed to create message tracking log directory: %1 because of error: %2.
MSExchangeTransportLogSearch 7032	General	Error	The Microsoft Exchange Transport Log Search service was unable to access registry. The following error was

			encountered: %1.
MSExchangeTransportLogSearch 7003	General	Information	The Microsoft Exchange Transport Log Search service has finished indexing all log files. The time taken to complete the indexing was: %1 seconds.
MSExchangeTransportLogSearch 7001	General	Information	The Microsoft Exchange Transport Log Search service has started successfully.

1.8 Mailbox

Mailbox

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-25*

The Mailbox server role hosts mailbox and public folder databases. It also generates the offline address book (OAB). Mailbox servers provide services that calculate e-mail address policies and address lists for recipients and enforce managed folders.

The following topics are gateways to information about Mailbox servers in Exchange 2010.

1.8.1 Understanding Mailbox

Understanding Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-17*

Microsoft Exchange Server 2010 Mailbox servers host mailbox databases and provide e-mail storage and advanced scheduling services for Microsoft Outlook and Microsoft Office Outlook Web App users. In addition, Mailbox servers can also host a public folder database, which provides a foundation for workflow, document sharing, and other forms of collaboration.

The following topics provide detailed information about the Mailbox features in Exchange 2010:

Overview of the Mailbox Server Role

Understanding Address Lists

Understanding Calendar Repair

Understanding E-Mail Address Policies

Understanding the Exchange 2010 Store

Understanding Exchange Search

Understanding Hierarchical Address Books

Understanding Mailbox Import and Export Requests

Understanding Move Requests

Understanding Offline Address Books

Understanding Public Folders

Understanding Quota Messages

Understanding Recipients

Understanding Recoverable Items

1.8.1.1 Overview of the Mailbox Server Role

Overview of the Mailbox Server Role

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-09*

In Microsoft Exchange Server 2010, the Mailbox server role is one of several server roles

that you can install and configure on a server running Windows Server 2008. The Mailbox server role is the most common server role and is at the core of an Exchange organization. Servers on which the Mailbox server role is installed are called *Mailbox servers*.

Mailbox servers perform the following functions:

- Host mailbox databases
- Provide e-mail storage
- Host public folder databases
- Calculate e-mail address policies
- Generate address lists and offline address books (OABs)
- Conduct Multi-Mailbox Searches
- Provide high availability and site resiliency
- Provide content indexing
- Provide messaging records management (MRM) and retention policies

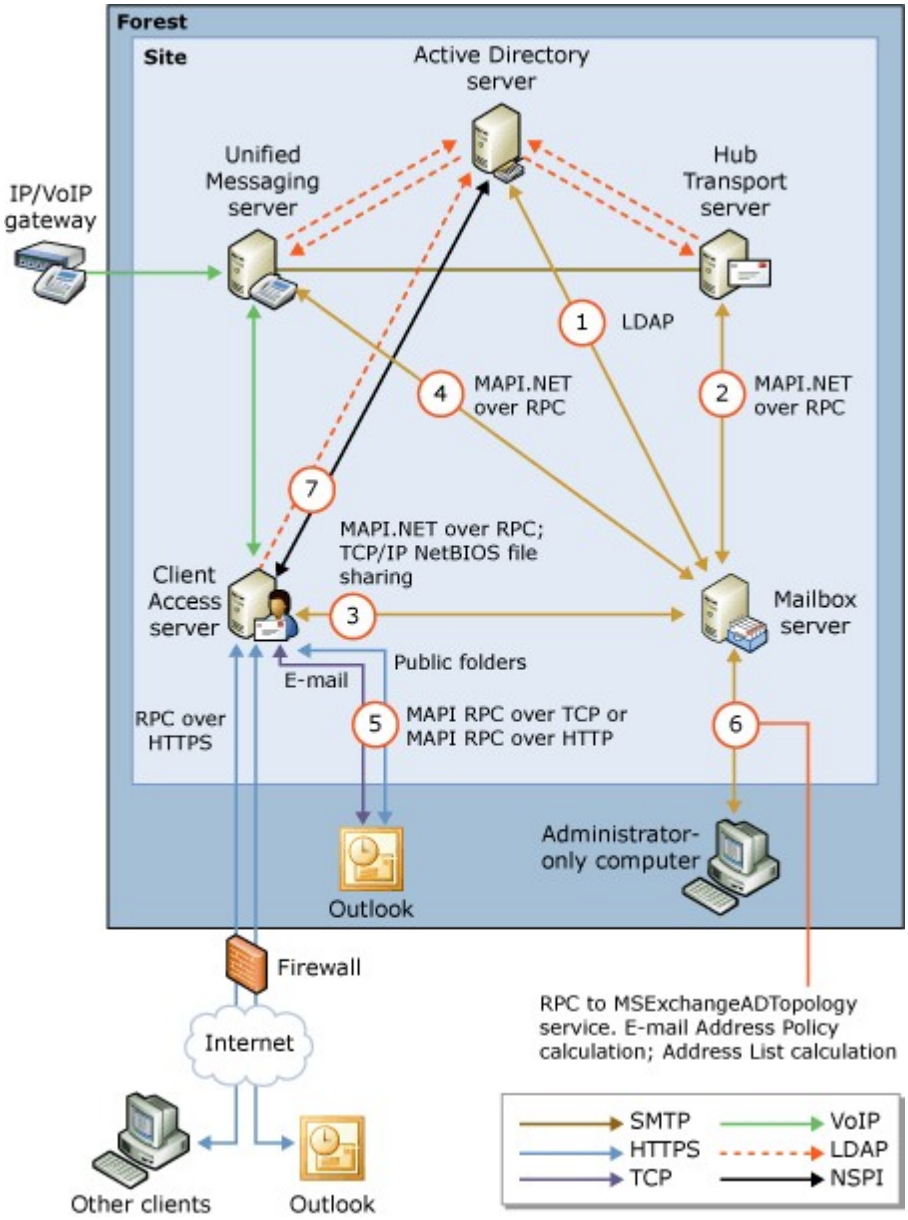
Looking for management tasks related to Mailbox servers? See Managing Mailbox Servers.

Contents

Mailbox Server Interactions

The Mailbox server must interact directly with the following:

- Active Directory
- Client Access server
- Hub Transport server
- Unified Messaging server
- Microsoft Outlook clients



The following process applies:

1. The Mailbox server uses LDAP to access recipient, server, and organization configuration information from Active Directory.
2. The store driver on the Hub Transport server places messages from the transport pipeline into the appropriate mailbox. The store driver on the Hub Transport server also adds messages from a sender's Outbox on the Mailbox server to the transport pipeline. To learn more about the store driver, see Understanding Moderated Transport.
3. The Client Access server sends requests from clients to the Mailbox server, and returns data from the Mailbox server to the clients. The Client Access server also accesses OAB files on the Mailbox server through NetBIOS file sharing. The types of data that the Client Access server sends between the client and the Mailbox server include messages, free/busy data, client profile settings, and OAB data.
4. The Unified Messaging server retrieves e-mail, voice mail messages, and calendar information from the Mailbox server for Outlook Voice Access. The

Unified Messaging server also retrieves storage quota information from the Mailbox server. To learn more about Outlook Voice Access, see Understanding Outlook Voice Access.

5. Outlook clients inside your firewall access the Client Access server to send and retrieve messages. Outlook clients outside the firewall can access the Client Access server by using Outlook Anywhere (which uses RPC over HTTP). However, Outlook clients that are viewing or modifying public folders access the Client Access server by using RPC over TCP. To learn more about Outlook Anywhere, see Understanding Outlook Anywhere.
6. The administrator-only computer retrieves Active Directory topology information from the Microsoft Exchange Active Directory Topology service. It also retrieves e-mail address policy information and address list information.
7. The Client Access server uses LDAP or Name Service Provider Interface (NSPI) to contact the Active Directory server and retrieve users' Active Directory information.

Return to top

Coexisting with Other Server Roles

The Client Access server role, Hub Transport server role, Mailbox server role, and Unified Messaging server role can coexist on the same computer in any combination. When considering what combination of server roles to deploy, you should base your decision on capacity and performance planning and on your security and availability requirements. For more information, see Mailbox Server Storage Design.

Return to top

Server Role Configuration

To configure the Mailbox server role, use the Set-MailboxServer cmdlet in the Exchange Management Shell. To retrieve Mailbox server role settings, use the Get-MailboxServer cmdlet. For more information, see Configure Mailbox Server Properties.

Return to top

Services and Port Executables

When you install the Exchange 2010 Mailbox server role on a computer running Windows Server 2008, the services and port executables shown in the following table are installed. The Microsoft Search (Exchange Server) and Microsoft Exchange Monitoring services are set to start manually. All other services are set to start automatically.

Services

Service short name	Service name	Associated executable	Port name
MSExchangeIS	Microsoft Exchange Information Store	Store.exe	MSExchangeISPorts
MSExchangeADTopology	Microsoft Exchange Active Directory Topology	MSExchangeADTopologyService.exe	MSExchangeADTopologyPorts
MSExchangeMailboxAssistants	Microsoft Exchange Mailbox Assistants	MSExchangeMailboxAssistants.exe	MSExchangeMailboxAssistantsPorts

MSExchangeSearch	Microsoft Exchange Search Indexer	Microsoft.Exchange.Search.ExSearch.exe	MSExchangeSearchPorts
MSExchangeServiceHost	Microsoft Exchange Service Host	Microsoft.Exchange.ServiceHost.exe	MSExchangeServiceHostPorts
MSExchangeMonitoring	Microsoft Exchange Monitoring	Microsoft.Exchange.Monitoring.exe	MSExchangeMonitoringPorts
MSExchangeSA	Microsoft Exchange System Attendant	Mad.exe	MSExchangeSAPorts
MSExchangeMailSubmission	Microsoft Exchange Mail Submission	MSExchangeMailSubmission.exe	MSExchangeMailSubmissionPorts
msftesql-Exchange	Microsoft Search (Exchange Server)	Msftesql.exe	msftesql-ExchangePorts
MSExchangeTranport LogSearch	Microsoft Exchange Transport Log Search	MSExchangeTransportLogSearch.exe	MSExchangeTransportLogSearchPorts

Return to top

Planning for Public Folders

Before you deploy public folders, it's important to familiarize yourself with the functionality that public folders provide to make sure that the public folders meet the needs of your organization.

Exchange public folders are intended to serve as a repository for information that's shared among many users. You should use public folders when your business requires data replication to multiple servers. Access to public folders is integrated with regular mailbox access through the MAPI protocol. For more information about public folders, see Understanding Public Folders and Managing Public Folders.

Return to top

1.8.1.2 Understanding Address Lists

Understanding Address Lists

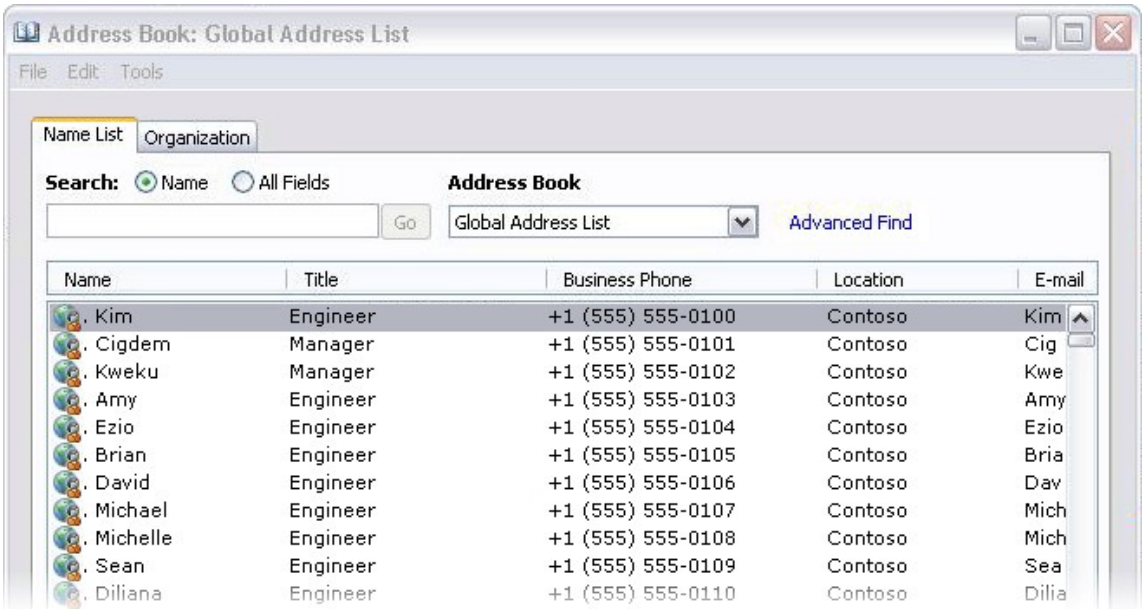
Exchange Server 2010 > Mailbox > Understanding Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-01*

An *address list* is a collection of recipient and other Active Directory objects. Each address list can contain one or more types of objects (for example, users, contacts, groups, public folders, conferencing, and other resources). You can use address lists to organize recipients and resources, making it easier to find the recipients and resources you want. Address lists are updated dynamically. Therefore, when new recipients are added to your organization, they're automatically added to the appropriate address lists.

As shown in the following figure, client applications, such as Microsoft Outlook, display the available address lists that Exchange provides.



Address lists reside in Active Directory. Therefore, mobile users who are disconnected from the network are also disconnected from these server-side address lists. However, you can create offline address books (OABs) for users who are disconnected from the network. These OABs can be downloaded to a user's hard disk. Frequently, to conserve resources, OABs are subsets of the information in the actual address lists that reside on your servers. For more information, see Understanding Offline Address Books.

Changes to Address Lists in Exchange 2010 SP2

Global address list (GAL) segmentation (also known as GAL segregation) is the process whereby you segment users into specific groups to provide customized views of your organization's GAL. In Exchange Server 2007 and earlier, segmenting the GAL was complicated, requiring you to use either a Query Base DN (which acted as a root for directory searches) or access control lists (ACLs) to allow or deny access to each address list.

To simplify the process, Exchange 2010 Service Pack 2 (SP2) introduces address book policies (ABPs). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs.

To learn more about ABPs, see Understanding Address Book Policies.

Default Address Lists

When users want to use their client application to find recipient information, they can select from available address lists. Several address lists, such as the global address list (GAL), are created by default. Exchange contains the following default address lists, which are then automatically populated with new users, contacts, groups, or rooms as they're added to your organization:

- **All Contacts** This address list contains all mail-enabled contacts in your organization. Mail-enabled contacts are those recipients who have an external e-mail address. If you want mail-enabled contact information to be available to all users in your organization, you must include the contact in the GAL. To learn more about mail contacts, see Understanding Recipients.
- **All Groups** This address list contains all mail-enabled groups in your organization. Mail-enabled groups are groups of recipients that are created to expedite the mass sending of e-mail messages and other information. When an e-mail message is sent to a mail-enabled group, all members of that list receive a copy of the message. To learn more about mail-enabled groups, see Understanding Recipients.
- **All Rooms** This address list contains all resources that have been designated as a room in your organization. Rooms are resources in your organization that can be scheduled by sending a meeting request from a client application. The user account that's associated with a room is disabled. For instructions about how to add resource mailboxes to an address list, see Add Resource Mailboxes to an Address List. To learn more about resource mailboxes, see Understanding Recipients.
- **All Users** This address list contains all mail-enabled users in your organization. A mail-enabled user represents a user outside your Exchange organization. Each mail-enabled user has an external e-mail address. All messages sent to mail-enabled users are routed to this external e-mail address. A mail-enabled user is similar to a mail contact, except that a mail-enabled user has Active Directory logon credentials and can access resources. To learn more about mail-enabled users, see Understanding Recipients.
- **Default Global Address List** This address list contains all mail-enabled users, contacts, groups, or rooms in the organization. During setup, Exchange creates various default address lists. The most familiar address list is the GAL. By default, the GAL contains all recipients in an Exchange organization. In other words, any mailbox-enabled or mail-enabled object in an Active Directory forest that has Exchange installed is listed in the GAL. For ease of use, the GAL is organized by name, not by e-mail address. For more information, see Managing Address Lists.
- **Public Folders** This address list contains all public folders in your organization. Access permissions determine who can view and use the folders. Public folders are stored on computers running Exchange. For more information about public folders, see Managing Public Folders.

Custom Address Lists

An Exchange organization can contain thousands of recipients. If you compile all your recipients in the default address lists, those lists could become quite large. To prevent this, you can create custom address lists to help users in your organization find what they are looking for more easily.

For example, consider a company that has two large divisions and one Exchange organization. One division, named Fourth Coffee, imports and sells coffee beans. The other division, Contoso, Ltd, underwrites insurance policies. For most day-to-day

activities, the employees at Fourth Coffee don't communicate with the employees at Contoso, Ltd. Therefore, to make it easier for employees to find recipients who exist only in their division, you can create two new custom address lists—one for Fourth Coffee and one for Contoso, Ltd. When searching for recipients in their division, these custom address lists allow employees to select only the address list that's specific to their division. However, if an employee is unsure about the division in which the recipient exists, the employee can search within the GAL, which contains all recipients in both divisions.

You can also create subcategories of address lists called hierarchical address lists. For example, you can create an address list that contains all recipients in Manchester and another that contains all recipients in Stuttgart.

Best Practices for Creating Address Lists

Although address lists are useful tools for users, poorly planned address lists can cause frustration. To make sure that your address lists are practical for users, consider the following best practices:

- Avoid creating so many address lists that users won't be sure which list to search for recipients.
- Name your address lists in such a way that, when users glance at them, they will know immediately which recipient types are contained in the list. If you have difficulty naming your address lists, create fewer lists and remind users that they can find anyone in your organization by using the GAL.

For detailed instructions about creating an address list, see Create an Address List.

1.8.1.3 Understanding Address Book Policies

Understanding Address Book Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-28*

Global address list (GAL) segmentation (also known as GAL segregation) is the process whereby administrators can segment users into specific groups to provide customized views of their organization's GAL. In Microsoft Exchange Server 2007 and earlier versions, segmenting the GAL was complicated and required that you use either a Query Base DN (which acted as a root for directory searches) or access control lists (ACLs) to allow or deny access to each address list. To learn more about how to configure GAL segmentation in Exchange 2007, see Configuring Virtual Organizations and Address List Segregation in Exchange 2007.

To simplify the process, Microsoft Exchange Server 2010 Service Pack 2 (SP2) introduces address book policies (ABPs). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs.

Note:

ABPs are intended to optimize the GAL for each group of users, not make it impossible for them to see each other or to resolve other users in your organization. ABPs create only a

virtual separation of users, not a legal separation.

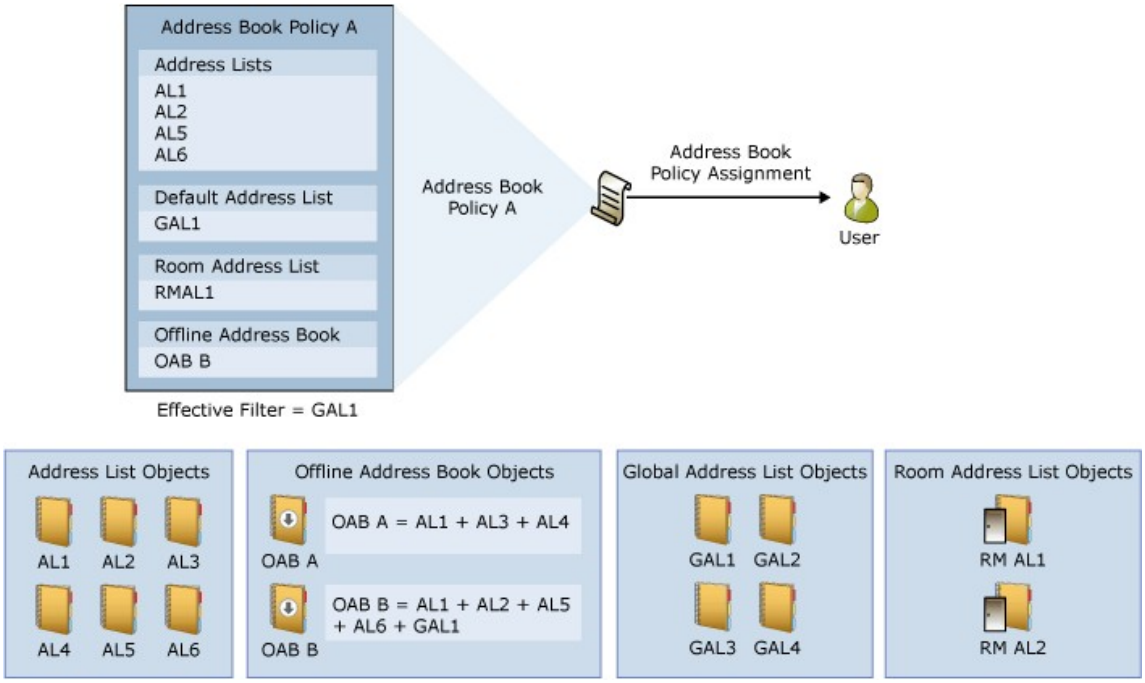
Important:
ABPs aren't available in Office 365. As a result, if you're in a hybrid deployment, the entire address book will be visible to your users with cloud-based mailboxes.

How ABPs Work

ABPs contain the following lists:

- One GAL
- One OAB
- One room list (for booking purposes)
- One or more address lists

In the following figure, Address Book Policy A consists of a subset of the various address objects that exist in the organization (shown in the bottom half of the figure). The resulting scope of an ABP is equal to that of the GAL contained in the policy, in this case GAL1. When the ABP is created and assigned to a user, the address objects in the ABP become the scope of the objects the user is able to view.



You can use the following methods to assign ABPs to individual mailbox users:

New or existing mailbox?	Shell	Exchange Management Console
New	**New-Mailbox** cmdlet with the *AddressBookPolicy* parameter	**Mailbox Settings** tab in the New Mailbox wizard
Existing	**Set-Mailbox** cmdlet with the *AddressBookPolicy* parameter	**Mailbox Settings** tab in the mailbox's property page

ABPs take effect when a user's client application connects to the Microsoft Exchange Address Book service on the Client Access server. If you change the ABP, the updated ABP doesn't take effect until the user restarts Outlook Outlook Web Access, or until you

restart the Microsoft Exchange Address Book service. To learn more, see Understanding the Address Book Service.

Entourage, Outlook for Mac, and ABPs

ABPs won't function for Entourage users or Outlook for Mac users who are connected to their corporate network. When inside the corporate network, Entourage and Outlook for Mac clients connect directly to the global catalog server and query Active Directory directly instead of using the Microsoft Exchange Address Book service. However, Outlook for Mac 2011 clients that connect from the Internet can use an OAB or Exchange Web Services (EWS). As a result, these clients can view the GAL based on the assigned ABP. To learn more about administering Outlook for Mac 2011, see Planning for Outlook for Mac 2011

Deploying ABPs

This section provides information about deploying ABPs in your organization, including best practices, scenarios, and general steps. To review all ABP management tasks, see Managing Address Book Policies.

Considerations and Best Practices

Consider the following when setting up ABPs in your organization:

- For ABPs to work correctly, the user mailbox to which you apply the ABP must be on a Microsoft Exchange Server 2010 SP2 server.
- Don't run the Client Access server role on the global catalog server. Doing so results in Active Directory being used for Name Service Provider Interface (NSPI) instead of the Microsoft Exchange Address Book service.
- You can't use hierarchical address books (HABs) and ABPs at the same time. To learn more about HABs, see Understanding Hierarchical Address Books.
- Any user assigned an ABP should exist in their own GAL.
- If you allow client applications to access Active Directory directly through LDAP, they will bypass the logic built into ABPs. Because Outlook 2011 and Entourage 2008 use direct LDAP queries to access, Active Directory those client applications won't function properly with ABPs if a domain controller or global catalog server is specified or provided to them by the Autodiscover service. Outlook 2011 can use EWS or a local OAB to access directory information. However, if Outlook 2011 can directly access an LDAP service, it will try to do so.
- The GAL used in an ABP must, at a minimum, contain all of the address lists, including the room address list, defined and specified in an ABP. Don't create a GAL that contains fewer objects than any of the address lists in the same ABP.
- We recommend creating distribution groups that don't cross virtual organization boundaries. Creating distribution groups that contain members of multiple virtual organizations results in the following issues:
  - If group members request delivery or read receipts when sending mail to the distribution group, they'll be able to see the e-mail addresses of the group members in other virtual organizations
  - If an encrypted message is sent to the distribution group and some group members don't have valid digital IDs, the sender will receive a warning message that includes the total number of members who don't have valid IDs and a list of their e-mail addresses. However, if some of those members without valid digital IDs are in a different organization than the sender, the warning message will include the correct count but won't include the e-mail addresses of the members in the other organization. As a result, the total count won't match the list of member addresses.

    For example, let's say a distribution group contains five members total from two organizations, Agency A and Agency B. Three group members are from Agency A, and one of those members

has as invalid digital ID. The other two members are from Agency B, and both of them have invalid digital IDs. If a member from Agency A sends an encrypted message to the distribution group, that member will receive a warning message stating that there are a total of three recipients without valid digital IDs. However, only the e-mail address for the recipient from Agency A will be listed in the warning message.

- ABP's don't apply to the Get-Group cmdlets. Therefore, any user or process that is able to run **Get-Group** will see all members of any group they have access to.

  We recommend that you modify the group management settings of the Exchange Control Panel (ECP) so users can't use ECP to manage groups. To prevent users from using ECP to manage groups, exclude the users from the MyDistributionGroupMembership RBAC role. For details see MyDistributionGroupMembership Role and Turn Off User's Ability to Create Distribution Groups.

- If you allow users to use Outlook or Outlook Web App to manage groups, the group owners must have full visibility to the group membership list.

- All ABPs must contain a room address list. However, if your organization doesn't use room address lists, you can create a default empty room address list.
- Deploying ABPs doesn't prevent users in one virtual organization from sending e-mail to users in another virtual organization. If you want to prevent users from sending e-mail across organizations, we recommend that you create a transport rule. For example, to create a transport rule that prevents Contoso users from receiving messages from Fabrikam users, but still allows Fabrikam's senior leadership team to send messages to Contoso users, run the following Shell command:

```
New-TransportRule -Name "StopFabrikamtoContosoMail" -FromMemberOf "AllF
```

  To learn more, see Create a Transport Rule.
- If you want to enforce the ABP in the Lync client, you can set the `msRTCSIP-GroupingID` attribute on specific user objects. For details, see PartitionByOU Replaced with msRTCSIP-GroupingID topic.

Deployment Scenarios

The following three scenarios describe possible deployment solutions for three different organization types. Although there are many more scenarios, the most common ones are covered here. The address lists and GALs in these scenarios were created based on filters, such as Custom Attributes, that grouped the objects logically.

Scenario 1: Two Separate Companies - One Exchange Organization

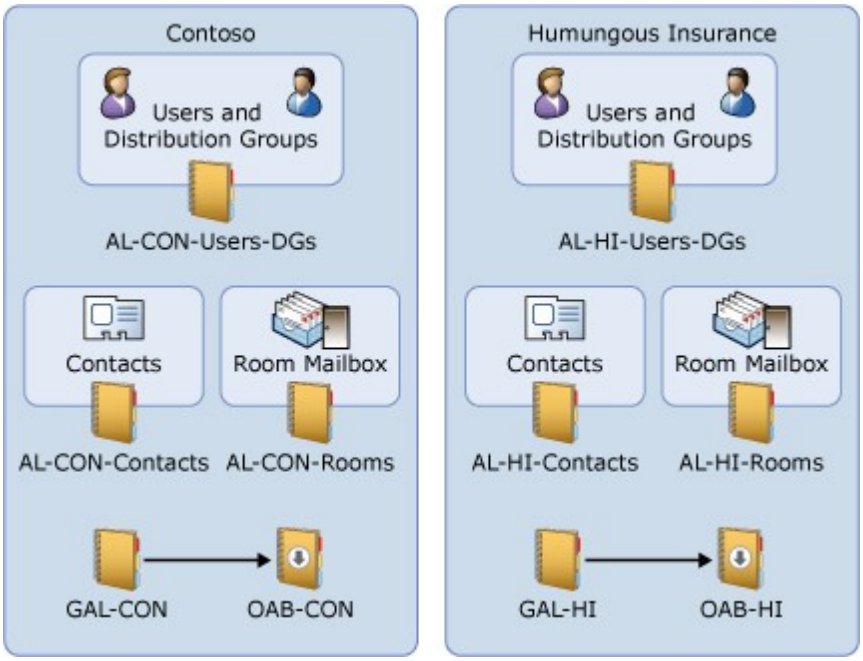
This scenario is applicable to companies that have separate agencies, divisions, or departments that are:

- Within the same Exchange organization.
- Don't share employees.
- Don't share a common reporting chain.

In addition, the agencies, divisions, or departments don't have any special security or privacy concerns.

In this scenario, two ABPs are created with the following settings:

- Employees who view the GAL or distribution group membership can see only recipients within their company.
- There are no distribution groups that span across both companies.



The following table lists the address lists, GALs, room lists, and OABs that are included in the ABPs for Contoso and Humongous Insurance. The ABP components were created by using the *CustomAttribute15* parameter to group the objects. Because the two companies are separate without any interaction between them, they don't share any address lists.

ABP component	Contoso	Humongous Insurance
Address lists	AL_CON_Groups AL_CON_Users_DGs AL_CON_Contacts	AL_HI_Groups AL_HI_Users_DGs AL_HI_Contacts
GAL	GAL_CON	GAL_HI
Room list	AL_CON_Rooms	AL_HI_Rooms
OAB	OAB_CON	OAB_HI

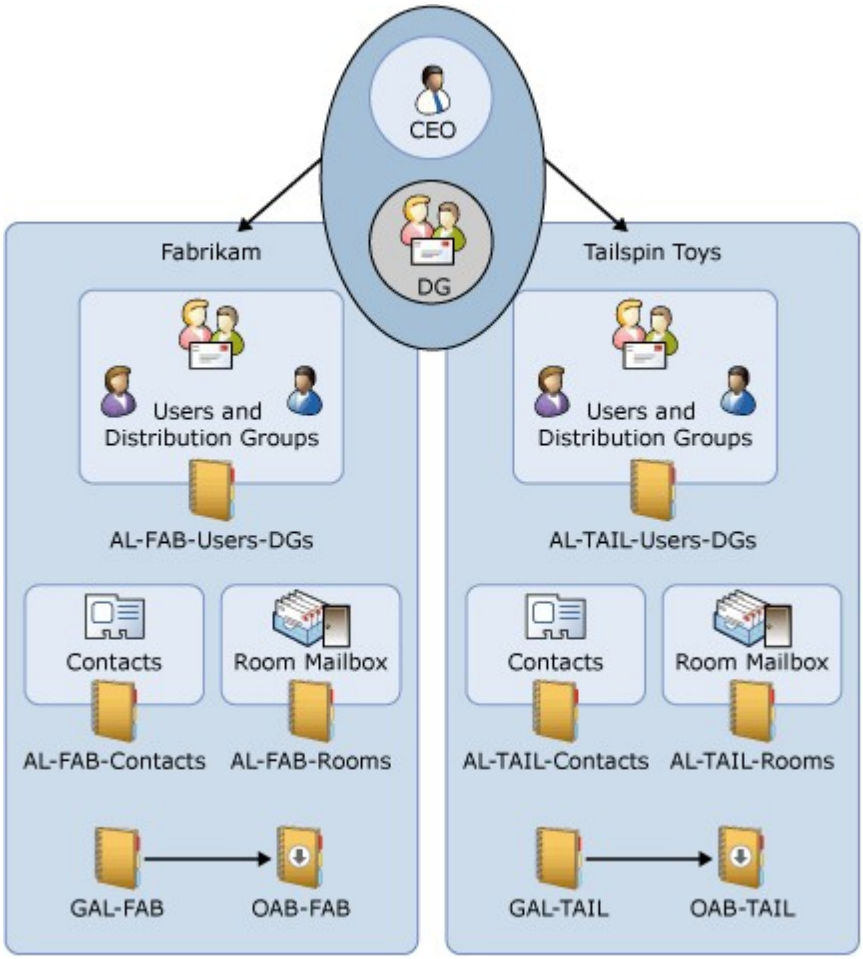
Scenario 2: Two Companies Sharing a CEO

This scenario is applicable to companies that are:

- Within the same Exchange organization.
- Share the same CEO.
- Don't share employees.

In this scenario, three ABPs are created with the following settings:

- Employees who view the GAL or distribution group membership can see only recipients within their company.
- In each company, there is a distribution group named SeniorLeaders, which includes the senior leaders of that company and the shared CEO.
- Employees who view the CEO's group membership can see only groups within their company.
- Three ABPs are created: Fabrikam, Tailspin Toys, and CEO.



ABP component	Fabrikam	Tailspin Toys	CEO
Address lists	AL_FAB_Users_DGs AL_FAB_Contacts	AL_TAIL_Users_DGs AL_TAIL_Contacts	AL_FAB_Users_DGs AL_FAB_Contacts AL_TAIL_Users_DGs AL_TAIL_Contacts
GAL	GAL_FAB	GAL_TAIL	Default GAL
Room list	AL_FAB_Rooms	AL_TAIL_Rooms	Default All Rooms
OAB	OAB_FAB	OAB_TAIL	Default OAB

When the CEO is added to the distribution groups in each company and falls within the scope of each company's ABP, the CEO becomes visible to each company. The CEO is visible in both the Fabrikam and Tailspin Toys GALs and can create distribution groups that span both companies. However members of the distribution group can view only members that are within their own company.

Scenario 3: Education

This scenario is applicable to schools or universities where a division of classrooms is necessary to ensure the privacy of the students.

In this scenario, ABPs are created with the following settings:

- Students can view only other students in their classroom, their teacher, and the principal.
- Teachers can view only students in their classroom, all teachers, and the principal.
- Distribution groups are created for each classroom's parents and the faculty.

	Students_ClassA	Teachers_ClassA	Principal
Address Lists	AL_ClassA AL_Principal	AL_ClassA AL_AllTeachers AL_AllGroups AL_Principal	AL_ClassA AL_ClassB AL_AllTeachers AL_AllStudents AL_AllGroups
Global address list	GAL_StudentsClassA	GAL_TeachersClassA	GAL_Everyone
Room address list	AL_BlankRoom	AL_BlankRoom	Default All Rooms
Offline address book	OAB_StudentsClassA	OAB_TeachersClassA	Default OAB

General Deployment Steps

This section provides the general steps for deploying ABPs in your organization, including how to migrate from Exchange 2007 address list segmentation.

Migrating from Address List Segmentation to ABPs

If you're currently using Exchange 2007 address list segmentation (per the instructions in the white paper Configuring Virtual Organizations and Address List Segregation in Exchange 2007) and you want to migrate to ABPs, follow the steps outlined in Migrate to Exchange 2010 Address Book Policies from Exchange 2007 Address List Segregation. This procedure requires some downtime for your organization so be sure plan accordingly.

New Deployment of ABPs

If you aren't using Exchange 2007 address list segmentation, follow the steps listed in this section to deploy ABPs in your organization.

The following steps apply to Scenario 2: Two Companies Sharing a CEO. In this scenario, Fabrikam and Tailspin Toys are separate companies that share a CEO and senior leadership team. This scenario requires three ABPs:

- ABP_FAB
- ABP_TAIL

- ABP_CEO

Step 1: Divide your virtual organizations
You'll need to develop a way to divide your organization into virtual organizations. When making this division, we recommend using the Custom Attribute properties on the mailboxes, contacts, and groups instead of the precanned conditional attributes (such as **Company**, **Department**, or **State/Province**). Using Custom Attributes instead of precanned attributes includes the following benefits:

- Not all recipient types have precanned conditional attributes in Active Directory. For example, the Active Directory objects **Distribution Group** and **Dynamic Distribution Group** don't support the **Company**, **Department**, or **State/Province** attributes.
- Not all precanned conditional attributes are exposed in cmdlets for some recipients. For example, the *Company*, *Department*, and *StateOrProvince* parameters aren't available in the cmdlets for mail users, contacts, distribution groups, and mail-enabled public folders.
- Multiple cmdlets are required to segment recipients when you use precanned conditional attributes. For example, to set the *Company*, *Department*, or *StateOrProvince* parameters for a user mailbox, you must run the **Set-User** cmdlet after you run the **New-Mailbox** or **Set-Mailbox** cmdlets. However, the *CustomAttribute* parameters are exposed in the **Set-*** cmdlets for each recipient type, so there's no need to also run the **Set-User** cmdlet.
- Custom Attribute properties are explicitly reserved to customize an organization and are controlled entirely by organization administrators.

To learn more about custom attributes, see Understanding Custom Attributes.

Another best practice to consider when dividing your organization is to use company identifiers in the names of distribution groups and dynamic distribution groups. One method for doing this is to use group naming policies. These policies allow you to specify that a prefix, a suffix, or both be applied to distribution group names. This is helpful when dividing your organization because you can use these policies to specify a suffix or prefix based on user attributes such as the creator of the distribution group's **Company**, **State/Province**, **Department**, and Custom Attribute properties. This is especially important if you allow users to create their own distribution groups. For more information, see Create a Distribution Group Naming Policy.

Note:
Because group naming policies don't apply to dynamic distribution groups, you must manually apply a naming policy.

Step 2: Create the address lists, room list, GALs, and OABs
When you create the address lists and GALs, don't use the *IncludedRecipient* and *ConditionalX* parameters, such as *ConditionalCompany* and *ConditionalCustomAttribute5*. Instead, we recommend that you use recipient filters. To learn more about recipient filters, see Creating Filters in Recipient Commands.

Note:
All procedure in this section use Shell commands because you can't use the EMC to create recipient filters.

Create the address lists

When you create the ABP, you include multiple address lists based on how you want your users to view the lists in Outlook or Outlook Web App. This scenario requires four address lists:

- AL_FAB_Users_DGs
- AL_FAB_Contacts
- AL_TAIL_Users_DGs
- AL_TAIL_Contacts

This example creates the address list AL_TAIL_Users_DGs. The address list contains all users and distribution groups where *CustomAttribute15* equals `TAIL`.

```
New-AddressList -Name "AL_TAIL_Users_DGs" -RecipientFilter {((RecipientType -eq '
```

The above command would then be run to create the remaining address lists: AL_FAB_Users_DGs, AL_FAB_Contacts, and AL_TAIL_Contacts.

For detailed syntax and parameter information, see New-AddressList.

To learn more about creating address lists by using recipient filters, see Create an Address List By Using Recipient Filters.

Create the room lists

This scenario requires three room lists:

- AL_FAB_Rooms
- AL_TAIL_Rooms
- Default All Rooms (created by default)

ABPs must contain a room list. If your organization doesn't have resource mailboxes (such as room or equipment mailboxes), we recommend that you create a blank room list. The following example creates the blank room list AL_BlankRoom.

```
New-AddressList -Name AL_BlankRoom -RecipientFilter ((Alias -ne $null) -and ((Rec
```

However, in this scenario, Fabrikam and Tailspin Toys both have room mailboxes. This example creates the room list for Tailspin Toys by using a recipient filter where *CustomAttribute15* equals `TAIL`.

```
New-AddressList -Name AL_TAIL_Rooms -RecipientFilter {(Alias -ne $null) -and (Cus
```

The above command would then be run to create the room list for Fabrikam (AL_FAB_Rooms).

For detailed syntax and parameter information, see New-AddressList.

Create the GALs

This scenario requires three GALs:

- GAL_FAB
- GAL_TAIL
- Default GAL (created by default)

The GAL used in an ABP must be a superset of the address lists. Don’t create a GAL with fewer objects than exists in any or all of the address lists in the ABP.

This example creates the GAL for Tailspin Toys. It includes all the recipients that exist in the address lists and room list.

```
New-GlobalAddressList -Name "GAL_TAIL" -RecipientFilter {(CustomAttribute15 -eq "
```

The above command would then be run to create the GAL for Fabrikam (GAL_FAB).

For detailed syntax and parameter information, see New-GlobalAddressList.

Create the OABs

This scenario requires three GALs:

- OAB_FAB

- OAB_TAIL
- Default OAB (created by default)

When using the **New-OfflineAddressBook** or **Set-OfflineAddressBook** to create the OAB, include the appropriate address lists or GAL in the *AddressLists* parameter to make sure no entry is unexpectedly missed. For example, if you want to customize the set of lists a user will see when viewing the OAB, or if you simply want to reduce the OAB's download size, you can use the *AddressLists* parameter to specify the address lists available to the OAB. However, if you want users to see the full set of GAL entries in OAB, make sure you include the GAL in the *AddressLists* parameter.

This example creates the OAB for Tailspin Toys. The entire GAL (GAL_TAIL) is included in the OAB..

```
New-OfflineAddressBook -Name "OAB_TAIL" -AddressLists "GAL_TAIL"
```

The above command would then be run to create the OAB for Fabrikam (OAB_FAB).

For detailed syntax and parameter information, see New-OfflineAddressBook.

Step 3: Create the ABPs
After all the required lists are created, you can create the ABPs.

This example creates the ABP for Tailspin Toys.

```
New-AddressBookPolicy -Name "ABP_TAIL" -AddressLists "AL_TAIL_Users_DGs","AL_TAIL
```

The above command would then be run to create the ABPs for Fabrikam (ABP_FAB) and the organization's CEO (ABP_CEO).

For detailed syntax and parameter information, see New-AddressBookPolicy.

Step 4: Assign the ABPs to mailboxes
Assigning the ABPs to users is the last step in the process. ABPs take effect when a user's application connects to the Microsoft Exchange Address Book service on the Client Access server. Users who are already connected to Outlook or Outlook Web App when the ABP is applied to their account will have to close and then restart the client application before they can see their new address lists and GAL.

This example assigns the address book policy ABP_TAIL to all mailboxes where *CustomAttribute15* equals TAIL.

```
Get-Mailbox -resultsize unlimited | where {$_.CustomAttribute15 -eq "TAIL"}| Set-
```

For more details, see Assign an Address Book Policy to a Mail User.

1.8.1.3.1 Migrate to Exchange 2010 Address Book Policies from Exchange 2007 Address List Segregation

Migrate to Exchange 2010 Address Book Policies from Exchange 2007 Address List Segregation

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The instructions in this topic will walk you through the steps required to migrate from Exchange 2007 ACL-based global address list (GAL) segmentation (also known as GAL

segregation) to Exchange 2010 Service Pack 2 (SP2) address book policies (ABPs).

Important:
Several procedures in this topic will impact users. As a result, scheduled downtime is often required.

Prerequisites

- Although not a specific prerequisite, it's highly recommended that you review the considerations and best practices in Understanding Address Book Policies before performing the procedures in this topic.
- The procedures in this topic assume that you followed the steps in the white paper Configuring Virtual Organizations and Address List Segregation in Exchange 2007 to configure your Exchange 2007 organization.
- If you followed the steps in the white paper listed above to implement GAL segmentation in your Exchange 2010 organization, you are officially in an unsupported state. To successfully perform the procedures in this topic, you must first return your organization to a supported state.
- Most of the code and Shell examples in this document use **Contoso** as the Active Directory domain name and the Exchange organization name, and **Fabrikam**, and **Tailspin Toys** as the sub-organization names. Be sure to change the name of the Exchange organization, domain, and sub-organizations to match your configuration.
- You will need the scripts that you used to segment the virtual organizations in Exchange 2007.

Setting Up the Scenario

In this scenario, Tailspin Toys and Fabrikam are subsidiaries of the parent company Contoso.

Step1: Prepare to install Exchange 2010 SP2 in an existing Exchange 2007 organization that has configured GAL segmentation (downtime required)

If your organization is using Exchange 2007 GAL segmentation, installing Exchange 2010 will fail because using GAL segmentation required you to remove all the default settings and permissions from the default GAL.

1. On a domain controller in the Exchange 2007 organization, run the following command at the command prompt to allow access to the default GAL.

```
DSACLS "CN=Default Global Address List,CN=All Global Address Lists,CN=
```

2. On a domain controller that has Windows PowerShell installed or on an Exchange server using the Exchange Management Shell, run the following commands to reconfigure the default settings on the GAL.

Note:
After you complete this step, Outlook 2007 users will be able to see the default GAL. However, Outlook Web App users won't be able to see the default GAL because Outlook Web App uses the `QueryBaseDN` attribute to query the GAL.

```
$container = "CN=Default Global Address List,CN=All Global Address Lis
```

You will receive the following warning and output:

```
WARNING: Appropriate ACE is already present on object "CN=Default Glob
Identity             User                 Deny  Inherited Rights
--------             ----                 ----  --------- ------
\Default Global A... NT AUTHORITY\Auth... False False     Open-Address
\Default Global A... NT AUTHORITY\Auth... False False     ReadProperty
\Default Global A... NT AUTHORITY\Auth... False False     ListObject,
\Default Global A... NT AUTHORITY\Auth... False False     ListChildren
```

Step 2: Install the first Exchange 2010 server

For detailed instructions, see Upgrade from Exchange 2007 Client Access

Step 3: Secure the default GAL

After you install Exchange 2010 SP2, you can remove the address lists that are created during installation and then secure the default GAL again. After you complete this step, you can continue to install additional Exchange 2010 SP2 servers in your organization. For more information, see Understanding Upgrade from Exchange 2007 to Exchange 2010.

1. (Optional) On an Exchange 2010 server, use the Shell to remove the newly created address lists.

```
Remove-AddressList "All Contacts"
Remove-AddressList "All Groups"
Remove-AddressList "All Users"
Remove-AddressList "Public Folders"
```

   For more detail, see Remove an Address List.

2. On an Exchange 2010 server, use the Shell to secure the GAL based on the instructions in the white paper Configuring Virtual Organizations and Address List Segregation in Exchange 2007.

```
Get-GlobalAddressList "Default Global Address List" | Add-ADPermission
```

3. To verify that the commands were successful, run the following commands.

```
$galContainer = "CN=All Global Address Lists,CN=Address Lists Containe
Get-ADPermission $galContainer -user "authenticated users"
```

   The output of this command should resemble the following:

```
Identity             User                 Deny  Inherited Rights
--------             ----                 ----  --------- ------
All Global Addres... NT AUTHORITY\Auth... False False     GenericRead
All Global Addres... NT AUTHORITY\Auth... False False     Open-Address
All Global Addres... NT AUTHORITY\Auth... False True      ListChildren
All Global Addres... NT AUTHORITY\Auth... True  True      ReadProperty
```

Step 4: Switchover to Exchange 2010 servers (downtime required)

Before moving any mailboxes to Exchange 2010 SP2 servers, you must switchover external URL names. This requires configuring Outlook Anywhere, Outlook Web App, Exchange Web Services (EWS), Exchange Control Panel (ECP), AutoDiscover, and offline address books (OABs) to use Exchange 2010 servers instead of Exchange 2007 servers. There are many steps in this process, and you should refer to the information in Exchange 2007 - Planning Roadmap for Upgrade and Coexistence for more detail.

Note:

The following steps outline only the key procedures in the overall process and explain what each of them accomplishes. You may need to run some of these commands on each

server in your organization (some only once), and most will result in some period of downtime. Therefore, it's strongly recommended that you spend adequate time testing your entire switchover process to ensure minimal impact to your clients.

1. Use the Shell to move all OAB generation to an Exchange 2010 Mailbox server. Moving the OAB generation to Exchange 2010 SP2 servers allows OABs to use GALs and not just address lists as sources for the OAB content.

```
Get-OfflineAddressBook | Move-OfflineAddressBook -Server "MBX01_Ex2010
```

   For more detail, see Move the Offline Address Book Generation to Another Server.
2. Set the virtual directory for the OAB to include an Exchange 2010 virtual organization. This will distribute copies of the OABs to the Exchange 2010 servers.
   This example ensures both the Exchange 2007 and Exchange 2010 servers have copies of all OABs.

```
Get-OfflineAddressBook | Set-OfflineAddressBook -virtualdirectories "C
```

   For more detail, see Configure Offline Address Book Distribution Properties.
3. Before any mailboxes can be moved to Exchange 2010, you must route all incoming Outlook Anywhere traffic through Exchange 2010.
   This example enables Outlook Anywhere on an Exchange 2010 server and disables it on an Exchange 2007 server.

```
Enable-OutlookAnywhere -Server:CAS1_Ex2010SP2 -ExternalHostname:mail.c
Disable-OutlookAnywhere  -Server:CAS1_Ex2007
```

   For more detail, see the following topics:
   - Enable Outlook Anywhere
   - Disable Outlook Anywhere
4. To allow AutoDiscover to properly return URLs from Exchange 2010 servers, you must configure Outlook Web App, Exchange ActiveSync, EWS, and ECP on all Exchange 2010 servers to have valid external URL properties for the virtual directories.
   The following examples assume that mail.contoso.com is the external name used to access the Exchange 2010 servers.

```
Set-ActiveSyncVirtualDirectory -Identity 'CAS1_Ex2010SP2\Microsoft-Ser
Set-WebServicesVirtualDirectory  -Identity 'CAS1_Ex2010SP2\EWS*' -Exte
Set-OWAVirtualDirectory -Identity 'CAS1_Ex2010SP2\OWA*' -ExternalURL h
Set-EcpVirtualDirectory -Identity 'CAS1_Ex2010SP2\ECP*' -ExternalURL h
```

   For more detail about how to configure the above settings, see the following topics:
   - Configure Exchange ActiveSync Autodiscover Settings
   - Configure Exchange Services for the Autodiscover Service
   - View or Configure Outlook Web App Virtual Directories
   - Configure ECP Virtual Directory Properties
5. To allow Exchange 2010 to redirect Outlook Web App and EWS requests back to Exchange 2007 for those users with mailboxes on Exchange 2007 servers, you need to configure the Outlook Web App and EWS external URL for 2007 to use legacy.contoso.com. This namespace is the external name used to access the Exchange 2007 servers.

```
Set-WebServicesVirtualDirectory -Identity 'CAS1_Ex2007\EWS*' -External
Set-OWAVirtualDirectory -Identity 'CAS1_Ex2007\OWA*' -ExternalURL http
```

6. To allow Exchange 2010 to proxy all incoming Exchange ActiveSync connections to Exchange 2007, clear the 2007 external URL for Exchange ActiveSync.

```
Set-ActiveSyncVirtualDirectory -Identity 'CAS1_Ex2007\Microsoft-Server
```

7. The final step in the process is to change the public DNS so that mail.contoso.com (in the example we provided) and autodiscover.contoso.com resolve to Exchange 2010, and the legacy.contoso.com DNS record resolves to Exchange 2007. All client

connections will go through Exchange 2010, and then Exchange 2010 will either redirect (in the case of Outlook Web App), proxy (in the case of Exchange ActiveSync), or provide version-specific URLs (in the case of EWS) to clients via AutoDiscover.

Step 5: Create ABPs that mirror the Exchange 2007 address list segmentation ACLs

The next step is to figure out what address lists, GALs, and OABs the virtual organizations have access to using GAL segmentation, and then create an ABP for each virtual organization that mirrors them.

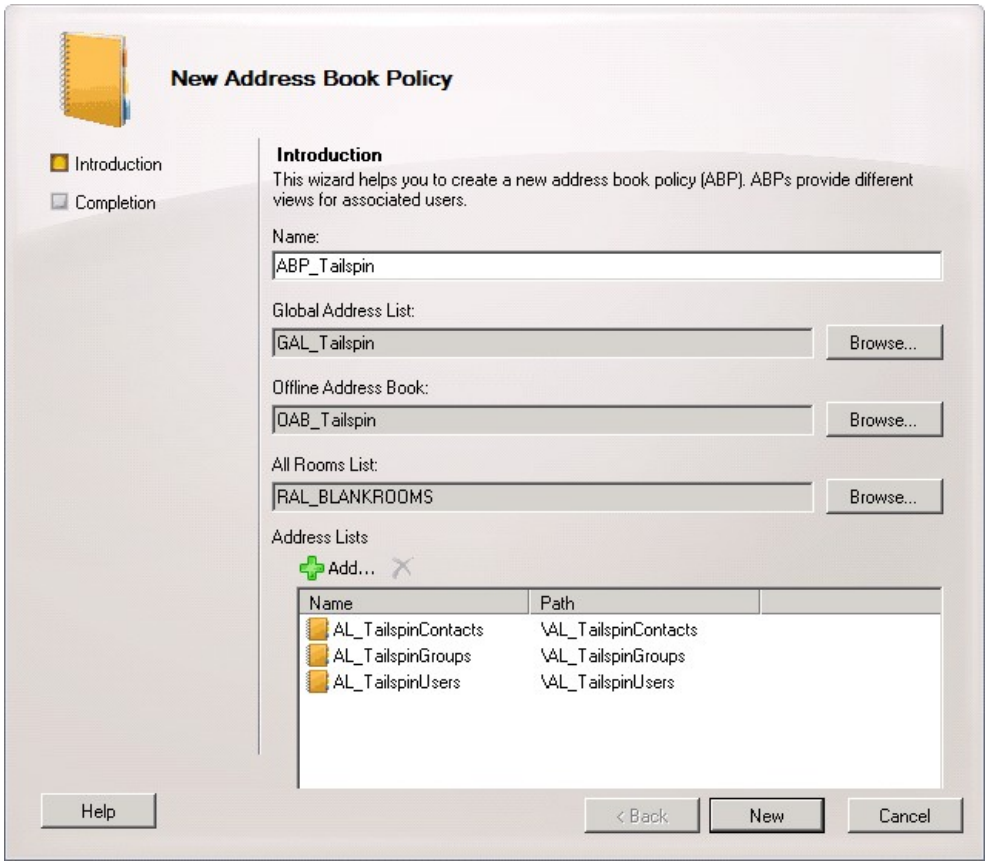
1. If you used the steps in Configuring Virtual Organizations and Address List Segregation in Exchange 2007 to set up your Exchange 2007 organization, you created scripts that segmented your virtual organizations. View those scripts that you used to create the virtual organizations in Exchange 2007 to determine the GAL, address lists, and OAB for each virtual organization. For each virtual organization, you should find one GAL, at least one address list, and one OAB.

   Note:
   ABPs must have a room list. If you don't use room lists in your organization, create a blank room address list and then use that address list when configuring the ABP or set the room list property in the ABP to use the same address list you specify for the GAL.

   For example, when viewing the script used to segment the child company Tailspin Toys, the following information is located:
   - Tailspin Toys users are all contained in a security group called Tailspin_SG.
   - The security group Tailspin_SG grants users read/open access to the following:

Address Lists	GAL	OAB
AL_TailspinUsers AL_TailspinGroups AL_TailspingContacts	GAL_Tailspin	OAB_Tailspin

   - Tailspin Toys doesn't have a room address list.
2. Create an ABP that matches the Tailspin Toys organization.
3. For example, if you use the Exchange Management Console to create the ABP in, input the following information in the New Address Book Policy wizard:



If you use the Shell to create the ABP, run the following command.

```
New-AddressBookPolicy -Name 'ABP_Tailspin' -GlobalAddressList '\GAL_Ta
```

For more detail, see Create an Address Book Policy.

4. Follow the above instructions for each of your virtual organizations. For example, Fabrikam.

Step 6: Move mailboxes from Exchange 2007 servers to Exchange 2010 servers (downtime required)

In moving mailboxes to the Exchange 2010 servers, you will be switching over from using the ACLs to using ABPs.

Note:

We recommend that you create a script that performs this procedure in one step.

1. Move the mailboxes using the **MoveRequest** cmdlets. For more information, see Create a Local Move Request.
2. Assign the ABP to moved mailboxes. For more information, see Assign an Address Book Policy to a Mailbox User (EPW).
3. Clear the QueryBaseDN from the user object. This can be done directly via the Adsiedit.msc console or by using a multi-step process from the Shell. This example shows how to clear the QueryBaseDN by using the Shell.

```
$user = ([ADSI]"LDAP://CN=Bob,CN=Users,DC=Contoso,DC=com").psbase
$user.Properties["msExchQueryBaseDN"].Value=$null
$user.CommitChanges()
```

4. Remove the OAB setting from the mailbox.
   This example removes the OAB from John's mailbox:

```
Set-Mailbox -Identity John -OfflineAddressBook $null
```

After the mailboxes are moved and all of the other settings have been configured, users using Outlook will get the following error and they will be required to close and restart Outlook: "The Microsoft Exchange Administrator has made a change that requires you to quit and restart Outlook."

Step 7: What's next?

So, after you've moved all of your mailboxes to Exchange 2010 SP2 and all of the mailboxes are running on ABPs with your ACLs decommissioned, you can start following the standard Exchange guidance for removing the Exchange 2007 organization.

Removing and Modifying Exchange 2007

How to Remove an Exchange 2007 Organization

If you get stuck, this Microsoft Knowledge Base article may help:

How to Remove Exchange 2007 from a computer

1.8.1.4 Understanding Calendar Repair

Understanding Calendar Repair

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-15*

The *Calendar Repair Assistant* is a configurable mailbox assistant that runs within the Microsoft Exchange Mailbox Assistants service on Microsoft Exchange Server 2010 Mailbox servers. The Calendar Repair Assistant detects and corrects inconsistencies with single and recurring meeting items for mailboxes located on that Mailbox server. As a result, recipients won't miss meeting announcements or have unreliable meeting information.

By default, the CRA is not set to run automatically. To configure the CRA to run and repair calendar inconsistencies, use the **set-mailboxserver** cmdlet in the Exchange Management Shell to set the work cycle and work cycle checkpoint. The Exchange Management Console cannot be used to configure calendar repair log settings.

Contents

Looking for management tasks related to calendars? See Managing Calendars.

Calendar Repair Assistant Tasks

The Calendar Repair Assistant performs the following functions:

1. **Detects inconsistencies** The Calendar Repair Assistant uses the organizer's copy of the calendar item as a master copy for all meeting items. The assistant compares the attendee's calendar item with the organizer's calendar item for inconsistencies. The only exception to this rule is when the assistant compares the attendee's and organizer's response status. The assistant assumes that the attendee's response status is the correct one, and, if necessary, updates the organizer's tracking information.
2. **Determines if inconsistencies were intentional** If an inconsistency is detected, the Calendar Repair Assistant determines whether the attendee intentionally introduced the inconsistency. For example, an attendee can introduce an inconsistency by deleting the meeting request and not notifying the organizer. If the assistant determines that the attendee didn't introduce the inconsistency, it corrects the problem. If the assistant can't determine if the inconsistency was intentional, it performs no further action.
3. **Corrects inconsistencies** The Calendar Repair Assistant corrects inconsistencies on the Mailbox server on which it runs. However, if the organizer's mailbox is on a different server than the attendee's mailbox, the assistant reads from other Exchange 2010 Mailbox servers to compare the calendar items. The assistant doesn't overwrite the recipient's calendar information. Instead, it merges the information so data isn't lost. In addition, the repair update messages are moved to the recipient's Deleted Items folder. For more information about the inconsistencies detected and repaired, see Conflict Detection and Resolution later in this topic.
4. **Sends a calendar repair update message if a correction was made** Calendar repair update messages are sent to users whose calendar items were updated by the Calendar Repair Assistant. Instead of sending the message to the user's Inbox, the assistant sends the message to the user's Deleted Items folder. By doing so, a record of the repair is kept in the mailbox without causing user confusion. If the user is experiencing calendar inconsistencies, you can advise the user to look in the Deleted Items folder for troubleshooting purposes. The assistant only sends repair update messages if the issue is fixed.

For more information about configuring the Calendar Repair Assistant, see Managing Calendars.

Return to top

Conflict Detection and Resolution

The Calendar Repair Assistant detects and corrects the conflicts described in the following table.

Calendar Repair Assistant conflict resolution

Conflict	Resolution
An attendee accepted the organizer's meeting request or recurring meeting request, but the meeting isn't on the attendee's calendar.	The assistant checks the attendee's record in the mailbox database and finds that the attendee deleted the calendar item without sending a response. If the assistant can't determine that the meeting item was intentionally deleted by the attendee, the assistant creates the meeting request again. If the assistant determines that the attendee intentionally deleted the meeting request,

	no further action is taken.
An attendee is missing an occurrence or exception within a recurring meeting series.	The assistant checks the organizer's copy for a deleted occurrence or exception and finds that the attendee deleted the meeting request without sending a response. If the assistant can't determine that the meeting item was intentionally deleted by the attendee, the assistant creates the meeting request again. If the assistant determines that the attendee intentionally deleted the occurrence or exception, no further action is taken.
An attendee's response status for the meeting doesn't match the status on the organizer's calendar item.	The assistant updates the organizer's tracking status with the status on the attendee's calendar item.
Attendees have the meeting on their calendars, but the organizer doesn't have those attendees listed in the attendee list.	The assistant adds the attendees to the organizer's list of attendees. **Note:** If the meeting request was sent to a distribution group with more than 200 members, the Calendar Repair Assistant won't add the attendees to the organizer's attendee list.
An attendee is listed on some of the organizer's recurring meetings, but the attendee's recurrence pattern doesn't match the organizer's recurrence pattern.	The assistant replaces the attendee's recurrence pattern with the organizer's recurrence pattern.
The location of an attendee's meeting doesn't match the location recorded in the organizer's calendar item.	If the attendee intentionally changed the meeting location, no action is taken. If the assistant can't determine that the location was intentionally changed by the attendee, the attendee's calendar item is appended with the meeting location on the organizer's calendar item.
An attendee's start or end time is different from that of the organizer's start or end time.	If the assistant determines that the attendee intentionally changed the time, no further action is taken. If the assistant determines that the conflict was unintentional, the start or end time is changed if either time differentiates more than two hours from the organizer's start or end time.
The organizer or attendee has multiple meetings that have the same MAPI property identifier: LIL_GLOBAL_OBJID.	The assistant compares all the duplicates and performs the following steps to correct the inconsistency: 1. Checks the sequence numbers of all the duplicates. The duplicate with the highest sequence number is kept. The other meeting items are deleted. 2. If the assistant can't determine which item to keep based on the sequence number, it checks the **OwnerCriticalChangeTime** property. If one of the duplicates is the most recent copy, it keeps that duplicate item. The other meeting items are deleted. 3. If the assistant can't determine which

	item to keep based on the most recent copy, it checks the **LastModifiedTime** property. If one of the duplicates has the last modified time, the assistant keeps that duplicate item. The other meeting items are deleted. 4. If the assistant can't determine which item to keep based on the last modified time, it keeps the first calendar item returned by the database when querying for duplicate meetings. The other meeting items are deleted.
An attendee has a single or recurring meeting on his or her calendar, but the organizer doesn't have this item on his or her calendar.	The assistant checks whether the organizer intentionally deleted the meeting. If the organizer intentionally deleted the meeting, the assistant sends a cancellation to the attendees. If the assistant determines that the organizer didn't intentionally delete the meeting, the meeting is added back to the organizer's calendar. If the assistant can't determine the organizer's intent, no action is performed.

Return to top

Calendar Repair Log

Every time the Calendar Repair Assistant changes a calendar item on a user's mailbox, it writes the change to a calendar repair log (.log) file. The output of this .log file doesn't reveal personal data, such as the body of the message or attachments. The file only contains the minimum information to identify the meeting that was repaired and what repair actions were taken. Each time the assistant runs, one calendar repair log file is created for every mailbox. By default, calendar repair logging is enabled.

The calendar repair log is configurable and can be turned on or off for a server or user. For more information, see Managing Calendars.

The default calendar repair log path is *<Exchange Installation Path>*\v14\Logging\Calendar Repair Assistant.

The log files are created with the following naming convention:

CRAYYYYMMDDHH-X.Alias.log

- *CRA* = Calendar Repair Assistant prefix
- *YYYY* = year
- *MM* = month
- *DD* = day
- *HH* = hour
- *X* = instance
- *Alias* = mailbox alias

For example, the following repair log file indicates that a repair was made on Tony's mailbox on April 18, 2010, at 15:00 (3:00 P.M.), and that the repair was the third one made within that hour:

CRA2010041815-3.tony.log

Return to top

Client Application Experience

The Calendar Repair Assistant can't access the same data for all client applications. As a result, users may get a different experience depending on which client application they use to review mail. Therefore, the assistant may not be able to determine if the action made by the user was intentional. As previously stated, the assistant corrects conflicts only if it can successfully determine that the attendee didn't intentionally introduce the conflict. If the assistant can't make this determination, no further action is taken.

The following table lists the different end-user calendaring tasks that could result in a calendar conflict. Based on which client application was used, the Calendar Repair Assistant can determine the user's intent.

Calendaring tasks

Scenario	Client application	Property recorded
Organizer opens the calendar item and modifies its properties.	• Microsoft Office Outlook Web App • Client applications that use Exchange Web Services • Mobile client applications that use Microsoft Exchange ActiveSync	**ModifiedStartTime** **ModifiedEndTime** **ModifiedLocation**
Organizer drags the meeting in his or her calendar view to a different time.	• Outlook Web App • Client applications that use Exchange Web Services **Note:** This scenario isn't supported for client applications that use Exchange ActiveSync.	**ModifiedStartTime** **ModifiedEndTime**
Attendee responds as either accepted or tentatively accepted with or without sending a response message to the organizer.	• Outlook Web App • Client applications that use Exchange Web Services • Mobile client applications that use Exchange ActiveSync	**RespondedAccepted** **RespondedTentative**
Attendee declines a meeting request with or without sending a response message to the organizer.	• Outlook Web App • Client applications that use Exchange Web Services • Mobile client applications that use Exchange ActiveSync	**DeletedWithNoResponse** **RespondedDeclined**
Attendee declines an instance of a recurring meeting request with or without sending a response message to the organizer.	• Outlook Web App • Client applications that use Exchange Web Services • Mobile client applications that use Exchange ActiveSync	**DeletedExceptionWithNoResponse** **RespondedExceptionDecline**
Organizer cancels a meeting.	• Outlook Web App • Client applications that use Exchange Web Services • Mobile client applications that use Exchange	**MeetingExceptionCanceled**

	ActiveSync

1.8.1.5 Understanding E-Mail Address Policies

Understanding E-Mail Address Policies

Exchange Server 2010 > Mailbox > Understanding Mailbox >

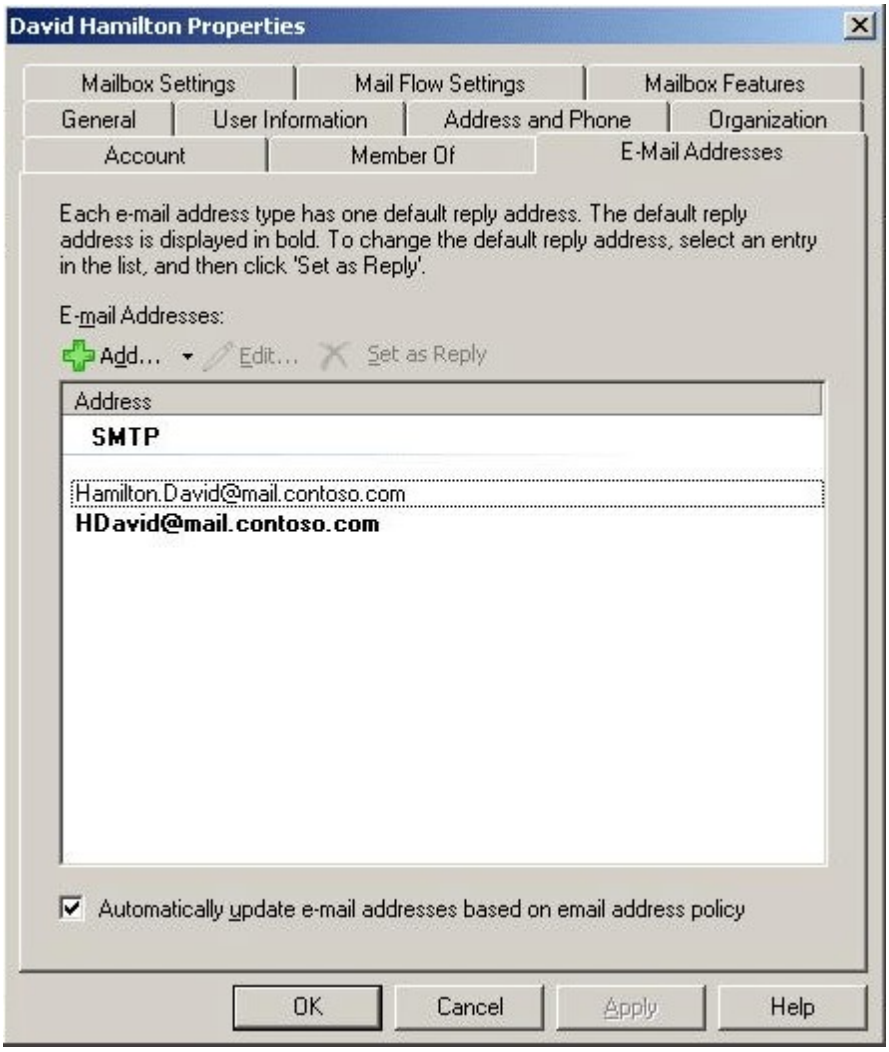
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Recipients (which include users, resources, contacts, and groups) are any mail-enabled object in Active Directory to which Microsoft Exchange can deliver or route messages. For a recipient to send or receive e-mail messages, the recipient must have an e-mail address. E-mail address policies generate the primary and secondary e-mail addresses for your recipients so they can receive and send e-mail.

By default, Exchange contains an e-mail address policy for every mail-enabled user. This default policy specifies the recipient's alias as the local part of the e-mail address and uses the default accepted domain. The local part of an e-mail address is the name that appears before the at sign (@). However, you can change how your recipients' e-mail addresses will display. For example, you can specify that your recipients' e-mail addresses display as *firstname*.*lastname*@contoso.com.

Furthermore, if you want to specify additional e-mail addresses for all recipients or just a subset, you can modify the default policy or create additional policies. For example, the following figure illustrates a configuration in which the recipient David Hamilton can receive e-mail messages addressed to hdavid@mail.contoso.com and hamilton.david@mail.contoso.com.



Looking for management tasks related to e-mail address policies? See Managing E-Mail Address Policies.

Behaviors of Recipient Policies

Exchange applies a policy to all recipients that match the recipient filtering criteria:

- The recipient policy functionality is divided into two features: e-mail address policies and accepted domains.

  Note:
  A detailed discussion about accepted domains is outside the scope of this topic. For information about accepted domains, see Understanding Accepted Domains.

- When you run the **Update-EmailAddressPolicy** cmdlet in the Exchange Management Shell, the recipient object is updated with the e-mail address policy. For detailed syntax and parameter information, see Update-EmailAddressPolicy.
- Each time a recipient object is modified and saved, Exchange enforces the correct application of the e-mail address criteria and settings. When an e-mail address policy is modified and saved, all associated recipients are updated with the change. In addition, if a recipient object is modified, that recipient's e-mail address policy membership is reevaluated and enforced.

Creating E-Mail Address Policies

When creating an e-mail address policy, you can use the following e-mail address types:

- **Precanned SMTP e-mail address**. *Precanned* SMTP e-mail addresses are commonly used e-mail address types provided for you.
- **Custom SMTP e-mail address**. If you don't want to use one of the precanned SMTP e-mail addresses, you can specify a custom SMTP e-mail address. When creating a custom SMTP e-mail address, you can use the variables in the following table to specify alternate values for the local part of the e-mail address.

Custom SMTP e-mail address

Variable	Value
%g	Given name (first name)
%i	Middle initial
%s	Surname (last name)
%d	Display name
%m	Exchange alias
%*x*s	Uses the first *x* letters of the surname. For example, if *x* = 2, the first two letters of the surname are used.
%*x*g	Uses the first *x* letters of the given name. For example, if *x* = 2, the first two letters of the given name are used.

- **Non-SMTP e-mail address**. The following types of non-SMTP e-mail addresses are supported:
  - EX (Legacy DN Proxy Address Prefix DisplayName)
  - X.500
  - X.400
  - MSMail
  - CcMail
  - Lotus Notes
  - Novell GroupWise
  - Exchange Unified Messaging proxy address (EUM proxy address)

Important:
In Exchange, all non-SMTP e-mail addresses are considered custom addresses. Exchange doesn't provide unique dialog boxes or property pages for X.400, GroupWise, or Lotus Notes e-mail address types. If you add a non-SMTP custom e-mail address, you must have the appropriate dynamic-link library (DLL) files. If you don't provide the appropriate DLL files, you won't be able to create a customized e-mail address policy. The following error will be logged in Event Viewer: "The e-mail address description object in the Microsoft Exchange directory for the 'SADF' address type on 'i386' machines are missing."

For detailed instructions about how to create an e-mail address policy, see the following topics:

- Create an E-Mail Address Policy
- Create an E-Mail Address Policy By Using Recipient Filters

1.8.1.6 Understanding the Exchange 2010 Store

Understanding the Exchange 2010 Store

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-27*

The Exchange store is a storage platform that provides a single repository for managing multiple types of information in one infrastructure. The Exchange store (store.exe) is the core data storage repository for Microsoft Exchange Server 2010.

Contents

Databases in Editions of Exchange 2010

Exchange 2010 is available in two server editions: Standard Edition and Enterprise Edition. Exchange 2010 Standard Edition is designed to meet the messaging and collaboration needs of small and medium corporations, and it may also be appropriate for specific server roles or branch offices. Exchange 2010 Enterprise Edition is designed for large enterprises.

Exchange 2010 Standard Edition supports up to five databases. Exchange 2010 Enterprise Edition supports up to 100 databases.

Logical Components of the Exchange Store

The primary components of the Exchange store are mailbox databases and public folder databases. These components can reside on a single server, or they can be distributed across multiple servers.

Mailbox databases contain the data, data definitions, indexes, checksums, flags, and other information that comprise mailboxes in Exchange 2010. Mailbox databases hold data that's private to an individual user and contain mailbox folders generated when a mailbox is created for that user. A mailbox database is stored as an Exchange database (.edb) file.

Public folder databases contain the data, data definitions, indexes, checksums, flags, and

other information that comprise any public folders in your Exchange organization.

In Exchange 2010, you manage public folders by using the Exchange Management Shell. (You can also perform a limited number of public folder database management tasks in the Exchange Management Console.) For more information about managing public folders, see Managing Public Folders and Understanding Public Folders.

Return to top

File Structure of the Exchange Store

You manage the Exchange store by working with its logical components, such as databases. However, Exchange 2010 stores data in a specialized set of data files, such as Exchange database (.edb) files, transaction log (.log) files, and checkpoint (.chk) files. Unless you're backing up or restoring data, you rarely interact with these files directly. The following table describes each of these files in more detail.

File structure of Exchange store

Data file	Description
Exchange database (.edb)	These files are the repository for mailbox data. They're accessed by the Extensible Storage Engine (ESE) directly and have a B-tree structure designed for quick access. This enables users to access any page of data within one input/output (I/O) cycle, which is a four-fold increase compared to Microsoft Exchange Server 2007. Exchange databases are composed of multiple B-trees, with ancillary trees that work with the main tree by holding indexing and views.
Transaction log (.log)	These files are the repository for database operations such as creating or modifying a message. Committed operations are later written to the database itself (in an .edb file). This approach guarantees that all complete and incomplete transactions are logged to maintain data integrity in case of a service interruption. Each database has its own set of transaction logs.
Checkpoint (.chk)	These files are the repository for data that indicates when an operation is successfully saved to the database on the hard disk. Exchange 2010 uses .chk files so an instance of the ESE can automatically replay log files into an inconsistent database when recovering from a service interruption, starting with the next unwritten operation. The .chk files are placed in the same log location as the .log files.

Return to top

Understanding Transaction Logging

Exchange transaction logging is a robust recovery mechanism of the ESE designed to reliably restore an Exchange database to a consistent state after any sudden stop of the database. The logging mechanism is also used when restoring online backups. This section describes the details of Exchange 2010 transaction logging and includes a brief description of circular logging.

Exchange Transaction Logging

Before changes are made to an Exchange database file, Exchange writes the changes to a transaction log file. After a change is safely logged, it can then be written to the database file. It's common for these changes to become available to end users just after the changes are secured to the transaction log, but before the changes are written to the database file.

Exchange employs a sophisticated internal memory management system tuned for high performance, which efficiently manages the caching of dozens of gigabytes (GB) of database pages. Physically writing changes to the database file is a low-priority task during normal operation.

If a database suddenly stops, cached changes aren't lost just because the memory cache was destroyed. When the database restarts, Exchange scans the log files, and reconstructs and applies any changes not yet written to the database file. This process is called replaying log files. The database is structured so that Exchange can determine whether any operation in any log file has already been applied to the database, needs to be applied to the database, or doesn't belong to the database.

Rather than write all log information to a single large file, Exchange uses a series of log files, each exactly one megabyte (MB), or 1,024 kilobytes (KB), in size. When a log file is full, Exchange closes it and renames it with a sequential number. The first log filled ends with the name E*nn*00000001.log. The *nn* refers to a two-digit number known as the base name or log prefix.

Log files for each database are distinguished by file names with numbered prefixes (for example, E00, E01, E02, or E03). The log file currently open for a database is named E*nn*.log. It doesn't have a sequence number until it has been filled and closed.

The checkpoint file (E*nn*.chk) tracks how far Exchange has progressed in writing logged information to the database files. There's a checkpoint file for each log stream, and a separate log stream for each database.

Log files are numbered in a hexadecimal manner, so the log file after E0000000009.log is E000000000A.log, and not E0000000010.log. You can convert log file sequence numbers to their decimal values by using the Windows Calculator (Calc.exe) application in **Scientific** mode. To do this, run Calc.exe, and then from the **View** menu, click **Scientific**.

To view the decimal sequence number for a specific log file, you can examine its header by using the Exchange Server Database Utilities (Eseutil.exe) tool. The first 4-KB page of each log file contains header information that describes and identifies the log file and the databases it belongs to. The command **Eseutil /ml [log file name]** displays the header information.

If you use the wrong switch for displaying a header (for example, by using **/ml** with a database header instead of **/mh)**, an error is displayed or the header information displayed may be garbled or incorrect.

You can't view the header of a database while it's mounted. You also can't view the header of the current log file (E*nn*.log) while any database is mounted. Exchange holds the current log file open as long as one database is using it. However, you can view the checkpoint file header while databases are mounted. Exchange updates the checkpoint file every thirty seconds, and its header is viewable except during the moment when an update is occurring.

As an Exchange administrator, it's valuable to understand Exchange file headers. If you understand file headers, you can determine which database and log files belong together and which files are needed for successful recovery.

In the following log file header example, note the first four lines.

```
Base name: e00
Log file: e00.log
lGeneration: 11 (0xB)
Checkpoint: (0xB,7DC,6F)
```

These log file header lines show that this log file is the current log file because the log file name doesn't have a sequence number. The `lGeneration` line shows that when the log is filled and closed, its sequence number is `B`, corresponding to the decimal value 11. The base name is `e00`, and therefore the final log file name will be E000000000B.log.

The `Checkpoint` value in the previous header example isn't actually read from the log file header, but it's displayed as if it were. Eseutil.exe reads the `Checkpoint` value directly from E*nn*.chk, so you don't have to enter a separate command to learn where the checkpoint file is. If the checkpoint file has been destroyed, the `Checkpoint` value reads `NOT AVAILABLE`. In this case, the checkpoint is in the current log file (`0xB`), and the numbers `7DC` and `6F` indicate how far into the log file the checkpoint is. Note that you seldom have a practical need for this information.

If the checkpoint file is destroyed, Exchange can still recover and replay log files appropriately. But to do so, Exchange begins scanning log files, beginning with the oldest file available, instead of starting at the checkpoint log. Exchange skips data that has already been applied to the database and works sequentially through the logs until data that must be applied is encountered.

Typically, it takes only one or two seconds for Exchange to scan a log file that has already been applied to the database. If there are operations in a log file that must be written to the database, it can take anywhere from 10 seconds to several minutes to apply them. On average, a log file's contents can be written to the database in 30 seconds or less.

When an Exchange database shuts down normally, all outstanding data is written to the database files. After normal shutdown, the database file set is considered consistent, and Exchange detaches it from its log stream. This means that the database files are now self-contained (up to date). The transaction logs aren't required to start the database files.

You can tell whether a database has been shut down cleanly by running the command **Eseutil /mh** and examining the file headers.

With all databases disconnected and in a Clean Shutdown state, all log files can be safely deleted without affecting the databases. If you were then to delete all log files, Exchange would generate a new sequence of logs starting with E*nn*00000001.log. You could move the database files to a different server that has existing log files, and the databases would attach themselves to a different log stream.

Note:

Although you can delete the log files after all databases have been shut down, doing so affects your ability to restore older backups and roll forward. The current database no longer needs the existing log files, but they may be necessary if you must restore an older database.

If a database is in a Dirty Shutdown state, all existing transaction logs from the checkpoint forward must be present before you can mount the database again. If these logs are unavailable, you must repair the database by running the command **Eseutil /p** to make the database consistent and ready to start.

Caution:
If you have to repair a database, some data will be lost. Data loss is frequently minimal; however, it may be catastrophic. After running **Eseutil /p** on a database, you should run **Eseutil/ d** to defragment the database. This operation discards and rebuilds all database indexes and space trees.

In addition to allowing Exchange to recover reliably from an unexpected database stop, transaction logging is also essential to making and restoring online backups. For more information about making and restoring online backups, see Understanding Backup, Restore and Disaster Recovery.

Return to top

Circular Logging

You can configure Exchange to save disk space by enabling circular logging. Circular logging allows Exchange to overwrite transaction log files after the data that the log files contain is committed to the database. However, if circular logging is enabled, you can recover data only up until the last full backup. For example, you can enable circular logging when using Exchange native data protection, in which you don't make backups. To prevent log buildup, you need to enable circular logging.

In the standard transaction logging used by Exchange 2010, each database transaction is written to a log file and then to the database. When a log file reaches one MB in size, it's renamed, and a new log file is created. Over time, this results in a set of log files. If Exchange stops unexpectedly, you can recover the transactions by replaying the data from these log files into the database. Circular logging overwrites and reuses the first log file after the data it contains has been written to the database.

In Exchange 2010, circular logging is disabled by default. By enabling it, you reduce drive storage space requirements. However, without a complete set of transaction log files, you can't recover any data more recent than the last full backup. In a normal production environment, circular logging isn't recommended.

For information about how to enable and disable circular logging, see Configure Mailbox Database Properties.

Return to top

Extensible Storage Engine

Exchange mailbox databases and the queue on Hub Transport servers and Edge Transport servers utilize the ESE database. ESE is a multiuser, indexed sequential access method (ISAM) table manager with full data manipulation language (DML) and data definition language (DDL) capability. ESE allows applications to store records and create indexes to access those records in different ways. For more information about ESE, see Extensible Storage Engine Architecture. For improvements in Exchange 2010 ESE, see New Exchange Core Store Functionality.

Return to top

Store Health

The Exchange store can detect and correct several scenarios that can cause the store to become unhealthy. The Exchange store can handle poison mailboxes and thread time-outs, use report and alert features to signal an unhealthy Exchange store state, and detect and repair mailbox database and public folder database issues.

Poison Mailbox Detection and Correction

A single mailbox with corrupted data (logical or physical) may in some cases cause the Exchange store to fail, and deny service to all mailboxes hosted by the server. Similarly, a poison mailbox could also cause the Exchange store to repeatedly fail. This section describes the actions the Exchange store takes to detect and cut off poison mailboxes.

Isolating the Poison Mailbox

There are several types of events for which the Exchange store tags a mailbox as a potential threat:

- If a thread doing work for that mailbox fails
- If there are more than five threads in that mailbox that haven't made progress for a long time

A mailbox that's a potential threat is tagged, along with a count of how many times it has been tagged. This information is stored in the registry. The Exchange store also keeps timestamp information about when the mailbox was identified as a potential threat.

During a database mount, the Exchange store reads the time that the mailboxes were identified as potential threats. If more than two hours has elapsed, the registry key for the mailbox is deleted. The advantage of keeping this information in the registry is that in a high availability environment, it's replicated by the cluster database. Even during an Exchange store failover, the other computers have this information. The registry path used for isolating the poison mailbox is **HKLM\SYSTEM\CurrentControlSet\Services\MSExchangeIS\<Server Name>\Private-{db guid}\QuarantinedMailboxes\{mailbox guid}**. The keys for this path are **CrashCount** and **LastCrashTime**.

The settings for how many failures lead to quarantining a mailbox as well as how long a mailbox should stay quarantined are stored in the **MailboxQuarantineCrashThreshold** and **MailboxQuarantineDurationInSeconds** keys in the registry path **HKLM\SYSTEM\CurrentControlSet\Services\MSExchangeIS\<Server Name>\Private-{db guid}\QuarantinedMailboxes**.

The default values for these keys are three failures for **MailboxQuarantineCrashThreshold** and 21,600 seconds (six hours) for **MailboxQuarantineDurationInSeconds**.

Acting on the Poison Mailbox

By default, if a mailbox is identified as causing a failure or deadlock three times within two hours, the Exchange store tags it as quarantined in the registry. No access is allowed to the mailbox unless the OPEN_AS_ADMIN flag is passed. None of the Exchange processes (for example, content indexing or the Mailbox assistants) are allowed to log on. The **QuarantineState** and **QuarantineTime** registry keys keep track of whether the mailbox is quarantined. If the mailbox hasn't caused any failures in the last two hours and isn't quarantined, the registry path for the mailbox is cleaned up by the Exchange store. If a mailbox has been quarantined for longer than the **MailboxQuarantineDurationInSeconds** value since it's **LastCrashTime** value, it's released from quarantine automatically.

Resetting the Quarantined Mailbox

When the cause of the poison mailbox has been identified and corrected, the registry key for the quarantined mailbox should be reset manually by deleting it. However, if this manual step is forgotten, the Exchange store automatically resets quarantined mailboxes six hours after the quarantined flag was set. If the issue isn't debugged and fixed within that time period, this may lead to another set of failures before the mailbox or message is quarantined again.

Note:

The database hosting the mailbox needs to be remounted, or the Exchange store restarted, for the reset of the quarantined mailbox to take effect.

The time period for resetting quarantined mailboxes can be controlled by the registry key **HKLM\SYSTEM\CurrentControlSet\Services\MSExchangeIS\<Server Name>\Private-{db guid}\QuarantinedMailboxes\MailboxQuarantineDurationInSeconds**.

Reporting and Alerts

You can use the Get-MailboxStatistics cmdlet to report the quarantined state of a mailbox. The Exchange store has a Performance Monitor counter for the number of quarantined mailboxes. The counter name is MSExchangeIS Mailbox\Quarantined Mailbox Count.

The Exchange store also writes an event whenever it quarantines a mailbox, with details about which mailbox and what time. The event 10018 identifies a quarantined mailbox.

Return to top

Database Repair

In Exchange 2010 Service Pack 1 (SP1), you can use the New-MailboxRepairRequest cmdlet to detect and repair mailbox corruptions. You can run this cmdlet against a specific mailbox or against a mailbox database. While this task is running, mailbox access is disrupted for the mailbox being repaired. If you run this cmdlet against a mailbox database, only access to the mailbox being repaired is disrupted. All other mailboxes in the database remain operational. For more information, see Create a Mailbox Repair Request.

The **New-MailboxRepairRequest** cmdlet detects and repairs the following types of mailbox corruptions:

- Search folder corruptions (using the `SearchFolder` value of the *CorruptionType* parameter)
- Aggregate counts on folders that aren't reflecting correct values (using the `AggregateCounts` value of the *CorruptionType* parameter)
- Views on folders that aren't returning the correct content (using the `FolderView` value of the *CorruptionType* parameter)
- Provisioned folders incorrectly pointing to parent folders that aren't provisioned (using the `ProvisionedFolder` value of the *CorruptionType* parameter)

After you run the **New-MailboxRepairRequest** cmdlet, you can use Event Viewer to view the details of the request. For more information, see View Mailbox Repair Request Entries in Event Viewer.

You can also use the New-PublicFolderDatabaseRepairRequest cmdlet to detect and fix replication issues in the public folder database. Public folders in the public folder database can still be accessed while the request is running. However, access isn't available to the public folder currently being repaired. For more information, see Create a Public Folder Database Repair Request.

Return to top

Time-Out Detection and Reporting

Another indication of an unhealthy Exchange store is that threads are either deadlocked or otherwise not making any progress. If there are more than five threads on a single mailbox, ten threads on a single database, or twenty threads on a single server that hasn't made progress in one minute, a time-out is reported on the server. The performance counter that indicates detected time-outs is MSExchangeIS\ RPC Request Timeout Detected.

The Exchange store also writes the following events to the server:

- 10025, which reports a time-out on the Exchange server
- 10026, which reports a time-out on the database
- 10027, which reports a time-out on an individual mailbox

If the time-out is detected on a single mailbox, the mailbox is considered potentially poison, and is handled similar to a failure by increasing the **CrashCount** key. This makes it susceptible to being quarantined.

Return to top

Low Disk Space on Database Logs or Database Drives

When the Exchange store detects that the space available on a log or database drive is below 1 GB, it cuts off all transport delivery to that database. This is to prevent a disk running out of space. When a disk runs out of space, the database can't be mounted or debugged. The database space also can't be reclaimed. This is a self-protecting mechanism that only occurs if you don't react to the space issue warnings from your monitoring infrastructure.

When the disk space goes above 1.5 GB, the Exchange store allows deliveries to continue. The following performance counters indicate this behavior:

- MSExchangeIS Mailbox\ Delivery Blocked: Low Database Space
- MSExchangeIS Mailbox\ Delivery Blocked: Low Log Space

The Exchange store also writes the following events to the server:

- 10014, which indicates low disk space on the log
- 10015, which indicates low disk space on the database

If you encounter low disk space issues, you can perform the following actions to correct the issue:

- Delete content from mailboxes. Specifically, you can delete messages from the Deleted Items and Sent Items folders.
- Purge items from the Recoverable Items folder. For details, see Clean Up the Recoverable Items Folder.
- Run database maintenance. For details, see Maintain Mailbox Databases.
- Purge transaction logs. For details, see Understanding High Availability Factors.
- Enable circular logging. For details, see Configure Mailbox Database Properties.
- Change the database path to a hard disk drive that has more space. For details, see Move the Mailbox Database Path for a Mailbox Database Copy.

Return to top

Exchange Store Limits

In Exchange 2010, connection and usage limits are placed on the Exchange store to prevent a single application or a single user from using all the available connections to the Exchange store. If a single user or application uses all the connections, other users or applications won't be able to access the Exchange store, which can result in downtime.

For more information, see Exchange Store Limits.

Return to top

Exchange Store Limits

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-03-08*

In Microsoft Exchange Server 2010, connection and usage limits have been placed on the Exchange store to prevent a single application or a single user from using all the available connections to the Exchange store. If a single user or application is allowed to use all of the connections, other users or applications cannot be able to access the Exchange store, which could result in downtime.

Note:

For any connections made by accounts that have administrative privileges, the session limits have been increased to 64,000 maximum sessions per server.

Contents

Terminology

Knowledge of the following terms will help you understand the types of connections referenced in this topic.

Sessions

Sessions represent the connections used by services and client applications, such as Microsoft Outlook, to connect to the Exchange store. Services and clients can have multiple sessions at a particular time. The terms *connections* and *sessions* can be used interchangeably.

Threads

Threads represent concurrently executing requests to the Exchange store. For example, if a user opens a folder in Outlook, Outlook executes a request to the Exchange store on behalf of the user. That executing request is a single thread.

For example, 75 users being logged on to a server at the same time is equal to 75 sessions. However, out of those 75 sessions, only 5 of those sessions could be making requests through threads.

Return to top

Session Limits

The following table lists the types of client connections to the Exchange store and the limits based on those connections. If you want to modify the session limits, see "Configure Session Limits" immediately following the table.

The types of connections are as follows:

- **Max concurrent threads per server** Specifies the maximum number of

concurrent threads that an Exchange service can execute on a Mailbox server.

- **Max sessions per server** Specifies the maximum number of sessions that an Exchange service can have open at one time on a Mailbox server.
- **Max user sessions per server** Specifies the maximum number of sessions for a particular protocol for a single user.

Client type	Max concurrent threads per server	Max sessions per server	Default number of user sessions per server
Admin	50	10,000	Not applicable
Availability service	50	10,000	16
Content indexing	50	10,000	Not applicable
Exchange ActiveSync	Not applicable	Not applicable	16
Exchange Web Services	Not applicable	Not applicable	16
Management	Not applicable	Not applicable	16
MAPI on the Middle Tier (MoMT)	Not applicable	Not applicable	32
MSExchangeMailboxAssistants: Events	50	10,000	Not applicable
MSExchangeMailboxAssistants: Timed	50	10,000	Not applicable
MSExchange Remote Procedure Call	Not applicable	Not applicable	16
Microsoft Office Outlook Web App	Not applicable	Not applicable	16
POP3 and IMAP4	Not applicable	Not applicable	16
Transport	50	10,000	Not applicable
Unified Messaging	Not applicable	Not applicable	16
Others	Not applicable	Not applicable	16

Configure Session Limits

You can modify the default session limits.

Note:

If you want to modify the session limits, you need to modify them on all Mailbox servers within any database availability groups (DAGs). If you don't make the same changes on all servers, the results will be inconsistent. To increase the session limit on the Client Access server, the RCAMaxConcurrency value must be increased on the throttling policy. For more information, see Set-ThrottlingPolicy.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Start Registry Editor (regedit).
2. Navigate to the following registry subkey:
   \\HKEY_LOCAL_MACHINE \SYSTEM\CurrentControlSet\Services

\MSExchangeIS\ParametersSystem.

3. Right-click **ParametersSystem**, point to **New**, and then click **DWORD (32-bit) Value.**
   The new value is created in the result pane.
4. Rename the key to one of the following values, and then press Enter:
   - **Maximum Allowed Sessions Per User** This limit specifies the maximum allowable sessions per user.
   - **Maximum Allowed Service Sessions Per User** This limit specifies the maximum allowed service sessions per user.
   - **Maximum Allowed Exchange Sessions Per Service** This limit specifies the maximum allowed Exchange sessions per service. The default value is 10,000, and the Maximum value is 65536.
   - **Maximum Allowed Concurrent Exchange Sessions Per Service** This limit specifies the maximum allowed concurrent Exchange sessions per service.
   - **Disable Session Limit** This limit disables session limits. Set the value to **0** to turn off session limits. Set the value to **1** to turn on session limits.
5. Right-click the newly created key, and then click **Modify**.
6. In the **Value data** box, type the number of objects to which you want to limit this entry, and then click **OK**. Use the preceding table to view the default settings.

Return to top

Open Item Limits

Open item limits are limits placed on the number of items that can be opened by a single mailbox in a single session. However, a user can have multiple sessions opened simultaneously. For example, if a user has two sessions opened, the user could open 1,000 folders.

If you want to modify these limits, see "Configure Open Item Limits" immediately following the table.

Item type	Registry object type	Max opened per session
ACL View	objtACLView	50
Attachment	objtAttachment	500
Attachment View	objtAttachmentView	500
Cstream	objtCStream	50
Folder	objtFolder	500
Folder View	objtFolderView	500
FX Destination Stream	objtFXDstStrm	50
FX Source Stream	objtFXSrcStrm	50
Message	objtMessage	250
Message View	objtMessageView	500
Notification	objtNotify	500,000
Rule View	objtRulesView	50
Stream	objtStream	250

Configure Open Item Limits

You can limit the maximum number of resources that a MAPI client can use simultaneously.

Note:

If you want to modify the open item limits, you need to modify them on all Mailbox servers within any DAGs and client access arrays. If you don't make the same changes on all servers, the results will be inconsistent.

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Start Registry Editor (regedit).
2. Navigate to the following registry subkey:
   \\HKEY_LOCAL_MACHINE \SYSTEM\CurrentControlSet\Services \MSExchangeIS\ParametersSystem
3. Right-click **ParametersSystem**, point to **New**, and then click **Key**.
   A new key is created in the console tree.
4. Rename the key **MaxObjsPerMapiSession**, and then press Enter.
5. Right-click **MaxObjsPerMapiSession**, point to **New**, and then click **DWORD (32-bit) Value**.
   The new value is created in the result pane.
6. Rename the key to <*Object_type*>, where <*Object_type*> is the name of the registry object type that you're modifying. For example, to modify the number of messages that can be opened, use *objtMessage*. Press Enter.
7. Right-click the newly created key, and then click **Modify**.
8. In the **Value data** box, type the number of objects that you want to limit this entry to, and then click **OK**. For example, type **350** to increase the value for the object.
9. Restart the Microsoft Exchange Information Store service.

Return to top

Item Size Limits

Item size limits are the limits placed on items within a user's mailbox.

Item size limits are configurable by using the *MaxSendSize* and *MaxReceiveSize* parameters on the following cmdlets:

- Set-Mailbox
- Set-RemoteMailbox
- Set-MailUser
- Set-MailContact

Item type	Limit
Message (saved)	Maximum size of the SendLimit, ReceiveLimit
Message (sent)	Maximum size of the SendLimit
Attachments	Maximum number of attachments per message = 1,024

Understanding Database Maintenance

See Also

Mailbox > Understanding Mailbox > Understanding the Exchange 2010 Store >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-08-24*

Architectural changes that were made to the database engine in Microsoft Exchange Server 2010 significantly improve its performance and robustness. However, these architectural changes also change the behavior of database maintenance tasks from earlier versions of Exchange Server. This topic describes the database maintenance tasks that must be routinely performed against Exchange Server 2010 databases.

All the tasks that are described in this topic are collectively known as background database maintenance.

Database Compaction

Database compaction must be completed to free up unused space in the database file. Database compaction does not return that unused space to the file system. Instead, it frees pages in the database by compacting records into the fewest possible number of pages, and reduces the I/O that is required to access the pages. To do this, the ESE database engine uses the database metadata, which is the information that describes tables in the database. For each table, the ESE database engine examines every page in the table, and tries to move the records to logically ordered pages.

Database compaction is important because it reduces the time associated with backing up the database file, and it helps maintain a predictable database file size. This is important to accurately determine server/storage size.

Database compaction was redesigned for Exchange Server 2010. Most significantly, the operation now gives preference to data contiguity over the amount of compaction. In earlier versions of Exchange Server, the focus was greater on space compaction. This resulted in pages that were always in random order after the process reordered records into free space across pages. In combination with the store schema architecture, this random reordering meant that any request to pull a set of data (such as downloading items inside a folder) always resulted in random I/O. In Exchange Server 2010, random I/O is reduced by keeping records in order on the pages.

Also in earlier versions of Exchange Server, database compaction operations were performed during the online maintenance window. In Exchange 2010, database compaction is now a background process that runs continuously.

Database Defragmentation

Database defragmentation (also known as OLD v2 and B+ tree defragmentation) is a new maintenance task in Exchange Server 2010. Database defragmentation is important to maintain efficient utilization of disk resources over time (i.e., make the I/O more sequential instead of random) and to maintain the compactness of tables that are marked as sequential.

Database defragmentation is a background process that analyzes the database continuously as operations are performed, and then triggers asynchronous work when it is necessary. The process monitors all tables for free pages. If a table reaches a threshold at which a significantly high percentage of the total B+ Tree page count is free, the free pages are returned to the root. The process also works to maintain contiguity throughout a table set with sequential space hints (a table that was created with a known sequential usage pattern). If database defragmentation sees a scan/pre-read on a sequential table, and if the records are not stored on sequential pages within the table, the process defragments that section of the table by moving all the affected pages to a new extent in the B+ tree. You can use performance counters to see the low level of active work performed by database defragmentation when a steady state is reached.

Database defragmentation has the following controls to regulate how it completes tasks:

- **The max number of outstanding tasks** This keeps database defragmentation from doing too much work during the first pass if a very large change has occurred in the database.
  A latency throttle of 100ms When the system is overloaded, database defragmentation will delay defragmentation work. Delayed work is completed the next time that the database follows that same operational pattern and the system has more resources.

Online database scanning (Database Checksumming)

Online database scanning (also known as database checksumming) is the process by which the database is read in large chunks, and every page is examined for physical page corruption. The main purpose of checksumming is to detect physical corruption and lost flushes that may not be detected by transactional operations (stale pages).

Note:

In Exchange Server 2007 and earlier versions, the checksumming operations occurred during the backup process. However, this caused a problem for replicated databases because only the copy that was being backed up was checksummed. If the passive copy was backed up, the active copy was not being checksummed. To resolve this issue, a new optional online maintenance task named Online Maintenance Checksum was added to Exchange Server 2007 Service Pack 1 (SP1). For more information, see How to Configure Online Maintenance Database Scanning in Exchange 2007 SP1 and SP2.

In Exchange 2010, online database scanning checksums the database and performs post Exchange 2010 Store crash operations. Space can leak because of crashes. Online database scanning finds and recovers lost space. The system in Exchange 2010 is designed with the expectation that every database is fully scanned one time every seven days. A warning event is fired if a database is not completely scanned in this timeframe. In Exchange 2010, there are now two modes to run online database scanning on active database copies:

- Run as the last task in the scheduled Mailbox Database Maintenance process: You can configure how long it runs by changing the Mailbox Database Maintenance schedule. You can use this option for smaller databases that are less than 1 terabyte and that require less time to be completely scanned.
- Run the default behavior in the background 24 hours a day, seven days a week: This option works well for all database sizes, but we recommend this for large database sizes (1-2 TB). Exchange scans the database no more than one time per day. This read I/O is 100 percent sequential (which makes it easy on the disk), and equates to a scanning rate of about 5 megabytes (MB)/sec on most systems.

Note:

- The Shell, EMC, and JetStress refer to database checksumming as

background database maintenance. To enable database checksumming in the EMC, select the **Enable background database maintenance (24 X 7 ESE scanning)** check box in **Properties**.
- To enable database checksumming in the shell, enter the following cmdlet: **Set-MailboxDatabase -Identity MDB1 -BackgroundDatabaseMaintenance $true**
- To enable database checksumming in Jetstress 2010, select the **Run background database maintenance** check box on the **Select Test Type** page.

Page Patching

Page patching replaces corrupted pages with healthy copies. Corrupted page detection is a function of database checksumming. In addition, corrupted pages are detected at run time when the page is stored in the database cache. Page patching works against highly available (HA) database copies. How a corrupted page is repaired depends on whether the HA database copy is active or passive.

Page patching process on active database copies

- A corrupted page(s) is detected.
- A marker is written into the active log file. This marker indicates the corrupted page number. It also indicates that the page requires replacement.
- An entry is added to the page patch request list.
- The active log file is closed.
- The Replication service sends the log file to passive database copies.
- The Replication service on a target Mailbox server receives the sent log file and inspects it.
- The Information Store on the target server replays the log file, and replays up to marker, retrieves its healthy version of the page, invokes Replay Service callback, and then ships the page to the source Mailbox server.
- The source Mailbox server receives the healthy version of the page, confirms that an entry exists in the page patch request list, and then writes the page to the log buffer. Correspondingly, the page is inserted into the database cache.
- The corresponding entry in the page patch request list is removed.
- At this point, the database is considered patched. (At some later point, the checkpoint will advance, the database cache will be flushed, and the corrupted page on disk will be overwritten.)
- Any other copy of this page (received from another passive copy) will be silently dropped. This is because no corresponding entry exists in the page patch request list.

Page patching process on passive database copies

- On the Mailbox server on which the corrupted pages are detected, log replay is paused for the affected database copy.
- The replication service coordinates with the Mailbox server that is hosting the active database copy, and it retrieves the corrupted pages and the required log range from the active copy's database header.
- The Mailbox server updates the database header for the affected database copy, and it inserts the new required log range.
- The Mailbox server notifies the Mailbox server that is hosting the active database copy about which log files it requires.
- The Mailbox server receives the required log files, and it inspects them.
- The Mailbox server injects the healthy versions of the database pages it retrieved from the active database copy. The pages are written to the log buffer. Correspondingly, the page is inserted into the database cache.
- The Mailbox server resumes log replay.

Page Zeroing

Database Page Zeroing is a security measure by which deleted pages in the database are overwritten with a pattern (zeroed). This makes discovering the data much more difficult.

In Exchange Server 2007 and earlier versions, page zeroing operations occur during the streaming backup process. Because they occur during the streaming backup process, page zeroing does not cause the generation of log files. This raises an issue for replicated databases because the passive copies never have their pages zeroed. Also, the active copies have their pages zeroed if a streaming backup is finished. In Exchange Server 2007 SP1, we introduced a new optional online maintenance task to address this issue: Zero Database Pages during Checksum. When Zero Database Pages during Checksum is enabled, this task zeroes out pages during the online maintenance window, and then logs the changes. The changes are then replicated to the passive copies.

However, in the Exchange Server 2007 SP1 implementation, the zeroing process occurs during a scheduled maintenance window. This creates a delay between the time that a page is deleted and the time that it is zeroed. Therefore, the page zeroing task becomes a runtime event that operates continuously in Exchange Server 2010 SP1. Typically, the task now zeroes out pages at transaction time when a hard delete occurs.

In addition, database pages can be scrubbed during the online checksum process. The pages targeted in this case are as follows:

- Deleted records that couldn't be scrubbed during runtime because of dropped tasks (if the system is too overloaded) or because the store crashed before the tasks got to scrub the data.
- Deleted tables and secondary indices. When these are deleted, we do not scrub their contents. Therefore, online checksum detects that these pages don't belong to any valid object any longer and it scrubs the pages.

For more information about page zeroing in Exchange 2010, see Understanding Exchange 2010 Page Zeroing.

Use performance counters to track the background maintenance tasks

In Exchange Server 2010, events are not recorded for the defragmentation and compaction maintenance tasks. However, you can use performance counters to track the background maintenance tasks. The following table describes the performance counters to use under the **MSExchange Database ==> Instances** object.

Counter	Description
Database Maintenance Duration	The number of seconds that have passed since the maintenance started for this database. If the value is 0, maintenance has been finished for the day.
Database Maintenance Pages Bad Checksums	The number of non-correctable page checksums encountered during a database maintenance pass
Defragmentation Tasks	The count of background database defragmentation tasks that are currently running
Defragmentation Tasks Completed/sec	The rate at which background database defragmentation tasks are being finished

The following table describes the page zeroing counters to use under the **MSExchange Database** object:

Counter	Description
Database Maintenance Pages Zeroed	Indicates the number of pages zeroed by the database engine since the performance counter was invoked
Database Maintenance Pages Zeroed/sec	Indicates the rate at which pages are zeroed by the database engine

White space

In a database, you can have thousands of tables. You can have at least one table for every folder in every mailbox. The messages tables, folders tables, and attachments tables represent 90 percent of the space that is used in the database. These tables have the greatest percentage of free space (also known as white space) in the database.

To determine how much white space exists in a database, and reclaim the white space, follow these steps:

1. Unmount the database.
2. Complete a space dump by using the Exchange Server Database Utilities (Eseutil) tool together with the */MS* switch. For more information about how to do this, see How to Run Eseutil /M in File Dump Mode.
   At the end of the dump file is a line similar to the following:

   ```
   ------------------------------------------------------------------------
   253
   ```

   This is a summation of the total number of pages that are available in all the tables. Multiply this value by 32K to determine the true amount of white space in the database.

Note:
For an example of the Eseutil dump file, see Determining the True Amount of Space in an Exchange Database.

After you determine how much white space is in a database, you may also want to reclaim the white space.

If you encounter a database that has a significant amount of white space, and you do not expect that the typical operations will reclaim the space, we recommend the following steps:

1. Create a new database and its associated database copies.
2. Move all mailboxes to the new database.
3. Delete the original database and its associated database copies.

Understanding the Impact of Named Property and Replica Identifier Limits on Exchange Databases

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2013-01-08*

Microsoft uses the Messaging API (MAPI) to connect different messaging transport components. The MAPI specification presents most objects as properties. To identify these properties, MAPI uses identifiers, known as property identifiers or PropIDs.

Property identifiers are a set of hexadecimal values that range from 1 to 0xFFFF. This provides sufficient values for 65,534 properties. These properties are divided into the following groups, known as ranges:

- **Transmittable properties** –Properties that Exchange can send together with a message
- **Internal properties** - Properties that can be set only by Exchange
- **Non-transmittable properties** – Properties that are not delivered outside the organization when Exchange delivers a message

The properties in these ranges are known as standard properties. Standard MAPI properties have fixed IDs, and represent all properties that are below 0x8000.

There is one additional range, which is the largest of the groups and which represents all properties that are at 0x8000 and above. The properties in this range are known as *named properties*. Named properties provide a way for vendors to extend the standard MAPI property set by adding their own properties.

Named properties fall into the following main categories:

- Properties that have numbers for names – These named properties are used by such programs as Microsoft Outlook, and are generally defined in a source file.
- Properties that have string values for names - These named properties are known as "String Named Properties." In addition to a name, each of these properties has an associated GUID. This lets developers divide named properties into property sets.

Because named properties do not have specific IDs assigned to them, MAPI provides a facility to dynamically create unique IDs for named properties and to maintain a persistent mapping between a named property and its unique ID. However, the dynamic creation of these IDs means that the property IDs for named properties can vary from computer to computer.

The Microsoft Exchange Information Store service maintains a table of named properties for each mailbox. Messages that are sent over the Internet are transferred in a format that is known as Message/RFC822. This is a text format that includes messages in plain text together with headers that contain a set of key-and-value pairs. RFC822 includes support for a set of properties that are called X-headers. When the transport service processes a message that contains custom information, the transport service contacts the information store service to register named properties for X-headers.

Note:

Any subsequent messages that include the same X-header do not cause Exchange to register additional named properties.

Exchange stores these named properties together with the messages that contain the

related X-header. Microsoft uses the extensible namespace PS_INTERNET_HEADERS to group the X-headers from messages that were received over the Internet.

Named Properties Limits

The following list summarizes some important points about named properties:

- X-headers are fields in Message/RFC822 messages that hold certain important values.
- Named properties is the method that Exchange uses to reserve an ID for a particular value.
- After a named property has been allocated, it may not be deallocated. The property remains reserved for the particular name and GUID combination.

Because there are a fixed number of named properties available, Exchange uses a quota system to track the number of allocated named properties. In this system, the information store service warns you when available named property IDs are close to becoming exhausted. When a second threshold is reached, the information store service stops allocating named property IDs.

Named Property Exhaustion

Although many programs use named properties, Outlook uses the majority of them. When named property IDs are exhausted, Outlook cannot map a named property. In this scenario, you may experience symptoms that resemble the following:

- Event IDs 9666 and 9667 are logged in the Application log. For more information, see Events 9666, 9667, 9668, and 9669 Received When Named Properties or Replica Identifiers Are Depleted for An Exchange Database.
- Messages that contain properties that cannot be mapped are not delivered. When you examine the message tracking information for an affected message, the information resembles the following:

  ```
  550 5.2.0 STOREDRV.Deliver: The Microsoft Exchange Information Store service reported an error. The following information should help identify the cause of this error:
  MapiExceptionNamedPropsQuotaExceeded: 16.18969
  ```

- When an add-in that adds named properties or X-headers to messages is installed in Outlook, certain messages may not be sent to other users in the organization. In this scenario, the sending user receives a non-delivery report (NDR) that resembles the following:

  ```
  The message reached the recipient's e-mail system, but delivery was refused. Attempt to resend the message. If it still fails, contact your system administrator.
  ```

To recover named properties in Microsoft Exchange Server 2010, use the **New-MoveRequest** cmdlet together with the *DoNotPreserveMailboxSignature* parameter. For more information, see New-MoveRequest.

Note:

Doing this depletes the named property IDs by retaining only named properties that exist on at least one message in the mailbox. If all named properties still exist on any message, none will be reclaimed.

Property Changes in Exchange 2010

Exchange Server 2010 includes improvements to address issues that may occur in

Microsoft Exchange Server 2007. In Exchange 2010, named property resources are moved to the mailbox level instead of the database level. For more information about the property change issues that may occur in Exchange 2007, see Understanding the Impact of Named Property and Replica Identifier Limits on Exchange Databases.

For More Information

For more information about managing databases, see Managing Storage Groups and Databases.

1.8.1.7 Understanding Exchange Search

Understanding Exchange Search

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-29*

With increasing mailbox sizes and increasing amounts of data being stored in mailboxes in the form of messages and attachments, it's crucial for users to be able to quickly search and locate the messages they need. In Microsoft Exchange Server 2010, you can provision personal archives for your users, helping you reduce or eliminate the use of .pst files. This results in more mailbox data being stored by a user, and it makes searching across the user's primary and archive mailboxes an important productivity tool.

In Exchange 2010, authorized users can use Multi-Mailbox Search to perform mailbox searches across the entire Exchange 2010 organization for complying with electronic discovery (eDiscovery) requests, regulatory audits, or internal investigations. Multi-Mailbox Search also uses the content indexes created by Exchange Search.

Exchange Search is different from full-text indexing available in Exchange Server 2003. Improvements were made to performance, content indexing, and search. New items are indexed almost immediately after they're created or delivered to the mailbox, providing users with a fast, stable, and more reliable way of searching mailbox data. In Exchange 2010 and Exchange Server 2007, content indexing is enabled by default on all mailbox databases, and there's no initial setup or configuration required.

Note:
Exchange Search doesn't index public folder databases.

Contents

Exchange Search and Localization

Exchange Search and Database Availability Groups

Content Indexing

When Exchange Search services are started, Exchange Search determines the search status of all mailbox databases on the Mailbox server. If a mailbox database is mounted and enabled for search, Exchange Search assigns it one of following status values:

- **New** When the status of a mailbox database is New, Exchange Search creates a content index catalog for the database. After it's created, Exchange Search changes the status of the database to Crawling.
- **Crawling** When the status of a mailbox is Crawling, Exchange Search indexes mailboxes in the database. The status remains Crawling until all mailboxes in the database have been indexed. After all mailboxes in the databases have been indexed, Exchange Search changes the status of the database to Notification.
- **Notification** After the initial crawl has occurred on a database, Exchange Search is notified by the Exchange store of new events such as message creation, delivery, or deletion. Events are added to the notification queue to be indexed. This happens quickly, so the content index is never more than a few minutes out of date. New messages delivered to a mailbox are indexed within a few seconds of delivery.

Return to top

Exchange Search Performance

Exchange Search offers significant performance improvements compared to full-text indexing in Exchange 2003. The search model has changed from a crawl mode to an always up-to-date mode. Several improvements were made to optimize system resources such as CPU, memory, disk input/output (I/O), and disk space required for indexes. These performance improvements result in over 35x improvement in indexing speed. Although a full crawl of the database is much faster, it can use a significant amount of resources on a Mailbox server, depending on the size of the mailbox database. During more intensive phases, this can disrupt mail flow. Because delivery of mail should take precedence over content indexing, a new throttling feature in Exchange Search automatically throttles indexing for a particular mailbox database or set, reducing disk I/O and CPU utilization.

Return to top

Exchange Search Clients

Exchange Search provides a service that's consumed by search clients. These clients include Microsoft Outlook, Microsoft Office Outlook Web App, Windows Mobile, the Multi-Mailbox Search feature in Exchange 2010, and Exchange Web Services.

In Outlook 2010 and Office Outlook 2007, Outlook profiles used to configure Outlook features on users' computers can be configured to use Cached Exchange Mode. When Outlook is connected to Exchange in an *online mode* and accesses the Exchange mailbox, changes such as creation of mailbox items, new mail delivery, and deletion of mailbox items takes place on the Mailbox server. In Cached Exchange Mode, Outlook creates a local replica of the Exchange mailbox on the user's computer. This replica is stored in an .ost file in the user's profile. Changes to mailbox items happen in the local replica, which is

then synchronized with the Exchange mailbox. For details about Cached Exchange Mode, see About Cached Exchange Mode.

In Cached Exchange Mode, Outlook uses Windows Search, a component built-in in Windows 7 and Windows Vista. Windows Search performs content indexing and provides search functionality to Outlook. Interfacing with a local content indexing and search service provides Outlook users running in Cached Exchange Mode a more efficient way to search their mailbox. In addition to indexing e-mail in the offline store, Windows Search also indexes other data residing in the file system. For details about Windows Search, see Windows Search.

Outlook 2010 and Outlook 2007 provide your users an easily accessible **Instant Search** box located on top of the message list pane, so that users can quickly search mailbox content. Additionally, using the Advanced Find feature, users can create more complex search queries using a number of fields and parameters.

Return to top

Advanced Query Syntax

With increasing number of e-mail messages received by users, larger mailboxes, and the resulting information overload, the ability to quickly search messages enhances user productivity, and boosts satisfaction with e-mail. Using Advanced Query Syntax (AQS), users can quickly create advanced search queries and find the messages they need. AQS search queries can be entered directly in the **Instant Search** box in Outlook.

For example, to search messages sent by user April Stewart that have attachments and contain the word Contoso in the subject field, a user can use the following search query: `From:"April Stewart" HasAttachments:true Subject:Contoso`. To further narrow it to unread messages, the user can add the following keyword and value: `unread:true`. To further narrow it to messages sent by April last month, the user can add the following keyword and value: `Sent:lastmonth`.

AQS is supported by both Exchange Search on the server and by Windows Search on the desktop. Search queries using AQS work in Outlook 2010 and Outlook 2007 in online and cached modes. In Exchange 2010, users can also use AQS queries in Outlook Web App and Windows Mobile. Exchange Search clients such as Multi-Mailbox Search also support AQS search queries.

Outlook 2010 and Outlook 2007 support a large number of AQS keywords. Additionally, Exchange Search also supports the keywords shown in the following table.

Exchange Search keywords

Property	Example	Search results
Attachments	attachment:annualreport.pptx	Messages that have an attachment named annualreport.pptx. The use of attachment:annualreport or attachment:annual* returns the same results as using the full name of the attachment.
Cc	cc:paul shen cc:pauls	Messages with Paul Shen in the Cc field.

	cc:pauls@contoso.com	
From	from:bharat suneja from:bsuneja from:bsuneja@contoso.com	Messages sent by Bharat Suneja.
Keywords in retention policy	retentionpolicy:business critical	Messages that have the Business Critical retention tag applied.
Date when messages expire according to policy	expires:4/1/2010	Messages that expire on April 1, 2010.
Sent	sent:yesterday	All messages sent yesterday.
Subject	Subject:"patent filing"	All messages where the phrase "patent filing" appears in the Subject field.
To	to:"ben smith" to:bsmith to:besmith@contoso.com	Messages that have Ben Smith in the To field.

Return to top

Exchange Search and Attachments

Exchange Search indexes text content contained in e-mail attachments. Support for different file formats is provided using search filters. Exchange Setup installs a number of search filters by default, providing support for indexing many popular file formats, including Microsoft Office files. For a list of search filters installed by Exchange Setup, see Default Filters for Exchange Search. You can install additional search filters for file formats that you want Exchange Search to index. Search filters for different file formats are available from many partners and third parties. The following applies to indexing:

- **Unsearchable items** When Exchange Search can't index a file because a search filter for the file format isn't installed on the Mailbox server, the item is treated as an unsearchable item. An item may also be marked as unsearchable due to other reasons. You can retrieve a list of unsearchable items per mailbox, mailbox database, or mailbox server, using the **Get-FailedContentIndexDocuments** cmdlet. For details, see Diagnose Exchange Search Issues. You can also include unsearchable items when you perform a discovery search using Multi-Mailbox Search.
- **Safe list** Certain file types are considered to have no content that can be indexed by Exchange Search. These file types are added to a safe list by creating a null filter value in the registry. Exchange Setup creates a null filter registry value for several file types. Mailbox items containing these file types aren't returned in the list of unsearchable items. For a list of default search filters and default null filter entries, see Default Filters for Exchange Search.
- **Encrypted items** Messages encrypted using S/MIME aren't indexed by Exchange Search. Encrypted messages are returned as unsearchable items if you use the Get-FailedContentIndexDocuments cmdlet.
- **IRM-protected items** Messages protected using Information Rights Management (IRM) are indexed by Exchange Search and included in search results. Messages must be protected by using an Active Directory Rights

Management Services (AD RMS) server in the same Active Directory forest as the Exchange 2010 Mailbox server. For details, see Information Rights Management.

Note:
In Cached Exchange Mode, attachments are also indexed by Windows Search. Windows Search uses search filters installed on the user's computer.

Return to top

Improvements Over Exchange Server 2003 Content Indexing

The search functionality in Exchange 2003 (content indexing) is replaced with Exchange Search in Exchange 2010. Exchange Search provides the following feature and functionality improvements over content indexing:

- Utilization of system resources such as CPU, memory, disk I/O, and disk space required for its indexes is improved, which significantly increases overall performance.
- New messages are typically indexed within 10 seconds of arrival, and query results are returned within seconds.
- Exchange Search is automatically enabled upon installation and doesn't require any configuration.
- Attachments can now be indexed. Several attachment types are supported, including Microsoft Office documents, text attachments, and HTML attachments.
- Indexing is automatically withheld for a specific mailbox database, which reduces the disk I/O load. Also, indexing is automatically withheld for the entire Mailbox server, which reduces both disk I/O and CPU utilization for Exchange Search.
- There is an easily accessible search bar in Outlook Web App and query builder support in Outlook 2010 and Outlook 2007.

Return to top

Difference Between Exchange Search and Exchange Store Search

Exchange Search allows you to quickly search text in messages through the use of pre-built indexes. Exchange store search is based on a sequential scan of all the messages in the search scope instead of using the pre-built indexes The following table compares some of the differences between Exchange Search and Exchange store search.

Exchange Search vs. Exchange store search

Exchange Search	Exchange store search
Faster	Slower
Searches the content index created by crawling the mailbox database	Searches the store
Indexes new items within seconds of creation or delivery to a mailbox	May not return newer items
Uses words, phrases, and sentences, ignores punctuation and spaces, not case-	Searches stream of bytes, finds only exact matches

sensitive	
Supports only prefix searches, doesn't support substring matches	Supports substring matches
Searches attachments using available search filters	Doesn't search within attachments
Can search messages in different languages	Not language-aware

Return to top

Exchange Search and Localization

Localization support for Exchange Search is limited to scenarios in which the client locale matches the message locale (which must also match the language used in the message body). Exchange Search doesn't support instances where a single message has multiple languages embedded in the body or where the client locale is different from the message locale.

To get consistent results for localized searches, the following must be true:

- An e-mail message must be written in a single language and that language must match the locale of the message.
- The search expression must be in a single language.
- The language must match the locale of the client computer, as identified by the connection to the server.

Return to top

Exchange Search and Database Availability Groups

In organizations that have a database availability group (DAG), during the seeding process, DAG members with a passive mailbox database copy replicate the content index catalog from the DAG member that has the active mailbox database copy. The content index is typically 10 percent the size of the mailbox database. After initial seeding, the server with the passive database copy gets message data from the server with the active database and performs content indexing locally. The bandwidth used for copying message content for indexing is in addition to the bandwidth used for replication of transaction logs. When planning a high availability deployment, you must consider the bandwidth used by Exchange Search.

The Exchange 2010 Mailbox Server Role Requirements Calculator includes content indexing considerations when calculating the bandwidth required for content indexing in a DAG. For more information about the calculator, including a link to download the calculator, see the Exchange Server Team Blog article Exchange 2010 Mailbox Server Role Requirements Calculator.

To learn more about DAGs, see Understanding Database Availability Groups.

1.8.1.8 Understanding Hierarchical Address Books

Understanding Hierarchical Address Books

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

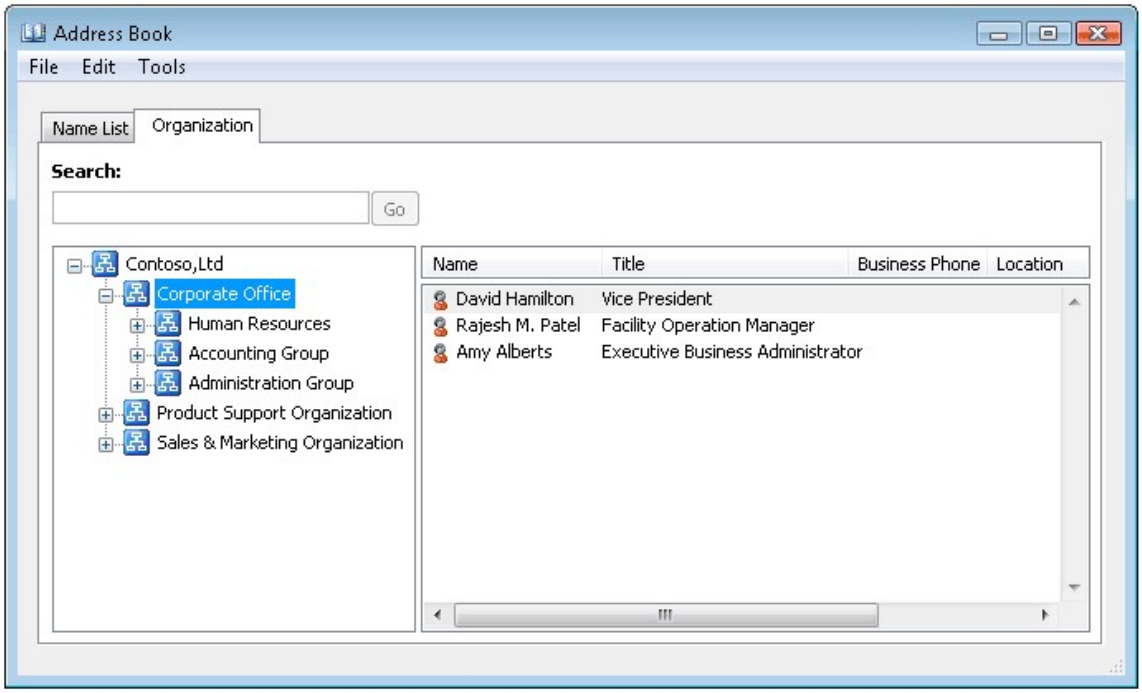
Topic Last Modified: *2010-09-30*

The hierarchical address book (HAB) is a feature in Microsoft Exchange Server 2010 and the Microsoft Outlook 2010 address book that enables end users to browse for recipients in their Exchange organization using an organizational hierarchy. In most Exchange 2010 deployments, users are limited to the default global address list (GAL) and its associated recipient properties. Additionally, the structure of the GAL often doesn't accurately reflect the management or seniority relationships among recipients in your organization. Being able to customize an HAB that maps to your organization's unique business structure provides your users with an efficient method for locating internal recipients.

Using Hierarchical Address Books

In an HAB, your root organization (for example, Contoso, Ltd) is used as the top-level tier. Under this top-level tier, you can add several child tiers to create a customized HAB that's segmented by division, department, or any other organizational tier you want to specify. The following figure illustrates an HAB for Contoso, Ltd with the following structure:

- The top-level tier represents the root organization Contoso, Ltd.
- The second-level child tiers represent the business divisions within Contoso, Ltd: Corporate Office, Product Support Organization, and Sales & Marketing Organization.
- The third-level child tiers represent departments within the Corporate Office division: Human Resources, Accounting Group, and Administration Group.



You can provide an additional level of hierarchical structure by using the *SeniorityIndex* parameter. When creating an HAB, use the *SeniorityIndex* parameter to rank individual recipients or organizational groups by seniority within these organizational tiers. This

ranking specifies the order in which the recipients or groups are displayed in the HAB. For example, in the preceding example, the *SeniorityIndex* parameter for the recipients in the Corporate Office division is set to the following:

- 100 for David Hamilton
- 50 for Rajesh M. Patel
- 25 for Amy Alberts

Note:

If the *SeniorityIndex* parameter isn't set or is equal for two or more users, the HAB sorting order uses the *PhoneticDisplayName* parameter value to list the users in ascending alphabetical order. If the *PhoneticDisplayName* parameter value isn't set, the HAB sorting order defaults to the *DisplayName* parameter value and lists the users in ascending alphabetical order.

Configuring Hierarchical Address Books

Detailed instructions for creating HABs are included in the topic Configure Hierarchical Address Books. The general steps are as follows:

1. Create a distribution group that will be used for the root organization (top-level tier). If desired, you can use an existing organizational unit in your Exchange forest for the distribution group.
2. Create distribution groups for the child tiers and designate them as members of the HAB. Modify the *SeniorityIndex* parameter of these groups so they're listed in the proper hierarchical order within the root organization.
3. Add organization members. Modify the *SeniorityIndex* parameter of the members so they're listed in the proper hierarchical order within the child tiers.
4. For accessibility purposes, you can use the *PhoneticDisplayName* parameter, which specifies a phonetic pronunciation of the *DisplayName* parameter. To learn more about the *PhoneticDisplayName* parameter and speech recognition, see Understanding Automatic Speech Recognition Directory Lookups.

1.8.1.9 Understanding Mailbox Import and Export Requests

Understanding Mailbox Import and Export Requests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 Service Pack 1 (SP1) introduces a new method for importing and exporting mailboxes. Using the **MailboxImportRequest** or **MailboxExportRequest** cmdlet sets, you can import data from or export data to .pst files. After you initiate a mailbox import or export request, the process is completed asynchronously by the Microsoft Exchange Mailbox Replication service (MRS). MRS resides on all Exchange 2010 Client Access servers and is the service responsible for moving mailboxes, importing and exporting .pst files, and restoring disabled and soft-deleted mailboxes.

For information about how to perform mailbox import and export requests, see Managing Mailbox Import and Export Requests.

Contents

Reasons to Import or Export Mailbox Data

There are several reasons why you may want to import or export mailbox data:

- **Satisfy compliance requirements** You can export mailbox content to a .pst file for legal discovery purposes. After the export is complete, you can import the content to a mailbox used specifically for compliance purposes.
- **Create a point-in-time snapshot of a mailbox** By creating a snapshot of specific mailboxes, you avoid having to retain an entire backup set for a mailbox database.
- **Move a user's .pst file into his or her mailbox or personal archive** Microsoft Outlook users can save their e-mail locally as .pst files. Using the New-MailboxImportRequest cmdlet, you can move data from a user's .pst file to his or her mailbox or personal archive. This is an easy method for transferring e-mail from a user's local computer to Exchange servers. To learn more, see Understanding Personal Archives.

Return to top

Limitations to Importing and Exporting Mailbox Data in Previous Versions of Exchange

Exchange Server 2007 and the release to manufacturing (RTM) version of Exchange 2010 use the **Import-Mailbox** and **Export-Mailbox** cmdlets to import and export .pst files. There are limitations to using these cmdlets:

- You must install Outlook on an Exchange server dedicated to importing and exporting mailbox data. As a result, you must purchase both an Exchange and an Outlook license solely for this purpose.
- The .pst file must reside on the server dedicated to importing and exporting mailbox data.
- The import or export operation is performed by the related cmdlet, and content in the .pst file moves through the dedicated server. Therefore, you can't shut down the session until the import or export is complete.

Return to top

Advantages to Using Import and Export Requests

The following are advantages to using import and export requests in Exchange 2010 SP1:

- A .pst provider is included in Exchange 2010 SP1 that can read and write .pst files.
- Import and export requests are asynchronous. The process is performed by MRS, which takes advantage of the queuing and throttling frameworks.
- The .pst files can be imported directly to a user's personal archive.
- Multiple .pst files can be imported or exported at the same time.
- Import and export cmdlets can be run against any Exchange 2010 SP1 server in your organization.
- The .pst files can reside on any shared network drive accessible by your Exchange servers.
- The following types of .pst files are supported by Exchange 2010 SP1:
  - Unicode and ANSI files created by Office Outlook 2003
  - Unicode files created by Office Outlook 2007 and Outlook 2010
  - Unicode files created by the Exchange 2010 SP1 New-MailboxExportRequest cmdlet
  - ANSI files created by the Exchange Server Mailbox Merge wizard (ExMerge)

Return to top

Permissions

You must have the correct permissions to import or export mailbox data. By default, none of the role groups include the Mailbox Import Export role. You must add the Mailbox Import Export role to a role group. If you try to run the import or export cmdlets without the correct permissions, you receive an error stating that the cmdlet doesn't exist.

For details, see Add the Mailbox Import Export Role to a Role Group.

Note:

After you add the Mailbox Import Export role to a role group, you must restart the Exchange Management Shell.

Return to top

Considerations

Before you import or export mailbox data, consider the following:

- To import or export mailbox data, a network shared folder accessible by your Exchange servers must be set up. You must also grant read/write permissions to the Exchange Trusted Subsystem group so that group can access the network share where you import and export mailbox data. If you don't grant this permission, you receive an error message stating that Exchange is unable to establish a connection to the target mailbox.
- The maximum .pst file size supported by Outlook is 50 gigabytes (GB). Therefore, we recommend that you don't import a .pst file larger than 50 GB. You can create multiple .pst files for mailboxes larger than 50 GB by specifying specific folders to include or exclude or by using a content filter.
- Import and export requests are performed by MRS, which also processes move requests and mailbox restore requests. All requests are queued and throttled by MRS. To learn more, see Throttling the Mailbox Replication Service.
- Importing and exporting mailbox data may take several hours depending on

file size, network bandwidth, and MRS throttling.
- Data can't be imported to a public folder or public folder database.

Return to top

Importing Mailbox Data

Use the **MailboxImportRequest** cmdlet set to import data from a .pst file to a mailbox or personal archive. The following is a list of options you can specify when importing mailbox data from a .pst file:

Note:
The mailbox to which you import the data must exist. You can't import data to a user account that doesn't have a mailbox.

- You can import data to a different user account than the one from which it was exported. For example, you can export data from john@contoso.com and import it to legaldiscovery@contoso.com.
- You can import items to only the user's personal archive by specifying the *IsArchive* parameter.
- If associated folder messages exist in the .pst file, you can import them using the *AssociatedMessagesCopyOption* parameter. Associated messages contain hidden data with information about rules, views, and forms. If they exist in the .pst file, all messages from the transport dumpster are imported.
- You can include or exclude specific folders using the *IncludeFolders* or *ExcludeFolders* parameter.
- You can exclude the Recoverable Items folder using the *ExcludeDumpster* parameter. By default, an import request includes the user's Recoverable Items folder if it's present in the .pst file.

MailboxImportRequest Cmdlet Set

Use the following cmdlets for mailbox import requests.

Cmdlet	Description	Topic
New-MailboxImportRequest	Start the process of importing a .pst file to a mailbox or personal archive. You can create more than one import request per mailbox. Each request must have a unique name.	Create a Mailbox Import Request
Set-MailboxImportRequest	Change import request options after the request is created or recover from a failed request.	Configure Mailbox Import Request Properties
Suspend-MailboxImportRequest	Suspend an import request any time after the request is created but before the request reaches the status of Completed.	Suspend a Mailbox Import Request
Resume-MailboxImportRequest	Resume an import request that's suspended or failed.	Resume a Mailbox Import Request
Remove-MailboxImportRequest	Remove fully or partially completed import requests. Completed import requests aren't automatically cleared.	Remove a Mailbox Import Request

	You must use this cmdlet to remove them.	
Get-MailboxImportRequest	View general information about an import request.	View Mailbox Import Request Properties
Get-MailboxImportRequestStatistics	View detailed information about an import request.	View Mailbox Import Request Properties

Return to top

Exporting Mailbox Data

Use the **MailboxExportRequest** cmdlet set to export mailbox data to a .pst file. You can export one mailbox or several mailboxes, but only one request is written to each .pst file at a time. The following is a list of options you can specify when exporting mailbox data to a .pst file:

- You can export personal archive data using the *IsArchive* parameter.
- You can filter the messages that are exported using the *ContentFilter* parameter. You can filter by message content, attachment, senders, recipients, Inbox category, importance, message type, message size, and when the message was sent, received, or expired. For more information, see Filterable Properties for the -ContentFilter Parameter.
- You can specify folders to include or exclude using the *IncludeFolders* or *ExcludeFolders* parameter. If exporting data from an Exchange 2010 mailbox, you can also exclude the Recoverable Items folder using the *ExcludeDumpster* parameter.
- You can export associated messages using the *AssociatedMessagesCopyOption* parameter. Associated messages contain hidden data with information about rules, views, and forms. By default, associated items aren't copied to the .pst file.

MailboxExportRequest Cmdlet Set

Use the following cmdlets for mailbox export requests.

Cmdlet	Description	Topic
New-MailboxExportRequest	Start the process of exporting data from a primary mailbox or personal archive to a .pst file. You can create more than one export request per mailbox. Each request must have a unique name.	Create a Mailbox Export Request
Set-MailboxExportRequest	Change export request options after the request is created or recover from a failed request.	Configure Mailbox Export Request Properties
Suspend-MailboxExportRequest	Suspend an export request any time after the request is created but before the request reaches the status of Completed.	Suspend a Mailbox Export Request
Resume-	Resume an export request	Resume a Mailbox Export

MailboxExportRequest	that's suspended or failed.	Request
Remove-MailboxExportRequest	Remove fully or partially completed export requests. Completed export requests aren't automatically cleared. You must use this cmdlet to remove them.	Remove a Mailbox Export Request
Get-MailboxExportRequest	View general information about an export request.	View Mailbox Export Request Properties
Get-MailboxExportRequestStatistics	View detailed information about an export request.	View Mailbox Export Request Properties

Return to top

1.8.1.10 Understanding Move Requests

Understanding Move Requests

Exchange Server 2010 > Mailbox > Understanding Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-28*

When you move a mailbox, you're moving it from a *source mailbox database* to a *target mailbox database*. The target mailbox database can be on the same server, on a different server, in a different domain, in a different Active Directory site, or in another forest.

Note:
This topic doesn't cover moving mailboxes to or from Microsoft Office Outlook Web App.

Contents

Personal Archives

Shared Mailboxes and Resource Mailboxes

Mailbox Moves During Server Failures

Client Experience

Looking for management tasks related to move requests? See Managing Move Requests.

Cautions

When moving mailboxes, consider the following:

- You can't use the Exchange System Manager or Active Directory Users and Computers to move mailboxes from Microsoft Exchange Server 2003 to Exchange Server 2010.
- You can't use the **Move-Mailbox** cmdlet in Exchange Server 2007 to move mailboxes from Exchange 2007 to Exchange 2010.
- When you move mailboxes, users won't be able to view their message tracking information.

Return to top

Changes in Exchange 2010 SP1

The following changes were made to move request functionality in Exchange 2010 Service Pack 1 (SP1):

- Exchange 2010 SP1 now *soft deletes* the mailbox on the source database, so that you can recover the mailbox in the event of a Mailbox server failover or data loss. You can restore a soft-deleted mailbox by using the **MailboxRestoreRequest** cmdlet set. To learn more, see Soft-Deleted Mailboxes later in this topic.

  Note:
  Soft-deleted mailboxes require that both the source Mailbox server and the Client Access server performing the request be running Exchange 2010 SP1.

- The **MoveRequest** cmdlet set has been updated to support moving archives to a separate database.

Return to top

Limitations to Moving Mailboxes in Previous Versions of Exchange

Exchange 2007 uses the **Move-Mailbox** cmdlet to move mailboxes between mailbox databases. There are limitations to using this cmdlet:

- Mailbox moves are offline. While you move a mailbox, which can take several hours, the user can't access the mailbox.
- Moving mailboxes is synchronous. The cmdlet does the actual move, and you can't close the Exchange Management Shell session while the move is being performed.
- The Dumpster folder isn't moved with the mailbox.
- Content indexing doesn't begin until after the move is completed. This results in a poor search experience for users until the indexing is completed.

- Move throttling is manually controlled by administrators.
- Moving mailboxes across forests requires direct access to Active Directory and the mailbox database.

Return to top

Advantages of Move Requests

Move requests are a new feature in Exchange 2010. There are multiple advantages to using move requests:

- Mailbox moves are asynchronous and are performed by the Microsoft Exchange Mailbox Replication service (MRS). To learn more, see Asynchronous Mailbox Moves later in this section.
- Mailboxes are kept online during the asynchronous moves. To learn more, see Online Mailbox Moves later in this section.
- The items in a mailbox's Recoverable Items folder are moved with the mailbox.

  Note:
  The Recoverable Items folder is available only in Exchange 2010. To learn more, see Understanding Recoverable Items.

- As soon as the mailbox move begins, content indexing starts to scan the mailbox so that fast searching is available upon completion of the move.
- You can configure throttling for each MRS instance, each mailbox database, or each Mailbox server.
- Remote mailbox moves work over the Internet by way of the Microsoft Exchange Mailbox Replication Proxy (MRSProxy) service. You don't need to set up a direct back-end server and Active Directory access between the forests.
- Mailbox moves can be managed from any Exchange 2010 server within the organization.
- Mailbox content doesn't move through an administrative computer. For example, in Exchange 2007, when you run the **Move-Mailbox** cmdlet, the data move is managed by the computer on which you run the cmdlet. You can't shut down that session of Exchange until the move completes.
- The mailbox's move history is maintained in the mailbox.

Asynchronous Mailbox Moves

Using the move request cmdlets in Exchange 2010, you can perform an asynchronous move because the cmdlets don't perform the actual move. The move is performed by MRS, a service that runs on all Client Access servers in your Exchange 2010 organization. Using MRS is beneficial because you can manage mailbox moves from any Exchange 2010 server within your organization after the move request is started. For more information, see Microsoft Exchange Mailbox Replication Service later in this topic.

Online Mailbox Moves

In an *online mailbox move*, end users can still access their e-mail accounts during the move. The user is only locked out of the account for a brief time at the end of the process (when the final synchronization occurs). Online mailbox moves are supported between Exchange 2010 databases and between Exchange 2007 SP3 and Exchange 2010 databases. You can perform online mailbox moves across forests or in the same forest. The process for local mailbox moves and remote mailbox moves is different from online moves and is discussed later in this topic.

Return to top

Reasons for Moving Mailboxes

You may need to move mailboxes in the following scenarios:

- **Transition** When you transition an existing Exchange 2007 or Exchange

Server 2003 organization to Exchange 2010, you move mailboxes from the existing Exchange servers to an Exchange 2010 Mailbox server.

- **Realignment** You can move mailboxes for realignment purposes. For example, you may want to move a mailbox from one database to a database that has a larger mailbox size limit.
- **Investigating an issue** If you need to investigate an issue with a mailbox, you can move that mailbox to a different server. For example, you can move all mailboxes that have high activity to another server.
- **Corrupted mailboxes** If you encounter corrupted mailboxes, you can move the mailboxes to a different server or database. The corrupted messages won't be moved.
- **Physical location changes** You can move mailboxes to a server in a different Active Directory site. For example, if a user moves to a different physical location, you can move that user's mailbox to a server closer to the new location.
- **Separation of administrative roles** You may want to separate Exchange administration from Windows operating system account administration. To do this, you can move mailboxes from a single forest into a resource forest scenario. In this scenario, the Exchange mailboxes reside in one forest and their associated Windows user accounts reside in a separate forest.
- **Outsourcing e-mail administration** You may want to outsource the administration of e-mail and retain the administration of Windows user accounts. To do this, you can move mailboxes from a single forest into a resource forest scenario.
- **Integrating e-mail and user account administration** You may want to change from a separated or outsourced e-mail administration model to a model in which e-mail and user accounts can be managed from within the same forest. To do this, you can move mailboxes from a resource forest scenario to a single forest. In this scenario, the Exchange mailboxes and Windows user accounts reside in the same forest.

Return to top

Supported Scenarios for Moving Mailboxes

The following table lists the supported scenarios for moving Exchange mailboxes and includes links to related topics.

Supported scenarios for moving mailboxes

Moving from	Moving to	Supported	Online move supported	Related topic
Exchange 2010	Exchange 2010	Yes	Yes	Managing Move Requests
Exchange 2007 SP3	Exchange 2010	Yes	Yes	Move Mailboxes from Exchange 2007 Servers to Exchange 2010 Servers
Exchange 2007 SP1	Exchange 2010	No	No	Move Mailboxes from Exchange 2007 Servers to Exchange 2010 Servers

Exchange 2003 SP2	Exchange 2010	Yes	No	Move Mailboxes from Exchange 2003 Servers to Exchange 2010 Servers
Exchange 2010	Exchange 2007 SP3	Yes	No	Move Mailboxes from Exchange 2010 Servers to Exchange 2007 Servers
Exchange 2010	Exchange 2003 SP2	Yes	No	Move Mailboxes from Exchange 2010 Servers to Exchange 2003 Servers
Exchange 2000	Exchange 2010	No	No	Not applicable
Exchange 2010	Exchange 2000	No	No	Not applicable

Return to top

Services Used in Move Requests

Move requests are processed by two services:

- Microsoft Exchange Mailbox Replication service (MRS)
- Microsoft Exchange Mailbox Replication Proxy (MRSProxy) service

Microsoft Exchange Mailbox Replication Service

When you use the move request cmdlets to move mailboxes, MRS processes the move process. As stated earlier, MRS resides on an Exchange 2010 Client Access server and is the service that moves mailboxes from the source database to the target database. In Exchange 2007, the mailbox move is performed by the **Move-Mailbox** cmdlet. By using a service as the agent of the move, mailboxes can be moved while simultaneously remaining accessible to users. During the move, you can view, cancel, and manage the move request from any Exchange 2010 server in your organization.

You can start and stop MRS as you would any service. MRS constantly checks for all move requests in its own Active Directory site. In addition, there's a sharing mechanism between all instances of MRS so that no two servers will attempt to perform the same move request.

All MRS instances in an Active Directory site work together so that database and Client Access server throttling is handled across all instances of MRS. MRS throttling is controlled by a configuration file. For more information about how to modify the configuration file, see Throttling the Mailbox Replication Service.

Microsoft Exchange Mailbox Replication Proxy Service

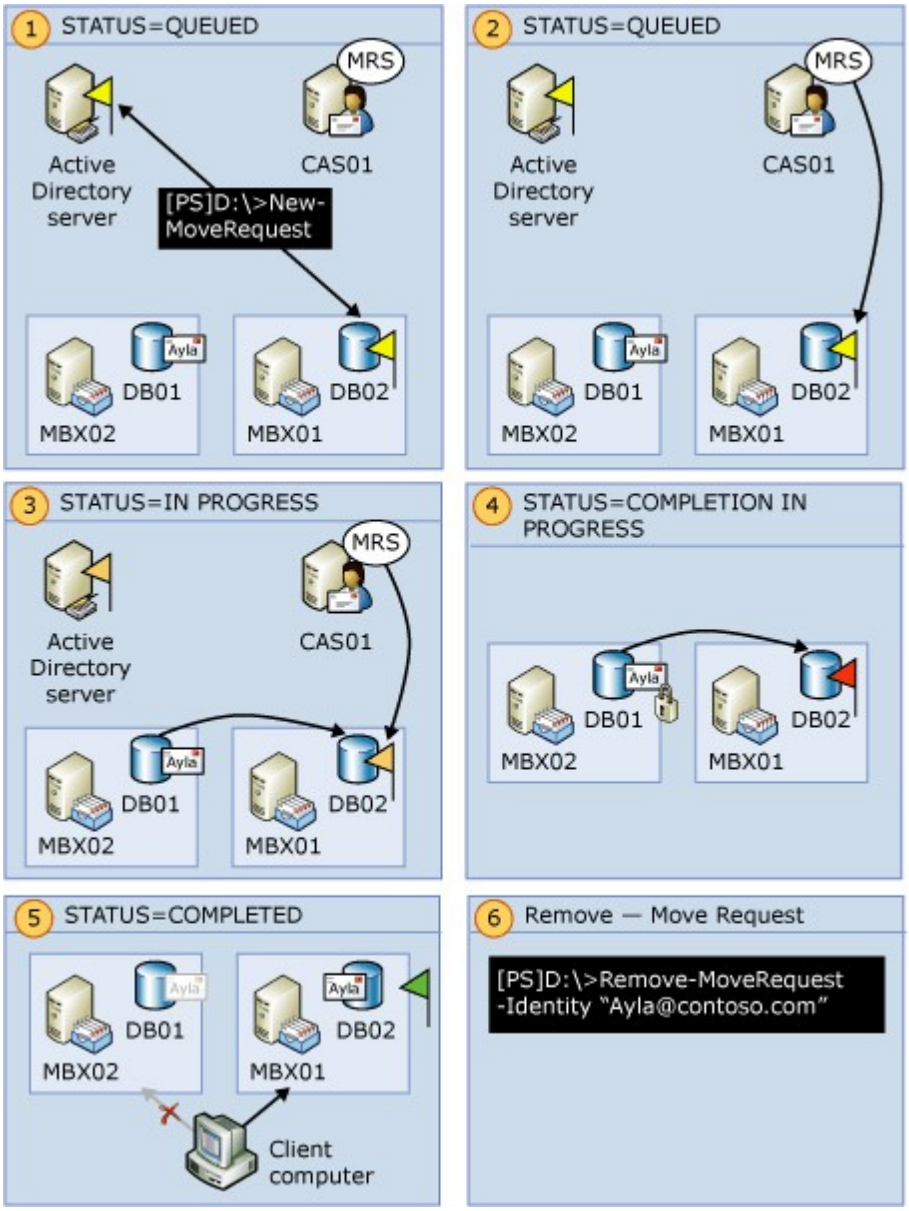
In addition to MRS, the MRSProxy service is installed on every Exchange 2010 Client Access server. MRSProxy helps to facilitate cross-forest move requests and runs on the remote forest's Exchange 2010 Client Access server. However, MRSProxy is disabled by default. You need to turn on the MRSProxy service on the remote forest. We recommend that you enable MRSProxy on all Client Access servers in the remote forest.

For more information, see Start the MRSProxy Service on a Remote Client Access Server.

Return to top

Basic Move Request Process

The following figure illustrates the basic process for local move requests.



In this scenario, Ayla's mailbox will be moved from the source database DB01 on Mailbox server MBX02 to the target database DB02 on Mailbox server MBX01. To do this, you run the following command.

```
New-MoveRequest -Identity Ayla@contoso.com -TargetDatabase "DB02"
```

The following steps describe the basic process for local move requests:

1. The command updates Active Directory, and then places a special message in the system mailbox within that Active Directory site that a move request has been initiated and is set to a status of **Queued**. Information about the move request is stored in two places: the target database's system mailbox and in Active Directory. If the move is an offline move, the mailbox is locked and

can't be accessed until the move reaches a status of **Completed**.

2. All instances of MRS periodically check the system mailbox on every database in its Active Directory site to verify if there are any queued move requests. In this example, the MRS instance on CAS01 finds Ayla's mailbox in the **Queued** status.

   Note:
   The **New-MoveRequest** cmdlet selects an instance of MRS and requests that the service process the move request immediately. If the selected instance of MRS is available, it starts the move immediately. If not, the mailbox remains in the **Queued** status until an MRS instance finds the move request.

3. MRS begins to move the data from DB01 to DB02. MRS updates the mailbox's status in the system mailbox to **In Progress**.
4. When the move is almost finished, Ayla's mailbox is locked for a short time while the final mailbox synchronization is completed. At this point, the move request status changes to **Completion In Progress**.
5. When the move is complete, Ayla's new mailbox on DB02 is activated, and the old mailbox on DB01 is soft deleted. The move request status changes to **Completed**. Depending on Ayla's e-mail client, she may need to log off and log on again to access her mailbox. For more information, see Client Experience later in this topic.
6. The administrator clears the move request information from Active Directory and on the system mailbox on DB02. Until the move request information is cleared, you can't move the mailbox again. For details about how to clear a move request, see Clear or Remove Move Requests.
   A record of the move is kept in Ayla's mailbox and can be accessed by running the Get-MailboxStatistics cmdlet with the *IncludeMoveReport* parameter. For more information, see View Move Request Properties.

Return to top

Remote Mailbox Moves

Remote mailbox moves are also known as cross-forest mailbox moves. Exchange 2010 supports two types of remote mailbox moves:

- **Remote mailbox moves that have Exchange 2010 in both forests** In this scenario, one forest is an Exchange 2010 forest, and the other forest has at least one Exchange 2010 Client Access server. You can use the Exchange Management Console (EMC) or the Exchange Management Shell to perform these mailbox moves. For details, see Create a Remote Move Request That has Exchange 2010 in Both Forests.
- **Remote mailbox moves with a legacy Exchange forest** In this scenario, one forest contains Exchange 2010, and the other forest contains Exchange 2003 SP2, Exchange 2007 SP3, or a combination of both. No Exchange 2010 Client Access server is installed in the legacy forest. You can't use the EMC to perform these mailbox moves. You must use the Shell. For details, see Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010.

Prerequisites for Moving Mailboxes Across Forests

The prerequisites for moving mailboxes across forests are extensive. For details, see Prepare Mailboxes for Cross-Forest Move Requests.

Using the TargetDatabase or the RemoteTargetDatabase Parameters

The New-MoveRequest cmdlet uses the *TargetDatabase* and the *RemoteTargetDatabase* parameters to identify the target database to which you're moving mailboxes.

TargetDatabase Parameter

The *TargetDatabase* parameter specifies the identity of the database to which you're moving the mailbox. Use this parameter to perform local and remote mailbox moves when initiating the move from the target forest. When you initiate the move from the source forest, MRS pulls the mailbox from the source forest to the target forest.

Note:

Using the *TargetDatabase* parameter is optional. If you don't specify this parameter, its usage is implied, and the mailbox provisioning load balancer specifies a target database. If you don't want the load balancer to select a database, either use the *TargetDatabase* parameter or specify the databases you want to exclude from provisioning by setting the *IsExcludedFromProvisioning* parameter to `$true` in the Set-MailboxDatabase cmdlet.

RemoteTargetDatabase Parameter

The *RemoteTargetDatabase* parameter specifies the identity of the target database in the remote forest. Use this parameter for remote mailbox moves only when you need to initiate the move from the source forest. For example, if you're moving a mailbox from an Exchange 2010 server to an Exchange 2007 or Exchange 2003 server, you initiate the move from the Exchange 2010 forest, which is the source forest. When you initiate a move from the source forest, MRS pushes the mailbox from the Exchange 2010 server to the Exchange 2007 or Exchange 2003 server.

This example pushes Tony Smith's mailbox to the remote forest.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteLegacy -RemoteTarg
```

Remote Mailbox Moves with Exchange 2010 in Both Forests

The following describes a remote mailbox move scenario:

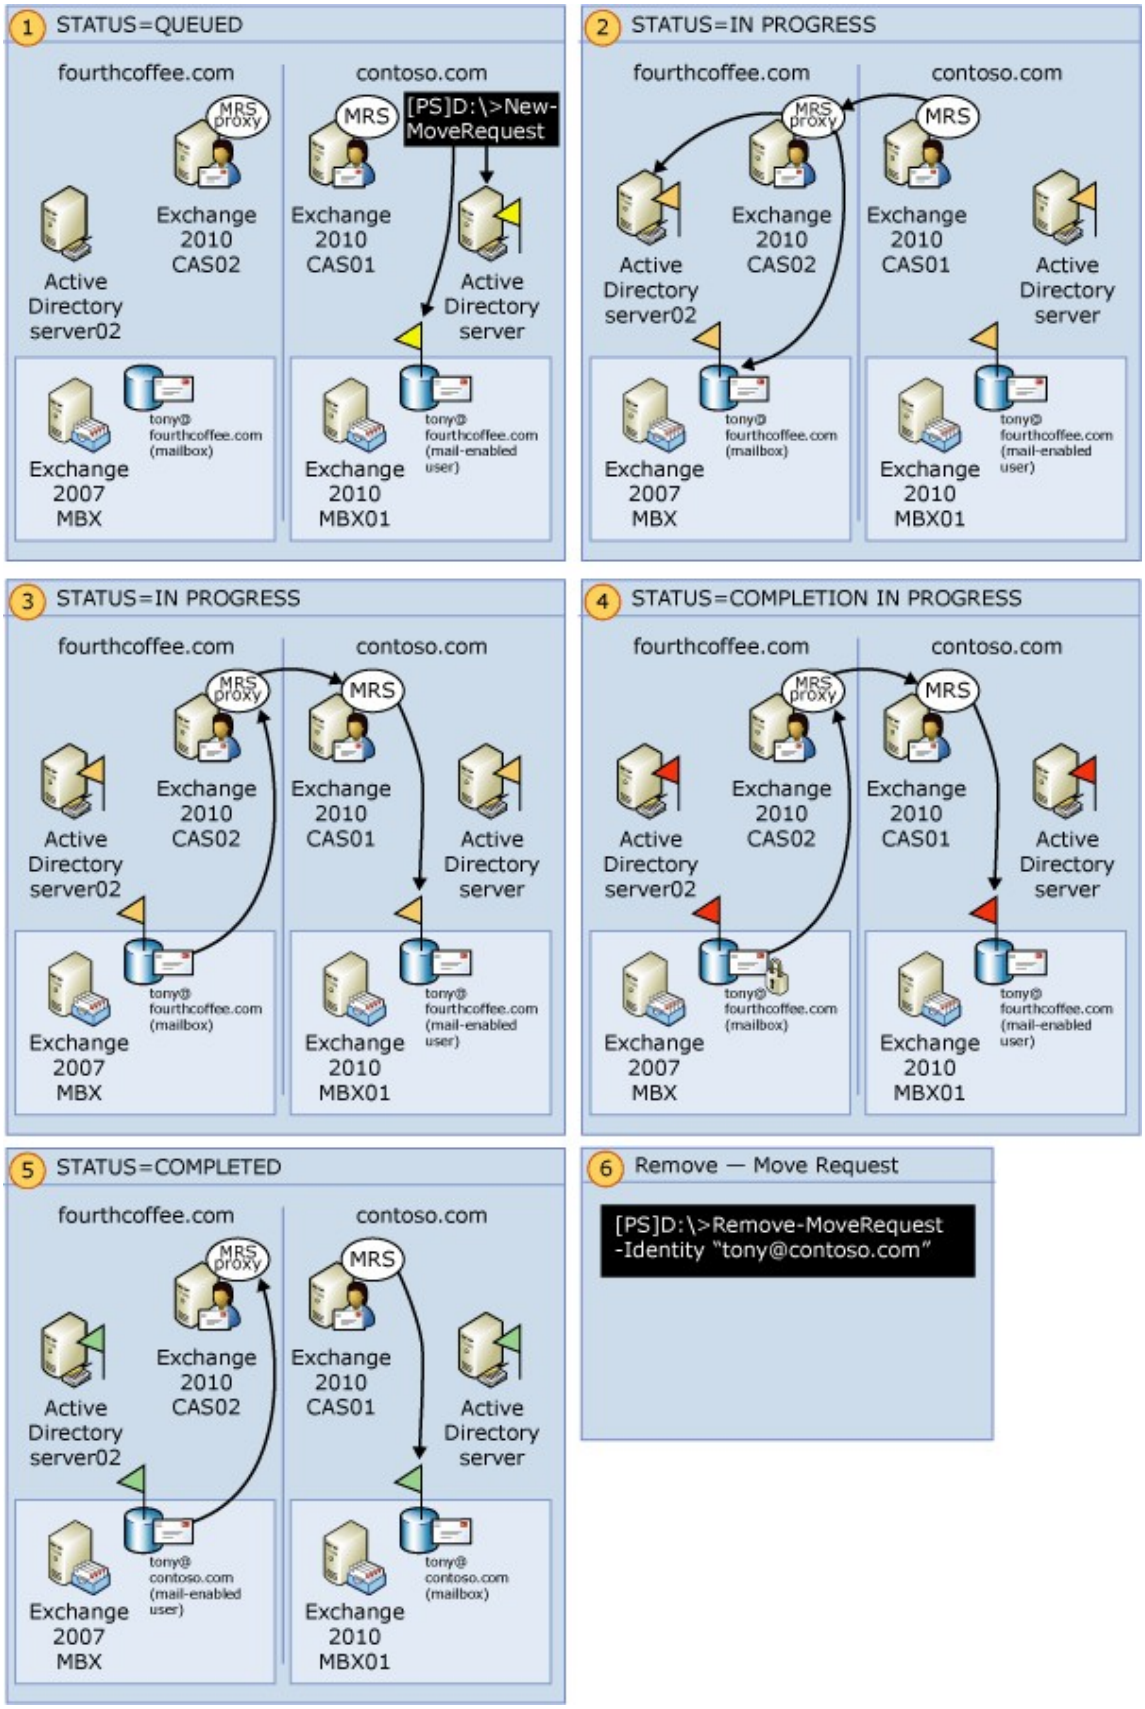
- One forest is an Exchange 2010 forest and the other forest has at least one Exchange 2010 Client Access server.
- MRS and MRSProxy exist on all Exchange 2010 Client Access servers. MRS processes the cross-forest moves.
- The Fourth Coffee and Contoso forests both contain Exchange 2010 Client Access servers, but only Contoso contains Exchange 2010 Mailbox servers. Fourth Coffee contains only Exchange 2007 SP3 Mailbox servers.
- Fourth Coffee contains the mailbox for tony@fourthcoffee.com. Contoso contains a mail-enabled user for tony@fourthcoffee.com that has all the prerequisite settings configured.
- The following command is run from the target forest, Contoso.com.

```
New-MoveRequest -Identity 'tony@fourthcoffee.com' -TargetDatabase DBa
```

Note:

If Tony's mailbox were being moved from an Exchange 2003 server, the move would be offline, and Tony wouldn't be able to access his mailbox until the move was complete.

The following figure illustrates this remote mailbox move scenario.



1 STATUS=QUEUED

tony@contoso.com (mailbox)
6 Remove — Move Request
[PS]D:\>Remove-MoveRequest -Identity "tony@contoso.com"

1. The **New-MoveRequest** cmdlet prompts MRS on the Client Access server in the Contoso forest. The cmdlet updates the Contoso Active Directory information and the system mailbox on the target database. At this point, the move request status is **Queued**.
2. To initiate the move, MRS in the Contoso forest communicates through MRSProxy in the Fourth Coffee forest. MRSProxy then updates the Fourth Coffee Active Directory information and the system mailbox on the remote database. At this point, the status changes to **In Progress**.
3. The MRS server in the Contoso forest pulls Tony's mailbox data from the Mailbox server through the MRSProxy server in Fourth Coffee to the mail-enabled user tony@fourthcoffee.com. At this point, the status is **In Progress**.
4. When the mailbox move is almost complete, MRSProxy locks Tony's mailbox at Fourth Coffee for a short time while final synchronization is completed. At this point, the status is **Completion In Progress**.
5. In the Contoso forest, MRS converts the mail-enabled user tony@fourthcoffee.com to the mailbox tony@contoso.com. In the Fourth Coffee forest, MRSProxy converts the mailbox tony@fourthcoffee.com to the mail-enabled user tony@contoso.com, and the mailbox is soft deleted. At this point, the status is **Completed**. Tony can now access his mailbox in the Contoso forest. Depending on Tony's e-mail client, he may need to log off and log on again to access his mailbox. For more information, see Client Experience later in this topic.
6. The administrator clears the move request information from Active Directory and from the system mailbox. Until the move request information is cleared, you can't move the mailbox again. For details about how to clear a move request, see Clear or Remove Move Requests.
   A record of the move is kept in Tony's mailbox and can be accessed by running the Get-MailboxStatistics cmdlet with the *IncludeMoveReport* parameter.

Note:

If you want to move the mailbox back to the remote forest, you must initiate the move in the Contoso forest. This is because the Contoso Mailbox server is running the latest version of Exchange (in this case, Exchange 2010). In addition, you must use the *RemoteTargetDatabase* parameter when you run the **New-MoveRequest** cmdlet.

Remote Legacy Mailbox Moves

If you're moving mailboxes remotely to or from Exchange 2007 or Exchange 2003 organizations, and those organizations don't contain an Exchange 2010 Client Access server, MRS in the Exchange 2010 forest will directly access the remote legacy database and the remote organization's Active Directory server. When performing a remote legacy move request, you must supply the following information in the command:

- Identity of the mail-enabled user
- *RemoteLegacy* switch
- Fully qualified domain name (FQDN) of the remote global catalog server
- FQDN of the external e-mail address created in the source forest for the mail-enabled user when the move request is complete
- Target database when moving mailboxes to Exchange 2010 or the remote target database when moving mailboxes from Exchange 2010 to the remote legacy database

The following describes a remote legacy mailbox move scenario:

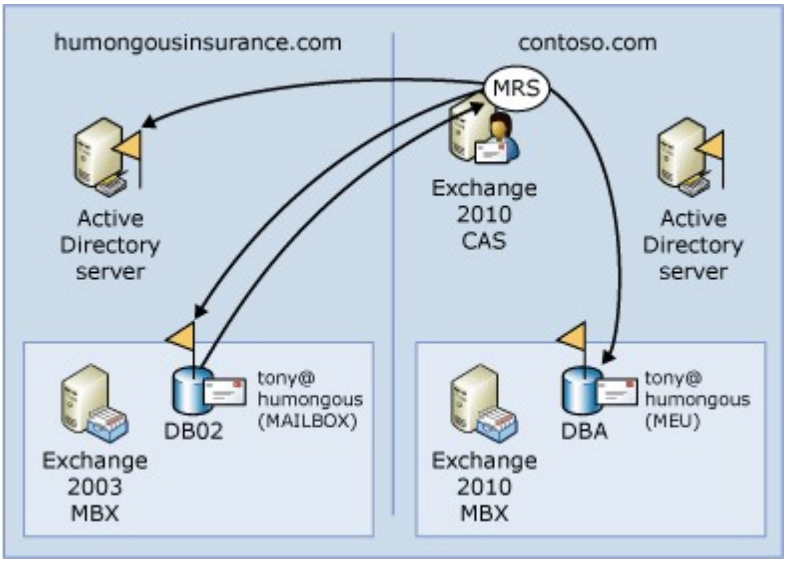
- The legacy forest (Humongous Insurance) doesn't contain an Exchange 2010 Client Access server. This scenario is similar to the remote move request process. However, because the remote legacy forest doesn't have an instance of MRSProxy to connect with, MRS in the Contoso forest connects directly to the Humongous Insurance Active Directory server and system mailbox on the Exchange 2003 mailbox database.
- When you move Exchange 2003 mailboxes to Exchange 2010, the mailbox

move will be offline. During the move, the users won't be able to access their mailboxes. When you move Exchange 2007 SP3 to Exchange 2010 mailboxes, the move will be online, and the users can access their mailboxes during the move.

- The following command is run from the target forest, Contoso.com.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteLegacy
-TargetDatabase DB02  -RemoteGlobalCatalog 'GC01.humongousinsurance.com
```

The following figure illustrates this remote legacy mailbox move scenario.



Return to top

Mailbox Moves Using a Script

The MoveMailbox.ps1 script in Exchange 2010 provides a synchronous mailbox move management experience similar to the Exchange 2007 **Move-Mailbox** cmdlet. By default, scripts are installed at C:\Program Files\Microsoft\Exchange Server\V14\Scripts. For more information, see Move Mailboxes by Using the MoveMailbox.ps1 Script in the Shell.

Note:
You can use this script for local moves only. You can't use this script for cross-forest moves.

MoveMailbox.ps1 performs the following tasks:

1. Creates a local move request.
2. Waits for the mailbox move to complete.
3. Removes the move request after it's complete.

Return to top

Soft-Deleted Mailboxes

When mailboxes are moved from an Exchange 2010 SP1 database to any other database, Exchange doesn't fully delete the mailbox from the source database immediately upon completion of the move. Instead, the mailbox in the source mailbox database is switched to a soft-deleted state. Mailbox data can be accessed during a mailbox restore operation

using the **MailboxRestoreRequest** cmdlet set. The soft-deleted mailboxes are retained in the source database until either the deleted mailbox retention period expires or you use the Remove-StoreMailbox cmdlet to purge the mailbox.

Note:

Soft-deleted mailboxes require that both the source Mailbox server and the Client Access server performing the request be running Exchange 2010 SP1.

To view soft-deleted mailboxes, run the Get-MailboxStatistics cmdlet against a database and look for results that have a **DisconnectReason** property with a value of `SoftDeleted`.

Personal Archives

In the release to manufacturing (RTM) version of Exchange 2010, if a personal archive exists for a mailbox that you want to move, the archive gets moved with the primary mailbox. This is because the personal archive and the primary mailbox must reside on the same mailbox database. Before moving mailboxes that have a personal archive, you should consider the size of the archive. Consider database size and how that size might impact the time the move will take to complete.

In Exchange 2010 SP1, personal archives and mailboxes can exist on separate databases. The move request cmdlets and the move request user interface (UI) in the EMC support moving mailboxes and personal archives together or separately. By default, the primary mailbox and the archive are moved together. For more information about moving an archive and primary mailbox separately, see Create a Local Move Request.

If you're moving mailboxes from an Exchange 2010 server to an Exchange 2007 or Exchange 2003 server, you must first disable the personal archive before you can move the mailbox. For details, see Disable a Personal (On-Premises) or Cloud-Based Archive for a Mailbox.

To learn more about personal archives, see Understanding Personal Archives.

Return to top

Shared Mailboxes and Resource Mailboxes

In addition to the default user mailboxes, you can move shared mailboxes and resource mailboxes. A *shared mailbox* is a mailbox to which multiple users can log on. A *resource mailbox* is a mailbox that represents a type of resource, such as a conference room or video equipment. Resource mailboxes have additional properties in Active Directory that user mailboxes and shared mailboxes don't have, such as capacity.

Exchange 2003 doesn't support resource mailboxes. Instead, you must use shared mailboxes to represent resources. If you move a shared mailbox from Exchange 2003 to Exchange 2010, MRS creates the mailbox as a shared Exchange 2010 mailbox. After you move the mailbox to Exchange 2010, you can convert it to a resource mailbox. For details about how to convert a shared mailbox to a resource mailbox, see Convert a Mailbox.

Return to top

Mailbox Moves During Server Failures

Move requests can handle transient errors. MRS conducts checkpoints every 5 minutes to make sure that the database to which the mailbox being moved is still operational. If MRS finds that the target database isn't operational, MRS will pause for 30 seconds, and then retry the move. If you experience a failover, the move won't fail. Instead, MRS will detect

a database failover, determine the new location of the database, and then restart the move process.

Another error that could occur is if the Client Access server on which MRS is running stops responding. If this happens, the move stops, and one of the other MRS instances will continue the process and complete the move.

For more information, see Troubleshooting Mailbox Moves.

Return to top

Client Experience

The following table lists the different experiences end users will have, based on the version of Exchange that their mailbox is being moved to and from, and based on which client application they're using when the move request begins.

Client experience based on Exchange version and client application

Moving from	Moving to	Client application being used when the move starts	End-user experience
Exchange 2010 or Exchange 2007 SP2	Exchange 2010	Microsoft Outlook 2010, Office Outlook 2007, or Office Outlook 2003	When the move request has a status of **Completion in Progress**, the mailbox will be locked for a short time. When the move is complete, Outlook displays a message notifying the user to close and restart Outlook.
Exchange 2010	Exchange 2010	Outlook Web App	When the move request has a status of **Completion in Progress**, the mailbox is locked for a short time. If users are logged on to Outlook Web App when the mailbox is locked, or if they attempt to log on while the mailbox is locked, they will receive an error stating that the mailbox is being moved, and they won't be able to log on until the move is complete. If users aren't logged on at the time, they won't be aware of the move unless the URL

			that they use to access Outlook Web App changed. If the URL changed, users receive a message similar to the following: "Use the following link to open this mailbox with the best performance: https://mail.contoso.com/owa" When users click the link, they are directed to the new location and can log on using their credentials.
Exchange 2007 SP3	Exchange 2010	Microsoft Outlook Web Access	When the move request has a status of **Completion in Progress**, the mailbox is locked for a short time. If users are logged on to Outlook Web Access when the mailbox is locked, they are automatically logged off and need to log on again to view their mailbox. If users aren't logged on at the time, they won't be aware of the move unless the URL that they use to access Outlook Web Access changed. If it changed, users receive a message similar to the following: "Use the following link to open this mailbox with the best performance: https://mail.contoso.com/owa" When users click the link, they are directed to the new location and can log on using

			their credentials.
Exchange 2010 or Exchange 2007 SP3	Exchange 2010	Outlook Mobile Access	When the move request has a status of **Completion in Progress**, the mailbox is locked for a short time. Users experience an interruption only if the Outlook Web App URL that they use has changed. If the URL has changed, users must modify the URL in their phone's e-mail settings.
Exchange 2010 or Exchange 2007 SP3	Exchange 2010	Third-party client application	When the move request has a status of **Completion in Progress**, the mailbox is locked for a short time. If users are using a third-party client application (such as Eudora), check with the manufacturer to determine whether users need to log off and then log on again after the move request is complete.
Exchange 2003 SP2 or SP3	Exchange 2010	Outlook 2003 and Outlook Web Access	This is an offline move, and users can't access their mailbox during the move request process. However, users can use Outlook to access mail archived locally. User can't use Outlook Web Access during this time. When the move is complete, Outlook displays a message notifying users to close and restart Outlook.
Exchange 2003 SP2	Exchange 2010	Outlook Mobile Access	When the move request has a status of **Completion in Progress**, the mailbox

			is locked for a short time. Users experience an interruption only if the Outlook Web Access URL that they use has changed. If the URL has changed, users must modify the URL in their phone's e-mail settings.
Exchange 2010	Exchange 2007 SP3	Outlook 2007 and Outlook Web Access	This is an offline move, and users can't access their mailbox during the move request process. However, users can use Outlook to access mail archived locally. Users can't use Outlook Web Access during this time. When the move is complete, Outlook displays a message notifying users to close and restart Outlook.
Exchange 2010	Exchange 2003 SP2	Outlook 2003 and Outlook Web Access	This is an offline move, and users can't access their mailbox during the move request process. However, users can use Outlook to access mail archived locally. Users can't use Outlook Web Access during this time. When the move is complete, Outlook displays a message notifying users to close and restart Outlook.

1.8.1.11 Understanding Offline Address Books

Understanding Offline Address Books

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-10*

An offline address book (OAB) is a copy of a collection of address lists that has been downloaded so that a Microsoft Outlook user can access the information it contains while disconnected from the server. Microsoft Exchange generates the new OAB files, compresses the files, and then places the files on a local share. Exchange administrators can choose which address lists are made available to users who work offline, and they can also configure the method by which the address books are distributed.

For more information about address lists, see Understanding Address Lists.

Important:

OAB data is produced by the Microsoft Exchange System Attendant service running as Local System. If an administrator uses the security descriptor to prevent users from viewing certain recipients in Active Directory, users who download the OAB will be able to view those hidden recipients. Therefore, to hide a recipient from an address list, you set the *HiddenFromAddressListsEnabled* parameter on the **Set-PublicFolder**, **Set-MailContact**, **Set-MailUser**, **Set-DynamicDistributionGroup**, **Set-Mailbox**, and **Set-DistributionGroups** cmdlets. Alternatively, you can create a new default OAB that doesn't contain the hidden recipients. For more information about how to add or remove address lists from an OAB, see Add or Remove an Address List from an Offline Address Book.

Looking for management tasks related to managing Mailbox servers? See Managing Mailbox Servers.

Contents

Moving OABs Between Exchange Versions

Exchange supports moving OABs only in the following configurations:

- Between servers running Microsoft Exchange Server 2010
- From Exchange 2010 to Exchange Server 2007 servers
- From Exchange 2007 to Exchange 2010 servers
- From Exchange Server 2003 to Exchange 2010 servers

Exchange doesn't support moving OABs from Exchange 2010 to Exchange 2003 servers.

Return to top

Outlook Clients and OAB Version

You can specify the OAB versions that are generated for client download. The following options are available:

- **OAB version 2 (ANSI OAB)** This OAB format is used with both Microsoft Exchange 2000 Server and Exchange Server version 5.5. Exchange 2003 also supports ANSI OABs. The following versions of Outlook supports OAB version 2:
  - Outlook 2010
  - Office Outlook 2007
  - Office Outlook 2003
  - Outlook 2002
  - Outlook 2000
  - Outlook 98
- **OAB version 3 (Unicode OAB)** This OAB is used for Exchange 2003. This OAB has additional information that helps Outlook reduce server remote procedure calls (RPCs). Additionally, the Unicode OAB has new features that are related to sorting rules for different language locales. These features permit the following versions of Outlook to use the correct sorting rule for the language locale with the OAB:
  - Outlook 2010
  - Outlook 2007
  - Outlook 2003
- **OAB version 4 (Unicode OAB)** This OAB was introduced in Exchange 2003 Service Pack 2 (SP2) and is supported by Outlook 2003 (SP2), Outlook 2007, and Outlook 2010. This Unicode OAB allows client computers to receive differential updates rather than full OAB downloads.

Outlook Clients That Use OAB Version 3 and Version 2

For Outlook clients that use OAB version 3 and version 2, if the size of the Changes.oab file is one-eighth (or more) the size of the entire OAB file, Outlook initiates a full OAB download.

For example, Outlook will obtain the size of the compressed Changes.oab files. Outlook will then obtain the total size of all the compressed full OAB files on the server, including the templates. If the size of the Changes.oab files is greater than one-eighth the size of the full OAB files, Outlook will download the full OAB instead of the incremental files.

Minor changes to recipient attributes will cause all recipient information to be included in the Changes.oab file. The following are examples of these minor changes:

- Updating phone numbers to reflect a new area code for a large number of recipients
- Adding an additional proxy address to a large number of recipients

Therefore, changing minimal bytes of information for half of your recipients could create a Changes.oab file that's larger than one-eighth the size of your entire OAB file.

Outlook Clients That Use OAB Version 4

For Outlook 2010, Outlook 2007, and Outlook 2003 SP2 clients that use OAB version 4, if the size of the Changes.oab files is one-half (or more) the size of the entire OAB files, Outlook initiates a full OAB download. For more information about improvements that have been made in OAB version 4, see "Improvements in Exchange 2003 SP2 and Outlook 2003 SP2" in Improvements for Offline Address Books.

Return to top

OAB Distribution Methods

You can choose which address books are made available to users who work offline. When the OAB generation (OABGen) process occurs, Exchange generates new OAB files,

compresses the files, and then places the files on a local share. You can then configure the method by which the address books are distributed. There are two methods by which the OAB is distributed to client computers:

- Web-based distribution
- Public folder distribution

Web-Based Distribution

Web-based distribution is the distribution method by which Outlook 2010 or Outlook 2007 clients that are working offline or through a dial-up connection access the OAB. If you use Web-based distribution, you don't have to use public folders.

With Web-based distribution, after the OAB is generated, the Client Access server replicates the files. Web-based distribution uses HTTPS and Background Intelligent Transfer Service (BITS). For an overview about how BITS works, see About BITS.

Important:

Although Web-based distribution is enabled by default and doesn't require further configuration, we recommend that you enable Secure Sockets Layer (SSL) for the OAB distribution point. For more information, see Require SSL for Offline Address Book Distribution.

There are several advantages to using Web-based distribution, including:

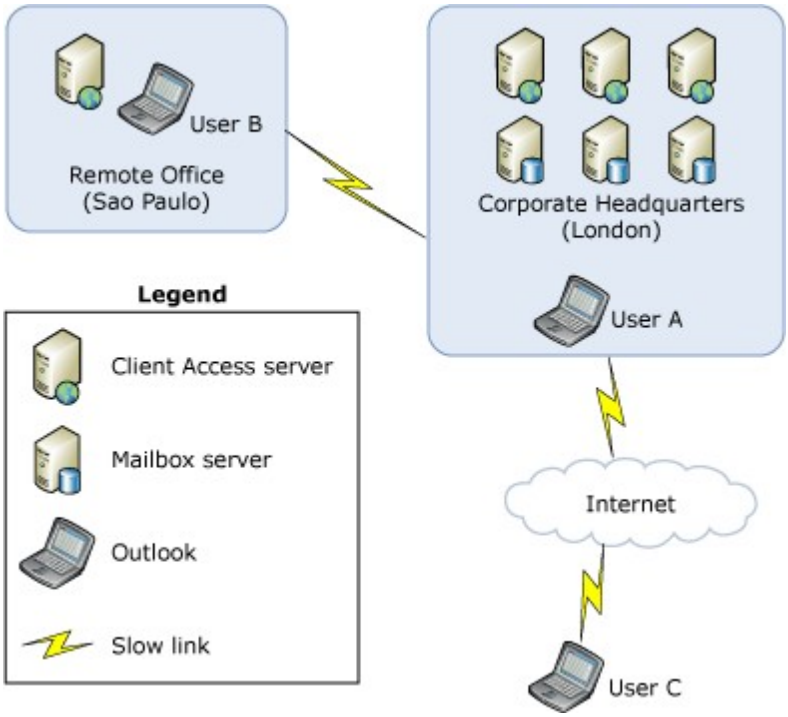
- Support of more concurrent client computers.
- Reduction in bandwidth usage.
- More control over the OAB distribution points. With Web-based distribution, the distribution point is the HTTPS Web address where client computers can download the OAB.

To benefit most from Web-based distribution, client computers must be running Outlook 2010 or Outlook 2007. Organizations that also have client computers running Outlook 2003 or earlier can use both public folder distribution and Web-based distribution. The Outlook 2003 Service Pack 1 (SP1) and earlier clients will still access their OABs by using public folders, while Outlook 2010 or Outlook 2007 clients will take advantage of the new Web-based distribution method.

To function properly, Web-based distribution depends on the following components:

- **OAB generation process** This is the process by which Exchange creates and updates the OAB. To create and update the OAB, the OABGen service runs on the OAB generation server. To support OAB distribution, this server must be an Exchange Mailbox server.
- **Microsoft Exchange File Distribution service** The Microsoft Exchange File Distribution service runs on Client Access servers and is responsible for gathering the OAB and keeping the content synched with the content on the Mailbox server.
- **OAB virtual directory** The OAB virtual directory is the distribution point used by the Web-based distribution method. By default, when Exchange is installed, a new virtual directory named OAB is created in the default internal Web site in Internet Information Services (IIS). If you have client-side users that connect to Outlook from outside your organization's firewall, you can add an external Web site. Alternatively, when you run the **New-OABVirtualDirectory** cmdlet in the Exchange Management Shell, a new virtual directory named OAB is created in the default IIS Web site on the local Exchange Client Access server. For information, see Create an Offline Address Book Virtual Directory.
- **Autodiscover service** This is a feature available in Outlook 2010 or Outlook 2007 and in some mobile devices that automatically configure the clients for access to Exchange. The service runs on a Client Access server and returns the correct OAB URL for a specific client connection. For more information about the Autodiscover service, see Understanding the Autodiscover Service.

The following figure illustrates workflow for the OAB Web-based distribution method. The figure assumes that all client users have the same OAB and that the OAB is distributed to all Client Access servers.



In this figure, a company has offices in London and Sao Paulo. The Mailbox servers for the entire company are in the corporate headquarters in London. Sao Paulo, which is a slow link, has Client Access servers to which the Sao Paulo client users connect to Outlook. In addition, the company has users who work remotely and connect to the corporate network through the Internet.

Before a user connects to a MAPI-based client computer, such as Outlook, the following happens:

1. The OAB is generated on one of the Mailbox servers in the London office.
2. On each of the Client Access servers in London, the Microsoft Exchange File Distribution service copies the new OAB files from the OAB Mailbox server in London.
3. On the Client Access server in Sao Paulo, the Microsoft Exchange File Distribution service copies the files over the slow link from the Mailbox server in London. Depending on the speed of the slow link, the copy process may take from several minutes to several hours. The new OAB isn't made available to client computers until it's completely copied and verified.

Note:
Not all Client Access servers will copy the new OAB at the exact same time. There is a poll interval (the default is 8 hours) that starts copying if there are new differential files. The first poll occurs when the Microsoft Exchange File Distribution service starts. Therefore, unless the Client Access servers were started at the same time, the server polls will be different on each Client Access server.

After all of the Client Access servers have copied the OAB content, there are several scenarios by which the client user will download the OAB:

- **Scenario 1** Onsite user

In this scenario, all actions occur in the London office:

.1.User A, who's located in the London office and whose Outlook is set to Cached Exchange Mode, connects to Outlook.
.2.Outlook connects to the Autodiscover service to obtain the URL to the closest OAB distribution point.
.3.The Autodiscover service returns the URL to one of the Client Access servers in London.
.4.Outlook uses BITS to connect to the URL that was provided by the Autodiscover service.
.5.Outlook downloads the OAB.

- **Scenario 2** Slow link user
  In this scenario, the User B mailbox resides in the London office because there are no Mailbox servers in the Sao Paulo office. Because User B is preparing to leave for a business trip and requires a local copy of the OAB, User B must download the OAB. The User B OAB will be downloaded from the Client Access server that's closest to the Sao Paulo office:
  .1.User B, who's located in the Sao Paulo office, connects to Outlook.
  .2.Outlook connects to the Autodiscover service to obtain the URL to the closest OAB distribution point.
  .3.The Autodiscover service returns the URL to the Client Access server in Sao Paulo.
  .4.Outlook uses BITS to connect to the URL that was provided by the Autodiscover service.
  .5.Outlook downloads the OAB. However, because the Sao Paulo Client Access server copies the OAB to London over a slow link, User B may not get the most recent version of the OAB.
- **Scenario 3** Internet user
  In this scenario, because the user connects using the Internet, Exchange can't locate the Client Access server that's closest to the user's physical location. Therefore, Exchange defaults to a Client Access server that's close to the user's Mailbox server:
  .1.User C, whose Mailbox server is in London, connects to Outlook from the Internet.
  .2.Outlook connects to the Autodiscover service to obtain the URL to the closest OAB distribution point.
  .3.Because the User C mailbox is located on the Mailbox server in London, the Autodiscover service returns the URL to one of the Client Access servers in London.
  .4.Outlook connects to the URL that was provided by the Autodiscover service by using BITS.
  .5.Outlook downloads the OAB.

Public Folder Distribution

Public folder distribution is the distribution method by which Outlook 2003 SP1 or earlier clients that are working offline or through a dial-up connection access the OAB. With public folder distribution, the OAB generation process places the files directly in one of the public folders, and then Exchange store replication copies the data to other public folder distribution points.

With public folder distribution, every request for a full OAB download is served immediately. For example, if a public folder that's serving 10,000 users receives 1,000 requests in one hour, and the OAB size is 5 megabytes (MB), the server will immediately transmit 5 gigabytes (GB) of data. Depending on network speed and available bandwidth, this volume of traffic could potentially overload the network for an extended period.

To prevent this overload, you can set a bandwidth threshold to limit the network bandwidth that results from OAB downloads. This process is called *throttling*.

By default, throttling is turned off. You can activate throttling by adding the following entry to the registry on all public folder servers that host OAB system folders.

Caution:
Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\MSExchangeIS\ParametersSystem

Type: DWORD

Value: OAB Bandwidth Threshold (KBps)

Value Data: bandwidth threshold setting (Range: 0 to 4194304 (decimal))

The bandwidth threshold setting is in kilobytes per second (KBps) and should be configured with a decimal value. For example, setting the registry key to a decimal value of 5,000 configures the public folder server to use 5,000 KBps as the bandwidth threshold for OAB downloads, which is approximately 40,960 kilobits per second (Kbps), or 40.96 megabits per second (Mbps). After the setting has been added and configured, Exchange will dynamically detect the registry entry and begin enforcing the bandwidth limit without requiring the Microsoft Exchange Information Store service to restart.

Each time an OAB download request occurs, administrative rights on the Exchange server are verified for the requestor. If the security context that's used for the request is the equivalent of the local administrator on the Exchange server, it's assumed that an internal function is requesting the download. In this event, the requestor is allowed to proceed with a full OAB download. However, the bytes that are transmitted to the administrative client are still calculated as part of the average full OAB bytes downloaded. If the requestor doesn't have administrative rights, the average full OAB bytes that are downloaded over the last 10 seconds are determined. If this value is less than the configured threshold, a full OAB download is allowed.

Note:
Setting the registry key to 0 allows a maximum of one client without administrative rights, in 10 second intervals, at a time to download a full OAB.

When setting the OAB download bandwidth threshold, we recommend that you configure thresholds on the individual servers to values that won't cause an overload of the Exchange server's network adapter or the network. If you haven't already gathered and analyzed network and Exchange server performance data, you should do so before you configure the registry entry.

Effects of OAB Downloads on the Network When Using Public Folder Distribution

Because there are several cases that can cause a large number of full OAB downloads, you should understand the effect on bandwidth that a large OAB download has on the network.

The Exchange server can easily handle many download requests for the OAB. As a result, multiple attempts to download a full OAB over a slow link can saturate a network. (All the available bandwidth is being used.) When this happens, there are two significant effects:

- Applications that must use the wide area network (WAN) will perform slowly. This is because they wait for their network requests to traverse the saturated WAN link.
- The actual traffic needed on the WAN increases because individual network requests may time out, resulting in additional requests being made.

When the network becomes saturated, the latency increases, not only the time it takes for each client computer to download the OAB, but the overall duration of the download

process. Normally, this means that the data rate for each client computer is reduced. However, if the latency is too high, RPC packets will time out, causing additional RPC requests for the same data to be retrieved. Also, if an Outlook user attempts to download the OAB and the download is canceled or fails, Outlook deletes the data that has been downloaded and attempts to download the OAB again. As a result, more data is requested, which in turn, increases the overall duration for a large set of OAB downloads.

Outlook downloads the OAB from the Exchange server through a series of RPC packets. Each packet is received and acknowledged, and then the next packet is sent. Based on the latency between Outlook and Exchange, a single Outlook client is limited to how quickly it can receive and acknowledge each packet. Because of this delay, a single Outlook client may not be able to saturate a network link. However, as more Outlook clients begin to download the OAB, the combined download rate of all clients could saturate the link. The link will remain saturated until the full OABs are downloaded.

The relationship is linear in that the larger the latency between the Outlook client and the Exchange server, the fewer packets can be received. Fewer clients are able to download an OAB before a slow link is saturated. The reverse is also true. If latency is low, more clients are needed to saturate a slow link. The number of Outlook clients that can download the OAB simultaneously without saturating the WAN will increase as either network latency decreases or network bandwidth increases.

Return to top

OAB Considerations

As a best practice, whether you use a single OAB or multiple OABs, consider the following factors as you plan and implement your OAB strategy:

- Size of each OAB in your organization. For more information, see "OAB Size Considerations" later in this topic.
- Number of OAB downloads.
- Number and frequency of parent distinguished name changes.
- SMTP address mismatches.
- Overall number of changes made to the directory.

OAB Size Considerations

For some organizations, the OAB is a small file that remote users occasionally download. For these organizations, downloading the OAB is usually not a concern. However, for some large organizations that have large directories, or for organizations that have deployed Outlook 2003 in Cached Exchange Mode, it may be a concern, especially if the organizations have consolidated Exchange servers into a regional data center.

OAB sizes can vary from a few megabytes to a few hundred megabytes. The following factors can affect the size of the OAB:

- Usage of certificates in a company. The more public key infrastructure (PKI) certificates, the larger the OAB. PKI certificates range from 1 kilobyte (KB) to 3 KB. They're the single largest contributor to the OAB size.
- Number of mail recipients in Active Directory.
- Number of distribution groups in Active Directory.
- Information that a company adds to Active Directory for each mailbox-enabled or mail-enabled object. For example, some organizations populate the address properties on each user; others don't.

Return to top

1.8.1.12 Understanding Public Folders

Understanding Public Folders

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-17*

Public folders, introduced in the first version of Microsoft Exchange, are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. Public folders are hierarchically organized, stored in dedicated databases, and can be replicated between servers running Exchange.

Public folders aren't designed for the following purposes:

- **Archiving data** Public folders aren't designed for archiving data. Users who have mailbox limits sometimes use public folders instead of their personal folders (.pst) files to archive data. This practice isn't recommended because it affects storage on public folder servers and undermines the goal of mailbox limits.
- **Document sharing and collaboration** Public folders aren't designed for document sharing and collaboration. Public folders don't provide versioning or other document management features, such as controlled check-in and check-out functionality, and automatic notifications of content changes.

In Exchange Server 2010, public folders are an optional feature. If all client computers in your organization are running Microsoft Outlook 2010 or Office Outlook 2007, there are no dependencies on public folders for features such as free and busy information and offline address book (OAB) downloads. Instead of using public folders for OAB downloads and free and busy information, in Exchange 2010, these features are serviced by the Autodiscover service, the Microsoft Exchange System Attendant service, and the Microsoft Exchange File Distribution service.

Until all client computers in your organization are running Outlook 2010 or Outlook 2007, you should continue using public folders.

Contents

Public Folder Database Creation During Setup

Computers running Outlook 2003 and earlier or Microsoft Entourage require a public folder database (previously called the public folder store) to connect to Exchange. Therefore, in a pure Exchange 2010 organization, as you install the Mailbox server role on the first server, Setup prompts you with the question: **Do you have any client computers running**

Outlook 2003 and earlier or Entourage in your organization? If the answer is yes, a public folder database is created. If the answer is no, a public folder database isn't created.

When you install the second server, you aren't prompted with the question, and Setup doesn't create a public folder database. Whether a public folder database is needed in the organization is decided only when you install the first server. After that, all public folder databases are optional. If you don't create a public folder database during Setup, you can always create one anytime after Setup is complete. For more information about how to create a public folder database, see Create a Public Folder Database.

In a mixed Exchange organization, Setup doesn't prompt you with the question. In these organizations, to ensure backward compatibility to Exchange versions prior to Exchange Server 2007, a public folder database is created by default. Specifically, because Exchange 2010 is installed in its own administrative group, this public folder database will support legacy Schedule+ free and busy functionality.

For more information about installing Exchange 2010, see Deploying Exchange 2010.

Return to top

Public Folder Trees

The MAPI folder tree is divided into the following subtrees:

- **Default public folders (also known as the IPM_Subtree)** Users can access these folders directly by using client applications such as Outlook.
- **System public folders (also known as the Non_IPM_Subtree)** Users can't access these folders directly by using conventional methods. Client applications such as Outlook use these folders to store information such as free and busy data, OABs, and organizational forms. Other system folders contain configuration information used by custom applications or by Exchange. The public folder tree contains additional system folders, such as the EFORMS REGISTRY folder, that don't exist in general purpose public folder trees. System folders include the following:
  - **EFORMS REGISTRY and Events Root** By default, one content replica of each of these folders resides in the default public folder database on the first Exchange server installed in the first administrative group. This is the location where organizational forms are stored for legacy Outlook clients (clients using an Outlook version earlier than Outlook 2007).
  - **Offline Address Book and Schedule+ Free Busy** The Offline Address Book folder and the Schedule+ Free Busy folder automatically contain a subfolder for each administrative group (or site) in your topology. By default, a content replica of a specific administrative group folder resides on the first server installed in the administrative group. These folders are used to store legacy free and busy information and OAB data for legacy Outlook clients. Legacy Outlook clients don't support the new features in Exchange 2010 or Exchange 2007 that manage free and busy information and OAB data. (These features include the Availability service, the Autodiscover service, and OAB distribution on Client Access servers.)
  - **OWAScratchPad** Each public folder database has an OWAScratchPad folder, which is used to temporarily store attachments that are being accessed by using Microsoft Office Outlook Web App. Don't modify this folder.
  - **StoreEvents** Each public folder database has a StoreEvents folder, which holds registration information for custom Exchange database events. Don't modify this folder.
  - **Other folders** To support internal Exchange database operations, a tree may contain several other system folders, such as schema-root. Don't modify these folders.

Return to top

Public Folder Replication

Public folder databases replicate two types of public folder information:

- **Hierarchy** Properties of the folders and organizational information about the folders (including the tree structure). All public folder databases have a copy of the hierarchy information. For a specific folder, the public folder database can use hierarchy information to identify the following:
  - Permissions on the folder
  - Servers that hold content replicas of the folder
  - Folder's position in the public folder tree (including its parent and child folders, if any)
- **Content** Messages that form the content of the folders. To replicate content, you must configure a folder to replicate its content to a specific public folder database or list of databases. Only the databases that you specify will have copies of the content. A copy of the folder that includes content is called a content replica.

Note:

Public folder content replication isn't controlled by database availability groups (DAGs). You can have public folder databases on servers that have DAGs; however, the public folders will use their own public folder replication methods outside of the DAG.

To learn more about public folder replication, see Understanding Public Folder Replication.

Return to top

Public Folder Referrals

When a client application, such as Outlook, attempts to open an Exchange public folder, the Exchange server determines which folder replica the client application should access. This process is called *public folder referral*. If a replica of the requested content exists on the Exchange server that serves the request, the client application accesses the local replica. If the replica doesn't exist on the local server, Exchange attempts to locate a replica in the same Active Directory site. You can modify the flow of user traffic to allow referrals over certain connectors by specifying a list of referral servers and assigning a routing cost to each server.

For more information about public folder referrals, see Understanding Public Folder Referrals.

Return to top

Mail-Enabled Public Folders

Mail-enabling a public folder provides an extra level of functionality to users. In addition to being able to post messages to the folder, users can send e-mail messages to, and sometimes receive e-mail messages from, the folder. If you're developing custom applications, you can use this feature to move messages or documents into or out of public folders.

A mail-enabled folder is a public folder that has an e-mail address. Depending on how the folder is configured, it may appear in the global address list (GAL). Each mail-enabled folder has an object in Active Directory that stores its e-mail address, address list name, and other mail-related attributes.

Because mail sent to public folders is directed to the public folder database instead of to a mailbox in the mailbox database, Exchange routes e-mail messages by using a method that's slightly different from the method used to route e-mail messages to a regular mailbox.

Return to top

Public Folder Access

In Exchange 2010, the following client applications can access public folders:

- Outlook 2010
- Outlook 2007
- Outlook 2003

For more information about how to create and manage public folders by using Outlook 2007, see Create and share a public folder.

For more information about how to create and manage public folders by using Outlook 2003, see Using Public Folders.

Return to top

Considerations with Mixed Exchange 2010 and Exchange 2007 Organizations

In a mixed Exchange 2010 and Exchange 2007 organization, you need to manage your public folders and public folder databases from Exchange 2010. Exchange 2007 servers don't recognize Exchange 2010 public folder databases due to Active Directory schema changes. The following table describes the expected behaviors when performing certain public folder management tasks on Exchange 2007 servers and Exchange 2010 servers.

Tasks	Exchange 2007 servers	Exchange 2010 servers
Create a public folder database	If any Exchange 2010 mailbox databases are in your organization and don't have the **msExchHomePublicDB** attribute populated, the Exchange 2007 server can't update the Exchange 2010 mailbox database's **msExchHomePublicDB** setting. Although you receive an error message, the public folder database is created. After you create the public folder database, you need to change the default public folder database. You need to perform this procedure from an Exchange 2010 server. For details, see Change the Default Public Folder Database for a Mailbox Database.	Always works.
Remove the default public folder database	If any mailbox databases are pointing to the public folder database that you're trying to remove, you receive an error message advising that you need	Works on both Exchange 2007 and Exchange 2010 servers provided that no mailbox

	to change the default public folder database. To change the default public folder database, perform the following steps: 1. On an Exchange 2010 server, change the default public folder database for the mailbox database. For details, see Change the Default Public Folder Database for a Mailbox Database. 2. On the Exchange 2007 server, remove all replicas of that public folder database. For details, see Remove Multiple Public Folders from a Public Folder Database. 3. On the Exchange 2007 server, remove the public folder database. For details, see Remove Public Folder Databases. **Note:** If the new default public folder database that you're pointing the mailbox databases to is an Exchange 2010 public folder database, see "Set an Exchange 2010 public folder database as the default public folder database for an Exchange 2007 mailbox database" later in this table.	databases have the public folder database that you're trying to remove as the default public folder database.
Remove the last public folder database in the organization	If this is the last Exchange 2007 public folder database in the organization, the **Remove-PublicFolderDatabase** cmdlet needs to update the **msExchFirstInstance** property on the Exchange 2010 public folder database to `$true`. This fails because the object version of the Exchange 2010 object is higher. Run the Remove-PublicFolderDatabase cmdlet from the Exchange 2010 server.	Works on both Exchange 2007 and Exchange 2010 servers provided that no mailbox databases have the public folder database that you're trying to remove as the default public folder database.
Set an Exchange 2010 public folder database as the default public folder database for an Exchange 2007 mailbox database	Changing the default public folder database doesn't work on an Exchange 2007 server if either the mailbox database or the public folder database is an Exchange 2010 database. Because Exchange 2007 servers don't recognize the Exchange 2010 public folder databases, the **Set-MailboxDatabase** cmdlet must be run on an Exchange 2010 server.	Always works and should be used to change the default public folder databases if your public folder database and your mailbox database are associated with different versions of Exchange.

	On the Exchange 2010 server, change the default public folder database for the Exchange 2007 mailbox database. For details, see Change the Default Public Folder Database for a Mailbox Database.	

Return to top

Considerations with Mixed Exchange 2010 and Exchange 2003 Organizations

When you install Exchange 2010 in an Exchange 2003 organization, Setup automatically creates an administrative group and routing group within the Exchange 2003 organization. The Exchange 2010 servers added to your organization are included in the new administrative group and routing group. As previously mentioned, Setup also installs a public folder database on the first Exchange 2010 Mailbox server. In that public folder database, Setup creates a free and busy folder for the new administrative group. The **legacyExchangeDN** property for users whose mailboxes were created on an Exchange 2010 server (and not migrated from Exchange 2003) maps to the Exchange 2010 administrative group name, and therefore also maps to the Free/Busy folder. By default, to facilitate free and busy searches from Outlook 2003 and earlier client users whose mailboxes reside on an Exchange 2003 server, the client users' free and busy information is posted to the Free/Busy public folder.

Management

In a mixed Exchange 2010, Exchange 2007, and Exchange 2003 organization, you can use Exchange System Manager to manage public folders. The following scenarios are supported:

- Exchange System Manager should only connect to the Exchange 2003 public folder database for administration. From there, changes replicate to Exchange 2010.
- In a pure Exchange 2010 environment or a mixed Exchange 2010 and Exchange 2007 organization, you can't reinstall Exchange System Manager to manage public folders. You must use the Exchange Management Shell.
- When verifying hierarchy replication or when viewing the Local Replica Age Limit value on a folder, we recommend using Exchange System Manager for public folders that exist on an Exchange 2003 server and using the Shell for public folders that exist on an Exchange 2010 or Exchange 2007 server.

Outlook Web App

In a mixed Exchange 2010, Exchange 2007, and Exchange 2003 organization, one of the Exchange 2010 and Exchange 2007 Client Access servers has a virtual directory named **/public**. You can fully access public folders from Outlook Web App without having to use the **/public** virtual directory.

Important:
Exchange 2010 Outlook Web App clients can’t view public folders that reside on Exchange 2003 servers.

In addition, the following public folder features are available in Outlook Web App:

- Full access to public folders on Exchange 2010 Mailbox servers without having to keep an Exchange 2003 Mailbox server available for public folder access from Outlook Web App
- Public folder search capabilities

- Web Parts support

Return to top

Updating the Public Folder Hierarchy

If you notice that the public folder hierarchy on one server is different from the public folder hierarchy on other servers, you may want to synchronize the hierarchy. In Exchange 2003 Service Pack 2 (SP2), the **Synchronize Hierarchy** command is used to synchronize the public folder hierarchy on an Exchange 2003 server with the other servers in your organization. In Exchange 2010, the **Update-PublicFolderHierarchy** cmdlet is used to synchronize the public folder hierarchy on the Exchange 2010 server with the rest of the servers in your organization.

Note:

You can't run the **Synchronize Hierarchy** command on an Exchange 2010 server. Similarly, you can't run the **Update-PublicFolderHierarchy** cmdlet on an Exchange 2003 server. However, running either command updates the public folder hierarchy in your entire organization.

For more information, see Update a Public Folder Hierarchy.

Return to top

Public Folder Content Replication

To help stop public folder content replication errors in your organization, you can suspend the replication of public folder content. Suspending replication allows you to reconfigure the public folder hierarchy and replication schedules.

To suspend or resume the replication of public folder content in a mixed organization, on an Exchange 2010 server, run the **Suspend-PublicFolderReplication** cmdlet or the **Resume-PublicFolderReplication** cmdlet in the Shell. Although you run these cmdlets on an Exchange 2010 server, they will suspend or resume the replication of public folder content on all servers in your mixed organization. For information about using the Shell to suspend or resume the replication of public folder content, see the following topics:

- Suspend Public Folder Content Replication
- Resume Public Folder Content Replication

Return to top

Best Practices

This section provides the best practices to consider when performing the following public folder tasks in your Exchange organization:

- Creating public folder databases
- Designing the public folder hierarchy
- Performing nightly maintenance

Creating Public Folder Databases

When you plan how many public folder databases to create in your organization, consider the following best practices:

- For large enterprise topologies where public folders are heavily used, deploy dedicated public folder servers. This best practice stems from the general best practice of dedicating CPU resources and disk resources to isolated server functions.

- Having fewer larger public folder databases scales better and is more easily managed than having several smaller public folder databases. By reducing the number of public folder databases, you can decrease the time required to back up and restore many smaller databases. You also reduce the amount of background replication traffic. Additionally, online maintenance of fewer larger databases is quicker than online maintenance of many smaller databases. Also, it is easier to manage a smaller number of public folder databases from the perspective of applying permissions and content access, and implementing efficient replication and referrals.
  The best practice of having fewer larger public folder databases is especially helpful when you consider your topology from the organization level. However, at the server level, some management and maintenance tasks, such as backup and restore processes, can be more quickly performed if you have several smaller databases. Ultimately, the number of public folder databases that you deploy must address your business requirements. As you determine the number of databases that you want to deploy, you must balance the cost of replication traffic against the costs of database backup, maintenance, and restore times.

Designing the Public Folder Hierarchy

As you design your public folder hierarchy, you must recognize the effect of hierarchy replication in your environment. Deep public folder hierarchies scale better than wide hierarchies. A *deep hierarchy* consists of many vertically nested folders, instead of many higher-level folders. A *wide hierarchy* consists of many higher-level folders with fewer vertically nested subfolders.

For example, consider how 250 folders might be arranged in a specific hierarchy. A wide hierarchy might have 250 direct subfolders under one parent folder. A deep hierarchy might have five top-level folders, each with five direct subfolders. Inside each of those subfolders may be 10 subfolders.

In both these examples, there are 250 folders (5 × 5 × 10 = 250). However, the deep hierarchy offers better performance than the wide hierarchy for the following reasons:

- The way that replication handles folders that have different permissions applied to them is more efficient in deep hierarchies.
- Client computer actions (such as sort, search, and expand) against a folder that has 10 subfolders is much less expensive than a folder that has 250 subfolders.

Although deep hierarchies scale better than wide hierarchies, it's a best practice not to exceed 250 subfolders per folder. Exceeding 250 subfolders likely will cause an unacceptable client experience when a client computer requests access.

A factor to consider as you implement a hierarchy is the effect that permissions have on the experience users have when they want to gain access to public folders. When each public folder subfolder has its own access control list (ACL) entries defined, every time that the Exchange server receives a new public folder replication message, the ACL for the parent public folder must be evaluated to determine which users have rights to view the changes to the parent public folder. If the parent public folder has a large discretionary access control list (DACL) entry, it may take a long time to update the view for each public folder subscriber.

Note:

The DACL for the parent folder consists of the sum of the DACLs of all the public folder subfolders.

You may have many megabytes (MB) of DACL data that must be parsed if the following conditions are true:

- There are many subfolders under a single parent public folder.
- Each of those subfolders has its own ACL defined.

This DACL data must be parsed so that the display can be updated for all the public folder subscribers every time that a public folder replication message is received.

Therefore, we recommend that you arrange your public folder hierarchy according to the user sets that gain access to the parent folders. Additionally, don't implement complex permission models for your public folder hierarchies.

Performing Nightly Maintenance

To make sure that your databases continue to operate efficiently, we recommend that you perform nightly maintenance on mailbox databases and public folder databases. Exchange Mailbox servers automate the tasks based upon the schedule that you set.

Return to top

1.8.1.12.1 Understanding Public Folder Permissions

Understanding Public Folder Permissions

Mailbox > Understanding Mailbox > Understanding Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-13*

You can configure public folder permissions for administrators or for users of client programs such as Microsoft Outlook. Public folder permissions consist of various access rights that specify the level of control a client user or administrator has over a public folder or public folder hierarchy.

Looking for management tasks related to public folder permissions? Check out Managing Public Folder Permissions.

Client User Access Rights and Roles

Use the Exchange Management Shell to configure the permissions for users who use client programs such as Outlook to access public folders. Whether you want to manually select the access rights or use predefined roles that contain specific access rights, you'll use the Add-PublicFolderClientPermission cmdlet.

Important:

To make sure users can send e-mail messages to a mail-enabled public folder, the public folder must have at least the CreateItems access right granted to the Anonymous account.

The following is a list of client user access rights (followed by a table that shows the predefined permission roles):

- **ReadItems** The user can read items within the specified public folder.
- **CreateItems** The user can create items within the specified public folder and send e-mail messages to the public folder if it's mail-enabled.
- **EditOwnedItems** The user can edit the items that the user owns in the specified public folder.
- **DeleteOwnedItems** The user can delete items that the user owns in the specified public folder.
- **EditAllItems** The user can edit all items in the specified public folder.
- **DeleteAllItems** The user can delete all items in the specified public folder.
- **CreateSubfolders** The user can create subfolders in the specified public

folder.

- **FolderOwner** The user is the owner of the specified public folder. The user can view and move the public folder, create subfolders, and set permissions for the folder. The user can't read, edit, delete, or create items.
- **FolderContact** The user is the contact for the specified public folder.
- **FolderVisible** The user can view the specified public folder, but can't read or edit items within the specified public folder.

The following table lists the predefined public folder roles and the access rights that are included in each role. The table headers reflect the access rights listed previously in this topic.

Note:
The FolderOwner access right and the Owner role have different permissions as shown in the following table.

Access rights included with each predefined public folder role

Role	CreateItems	ReadItems	CreateSubfolders	FolderOwner	FolderContact	FolderVisible	EditOwnedItems	EditAllItems	DeleteOwnedItems	DeleteAllItems
None						X				
Owner	X	X	X	X	X	X	X	X	X	X
PublishingEditor	X	X	X			X	X	X	X	X
Editor	X	X				X	X	X	X	X
PublishingAuthor	X	X	X			X	X		X	X
Author	X	X				X	X		X	
Non-Editing Author	X	X				X				
Reviewer		X				X				
Contributor	X					X				

Note:
Client users can use Outlook to manage public folder permissions for public folders that reside on a server running Microsoft Exchange Server 2010. For information about how to manage public folder permissions from Microsoft Office Outlook 2007 or Outlook 2010, see Create and Share a Public Folder. For information about how to manage public folder permissions for public folders that reside on Exchange 2010 servers from Office Outlook 2003, see Outlook folder permissions.

Administrator Access Rights

In Exchange 2010, there are two ways to grant administrators the rights to manage public folders:

- Public Folder Management role group
- Add-PublicFolderAdministrativePermission cmdlet

The following table describes the differences between the rights that are granted by the Public Folder Management role group and the rights that are granted by using the **Add-PublicFolderAdministrativePermission** cmdlet.

Administrator access rights differences

Public Folder Management role group	Add-PublicFolderAdministrativePermission cmdlet
The user can create top-level public folders.	The user can't create top-level public folders.
The user is granted the AllExtendedRights permission to public folders and the rights to run the public folder cmdlets.	The user can be granted or denied specific rights to public folders.
The user can administer any top-level public folder, child public folder, and system public folders in the public folder tree. In addition, this user's access rights can't be revoked by using the Remove-PublicFolderAdministrativePermission cmdlet.	The user can be granted the right to administer specific top-level public folders and specific child public folders. However, the user's access rights can be revoked by using the Remove-PublicFolderAdministrativePermission cmdlet.
The Public Folder Management role group is a Role Based Access Control (RBAC) role group that consists of the following roles: • Mail-Enabled Public Folders role • Public Folders role • Public Folder Replication role For more information, see Public Folder Management.	Not applicable

The following list describes the standard set of administrative access rights that can be set on a public folder:

- **None** The administrator doesn't have any rights to modify public folder attributes.
- **ModifyPublicFolderACL** The administrator has the right to modify Client Access server role permissions for the specified folder.
- **ModifyPublicFolderAdminACL** The administrator has the right to modify administrator permissions for the specified public folder.
- **ModifyPublicFolderDeletedItemRetention** The administrator has the right to modify the Public Folder Deleted Item Retention attributes (*RetainDeletedItemsFor*, *UseDatabaseRetentionDefaults*).
- **ModifyPublicFolderExpiry** The administrator has the right to modify the Public Folder Expiration attributes (*AgeLimit*, *UseDatabaseAgeDefaults*).
- **ModifyPublicFolderQuotas** The administrator has the right to modify the Public Folder Quota attributes (*MaxItemSize*, *PostQuota*, *PostWarningQuota*, *UseDatabaseQuotaDefaults*)
- **ModifyPublicFolderReplicaList** The administrator has the right to modify the replica list attribute for the specified public folder (*Replicas*).
- **AdministerInformationStore** The administrator has the right to modify all other public folder properties not defined previously.
- **ViewInformationStore** The administrator has the right to view public folder properties.
- **AllExtendedRights** The administrator has the right to modify all public folder

properties.

Creating Custom Role Groups

In addition to the Public Folder Management role group and the **Add-PublicFolderAdministrativePermission** cmdlet, you can create custom role groups that will allow a user to only perform certain tasks. For example, if you want to allow an administrator to manage public folders and mail-enabled public folders, but not public folder replication, you can create a custom role group that includes only the Mail Enabled Public Folders role and the Public Folders role. For more information about creating role groups, see Create a Role Group.

1.8.1.12.2 Understanding Public Folder Replication

Understanding Public Folder Replication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-07*

Public folder replication is the process by which public folder content and the public folder hierarchy are replicated across multiple servers for efficiency and fault tolerance purposes. When multiple public folder databases located on separate servers support a single public folder tree, Microsoft Exchange uses public folder replication to keep the databases synchronized. Public folder content exists only in Exchange stores configured to have a replica of a specific folder. Content and hierarchy information are replicated separately. Each public folder database retains a copy of the hierarchy, which includes lists of the other public folder databases that retain content replicas of each folder. Content replicas exist only on the public folder databases that you specify. For more information about how to configure public folder replication, see Configure Public Folder Replication.

Note:

Unlike in Exchange Server 2007, you can't use continuous replication in Exchange Server 2010 to replicate public folders. In Exchange 2010, continuous replication is for mailbox databases only. A public folder database can be hosted on a Mailbox server in a database availability group (DAG), but you must use multiple public folder databases and public folder replication for data redundancy.

Public folder databases replicate two types of public folder information:

- **Hierarchy** Hierarchy replication occurs when the properties of the folders and organizational information about the folders have been modified. All public folder databases have a copy of the hierarchy information. Modifying the following public folder information results in hierarchy replication:
  - Folder name
  - Replica list
  - Folder's position in the public folder tree (including any parent and child folders)
  - Permissions

  Note:

  Hierarchy replication doesn't occur when you change the e-mail addresses for a mail-enabled public folder. The e-mail addresses are stored on the directory object in Active Directory. Only by changing the properties within the public store database does hierarchy replication occur.
- **Content** Content replication occurs when messages are sent to public folders or when data is added. For example, sending e-mail messages to a mail-

enabled public folder or adding an organizational form to a public folder results in content replication. To replicate content, you must configure a folder to replicate its content to a specific public folder database or list of databases. Only the databases that you specify will have copies of the content. A copy of the folder that includes content is called a *content replica*.

Contents

Looking for management tasks related to public folders? See Managing Public Folders.

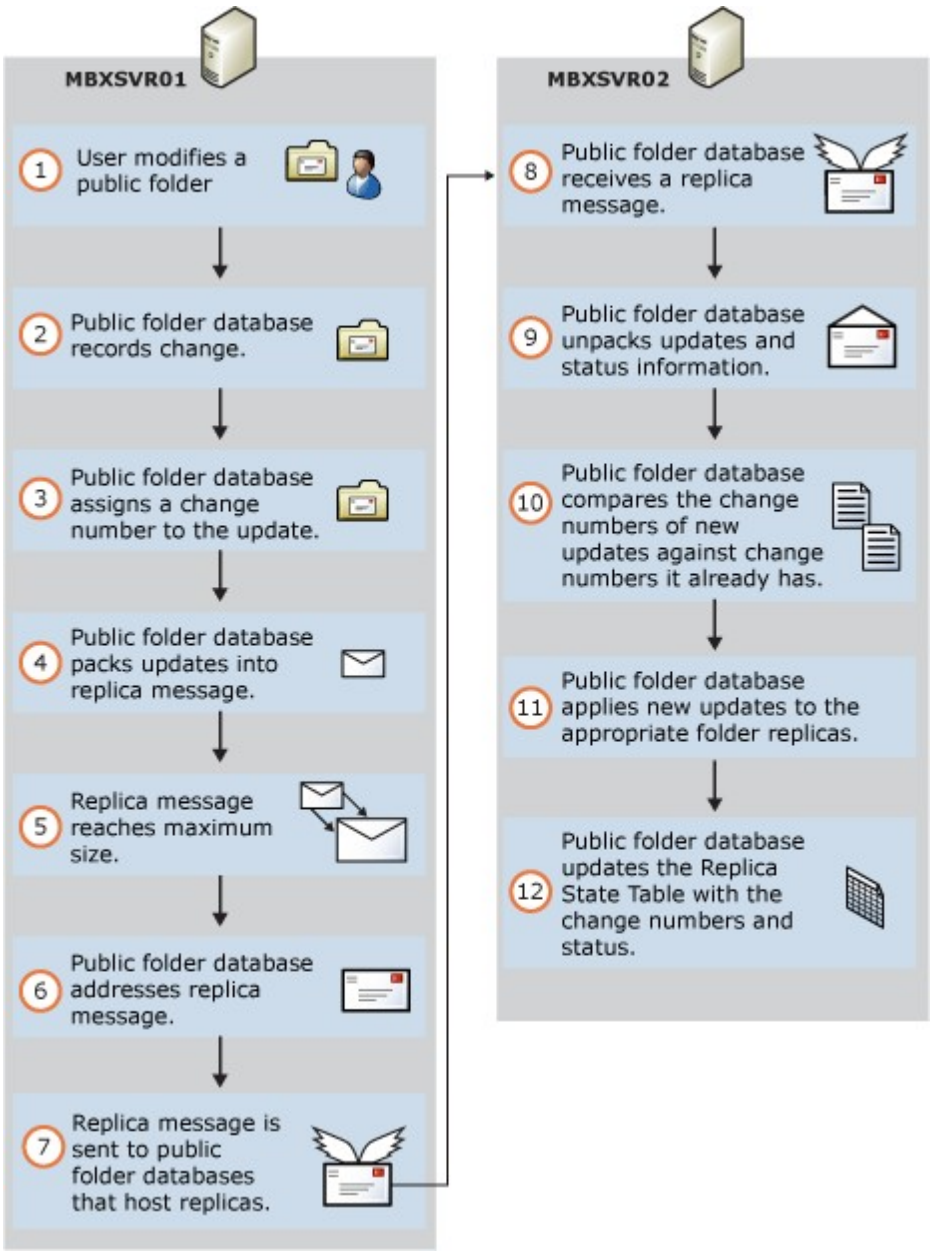
How Public Folder Replication Works

When you modify a public folder or its contents, the public folder database that contains the replica of the public folder that was changed sends a descriptive e-mail message to the other public folder databases that host a replica of the public folder. To reduce traffic on your network, Exchange includes information about multiple changes in one e-mail message. The amount of information included in these messages depends on the size limit you set for replication messages. If any message exceeds the specified size limit, that message is sent as a separate replication message. Exchange routes these replication messages the same way that it routes other e-mail messages.

If you make changes to the public folder hierarchy that affect several folders, the replication process may require considerable network bandwidth. For example, to move public folders from one server to another, you must create replicas on the server to which you want to move the public folders, wait for the hierarchy changes to replicate to the original server, and then wait for the content to replicate to the new replicas. After the replicas are synchronized, you must remove the replicas from the old server. Even removing the replicas from the old server generates network traffic because removing replicas must replicate as a hierarchy change. To learn more about how these changes to the public folder hierarchy can affect your system, see "Status Requests and Status Messages" later in this topic.

Basic Hierarchy and Content Replication Process

The following figure and the explanatory text that follows describe the basic process by which public folder hierarchy and public folder content are replicated.



The details of the process are as follows:

1. A user modifies the public folder.
2. The local public folder database records the change.
3. At the next scheduled replication cycle (which is determined by the replication interval that you set for the public folder database), the public folder database checks the folder properties to determine which other servers contain a replica of that folder. If other replicas exist, the database determines what information must be replicated to them. This information becomes the update to the replicas.
   Public folder replication is object-based. If one property of an object is modified, the entire object must be replicated. Because the database that replicates the change can't assume that all of the receiving replicas are up to date, it must replicate the entire object. The implications for the different types of replication are as follows:
   - **Hierarchy replication** The replication of new hierarchy changes occurs

when a public folder is created or deleted, or when a change is made to the properties of a public folder (such as a change to the replica list, client permissions, description, administrative note, or storage limits).
- **Content replication** If a new message is posted or an existing message is modified, the update includes the entire message and its properties.

4. The public folder database assigns a change number to the update.
   When a folder replicates an update to another server, the change number is included with the update. The receiving server then uses the change number to determine whether the update represents a new change, and whether the server is missing any data.
5. The public folder database packs updates into a replication message. The change numbers of all of the updates in the message are called a *change number set* (CNSet).
   Along with the updates, the public folder database packs information from the folder's entries that are in the replication state table, including the CNSets that were previously applied to the replica. For more information about the replication state table, see "Replication State Table" later in this topic.
6. To reduce mail traffic, the public folder database packs multiple hierarchy updates into a single replication message. Likewise, the database packs multiple content updates for the same folder into a single replication message. However, the database can't pack hierarchy updates into the same replication message as content updates, and each content replication message contains updates for a single folder.
7. The public folder database addresses the replication message to the other public folder databases that host replicas of the updated folder. The database sends the message, along with any other messages that have been packed since the previous replication cycle.
   To deliver replication messages, the public folder database relies on the internal routing components in Exchange. The database doesn't attempt to split replication messages based on topology details. If the contents of a folder are modified and the folder has five other replicas, the database generates a single replication message and addresses it to all five databases that host those replicas. The routing components determine how to route and deliver the message.
8. The public folder database receives the replication message.
9. The receiving public folder database unpacks the update and status information from the replication message.
10. The database compares the change numbers of the new updates to the list of change numbers that it already contains, and then identifies which updates it hasn't previously received.
11. The database applies the new updates to the appropriate folder replicas.
12. For each updated replica, the database updates the replication state table with the change numbers of the current update and the folder status information from the replication message.
    If the information in the replication state table indicates that other CNSets have been applied to other replicas of the folder but not to replicas on this database, the database records the CNSets that are missing in a location called the *backfill array*, and then prepares to send a backfill request. For more information about backfill requests, see "Backfill Requests and Backfill Messages" later in this topic.

Return to top

Replication Messages

The replication process uses the Active Directory attributes of the public folder databases, and not the Active Directory attributes of individual public folders. The Active Directory attributes for individual public folders are used only to send regular e-mail messages to or

from the folders. A public folder database object is configured and maintained automatically and resides in the Configuration container in Active Directory.

Replication messages differ from other e-mail messages in that Exchange treats replication messages as system messages. This means that replication messages aren't bound by the restrictions applied to user e-mail messages (such as size and delivery restrictions).

The following table lists the different types of replication messages that Exchange uses.

Note:
The values listed in parentheses in the following table are the hexadecimal notation of the message types. These notations are used in events and logs. You can use the hexadecimal value to troubleshoot replication issues.

Types of public folder replication messages and when they are used

Message type*	When used
Hierarchy (0x2)	Replicates hierarchy changes from the local public folder database to all other public folder databases that support the same hierarchy. Although Exchange handles hierarchy changes separately from changes to content replicas, it treats the hierarchy as if it was another folder. In some event messages and other operations, Exchange refers to the hierarchy as Folder 1-1.
Content (0x4)	Replicates content changes from one replica to all other content replicas of that folder. A content message only contains information that applies to a single folder.
Backfill request (0x8)	Requests missing data in CNSets from another database. This includes hierarchy and content change numbers.
Backfill response (0x80000002 or 0x80000004)	Sends missing data in CNSets to a database that requested missed updates.
Status (0x10)	Sends the current CNSet of a folder to one or more replicas of that folder. This includes hierarchy and content change numbers.
Status request (0x20)	Requests CNSets to be replicated or status messages to be returned. This includes hierarchy and content change numbers.

Replication State Table

Each public folder database maintains a replication state table to track the status of each replica in the database. The replication state table stores the following information:

- Basic information required to construct updates to each replica.
- Information about the last update to each replica that originated in the local database, including the change number of the update.
- Groups of updates that have been applied to all other known replicas of the folder. Change numbers identify the updates in each group. The set of change numbers for all updates in a group is called a CNSet. Update information is passed from one database to another as part of the replication process.

The following tables provide an example of how replication state tables function. In this example, the public folder databases on Server A and Server B both have replicas of a

folder named Projects. On each server, the replication state table tracks not only the status of the replica on that server, but also the status of the replica on the other server. Using this information, Server A determines whether its replica of Projects folder is synchronized with the replica of the Projects folder on Server B. Server B can likewise track its status relative to Server A.

Sample data from the replication state table for Server A

Replica	Data
Projects folder on Server A (local replica)	Last update sent: A-100
Projects folder on Server B	A-100 received B-50 received

Sample data from the replication state table for Server B

Replica	Data
Projects folder on Server A	A-100 received B-50 received
Projects folder on Server B (local replica)	Last update sent: B-50

By combining the lists of public folder databases that contain content replicas with the information in the replication state table, each public folder database can determine how up to date it is compared to the other public folder databases that support the public folder tree.

Return to top

Backfill Requests and Backfill Messages

Backfilling occurs when a public folder database determines that it hasn't received all the updates for a replicated folder (or for the hierarchy) and must therefore retrieve the missing updates from another public folder database.

To streamline the backfill process, Exchange stores information about missing updates in the backfill array.

The following events may alert a public folder database to missing updates that need to be backfilled:

- The status information in an incoming replication message indicates that the replica on the public folder database that sent the message has updates that are missing on the receiving database. The receiving database identifies the missing change numbers and stores them in its backfill array.
- A public folder database starts for the first time. The new database sends status requests to get information about the other databases in the hierarchy. After the corresponding status messages arrive, the database populates its replication state table and, if necessary, the backfill array. The backfill array may contain entries for both the hierarchy and for any content replicas that the database must host.
- An incoming hierarchy message indicates that a new content replica is to be placed in the public folder database. The new database sends status requests

to get information about content that might be available for this replica in the other databases in the hierarchy. After the corresponding status messages arrive, the database populates the replication state table and, if necessary, the backfill array.

The backfill array stores this information for a specified length of time (called the *backfill time-out*). If the missing updates arrive in subsequent replication messages during this time, they are removed from the backfill array. The following table lists the default backfill time-out values, which depend on where the missing updates exist and whether they were previously requested.

Default time-outs used for backfill requests

Type of request	Content exists on a database in the local Active Directory site	Content exists on a database in a remote Active Directory site
Initial backfill	6 hours	12 hours
First backfill retry	12 hours	24 hours
Subsequent backfill retries	24 hours	48 hours

If the backfill time-out expires, and the updates are still missing, Exchange creates one or more backfill requests and determines which servers to use as backfill sources.

To select servers to use as a backfill source, Exchange first creates a list of all the servers that have replicas of the folder, and then sorts the list according to the following sequence of criteria:

1. Sort according to server status. Servers that are down or unavailable drop to the end of the list.
2. Sort according to preferred backfill server (if any). Exchange checks the public folder database object in Active Directory for a preferred backfill server. This setting is seldom used. In most circumstances, the backfill process operates most efficiently if Exchange selects a backfill server automatically. Most deployments of Exchange don't need a preferred backfill server. Microsoft Customer Service and Support can provide a script that sets a preferred backfill server if your deployment requires it.
3. Sort according to transport cost (lowest to highest). Servers in the same routing group have priority over servers in remote Active Directory sites.
4. Sort according to Exchange version (newest to oldest).
5. Sort according to the number of necessary changes available on the server (largest to smallest). Servers that don't have any of the missing changes are dropped from the list.

If one server doesn't have all the necessary changes, Exchange selects the next server in the sorted list and sends a backfill request to that server as well. This process is repeated until all of the changes are requested.

If the selected server doesn't respond to the backfill request, the database marks that server as unavailable and repeats the selection process. Servers marked as unavailable move to the end of the list.

Status Requests and Status Messages

In addition to the status information in each replication message, Exchange uses status requests and status messages to determine whether public folders must issue backfill requests.

A public folder database sends a status request under the following circumstances:

- The database is notified of a change to the list of databases that hold replicas of a folder. For example, if you add a database to the list or remove a

database from the list, Exchange replicates this change by using hierarchy update messages. In this case, the database sends a status request that requires every database that contains a replica of the folder to respond.
- A new database has started for the first time. In this case, the database requests the status of the public folder hierarchy. The database sends a status request that requires every database that supports the public folder tree to respond.
- A database that has been restored by using Windows Server Backup starts for the first time after the restore completes. In this case, the database requests the status of the public folder hierarchy and all of the folders for which the database contains content replicas. This status request lists two or three databases as required responders. Required responders are databases that support this hierarchy and, according to an internal selection process, are dependable sources of folder content.

To indicate the current state of a particular folder on the sending database, the public folder database sends a status message to another database under the following circumstances:

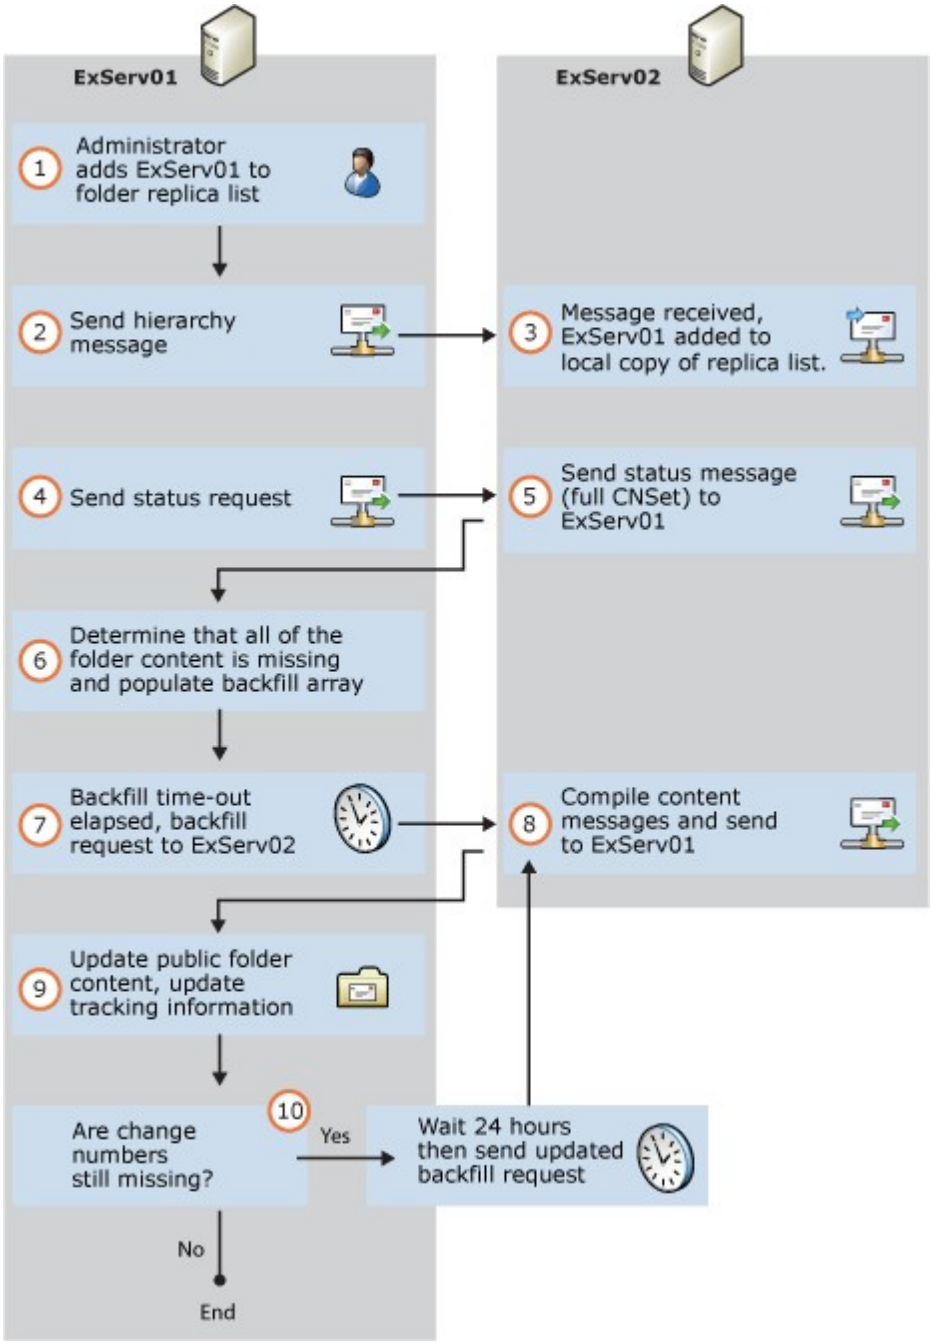
- In response to a status request sent by another database. The status message is sent only to the requesting database and only if the following are true:
  - The database that received the status request is in the requests list of required responders.
  - The replication state table indicates that the database that received the status request has updates that are missing from the database that sent the request.
- If there have been no subsequent updates 24 hours after the most recent update to a folder was received. Each time the database receives an update for a specific folder, the timer is reset to 24 hours. This status message is sent to the other public folder databases that contain replicas of the updated folder.

If a public folder database receives a status message indicating that the sending database has more recent information about the folder, the receiving database creates a backfill request. If the change numbers are shown to be equal (or the change numbers on the receiving server are more recent), no action is taken. For example, when a new public folder database starts for the first time, it sends status request messages to each database that supports the public folder hierarchy. Each database responds with information about the status of the hierarchy (as tracked by that database). The new database uses this information to identify which replicas (if any) it should have. The new database can then send backfill requests as needed to fill in the replica content.

Return to top

Examples of Replication Cycles

The following figure illustrates a simplified two-server scenario that shows the sequence of events that occurs when you add a content replica to a public folder database. This action adds the public folder database to the folder's replica list. Note that the sequence of steps depends on factors such as the timing of the replication intervals and the routing topology.

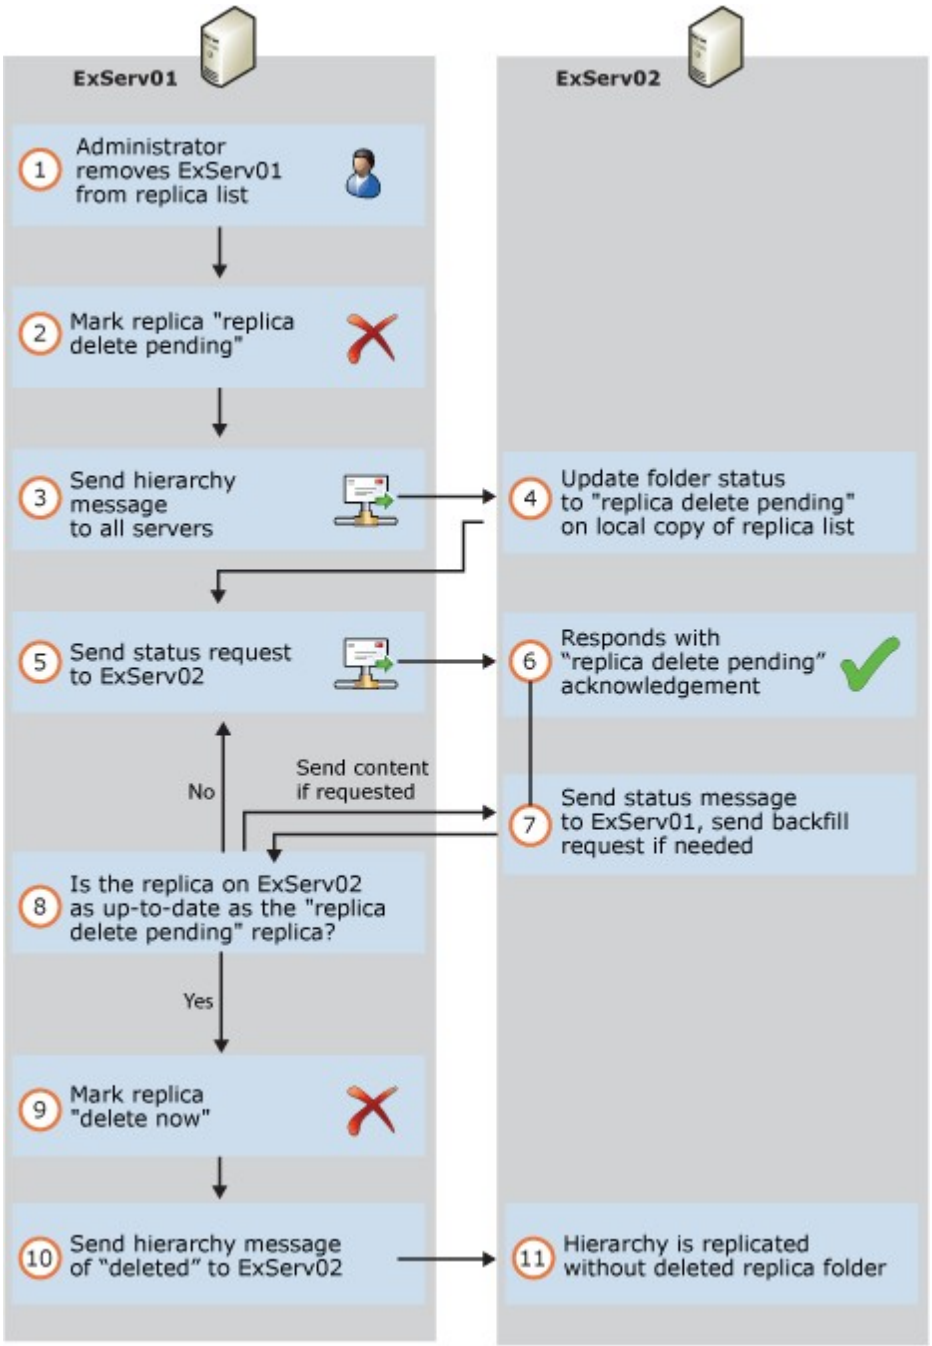


The details of the process are as follows:

1. Working on ExServ01, an administrator adds ExServ01 to a folder's replica list.
2. ExServ01 sends a hierarchy message.
3. ExServ02 adds ExServ01 to the local copy of the folder's replica list.
4. ExServ01 sends a status request to ExServ02.
5. ExServ02 sends a status message to ExServ01 that includes the full CNSet of the folder.
6. ExServ01 determines that all the folder content is missing and records the appropriate entries in the backfill array.
7. If the content is still missing when the backfill time-out elapses, ExServ01 creates a backfill request and sends it to ExServ02.

8. ExServ02 compiles the content messages and sends them to ExServ01.
9. ExServ01 uses the incoming content messages to update the folder content and related tracking information.
10. If change numbers still appear to be missing, ExServ01 waits 24 hours, and then sends an updated backfill request. If a server other than ExServ02 is available, ExServ01 might send the request to that server.

The following figure illustrates a simplified two-server scenario that shows the sequence of events that occur when you remove a replica from a public folder database. (This action removes the public folder database from the folder's replica list.) Note that the sequence of steps depends on factors such as the number of servers in the topology.



The details of the process are as follows:

1. Working on ExServ01, an administrator removes ExServ01 from a folder's replica list.
2. ExServ01 marks its replica (the copy of the folder on ExServ01) as **delete pending**.
   Clients can no longer access the folder by using this database.
3. ExServ01 sends a hierarchy message.
4. ExServ02 updates its copy of the folder's replica list to show that the folder is in the delete pending state on ExServ01.
   ExServ02 no longer refers clients that are looking for this folder to ExServ01.
5. ExServ01 sends a status request to ExServ02.
6. ExServ02 sends a status message to ExServ01. If the replica on ExServ02 isn't up to date, ExServ02 places the appropriate entries in the backfill array. Within five minutes, ExServ02 sends the corresponding backfill request to ExServ01.
7. ExServ01 checks that the folder replica on ExServ02 contains all of the information that the delete pending replica does. If it doesn't, ExServ01 sends the appropriate content updates and returns to Step 5. Otherwise, ExServ01 continues to Step 8.
   This process ensures that as long as other replicas exist, deleting a single replica doesn't result in a loss of content.
8. ExServ01 marks its replica as **delete now**. The next maintenance cycle will remove the replica from ExServ01.
9. ExServ01 sends a hierarchy message.
10. ExServ02 removes ExServ01 from its copy of the folder's replica list.

Return to top

Best Practices for Implementing Replication

Public folder replication in Exchange can be a resource-intensive operation. Replication requires network, CPU, and disk resources to operate. By implementing a solution that enables efficient public folder replication, especially in organizations with heavy public folder usage, you may greatly improve network, CPU, and disk load in your Exchange organization.

Generally, it's a best practice to minimize replication across the organization. By minimizing replication, you minimize the amount of data that travels over your network. Additionally, by minimizing replication, you can help make sure that multiple users are less likely to access different versions of data on multiple replicas. However, you should note that by minimizing replication, you decrease availability of the public folder data because fewer replicas of the folder are available to clients if a public folder database fails. If availability on a large scale is required for data in a specific public folder, you may require more replication.

1.8.1.12.3 Understanding Public Folder Referrals

Understanding Public Folder Referrals

Mailbox > Understanding Mailbox > Understanding Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-01-27*

When a user accesses a public folder by using a MAPI client application, such as Microsoft Outlook, the public folder database determines which public folder replica the client should access. This process is called *referral*. If a replica of the requested content exists on the server running Microsoft Exchange that serves the client request, the client accesses the local replica. When a user connects to a public folder database that doesn't contain a copy of the public folder content that the user wants, the user is redirected to another public folder database that has a copy of the content. As illustrated in the following figure, you can create a custom cost list for public folder referral to control this redirect traffic.

Note:

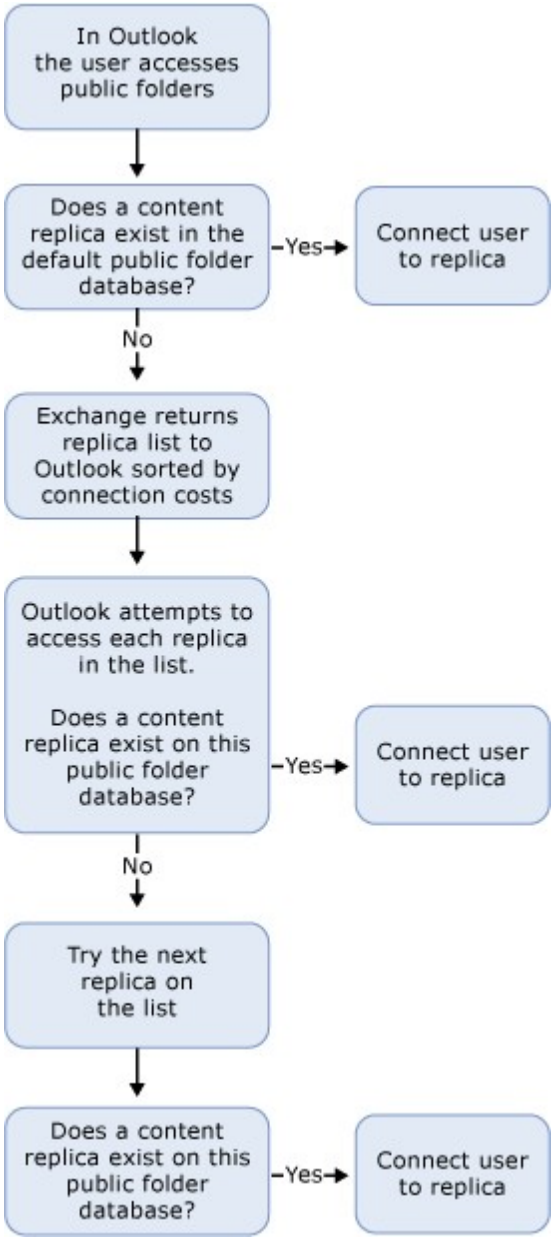
Public folder referrals have an associated *cost number*. The numbers range from 1 through 100. This cost number is used to optimize message flow. Specifically, e-mail messages are routed according to lowest cost number. If two or more routes are available with the same cost, the load is distributed as equally as possible between them. This cost is also used to calculate the most appropriate route that the client application can use to access public folders on remote servers.

Using the default referral configuration, Exchange Server 2010 follows the structure of your organization's Active Directory site to locate an appropriate server. However, to modify the flow of user traffic, Active Directory site administrators can redirect this configuration by specifying whether to allow referrals over certain connectors. For Exchange 2010 servers, you can also specify a list of referral servers and assign routing costs to each server to redirect server traffic. For example, you can limit referrals to a single Active Directory site or only allow referrals between certain servers in each Active Directory site.

Looking for management tasks related to public folders? See Managing Public Folders.

How Referrals Are Determined

When a user connects to Exchange and uses a MAPI client application to request access to a public folder, Exchange locates a content replica of the public folder by using information supplied by the public folder database associated with the user's mailbox database. The public folder database retrieves the replica list of the requested folder and, if necessary, retrieves routing and cost information from Active Directory Sites and Services. Exchange uses the process shown in the following figure to locate a content replica.



The details of the process are as follows:

1. The MAPI client connects to the user's mailbox database to access the user's private folders. The MAPI client also connects to the user's mailbox to retrieve the default public folder database for information about the public folder hierarchy. For more information about how to set the default public folder database, see Change the Default Public Folder Database for a Mailbox Database.
2. The MAPI client attempts to read the content for a specific public folder. Initially, the default public folder database is queried for the content. If that database is a content replica for the folder in question, the process is complete.
3. If there is no replica on the default public folder database, Exchange returns a list of replicas to the client, sorted by that server’s perspective of connection costs to each of the other listed content replicas. Connection costs are determined by querying Active Directory Sites and Services for the

site connector cost information of the other Mailbox servers in the organization on which a public folder database resides. Alternatively, you can specify costs to other servers by providing a custom override list to the public folder database. The list returned to the client doesn't include servers for which the cost is greater than 500.

Note:
Cost information is refreshed once every hour. Therefore, any changes to Active Directory site costs aren't available for up to one hour. In addition, any changes in the public folder custom list, including its initial configuration or complete removal, isn't available for up to one hour. Servers that aren't listed in the custom list of the public folder will never receive referrals from the server that has the custom list.

4. The MAPI clients attempt to access each replica in the list by connecting to the server, attempting to locate the folder, and then attempting to read the folder's content.
5. If a failure occurs, the client attempts to access the next replica server in the list until the client has attempted to access all replica servers in the custom list.

Note:
The MAPI client doesn't refresh its connection unless its current connection is terminated. In other words, if a preferred or low-cost replica can't be reached, the client attempts to access the next replica in the list, which may be expensive to reach. If the low-cost server becomes available, the MAPI client doesn't redirect the connection to the low-cost replica until the user logs off and then logs back on to the MAPI client.

Assigning Cost

Although Exchange administrators can create public folder referrals and site costs, we don't recommend that you do this because the maximum public folder referral cost that Exchange administrators can set for a public folder database is 100. By setting the maximum referral cost for a server to 100, the server may still be used for referrals.

Instead, public folder referrals and site costs should be determined by an administrator who is a member of the Domain Admins group or the Enterprise Admins group in Active Directory. In Active Directory Sites and Services, a user who has Domain Admin or Enterprise Admin permissions can set the public folder referral cost up to 500. This higher cost number helps ensure that a server won't be used for referrals.

Note:
To create efficient public folder referrals, you must understand the structure of your organization's Active Directory site. For more information about routing, Active Directory sites, routing costs, and Send and Receive connectors, see Understanding Message Routing.

For detailed steps about how to configure an Exchange 2010 server to use a specific list of servers and costs for referrals, see Configure Public Folder Referrals.

1.8.1.13 Understanding Quota Messages

Understanding Quota Messages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-13*

A *quota message* is an e-mail message that's automatically sent by Microsoft Exchange to the owners of a mailbox or a public folder when a size limit (called a *storage quota*) for the mailbox or public folder is exceeded. You can use the New-SystemMessage, Get-SystemMessage, Set-SystemMessage, and Remove-SystemMessage cmdlets in the Exchange Management Shell to view built-in quota messages or to create, view, modify, or remove customized quota messages.

Quota Messages in Exchange 2010 SP1

Exchange 2010 SP1 introduces a flag that controls whether a mailbox is checked to see if its size is equal to or greater than 50% of the **Prohibit send** quota.As a result, if the **Issue Warning** quota is set to a value less than 50% of the **Prohibit send** quota, the warning message associated with the **Issue warning** quota won't be sent to the user. For example, if a mailbox has a size limit of 10 MB, and you set the **Issue warning** quota to 3 MB and the **Prohibit send** quota to 8 MB, the user won't ever receive the warning specified by the **Issue warning** quota because the **Issue warning** quota limit isn't equal to or greater than 50% of the **Prohibit send** quota. Instead, the user will receive only the message associated with the **Prohibit send** quota (in this case, when the user's mailbox size reaches 8 MB).

In addition, the flag is cleared after you run the **Set-MailboxDatabase** cmdlet with the *QuotaNotificationSchedule* parameter. When you run that command, the mailbox won't be checked again until the flag is reset. Flags are reset when a message is saved in the mailbox or when a message is sent to or from the mailbox.At that point if the mailbox size is greater than 50% of the **Prohibit send** quota, the flag is reset and the mailbox is checked at the time specified by the *QuotaNotificationSchedule* parameter.

Storage Quotas

A *storage quota* is a storage size limit for a mailbox or a public folder. You can use the Exchange Management Console (EMC) or the Shell to view or set the storage quotas for all of the mailboxes or public folders in a database. You can also use the EMC or the Shell to set storage quotas on a per-mailbox basis, thereby overriding the storage quotas that are set at the database level. However, storage quotas for individual public folders can be viewed or set only in the Shell.

For more information about viewing and configuring storage quotas, see the following topics:

- Configure Mailbox Database Properties
- Configure Storage Quotas for a Mailbox
- Configure Archive Quotas for a Personal (On-Premises) Archive
- Set-MailboxDatabase
- Set-Mailbox
- Configure Public Folder Properties
- Set-PublicFolderDatabase
- Set-PublicFolder

Quota Messages

By default, Exchange sends a quota message to mailbox or public folder owners when a:

- Mailbox, personal archive, or public folder exceeds its **Issue warning** limit (the lowest storage quota).
- Mailbox exceeds its **Prohibit send** limit or a public folder exceeds its **Prohibit post** limit (the middle storage quota).
- Mailbox exceeds its **Prohibit send and receive** quota or a personal archive

exceeds its archive quota (the highest storage quota).

Quota messages for mailboxes are sent to mailbox owners. If a mailbox is owned by a security group (that is, if it's a shared mailbox), quota messages are sent to the security group. Quota messages for public folders are sent to every public folder owner. Owners of mailboxes and public folders can be users, contacts, or security groups.

Quota messages are sent with high importance and aren't subject to storage quotas. They're always delivered, even if the recipient's mailbox is full.

Exchange can generate quota messages in many languages. For a list of the supported language locales that are available for use with quota messages, see Supported Locales for Use with System Messages.

Quota Message Format

There are seven types of quota messages: four for mailboxes and three for public folders. All quota messages include the following:

- Text **Microsoft Exchange** in the **From** field
- Brief, non-customizable description of the situation in the **Subject** field
- Customizable message in the message body
- Graphical representation of the storage quota and the amount of storage used in the message body (except for mailboxes or public folders of unlimited size)

Default Quota Messages

The following tables list the subject and the default message text for the seven default English quota messages (four for mailboxes and three for public folders). The default message can be customized, but the subject text can't.

Note:

There are no specific archive quota messages. If a user's archive is meeting or exceeding any quotas, they will receive mailbox quota messages.

Mailbox quota and archive quota messages

Event	Subject of message	Default message text
Mailbox of unlimited size exceeds its **Issue warning** quota	Your mailbox is becoming too large	Please reduce your mailbox size. Delete any items you don't need from your mailbox and empty your Deleted Items folder.
Mailbox of limited size exceeds its **Issue warning** quota **Important:** The message associated with the **Issue warning** quota won't be sent to the user unless the value of the quota is greater than 50% of the value specified in the **Prohibit send** quota. For example, if you set the **Prohibit send** quota to 8 MB, you must set the **Issue warning** quota to at least 4 MB. If you don't, the **Issue warning** quota message won't be sent.	Your mailbox is almost full	Please reduce your mailbox size. Delete any items you don't need from your mailbox and empty your Deleted Items folder.

Mailbox of limited size exceeds its **Prohibit send** quota	Your mailbox is full	Your mailbox can no longer send messages. Please reduce your mailbox size. Delete any items you don't need from your mailbox and empty your Deleted Items folder.
Mailbox of limited size exceeds its **Prohibit send and receive** quota	Your mailbox is full	Your mailbox can no longer send or receive messages. Please reduce your mailbox size. Delete any items you don't need from your mailbox and empty your Deleted Items folder.

Public folder quota messages

Event	Subject of message	Default message text
Public folder of unlimited size exceeds its **Issue warning** quota	Your public folder is becoming too large	Please reduce the size of your public folder by deleting any items you don't need.
Public folder of limited size exceeds its **Issue warning** quota	Your public folder is almost full	Please reduce the size of your public folder by deleting any items you don't need.
Public folder of limited size exceeds its **Prohibit post** quota	Your public folder is full	Users can no longer post items to this folder. Please reduce the size of your public folder by deleting any items you don't need.

1.8.1.14 Understanding Recipients

Understanding Recipients

Exchange Server 2010 > Mailbox > Understanding Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-24*

The people and resources that send and receive messages are the core of any messaging and collaboration system. In an Exchange organization, these people and resources are referred to as *recipients*. A recipient is any mail-enabled object in Active Directory to which Exchange can deliver or route messages.

Recipient Types

Microsoft Exchange Server 2010 includes several explicit recipient types. Each recipient type is represented by a unique icon in the Exchange Management Console (EMC) and a unique name in the *RecipientTypeDetails* property in the Exchange Management Shell. The use of explicit recipient types has the following benefits:

- At a glance, you can differentiate between various recipient types.
- You can search, sort, and filter by each recipient type.
- You can more easily perform bulk management operations for each recipient

type.
- You can more easily view recipient properties because the EMC uses the recipient types to render different property pages. For example, the resource capacity is displayed for a conference room mailbox, but isn't present for a user mailbox.

The following table lists the available recipient types. All these recipient types are discussed in more detail later in this topic.

Exchange 2010 recipient types

Recipient type	Description
Dynamic distribution group	A distribution group that uses recipient filters and conditions to derive its membership at the time messages are sent.
Equipment mailbox	A resource mailbox that's assigned to a non-location specific resource, such as a portable computer projector, microphone, or a company car. Equipment mailboxes can be included as resources in meeting requests, providing a simple and efficient way of utilizing resources for your users.
Legacy mailbox	A mailbox that resides on a server running Exchange Server 2003.
Linked mailbox	A mailbox that's assigned to an individual user in a separate, trusted forest.
Mail contact	A mail-enabled Active Directory contact that contains information about people or organizations that exist outside the Exchange organization. Each mail contact has an external e-mail address. All messages sent to the mail contact are routed to this external e-mail address.
Mail forest contact	A mail contact that represents a recipient object from another forest. Mail forest contacts are typically created by Microsoft Identity Integration Server (MIIS) synchronization. **Important:** Mail forest contacts are read-only recipient objects that are updated only through MIIS or similar custom synchronization. You can't use the EMC or the Shell to remove or modify a mail forest contact.
Mail user	A mail-enabled Active Directory user that represents a user outside the Exchange organization. Each mail user has an external e-mail address. All messages sent to the mail user are routed to this external e-mail address. A mail user is similar to a mail contact, except that a mail user has Active Directory logon credentials and can access resources.

Mail-enabled non-universal group	A mail-enabled Active Directory global or local group object. Mail-enabled non-universal groups were discontinued in Exchange Server 2007 and can exist only if they were migrated from Exchange 2003 or earlier versions of Exchange. You can't use Exchange 2010 to create non-universal distribution groups.
Mail-enabled public folder	An Exchange public folder that's configured to receive messages.
Mail-enabled universal distribution group	A mail-enabled Active Directory distribution group object that can be used only to distribute messages to a group of recipients.
Mail-enabled universal security group	A mail-enabled Active Directory security group object that can be used to grant access permissions to resources in Active Directory and can also be used to distribute messages.
Microsoft Exchange recipient	A special recipient object that provides a unified and well-known message sender that differentiates system-generated messages from other messages. It replaces the System Administrator sender used for system-generated messages in earlier versions of Exchange. To learn more, see Understanding the Microsoft Exchange Recipient.
Room mailbox	A resource mailbox that's assigned to a meeting location, such as a conference room, auditorium, or training room. Room mailboxes can be included as resources in meeting requests, providing a simple and efficient way of organizing meetings for your users.
Shared mailbox	A mailbox that's not primarily associated with a single user and is generally configured to allow logon access for multiple users.
User mailbox	A mailbox that's assigned to an individual user in your Exchange organization. It typically contains messages, calendar items, contacts, tasks, documents, and other important business data.
Remote mailbox	New in Exchange 2010, a remote mailbox consists of a mail-enabled user that exists in the on-premises Active Directory and an associated mailbox that exists in the cloud-based service.
Linked user	New in Exchange 2010, a linked user is a user that resides in one forest while their mailbox resides in another forest.

Mailboxes

Mailboxes are the most common recipient type used by information workers in an Exchange organization. Each mailbox is associated with an Active Directory user account.

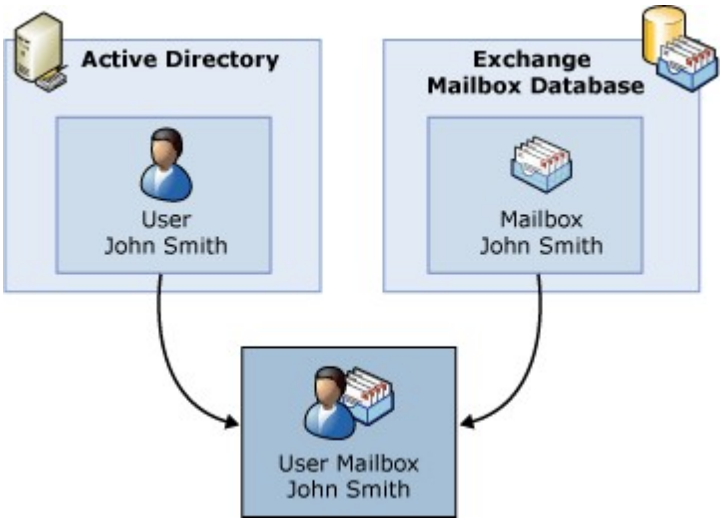
The user can use the mailbox to send and receive messages, and to store messages, appointments, tasks, notes, and documents. Mailboxes are the primary messaging and collaboration tool for the users in your Exchange organization.

Mailbox Components

Each mailbox consists of an Active Directory user and the mailbox data that's stored in the Exchange mailbox database (as shown in the following figure). All configuration data for the mailbox is stored in the Exchange attributes of the Active Directory user object. The mailbox database contains the actual data that's in the mailbox associated with the user account.

Important:

When you create a mailbox for a new or existing user, the Exchange attributes required for a mailbox are added to the user object in Active Directory. The associated mailbox data isn't created until the mailbox either receives a message or the user logs on to it.



Warning:

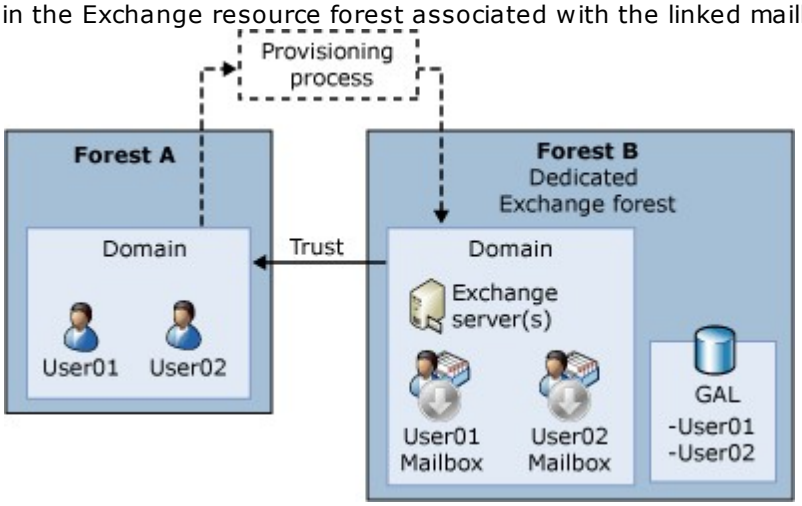
If you remove a mailbox, the mailbox data stored in the Exchange mailbox database is marked for deletion and the associated user account is also deleted from Active Directory. To retain the user account and delete only the mailbox data, you must disable the mailbox.

Mailbox Types

Exchange 2010 supports the following mailbox types:

- **User mailboxes** User mailboxes are assigned to individual users in your Exchange organization. User mailboxes provide your users with a rich collaboration platform. They can send and receive messages, manage their contacts, schedule meetings, and maintain a task list. Users can also have voice mail messages delivered to their mailboxes. User mailboxes are the most commonly used mailbox type and are typically the mailbox type assigned to users in your organization.
- **Linked mailboxes** Linked mailboxes are mailboxes that are accessed by users in a separate, trusted forest. Linked mailboxes may be necessary for organizations that deploy Exchange in a resource forest. The resource forest scenario allows an organization to centralize Exchange in a single forest, while allowing access to the Exchange organization with user accounts in one or more trusted forests.
  As stated earlier, every mailbox must have a user account associated with it. However, the user account that accesses the linked mailbox doesn't exist in the forest where Exchange is deployed. Therefore, a disabled user account that exists in the same forest as Exchange is associated with each linked mailbox. The following figure illustrates the relationship between the linked user account used to access the linked mailbox and the disabled user account

in the Exchange resource forest associated with the linked mailbox.



- **Remote mailboxes** When you create a remote mailbox, the mail-enabled user is created in your on-premises Active Directory. Directory synchronization, if it's configured, automatically synchronizes this new user object to the cloud-based service, which then converts it to a user mailbox. You can create remote mailboxes as regular user mailboxes or as resource mailboxes for meeting rooms and equipment.
- **Shared mailboxes** Shared mailboxes aren't primarily associated with individual users and are generally configured to allow logon access for multiple users.
  Although it's possible to grant additional users the logon rights to any mailbox type, shared mailboxes are dedicated for this functionality. The Active Directory user associated with a shared mailbox must be a disabled account. After you create a shared mailbox, you must grant permissions to all users that require access to the shared mailbox.

  Important:

  You can only use the Shell to manage shared mailboxes. Management tasks include creating, removing, enabling, and disabling. After you create a shared mailbox, you can use the EMC for some tasks such as viewing, modifying, or moving the shared mailboxes. We recommend that you use resource mailboxes or Microsoft SharePoint Portal Server portals for collaboration instead of shared mailboxes. To learn more about converting a shared mailbox to a resource mailbox, see Convert a Mailbox.
- **Legacy mailboxes** Legacy mailboxes are mailboxes that reside on servers running Exchange 2003. You can manage legacy mailboxes by using the EMC or the Shell. However, not all Exchange 2010 features will apply to these mailboxes.
- **Resource mailboxes** Resource mailboxes are special mailboxes designed to be used for scheduling resources. Like all mailbox types, a resource mailbox has an associated Active Directory user account, but it must be a disabled account. The following are the resource mailbox types:
  - **Room mailboxes** These are resource mailboxes that are assigned to meeting locations, such as conference rooms, auditoriums, and training rooms.
  - **Equipment mailboxes** These are resource mailboxes that are assigned to non-location specific resources, such as portable computer projectors, microphones, or company cars.

  You can include both types of resource mailboxes in meeting requests, providing a simple and efficient way to utilize resources for your users. You can configure resource mailboxes to automatically process incoming meeting requests based on the resource booking policies that are defined by the resource owners. For example, you can configure a conference room to

automatically accept incoming meeting requests except recurring meetings, which can be subject to approval by the resource owner. To learn more about using resource mailboxes, see Managing Resource Mailboxes and Scheduling.

System Mailboxes

System mailboxes are created by Exchange in the root domain of the Active Directory forest during installation. Users or administrators can't log on to these mailboxes. System mailboxes are created for Exchange 2010 features such as message approval and Multi-Mailbox Search. This table lists information about system mailboxes as they're displayed in Active Directory.

Mailbox	Common name (CN)
Discovery	SystemMailbox {e0dc1c29-89c3-4034-b678-e6c29d823ed9}
Message Approval	SystemMailbox {1f05a927-*xxxx*- *xxxx* - *xxxx* -*xxxxxxxxxxxx*} where *x* is a randomly assigned number
Federated E-mail	FederatedEmail 4c1f4d8b-8179-4148-93bf-00a95fa1e042

If you want to decommission the last Exchange 2010 Mailbox server in your organization, you should first disable these system mailboxes by using the Disable-Mailbox cmdlet. When you decommission a Mailbox server that contains these system mailboxes, you should move them to another Mailbox server to make sure that you don't lose functionality.

Planning for Mailboxes

Mailboxes are created in mailbox databases on Exchange servers that have the Mailbox server role installed. To help provide a reliable and effective platform for your mailbox users, detailed planning for the deployment of Mailbox servers and databases is essential. To learn more about planning for Mailbox servers and databases, see the following topics:

- Planning Roadmap for New Deployments
- Exchange 2003 - Planning Roadmap for Upgrade and Coexistence
- Exchange 2007 - Planning Roadmap for Upgrade and Coexistence
- Managing Mailbox Databases
- Managing Mailbox Servers

Distribution Groups

Distribution groups are mail-enabled Active Directory group objects that are primarily used for distributing messages to multiple recipients. Any recipient type can be a member of a distribution group.

Important:
Note the terminology differences between Active Directory and Exchange 2010. In Active Directory, a distribution group refers to any group that doesn't have a security context, whether it's mail-enabled or not. In Exchange 2010, all mail-enabled groups are referred to as distribution groups, whether they have a security context or not.

Exchange supports the following types of distribution groups:

- **Mail-enabled universal distribution groups** These are Active Directory distribution group objects that are mail-enabled. They can be used only to distribute messages to a group of recipients.
- **Mail-enabled universal security groups** These are Active Directory security group objects that are mail-enabled. They can be used to grant access permissions to resources in Active Directory and can also be used to distribute

messages.

- **Mail-enabled non-universal groups** These are Active Directory global or local group objects that are mail-enabled. You can create or mail-enable only universal distribution groups. You may have mail-enabled groups that were migrated from previous versions of Exchange that aren't universal groups. These groups can still be managed by using the EMC or the Shell.

Note:
To convert a domain-local or a global group to a universal group, you can use the Set-Group cmdlet in the Shell.

For more information about the changes from Exchange Server 2007 to Exchange Server 2010 that affect group management, see the Distribution Groups section in the "New Mailbox and Recipient Functionality" topic.

Dynamic Distribution Groups

Dynamic distribution groups are distribution groups whose membership is based on specific recipient filters rather than a defined set of recipients.

Unlike regular distribution groups, the membership list for dynamic distribution groups is calculated each time a message is sent to them, based on the filters and conditions that you specify. When an e-mail message is sent to a dynamic distribution group, it's delivered to all recipients in the organization that match the criteria defined for that dynamic distribution group.

Important:
A dynamic distribution group includes any recipient in Active Directory that has attributes that match the group's filter at the time a message is sent. If a recipient's properties are modified to match the group's filter, that recipient could inadvertently become a group member and start receiving messages that are sent to the dynamic distribution group. Well-defined, consistent account provisioning processes can reduce the chances of this issue occurring.

To help you create recipient filters for dynamic distribution groups, you can use precanned filters. A *precanned filter* is a commonly used filter that you can use to meet a variety of recipient-filtering criteria. You can use these filters to specify the recipient types that you want to include in a dynamic distribution group. In addition, you can also specify a list of conditions that the recipients must meet. You can create precanned conditions based on the following properties:

- Custom attributes 1–15
- State or province
- Company
- Department

You can also specify conditions based on recipient properties other than those previously listed. To do this, you must use the Shell to create a custom query for the dynamic distribution group. Keep in mind that the filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell. For an example of how to create a dynamic distribution group by using a custom query, see Create a Dynamic Distribution Group.

Note:
In the EMC, you use the **Distribution Group** node under **Recipient Configuration** to manage dynamic distribution groups. There isn't a separate node for dynamic distribution groups.

Mail Contacts

Mail contacts typically contain information about people or organizations that exist outside your Exchange organization. Mail contacts can appear in the global address list (GAL) and other address lists, and can be added as members to distribution groups. Each contact has an external e-mail address, and all e-mail messages that are sent to a contact are

automatically forwarded to that address. Contacts are ideal for representing people external to your Exchange organization who don't need access to any internal resources. The following are mail contact types:

- **Mail contacts** These are mail-enabled Active Directory contacts that contain information about people or organizations that exist outside your Exchange organization.
- **Mail forest contacts** These represent recipient objects from another forest. These contacts are typically created by MIIS synchronization. Mail forest contacts are read-only recipient objects that can be updated or removed only by means of synchronization. You can't use Exchange management interfaces to modify or remove a mail forest contact.

Mail Users

Mail users are similar to mail contacts. Both have external e-mail addresses, both contain information about people outside your Exchange organization, and both can be displayed in the GAL and other address lists. However, unlike a mail contact, mail users have Active Directory logon credentials and can access resources to which they are granted permission.

If a person external to your organization requires access to resources on your network, you should create a mail user instead of a mail contact. For example, you may want to create mail users for short-term consultants who require access to your server infrastructure, but who will use their own external e-mail addresses.

Another scenario is to create mail users in your organization for users who you don't want to maintain an Exchange mailbox. For example, after an acquisition, the acquired company may maintain their separate messaging infrastructure, but may also need access to resources on your network. For those users, you may want to create mail users instead of mailbox users.

Note:

In the EMC, you use the **Mail Contact** node under **Recipient Configuration** to manage mail users. There isn't a separate node for mail users.

Mail-Enabled Public Folders

Public folders are intended to serve as a repository for information shared among many users. Mail-enabling a public folder provides an extra level of functionality to users. In addition to being able to post messages to the folder, users can send e-mail messages to, and sometimes receive e-mail messages from, the public folder. Each mail-enabled folder has an object in Active Directory that stores its e-mail address, address book name, and other mail-related attributes.

You can manage public folders by using either the Shell or the Public Folder Management Console. To access the Public Folder Management Console, click the **Toolbox** node in the EMC. For more information about managing mail-enabled public folders, see Configure Public Folder Properties.

Microsoft Exchange Recipient

The Microsoft Exchange recipient is a special recipient object that provides a unified and well-known message sender that differentiates system-generated messages from other messages. It replaces the System Administrator sender that was used for system-generated messages in earlier versions of Exchange.

The Microsoft Exchange recipient isn't a typical recipient object, such as a mailbox, mail user, or mail contact, and it isn't managed by using the typical recipient tools. However, you can use the Set-OrganizationConfig cmdlet in the Shell to configure the Microsoft Exchange recipient.

To learn more about the Microsoft Exchange recipient, see Understanding the Microsoft Exchange Recipient.

Note:
When system-generated messages are sent to an external sender, the Microsoft Exchange recipient isn't used as the sender of the message. Instead, the e-mail address specified by the *ExternalPostmasterAddress* parameter in the Set-TransportConfig cmdlet is used. For more information about the external postmaster address, see Configure the External Postmaster Address.

1.8.1.14.1 Understanding Automatic Mailbox Distribution

Understanding Automatic Mailbox Distribution

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-07*

When you create or move a mailbox, or mail-enable an existing user, that mailbox needs to be stored in a mailbox database. In previous versions of Microsoft Exchange, you needed to specify the mailbox database when you performed one of those operations. With Microsoft Exchange Server 2010, you have the option of letting Exchange choose the database for you using automatic mailbox distribution.

With automatic mailbox distribution, Exchange looks at the mailbox databases in your organization, excludes databases that aren't suitable using criteria discussed later in this topic, and then randomly chooses a database where the mailbox should be located. This process randomly distributes mailboxes across all of the suitable mailbox databases in your organization.

Automatic distribution is used when you don't specify the *Database* parameter on the **New-Mailbox** and **Enable-Mailbox** cmdlets or the *TargetDatabase* parameter on the **New-MoveRequest** cmdlet.

Note:
Automatic mailbox distribution is performed only when a mailbox is created on an Exchange 2010 server, moved to an Exchange 2010 server, or when a user is mail-enabled. The **New-Mailbox**, **New-MoveRequest**, and **Enable-Mailbox** cmdlets must be run from a server running Exchange 2010. Exchange doesn't redistribute mailboxes to distribute load across databases automatically based on server load.

The following process is used to find a suitable mailbox database where a new or moved mailbox should be located:

1. Exchange retrieves a list of all mailbox databases in the Exchange 2010 organization.
2. Any mailbox database that's marked for exclusion from the distribution process is removed from the available list of databases. You can control which databases are excluded. For more information, see Exclude Databases from Automatic Distribution later in this topic.
3. Any mailbox database that's outside of the database management scopes applied to the administrator performing the operation is removed from the list of available databases. For more information, see Database Scopes later in this topic.
4. Any mailbox database that's outside of the local Active Directory site where the operation is being performed is removed from the list of available databases.
5. From the remaining list of mailbox databases, Exchange chooses a database randomly. If the database is online and healthy, the database is used by Exchange. If it's offline or not healthy, another database is chosen at

random. If no online or healthy databases are found, the operation fails with an error.

The process of selecting a mailbox database is performed by the Mailbox Resources Management Agent cmdlet extension agent. The `Mailbox Resources Management Agent` is one of several cmdlet extension agents that extend the functionality of running cmdlets. For more information about cmdlet extension agents, see Understanding Cmdlet Extension Agents.

If you never want mailboxes to be distributed automatically, you can disable the `Mailbox Resources Management Agent`. When you disable the agent, the change is applied to the entire Exchange 2010 organization. For more information about how to disable cmdlet extension agents, see Disable a Cmdlet Extension Agent.

Exclude Databases from Automatic Distribution

By default, all online and healthy mailbox databases on Exchange 2010 servers in the local Active Directory site can be chosen by automatic mailbox distribution to store a new or moved mailbox. However, you might want to exclude some databases from the distribution process for various reasons. For example, you may designate a mailbox database as a journaling database in which only mailboxes you manually specify should be located. Or you might want to temporarily remove a database from rotation to perform scheduled maintenance. Exchange 2010 gives you the option to either permanently or temporarily exclude databases from the exclusion process.

Every Exchange 2010 mailbox database has the two following properties that can be set using the **Set-MailboxDatabase** cmdlet:

- **IsExcludedFromProvisioning** Use this property if you want to indicate that the database should be permanently excluded from automatic mailbox distribution.
- **IsSuspendedFromProvisioning** Use this property if you want to indicate that the database should be temporarily excluded from automatic mailbox distribution.

Both properties have two valid values, `$True` and `$False`. The default value for each is `$False`. The property you choose is purely for your information. Setting either property to `$True` has the same result of excluding the database from the automatic distribution process. Both properties must be set to `$False` for a mailbox database to be included in the automatic distribution process.

Exchange 2010 provides these two properties for excluding a mailbox database from automatic distribution so that you can easily identify the databases that have been permanently excluded from automatic distribution and which have been temporarily excluded.

To set a mailbox database as permanently excluded from automatic distribution, use the following command:

```
Set-MailboxDatabase <database name> -IsExcludedFromProvisioning $True
```

To set a mailbox database as temporarily excluded from automatic distribution, use the following command:

```
Set-MailboxDatabase <database name> -IsSuspendedFromProvisioning $True
```

When a mailbox database is excluded from automatic distribution, the only way to create a mailbox in, or move a mailbox to, the database is to use the *Database* parameter on the

New-Mailbox and **Enable-Mailbox** cmdlets or the *TargetDatabase* parameter on the **New-MoveRequest** cmdlet.

If you want to make an excluded mailbox database available for selection in the automatic distribution process, set both properties to `$False`.

Database Scopes

Database management scopes are an additional level of control over the automatic mailbox distribution process that's been added to Microsoft Exchange Server 2010 Service Pack 1 (SP1). If a mailbox database is online and healthy, it's in the local Active Directory site, and it isn't excluded from the automatic distribution process, Exchange 2010 SP1 checks to see if the mailbox database is included in the database scope applied to the administrator running the cmdlet. If it's included in the database scope, it's included in the list of databases available to that administrator.

Database scopes are part of the Role Based Access Control (RBAC) permissions model. For more information about RBAC and database scopes, see the following topics:

- Understanding Role Based Access Control
- Understanding Management Role Scopes

Database scopes can be useful if you have many mailbox databases in your local Active Directory site that are available to automatic distribution, but you want to limit which databases can be used by certain sets of administrators. For example, your Exchange 2010 SP1 servers may serve several agencies but you only want to allow each agency to create or move mailboxes to mailbox databases that are allocated to them.

By default, all administrators in an Exchange 2010 SP1 organization can see all of the mailbox databases in the organization. To limit the databases that they can see, and therefore limit the databases they can potentially create mailboxes in or move mailboxes to, you must do the following:

1. Create a custom database management scope using the **New-ManagementScope** cmdlet that includes only the mailbox databases you want the administrator to use.
2. Associate the new database scope with a management role assignment in one of the following ways:
   - Add the new database scope to an existing management role assignment using the *CustomConfigWriteScope* parameter on the **Set-ManagementRoleAssignment** cmdlet. The database scope is now applied to the management role group, universal security group (USG), or user assigned the role assignment.
   - Create a management role assignment using the **New-ManagementRoleAssignment** cmdlet and use the *CustomConfigWriteScope* parameter to specify the new database scope. You can create a role assignment between a management role and a role group, USG, or user.
3. If you created a role assignment to a role group or USG, add users to the role group or USG so that the role assignment and database scope are applied to the users.
4. If applicable, remove the user (or users who are members of role groups or USGs you created in the preceding steps) you assigned the new role assignment to from any other role groups or USGs that might be assigned a database scope that contains databases you don't want them to access.
5. Verify that the administrators have access only to the databases they should have access to.

After you complete these steps, the administrators that are assigned role assignments with the database scopes you created will only be able to create mailboxes in or move mailboxes to the databases you specified.

For more information about how to use database scopes to limit which mailbox databases are available to administrators, see Control Automatic Mailbox Distribution Using Database Scopes.

1.8.1.14.2 Understanding Custom Attributes

Understanding Custom Attributes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-14*

Microsoft Exchange Server 2010 and Exchange Server 2007 include 15 extension attributes. You can use these attributes to add information about a recipient, such as an employee ID, organizational unit (OU), or some other custom value for which there isn't an existing attribute. These custom attributes are labeled in Active Directory as **ms-Exch-Extension-Attribute1** through **ms-Exch-Extension-Attribute15**. In the Exchange Management Shell, the corresponding parameters are *CustomAttribute1* through *CustomAttribute15*. These attributes aren't used by any Exchange components. They can be used to store Active Directory data without having to extend the Active Directory schema.

In Exchange Server 2003 and earlier, if you wanted to store this information in Active Directory, you had to create an attribute by extending the Active Directory schema. Schema extension requires planning, procuring object identifiers (OIDs) for new attributes, and testing the extension process in a test environment before you implement it in a production environment. In Exchange 2010 and Exchange 2007, user-defined Active Directory schema extensions can't be used in recipient filters used by address lists, e-mail address policies, and dynamic distribution groups.

Important:

In Exchange 2003, you can create user-defined Active Directory schema extensions. However, in Exchange 2010, you can't use Exchange 2003 user-defined schema extensions as filterable properties. If your organization has user-defined schema extensions, we recommend that you use the 15 custom attributes defined by Exchange 2010 for each recipient. However, if the 15 custom attributes defined by Exchange don't meet the needs of your organization, we recommend that you don't upgrade objects that use user-defined schema extensions.

Contents

Advantages of Custom Attributes

Some of the advantages of using custom attributes include:

- You avoid extending the Active Directory schema.
- The attributes are created by Exchange Setup.
- You can use the Exchange Management Console (EMC) or the Exchange

Management Shell to manage the attributes. You don't need to build custom controls or write scripts to populate and display these attributes.
- The attributes are filterable properties that can be used in the *Filter* parameter with recipient cmdlets such as **Get-Mailbox**. They can also used in the EMC and the Shell to create filters for e-mail address policies, address lists, and dynamic distribution groups.

Return to top

Custom Attribute Examples

In many Exchange deployments, creating an e-mail address policy for all recipients in an OU is a common scenario. The OU isn't a filterable property that can be used in the *RecipientFilter* parameter of an e-mail address policy or an address list.

Note:
Dynamic distribution groups have an additional parameter that you can use to restrict it to recipients in a particular OU or container.

If the recipients in that OU don't share any common properties that you can filter by, such as department or location, you can populate one of the custom attributes with a common value, as shown in this example.

```
Get-Mailbox -OrganizationalUnit Sales | Set-Mailbox CustomAttribute1 "SalesOU"
```

Now you can create an e-mail address policy for all recipients that have the *CustomAttribute1* property that equals SalesOU, as shown in this example.

```
New-EmailAddressPolicy -Name "Sales" -RecipientFilter { CustomAttribute1 -eq "Sal
```

Return to top

Custom Attribute Example with the ConditionalCustomAttributes Parameter

When creating dynamic distribution groups, e-mail address policies, or address lists, you don't need to use the *RecipeintFilter* parameter to specify custom attributes. You can use the *ConditionalCustomAttribute1* to *ConditionalCustomAttribute15* parameters instead. You can create a dynamic distribution group based on the recipients whose CustomAttribute1 is set to SalesOU, as shown in this example.

```
New-DynamicDistributionGroup -Name "Sales Users and Contacts" -IncludedRecipients
```

Note:
You must use the *IncludedRecipients* parameter if you use a *Conditional* parameter. In addition, you can't use *Conditional* parameters if you use the *RecipientFilter* parameter. If you want to include additional filters to create your dynamic distribution group, e-mail address policies, or address lists, you should use the *RecipientFilter* parameter.

Return to top

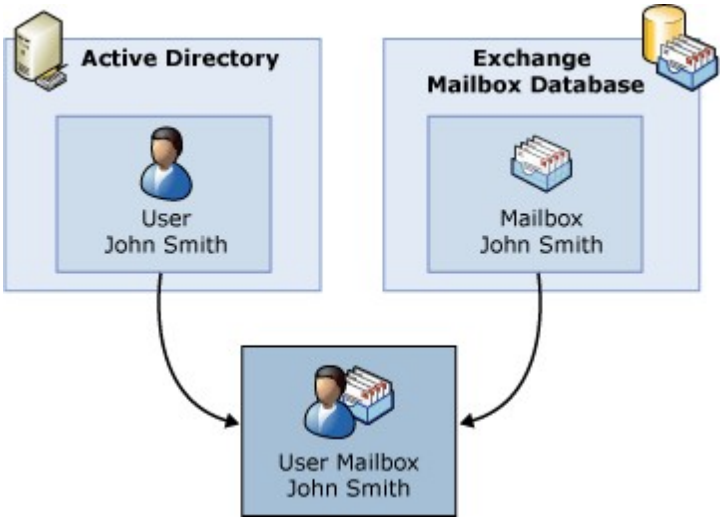
Understanding Disconnected Mailboxes

[This topic is in progress.]

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Each mailbox consists of an Active Directory user and the mailbox data stored in the Exchange mailbox database. (The following figure shows the components of a mailbox.) All configuration data for a mailbox is stored in the Exchange attributes of the Active Directory user object. The mailbox database contains the mail data that's in the mailbox associated with the user account.



A disconnected mailbox is a mailbox object in the mailbox database that isn't associated with an Active Directory user account. There are two types of disconnected mailboxes:

- **Disabled mailboxes** When a mailbox is disconnected or removed by using the **Disable-Mailbox** or **Remove-Mailbox** cmdlet, Exchange retains the deleted mailbox and the mailbox is switched to a disabled state. With disabled mailboxes, you can recover mailbox data without having to restore the entire mailbox database. Disabled mailboxes are retained in the mailbox database until the deleted mailbox retention period expires or until the mailbox is permanently deleted.
- **Soft-deleted mailboxes** When mailboxes are moved from a Microsoft Exchange Server 2010 Service Pack 1 (SP1) database to any other database, Exchange doesn't fully delete the mailbox from the source database upon completion of the move. Instead, the mailbox in the source mailbox database is switched to a *soft-deleted* state. With soft-deleted mailboxes, you can use the **MailboxRestoreRequest** cmdlet set to access mailbox data during a mailbox restore operation. Soft-deleted mailboxes are retained in the source database until either the deleted mailbox retention period expires or until the **Remove-StoreMailbox** cmdlet is used to purge the mailbox. For more information, see Restore a Soft-Deleted Mailbox.

For more information and detailed steps about how to manage disconnected mailboxes, see Managing Disconnected Mailboxes.

Working with Disabled Mailboxes

There are three operations you can perform on a disabled mailbox:

- Connect it to an existing user account in Active Directory
- Restore it to a new or existing user account in Active Directory
- Permanently delete it from the Exchange mailbox database

During the time a disabled mailbox is retained in the Exchange mailbox database, you can connect it to an existing Active Directory user account that isn't associated with another mailbox. Scenarios in which you may want to connect or restore a disabled mailbox include the following:

- You disabled a mailbox and now want to reconnect the mailbox to an Active Directory user account.
- You removed a mailbox by using the Remove-Mailbox cmdlet without the *Permanent* or *StoreMailboxIdentity* parameters and now want to reconnect the mailbox to a different Active Directory user account.
- You want to convert a user mailbox to a linked mailbox associated with a user account external to the forest in which your Exchange organization exists. The resource forest scenario is an example of when you would want to associate a mailbox with an external account. In a resource forest scenario, user objects in the Exchange forest have mailboxes, but the user objects are disabled for logon. You must associate these mailbox objects in the Exchange forest with enabled user objects in the external accounts forest.

Connecting or Restoring Disabled Mailboxes

In Exchange 2010 SP1, there are two methods by which you can reconnect a disabled mailbox. In the first method, you can still use the **Connect-Mailbox** cmdlet in the Exchange Management Shell or the Connect Mailbox wizard in the Exchange Management Console (EMC) to connect a disabled mailbox. This method was introduced in Exchange 2007. The Connect Mailbox wizard is available from the action pane when you select the **Disconnected Mailbox** node under **Recipient Configuration**.

The second method to reconnect a disabled mailbox uses the *MailboxRestoreRequest* cmdlet set in the Shell. This cmdlet set uses the Mailbox Replication Service (MRS) to reconnect the mailbox. You can't use the EMC to perform this process.

After you reconnect a mailbox to an existing Active Directory user account, that user account becomes the owner of the mailbox and has full access to any content within the mailbox.

For detailed instructions about how to connect disabled mailboxes, see Connect or Restore a Disabled Mailbox

Permanently Deleting a Disabled Mailbox

As stated previously, Exchange retains disabled mailboxes in the mailbox database based on the deleted mailbox retention settings configured for that mailbox database. After the specified retention period, a disabled mailbox is permanently deleted from the Exchange mailbox database. However, you can also permanently delete a disabled mailbox at any time by using one of the following two methods:

- You can use the Remove-Mailbox cmdlet in the Shell. To do this, you need to set the *Permanent* parameter to `$true` when you run the command.
  If you want to permanently delete the data within the mailbox database for a previously disabled mailbox, you must use the *StoreMailboxIdentity* parameter with the **Remove-Mailbox** cmdlet. You can use the Get-MailboxStatistics cmdlet to determine the value you need to supply to the *StoreMailboxIdentity* parameter for a disconnected mailbox. For an example of this scenario, see the third code example in the reference topic Remove-Mailbox.
- You can use the Remove-StoreMailbox cmdlet to purge a mailbox and all of its

message content from the mailbox database. This results in permanent data loss for the mailbox being purged. You can only run this cmdlet against disconnected mailboxes. For more information, see Permanently Delete a Disconnected Mailbox.

Working with Soft-Deleted Mailboxes

A soft-deleted mailbox is created when the mailbox is moved from one Exchange Server 2010 SP1 mailbox database to any other mailbox database. Exchange doesn't fully delete the mailbox from the source database after a move in case an error occurs causing the mailbox on the destination database to fail. You can always restore the source mailbox and try again. Exchange will retain the soft-deleted mailbox for the retention period.

There are two operations that you can perform on soft-deleted mailboxes:

1. You can restore the soft-deleted mailbox to an existing active directory user.
2. You can permanently delete the soft-deleted mailbox.

Restoring a Soft-Deleted Mailbox

Permanently Deleting a Soft-Deleted Mailbox

Working with Disconnected Personal Archives

Personal archives become disconnected when they are disabled. Similar to disabled mailboxes, a disconnected personal archive can be connected by using the **Connect-Mailbox** cmdlet with the *Archive* parameter.

The primary mailbox and the personal archive share the same legacy distinguished name (DN), so you must connect the personal archive to the same user mailbox that it was previously connected to. You can't connect the personal archive to a different user mailbox.

There are two operations that you can perform on disconnected personal archives:

- Connect it to an existing mailbox in Active Directory
- Permanently delete it from the Exchange mailbox database

Connecting Disconnected Personal Archives

A disconnected personal archive is retained in the mailbox database for a specified amount of time. By default, Exchange retains the disconnected personal archives for 30 days. During this time, you can recover the personal archive by associating it with an existing mailbox.

Note:

If you disable a personal archive for a user mailbox and then enable a personal archive for that same user, that user mailbox will get a new personal archive. You must use the **Connect-Mailbox** cmdlet to connect a disabled personal archive to an existing mailbox.

For more information, see Connect a Disconnected Personal (On-Premises) or Cloud-Based Archive.

Permanently Deleting a Disabled Personal Archive

Exchange retains disconnected personal archives based on the deleted mailbox retention settings configured for the mailbox database. The default retention period is 30 days. After the specified retention period, a disconnected personal archive is permanently deleted from the mailbox database.

You can also permanently delete a disconnected mailbox at any time by using the

Remove-Mailbox cmdlet with the *Archive* switch in the Shell. To do this, you need to set the *Permanent* parameter to `$true` when you run the command.

1.8.1.14.4 Understanding the Microsoft Exchange Recipient

Understanding the Microsoft Exchange Recipient

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-27*

This topic describes the configuration and management of the Microsoft Exchange recipient. The *Microsoft Exchange recipient* is a special Microsoft Exchange Server 2010 recipient object that provides a unified and well-known message sender that differentiates system-generated messages from other messages. The Microsoft Exchange recipient is functionally equivalent to an internal postmaster. The Microsoft Exchange recipient replaces the System Administrator sender that was used for system-generated messages in earlier versions of Exchange. Messages from the Microsoft Exchange recipient display **Microsoft Exchange** as the sender. The types of messages sent by the Microsoft Exchange recipient include:

- DSN messages
- Journal reports
- Quota messages
- Agent-generated messages

Contents

Configuring the Microsoft Exchange Recipient

Unlike a mailbox, mail user, or mail contact, the Microsoft Exchange recipient isn't a typical recipient object. The Microsoft Exchange recipient isn't managed by using the typical recipient tools found in the Exchange Management Console (EMC) or the Exchange Management Shell. However, you can use the Set-OrganizationConfig cmdlet in the Shell to perform the following configuration tasks:

- Allow or prevent the application of the default e-mail address policy to the Microsoft Exchange recipient. By default, the default mail address policy is applied to the Microsoft Exchange recipient.
- Configure a recipient object to receive messages that are sent to the Microsoft Exchange recipient. By default, no recipient is configured to receive messages that are sent to the Microsoft Exchange recipient.
- Configure the e-mail addresses of the Microsoft Exchange recipient. This includes specifying a primary SMTP address.

Microsoft Exchange Recipient Parameters

The following table describes the **Set-OrganizationConfig** parameters used to configure

the Microsoft Exchange recipient.

Microsoft Exchange recipient parameters in Set-OrganizationConfig

Parameter	Default value	Description
MicrosoftExchangeRecipientEmailAddresses	MicrosoftExchange329e71ec88ae4615bbc36ab6ce41109e@<*Accepted Domain*>. The <*Accepted Domain*> placeholder represents an accepted domain that's used in an e-mail address policy. For every accepted domain that's used in an e-mail address policy, there's a corresponding e-mail address.	The *MicrosoftExchangeRecipientEmailAddresses* parameter specifies one or more e-mail addresses for the Microsoft Exchange recipient. All valid Exchange 2010 e-mail address types may be used. You can specify multiple values for this parameter as a comma-delimited list. If the *MicrosoftExchangeRecipientEmailAddressPolicyEnabled* parameter is set to `$true`, the e-mail addresses are automatically generated by the default e-mail address policy, and you can't use the *MicrosoftExchangeRecipientEmailAddresses* parameter. E-mail addresses that you specify by using the *MicrosoftExchangeRecipientEmailAddresses* parameter replace any existing e-mail addresses that are already configured.
MicrosoftExchangeRecipientEmailAddressPolicyEnabled	`$true`	The *MicrosoftExchangeRecipientEmailAddressPolicyEnabled* parameter specifies whether the default e-mail address policy is automatically applied to the Microsoft Exchange recipient. The default value is `$true`. If this parameter is set to `$true`, Exchange 2010 automatically adds new e-mail addresses to the Microsoft Exchange recipient when e-mail address policies are added or modified in the Exchange organization. If this parameter is set to `$false`, you must manually add new e-mail addresses to the Microsoft Exchange recipient when e-mail address policies are added or modified. If you change the value of the *MicrosoftExchangeRecipientEmailAddressPolicyEnabled* parameter from `$false` to `$true`, any e-mail addresses that you defined by using the *MicrosoftExchangeRecipientEmailAddresses* parameter are preserved. However, the value of the *MicrosoftExchangeRecipientPrimarySmtpAddress parameter* reverts to

		MicrosoftExchange329e71ec88ae4615bbc36ab6ce41109e@<*Accepted Domain in Highest Priority E-mail Address Policy*>.
MicrosoftExchangeRecipientPrimarySmtpAddress	MicrosoftExchange329e71ec88ae4615bbc36ab6ce41109e@<*Accepted Domain in Highest Priority E-mail Address Policy*>	The *MicrosoftExchangeRecipientPrimarySmtpAddress* parameter specifies the primary return SMTP e-mail address for the Microsoft Exchange recipient. If the *MicrosoftExchangeRecipientEmailAddressPolicyEnabled* parameter is set to `$true`, you can't use the *MicrosoftExchangeRecipientPrimarySmtpAddress* parameter. If you modify the value of the *MicrosoftExchangeRecipientPrimarySmtpAddress* parameter, the value is automatically added to the list of e-mail addresses that are defined in the *MicrosoftExchangeRecipientEmailAddresses* parameter. The *MicrosoftExchangeRecipientPrimarySmtpAddress* parameter is meaningful only if the Microsoft Exchange recipient has more than one defined SMTP e-mail address. If the *MicrosoftExchangeRecipientEmailAddresses* parameter has only one defined SMTP e-mail address, the value of the *MicrosoftExchangeRecipientPrimarySmtpAddress* parameter and the *MicrosoftExchangeRecipientEmailAddresses* parameter are the same.
MicrosoftExchangeRecipientReplyRecipient	`$null`	The *MicrosoftExchangeRecipientReplyRecipient* parameter specifies the recipient that should receive messages that are sent to the Microsoft Exchange recipient. Typically, you would configure a mailbox to receive the messages that are sent to the Microsoft Exchange recipient. This parameter can take any of the following values for the specified recipient: • Distinguished name (DN) • Canonical name • GUID • Name • Display name • Alias

		• Exchange DN • Primary SMTP e-mail address If you don't configure a recipient for the Microsoft Exchange recipient, messages that are sent to the Microsoft Exchange recipient are discarded.

Internal and External Delivery of System Messages

The Microsoft Exchange recipient is used as the sender for system-generated messages sent to internal message senders. An internal sender is a recipient object that exists inside the Exchange organization. Specifically, the domain part of the primary SMTP e-mail address of the recipient object must be defined in the list of accepted domains for the Exchange organization.

When system-generated messages are sent to an external sender, the Microsoft Exchange recipient isn't used as the sender of the message. Instead, the e-mail address that's specified by the *ExternalPostmasterAddress* parameter in the Set-TransportConfig cmdlet is used. For more information, see Configure the External Postmaster Address.

However, under certain circumstances, the Microsoft Exchange recipient could be exposed to external recipients. These circumstances include but aren't limited to the following:

- Alternative recipients
- Externally forwarded meeting requests
- External out-of-office notifications
- Journal reports

Microsoft Exchange Recipient in Cross-Forest Scenarios

There's only one Microsoft Exchange recipient in an Exchange organization. Exchange 2010 determines that a message is sent from the Microsoft Exchange recipient by comparing the e-mail address of the message sender to the list of e-mail addresses that are defined by the *MicrosoftExchangeRecipientEmailAddresses* parameter. If Exchange 2010 determines that the sender is the Microsoft Exchange recipient, any messages from the sender are exempt from any configured message size limits that may exist in the Exchange organization.

However, in a cross-forest scenario, each forest has its own Microsoft Exchange recipient and its own message size limits. When messages are sent from the Microsoft Exchange recipient in the source forest, the target forest treats the sender as it would any other unauthenticated, external recipient. Even though the message is a system-generated message from the source forest, the message is still subject to any message size limits that are configured in the target forest.

To make sure that each forest can recognize messages that are sent from the Microsoft Exchange recipient in the other forest, you can configure the Microsoft Exchange recipient in each forest with an additional e-mail address that matches the primary e-mail address of the Microsoft Exchange recipient in the other forest. With this configuration, each forest can recognize messages that are sent from the Microsoft Exchange recipient in the other forest. This configuration correctly exempts messages that are sent from the Microsoft

Exchange recipient in both forests from any message size limits.

However, this configuration introduces issues if either forest allows messages to be sent to the Microsoft Exchange recipient by using the *MicrosoftExchangeRecipientReplyRecipient* parameter. Because the Microsoft Exchange recipient in each forest is configured by using the e-mail addresses of the Microsoft Exchange recipients of both forests, any messages that are sent to the Microsoft Exchange recipient will never leave the local forest from which the messages are sent. The messages will be sent to the recipient that's specified by the *MicrosoftExchangeRecipientReplyRecipient* parameter in the local forest. If one administrator is responsible for the messaging administration of both forests, that administrator can read the messages that are sent to the Microsoft Exchange recipient in both forests. However, if different administrators are responsible for each forest, the administrator of one forest can't manage the messages that are incorrectly sent to the Microsoft Exchange recipient in the other forest.

For more information about how to administer Exchange 2010 in cross-forest scenarios, see "Understanding Multiple Forest Administration" in Deploy Multiple Forest Topologies.

1.8.1.14.5 Understanding Recipient Restrictions

Understanding Recipient Restrictions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-02-01*

You can configure restrictions on the recipients in your organization. These restrictions allow you to use recipients consistent with your organization's policies.

Looking for management tasks related to managing Mailbox servers? See Managing Mailbox Servers.

Contents

Message Size Restrictions

Restrictions on the size of a message are the most commonly used restrictions in any messaging system. Setting a maximum message size prevents your messaging system, or the underlying network infrastructure, from being overwhelmed.

Depending on what you want to do, you can configure message size restrictions for several components. For example, you can restrict the total size of a message or the size of the individual message components (such as the message header, attachments, or the

number of recipients).

Although you can also specify whether message size restrictions are applied to your entire Microsoft Exchange Server 2010 organization or to a specific connector or user object, this section focuses only on message size restrictions that you can apply to recipients. For a complete list of message size restrictions that you can configure in an Exchange 2010 organization, see Understanding Message Size Limits.

When configuring message size restrictions for individual recipients, it's important to consider other message size restrictions that may exist in your organization. For example, assume that the Hub Transport servers in your organization are configured to restrict message size to 10 megabytes (MB). In this case, for a mail contact that has external addresses, you should set the maximum receive size to be no larger than 10 MB. Although a sender in your organization will be able to submit a message larger than 10 MB to this mail contact, the message would be rejected by the Hub Transport server. To learn more about how different message size restrictions affect each other and the order of precedence, see Understanding Message Size Limits.

Message Size Restrictions for All Recipient Types

Exchange 2010 can deliver or route messages to all recipients. Therefore, you can set a maximum receiving message size limit for any recipient type in your Exchange organization. If a sender attempts to send a message that's larger than the specified size, the message is returned to the sender with a descriptive error message.

In the Exchange Management Console (EMC), you set the maximum receiving message size by using the **Mail Flow Settings** tab of the recipient's properties. In the Exchange Management Shell, use the *MaxReceiveSize* parameter of the appropriate **Set-** cmdlet. For an example about how to configure receiving message size restrictions for a recipient, see Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder.

Message Size Restrictions Specific to Mailboxes and Mail-Enabled Public Folders

Mailboxes and mail-enabled public folders are the only recipient types that can submit messages to your Exchange messaging system. Therefore, in addition to setting receiving message size restrictions, you can also set sending message size restrictions.

In the EMC, you set the maximum sending message size of a mailbox by using the **Mail Flow Settings** tab of the mailbox properties. In the Shell, use the *MaxSendSize* parameter of the **Set-Mailbox** and **Set-MailPublicFolder** cmdlets. For an example about how to configure sending message size restrictions for mailboxes and mail-enabled public folders, see Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder.

Important:

If you implement sending message size restrictions for your mailbox users, you should also make sure that your Client Access servers are configured to accept client requests that are equal to or larger than the sending message size limit that you configured. Microsoft Office Outlook Web App uses ASP.NET and is thereby affected by the ASP.NET configuration. ASP.NET has a setting, **maxRequestLength**, which determines the maximum amount of data that the Web browser can submit to the Client Access server. If this limit is lower than the sending message size restriction, your users may receive a confusing error. To learn more about managing the maximum message size in Outlook Web App, see Configure Maximum Message Size in Outlook Web App.

Public Folder Management Console

The Public Folder Management Console is a Microsoft Management Console (MMC) 3.0-based interface that provides Exchange administrators with a graphical user interface (GUI) to create, configure, and manage public folders. You can also configure message size restrictions for a mail-enabled public folder by using the **Message Size Restrictions** option on the **Mail Flow Settings** tab of the public folder properties in the Public Folder Management Console. To learn more about the Public Folder Management Console, see

Using the Public Folder Management Console.

Return to top

Message Delivery Restrictions

With Exchange 2010, you can place restrictions on how messages are delivered to individual recipients. Message delivery restrictions apply to all recipient types and can be useful for controlling access to specific recipients in your Exchange 2010 organization. For example, several organizations specify that only a small set of users can send messages to large distribution groups.

You can configure the following message delivery restrictions for a recipient:

- **Accept messages from a specific list of senders** If you specify a list of senders from which to accept messages, the recipient will receive messages only from those senders. By default, all recipients are configured to accept messages from all senders.
  Use this restriction for recipients for which you want only a small number of authorized senders to be able to send messages. For example, you may want to configure a distribution group that contains all the employees in your organization to accept messages from only specific employees in the Human Resources department who are responsible for company-wide communications. Another scenario where you can use this restriction is for mail contacts that represent suppliers for a retail organization. You may want to configure each of these mail contacts to accept messages from only the buyers who work directly with those suppliers.
- **Reject messages from a specific list of senders** If you specify a list of senders from which to reject messages, the recipient will reject messages from those senders. By default, all recipients are configured not to reject messages from any senders.

  Note:
  This restriction overrides the **Accept messages from a specific list of senders** restriction. If a sender is listed in both lists, any messages sent by that sender will be rejected.

  Use this restriction to block specific users from sending messages to specific recipients. For an example about how this restriction is useful, consider the following scenario. You create a distribution group called All Employees. You configure that distribution group to accept messages from only those senders that are a member of the Human Resources distribution group. However, the Human Resources distribution group also includes mailboxes for interns whom you don't want to allow access to the All Employees distribution group. Therefore, to prevent the intern mailboxes from sending messages to the All Employees distribution group, you can specify the intern mailboxes when configuring the **Reject messages from a specific list of senders** restriction for the All Employees group.
- **Require that all senders are authenticated** If you configure a recipient to require that all senders are authenticated, any messages from senders that don't have valid logon credentials in your organization will be rejected. By default, only new distribution groups and dynamic distribution groups are configured to require all senders to be authenticated.

  Note:
  In previous versions of Exchange, by default, no recipients were configured to require all senders to be authenticated. Therefore, any distribution groups that you migrate from a previous version of Exchange won't have this restriction configured.

  Use this restriction to specify that recipients receive messages only from internal senders that have been successfully authenticated. For example, to

prevent messages that originate outside of your Exchange organization from being delivered to distribution groups that are used for internal communications, you can configure these groups to require sender authentication.

For details about how to configure message delivery restrictions for a recipient, see Configure Message Delivery Restrictions.

Return to top

Maximum Recipients per Message Restrictions

It can take a significant amount of time for a Hub Transport server to route messages that are addressed to a large number of recipients. As a result, this may affect the performance of the Hub Transport server, which could impact the overall message delivery in your Exchange organization.

To eliminate this risk, you can restrict the number of recipients that are allowed per message. Although you can configure this restriction at the mailbox level, you can also configure it at a higher level, such as the organization level, connector level (only for Receive connectors), and Hub Transport server level. Generally, it's a best practice to configure this setting at a higher level and use the mailbox-level configuration only for exceptions. For more information about the different levels at which you can configure this restriction, as well as a list of default values, see Understanding Message Size Limits.

For details about how to configure maximum recipients per message restrictions for a mailbox, see Restrict the Number of Recipients per Message.

Return to top

Mailbox Size Restrictions

You can configure storage quotas for mailboxes. By using storage quotas, you can control the size of mailboxes and manage the growth of mailbox databases. For detailed steps about how to configure storage quotas for a mailbox, see Configure Storage Quotas for a Mailbox.

Note:

You can also configure storage quotas at the mailbox database level. The quotas that you configure for a mailbox database apply to all mailboxes in that database, unless the mailbox is configured not to use mailbox database defaults. Generally, it's a best practice to configure storage quotas at the mailbox database level and use the mailbox level configuration only for exceptions. For detailed steps about how to configure storage quotas for a mailbox database, see Configure Mailbox Database Properties.

Because storage quotas have a direct impact on your storage capacity planning, you must plan your storage quotas carefully. Storage quotas, number of mailboxes per mailbox database, and the storage subsystem that hosts each mailbox database are all factors that you should consider when planning your deployment.

Before deploying Unified Messaging (UM) in your Exchange organization, you must review any existing storage quotas you've configured. Because Windows Media Audio (WMA) and waveform audio (.wav) files are attached to each voice message, voice messages may be larger than e-mail messages. As a result, voice messages may cause user mailboxes to exceed their quota more quickly than e-mail messages that don't include attachments. To learn more about the impact of Unified Messaging on storage quotas, see Understanding

Storage Quotas and Voice Mail.

Return to top

Public Folder Size Restrictions

Similar to mailboxes, you can configure storage quotas for your mail-enabled public folders. By using storage quotas, you can control the size of mail-enabled public folders and manage the growth of public folder databases.

In addition to storage quotas, you can also define age limits for your public folders. If you specify an age limit for a public folder, any items in that public folder that exceed the age limit without having been modified are removed automatically from that public folder. This provides administrators with an additional option for controlling the growth of their public folder databases. For detailed steps about how to configure storage quotas and age limits for public folders, see Configure Public Folder Properties.

Note:

Storage quotas and age limits also apply to public folders that aren't mail-enabled.

Return to top

1.8.1.14.6 Understanding Recipient Scope

Understanding Recipient Scope

Mailbox > Understanding Mailbox > Understanding Recipients >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-01-20*

You manage recipients by using the Exchange Management Console (EMC) and the Exchange Management Shell. These management interfaces provide the flexibility to view and manage recipients that are stored at various levels of an Active Directory hierarchy.

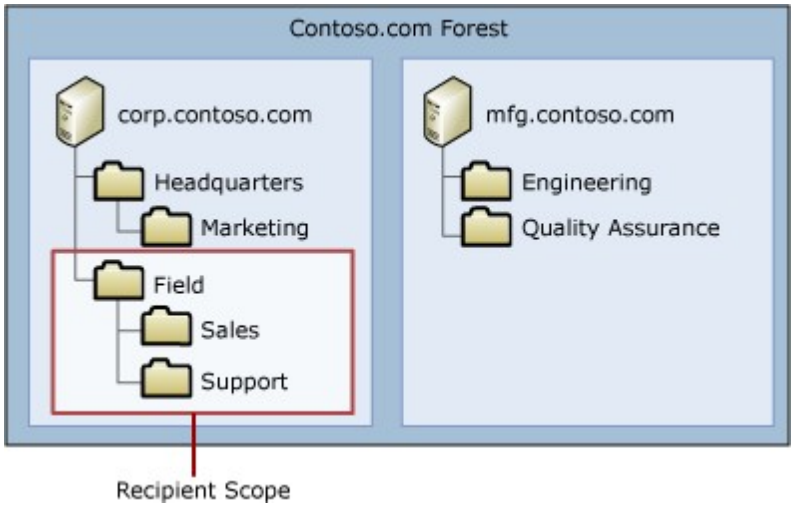
Microsoft Exchange Server 2010 management interfaces do this by using a concept called the *recipient scope*. Recipient scope refers to the specified portion of the Active Directory hierarchy that the EMC and the Shell will use for recipient management. When you set the recipient scope to a specific location within Active Directory, you can view and manage all recipients stored in that location and all the containers under it. For example, if you set the recipient scope to a domain, the Exchange management interface you're using lets you view and manage all recipients that are stored in all organizational units (OUs) within that domain.

Note:

The recipient scope is simply a view of Active Directory and has no security context. You can access and manage only the objects and containers to which your user account has been granted permission, regardless of the recipient scope setting.

Setting the recipient scope does more than limit the number of recipients returned. When you set the recipient scope, the management interface you are using operates within the recipient scope that you specified. When performing recipient management tasks, the management interface can view only the portion of Active Directory that you set as the recipient scope. For example, assume that your company has the Active Directory

structure shown in the following figure. If you set the recipient scope to the **Field** OU of the corp.contoso.com domain, the Exchange management interface can view only the portion of Active Directory that's highlighted in the following figure.



The recipient scope applies to the *first class* recipient objects. First class recipient objects refer to all mailboxes, mail contacts, mail users, distribution groups, and dynamic distribution groups.

Important:

The properties of first class recipient objects aren't bound by the recipient scope. For example, when adding members to a distribution group, you can select any recipient in the forest, regardless of the recipient scope. Similarly, when configuring the manager of a mailbox user, you can select any mail-enabled user or contact in the forest.

Looking for management tasks related to managing Mailbox servers? See Managing Mailbox Servers.

Recommendations for Working with Recipient Scope

The following are some recommendations for working with recipient scope:

- In large organizations, recipients may be spread across multiple domains or OUs. In these cases, setting a recipient scope that focuses on the specific set of recipients you're managing may reduce the number of recipients that are returned, thereby improving the performance of the Exchange management interfaces.
- Set the recipient scope to the entire forest only when performing specific tasks that apply to all recipients in the forest. When the recipient scope is set to the entire forest, the management interfaces use a global catalog server to access Active Directory. The recipient information that's displayed in the interfaces is dependent on the replication latencies of Active Directory. As a result, the information that's displayed may not be entirely up to date. Likewise, any updates made through the interfaces may not take effect until Active Directory replicates the changes.
  Furthermore, if you have a large Active Directory deployment with recipients spread across multiple domains, using a forest-wide recipient scope can reduce the performance of the management interfaces due to the sheer number of recipients returned.
- If you have a complex Active Directory replication topology, or if you have high

replication latency, specify the global catalog that's most up to date when setting the recipient scope to the entire forest.
- If you use a specific domain controller on which all updates to Active Directory are made, you can specify that domain controller as the preferred recipient domain controller when setting the recipient scope. For example, if you have an account provisioning system that works with a specific domain controller, you can specify that domain controller as the preferred recipient domain controller.

Setting the Recipient Scope

Exchange 2010 management interfaces always start with the recipient scope at the domain level. The default setting for the recipient scope is always set to the domain of the computer that's running the management interface. Neither the user account that's being used nor the Exchange servers being managed has bearing on the default value of the recipient scope.

To illustrate this point, consider a scenario where the organization contoso.com has an Active Directory forest with three domains: contoso.com (which contains all computer accounts), users.contoso.com (which contains all user accounts), and exchange.contoso.com (which contains the Exchange servers). To administer an Exchange server in exchange.contoso.com, an administrator logs on to a computer in contoso.com with a user account in users.contoso.com. When the administrator opens the EMC or the Shell, by default, the recipient scope is set to contoso.com.

Depending on the task you need to accomplish, you can change the recipient scope to a different location in Active Directory. You can set the recipient scope to a single OU, to the top level of an OU hierarchy, to a domain, or even to the entire forest.

Recipient Scope in the EMC

Changing the recipient scope in the EMC changes the set of recipients that are displayed in the result pane of the **Recipient Configuration** node. The dialog boxes that you use to select recipients or OUs (located on various wizard pages) also work within the same scope. For example, if you're mail-enabling an existing contact, the **Select Contact** dialog box in the New Mail Contact wizard displays only the contacts within the recipient scope that aren't already mail-enabled.

Note:

The Microsoft Management Console (MMC) saves any changes you make to a snap-in as preferences in your user profile on the administrator computer. The recipient scope setting is also saved as one of your preferences. As a result, the next time you start the EMC on the same computer, the default setting of the recipient scope is overwritten by the scope last specified. However, if you use another computer or a different user account to run the EMC, you will need to adjust the recipient scope again.

To modify the recipient scope in the EMC, select the **Recipient Configuration** node, and then click **Modify Recipient Scope** in the action pane. For more information about changing the recipient scope in the EMC, see Change the Recipient Scope.

Recipient Scope in the Shell

Because you must manually type all values in the Shell, it's important that you keep the recipient scope in mind as you manage recipients. If you make references to objects that are outside the recipient scope, you may receive errors. For example, if you try to create a new distribution group in an OU that isn't within the recipient scope you specified, you will receive the error, "Organizational unit *<OU name>* wasn't found. Please make sure you have typed it correctly".

You can view or modify the recipient scope by using the Set-AdServerSettings cmdlet.

When you change the recipient scope in the Shell, you change the set of recipients that

are returned for the **Get-** cmdlets of the recipient. The recipient scope is accessible by using the **Set-AdServerSettings** cmdlet.

Note:
The default scope isn't retained when you close the Shell. The Shell resets to the default domain-level recipient scope the next time that the Shell is opened.

1.8.1.15 Understanding Recoverable Items

Understanding Recoverable Items

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-14*

To protect from accidental or malicious deletion and to facilitate discovery efforts commonly undertaken before or during litigation or investigations, Microsoft Exchange Server 2010 introduces the Recoverable Items folder. The Recoverable Items folder replaces the feature known as the dumpster in Exchange Server 2007. The Recoverable Items folder is used by the following Exchange features:

- Deleted item retention
- Single item recovery
- Litigation hold
- Mailbox audit logging

Contents

Terminology

Knowledge of the following terms will help you understand the content in this topic.

Delete
: Describes when an item is deleted from any folder and placed in the Deleted Items default folder.

Soft delete
: Describes when an item is deleted from the Deleted Items default folder and placed in the Recoverable Items folder. Additionally describes when a Microsoft Outlook user deletes an item by pressing Shift+Delete, which bypasses the Deleted Items folder and places the item directly in the Recoverable Items folder.

Hard delete
: Describes when an item is marked to be purged from the mailbox database. This is also known as a *store hard delete*.

Return to top

Recoverable Items Folder

To better meet customers' legal compliance requirements, the dumpster is reinvented as

the Recoverable Items folder in Exchange 2010. The Recoverable Items folder resides in the non-IPM subtree of each mailbox. The non-IPM subtree is a storage area within the mailbox that contains operational data about the mailbox. This subtree isn't visible to users using Outlook, Microsoft Office Outlook Web App, or other e-mail clients.

This architectural change provides the following key benefits:

- When a mailbox is moved to another mailbox database, the Recoverable Items folder moves with it.
- The Recoverable Items folder is indexed by Exchange Search and can be discovered using Multi-Mailbox Search.
- The Recoverable Items folder has its own storage quota.
- Exchange can prevent data from being purged from the Recoverable Items folder.
- Exchange can track edits of certain content.

The Recoverable Items folder contains the following subfolders:

- **Deletions** This subfolder contains all items deleted from the Deleted Items folder. (In Outlook, you can soft delete an item by pressing Shift+Delete.) This subfolder is exposed to users through the Recover Deleted Items feature in Outlook and Outlook Web App.
- **Versions** If either litigation hold or single item recovery is enabled, this subfolder contains the original and modified copies of the deleted items. This folder isn't visible to end users.
- **Purges** If either litigation hold or single item recovery is enabled, this subfolder contains all items that are hard deleted. This folder isn't visible to end users.
- **Audits** If mailbox audit logging is enabled for a mailbox, this subfolder contains the audit log entries. To learn more about mailbox audit logging, see Understanding Mailbox Audit Logging.

Deleted Item Retention

An item is considered to be soft deleted in the following cases:

- A user deletes an item or empties all items from the Deleted Items folder.
- A user presses Shift+Delete to delete an item from any other mailbox folder.

Soft-deleted items are moved to the Deletions subfolder of the Recoverable Items folder. This provides an additional layer of protection so users can recover deleted items without requiring Help desk intervention. Users can use the Recover Deleted Items feature in Outlook or Outlook Web App to recover a deleted item. Users can also use this feature to permanently delete an item.

Items remain in the Deletions subfolder until the deleted item retention period is reached. The default deleted item retention period for a mailbox database is 14 days. You can modify this period for a mailbox database or for a specific mailbox. In addition to a deleted item retention period, the Recoverable Items folder is also subject to quotas. To learn more, see Recoverable Items Mailbox Quotas later in this topic.

After the deleted item retention period elapses, the item is moved to the Purges folder and is no longer visible to the user. When the Managed Folder Assistant processes the mailbox, items in the Purges subfolder are purged from the mailbox database.

Single Item Recovery

If an item is removed from the Deletions subfolder, either using the Recover Deleted Items feature or by an automated process such as the Managed Folder Assistant, the item can't be recovered by the user. In previous versions of Exchange, recovering these items required the administrator to restore the mailbox database or a mailbox from backup copies. This process generally delayed recovery by minutes or hours, depending on the backup mechanism used.

Exchange 2010 introduces *single item recovery*, a feature you can use to recover items without having to restore the mailbox databases using backup media. This results in considerably shorter recovery periods. When the Managed Folder Assistant processes the Recoverable Items folder for a mailbox that has single item recovery enabled, any item in the Purges subfolder isn't purged if the deleted item retention period hasn't elapsed for that item. Additionally, if the user changes certain properties of an item in any mailbox folder, a copy of the item is made before the modification is written to the Exchange store. The copy is stored in the Versions subfolder by a process known as *copy-on-write page protection*. You can recover different versions of a modified item until the deleted item retention period elapses.

The following table lists the contents of and actions that can be performed in the Recoverable Items folder if single item recovery is enabled.

Recoverable Items folder and single item recovery

State of single item recovery	Recoverable Items folder contains soft-deleted items	Recoverable Items folder contains modified and hard-deleted items	Users can purge items from the Recoverable Items folder	Managed Folder Assistant automatically purges items from the Recoverable Items folder
Enabled	Yes	Yes	No	Yes. By default, all items are purged after 14 days, with the exception of calendar items, which are purged after 120 days.
Disabled	Yes	No	Yes	Yes. By default, all items are purged after 14 days, with the exception of calendar items, which are purged after 120 days. If the Recoverable Items warning quota is reached before the deleted item retention period elapses, messages are deleted in first in, first out (FIFO) order.

Single item recovery isn't enabled by default for new mailboxes or mailboxes moved from a previous version of Exchange. You must use the Exchange Management Shell to enable single item recovery for a mailbox, and then configure or modify the deleted item retention period. To learn more about how to enable single item recovery for a mailbox and to perform single item recovery of deleted items, see the following topics:

- Enable Single Item Recovery for a Mailbox
- Perform Single Item Recovery

Litigation Hold

Exchange 2010 introduces Multi-Mailbox Search, a feature that administrators or records managers can use with delegated Discovery Management permissions to perform discovery searches of mailbox content. Exchange 2010 also introduces litigation hold, which you can use to preserve items in user mailboxes and protect the items from deletion by users or automated processes.

Placing a mailbox on litigation hold stops the Managed Folder Assistant from automatically purging messages from the Purges subfolder. Additionally, copy-on-write page protection is also enabled for the mailbox. Copy-on-write page protection creates a copy of the original item before any modifications are written to the Exchange store. After the mailbox is removed from litigation hold, the Managed Folder Assistant resumes automated purging.

The following table lists the contents of and actions that can be performed in the Recoverable Items folder if litigation hold is enabled.

Recoverable Items folder and litigation hold

State of litigation hold	Recoverable Items folder contains soft-deleted items	Recoverable Items folder contains modified and hard-deleted items	Users can purge items from the Recoverable Items folder	Managed Folder Assistant automatically purges items from the Recoverable Items folder
Enabled	Yes	Yes	No	No
Disabled	Yes	No	Yes	Yes

To learn more about Multi-Mailbox Search and litigation hold, see the following topics:

- Understanding Multi-Mailbox Search
- Understanding Litigation Hold

Copy-on-Write Page Protection and Modified Items

If a user who is placed on litigation hold (or has single item recovery enabled) modifies specific properties of a mailbox item, a copy of the original mailbox item is created before the changed item is written. The original copy is saved in the Versions subfolder. This process is known as copy-on-write page protection. Copy-on-write page protection applies to items residing in any mailbox folder. The Versions subfolder isn't visible to users.

The following table lists the message properties that trigger copy-on-write page protection.

Properties that trigger copy-on-write page protection

Item type	Properties that trigger copy-on-write page protection
Messages (IPM.Note*) Posts (IPM.Post*)	• Subject • Body • Attachments • Senders and recipients • Sent and received dates
Items other than messages and posts	Any change to a visible property, except the following: • Item location (when an item is moved between folders) • Item status change (read or unread)

	• Changes to a retention tag applied to an item
Items in the Drafts default folder	None. Items in the Drafts folder are exempt from copy-on-write page protection.

Important:
In Exchange 2010 Service Pack 1 (SP1), copy-on-write page protection doesn't save a version of the meeting when a meeting organizer receives responses from attendees and the meeting's tracking information is updated. Also, changes to RSS feeds aren't captured by copy-on-write page protection.

When litigation hold is removed from a mailbox and single item recovery is disabled, copies of modified items stored in the Versions folder are removed.

Return to top

Recoverable Items Mailbox Quotas

When an item is moved to the Recoverable Items folder, its size is deducted from the mailbox quota and added to the size of the Recoverable Items folder. In Exchange 2010, mailbox databases have a configurable Recoverable Items warning quota (*soft limit*) of 20 gigabytes (GB) and a Recoverable Items quota (*hard limit*) of 30 GB. By default, these limits are inherited by all mailboxes in the database. However, you can configure individual mailboxes with different quotas. To learn more, see Configure Deleted Item Retention and Recoverable Items Quotas.

When the Recoverable Items folder for a mailbox reaches the Recoverable Items quota, no more items can be stored in the folder. This impacts mailbox functionality in the following ways:

- Mailbox users can't delete items.
- The Managed Folder Assistant can't delete items based on retention tag or managed folder settings.
- For mailboxes that have single item recovery or litigation hold enabled, the copy-on-write page protection process can't maintain versions of items edited by the user.
- For mailboxes that have mailbox audit logging enabled, no mailbox audit log entries can be saved in the Audits subfolder.

For mailboxes that aren't placed on litigation hold, the Managed Folder Assistant automatically purges items from the Recoverable Items folder when the deleted item retention period elapses. If the folder reaches the Recoverable Items warning quota, the assistant automatically purges items in FIFO order.

When the Recoverable Items folder reaches the soft and hard limit defaults, you are notified by means of an event log and a Microsoft System Center Operations Manager alert. This alert fires when the Recoverable Items folder first reaches the soft and hard limit defaults, and then once daily afterward.

The following table lists the events logged when the Recoverable Items folder reaches the soft and hard limit defaults.

Recoverable Items quota warnings and errors

Event ID	Type	Source	Message
10024	Warning	MSExchangeIS Mailbox Store	The mailbox for *<mailbox user>* (*GUID*) has exceeded

			the Recoverable Items Warning Quota. Please remove items from Recoverable Items or increase the Recoverable Items Warning Quota and Recoverable Items Quota. If the Recoverable Items Quota is exceeded, the user will be unable to delete items from the mailbox.
10023	Error	MSExchangeIS Mailbox Store	The mailbox for *<mailbox user>* (*GUID*) has exceeded the maximum Recoverable Items Quota. Items cannot be deleted from this mailbox. The mailbox owner should be notified about the condition of the mailbox as soon as possible. Please remove items from Recoverable Items or increase the Recoverable Items Quota to restore functionality.
10023	Warning	MSExchangeMailboxAssistants	The mailbox:*<mailbox user>* Recoverable Items size has exceeded the warning quota limit. Items were deleted from Recoverable Items folders to prevent mailbox outage. Recoverable Items Warning Quota: 20 GB (21,474,836,480 bytes) Original Recoverable Items size: 21475005311 Current Recoverable Items size: 21474823820 Folder stats: - Folders processed: RecoverableItemsRoot, RecoverableItemsVer

			sions, RecoverableItemsPurges, RecoverableItemsDeletions - Original folder sizes: 21391661934, 55190914, 1987247, 26157788 (item counts: 276828, 400, 84, 646) - Current folder sizes: 21391480443, 55190914, 1987247, 26157788 (item counts: 276817, 400, 84, 646)

If the mailbox is placed on litigation hold, copy-on-write page protection can't maintain versions of modified items. To maintain versions of modified items, you must reduce the size of the Recoverable Items folder. You can use the Search-Mailbox cmdlet to copy messages from the Recoverable Items folder of a mailbox to a discovery mailbox, and then delete the items from the mailbox. Alternatively, you can also raise the Recoverable Items quota for the mailbox. For details, see Clean Up the Recoverable Items Folder.

1.8.2 Permissions to Manage Mailbox Servers

Permissions to Manage Mailbox Servers

Exchange Server 2010 > Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-12*

Mailbox Permissions

Allow Mailbox Access

Manage Send As Permissions for a Mailbox

Manage Full Access Permissions

Managing Public Folder Permissions

1.8.2.1 Allow Mailbox Access

Allow Mailbox Access

Exchange Server 2010 > Mailbox > Permissions to Manage Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to grant Full Access permission for a mailbox or Receive As permission for a mailbox database.

When you grant a user Full Access permission to a mailbox, that user has full access to only the mailbox for which the permissions are applied. With Full Access permission, the user can open and read the contents of the mailbox.

Important:

In Exchange 2010 Service Pack 1 (SP1), Outlook 2007 and Outlook 2010 clients automatically map to any mailbox to which a user has Full Access permissions. If a user is granted Full Access permissions to another user's mailbox or to a shared mailbox, Autodiscover automatically loads all mailboxes to which the user has full access. If the user has full access to a large number of mailboxes, performance issues may occur when starting Outlook. For example, in some Exchange organizations, administrators have full access to all the mailboxes in the organization. In this case, upon starting, Outlook attempts to open all mailboxes in the organization. Users can't control this behavior and have no way to turn it off.

However, the user can't send mail as that mailbox without additional permissions. For information about granting Send As permission, see Manage Send As Permissions for a Mailbox.

When you grant a user Receive As permission to a mailbox database, that user can log on to all mailboxes within that database, but can't send mail from those mailboxes. For example, you may want to grant access to the mailbox database for mobile access or for legal review.

Full Access or Receive As permissions aren't granted until the Microsoft Exchange Information Store service caches the permissions and updates the cache. To grant the permissions immediately, stop and then restart the Microsoft Exchange Information Store service.

Use the EMC to grant Full Access permission for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to grant Full Access permission.
3. In the action pane, under the mailbox name, click **Manage Full Access Permission**. The Manage Full Access Permission wizard opens.
4. On the **Manage Full Access Permission** page, click **Add**.
5. In **Select User or Group**, select the user to which you want to grant Full Access permission, and then click **OK**.
6. Click **Manage**.
7. On the **Completion** page, the **Summary** states whether Full Access permission was successfully granted. The summary also displays the Shell command used to grant Full Access permission.
8. Click **Finish**.

Use the Shell to grant Full Access permission for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

This example grants the user Ayla Kol Full Access permission to Chris Ashton's mailbox.

```
Add-MailboxPermission "Chris Ashton" -User "Ayla Kol" -AccessRights FullAccess
```

For detailed syntax and parameter information, see Add-MailboxPermission.

Use the Shell to grant Receive As permission for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to grant Receive As permission for a mailbox database.

This example grants the user Ayla Kol Receive As permission for mailboxes on mailbox database DB01. Ayla will be able to log on to every mailbox on that database.

```
Add-ADPermission -Identity "DB01" -User "Ayla" -ExtendedRights Receive-As
```

For detailed syntax and parameter information, see Add-ADPermission.

1.8.2.2 Manage Send As Permissions for a Mailbox

Manage Send As Permissions for a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use Send As permissions to configure a mailbox so that users other than the mailbox owner can use that mailbox to send messages. After this permission is granted, any messages that are sent from the mailbox will appear as if they were sent by the mailbox owner.

The Send As permission isn't granted until after replication has occurred. Replication times depend on your Exchange and network configuration. To grant the permission immediately, stop and then restart the Microsoft Exchange Information Store service.

Also, before you perform this procedure, be aware that you cannot send e-mail messages on behalf of a mailbox if the mailbox is hidden from address lists. When sending a message, Exchange requires that an e-mail address is resolved in the **From** field. In the case where a message is sent on behalf of a mailbox that is hidden from address lists, the SMTP address is interpreted as an address that isn't from your organization (known as a *foreign address*) and is rejected. For information about how to change your mailbox settings, see Configure User and Resource Mailbox Properties.

In Outlook, users will receive the following errors when attempting to send a message on behalf of a mailbox that is hidden from address lists:

- **Online mode** When users press **Send**, they will receive the following error: "You do not have permission to send on behalf of the specified user."

- **Cached Exchange Mode** Outlook initially sends the message, but users will receive a non-delivery report (NDR) containing the following message: "You are not allowed to send this message because you are trying to send on behalf of another user without permission to do so. Please verify that you are sending on behalf of the correct sender, or ask your system administrator to help you get the required permission."

Looking for other management tasks related to mailbox permissions? Check out Permissions to Manage Mailbox Servers.

What Do You Want to Do?

- Use the EMC to manage Send As permissions for a mailbox
- Use the Shell to manage Send As permissions for a mailbox

Use the EMC to manage Send As permissions for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send As permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select a recipient. You can manage Send As permission for the following recipient types:
   - Discovery mailboxes
   - User mailboxes
   - Resource mailboxes
3. In the action pane, click **Manage Send As Permission**.
4. On the **Manage Send As Permission** page, select the users or groups to which you want to grant the Send As permission or from which you want to remove the permission.
   - **Add** Click this button to open the **Select User or Group** dialog box. Use this dialog box to select the users or groups to which you want to grant the Send As permission.
   -  Select a user or group, and then click this button to remove the Send As permission from that user or group.
5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** close the wizard.

Use the Shell to manage Send As permissions for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send As permissions" entry in the Mailbox Permissions topic.

Use the **Add-ADPermission** cmdlet to manage Send As permissions for a mailbox. When you use the **Add-ADPermission** cmdlet, you must specify the name of the mailbox on

which the Send As permission should be added and the mailbox that should be granted the permission. Because the **Add-ADPermission** cmdlet controls many permissions, you must also specify the Send As permission with the *ExtendedRights* parameter. For example, to add the Send As permission to contoso\kim on the user mailbox John Simpson, use the following command:

```
Add-ADPermission "John Simpson" -User "Domain\User" -Extendedrights "Send As"
```

For detailed syntax and parameter information, see Add-ADPermission.

1.8.2.3 Manage Full Access Permissions

Manage Full Access Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-12*

Use the Manage Full Access Permission wizard to grant Full Access permissions to users or groups for a selected mailbox. You can also use this wizard to remove Full Access permissions from users or groups.

When you grant the Full Access permission to another user for a mailbox, that user becomes able to log on to the mailbox and access its entire contents.

Important:

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), Outlook 2010 and Outlook 2007 clients automatically map to any mailbox to which a user has Full Access permissions. If a user is granted Full Access permissions to another user's mailbox or to a shared mailbox, Autodiscover automatically loads all mailboxes to which the user has full access. If the user has full access to a large number of mailboxes, performance issues may occur when starting Outlook. For example, in some Exchange organizations, administrators have full access to all the mailboxes in the organization. In this case, upon starting, Outlook tries to open all mailboxes in the organization.
In Microsoft Exchange Server 2010, users can't control this behavior and can't turn it off.
In Microsoft Exchange Server 2010 Service Pack 2 (SP2), administrators can turn off the auto-mapping feature. For more information, see the third Exchange Management Shell example in this topic or read Disable Outlook Auto-Mapping with Full Access Mailboxes.

Granting Full Access permissions doesn't grant the right to send mail as the selected mailbox. To grant Send As permissions, see the following topics:

- Manage Send As Permissions for a Mailbox
- Manage Send As Permissions for Mail-Enabled Public Folders

Looking for other management tasks related to mailbox permissions? Check out Permissions to Manage Mailbox Servers.

What Do You Want to Do?

- Use the EMC to manage full access permissions for a mailbox
- Use the Shell to manage full access permissions for a mailbox

Use the EMC to manage full access

permissions for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select a recipient. You can manage Full Access permissions for the following recipient types:
   - Discovery mailboxes
   - User mailboxes
   - Resource mailboxes
3. In the action pane, click **Manage Full Access Permission**.
4. On the **Manage Full Access Permission** page, select the users or groups to which you want to grant the Full Access permission or from which you want to remove the permission. Select one of the following options:
   - **Add** Click this button to open the **Select User or Group** dialog box. Use this dialog box to select the users or groups to which you want to grant the Full Access permission.
   -  Select a user or group, and then click this button to remove the Full Access permission from that user or group.

   Important:

   By default, every mailbox has the security principal **NT AUTHORITY\SELF** listed. This security principal represents the mailbox owner. If you revoke the Full Access permission from this security principal, the mailbox owner is no longer able to log on to the mailbox.
5. On the **Completion** page, verify whether the command was completed successfully.
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task was not completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** close the wizard.

Use the Shell to manage full access permissions for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

This example grants Raymond Sam Full Access permissions to Terry Adams' mailbox.

```
Add-MailboxPermission -Identity "Terry Adams" -User RaySam -AccessRights Fullacce
```

This example removes Jim Hance's Full Access permissions to Ayla Kol's mailbox.

```
Remove-MailboxPermission -Identity Ayla -User 'JHance' -AccessRights FullAccess -
```

This example grants Mark Steele Full Access permissions to Jeroen Cool's mailbox and disables the auto-mapping feature.

```
Add-MailboxPermission -Identity JeroenC -User 'Mark Steele' -AccessRights FullAcc
```

For detailed syntax and parameter information, see Add-MailboxPermission.

1.8.2.4 Disable Outlook Auto-Mapping with Full Access Mailboxes

Disable Outlook Auto-Mapping with Full Access Mailboxes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-16*

In Exchange 2010 Service Pack 1 (SP1) Exchange introduced a feature that allows Outlook 2007 and Outlook 2010 clients to automatically map to any mailbox to which a user has Full Access permissions. If a user is granted Full Access permissions to another user's mailbox or to a shared mailbox, Outlook automatically loads all mailboxes to which the user has full access.

To accomplish this, Exchange populates the msExchDelegateListLink attribute in Active Directory to locate mailboxes for which the user has Full Access permission, and then provides this information to the Autodiscover service. Autodiscover then populates the `AlternateMailbox` attribute with the information necessary for Outlook to open the full access mailboxes. If the user has Full Access permissions to several mailboxes, performance issues may occur when starting Outlook. In Exchange 2010 SP1, there was no way to turn this feature off. However, in Exchange 2010 SP2, you can use the Shell to disable this feature.

Looking for other management tasks related to mailbox permissions? Check out Permissions to Manage Mailbox Servers

Use the Shell to disable auto-mapping

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

Note:
You can't' use the EMC to disable auto-mapping.

This example grants the user Mark Steele full access permission to Jeroen Cool's mailbox and disables the auto-mapping feature.

```
Add-MailboxPermission -Identity JeroenC -User 'Mark Steele' -AccessRight FullAcce
```

This example removes auto-mapping on an existing shared mailbox and removes the auto-mapping behavior for users who have already been granted Full Access permissions.

```
$FixAutoMapping = Get-MailboxPermission sharedmailbox |where {$_AccessRights -eq
$FixAutoMapping | Remove-MailboxPermission
$FixAutoMapping | ForEach {Add-MailboxPermission -Identity $_.Identity -User $_.U
```

For detailed syntax and parameter information, see the following topics:

- Remove-MailboxPermission
- Get-MailboxPermission
- Add-MailboxPermission

1.8.2.5 Managing Public Folder Permissions

Managing Public Folder Permissions

Exchange Server 2010 > Mailbox > Permissions to Manage Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-14*

1.8.2.5.1 Add Administrative Permissions for Users to Access Public Folders

Add Administrative Permissions for Users to Access Public Folders

Mailbox > Permissions to Manage Mailbox Servers > Managing Public Folder Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

There are two methods by which a user is granted the permissions to administer public folders:

- Public Folder Management role group
  Adding the user to the Public Folder Management role group is similar to assigning the Public Folder Administrator role in Exchange 2007. It grants the user all the permissions necessary for managing public folders.
- **PublicFolderAdminstrativePermission** cmdlet set
  Using these cmdlets is more granular and gives you the ability to specify the scope for the user in the organization by modifying the database's access control lists (ACLs).

Looking for other management tasks related to public folder permissions? Check out Managing Public Folder Permissions.

Use the Shell to add a user to the Public

Folder Management role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to add a user to the Public Folder Management role group.

This example adds the user Tony to the Public Folder Management role group.

```
Add-RoleGroupMember -Identity "Public Folder Management" -Member Tony
```

For detailed syntax and parameter information, see Add-RoleGroupMember.

Use the Shell to add administrative permissions for a user to access a specific public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder administrative permissions" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to add administrative permissions for a user to access a specific public folder.

Note:
Adding permissions to a specific folder also requires that the user has the correct Role Based Access Control (RBAC) permissions assigned so that they can access the public folder cmdlets.

This example adds AllExtendedRights permissions for the user Chris to access the public folder Marketing and all the public folders under it.

```
Add-PublicFolderAdministrativePermission -Identity "\Marketing" -User "Chris" -Ac
```

For detailed syntax and parameter information, see Add-PublicFolderAdministrativePermission.

1.8.2.5.2 Manage Send As Permissions for Mail-Enabled Public Folders

Manage Send As Permissions for Mail-Enabled Public Folders

Mailbox > Permissions to Manage Mailbox Servers > Managing Public Folder Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the Send As permission to configure a mail-enabled public folder so that users other than the public folder owner can use that mail-enabled public folder to send messages.

The Send As permission isn't granted until after replication has occurred. Replication times

depend on your Exchange and network configuration. To grant the permission immediately, stop and then restart the Microsoft Exchange Information Store service.

Also, before you perform this procedure, be aware that you cannot send e-mail messages on behalf of a mail-enabled public folder if the folder is hidden from address lists. When sending a message, Exchange requires that an e-mail address is resolved in the **From** field. In the case where a message is sent on behalf of a mail-enabled public folder that is hidden from address lists, , the SMTP address is interpreted as an address that is not from your organization (known as a *foreign address*) and is rejected. For more information about how to change public folder settings, see Configure Public Folder Properties.

In Outlook, users will receive the following errors when attempting to send a message on behalf of a mailbox that is hidden from address lists:

- **Online mode** When users press **Send**, they will receive the following error: "You do not have permission to send on behalf of the specified user."
- **Cached Exchange Mode** Outlook initially sends the message, but users will receive a non-delivery report (NDR) containing the following message: "You are not allowed to send this message because you are trying to send on behalf of another user without permission to do so. Please verify that you are sending on behalf of the correct sender, or ask your system administrator to help you get the required permission."

Looking for other tasks related to public folders? Check out Managing Public Folders.

What Do You Want to Do?

- Use the Public Folder Management Console to manage Send As permissions for a mailbox
- Use the Shell to manage Send As permissions for a mailbox

Use the Public Folder Management Console to manage Send As permissions for a mail-enabled public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send As permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the Public Folder Management Console tree, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, select the public folder, and then, in the action pane, click **Manage Send As Permission**.
5. On the **Manage Send As Permission** page, select the users or groups to which you want to grant the Send As permission or from which you want to remove the permission.
   - **Add** Click this button to open the **Select User or Group** dialog box. Use this dialog box to select the users or groups to which you want to grant the Send As permission, click **OK** and then click **Manage**.
   -  Select a user or group, and then click this button to remove the Send As permission from that user or group. After you've removed the user or group, click **Manage**.
6. On the **Completion** page, review the following, and then click **Finish** to close

the wizard:

- A status of **Completed** indicates that the wizard completed the task successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

7. Click **Finish** close the wizard.

Use the Shell to manage Send As permissions for a mail-enabled public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Send As permissions" entry in the Mailbox Permissions topic.

Use the **Add-ADPermission** cmdlet to manage Send As permissions for a mail-enabled public folder. When you use the **Add-ADPermission** cmdlet, you must specify the name of the public folder on which the Send As permission should be added and the public folder that should be granted the permission. Because the **Add-ADPermission** cmdlet controls many permissions, you must also specify the Send As permission with the *ExtendedRights* parameter. For example, to add the Send As permission to contoso\kim on the public folder Sales, use the following command:

```
Add-ADPermission Sales -User contoso\kim -Extendedrights "Send As"
```

1.8.2.5.3 Remove Public Folder Administrative Permissions

Remove Public Folder Administrative Permissions

Mailbox > Permissions to Manage Mailbox Servers > Managing Public Folder Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic shows you how to use the Exchange Management Shell to remove public folder administrative permissions from a user.

Note:

You can't use the **Remove-PublicFolderAdministrativePermission** cmdlet to remove the rights of a member of the Public Folder Management role group. You must use the **Remove-RoleGroupMember** cmdlet.

There are two methods by which a user is granted the permissions to administer public folders:

- Public Folder Management role group
  Adding the user to the Public Folder Management role group is similar to assigning the Public Folder Administrator role in Exchange 2007. It grants the user all the permissions necessary for managing public folders.
- **PublicFolderAdminstrativePermission** cmdlet set
  Using these cmdlets is more granular and gives you the ability to specify the scope for the user in the organization by modifying the database's access control lists (ACLs).

Looking for other management tasks related to public folder permissions? Check out

Managing Public Folder Permissions.

Use the Shell to remove a user from the Public Folder Management role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to remove a user from the Public Folder Management role group.

This example removes the user Chris from the Public Folder Management role group.

```
Remove-RoleGroupMember -Identity "Public Folder Management" -Member Chris
```

For detailed syntax and parameter information, see Remove-RoleGroupMember.

Use the Shell to remove administrative permissions for a user to access a specific public folder or public folder hierarchy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder administrative permissions" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to remove administrative permissions for a user to access a specific public folder or public folder hierarchy.

This example removes all administrative permissions to the entire public folder tree from the user Kim.

```
Remove-PublicFolderAdministrativePermission -Identity "\" -User "Kim" -AccessRigh
```

A warning appears asking if you're sure you want to perform this action. Type **Y** to confirm.

For detailed syntax and parameter information, see Remove-PublicFolderAdministrativePermission.

1.8.2.5.4 View Public Folder Administrative Permission Settings

View Public Folder Administrative Permission Settings

Mailbox > Permissions to Manage Mailbox Servers > Managing Public Folder Permissions >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

There are two methods by which a user is granted the permissions to administer public folders:

- Public Folder Management role group
  Adding the user to the Public Folder Management role group is similar to assigning the Public Folder Administrator role in Exchange 2007. It grants the user all the permissions necessary for managing public folders.
- **PublicFolderAdminstrativePermission** cmdlet set
  Using these cmdlets is more granular and gives you the ability to specify the scope for the user in the organization by modifying the database's access control lists (ACLs).

Looking for other management tasks related to public folder permissions? Check out Managing Public Folder Permissions.

Use the Shell to view members of the Public Folder Management role group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to view members of the Public Folder Management role group.

This example returns the members of the Public Folder Management role group.

```
Get-RoleGroupMember -Identity "Public Folder Management"
```

Note:
By default, a maximum of 1,000 role group members are displayed. If you want to display more, you must use the *ResultSize* parameter to override the maximum number of members that are returned. You can type either an integer value or the value `unlimited`. The value `unlimited` returns all members of the role group.

For detailed syntax and parameter information, see Get-RoleGroupMember.

Use the Shell to view information about administrative permissions for a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder administrative permissions" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to view information about administrative permissions for a public folder.

This example returns the user David's access rights for the public folder Marketing.

```
Get-PublicFolderAdministrativePermission -Identity "\Marketing" -User "David"
```

This example returns the administrative access rights sorted by user for the public folder Sales.

```
Get-PublicFolderAdministrativePermission -Identity "\Sales" | Format-List User,Ac
```

For detailed syntax and parameter information, see Get-

PublicFolderAdministrativePermission.

1.8.2.5.5 Use the Public Folder Management Console to Manage Public Folder Settings

Use the Public Folder Management Console to Manage Public Folder Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the Manage Public Folder Settings wizard to manage public folder settings for the selected public folder and subfolders. The wizard also allows you to add, remove, and modify client permissions.

Looking for other management tasks related to public folder permissions? Check out Managing Public Folder Permissions.

What Do You Want to Do?

- Add or modify public folder permissions for a client user
- Remove public folder permissions for a client user
- Overwrite child public folder settings with the parent public folder settings

Add or modify public folder permissions for a client user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, view or modify the following settings:
   - **Current root folder** This read-only field displays the path and the public folder you're modifying.
   - **Update client permissions** Click this button to update the client access permissions for this public folder.
   - **Apply client permission changes to this folder and all its subfolders** Select this check box if you want the changes that you make to the selected public folder to apply to all of the child public folders. This option is available only if the public folder you're modifying has one or more child public folders.
   - **Overwrite settings** Click this button if you want to override the settings of the child public folders with the selected parent public folder's settings. You can overwrite the age limits, keep per-user read/unread state, replicas, and replication schedule. This option is available only if the public folder you're modifying has one or more child public folders. If you select

this option, see Overwrite child public folder settings with the parent public folder settings later in this topic for details.

7. On the **Specify Action** page, you can specify whether you want to add or remove client user permissions:
   - **Add users** Click this button to add users and set their permissions. If users already have permission to this folder or a child folder, that permission will be replaced with new permissions.
   - **Remove Users** Click this button to remove users from folders to which they have permissions. If you select this option, see Remove public folder permissions for a client user later in this topic for details.

8. On the **Assign Permissions** page, you can grant users access to public folders. Complete the following fields:
   - **Add** Click this button to add a user to whom you want to assign permissions.
   - **Permission Level** Use this list and the associated check boxes to assign permissions to the selected user. For more information about the permissions and the level of access that each one grants, see the "Client User Access Rights and Roles" section of Understanding Public Folder Permissions.

     Note:
     The **Custom** permission level isn't listed in the **Permission Level** list. You can create a custom role by selecting or clearing the access right check boxes.

9. On the **Add Users** page, review your configuration settings. Click **Add** to add the user. Click **Back** to make configuration changes. Exchange will remove any existing permissions and then create the permissions for the user.

10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
11. Click **Finish** to close the wizard.

Remove public folder permissions for a client user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, complete the following fields:
   - **Update client permissions** Click this button to update the client access permissions for this public folder.
   - **Apply client permission changes to this folder and all its subfolders** Select this check box if you want the changes that you make to the

selected public folder to apply to all of the child public folders. This option is available only if the public folder you're modifying has one or more child public folders.

7. On the **Specify Action** page, click **Remove users** to remove users from folders to which they have permissions, and then click **Next**.

8. On the **Select Users** page, you can select users from whom you want to remove their permissions. Click **Add** to select the user you want to remove, and then click **Next**.
9. On the **Remove Users** page, review your configuration settings. Click **Remove** to remove the user's permissions. Click **Back** to make configuration changes. Exchange will remove any existing permissions from the user.
10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
11. Click **Finish** to close the wizard.

Overwrite child public folder settings with the parent public folder settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, click **Overwrite Settings** to override the child public folder settings with the selected parent public folder settings. You can overwrite the age limits, keep per-user read/unread state, replicas, and replication schedule. This option is available only if the public folder that you're modifying has one or more child public folders.

7. On the **Select Settings** page, select the settings to overwrite. For more information about the settings you can configure, see Configure Public Folder Properties.
    - **Age limits** Select this check box to copy the selected public folder's age limits to the child public folders.
    - **Keep per user read/unread state** Select this check box to copy the selected public folder's per-user read/unread settings to the child public folders. This setting allows users to see if a public folder message has been read or unread in Microsoft Outlook.
    - **Replicas** Select this check box to copy the selected public folder's replica settings to the child public folders.
    - **Replication schedule** Select this check box to copy the selected public folder's replication schedule to the child public folders.
8. On the **Overwrite Settings** page, review your configuration settings. Click **Overwrite** to overwrite the child public folder settings with the selected public folder. Click **Back** to make configuration changes.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:

- A status of **Completed** indicates that the wizard completed the task successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

10. Click **Finish** to close the wizard.

1.8.2.5.6 Add Permissions for Client Users to Access Public Folder Content

Add Permissions for Client Users to Access Public Folder Content

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When adding client permissions, you can either use predefined permission roles (which consist of specific access rights) or you can customize permissions by manually applying the available access rights. To specify the permissions for the client user, you can use the Public Folder Management Console, the **Add-PublicFolderClientPermission** cmdlet, or the **AddUsersToPFRecursive.ps1** user management script.

Note:

If a client user already has a specific access right to a public folder, you can't add the same access right again. Therefore, if you use the **AddUsersToPFRecursive.ps1** script, and the user already has one of the access rights that you're trying to grant, a warning will appear stating that the current access rights will be removed before new access rights are granted.

Looking for other management tasks related to public folder permissions? Check out Managing Public Folder Permissions.

Use the Public Folder Management Console to add public folder permissions for a client user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, complete the following fields:
   - **Update client permissions** Click this button to update the client access permissions for this public folder.
   - **Apply client permission changes to this folder and all its subfolders** Select this check box if you want the changes that you make to the selected public folder to apply to all of the child public folders. This option is

available only if the public folder you're modifying has one or more child public folders.

7. On the **Specify Action** page, click **Remove users** to remove users from folders to which they have permissions, and then click **Next**.
8. On the **Select Users** page, you can select users from whom you want to remove their permissions. Click **Add** to select the user you want to remove, and then click **Next**.
9. On the **Remove Users** page, review your configuration settings. Click **Remove** to remove the user's permissions. Click **Back** to make configuration changes. Exchange will remove any existing permissions from the user.
10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
11. Click **Finish** to close the wizard.

Use the Shell to add public folder permissions for a client user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to add public folder permissions for a client user.

This example adds Publishing Editor permissions for the user Kim to access the public folder West Coast.

```
Add-PublicFolderClientPermission -Identity "\Marketing\West Coast" -AccessRights
```

For detailed syntax and parameter information, see Add-PublicFolderClientPermission.

Use the AddUsersToPFRecursive.ps1 script to add client access rights to a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

This example adds Reviewer permissions for the user David to access the top-level public folder Sales and all of the public folders under it.

```
AddUsersToPFRecursive.ps1 -TopPublicFolder "\Sales" -User "David" -Permission Rev
```

For more information about how to use public folder management scripts, see Scripts for Managing Public Folders in the Exchange Management Shell.

Remove or Replace Public Folder Client Permissions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When removing public folder permissions, you can either use predefined permission roles (which consist of specific access rights) or manually remove the available access rights. To remove the permissions from the client user, you can use the Public Folder Management Console, the **Remove-PublicFolderClientPermission** cmdlet, or the **RemoveUserFromPFRecursive.ps1** user management script.

To replace the users or permissions, use the following scripts:

- **ReplaceUserWithUserOnPFRecursive.ps1** This script replaces a user with a new user in the client permissions list for a public folder and any folders that exist within it. Existing permissions for the first user are retained. Public folders that don't contain permissions for the user aren't modified.
- **ReplaceUserPermissionOnPFRecursive.ps1** This script replaces a user's permissions to a public folder and any folders that exist under it with a new set of permissions. Public folders that don't contain permissions for the user aren't modified.

Looking for other management tasks related to public folders? Check out Managing Public Folders or Managing Public Folder Permissions.

Use the Public Folder Management Console to remove a client user's permissions to public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, complete the following fields:
   - **Update client permissions** Click this button to update the client access permissions for this public folder.
   - **Apply client permission changes to this folder and all its subfolders** Select this check box if you want the changes that you make to the selected public folder to apply to all of the child public folders. This option is available only if the public folder you're modifying has one or more child public folders.
7. On the **Specify Action** page, click **Remove users** to remove users from folders to which they have permissions, and then click **Next**.
8. On the **Select Users** page, you can select users from whom you want to remove their permissions. Click **Add** to select the user you want to remove, and then click **Next**.
9. On the **Remove Users** page, review your configuration settings. Click

Remove to remove the user's permissions. Click **Back** to make configuration changes. Exchange will remove any existing permissions from the user.

10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
11. Click **Finish** to close the wizard.

Use the Shell to remove a client user's permissions to public folder items

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to remove a client user's permissions to public folder items.

This example removes the user David's permissions to create items in the public folder Oregon.

```
Remove-PublicFolderClientPermission -Identity "Sales\West Coast\Oregon" -User Dav
```

For detailed syntax and parameter information, see Remove-PublicFolderClientPermission.

Use the RemoveUserFromPFRecursive.ps1 script to remove a client user's permissions to access public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

This example removes the user David's permissions to access the public folder Oregon and all folders under it.

```
RemoveUserFromPFRecursive.ps1 -Server "SERVER01" -TopPublicFolder -"\Sales\Oregon
```

For more information about using the RemoveUserFromPFRecursive.ps1 script, see Scripts for Managing Public Folders in the Exchange Management Shell.

Use the ReplaceUserWithUserOnPFRecursive.ps1 script to replace a user with a new user in the client permissions list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

Using the script to replace public folder permissions saves you time because you only have to run the script once. If you were to use cmdlets to perform this task, you would have to perform multiple steps to accomplish the same task.

This example replaces the user David with the user Kim as a person who can access the items in the public folder Sales and all folders under it.

```
ReplaceUserWithUserOnPFRecursive.ps1 -TopPublicFolder "\Sales" -UserOld "David" -
```

For more information about using the ReplaceUserWithUserOnPFRecursive.ps1 script, see Scripts for Managing Public Folders in the Exchange Management Shell.

Use the ReplaceUserPermissionOnPFRecursive.ps1 script to replace client permissions with a new set of permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

Using the script to replace public folder permissions saves you time because you only have to run the script once. If you were to use cmdlets to perform this task, you would have to perform multiple steps to accomplish the same task.

This example replaces the user Kim's current permission to access the public folder Marketing and all folders under it with the Publishing Editor permissions.

```
ReplaceUserPermissionOnPFRecursive.ps1 -Server "SERVER01" -TopPublicFolder "\Mark
```

For more information about using the ReplaceUserPermissionOnPFRecursive.ps1 script, see Scripts for Managing Public Folders in the Exchange Management Shell.

1.8.2.5.8 View Public Folder Client Permissions Settings

View Public Folder Client Permissions Settings

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic shows you how to use the Exchange Management Shell to view information about the client access permissions to a public folder.

Note:

You can't use the Exchange Management Console (EMC) to perform this procedure.

Use the Shell to view client access permissions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

This example returns the entire list of the client access permissions for the public folder Marketing.

```
Get-PublicFolderClientPermission -Identity "\Marketing" | fl
```

This example returns the user David's client access permissions to the public folder East Coast.

```
Get-PublicFolderClientPermission -Identity "\Marketing\EastCoast" -User David
```

For detailed syntax and parameter information, see Get-PublicFolderClientPermission.

1.8.3 Managing Mailbox Servers

1.8.3.1 Change the Recipient Scope

Change the Recipient Scope

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Recipient scope is the specified portion of Active Directory hierarchy that the Exchange Management Console (EMC) and the Exchange Management Shell uses for recipient management. When you set the recipient scope to a specific location within Active Directory, you can view and manage all recipients stored in that location, including all the containers under it.

The EMC and Shell always start with the recipient scope at the domain-level of the computer that is running the management interface. Neither the user account that's being used nor the Exchange servers being managed has bearing on the default value of the recipient scope.

When you change the recipient scope of the EMC, you change the set of recipients that are displayed in the result pane of the **Recipient Configuration** node. The dialog boxes that you use to select recipients or OUs (located on various wizard pages) also work within the same scope. For example, if you're mail-enabling an existing contact, the **Select Contact** dialog box in the **New Mail Contact** wizard displays only the contacts within the recipient scope that are not already mail-enabled.

Note:

The Microsoft Management Console (MMC) saves any changes you make to a snap-in as preferences in your user profile on the administrator computer. The recipient scope setting is also saved as one of your preferences. As a result, the next time you start the EMC on the same computer, the default setting of the recipient scope is now the scope that you last specified. However, if you use another computer or a different user account to run the EMC, you'll need to adjust the recipient scope again.

When you change the recipient scope in the Shell, you change the set of recipients that are returned for the **Get-** cmdlets of the recipient. The recipient scope is accessible by using the **Set-ADServerSettings** cmdlet.

Note:

The default scope is not retained when you close the Shell. The Shell resets to the default domain-level recipient scope the next time that the Shell is opened.

What Do You Want to Do?

Use the EMC to change the recipient scope

Use the Shell to change the recipient scope

Use the EMC to change the recipient scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory Domain Services server settings" entry in the Exchange and Shell Infrastructure Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **Modify Recipient Scope**.
3. In **Recipient Scope** dialog box, select one of the following options:
   - **View all recipients in forest** Click this button to work with all recipients in the forest. To use a specific global catalog server, select the **Global Catalog** check box and then click **Browse**. In **Select Global Catalog**, select the global catalog server that you want to use. If you don't specify a global catalog server, Exchange automatically selects an available one.
   - **View all recipients in specified organizational unit** Click this button to work with all recipients in a specific organizational unit (OU) and all OUs under it. Click **Browse,** and then, in **Select Organizational Unit**, select the OU that you want to use.

     To use a specific domain controller, select the **Recipient Domain Controller** check box. If you don't specify a recipient domain controller, Exchange automatically selects an available one.
4. Click **OK**.

Use the Shell to change the recipient scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Active Directory Domain Services server settings" entry in the Exchange and Shell Infrastructure Permissions topic.

This example sets the recipient scope to the Marketing Users OU in the contoso.com domain for the current session.

```
Set-AdServerSettings -RecipientViewRoot "contoso.com/Marketing Users"
```

This example sets the scope of the current session to the entire forest and designates gc1.contoso.com as the preferred global catalog server.

```
Set-AdServerSettings -ViewEntireForest $true -PreferredGlobalCatalog gc1.contoso.
```

For detailed syntax and parameter reference, see Get-AdServerSettings.

1.8.3.2 Configure Mailbox Server Properties

Configure Mailbox Server Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

To configure the Mailbox servers in your organization, you can either use the **Mailbox** node in the Exchange Management Console (EMC) or the **Set-MailboxServer** cmdlet in the Exchange Management Shell.

What Do You Want to Do?

- Use the EMC to configure Mailbox server properties
- Use the Shell to configure Mailbox server properties

Use the EMC to configure Mailbox server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

1. In the console tree, select the forest you want, and then navigate to **Server Configuration** > **Mailbox**.
2. In the result pane, select the server you want to configure.
3. In the action pane, under the server name, click **Properties**.
4. On the **General** tab, you can view general information about the server:
   - **Version** This field displays the version of Exchange installed on the server.
   - **Edition** This field displays the Exchange Server edition. The edition is either Standard Edition or Enterprise Edition.
   - **Role(s)** This field displays the Exchange server roles installed on the server.
   - **Product ID** This field displays the product ID for the Exchange server. If you haven't yet entered the product key for the server, the product ID displayed is **Unlicensed**. To license an unlicensed version of Exchange, see Enter Product Key.
   - **Modified** This field displays the last date and time that a configuration change was made on this server.
5. On the **System Settings** tab, view the domain controller servers and global catalog servers. You can also enable an error reporting feature:
   - **Domain controller servers being used by Exchange** This read-only box displays a list of domain controller servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Global catalog servers being used by Exchange** This read-only box displays a list of global catalog servers used by the Exchange server.

     Note:
     This box isn't available on Edge Transport servers.
   - **Automatically send fatal service error report to Microsoft** Select this check box if you want to enable the error reporting feature and automatically send an error report to Microsoft in the event of a fatal error.

If you enable the error reporting feature, information about fatal service errors is sent to Microsoft over encrypted channels. The information is used to improve Microsoft products. When this feature is enabled and the issue reported has a known solution, the server receives feedback from Microsoft. This feedback contains a link to information that may help resolve the problem.

6. On the **Customer Feedback Options** tab, you can enroll the selected server into the Customer Experience Improvement Program. For more information, see Opt-in or Opt-out of the Customer Experience Improvement Program.

7. On the **Messaging Records Management** tab, configure the schedule for the Managed Folder Assistant. The Managed Folder Assistant is an Exchange Mailbox Assistant that places the managed folders that you have created into users' mailboxes and applies managed content settings to managed folders. When the Managed Folder Assistant is running, it processes all the mailboxes on a server. If the Managed Folder Assistant doesn't finish processing the mailboxes on the server in the time that you specified, it automatically resumes processing where it left off the next time it runs. There is one Managed Folder Assistant for each server. To learn more, see Configure the Managed Folder Assistant.
   - **Schedule the Managed Folder Assistant** Use this box to schedule the Managed Folder Assistant or to prevent it from running. The following options are available:
     Use Custom Schedule Select this option to configure the Managed Folder Assistant to run at specified times. If you select **UseCustom Schedule**, you must also click **Customize** to set a schedule. There is no default schedule.
     Never Run Select this option to prevent the Managed Folder Assistant from running.
   - **Customize** Click this button to open the **Schedule** dialog box and set a schedule for the Managed Folder Assistant. To set the schedule, click the time grid in the dialog box. The Managed Folder Assistant runs during the time slots that you select, which are marked in blue. You can select the same time slot every day by clicking a column header for a specific time slot. You can select an entire day by clicking the name of that day.
     The default time slot for the grid is one hour. For finer control, you can change the schedule grid to 15 minute intervals by clicking **15 Minutes**. Scheduled intervals must be at least 15 minutes apart.

Use the Shell to configure Mailbox server properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

This example sets the server override list to HubServer01, HubServer02, and HubServer03

```
Set-MailboxServer -Identity Server1 -SubmissionServerOverrideList HubServer01,Hub
```

This example sets the maximum size of the messaging records management (MRM) log directory to 1 GB.

```
Set-MailboxServer -Identity Exchange01 -LogDirectorySizeLimitForManagedFolders "1
```

This example sets the maximum size of the MRM log files to 20 MB.

```
Set-MailboxServer -Identity Exchange01 -LogFileSizeLimitForManagedFolders "20 MB"
```

For detailed syntax and parameter information, see Set-MailboxServer.

For More Information

Overview of the Mailbox Server Role

Managing Mailbox Servers

1.8.3.3 Creating Filters in Recipient Commands

Creating Filters in Recipient Commands

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-28*

You can use several Exchange Management Shell commands to filter a set of recipients. You can create the following types of filters in an Exchange command:

- Precanned filters
- Custom filters using the *RecipientFilter* parameter
- Custom filters using the *Filter* parameter
- Custom filters using the *ContentFilter* parameter

In Microsoft Exchange Server 2003 and earlier versions, LDAP filtering syntax is used to create custom address lists, global address lists (GALs), e-mail address policies, and distribution groups. In Exchange Server 2007 and Exchange Server 2010, the OPATH filtering syntax replaces the LDAP filtering syntax. Exchange supports existing LDAP filters, but you can't edit them. Before you can change an LDAP filter, you must upgrade it to an OPATH filter. For more information, see Upgrade Custom LDAP Filters to OPATH Filters.

Contents

Precanned Filters

A *precanned filter* is a commonly used Exchange filter that you can use to meet a variety of recipient-filtering criteria for creating dynamic distribution groups, e-mail address policies, address lists, or GALs. With precanned filters, you can either use Exchange Management Shell or a wizard in the Exchange Management Console (EMC). Using precanned filters,

you can do the following:

- Determine the scope of recipients.
- Add conditional filtering based on properties such as company, department, and state or region.
- Add custom attributes for recipients. For more information, see Understanding Custom Attributes.

The following parameters are considered precanned filters:

- *IncludedRecipients*
- *ConditionalCompany*
- *ConditionalDepartment*
- *ConditionalStateOrProvince*
- *ConditionalCustomAttribute1*–15.

Precanned filters are available for the following cmdlets:

- New-DynamicDistributionGroup
- Set-DynamicDistributionGroup
- New-EmailAddressPolicy
- Set-EmailAddressPolicy
- New-AddressList
- Set-AddressList
- New-GlobalAddressList
- Set-GlobalAddressList

Example

This example describes using precanned filters in the Shell to create a dynamic distribution group. The syntax in this example is similar but not identical to the syntax you would use to create an e-mail address policy, address list, or GAL. When creating a precanned filter, you should ask the following questions:

- From which organizational unit (OU) do you want to include recipients? (This question corresponds to the *RecipientContainer* parameter.)

  Note:

  Selecting the OU for this purpose applies only when creating dynamic distribution groups, and not when creating e-mail address policies, address lists, or GALs.

- What type of recipients do you want to include? (This question corresponds to the *IncludedRecipients* parameter.)
- What additional conditions do you want to include in the filter? (This question corresponds to the *ConditionalCompany*, *ConditionalDepartment*, *ConditionalStateOrProvince*, and *ConditionalCustomAttribute* parameters.)

This example creates the dynamic distribution group Contoso Finance for user mailboxes in the OU Contoso.com/Users and specifies the condition to include only recipients who have the **Department** attribute defined as Finance and the **Company** attribute defined as Contoso.

```
New-DynamicDistributionGroup -Name "Contoso Finance" -OrganizationalUnit Contoso.
```

This example displays the properties of this new dynamic distribution group.

```
Get-DynamicDistributionGroup -Identity "Contoso Finance" | Format-List *Recipient
```

Return to top

Custom Filters Using the RecipientFilter

Parameter

If precanned filters don't meet your needs for creating or modifying dynamic distribution groups, e-mail address policies, and address lists, you can create a custom filter by using the *RecipientFilter* parameter.

The recipient filter parameter is available for the following cmdlets:

- New-DynamicDistributionGroup
- Set-DynamicDistributionGroup
- New-EmailAddressPolicy
- Set-EmailAddressPolicy
- New-AddressList
- Set-AddressList
- New-GlobalAddressList
- Set-GlobalAddressList

For more information about the filterable properties you can use with the *RecipientFilter* parameter, see Filterable Properties for the -RecipientFilter Parameter.

Example

The following example uses the *RecipientFilter* parameter to create a dynamic distribution group. The syntax in this example is similar but not identical to the syntax you use to create an e-mail address policy, address list, or GAL.

This example uses custom filters to create a dynamic distribution group for user mailboxes that have the **Company** attribute defined as Contoso and the **Office** attribute defined as North Building.

```
New-DynamicDistributionGroup -Name AllContosoNorth -OrganizationalUnit contoso.co
```

Return to top

Custom Filters Using the Filter Parameter

You can use the *Filter* parameter to filter the results of a command to specify which objects to retrieve. For example, instead of retrieving all users or groups, you can specify a set of users or groups by using a filter string. This type of filter doesn't modify any configuration or attributes of objects. It only modifies the set of objects that the command returns.

Using the *Filter* parameter to modify command results is known as *server-side filtering*. Server-side filtering submits the command and the filter to the server for processing. The Shell also supports client-side filtering, in which the command retrieves all objects from the server and then applies the filter in the local console window. To perform client-side filtering, use the **Where-Object** cmdlet. For more information about server-side and client-side filtering, see "How to Filter Data" in Working with Command Output.

To find the filterable properties for cmdlets that have the *Filter* parameter, you can run the **Get** command against an object and format the output by pipelining the **Format-List** parameter. Most of the returned values will be available for use in the *Filter* parameter. The following example returns a detailed list for the mailbox Ayla.

```
Get-Mailbox -Identity Ayla | Format-List
```

The *Filter* parameter is available for the following cmdlets:

- Get-ActiveSyncDevice
- Get-ActiveSyncDeviceClass
- Get-CASMailbox

- Get-Contact
- Get-DistributionGroup
- Get-DynamicDistributionGroup
- Get-Group
- Get-Mailbox
- Get-MailContact
- Get-MailPublicFolder
- Get-MailUser
- Get-Message
- Get-Queue
- Get-Recipient
- Get-RemoteMailbox
- Get-RoleGroup
- Get-SecurityPrincipal
- Get-StoreUsageStatistics
- Get-ThrottlingPolicyAssociation
- Get-UMMailbox
- Get-User
- Remove-Message
- Resume-Message
- Resume-Queue
- Retry-Queue
- Suspend-Message
- Suspend-Queue

For more information about the filterable properties you can use with the *Filter* parameter, see Filterable Properties for the -Filter Parameter.

Example

This example uses the *Filter* parameter to return information about users whose title contains the word "manager".

```
Get-User -Filter {Title -like '*Manager*'}
```

Return to top

Custom Filters Using the ContentFilter Parameter

You can use the *ContentFilter* parameter to select specific message content to export when using the New-MailboxExportRequest cmdlet. If the command finds a message that contains the match to the content filter, it exports the message to a .pst file.

Example

This example creates an export request that searches Ayla's mailbox for messages where the body contains the phrase "company prospectus". If that phrase is found, the command exports all messages with that phrase to a .pst file.

```
New-MailboxExportRequest -Mailbox Ayla -ContentFilter {Body -like "*company prosp
```

For more information about the filterable properties you can use with the *ContentFilter* parameter, see Filterable Properties for the -ContentFilter Parameter.

Return to top

Additional OPATH Syntax Information

When creating your own custom filters, be aware of the following:

- Use braces { } around the entire OPATH syntax string with the *Filter* or *RecipientFilter* parameter.
- Include the hyphen before all operators. The most common operators include:
  - **-and**
  - **-or**
  - **-not**
  - **-eq** (equals)
  - **-ne** (not equal)
  - **-lt** (less than)
  - **-gt** (greater than)
  - **-like** (string comparison)
  - **-notlike** (string comparison)
- Many of the properties for the *RecipientFilter* and *Filter* parameters accept wildcard characters. If you use a wildcard character, use the **like** operator instead of the **eq** operator. The **like** operator is used to find pattern matches in rich types, such as strings, whereas the **eq** operator is used to find an exact match.
- Run the following commands to get information about operators you can use:
  - `Help about_logical_operator`
  - `Help about_comparison_operator`
- You can use most properties of recipient types to create filter strings. For information about filterable properties you can use with a specific cmdlet, see the cmdlet reference topics in Exchange Management Shell.

1.8.3.3.1 Filterable Properties for the -Filter Parameter

Filterable Properties for the -Filter Parameter

Mailbox > Managing Mailbox Servers > Creating Filters in Recipient Commands >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-07*

This topic lists the filterable properties for the *-Filter* parameter in Microsoft Exchange Server 2010.

Use the *-Filter* parameter to return the objects from a **Get-** command in a filtered list. For example, if you want the **Get-Contact** cmdlet to return a subset of all of the contacts in your Microsoft Exchange organization, you would use the *-Filter* parameter. The subset of objects that is returned is based on specific properties.

The *-Filter* parameter is used in the following cmdlets:

- Get-AcceptedDomain
- Get-ActiveSyncDevice
- Get-ActiveSyncDeviceAccessRule
- Get-ActiveSyncDeviceClass
- Get-ActiveSyncMailboxPolicy
- Get-ActiveSyncOrganizationSettings
- Get-ActiveSyncVirtualDirectory

- Get-AdminAuditLogConfig
- Get-AddressList
- Get-AddressRewriteEntry
- Get-AdSite
- Get-AdSiteLink
- Get-AttachmentFilterEntry
- Get-AttachmentFilterListConfig
- Get-AutodiscoverVirtualDirectory
- Get-AvailabilityAddressSpace
- Get-AvailabilityConfig
- Get-CalendarDiagnosticLog
- Get-CASMailbox
- Get-CASMailboxPlan
- Get-ClientAccessArray
- Get-ClientAccessServer
- Get-CmdletExtensionAgent
- Get-Contact
- Get-ContentFilterConfig
- Get-DatabaseAvailabilityGroup
- Get-DeliveryAgentConnector
- Get-DetailsTemplate
- Get-DistributionGroup
- Get-DistributionGroupMember
- Get-DomainController
- Get-DynamicDistributionGroup
- Get-EcpVirtualDirectory
- Get-EdgeSubscription
- Get-EdgeSyncServiceConfig
- Get-ExchangeAssistanceConfig
- Get-EmailAddressPolicy
- Get-ExchangeServer
- Get-FederatedOrganizationIdentifier
- Get-FederationTrust
- Get-ForeignConnector
- Get-GlobalAddressList
- Get-Group
- Get-IMAPSettings
- Get-IPAllowListConfig
- Get-IPAllowListProvider
- Get-IPAllowListProvidersConfig
- Get-IPBlockListConfig
- Get-IPBlockListProvider
- Get-IPBlockListProvidersConfig
- Get-IRMConfiguration
- **Get-LinkedUser**
- Get-ManagedContentSettings
- Get-ManagedFolder
- Get-ManagedFolderMailboxPolicy
- Get-ManagementRole
- Get-ManagementRoleAssignment
- Get-ManagementRoleEntry
- Get-ManagementScope
- Get-Mailbox
- Get-MailboxAuditBypassAssociation
- Get-MailboxDatabase
- Get-MailboxServer

- Get-MailContact
- Get-MailPublicFolder
- Get-MailUser
- Get-MessageClassification
- Get-MoveRequest
- Get-OABVirtualDirectory
- Get-OfflineAddressBook
- Get-OrganizationConfig
- Get-OrganizationRelationship
- Get-OrganizationalUnit
- Get-OutlookAnywhere
- Get-OutlookProvider
- Get-OwaMailboxPolicy
- Get-OwaVirtualDirectory
- **Get-PerimeterConfig**
- Get-POPSettings
- Get-PowerShellVirtualDirectory
- Get-PublicFolderDatabase
- Get-ReceiveConnector
- Get-RecipientFilterConfig
- Get-RemoteDomain
- Get-RemoteMailbox
- Get-RetentionPolicy
- Get-RetentionPolicyTag
- Get-RoleGroup
- Get-RoleGroupMember
- Get-RoutingGroupConnector
- Get-RpcClientAccess
- Get-Recipient
- Get-RecipientEnforcementProvisioningPolicy
- Get-ResourceConfig
- Get-RetentionPolicy
- Get-RoleAssignmentPolicy
- **Get-RMSTrustedPublishingDomain**
- Get-SecurityPrincipal
- Get-SendConnector
- Get-SenderFilterConfig
- Get-SenderIdConfig
- Get-SenderReputationConfig
- Get-SharingPolicy
- Get-SystemMessage
- Get-ThrottlingPolicy
- Get-ThrottlingPolicyAssociation
- Get-TransportConfig
- Get-TransportServer
- Get-Trust
- Get-UMAutoAttendant
- Get-UMDialplan
- Get-UMHuntGroup
- Get-UMIPGateway
- Get-UMMailbox
- Get-UMMailboxPIN
- Get-UMMailboxPolicy
- Get-UMServer
- Get-User
- Get-WebServicesVirtualDirectory

- Get-X400AuthoritativeDomain

Looking for management tasks related to creating filters? See Creating Filters in Recipient Commands.

Common Filterable Properties

The following table contains the common filterable properties for the *-Filter* parameter. This table lists the name of the property, the Lightweight Directory Access Protocol (LDAP) display name, a description of the property, the possible values that the property can take, and each of the cmdlets that accept this property for the *-Filter* parameter. You can use the LDAP display name to convert your Exchange Server 2003 or earlier LDAP filters into Exchange 2010 Opath filters. For more information about how to convert LDAP filters to Exchange 2010 Opath filters, see Upgrade Custom LDAP Filters to OPATH Filters.

Note:

Not all filterable properties have an LDAP display name. The properties that do not have an LDAP display name are not Active Directory directory service properties. They are properties that are calculated by Exchange.

Note:

Many of the properties for the *-Filter* parameter accept wildcard characters. If you use a wildcard character, use the *-like* operator instead of the *-eq* operator. The *-like* operator is used to find pattern matches in rich types, such as strings, whereas the *-eq* operator is used to find an exact match.

Property name	LDAP display name	Description	Value	Cmdlets that accept this property
AcceptMessagesOnlyFrom	*authOrig*	This property contains the mailbox users and mail-enabled contacts that can send e-mail messages to this distribution group.	• Distinguished name (DN) • Canonical name • Globally unique identifier (GUID) • Name • Display name • Alias • Exchange DN • Primary Simple Mail Transfer Protocol (SMTP) address	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailContact Get-MailboxPlan Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox

				Get-UmMailboxPin
AcceptMessagesOnlyFromDLMembers	*dLMemSubmitPerms*	This property contains the distribution groups that are allowed to send e-mail messages to this distribution group.	• DN • Canonical name • GUID • Name • Display name • Alias • Exchange DN • Primary SMTP address	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-UmMailboxPin
ActiveSyncAllowedDeviceIDs	*msExchMobileAllowedDeviceIds*	This property contains a list of device IDs that are allowed to synchronize with the mailbox.	Device IDs	Get-CASMailbox Get-UmMailboxPin
ActiveSyncDebugLogging	*msExchMobileDebugLogging*	This property specifies whether error logging is enabled for mobile devices.	• String • Wildcard character accepted	Get-CASMailbox Get-CASMailboxPlan Get-UmMailboxPin
ActiveSyncEnabled	Not applicable	This property specifies	• Boolean • $true or $false	Get-CalendarDiagn

		whether Exchange ActiveSync is enabled for the mailbox		osticLog Get-CASMailbox Get-CASMailboxPlan Get-UmMailboxPin
ActiveSyncMailboxPolicy	*msExchMobileMailboxPolicyLink*	This property contains the name of the Exchange ActiveSync mailbox policy for the mailbox.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-CASMailbox Get-CASMailboxPlan Get-DistributionGroupMember Get-UmMailboxPin Get-Recipient Get-RoleGroupMember
AddressListMembership	*showInAddressBook*	This property contains the address lists and global address list (GAL) of which the recipient is a member.	DN	Get-DistributionGroupMember Get-Recipient
Alias	*mailNickname*	This property contains the alias (the generic name used to identify a mail account) of the recipient. The alias can be a combination of characters that are separated by	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroup Get-DistributionGroupMember Get-

		periods without intervening spaces.		DynamicDistributionGroup Get-Group Get-LinkedUser Get-Mailbox Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-PublicFolderDatabase Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-SecurityPrincipal Get-UmMailboxPin Get-User
AllowUMCallsFromNonUsers	*msExchUMListInDirectorySearch*	This property specifies whether to exclude the mailbox from directory searches.	• 0 or None • 1 or SearchEnabled	Get-CalendarDiagnosticLog Get-Contact Get-UMMailbox Get-UMMailboxPin Get-UMMailboxPlan

				Get-User
AssistantName	*msExchAssistantName*	This property contains the assistant name of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
City	*L*	This property contains the city name of the recipient.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User

HiddenFromAddressListsEnabled	*msExchHideFromAddressLists*	This property specifies whether the user is visible in the address list.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Mailbox Get-MailContact

				Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-UMMailboxPin
HomePhone	*homePhone*	This property contains the home phone number of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-User Get-UMMailboxPin Get-User
IncludedRecipients	Not applicable	This property contains the recipient types that are used to build the dynamic distribution group.	• AllRecipients • MailboxUsers • Resources • MailContacts • MailGroups • Mail Users • None	Get-DynamicDistributionGroup
Initials	*initials*	This property contains the initials for the name of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-

				LinkedUser Get-UMMailboxPin Get-User
IsLinked	Not applicable	This property specifies whether a folder is linked to a master folder.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-UMMailboxpin Get-User
IsMailboxEnabled	Not applicable	This property specifies whether a mailbox is mailbox-enabled.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
IsResource	Not applicable	This property specifies whether a mailbox is a resource mailbox.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
IsShared	Not applicable	This property specifies whether a resource mailbox is shared.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin

IssueWarningQuota	*mDBStorageQuota*	This property contains the mailbox size at which a warning message is sent to the user.	Unlimited or integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxDatabase Get-MailboxPlan Get-OrganizationConfig Get-PublicFolderDatabase Get-UMMailboxPin
LanguagesRaw	*msExchUserCulture*	This property contains the language preference for this mailbox.	An acceptable value for this parameter is a combination of an International Organization for Standardization (ISO) 639 two-letter lowercase culture code that is associated with a language and an ISO 3166 two-letter uppercase subculture code that is associated with a country or region. For example, United States English is represented as `en-us`. To learn more about culture codes and for a full list of acceptable values, see CultureInfo Class in the MSDN Library.	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
LastName	*sn*	This property contains the ANR search for the last name of the recipient.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser

				Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
ManagedBy	*managedBy*	This property contains the DN of the user or contact that manages this group.	DN	Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Group Get-Recipient Get-RoleGroup Get-RoleGroupMember
ManagedFolderMailboxPolicy	*msExchMailboxTemplateLink*	This property contains the managed folder mailbox policy that controls messaging records management (MRM) for the mailbox.	• Name • GUID • DN	Get-CalendarDiagnosticLog Get-DistributionGroupMember Get-Mailbox Get-MailboxPlan Get-Recipient Get-RoleGroupMember Get-UMMailboxPin
Manager	*manager*	This property contains the manager of	• String • Wildcard character accepted	Get-CalendarDiagnosticLog

		the recipient.		Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
MaxBlockedSenders	*msExchMaxBlockedSenders*	This property contains the maximum number of senders that can be included in the Blocked Senders list.	Integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
MaxReceiveSize	*delivContLength*	This property contains the maximum size of messages that this recipient can receive.	Unlimited or integer	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-

				MoveRequest Get-RemoteMailbox Get-TransportConfig Get-UMMailboxPin
MaxSafeSenders	*msExchMaxSafeSenders*	This property contains the maximum number of senders that can be included in the Safe Senders list.	Integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
MaxSendSize	*submissionContLength*	This property contains the maximum size of messages that this recipient can send.	Unlimited or integer	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-TransportConfig

				Get-UMMailboxPin
MemberOfGroup	*memberOf*	This property contains the groups of which the recipient is a member.	String	Get-CalendarDiagnosticLog Get-CASMailbox Get-Contact Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Group Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailUser Get-MailPublicFolder Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin

Notes	*info*	This property contains specific comments about the recipient.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Group Get-LinkedUser Get-RoleGroupMember Get-Recipient Get-UMMailboxPin Get-User
Office	*physicalDeliveryOfficeName*	This property contains the office of the recipient.	String	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User

OfflineAddressBook	*msExchUseOAB*	This property contains the offline address book (OAB) that is associated with this mailbox.	• Name • GUID • DN	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxDatabase Get-MailboxPlan Get-UMMailboxPin
OperatorNumber	*msExchUMOperatorNumber*	This property contains the string of digits for the personal operator.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-UMMailbox Get-UMMailboxPin Get-UMMailboxPlan
OtherFax	*otherFacsimileTelephoneNumber*	This property contains the additional fax number of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
OtherHomePhone	*otherHomePhone*	This property contains the additional home phone number of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
OtherTelephone	*otherTelephone*	This property contains the additional telephone	• String • Wildcard character accepted	Get-CalendarDiagnosticLog

		number of the user or contact.		Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
Pager	*pager*	This property contains the pager number of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
Phone	*telephoneNumber*	This property contains the phone number of the recipient.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
PhoneticDisplayName	*msDS-PhoneticDisplayName*	This property contains a phonetic pronunciation of the *DisplayName* property. UM uses this property for Automatic	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DynamicDistributionGroup Get-Group

		Speech Recognition.		Get-LinkedUser Get-MailPublicFolder Get-UMMailboxPin Get-User
PoliciesExcluded	*msExchPoliciesExcluded*	This property contains the GUIDs of any policies that are excluded.	GUID	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-UMMailboxPin
PostalCode	*postalCode*	This property	• String • Wildcard	Get-CalendarDiagn

		contains the postal code of the user or contact.	character accepted	osticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
PostOfficeBox	*postOfficeBox*	This property contains the post office box number of the user or contact.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
PrimarySmtpAddress	Not applicable	This property contains the primary SMTP address, which is the e-mail address that external users will see when they receive a message from this recipient.	SMTP address	Get-CalendarDiagnosticLog Get-CASMailbox Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan

				Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin
ProhibitSendQuota	*mDBOverQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send messages.	Unlimited or integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxDatabase Get-MailboxPlan Get-UMMailboxPin
ProhibitSendReceiveQuota	*mDBOverHardQuotaLimit*	This property contains the mailbox size at which the user associated with this mailbox can no longer send or receive messages.	Unlimited or integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxDatabase Get-MailboxPlan Get-UMMailboxPin

PublicFolderContacts	*pFContacts*	This property contains the contacts for the public folder.	Multiple DNs	Get-MailPublicFolder
PublicFolderType	*msExchPFTreeType*	This property specifies the public folder type.	• GeneralPurpose • MAPI • Network News Transfer Protocol (NNTP) • NotSpecified	Get-MailPublicFolder
RecipientFilter	*msExchQueryFilter*	This property contains the recipient filter that has been applied.	String	Get-AddressList Get-DynamicDistributionGroup Get-EmailAddressPolicy Get-GlobalAddressList
RecipientLimits	*msExchRecipLimit*	This property contains the maximum number of recipients per message to which this mailbox can send.	Unlimited or integer	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailUser Get-RemoteMailbox Get-UMMailboxPin
RecipientType	Not applicable	This property specifies the recipient type.	• UserMailbox • MailUser • MailContact • MailUniversalDistributionGroup • MailUniversalSecurityGroup • MailNonUniversalGroup • DynamicDistributionGroup • PublicFolder	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroup Get-DistributionGroupMember

				Get-DynamicDistributionGroup Get-Group Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-UMMailboxPin Get-User
RecipientTypeDetails	Not applicable	This property specifies the recipient subtype.	• ConferenceRoomMailbox • EquipmentMailbox • LegacyMailbox • LinkedMailbox • UserMailbox • MailContact • DynamicDistributionGroup • MailForestContact • MailNonUniversalGroup • MailUniversalDistributionGroup • MailUniversalSecurityGroup	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroup Get-DistributionGroupMember Get-DynamicDistributionGroup Get-Group

			• MailUser • PublicFolder • SharedMailbox	Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MailPublicFolder Get-MoveRequest Get-Recipient Get-RemoteMailbox Get-RoleGroupMember Get-SecurityPrincipal Get-UMMailboxPin Get-User
RejectMessagesFrom	*unauthOrig*	This property contains the recipients from whom messages will be rejected by this recipient.	• DN • Canonical name • GUID • Name • Display name • Alias • Exchange DN • Primary SMTP address	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan

				Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-UMMailboxPin
RejectMessagesFromDLMembers	*dLMemRejectPerms*	This property specifies the distribution groups from which this recipient will reject messages.	• DN • Canonical name • GUID • Name • Display name • Alias • Exchange DN • Primary SMTP address	Get-CalendarDiagnosticLog Get-DistributionGroup Get-DynamicDistributionGroup Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-UMMailboxPin
ResourceCapacity	*msExchResourceCapacity*	This property contains the capacity of this resource mailbox.	Non-negative integer	Get-CalendarDiagnosticLog Get-Mailbox

				Get-MailboxPlan Get-UMMailboxPin
ResourceCustom	Not applicable	This property contains custom properties for this resource mailbox.	Custom property defined by **Set-ResourceConfig**	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
RetainDeletedItemsFor	*garbageCollPeriod*	This property contains the length of time to keep deleted items.	Time span: *dd.hh:mm:ss* where *dd* = days, *hh* = hours, *mm* = minutes, and *ss* = seconds	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-MailUser Get-RemoteMailbox Get-UMMailboxPin
RulesQuota	*msExchMDBRulesQuota*	This property contains the limit for the size of rules for this mailbox.	String	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
SamAccountName	*SamAccountName*	This property contains the logon name that is used to support client computers and servers running older versions of the operating system, such as Microsoft	String	Get-CalendarDiagnosticLog Get-CASMailbox Get-DistributionGroup Get-

		Windows NT 4.0, Windows 98, Windows 95, and LAN Manager.		DistributionGroupMember Get-Group Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailUser Get-Recipient Get-RemoteMailbox Get-RoleGroup Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin Get-User
SendOofMessageToOriginatorEnabled	*oOFReplyToOriginator*	This property specifies whether out-of-office messages from distribution group members are sent to the message sender.	• Boolean • $true or $false	Get-DistributionGroup Get-DynamicDistributionGroup
ServerName	Not applicable	This property contains the name of the server on which the object resides	Server name	Get-CalendarDiagnosticLog Get-CASMailbox Get-DistributionGroupMember Get-Mailbox

				Get-MailboxPlan Get-Recipient Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin
SimpleDisplayName	*displayNamePrintable*	This property contains an alternative display name of the object when only a limited set of characters is permitted.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-Group Get-LlinkedUser Get-Mailbox Get-MailContact Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-UMMailboxPin

				Get-User
StateOrProvince	*st*	This property contains the state or province information that is defined for this recipient.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
StreetAddress	*streetAddress*	This property contains the street address that is defined for the user or contact.	String	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
TelephoneAssistant	*telephoneAssistant*	This property contains the telephone number of the contact's assistant.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-LinkedUser Get-UMMailboxPin Get-User
Title	*title*	This property contains the title of the recipient.	String	Get-CalendarDiagnosticLog Get-Contact

				Get-DistributionGroupMember Get-LinkedUser Get-Recipient Get-RoleGroupMember Get-UMMailboxPin Get-User
UMDtmfMap	*msExchUMDtmfMap*	This property contains a user-defined dual tone multi-frequency (DTMF) map for the UM-enabled user. DTMF is also referred to as *touch-tone*.	• String • Wildcard character accepted	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroup Get-DynamicDistributionGroup Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailContact Get-MailPublicFolder Get-MailUser Get-MoveRequest Get-RemoteMailbox Get-UMMailbox Get-UMMailboxPin

				Get-User
UMEnabled	Not applicable	This property specifies whether UM is enabled for this mailbox.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-DistributionGroupMember Get-Mailbox Get-MailboxPlan Get-Recipient Get-UMMailbox Get-UMMailboxPin Get-UMMailboxPlan
UMMailboxPolicy	*msExchUMTemplateLink*	This property contains the UM mailbox policy for the mailbox. You use UM mailbox policies to set UM settings for UM-enabled users, such as personal identification number (PIN) policies and dialing restrictions.	String	Get-CalendarDiagnosticLog Get-DistributionGroupMember Get-Recipient Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin Get-UMMailboxPlan
UMRecipientDialPlanId	*msExchUMRecipientDialPlanLink*	This property contains the dial plan identifier for the mailbox, user, or contact.	DN	Get-CalendarDiagnosticLog Get-Contact Get-DistributionGroupMember Get-LinkedUser

				Get-Recipient Get-RoleGroupMember Get-UMMailbox Get-UMMailboxPin Get-UMMailboxPlan Get-User
UseDatabaseQuotaDefaults	*mDBUseDefaults*	This property specifies whether the mailbox uses the quota attributes for the mailbox database in which this mailbox resides. The quota attributes are: ProhibitSendQuota, ProhibitSendReceiveQuota, IssueWarningQuota, and RulesQuota.	• Boolean • $true or $false	Get-CalendarDiagnosticLog Get-Mailbox Get-MailboxPlan Get-UMMailboxPin
UserPrincipalName	*userPrincipalName*	This property contains the UPN for this recipient. The UPN is the logon name for the user, and consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides.	• User logon name • User principal name • Wildcard character accepted	Get-CalendarDiagnosticLog Get-DistributionGroupMember Get-LinkedUser Get-Mailbox Get-MailboxPlan Get-MailUser Get-Recipient Get-RemoteMailbox

				Get-RoleGroupMember Get-UMMailboxPin Get-User
WhenChanged	*WhenChanged*	This property contains the date and time stamp of when the object was last changed.	Date-time stamp	Get-AcceptedDomain Get-ActivesyncDevice Get-ActiveSyncDeviceAccessRule Get-ActivesyncDeviceClass Get-ActivesyncMailboxPolicy Get-ActiveSyncOrganizationSettings Get-ActivesyncVirtualDirectory Get-AdminAuditLogConfig Get-AddressList Get-AddressRewriteEntry Get-ADSite Get-ADSiteLink Get-AttachmentFilterEntry Get-AttachmentFilt

1.8.3.3.2 Filterable Properties for the -RecipientFilter Parameter

Filterable Properties for the -RecipientFilter Parameter

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The content for this topic will be similar to a previously published Exchange Server 2007 topic. For more information, see Filterable Properties for the -RecipientFilter Parameter in Exchange 2007 SP1 and SP2.

Filterable Properties for the -ContentFilter Parameter

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-30*

This topic lists the filterable properties for the *ContentFilter* parameter. The *ContentFilter* parameter is used to export messages to a .pst file that match the filter. The *ContentFilter* parameter is used in the New-MailboxExportRequest cmdlet.

Filterable Properties

Many of the properties for the *ContentFilter* parameter accept wildcard characters. If you use a wildcard character, use the **-like** operator instead of the **-eq** operator. The **-like** operator is used to find pattern matches in rich types, such as strings, whereas the **-eq** operator is used to find an exact match.

The following table contains a list of the filterable properties for the *ContentFilter* parameter. This table lists the name of the property, a description, the acceptable values, and a syntax example. For more information about OPATH filters, see Creating Filters in Recipient Commands.

Property	Description	Values	Example syntax
All	This property returns all messages that have a particular string in any of the indexed properties. For example, use this property if you want to export all messages that have "Ayla" as the recipient, the sender, or have the name mentioned in the message body.	String Wildcard	`-ContentFilter {All`
Attachment	This property returns messages that have the specified string in the content of an attachment or in the attachment's file name.	String Wildcard	`-ContentFilter {Atta`
BCC	This property returns sent messages that have the specified recipient in the Bcc field.	Display name Alias SMTP address LegacyDN Wildcard	`-ContentFilter {(BCC`

Body	This property returns messages that have the specified string within the message body.	String Wildcard	-ContentFilter {Body
Category	This property returns messages that have a matching category. Categories are set by users or Inbox rules.	String Wildcard	-ContentFilter {Cate
CC	This property returns sent messages that have the specified recipient in the Cc field.	Display name Alias SMTP address LegacyDN Wildcard	-ContentFilter {(CC
Expires	This property returns messages that have a specified expiration time stamp.	Date-Time stamp	-ContentFilter {Expi
HasAttachment	This property returns messages with or without attachments.	Boolean $true or $false	-ContentFilter {HasA
Importance	This property returns messages that have a specified importance level.	0 or "Low" 1 or "Normal" 2 or "High"	-ContentFilter {Impo -ContentFilter {Impo
IsFlagged	This property returns messages that have been flagged by the user or Inbox rule.	Boolean $true or $false	-ContentFilter {IsFl
IsRead	This property returns messages that have been read or not read by the user.	Boolean $true or $false	-ContentFilter {IsRe
MessageKind	This property returns messages that are of the specified type.	Email Meetings Tasks Notes Docs Journal Contacts	-ContentFilter {Mess -ContentFilter {Mess

		IM Voicemail Fax Posts RSSFeeds	
MessageLocale	This property returns messages that are of the specified locale.	CultureInfo	-ContentFilter {Mess -ContentFilter {Mess
Participants	This property returns messages that have the specified recipient in the To, Bcc, or Cc fields.	Display name Alias SMTP address LegacyDN Wildcard	-ContentFilter {(Par
PolicyTag	This property returns messages that have a policy tag. The Exchange store persists policy tags as GUIDs. Therefore, the string can contain either an explicit GUID value, which is then searched by the PR_POLICY_TAG, or a wildcard string. If the supplied value isn't a GUID, the command uses Active Directory information to resolve names to GUIDs.	String Wildcard	-ContentFilter {Poli
Received	This property returns messages that were received by the recipient with the specified Received time stamp.	Date-Time stamp	-ContentFilter {Rece {(Received -lt '01/0
Sender	This property returns messages that were received from the specified sender.	Display name Alias SMTP address LegacyDN	ContentFilter {Sende

		Wildcard	
Sent	This property returns messages that were sent by the recipient with the specified Sent time stamp.	Date-Time stamp	-ContentFilter {Sent -ContentFilter {(Sen
Size	This property returns messages that are of a specific size.	B (bytes) KB (kilobytes) MB (megabytes)	-ContentFilter {Size
Subject	This property returns messages that have the specified string within the subject of the message.	String Wildcard	-ContentFilter {Subj
To	This property returns sent messages that have the specified recipient in the To field.	Display name Alias SMTP address LegacyDN Wildcard	-ContentFilter {To -

1.8.3.4 Configure Message Delivery Restrictions

Configure Message Delivery Restrictions

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can place restrictions on how messages are delivered to individual recipients. Message delivery restrictions can be useful for controlling access to specific recipients. To learn more about message delivery restrictions, see Understanding Recipient Restrictions.

The message delivery restrictions covered in this topic apply to all recipient types. To learn more about the recipient types, see Understanding Recipients.

Looking for other management tasks related to Mailbox servers? Check out Managing Mailbox Servers.

Use the EMC to configure message delivery restrictions for all recipients, except mail-enabled public folders

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the recipient for which you want to configure message delivery restrictions.
3. In the action pane, under the recipient name, click **Properties**.
4. In **<Recipient> Properties**, click the **Mail Flow Settings** tab.
5. Select **Message Delivery Restrictions** from the list of mail flow settings, and then click **Properties**.
6. **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:
   All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
   Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.
   Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.
   No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.
   Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**
7. Click **OK** to return to the **Mail Flow Settings** tab.

Use the EMC to configure message delivery restrictions for mail-enabled public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail-enabled public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**, and then in the action pane, click **Open Tool**. The Public Folder Management Console appears in a separate Microsoft Management Console (MMC).
3. In the console tree, expand **Default Public Folders**, and then click the public folder that you want to configure. If the public folder you want to configure is a top-level public folder, click **Default Public Folders**.
4. In the result pane, click the public folder for which you want to configure message delivery restrictions.
5. In **<Recipient> Properties**, click the **Mail Flow Settings** tab.
6. Select **Message Delivery Restrictions** from the list of mail flow settings, and then click **Properties**.
7. **Message Delivery Restrictions** Select this setting and then click **Properties**

to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.

Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.

No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.

Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

8. Click **OK** to save your changes and return to the **Mail Flow Settings** tab.

Use the Shell to configure message delivery restrictions

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section and the "Mail-enabled public folders" entry in the Mailbox Permissions topic.

The following procedure shows you how to use the Shell to configure message delivery restrictions for a mailbox. For other recipient types, use the corresponding **Set-** cmdlet with the same parameters.

This example configures the mailbox John Smith to accept messages only from the users Lori Penor, Jeff Phillips, and members of the distribution group Sales Department.

```
Set-Mailbox -Identity "John Smith" -AcceptMessagesOnlyFrom "Lori Penor","Jeff Phi
```

Note:

If you're configuring a mailbox to accept messages only from individual senders, you must use the *AcceptMessagesOnlyFrom* parameter. If you're configuring a mailbox to accept messages only from senders that are members of a specific distribution group, you must use the *AcceptMessagesOnlyFromDLMembers* parameter.

This example configures the mailbox John Smith to require all senders to be authenticated.

```
Set-Mailbox -Identity "John Smith" -RequireSenderAuthenticationEnabled $true
```

This example configures the mailbox John Smith to reject messages from the users Joe Healy, Terry Adams, and members of the distribution group Sales Department Contractors.

```
Set-Mailbox -Identity "John Smith" -RejectMessagesFrom "Joe Healy","Terry Adams"
```

Note:
If you're configuring a mailbox to reject messages from individual senders, you must use the *RejectMessagesFrom* parameter. If you're configuring a mailbox to reject messages from senders that are members of a specific distribution group, you must use the *RejectMessagesFromDLMembers* parameter.

For detailed syntax and parameter information, see the following topics:

- Set-DistributionGroup
- Set-DynamicDistributionGroup
- Set-Mailbox
- Set-MailContact
- Set-MailPublicFolder
- Set-MailUser

1.8.3.5 Managing Address Lists

Managing Address Lists

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-20*

1.8.3.5.1 Apply an Address List

Apply an Address List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Address lists are a collection of recipient and other Active Directory objects. You apply an address list when the address list filter rule has been edited. To update the membership of the address list to include new recipients and remove those who no longer meet the filtering criteria, you must apply the address list.

Changes that you make to an address list aren't applied to recipients until you apply the list. You can apply changes to address lists immediately or at a scheduled time by using the New Address List wizard or the Edit Address List wizard.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

What Do You Want to Do?

- Use the EMC to apply an address list
- Use the Shell to apply an address list

Use the EMC to apply an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address Lists" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Address Lists** tab, and then click the address list that you want to apply.
3. In the action pane, click **Apply**.
4. On the **Introduction** page, complete the following fields:
   - **Apply the address list** Select one of the following options to specify when the address list should be applied:
     Immediately Click this button to apply the changes immediately.
     At the following time Click this button and use the corresponding list to specify a date and time to apply the changes.
   - **Cancel tasks that are still running after (hours)** Select this check box and use the corresponding text box to specify the length of time that the task is permitted to run. The default is 8 hours.
5. On the **Apply Address List** page, review your configuration settings. Click **Apply** to apply the address list. Click **Back** to make configuration changes.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to close the wizard.

Use the Shell to apply an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

This example applies the address list Washington State.

```
Update-AddressList "Washington State"
```

If you have more than one address list with the same name, you must specify the full path to the address list you want to update. For example, if you want to update the address list Sales under North America but there is also a Sales address list under Europe, use the following command:

```
Update-AddressList "North America\Sales"
```

For detailed syntax and parameter information, see Update-AddressList.

1.8.3.5.2 Create an Address List

Create an Address List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Address lists are a collection of recipient and other Active Directory objects. Each address list can contain one or more types of objects (for example, users, contacts, groups, public folders, conferencing, and other resources). Address lists also provide a mechanism to partition mail-enabled objects in Active Directory for the benefit of specific groups of users.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

What Do You Want to Do?

- Use the EMC to create an address list
- Use the Shell to create an address list

Use the EMC to create an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Address List**.
3. On the **Introduction** page, complete the following fields:
   - **Name** Use this box to type the name for the new address list. The name can contain as many as 64 characters, including wildcard characters, but can't contain the backslash character (****).
   - **Display Name** Use this box to type the for the new address list. This is the name that's displayed to users when they view the address list from a client such as Outlook. Although this field is automatically populated with the same name you type in the **Name** box, you can modify it.

- **Container** Click **Browse** to select the path to the container for the address list. To add the address list as a child to an existing address list, click the existing address list you want, and then click **OK**. To create a new parent address list, click **All Address Lists**, and then click **OK**.

4. On the **Filter Settings** page, complete the following fields:
   - **Select the recipient container where you want to apply the filter** The recipient container defines the organizational unit (OU) filter for an address list. Click **Browse** to open the **Select Organizational Unit** dialog box. Use this dialog box to specify the OU from which to select the recipients.
   - Select the recipient types you want to include. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:

     Users with Exchange mailboxes Select this check box if you want the address list to apply to users that have Exchange mailboxes. Users that have Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.

     Users with external e-mail addresses Select this check box if you want the address list to apply to users that have external e-mail addresses. Users that have external e-mail accounts have user domain accounts in Active Directory, but use e-mail accounts that are external to the organization. This enables them to be included in the GAL and added to distribution lists.

     Resource mailboxes Select this check box if you want the address list to apply to Exchange resource mailboxes. Resource mailboxes allow you to administer company resources through a mailbox, such as a conference room or company vehicle.

     Contacts with external e-mail addresses Select this check box if you want the address list to apply to contacts that have external e-mail addresses. Contacts that have external e-mail accounts don't have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.

     Mail-enabled groups Select this check box if you want the address list to apply to security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

     Note:

     If your address list contains distribution groups that aren't universal, these distribution groups aren't displayed when you preview the address list in the EMC. To make sure that all distribution groups are displayed when you click the **Preview** button (as described in Step 5), you must convert the non-universal distribution groups to universal distribution groups. For more information about converting a distribution group to a universal distribution group, see the example in Set-Group.

5. On the **Conditions** page, complete the following fields:

   Step 1: Select conditions Use this section to select one or more conditions for your address list. If you don't want to set any conditions for the list, don't select any of the check boxes.
   - **Recipient is in a State or Province** Select this check box if you want the address list to include only recipients from specific states or provinces. This information is contained on the **Address and Phone** tab in the recipient's properties.
   - **Recipient is in a Department** Select this check box if you want the address list to include only recipients in specific departments. This information is contained on the **Organization** tab in the recipient's

properties.

- **Recipient is in a Company** Select this check box if you want the address list to include only recipients in specific companies. This information is contained on the **Organization** tab in the recipient's properties.
- **Custom Attribute equals Value** There are 15 custom attributes for each recipient. There is a separate condition for each custom attribute. If you want the address list to include only recipients that have a specific value set for a specific custom attribute, select the check box that corresponds to that custom attribute.

Note:

The **State or Province**, **Department**, and **Company** conditions are based on attributes that are applicable only to mailboxes, mail users, and mail contacts. These conditions do not apply to mail-enabled distribution groups. If you configure any of these conditions for an address list, you will in effect be excluding all mail-enabled distribution groups.

Step 2: Edit the conditions by selecting an underlined value: If you select any conditions in Step 1, each condition you select will append to the definition of the address list. For example, if you selected the **Recipient is in a State or Province** check box in Step 1, you will see the **in the specified State or Province(s)** condition in Step 2.
For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.
If you click an underlined value for the **State or Province**, **Department**, or **Company** conditions, a dialog box appears in which you can specify the values for the condition. To create values for the condition, use the following buttons in the dialog box:

- **Add** Enter a value in the text box and click **Add**. You can add more than one value, but you cannot enter duplicate values.
- **Edit** To modify an existing value, select it from the list, and then click **Edit**.
-  To remove an existing value, select it from the list, and then click  .

If you click an underlined value for a custom attribute condition, a dialog box appears in which you can specify the value for the condition. You can specify a single value for each custom attribute. Type the value in the text box and click **OK**.

Important:

The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.

Preview Click this button to view the recipients that will be contained in the address list, based on the conditions that you specified.

6. On the **Schedule** page, complete the following fields:
Apply the address list Select one of the following options to specify when the address list should be applied:
   - **Do not apply** Click this button to create the address list without applying it to recipients. To apply this address list to the selected recipients, use the **Update-AddressList** cmdlet or the Apply Address List wizard. For more information, see Apply an Address List.
   - **Immediately** Click this button to apply the address list as soon as it is created.
   - **At the following time** Click this button and use the corresponding lists to specify a time to apply the new address list.

   Cancel tasks that are still running after (hours) Select this check box and use the corresponding text box to specify how long the new address list task

will run. The default is 8 hours.

7. On the **New Address List** page, review your configuration settings. Click **New** to create the address list. Click **Back** to make configuration changes.

8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
9. Click **Finish** to close the wizard.

Use the Shell to create an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

This example creates the address list MyAddressList by using the *RecipientFilter* parameter and includes recipients that are mailbox users and have `StateOrProvince` set to `Washington` or `Oregon`:

```
New-AddressList -Name MyAddressList -RecipientFilter {((RecipientType -eq 'UserMa
```

This example creates the child address list Building 34 Meeting Rooms in the All Rooms parent container, using built-in conditions.

```
New-AddressList -Name "Building 34 Meeting Rooms" -Container "\All Rooms" -Includ
```

Other Tasks

After you create an address list in the Shell, you must apply it. Use the **Update-AddressList** cmdlet or the Apply Address List wizard to apply the address list. For more information, see Apply an Address List.

For More Information

Configure Address List Properties

Understanding Address Lists

1.8.3.5.3 Create an Address List By Using Recipient Filters

Create an Address List By Using Recipient Filters

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-09*

This topic explains how to use the Exchange Management Shell to create an address list by using recipient filters. To learn more about address lists, see Managing Address Lists.

To use the *RecipientFilter* parameter to create a custom filter, you must specify a string for the filter. The Shell uses OPATH for the filtering syntax. OPATH is a querying language

designed to query object data sources. For more information about the OPATH filtering syntax, see Creating Filters in Recipient Commands.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to create an address list by using recipient filters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to create an address list by using recipient filters.

To create an address list by using the *RecipientFilter* parameter, use the following syntax.

```
New-AddressList -Name <String> -RecipientFilter <String>
```

This example creates an address list for all users with Exchange mailboxes who reside in Washington or Oregon.

```
New-AddressList -Name "Pacific Northwest Mailboxes" -RecipientFilter {((Recipient
```

This example creates an address list for all users with Exchange mailboxes who have AgencyB as the value for the *CustomAttribute15* parameter.

```
New-AddressList -Name "AgencyB" -RecipientFilter {(RecipientType -eq 'UserMailbox
```

For detailed syntax and parameter information, see New-AddressList.

1.8.3.5.4 Configure Address List Properties

Configure Address List Properties

Mailbox > Managing Mailbox Servers > Managing Address Lists >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Address lists are a collection of recipient and other Active Directory objects. Each address list can contain one or more types of objects (for example, users, contacts, groups, public folders, conferencing, and other resources). Address lists also provide a mechanism to partition mail-enabled objects in Active Directory for the benefit of specific groups of users.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Prerequisites

- You can't use the Exchange Management Console (EMC) to edit global address lists (GALs). You can only edit GALs by using the **Set-GlobalAddressList** cmdlet in the Shell.
- You can't use the EMC to move the address list from its container. You must

use the **Move-AddressList** cmdlet in the Shell. For more information, see Move an Address List.

- You can't use the EMC to edit the conditions or recipient types of the following default address lists: **All Contacts**, **All Groups**, **All Rooms**, **All Users**, and **Public Folders**. You must use the Shell to edit these default address lists.

What Do You Want to Do?

- Use the EMC to configure address list properties
- Use the Shell to configure address list properties

Use the EMC to configure address list properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Address List** tab, and then select the address list you want to configure.
3. In the action pane, click **Edit**.
4. On the **Introduction** page, complete the following fields:
   - **Name** Use this box to view the existing name or to type a new name for the address list. The name can contain as many as 64 characters, including wildcard characters, but can't contain the backslash (****) character.
   - **Display Name** Use this box to view the existing display name or to type a new display name for the address list. This is the name that's displayed to users when they view the address list from a client such as Outlook.
   - **Container** This read-only box displays the path to the address list's container that you specified when you created the list.
5. On the **Filter Settings** page, complete the following fields:

Note:

If you created this address list by using a recipient filter in the Shell, you can't edit the recipient types. You must use the Shell to modify the filter. For more information, see Create an Address List By Using Recipient Filters.

- **Select the Recipient container where you want to apply the filter** The recipient container defines the organizational unit (OU) filter for an address list. Click **Browse** to open the **Select Organizational Unit** dialog box. Use this dialog box to specify the OU from which to select the recipients.
- Select the recipient types you want to include. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:

  Users with Exchange mailboxes Select this check box if you want the address list to apply to users that have Exchange 2010 mailboxes. Users that have Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.

  Users with external e-mail addresses Select this check box if you want the address list to apply to users that have external e-mail addresses. Users that have external e-mail accounts have user domain accounts in Active Directory, but use e-mail accounts that are external to the organization. This enables them to be included in the GAL and added to distribution lists.

  Resource mailboxes Select this check box if you want the address list to apply to Exchange resource mailboxes. Resource mailboxes allow you to administer company resources through a

mailbox, such as a conference room or company vehicle.
Contacts with external e-mail addresses Select this check box if you want the address list to apply to contacts that have external e-mail addresses. Contacts that have external e-mail accounts don't have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.
Mail-enabled groups Select this check box if you want the address list to apply to security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

Note:
If your address list contains distribution groups that aren't universal, these distribution groups aren't displayed when you preview the address list in the EMC. To make sure that all distribution groups are displayed when you click the **Preview** button (as described in Step 6), you must convert the non-universal distribution groups to universal distribution groups. For more information about converting a distribution group to a universal distribution group, see the example in Set-Group.

6. On the **Conditions** page, complete the following fields:
Step 1: Select conditions Use this section to edit or set conditions for your address list. If you don't want to set any conditions for the list, don't select any of the check boxes.
- **Recipient is in a State or Province** Select this check box if you want the address list to include only recipients from specific states or provinces. This information is contained on the **Address and Phone** tab in the recipient's properties.
- **Recipient is in a Department** Select this check box if you want the address list to include only recipients in specific departments. This information is contained on the **Organization** tab in the recipient's properties.
- **Recipient is in a Company** Select this check box if you want the address list to include only recipients in specific companies. This information is contained on the **Organization** tab in the recipient's properties.
- **Custom Attribute equals Value** There are 15 custom attributes for each recipient. There is a separate condition for each custom attribute. If you want the address list to include only recipients that have a specific value set for a specific custom attribute, select the check box that corresponds to that custom attribute.

Note:
The **State or Province**, **Department**, and **Company** conditions are based on attributes that are applicable only to mailboxes, mail users, and mail contacts. These conditions do not apply to mail-enabled distribution groups. If you configure any of these conditions for an address list, you will in effect be excluding all mail-enabled distribution groups.

Step 2: Edit the conditions by selecting an underlined value If you select any conditions in Step 1, each condition you select will append to the definition of the address list. For example, if you selected the **Recipient is in a State or Province** check box in Step 1, you will see **in the specified State or Province(s)** condition in Step 2.
For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.
If you click an underlined value for the **State or Province**, **Department**, or **Company** conditions, a dialog box appears in which you can specify the

values for the condition. To create values for the condition, use the following buttons in the dialog box:

- **Add** Enter a value in the text box and click **Add**. You can add more than one value, but you cannot enter duplicate values.
- **Edit** To modify an existing value, select it from the list, and then click **Edit**.
-  To remove an existing value, select it from the list, and then click  .

If you click an underlined value for a custom attribute condition, a dialog box appears in which you can specify the value for the condition. You can specify a single value for each custom attribute. Type the value in the text box, and then click **OK**.

Important:

The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.

7. On the **Schedule** page, complete the following fields:
   Apply the address list Select one of the following options to specify when the address list changes are applied:
   - **Do not apply** Click this button if you don't want to apply the changes. To apply this address list to the selected recipients, use the **Update-AddressList** cmdlet or the Apply Address List wizard. For more information, see Apply an Address List.
   - **Immediately** Click this button to apply the changes immediately.
   - **At the following time** Click this button and use the corresponding lists to specify a time to apply the changes.

   Cancel tasks that are still running after (hours) Select this check box and use the corresponding text box to specify the length of time that the task is permitted run. The default is 8 hours.

8. On the **Edit Address List** page, review your configuration settings. Click **Edit** to apply your changes to the address list. Click **Back** to make configuration changes.

9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
10. Click **Finish** to close the wizard.

Use the Shell to configure address list properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

This example configures the address list Contoso California Branch to include recipients that work in the branch office of the company Contoso in California:

```
Set-AddressList -Identity "Contoso California Branch" -ConditionalCompany Contoso
```

1.8.3.5.5 Move an Address List

Move an Address List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to move an existing address list to a new container under the root address list.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to move an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to move an address list.

This example uses the address list's GUID to move the address list to the Building 4 container, which is located in the All Users\Sales container.

```
Move-AddressList -Identity c3fffd8e-026b-41b9-88c4-8c21697ac8ac -Target "\All Use
```

Type **Y** to confirm that you want to move this address list, and then press ENTER.

For detailed syntax and parameter information, see Move-AddressList.

1.8.3.5.6 Remove an Address List

Remove an Address List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to remove an address list. You can't remove the default global address list (GAL).

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the EMC to remove an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Address Lists** tab, click the address list that you want to remove.
3. In the action pane, click **Remove**. A warning appears, asking if you are sure

that you want to remove the address list. Click **Yes** to remove the address list.

4. You can track the progress in the status bar on the bottom of the EMC. When the process is complete, the address list will be removed from the result pane.

Note:

You can't remove a parent address list that contains child address lists. However, you can remove both the child and parent address lists by pressing the CTRL key on the keyboard, and then selecting the parent and child address lists. If you attempt to remove a parent address list without removing the child address lists, you'll receive an error.

Use the Shell to remove an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

To remove an address list, use the following syntax.

```
Remove-AddressList -Identity <AddressListIDParameter>
```

This example removes the address list Sales Department, which doesn't contain child address lists.

```
Remove-AddressList -Identity "Sales Department"
```

Type **Y** to confirm that you want to remove this address list, and then press ENTER.

For detailed syntax and parameter information, see Remove-AddressList.

Use the Shell to remove an address list that contains child address lists

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to remove an address list that contains child address lists.

To remove an address list that contains child address lists, use the following syntax.

```
Remove-AddressList -Identity <AddressListIDParameter> -Recursive
```

This example removes the parent address list Departments and all of its child address lists.

```
Remove-AddressList -Identity Departments -Recursive
```

Type **Y** to confirm that you want to remove the parent address list and its child address lists, and then press ENTER.

For detailed syntax and parameter information, see Remove-AddressList.

1.8.3.5.7 View the Members of an Address List by Using the Exchange Management Shell

View the Members of an Address List by Using the Exchange Management Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to view the members of an address list.

You can view the members of an address list by using the Edit Address List wizard or the New Address List wizard in the Exchange Management Console (EMC). However, if you used the Shell to create the address list, you can't use the EMC to view the members of the list. Instead, you must use the **Get-Recipient** cmdlet in the Shell. For more information about how to view the members of an address list by using the EMC, see Configure Address List Properties.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to view the members of an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to view the members of an address list that was created using the Shell.

This example finds the distinguished name (DN) of an address list named Humongous Insurance.

```
Get-AddressList -Identity "Humongous Insurance" | fl DistinguishedName
```

This example lists the members of the Humongous Insurance address list by using the DN.

```
Get-Recipient -Filter {AddressListMembership -eq 'CN=Humongous Insurance,CN=All A
```

For detailed syntax and parameter information, see Get-AddressList and Get-Recipient.

1.8.3.5.8 Set the Default Address List View for an Outlook User

Set the Default Address List View for an Outlook User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), you can determine whether the global address list (GAL) should be the default address list displayed to Microsoft Outlook

users. If users aren't intended to use the GAL as their default view, you can configure it so that Outlook automatically displays the user's Contacts list instead. However, Outlook users can still view the GAL by using the Address Book list. By default, the GAL is displayed to all users.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to set the default address list view for a user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access user settings" entry in the Client Access Permissions topic.

Note:
You can't use the EMC to set the default address list view for a user.

This example sets Tony's Contacts list as his default view in Outlook.

```
Set-CASMailbox -Identity Tony -ShowGalAsDefaultView $false
```

This example sets Ayla's GAL as her default view in Outlook.

```
Set-CASMailbox -Identity Ayla -ShowGalAsDefaultView $true
```

For detailed syntax and parameter information, see Set-CASMailbox.

1.8.3.5.9 Create a Global Address List

Create a Global Address List

Mailbox > Managing Mailbox Servers > Managing Address Lists >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-18*

The global address list (GAL) is a directory that contains entries for every group, user, and contact within an organization's implementation of Microsoft Exchange. If your organization uses address book policies, you may want to create additional GALs. To learn more, see Understanding Address Book Policies.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to create a GAL using conditional filter properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Global address lists" entry in the Mailbox Permissions topic.

Note:
You can't use the Exchange Management Console to create a GAL.

This example creates a GAL named GAL_Contoso that includes recipients who are mailbox users and have their company listed as Contoso.

```
New-GlobalAddressList -Name "GAL_Contoso" -IncludedRecipients MailboxUsers -Condi
```

Note:
If you are using precanned conditional filter properties, the *IncludedRecipients* parameter can't be blank.

For detailed syntax and parameter information, see New-GlobalAddressList.

Use the Shell create a GAL using a recipient filter

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Global address lists" entry in the Mailbox Permissions topic.

Note:
You can't use the Exchange Management Console to create a GAL.

This example creates a GAL named GAL_AgencyA that includes recipients for which the *CustomAttribute15* parameter has a value of AgencyA.

```
New-GlobalAddressList -Name "GAL_AgencyA" -RecipientFilter {CustomAttribute15 -li
```

For more information about recipient filters, see Creating Filters in Recipient Commands.

For detailed syntax and parameter information, see New-GlobalAddressList.

1.8.3.5.10 Configure Global Address List Properties

Configure Global Address List Properties

Mailbox > Managing Mailbox Servers > Managing Address Lists >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to modify a global address list's (GAL) settings by using the Exchange Management Shell.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Important:
You can't edit the settings of the default GAL.

Use the Shell to configure GAL properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to modify a GAL.

This example assigns a new name, FourthCoffee, to the GAL that has the GUID 96d0c505-eba8-4103-ad4f-577a1bf4ad7b.

```
Set-GlobalAddressList -Identity 96d0c505-eba8-4103-ad4f-577a1bf4ad7b -Name Fourth
```

Note:

If you're using precanned conditional filter properties, the value for the *IncludedRecipients* parameter can't be blank.

This example changes the recipients who will be included in the Fourth Coffee global GAL to those whose company is set to Fourth Coffee.

```
Set-GlobalAddressList -Identity Fourth Coffee -RecipientFilter {Company -eq "Four
```

For detailed syntax and parameter information, see Set-GlobalAddressList.

Other Tasks

After you make changes to a GAL, you may also want to update the GAL. For detailed steps, see Update a Global Address List.

1.8.3.5.11 Remove a Global Address List

Remove a Global Address List

Mailbox > Managing Mailbox Servers > Managing Address Lists >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The global address list (GAL) is a directory that contains entries for every group, user, and contact within an Exchange organization.

Important:

You can't remove the default GAL.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to remove a GAL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Global address lists" entry in the Mailbox Permissions topic.

Note:

You can't use the Exchange Management Console (EMC) to remove a GAL.

This example removes the GAL Fourth Coffee from the domain controller ad-server.fourthcoffee.com.

```
Remove-GlobalAddressList -Identity "Fourth Coffee" -DomainController ad-server.fo
```

To confirm that you want to remove the GAL, type **Y**, and then press ENTER.

For detailed syntax and parameter information, see Remove-GlobalAddressList.

1.8.3.5.12 Update a Global Address List

Update a Global Address List

Mailbox > Managing Mailbox Servers > Managing Address Lists >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the Shell to update a global address list (GAL). A GAL is a directory that contains entries for every group, user, and contact within an organization's implementation of Microsoft Exchange.

Looking for other management tasks related to address lists? Check out Managing Address Lists.

Use the Shell to update a GAL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Global address lists" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to update a GAL.

To update a GAL, use the following syntax.

```
Update-GlobalAddressList -Identity <GlobalAddressListIdParameter> -DomainControll
```

Note:
Running this command only starts the update process. It may take several hours for the GAL to be updated.

This example updates a GAL for the Fourth Coffee company.

```
Update-GlobalAddressList -Identity "Fourth Coffee"
```

For detailed syntax and parameter information, see Update-GlobalAddressList.

1.8.3.6 Managing Address Book Policies

Managing Address Book Policies

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-18*

- Create an Address Book Policy
- Configure Address Book Policy Properties
- Assign an Address Book Policy to a Mail User
- Remove an Address Book Policy

- Understanding Address Book Policies
- Migrate to Exchange 2010 Address Book Policies from Exchange 2007 Address List Segregation

1.8.3.6.1 Create an Address Book Policy

Create an Address Book Policy

Mailbox > Managing Mailbox Servers > Managing Address Book Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-29*

Address book policies (ABPs) allow you to segment users into specific groups to provide customized views of your organization's global address list (GAL). When creating an ABP, you assign a GAL, an offline address book (OAB), a room list, and one or more address lists to the policy. You can then assign the ABP to mailbox users, providing them with access to a customized GAL in Outlook and Outlook Web App. The goal is to provide a simpler mechanism to accomplish GAL segmentation for on-premises organizations that require multiple GALs. To learn more about ABPs, see Understanding Address Book Policies.

Looking for other management tasks related to ABPs? Check out Managing Address Book Policies.

What Do You Want to Do?

- Use the EMC to create an address book policy
- Use the Shell to create an address book policy

Use the EMC to create an address book policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Address Book Policy**.
3. On the **Introduction** page, complete the following fields:
   - **Name** Use this field to type the name of the ABP. This field accepts a maximum of 64 characters.
   - **Global address list** Click **Browse** to select a GAL to assign to this policy. Each ABP must contain one GAL.
   - **Offline address book** Click **Browse** to select an OAB to assign to this policy. Users who are assigned to this ABP will download the OAB you specify. Each ABP must contain one OAB.
   - **Room list** Click **Browse** to select a room list. The room list is used for room booking purposes. Each ABP must contain one room list. If your organization doesn't use room lists, we recommend that you create one that doesn't contain rooms, and then assign it to the ABP.
   - **Address Lists** Click **Add** to add one or more address lists to the ABP.
4. Click **New** to create the ABP.

5. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
6. Click **Finish** to close the wizard.

Use the Shell to create an address book policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

This example creates an ABP with the following settings:

- **Name:** All Fabrikam ABP
- **GAL:** All Fabrikam
- **OAB:** Fabrikam-All-OAB
- **Room list:** All Fabrikam Rooms
- **Address lists:** All Fabrikam, All Fabrikam Mailboxes, All Fabrikam DLs, and All Fabrikam Contacts.

```
New-AddressBookPolicy -Name "All Fabrikam ABP" -AddressLists "\All Fabrikam","\Al
```

For detailed syntax and parameter information, see New-AddressBookPolicy.

Other Tasks

After you create the ABP, you may want to assign it to a user. For details, see Assign an Address Book Policy to a Mail User.

1.8.3.6.2 Configure Address Book Policy Properties

Configure Address Book Policy Properties

Mailbox > Managing Mailbox Servers > Managing Address Book Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-11-29*

After you create an address book policy (ABP), you can view or modify the name and the assigned global address list (GAL), offline address book (OAB), room list, and address lists

Looking for other management tasks related to ABPs? Check out Managing Address Book Policies.

What Do You Want to Do?

- Use the EMC to configure ABP properties
- Use the Shell to configure ABP properties

Use the EMC to configure ABP properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Address Book Policies** tab, click the ABP you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view or modify the name of the ABP.
5. Use the **Address Book Policy Detail** tab to view or modify the following settings:
   - **Global Address List** Click **Browse** to change the GAL that's assigned to this policy. Each ABP must contain one GAL.
   - **Offline Address Book** Click **Browse** tochange the OAB that's assigned to this policy. Users who are assigned to this ABP will download the OAB you specify. Each ABP must contain one OAB.
   - **Room list** Click **Browse** to change the room list that's assigned to this policy. The room list is used for room booking purposes. Each ABP must contain one room list. If your organization doesn't use room lists, we recommend that you create one that doesn't contain rooms, and then assign it to the ABP.
   - **Address Lists** Click **Add** to add address lists to the ABP. Click  to remove an address list from the ABP.

Use the Shell to configure ABP properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

This example changes the OAB, room list, and GAL that will be used by mailbox users who are assigned the ABP named All Fabrikam ABP.

```
Set-AddressBookPolicy -Identity "All Fabrikam ABP" -OfflineAddressBook \Fabrikam-
```

This example adds the address lists Contoso-Chicago and Contoso-Seattle to the ABP named ABPContoso

```
Set-AddressBookPolicy -Identity "ABPContoso" -AddressLists @{Add="Contoso-Chicago
```

This example removes the address lists Fabrikam-HR and Fabrikam-Finance from the ABP named ABPFabrikam

```
Set-AddressBookPolicy -Identity "ABPFabrikam" -AddressLists @{Remove="Fabrikam-HR
```

This example replaces the address lists GovernmentAgencyA-ALL and GovernmentAgenceB-ALL with address lists GovernmentAgencyA-Atlanta and GovernmentAgencyA-Moscow for the ABP named GovernmentAgencyA.

```
Set-AddressBookPolicy -Identity GovernmentAgencyA -AddressLists @{Remove="Governm
```

For detailed syntax and parameter information, see Set-AddressBookPolicy.

Assign an Address Book Policy to a Mail User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create an address book policy (ABP), you must assign it to mailbox users. Users aren't assigned a default ABP when their user account is created. If you don't assign an ABP to a user, the global address list (GAL) for your entire organization will be accessible to the user through Outlook and Outlook Web App. To learn more, see Understanding Address Book Policies.

Looking for other management tasks related to ABPs? Check out Managing Address Book Policies.

Prerequisites

You have an existing ABP. If you haven't created one, see Create an Address Book Policy.

Use the EMC to assign an ABP to mailbox users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox user or users to which you want to assign the ABP. You can select multiple users by holding down the Ctrl key.
3. In the action pane, click **Properties**.
4. In **<User Mailbox> Properties**, on the **Mailbox Settings** tab, click **Address Book Policy**, and then click **Properties**.
5. In **Address Book Policy**, select the **Address Book Policy** check box, and then click **Browse**.
6. In **Select Address Book Policy**, select the ABP you want to assign to the user or users, and then click **OK**.
7. In **Address Book Policy**, click **OK** .
8. In **<User Mailbox> Properties**, click **OK** to apply the ABP and close the property page.

Note:

If you apply the ABP to more than one mailbox user, the **Bulk Edit Summary** dialog box will appear. Confirm the changes, and then click **OK**.

Use the Shell to assign an ABP to mailbox users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

This example assigns the ABP named All Fabrikam to the existing mailbox user joe@fabrikam.com.

```
Set-Mailbox -Identity joe@fabrikam.com -AddressBookPolicy "All Fabrikam"
```

This example assigns the ABP named ABP_EngineeringDepartment to all mailbox users whose CustomAttribute11 value contains "Engineering Department".

```
Get-Mailbox -Filter {(CustomAttribute11 -like "Engineering Department")} | Set-Ma
```

For detailed syntax and parameter information, see Set-Mailbox and Get-Mailbox.

1.8.3.6.4 Remove an Address Book Policy

Remove an Address Book Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Use this procedure to remove an address book policy (ABP).

Looking for other management tasks related to ABPs? Check out Managing Address Book Policies.

Prerequisites

You can't remove an ABP if it is assigned to a user's mailbox. To determine if an ABP is assigned to a user, run the following command in the Shell:

```
Get-Mailbox | Where $._AddressBookPolicy -eq <AddressBookPolicyName>
```

To remove an ABP from a user's mailbox, you can use the **Mailbox Settings** tab of the mailbox's property page or the **Set-Mailbox** cmdlet. For details, see Configure User and Resource Mailbox Properties.

Use the EMC to remove an ABP

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Address Book Policies** tab, select the ABP you want to remove.
3. In the action pane, click **Remove**.
4. In the warning dialog box that appears, click **Yes** to remove the ABP.

Use the Shell to remove an ABP

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address book policies" entry in the Mailbox Permissions topic.

This example removes the ABP named ABP_TailspinToys

```
Remove-AddressBookPolicy -Identity "ABP_TailspinToys"
```

For detailed syntax and parameter reference, see Remove-AddressBookPolicy.

1.8.3.7 Managing Automatic Replies

Managing Automatic Replies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-21*

Enable External Automatic Replies on a Per-User Basis

1.8.3.7.1 Enable External Automatic Replies on a Per-User Basis

Enable External Automatic Replies on a Per-User Basis

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to configure the *Automatic Replies* feature on a per-user basis. For example, you can configure Automatic Replies so that users in the Sales and Marketing divisions can send automatic reply messages to external contacts, but users in the Research division can't. By default, the Automatic Replies feature allows all users to send external automatic reply messages.

Use the Shell to enable external automatic replies

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to enable external automatic replies.

This example enables the external automatic reply messages for Ellen Adams' mailbox.

```
Set-Mailbox "Ellen Adams" -ExternalOofOptions External
```

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.8 Managing Calendars

Managing Calendars

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-16*

Configure Calendar Repair Log Settings

Configure Calendar Repair Assistant Settings

Enable or Disable Calendar Repair for a Mailbox

Enable Internet Calendar Publishing

Disable Internet Calendar Publishing

1.8.3.8.1 Configure Calendar Repair Log Settings

Configure Calendar Repair Log Settings

Mailbox > Managing Mailbox Servers > Managing Calendars >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Every time the Calendar Repair Assistant (CRA) changes a calendar item on a user's mailbox, it writes to a log file. The log file contains information that identifies the calendar item that was repaired and what repair actions occurred. By default, calendar repair logging is enabled.

You can use the following **Set-MailboxServer** cmdlet parameters to configure calendar repair log settings:

- *CalendarRepairLogEnabled*
- *CalendarRepairLogPath*
- *CalendarRepairLogFileAgeLimit*
- *CalendarRepairLogDirectorySizeLimit*
- *CalendarRepairLogSubjectLoggingEnabled*

Looking for other tasks related to calendar repair? Check out Managing Calendars.

Use the Shell to enable or disable calendar repair logging

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure calendar repair log settings.

This example disables calendar repair logging for the server MBX01.

```
Set-MailboxServer -Identity MBX01 -CalendarRepairLogEnabled $false
```

This example enables calendar repair logging for the server MBX01.

```
Set-MailboxServer -Identity MBX01 -CalendarRepairLogEnabled $true
```

For detailed syntax and parameter reference, see Set-MailboxServer.

Use the Shell to change the calendar repair log path

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure calendar repair log settings.

The default installation path for the calendar repair log is *<Exchange installation path>*\v14\Logging\Calendar Repair Assistant.

This example changes the log file path to C:\Log Files\Calendar Repair Assistant for the server MBX01.

```
Set-MailboxServer -Identity MBX01 -CalendarRepairLogPath "C:\Log Files\Calendar R
```

For detailed syntax and parameter reference, see Set-MailboxServer.

Use the Shell to change the calendar repair log file age limit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure calendar repair log settings.

The log file age limit specifies how long to retain calendar repair logs. Log files that exceed the maximum retention period are deleted. The default value for the age limit is 00.00:00:00, which means that there is no limit and all log files are retained.

This example changes the calendar repair log age limit to 90 days for the server MBX01.

```
Set-MailboxServer -Identity MBX01 -CalendarRepairLogFileAgeLimit 90
```

For detailed syntax and parameter reference, see Set-MailboxServer.

Use the Shell to change the calendar repair log directory size limit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure calendar repair log settings.

The directory size limit determines the size limit for all Calendar Repair Assistant log files on a Mailbox server. After the limit is reached, the oldest files are deleted. The default size value is unlimited.

This example changes the calendar repair log directory size limit to 1 gigabyte (GB) for the server MBX01.

```
Set-MailboxServer -Identity MBX01 -CalendarRepairLogDirectorySizeLimit 1GB
```

For detailed syntax and parameter reference, see Set-MailboxServer.

Use the Shell to enable or disable logging the subject of meetings in the log files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox server configuration" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure calendar repair log settings.

You can include the subject of repaired calendar items in the calendar repair logs. By default, subject logging is enabled.

This example disables subject logging for the Mailbox server MBX01.

```
Set-MailboxServer MBX01 -CalendarRepairLogSubjectLoggingEnabled $false
```

For detailed syntax and parameter reference, see Set-MailboxServer.

1.8.3.8.2 Configure Calendar Repair Assistant Settings

Configure Calendar Repair Assistant Settings

See Also

Mailbox > Managing Mailbox Servers > Managing Calendars >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-28*

The *Calendar Repair Assistant* (CRA) is a configurable mailbox assistant that runs within the Microsoft Exchange Mailbox Assistants service on Microsoft Exchange Server 2010 Mailbox servers. The CRA detects and corrects inconsistencies that occur in single and recurring calendar items for mailboxes that are homed on the Mailbox server that is running the CRA. The purpose of this process is to make sure that recipients won't miss meetings or have unreliable meeting information.

In Exchange 2010 Service Pack 1 (SP1), the CRA was changed from a time-based assistant to a throttle-based assistant.

By default, the CRA is not set to run automatically. To configure the CRA to run and repair calendar inconsistencies, use the **set-mailboxserver** cmdlet in the Exchange Management Shell to set the work cycle and work cycle checkpoint. The Exchange Management Console cannot be used to configure calendar repair log settings.

You must use the following **Set-MailboxServer** cmdlet parameters to configure the CRA settings:

- *CalendarRepairIntervalEndWindow* This parameter specifies the number of days into the future to repair calendars. For example, if this parameter is set to 90, the CRA repairs calendars on the Mailbox server 90 days from the date it was set. The default value is 30 days.
- *CalendarRepairMissingItemFixDisabled* This parameter specifies that the CRA won't fix missing attendee calendar items for mailboxes homed on this Mailbox server. If an attendee is missing a calendar item, the item will be re-created. The default value is `$false`.
- *CalendarRepairWorkCycle* and *CalendarRepairWorkCycleCheckpoint* These parameters work together. The *CalendarRepairWorkCycle* parameter specifies the time span in which all mailboxes on the specified server will be scanned by the CRA. For example, if you specify seven days for this parameter, the CRA will process all mailboxes on this server every seven days. Calendars that have inconsistencies will be flagged and repaired according to the interval specified by the *CalendarRepairWorkCycleCheckpoint* parameter. For example, if you specify one day for this parameter, the CRA will query every day for new mailboxes that require processing.

Looking for other management tasks related to calendar repair? Check out Managing Calendars.

Use the Shell to change the calendar repair interval window

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar repair" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to change the calendar repair interval window.

This example changes the number of days into the future that the CRA validates calendars to 90 days on Mailbox server MBX02.

```
Set-MailboxServer -Identity MBX02 -CalendarRepairIntervalEndWindow 90
```

For detailed syntax and parameter information, see Set-MailboxServer.

Use the Shell to set the calendar repair work cycle

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar repair" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to set the calendar repair work cycle.

This example sets the CRA to check all mailboxes on the server MBX02 every seven days and to process all calendars that require repairs every day in that seven day cycle.

```
Set-MailboxServer -Identity MBX02 -CalendarRepairWorkCycle 7.00:00:00 -CalendarRe
```

For detailed syntax and parameter information, see Set-MailboxServer.

Use the Shell to enable or disable the fixing of missing items

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar repair" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to enable or disable the fixing of missing items.

This example disables the automatic fixing of missing calendar items for Mailbox server MBX02.

```
Set-MailboxServer -Identity MBX02 -CalendarRepairMissingItemFixDisabled $true
```

For detailed syntax and parameter information, see Set-MailboxServer.

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-28*

The *Calendar Repair Assistant* (CRA) is a configurable, throttle-based Mailbox Assistant that runs within the Microsoft Exchange Mailbox Assistants service on Mailbox servers that run Microsoft Exchange Server 2010. CRA detects and corrects inconsistencies that occur for single and recurring calendar items for mailboxes that are homed on the Mailbox server that is running CRA. The purpose of this process is to make sure that recipients won't miss meetings or have unreliable meeting information.

By default, the CRA is not set to run automatically. To configure the CRA to run and repair calendar inconsistencies, use the **set-mailboxserver** cmdlet in the Exchange Management Shell to set the work cycle and work cycle checkpoint. The Exchange Management Console cannot be used to configure calendar repair log settings.

You can turn on or turn off calendar repair for a mailbox by using the **Set-Mailbox** cmdlet in the Shell.

Looking for other management topics related to calendar repair? Check out Managing Calendars.

Use the Shell to disable calendar repair for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar repair" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to disable calendar repair for a mailbox.

Mailboxes for which calendar repair is disabled won't have their calendar items repaired by the CRA.

This example disables the CRA for the user mailbox tony@contoso.com.

```
Set-Mailbox -Identity tony@contoso.com -CalendarRepairDisabled $true
```

For detailed syntax and parameter reference, see Set-Mailbox.

Use the Shell to enable calendar repair for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar repair" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable calendar repair for a mailbox.

This example enables the CRA for the user mailbox ayla@contoso.com.

```
Set-Mailbox -Identity ayla@contoso.com -CalendarRepairDisabled $false
```

For detailed syntax and parameter reference, see Set-Mailbox.

1.8.3.8.4 Enable Internet Calendar Publishing

Enable Internet Calendar Publishing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Users in Microsoft Exchange Server 2010 organizations can share calendar availability (free/busy) information with users in non-Exchange organizations and other individuals with Internet access. In versions of Exchange earlier than Exchange 2010 Service Pack 1 (SP1), sharing calendar availability information required you to either:

- Set up Active Directory trusts, manage credentials, and manage replication with multiple external Exchange organizations.
- Establish a federation trust with the Microsoft Federation Gateway and configure organization relationships or sharing policies with other external Exchange organizations.

These methods often resulted in limited sharing capabilities, required complex setup and ongoing maintenance, and were limited solely to sharing calendar availability information between Exchange organizations.

In Exchange 2010, Internet calendar publishing provides increased flexibility and increases the number of users who can share calendar availability information. Enabling Internet calendar publishing consists of three general steps:

1. Configure the Web proxy URL for the Mailbox server.
2. Enable the publishing virtual directory for the Client Access server.
3. Create a sharing policy specifically for Internet calendar publishing. This policy allows users in your Exchange organization to invite other users who have Internet access to view limited calendar availability information by accessing a published URL.

To learn more about Internet calendar publishing and sharing policies, see Understanding Federated Delegation. Looking for other management tasks related to calendars? Check out Managing Calendars.

Prerequisites

- An Exchange 2010 Client Access server exists in the Exchange organization that's sharing user's calendar information.
- User mailboxes are on Exchange 2010 Mailbox servers in the Exchange organization that's sharing user's calendar information.

Step 1: Use the Shell to configure the Web proxy URL

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Sharing policies" entry in the Mailbox Permissions topic.

Note:
You can't use the Exchange Management Console (EMC) to configure the Web proxy URL.

This example configures a Web proxy URL on Mailbox server MAIL01.

```
Set-ExchangeServer -Identity "MAIL01" -InternetWebProxy "<Webproxy URL>"
```

For detailed syntax and parameter information, see Set-ExchangeServer.

Step 2: Use the Shell to enable the publishing virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Sharing policies" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable the publishing virtual directory.

This example enables the publishing virtual directory on Client Access server CAS01.

```
Set-OwaVirtualDirectory -Identity "CAS01" -ExternalUrl "<URL for the CAS01>" -Cal
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

Step 3: Use the EMC or the Shell to create a sharing policy for Internet calendar publishing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Sharing policies" entry in the Mailbox Permissions topic.

Use the EMC

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Sharing Policy** to start the New Sharing Policy wizard.

   Note:
   Although you can add the Anonymous domain used for Internet calendar publishing to the default or existing sharing policies, we recommend that you create a separate sharing policy for Internet calendar publishing.

3. On the **Introduction** page, complete the following fields:
   - **Name** In this box, type **Internet** for the sharing policy name.
   - **Add** Click this button to open the **Add Action to Sharing Policy Domain** dialog box. Complete the following fields, and then click **OK**:
     Specify a domain of an external Exchange organization, or "*" for any domain Type **Anonymous** as the domain for the Internet calendar publishing sharing policy.

Specify the actions that apply to the federated domain Use this list to select the level of sharing you want to enforce for this policy. For this example, select **Calendar sharing with free/busy information, plus subject and location**.

- **Enable sharing policy** Select this check box to enable the Anonymous domain.

4. On the **Mailboxes** page, click **Add** to select the mailboxes to which you want to apply this sharing policy.

Note:
After creating the sharing policy, you can apply it to more mailboxes by using the **Mailboxes** tab in the sharing policy's property page or by using the **Mailbox Settings** tab in the mailbox's property page.

5. On the **New Sharing Policy** page, review your configuration settings. Click **New** to create the sharing policy. Click **Back** to make configuration changes.

Note:
A warning will be displayed by the New Sharing Policy wizard upon completion as a reminder that you've allowed users to share their calendars, and to make sure that the Client Access server publishing the virtual directory is enabled so that published calendars will be accessible.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell

This example creates the Internet calendar publishing sharing policy Internet and configures the policy to share only availability information. The policy is enabled.

```
New-SharingPolicy -Name "Internet" -Domains 'Anonymous: CalendarSharingFreeBusySi
```

This example adds the sharing policy Internet to a user mailbox.

```
Set-Mailbox -Identity <user name> -SharingPolicy "Internet"
```

This example adds the sharing policy Internet to an organizational unit (OU).

```
Set-Mailbox -OrganizationalUnit <OU name> -SharingPolicy "Internet"
```

For detailed syntax and parameter information, see New-SharingPolicy and Set-Mailbox.

Other Tasks

After you enable Internet calendar publishing, you may also want to configure publishing or sharing settings on a calendar folder of a specified mailbox. For detailed steps, see Set-MailboxCalendarFolder.

1.8.3.8.5 Disable Internet Calendar Publishing

Disable Internet Calendar Publishing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you disable a sharing policy used for defining Internet calendar publishing, users who are provisioned to use the policy won't be able to share calendar information with the Anonymous Internet domain specified in the policy. However, you can't delete the sharing policy until all the users who are provisioned to use the policy have the sharing policy setting removed from their mailboxes.

Note:

When the sharing policy is disabled, users provisioned to use the policy will continue to share information until the Sharing Policy Assistant runs. To specify how often the Sharing Policy Assistant runs, use the Set-MailboxServer cmdlet with the *SharingPolicySchedule* parameter.

To fully disable Internet calendar publishing, you should also disable the Microsoft Office Outlook Web App virtual directory used for calendar publishing. Doing this prohibits access to the published calendar links previously shared by your Exchange organization users with external Internet users.

To learn more about Internet calendar publishing and sharing policies, see Understanding Federated Delegation.

Looking for other management tasks related to calendars? Check out Managing Calendars.

Step 1: Use the EMC or the Shell to disable the sharing policy for Internet calendar publishing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Sharing policies" entry in the Mailbox Permissions topic.

Use the EMC

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Sharing Policies** tab.
3. In the result pane, click the sharing policy you set up for Internet calendar publishing.
4. In the action pane, under the sharing policy name, click **Properties**.
5. In **Properties**, clear the **Enable sharing policy** check box, and then click **OK** to disable the policy.
6. On the **Sharing Policies** tab, verify that the **Enabled** column for the sharing policy is set to **False**.

Use the Shell

This example disables the Internet calendar publishing sharing policy Internet.

```
Set-SharingPolicy -Identity "Internet" -Enabled $false
```

For detailed syntax and parameter information, see Set-SharingPolicy.

Step 2: Use the Shell to disable the Outlook Web App virtual directory used for calendar publishing

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Sharing policies" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to disable the Outlook Web App virtual directory used for calendar publishing.

This example disables calendar publishing for the Outlook Web App virtual directory on Client Access server CAS01.

```
Set-OwaVirtualDirectory -Identity "CAS01" -CalendarPublishingEnabled -$false
```

For detailed syntax and parameter information, see Set-OwaVirtualDirectory.

1.8.3.9 Managing Details Templates

Managing Details Templates

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-22*

Customize Details Templates

Restore a Details Template to the Default Configuration

1.8.3.9.1 Customize Details Templates

Customize Details Templates

Mailbox > Managing Mailbox Servers > Managing Details Templates >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the Details Templates Editor to customize the client-side graphical user interface (GUI) presentation of object properties that are accessed by using address lists in the Microsoft Outlook client application. For example, when a user opens an address list in Outlook, the properties of a particular object are presented as defined by the details template in the Exchange organization. The objects can be customized by changing field sizes, adding or removing fields, adding or removing tabs, and rearranging fields. The layout of these templates may vary by language.

You can use the default details template or you can customize the template to better suit the needs of your users. Use the Details Templates Editor to customize the following Outlook objects:

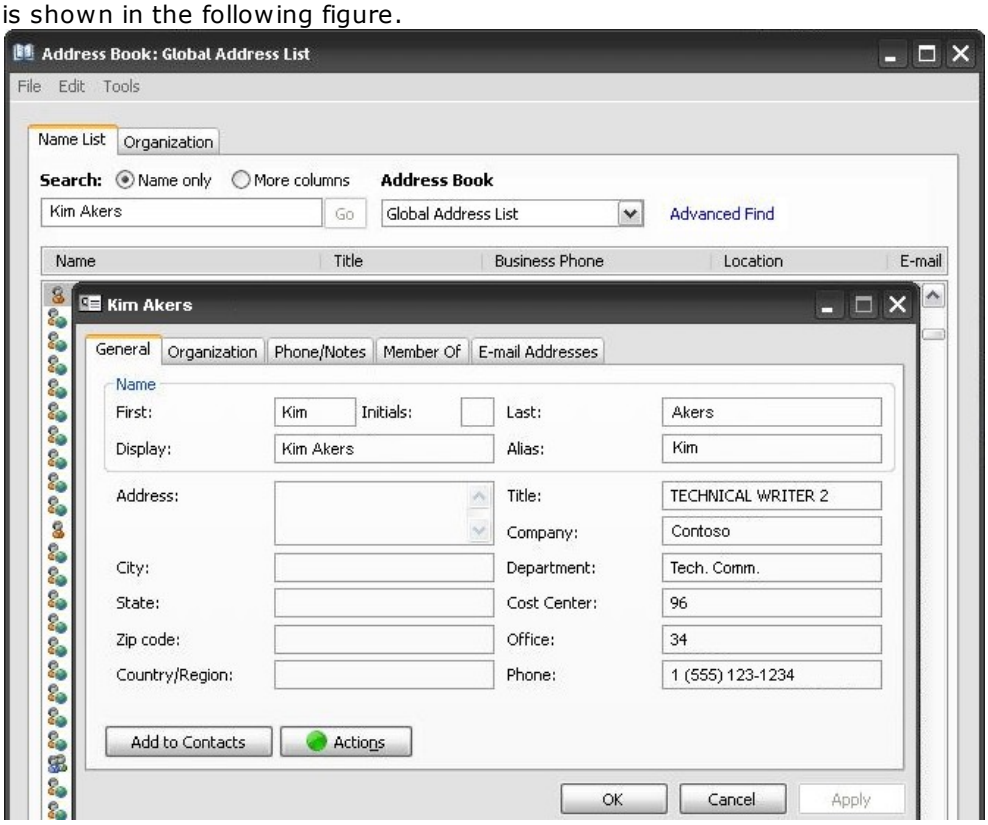
- Contacts
- Users
- Groups
- Mailbox agents
- Public folders
- Search dialog boxes

Not what you're looking for? Try Managing Details Templates.

Customize the details template

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Details templates" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Details Templates Editor**, and then in the action pane, click **Open Tool**.
3. In the console tree of the Details Templates Editor, click **Details Template**. In the details pane, the following columns are displayed:
   - **Language** This column lists the language in which the template was created.
   - **Template Type** This column lists the type of template that you can customize.
   - **Identity** This column lists the unique identity of the template.
   - **Created** This column lists the date and time that the template was created.
   - **Modified** This column lists the date and time that the template was last modified.
4. To edit a template, click the template you want, and then, in the action pane, click **Edit**. For example, the **English (United States)** contacts details template is shown in the following figure.



5. After you click **Edit**, there are several tasks you can perform to customize a details template:
   - To move an object in the designer pane, select the object, and then drag it to its new location on the template. As you move the object, you are provided with alignment lines.
   - To change a label's text, select the label in the design pane. In the properties pane, type the new text in the **Text** box. To create keyboard

shortcuts, you can use the ampersand (&) symbol. Place the ampersand (&) before the letter that you want to use as the shortcut.

- To change the size of an object, select the object, and then drag the sizing handles until the object is the shape and size you want.
- To delete an object, select the object, and then press the DELETE key.

> **Note:**
> The Details Templates Editor doesn't contain an **Undo** button, nor can you use a keyboard shortcut to undo an action. To undo an addition you made to the template, you must use the DELETE key. To undo a deletion, you must reapply the setting. You can also revert to the original settings by exiting the Details Templates Editor without saving your changes. If you want to undo changes after you have saved, you can restore the template. When you restore a template, all customization is lost, and the template is restored to its original configuration. For more information about how to restore the details template, see Restore a Details Template to the Default Configuration.

- To add an "Edit" text boxes, list boxes, multi-valued drop-down boxes, or multi-valued list boxes, in the toolbox pane, drag the object to the design pane. Set the attribute of the object by clicking the attribute drop-down box in the properties pane and then selecting the attribute that will be used by Exchange.

> **Note:**
> You must link the object to an attribute for it to be used by Exchange. In addition, the attribute determines the content that is displayed to the end user in Outlook. If you don't select an attribute, a random attribute is selected automatically.

- To add a group box, drag the object to the design pane. Then, in the properties pane, type a name in the **Text** box. Use group boxes to group similar objects.
- To add a tab to the template, right-click an existing tab, and then click **Add Tab**. A blank tab appears. To name the tab, type the name in the **Text** box in the properties pane.
- To remove a tab from the template, right-click the tab, and then click **Remove Tab**. A warning appears. Click **OK** to confirm that you want to remove the tab.
- To change the tabbing order of the objects on a tab so that users can use the TAB key to navigate the objects in the order you want, select the object in the design pane. Then, in the properties pane, use the **TabIndex** box to change the order.

> **Note:**
> To make sure that users cannot use the TAB key to access the labels of an object (for example **Name** or **Alias**), change the order of the labels so that they are last in the tabbing order.

6. To save changes to the details template, on the **File** menu, click **Save**.
7. To close the template, on the **File** menu, click **Exit**.

Restore a Details Template to the Default Configuration

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Details Templates Editor doesn't contain an **Undo** button, nor can you use a keyboard shortcut to undo an action. To undo an addition you made to the template, you must use the DELETE key. To undo a deletion, you must reapply the setting. You can also revert to the original settings by exiting the Details Templates Editor without saving your changes. If you want to undo changes after you have saved, you can restore the template. When you restore a template, all customization is lost, and the template is restored to its original configuration.

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to restore a details template to its default configuration.

Looking for other tasks related to details templates? Check out Managing Details Templates.

Use the EMC to restore a details template to the default configuration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Details templates" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Details Templates Editor**, and then, in the action pane, click **Open Tool**. The Details Templates Editor appears.
3. In the details pane, select the template you want to restore, and then in the action pane, click **Restore**.
4. Click **Yes** to confirm that you want to restore the template to its original state. All customization will be lost.

Use the Shell to restore a details template to the default configuration

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Details templates" entry in the Mailbox Permissions topic.

This example restores the United States English contacts details template:

```
Restore-DetailsTemplate -Identity "en-US\Contact"
```

For detailed syntax and parameter information, see Restore-DetailsTemplate.

1.8.3.10 Managing Distribution Groups

Managing Distribution Groups

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-31*

1.8.3.10.1 Add a Member to a Distribution Group

Add a Member to a Distribution Group

Mailbox > Managing Mailbox Servers > Managing Distribution Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create a distribution group, you can manually add or remove members. Members who belong to a distribution group will receive e-mail messages sent to that group.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the EMC to add a member to a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the distribution group to which you want to add a member.
3. In the action pane, under the distribution group name, click **Properties**.
4. In **<Distribution Group> Properties**, on the **Members** tab, click **Add** to open the **Select Recipient** dialog box.
5. In **Select Recipient**, click the recipient you want to add to the distribution group, and then click **OK**.

   Note:
   To add multiple recipients, hold down the CTRL key while selecting recipients.
6. Click **OK** to save your changes.

Use the Shell to add a member to a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example adds the user adam@contoso.com to the distribution group Marketing Managers.

```
Add-DistributionGroupMember -Identity "Marketing Managers" -Member adam@contoso.c
```

For detailed syntax and parameter information, see Add-DistributionGroupMember.

1.8.3.10.2 Change the Ownership of a Distribution Group

Change the Ownership of a Distribution Group

Mailbox > Managing Mailbox Servers > Managing Distribution Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-06*

In Microsoft Exchange Server 2010, users can create and manage distribution groups and distribution group membership. These users are delegated ownership of the group by the **ManagedBy** property. The default owner of a distribution group is the user or administrator who creates the group. However, you can use the EMC or the Shell to change the ownership of a distribution group.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Note:
In addition to being one of the group owners, users must be assigned a management role assignment policy that contains the My Distribution Groups and My Distribution Group Membership roles.

Use the EMC to change the ownership of a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the distribution group that you want to modify.
3. In the action pane, click **Properties**.
4. On the **Group Information** tab, under **Managed by**, you can perform the following tasks:
   - To add an owner to the distribution group, click **Add**, and then select the user from the **Select Mailbox or Mail-Enabled User** dialog box.
   - To remove an owner from the distribution group, select the user, and then click  .

     Note:
     You can't remove the last owner from a distribution group. You must add a new owner before removing the last one.
5. Click **OK**.

Use the Shell to change the ownership of a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example replaces the current owner of the distribution group Volunteers with the new owner john@contoso.com.

```
Set-DistributionGroup -Identity Volunteers -ManagedBy john@contoso.com
```

Note:
If you want to add more than one owner to the distribution group, separate users by using a comma. If you don’t include the current owners in the command, the current owners will be replaced by the new list.

This example adds John and Ayla to the list of owners and bypasses getting permission from the group's current manager Administrator.

```
Set-DistributionGroup -Identity 'contoso.com/Users/Summer Interns'-BypassSecurity
```

For detailed syntax and parameter information, see Set-DistributionGroup.

Create a Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Use the New Distribution Group wizard to create a new distribution group in your Exchange organization or to mail-enable an existing group in Active Directory.

There are two types of distribution groups:

- *Mail-enabled universal distribution groups* can be used only to distribute messages.
- *Mail-enabled universal security groups* can be used to distribute messages as well as to grant access permissions to resources in Active Directory.

It's important to note the terminology differences between Active Directory and Exchange 2010. In Active Directory, a distribution group refers to any group that doesn't have a security context, whether it's mail-enabled or not. In contrast, in Exchange 2010, all mail-enabled groups are referred to as distribution groups, whether they have a security context or not.

Caution:

You can create or mail-enable only universal distribution groups. To convert a domain-local or a global group to a universal group, you can use the Set-Group cmdlet in the Exchange Management Shell. You may have mail-enabled groups that were migrated from previous versions of Exchange that are not universal groups. You can use the Exchange Management Console (EMC) or the Shell to manage these groups

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

What Do You Want to Do?

- Use the EMC to create a distribution group
- Use the Shell to create a distribution group

Use the EMC to create a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Distribution Group**.
3. On the **Introduction** page, select whether to create a new group or to mail-enable an existing group.
   - **New group** Click this button to create a new distribution group.
   - **Existing group** Click this button to mail-enable an existing group in Active Directory, and then click **Browse** to select the existing group.
4. On the **Group Information** page, complete the following fields.
   - **Group type** Click **Distribution** to create a mail-enabled universal distribution group, or click **Security** to create a mail-enabled universal security group.
   - **Specify the organizational unit rather than using a default one** Select this

check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.

- **Name** Use this box to type the name of the group, which can't exceed 64 characters.

  Note:
  If a group naming policy is applied, you must follow the naming constraints enforced for your organization. For more information see, Create a Distribution Group Naming Policy. If you want to override your organization's group naming policy, see Override a Distribution Group Naming Policy.

- **Name (pre-Windows 2000)** Use this box to type the name for the group that is compatible with the legacy versions of Windows (prior to the release of Windows 2000 Server). This required field is automatically populated based on the **Name** field.

  The name of the group that is compatible with earlier versions of Windows can't exceed 64 characters. It can contain letters, numbers, and the following characters: **! # $ % ^ & - . _ { } | ~**.

- **Alias** Use this box to type the name of the alias for the group. The alias cannot exceed 64 characters and must be unique in the forest.

5. On the **New Distribution Group** page, review your configuration settings. To make any configuration changes, click **Back**. To create the new distribution group, click **New**.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish**.

Use the Shell to create a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example creates the distribution group Managers with the SAM account name Managers in the organizational unit Contoso.com/users.

Note:
If a group naming policy is applied, you must follow the naming constraints enforced for your organization. For more information see, Create a Distribution Group Naming Policy. If you want to override your organization's group naming policy, see Override a Distribution Group Naming Policy.

```
New-DistributionGroup -Name "Managers" -OrganizationalUnit "Contoso.com/users" -S
```

Understanding Recipients

Managing Distribution Groups

1.8.3.10.4 Create a Dynamic Distribution Group

Create a Dynamic Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Dynamic distribution groups are mail-enabled Active Directory group objects that are created to expedite the mass sending of e-mail messages and other information within an Exchange organization. Use the New Dynamic Distribution Group wizard to create a dynamic distribution group in your Exchange organization.

Unlike regular distribution groups that contain a defined set of members, the membership list for dynamic distribution groups is calculated each time a message is sent to the group, based on the filters and conditions that you define. When an e-mail message is sent to a dynamic distribution group, it is delivered to all recipients in the organization that match the criteria defined for that group.

Caution:

A dynamic distribution group includes any recipient in Active Directory with attributes that match its filter. If a recipient's properties are modified to match the filter, the recipient could inadvertently become a group member and start receiving messages that are sent to the group. Well-defined, consistent account provisioning processes will reduce the chances of this issue occurring.

Looking for other management tasks related to dynamic distribution groups? Check out Managing Distribution Groups.

What Do You Want to Do?

- Use the EMC to create a dynamic distribution group
- Use the Shell to create a dynamic distribution group

Use the EMC to create a dynamic distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Dynamic Distribution Group**.
3. On the **Introduction** page, complete the following fields. All fields on this page are required:

- **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
- **Name** Use this box to type the name for the dynamic distribution group. The name cannot exceed 64 characters.
- **Alias** Use this box to type the alias of the dynamic distribution group. The alias cannot exceed 64 characters and must be unique in the forest.

4. On the **Filter Settings** page, define the recipient filter for the new dynamic distribution group:
   - **Browse** Click this button to open the **Select Organizational Unit** dialog box. Use this dialog box to specify the OU from which to select the recipients. A dynamic distribution group contains all recipients that are in the specified OU and any other OUs under it.
   - Select the recipient types you want to include. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:
     Users with Exchange mailboxes Select this check box if you want to include users that have mailboxes. Users that have Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.
     Users with external e-mail addresses Select this check box if you want to include users that have external e-mail addresses. Users that have external e-mail accounts have user domain accounts in Active Directory, but use e-mail accounts that are external to the organization. This enables them to be included in the global address list (GAL) and added to distribution lists.
     Resource mailboxes Select this check box if you want to include Exchange resource mailboxes. Resource mailboxes allow you to administer company resources through a mailbox, such as a conference room or company vehicle.
     Contacts with external e-mail addresses Select this check box if you want to include contacts that have external e-mail addresses. Contacts that have external e-mail accounts do not have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.
     Mail-enabled groups Select this check box if you want to include security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

5. On the **Conditions** page, define any additional optional conditions to further restrict the recipients that are included in this dynamic distribution group
   - **Step 1: Select conditions** Use this section to select one or more conditions. If you don't want to set any conditions for the list, don't select any of the check boxes.
   - **Step 2: Edit the conditions by selecting an underlined value** If you select any conditions in Step 1, each condition you select will append to the definition. For example, if you selected the **Recipient is in a State or Province** check box in Step 1, you will see the **in the specified State or**

Province(s) condition in Step 2.

For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.

Important:

The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.

- **Preview** Click this button to view the recipients that will be included, based on the conditions that you specified.

Note:

If you want to specify conditions other than the ones available on this page, you must use the Exchange Management Shell to create a custom query for the dynamic distribution group. Keep in mind that the filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell. For an example of how to create a dynamic distribution group with a custom query, see Use the Shell to create a new dynamic distribution group later in this topic. For more information about recipient filters, see Creating Filters in Recipient Commands.

6. On the **New Dynamic Distribution Group** page, review your configuration settings. To make any changes, click **Back**. To create the new dynamic distribution group, click **New**.

7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
8. Click **Finish** to close the wizard.

Use the Shell to create a dynamic distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

This example creates the dynamic distribution group Mailbox Users DDG that contains only mailbox users.

```
New-DynamicDistributionGroup -IncludedRecipients MailboxUsers -Name "Mailbox User
```

This example creates a dynamic distribution group with a custom recipient filter. The dynamic distribution group contains all mailbox users on a server called Server1:

```
New-DynamicDistributionGroup -Name "Mailbox Users on Server1" -OrganizationalUnit
```

For More Information

Configure Dynamic Distribution Group Properties

Managing Distribution Groups

Understanding Recipients

1.8.3.10.5 Create a Distribution Group Naming Policy

Create a Distribution Group Naming Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A *group naming policy* is a template applied to the distribution group names in your Microsoft Exchange organization. Specifically, you can specify that a prefix, a suffix, or both be applied to all distribution group names. You can also block certain words from being used in the names.

Prefixes and suffixes can be a string, an attribute, or a combination of both. A prefix or suffix can contain sequences of multiple attributes or strings. You can use the following attributes, which will be gathered from the user who creates the distribution group settings:

- Department
- Company
- Office
- StateOrProvince
- CountryorRegion
- CountryCode
- Title
- CustomAttribute1 to CustomAttribute15

Important:

The maximum length for a distribution group name is 64 characters. This includes the combined number of characters in the prefix, the group name provided by the user, and the suffix.

To use an attribute to create a naming policy, use the following syntax: "<PrefixAttribute><GroupName><SuffixAttribute>". For example, to create a naming policy using Department as a prefix and CustomAttribute1 as the suffix, you would use the following:"<Department><GroupName><CustomAttribute1>".

To use strings to create a naming policy, use the following syntax: "string<GroupName>string". For example, to create a naming policy using the string DL_ as the prefix, you would use the following: "DL_<GroupName>".

Note:

Don't set the <*GroupName*> value; it's used as a placeholder. When a user or administrator creates a distribution group, <*GroupName*> is replaced by the name they provide.

Looking for other management tasks related to distribution groups? Check out Managing

Distribution Groups.

Use the Shell to create a naming policy for a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange server configuration settings" entry in the Exchange and Shell Infrastructure Permissions topic.

Note:

You can't use the Exchange Management Console (EMC) to create a naming policy for a distribution group.

This example creates a distribution group naming policy with the following settings:

- Distribution groups will be created in the Users\Groups container.
- The words "bad", "curse", and "offensive" will be blocked from use in distribution group names.
- All distribution groups will have the prefix "DL_"
- All distribution groups will have the suffix of an underscore (_) followed by the user's department and country code.

```
Set-OrganizationConfig -DistributionGroupDefaultOU Users\Groups -DistributionGrou
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

Other Tasks

After you create the distribution group naming policy, you may also want to override the policy when creating distribution groups. For detailed steps, see Override a Distribution Group Naming Policy.

1.8.3.10.6 Override a Distribution Group Naming Policy

Override a Distribution Group Naming Policy

Mailbox > Managing Mailbox Servers > Managing Distribution Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A *group naming policy* is a template applied to the distribution group names in your Microsoft Exchange organization. As an administrator, there may be times when you need to override the naming policy.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the Shell to override the distribution group naming policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions

topic.

Note:
You can't use the Exchange Management Console (EMC) to override the distribution group naming policy.

This example creates the distribution group ITDepartment and overrides the naming policy.

```
New-DistributionGroup -Name "ITDepartment" -IgnoreNamingPolicy
```

This example changes the name of an existing distribution group and overrides the naming policy.

```
Set-DistributionGroup -Identity "DL_HRDept" -Name "Department_HR_AllStaff" -Ignor
```

For detailed syntax and parameter information, see New-DistributionGroup and Set-DistributionGroup.

1.8.3.10.7 Create a Room List Distribution Group

Create a Room List Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Office Outlook 2007 or earlier, if you wanted to search for a conference room's availability while setting up a meeting, you needed to add all possible conference rooms to the meeting request, and then use the Scheduling Assistant to view available conference rooms.

In Microsoft Exchange Server 2010, you can create *room list* distribution groups to generate a list of building locations so that Outlook 2010 users can select a building and get information about room availability without having to manually add all the rooms in the building.

You can only add room mailboxes to a room list distribution group.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the Shell to create a room list distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to create a room list distribution group.

This example creates a room list for all of the conference rooms in Building 31 by using the *Filter* parameter. In this example, `CustomAttribute1` is used to specify that the conference rooms are in Building 31.

1. Save the list of members in a $Members variable.

```
$Members=Get-Mailbox -Filter {(RecipientTypeDetails -eq "RoomMailbox")
```

2. Create the distribution group by using the $Members variable as the value for the *Members* parameter.

```
New-DistributionGroup -Name "Building 31 Conference Rooms" -Organizait
```

For detailed syntax and parameter reference, see Get-Mailbox and New-DistributionGroup.

1.8.3.10.8 Create a Security Group

Create a Security Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A mail-enabled security group can be used to distribute messages as well as to grant access permissions to resources in Active Directory.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Note:

By default, all new distribution groups require that all senders be authenticated. This prevents external senders from sending messages to distribution groups. This setting is different from previous versions of Exchange where, by default, new distribution groups accepted messages from all senders. To configure a distribution group to accept messages from all senders, you must modify the message delivery restriction settings for that distribution group. For more information about configuring message delivery restrictions, see Configure Message Delivery Restrictions.

Use the EMC to create a security group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Distribution Group**.
3. On the **Introduction** page, click **New Group**, and then click **Next**.
4. On the **Group Information** page, complete the following fields:
   - **Group type** Click **Security** to create a mail-enabled universal security group.
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes,

see Understanding Recipient Scope.

- **Name** Use this box to type the name of the group, which can't exceed 64 characters.
- **Name (pre-Windows 2000)** Use this box to type the name for the group that's compatible with the legacy versions of Windows (prior to the release of Windows 2000 Server). This required field is automatically populated based on the **Name** field.

  The name of the group that's compatible with earlier versions of Windows can't exceed 64 characters. It can contain letters, numbers, and the following characters: **! # $ % ^ & - . _ { } | ~**.
- **Alias** Use this box to type the name of the alias for the group. The alias can't exceed 64 characters and must be unique in the forest.

5. On the **New Distribution Group** page, review your configuration settings. To make any configuration changes, click **Back**. To create the security group, click **New**.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a security group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example creates a security group named Managers.

```
New-DistributionGroup -Name "Managers" -OrganizationalUnit "contoso.com/Users" -S
```

For detailed syntax and parameter information, see New-DistributionGroup.

1.8.3.10.9 Convert a Distribution Group into a Room List

Convert a Distribution Group into a Room List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Office Outlook 2007 or earlier, if you wanted to search for a conference room's availability while setting up a meeting, you needed to add all possible conference rooms to the meeting request, and then use Scheduling Assistant to view available conference rooms.

In Microsoft Exchange Server 2010, you can create *room list* distribution groups to generate a list of building locations so that in Outlook 2010, users can select a building and get information about room availability in that building without having to manually add all the rooms in the building.

Note:

In Exchange, you can convert a distribution group to a room list only if all the members of

the distribution group are room mailboxes. In addition, after the distribution group is converted to a room list, or after you create a room list, you can only add room mailboxes to the group.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Prerequisite

You have a distribution group that contains only room mailboxes. For details about how to create a room list, see Create a Distribution Group.

Use the Shell to convert a distribution group into a room list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to convert a distribution group into a room list.

This example converts the Bldg34 Conf Rooms distribution group to a room list.

```
Set-DistributionGroup -Identity "Bldg34 Conf Rooms" -RoomList
```

For detailed syntax and parameter information, see Set-DistributionGroup.

1.8.3.10.10 Configure Distribution Group Properties

Configure Distribution Group Properties

Mailbox > Managing Mailbox Servers > Managing Distribution Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Distribution groups are mail-enabled Active Directory group objects that are created to expedite the mass sending of e-mail messages and other information within an Exchange organization.

There are two types of distribution groups:

- *Mail-enabled universal distribution groups* can be used only to distribute messages.
- *Mail-enabled universal security groups* can be used to distribute messages as well as to grant access permissions to resources in Active Directory.

It's important to note the terminology differences between Active Directory and Exchange 2010. In Active Directory, a distribution group refers to any group that doesn't have a security context, whether it's mail-enabled or not. In contrast, in Exchange 2010, all mail-enabled groups are referred to as distribution groups, whether they have a security context or not.

Looking for other management tasks related to distribution groups? Check out Managing

Distribution Groups.

What Do You Want to Do?

- Use the EMC to configure distribution group properties
- Use the Shell to configure distribution group properties

Use the EMC to configure distribution group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, click the distribution group that you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to view or modify the display name, alias, and custom attributes for the distribution group.
   - **Display name** Use this unlabeled box at the top of the page to view or change the display name for the distribution group.
   - **Organizational unit** This read-only field displays the organizational unit (OU) that contains the distribution group.
   - **Modified** This read-only field displays the last date and time a configuration change was made.

     Note:
     Configuration changes made through any other method, such as the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.

   - **Alias** Use this box to view or change the alias of the distribution group. The alias cannot exceed 64 characters and must be unique in the forest.
   - **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**. To learn more, see Understanding Custom Attributes.

5. Use the **Group Information** tab to view or change the Active Directory information for the distribution group.
   - **Name** Use this text box to view or change the name of the group. The name cannot exceed 64 characters.
   - **Name (pre-Windows 2000)** Use this text box to type the name of the group that is compatible with legacy versions of Windows (prior to the release of Windows 2000 Server).

     The name of the group that is compatible with earlier versions of Windows can't exceed 20 characters. It can contain letters, numbers, and the following characters: **! # $ % ^ & - . _ { } | ~**.
   - **Managed By** The recipient that is designated as the manager for this distribution group will be visible when users view the properties of this group in Outlook or Outlook Web App. If the delivery reports option on the **Advanced** tab is set to **Send delivery reports to group manager**, the manager will also receive delivery reports for the group.

     Click **Add** to open the **Select Mailbox or Mail-enabled User** dialog box. Use this dialog box to select the recipient you want to add as a manager of the distribution group, and then click

OK.

Click to remove the selected manager from the distribution group.

- **Notes** Use this box to view or modify administrative notes about the distribution group. These notes are also visible from Outlook. When a user views the properties of the distribution group in Outlook, the notes will be displayed on the **General** tab.

6. Use the **Members** tab to add members to or remove members from the distribution group.
   - Click **Add** to open the **Select Recipient** dialog box. Use this dialog box to select the recipients you want to add to the distribution group, and then click **OK**.

     Click to remove the selected members from the distribution group.

7. Use the **Membership Approval** tab to configure how membership requests should be handled for this distribution group.

   Choose whether owner approval is required to join the group
   - **Open** Click this button to allow users to join this distribution group without the approval of the distribution group owners.
   - **Closed** Click this button to specify that only distribution group owners can add members to this distribution group. Requests to join this distribution group will be rejected automatically.
   - **Owner approval** Click this button to specify that users can request membership to this distribution group. Requests to join the distribution group must be approved by a distribution group owner before the user can join.

   Choose whether the group is open to leave
   - **Open** Click this button to allow users to leave this distribution group without the approval of the distribution group owners.
   - **Closed** Click this button to specify that only distribution group owners can remove members from this distribution group. Requests to leave this distribution group will be rejected automatically.

8. Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

9. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.
   - **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:

     SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address.

     EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the

extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
-  Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:
  This button is enabled when an address other than the external e-mail address is selected.

- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

10. Use the **Advanced** tab to view or change the advanced distribution group settings, such as the expansion server and delivery report options.
    - **Simple display name** Use this box to view or modify the simple display name for the recipient. The **Display Name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode. The simple display name field accepts only ASCII characters.
    - **Set expansion server** For each message that is sent to a distribution group, Exchange must access the full membership list to route the message to all recipients. This process is known as *distribution group expansion*. Use this box and corresponding **Browse** button to select a Hub Transport server in your Exchange organization that will be responsible for expanding the membership list for this distribution group.
      Expansion of very large distribution groups is a resource intensive process. If it occurs on a production server, it may impact mail flow. To avoid any production impact, you may want

to specify expansion servers for very large distribution groups.

- **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.
  After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.
- **Send out-of-office message to originator** Select this check box to allow Out of Office messages from group members to be sent to the message sender. If this check box is selected, users who send messages to the distribution group will receive Out of Office replies from any member that has an Out of Office rule turned on.
  Clear this check box to prevent Out of Office replies from distribution group members to be sent to the message sender.
- **Send delivery reports to group manager** Click this button to send non-delivery reports (NDRs) to only the distribution group manager.
- **Send delivery reports to message originator** Click this button to send NDRs to the message sender.
- **Do not send delivery reports** Click this button to prevent the sending of NDRs.

11. Use the **Mail Flow Settings** tab to configure message size or message delivery restrictions for the distribution group. To view or change a mail flow setting, select the setting from the list, and then click **Properties**.
    - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. Use this dialog box to configure the maximum message size in kilobytes (KB) that users are allowed to send to this distribution group.
      If a message larger than the specified size is sent to the distribution group, the message will be returned to the sender with a descriptive error message.
      In the **Message Size Restrictions** dialog box, select the **Maximum message size (in KB)** check box to set the maximum size for messages that can be received by this distribution group. Use the corresponding box to specify the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB.
      Clear the **Maximum message size (in KB)** check box to remove the size restrictions for receiving messages.
    - **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:
      All senders Click this button to allow the group to accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
      Only senders in the following list Click this button to specify that the group can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.
      Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the group. By default, this check box is selected for distribution

groups. This prevents external senders from sending messages to distribution groups.
No Senders Click this button to specify that the group will not reject messages from any senders in the Exchange organization. This button is selected by default.
Senders in the following list Click this button to specify that the group will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

- **Message Moderation** Select this setting and then click **Properties** to open the **Message Moderation** dialog box. Use this dialog box to configure whether messages sent to this distribution group must be approved by a moderator before they are delivered to the distribution group members.
  In the **Message Moderation** dialog box, select the **Messages sent to this group have to be approved by a moderator** check box to require all messages sent to the group to be approved by a moderator.
  In the **Specify group moderators** field, click **Add** to open the **Select Recipient** dialog box. Use this dialog box to select the recipients you want to add as moderators of the distribution group, and then click **OK**.
  Click  to remove the selected moderator from the distribution group.
  In the **Specify senders who don't require message approval** field, click **Add** to open the **Select Recipient** dialog box. Use this dialog box to select the recipients who don't require message approval to send to the distribution group, and then click **OK**.
  Click  to remove the selected recipients who should no longer be allowed to send messages to the group without approval from the group.

Use the Shell to configure distribution group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example changes the *MaxReceiveSize* parameter to 20 MB for the distribution group Seattle Employees.

```
Set-DistributionGroup "Seattle Employees" -MaxReceiveSize 20MB -ModerationEnabled
```

This example enables moderation for the distribution group Customer Support and sets the moderator to Amy. In addition, this moderated distribution group will notify senders who send mail from within the organization if their messages aren't approved.

```
Set-DistributionGroup -Identity 'Customer Support' -ModeratedBy "Amy" -Moderation
```

This example changes the user-created distribution group Dog Lovers to require the group manager to approve users' requests to join the group. In addition, by using the *BypassSecurityGroupManagerCheck* parameter, the group manager will not be notified that a change was made to the distribution group's settings.

```
Set-DistributionGroup -Identity 'Dog Lovers' -MemberJoinRestriction 'ApprovalRequ
```

Understanding Recipients

Managing Distribution Groups

1.8.3.10.11 Configure Dynamic Distribution Group Properties

Configure Dynamic Distribution Group Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-20*

Dynamic distribution groups are mail-enabled Active Directory group objects that are created to expedite the mass sending of e-mail messages and other information within an Exchange organization.

Unlike regular distribution groups that contain a defined set of members, the membership list for dynamic distribution groups is calculated each time a message is sent to the group, based on the filters and conditions that you define. When an e-mail message is sent to a dynamic distribution group, it's delivered to all recipients in the organization that match the criteria defined for that group.

Caution:

- A dynamic distribution group includes any recipient in Active Directory with attributes that match its filter. If a recipient's properties are modified to match the filter, the recipient could inadvertently become a group member and start receiving messages that are sent to the group. Well-defined, consistent account provisioning processes will reduce the chances of this issue occurring.
- Take caution when creating or modifying dynamic distribution groups within search scopes, such as organizational unit (OU).
- Avoid creating multiple levels of dynamic distribution group membership (also known as nested groups) as this may cause increased LDAP requests and initiate slow LDAP responses.

Looking for other management tasks related to dynamic distribution groups? Check out Managing Distribution Groups.

What Do You Want to Do?

- Use the EMC to configure dynamic distribution group properties
- Use the Shell to dynamic distribution group properties

Use the EMC to configure dynamic distribution group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.

2. In the result pane, click the dynamic distribution group that you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to view or modify the display name, alias, and custom attributes for the dynamic distribution group.
   - **Display name** Use this unlabeled text box at the top of the page to view or change the display name for the group.
   - **Organizational unit** This read-only field displays the organizational unit (OU) that contains the group.
   - **Modified** This read-only field displays the last date and time a configuration change was made.

     Note:
     Configuration changes made through any other method, such as the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.

   - **Alias** Use this box to view or change the alias of the group. The alias cannot exceed 64 characters and must be unique in the forest.
   - **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**. To learn more, see Understanding Custom Attributes.

5. Use the **Group Information** tab to change the Active Directory information for the dynamic distribution group.
   - **Name** Use this box to view or change the name of the group. The name can't exceed 64 characters.
   - **Managed By** The recipient that's designated as the manager for this dynamic distribution group will be visible when users view the properties of this group in Outlook or Outlook Web App. If the delivery reports option on the **Advanced** tab is set to **Send delivery reports to group manager**, the manager will also receive delivery reports for the group.

     Click **Add** to open the **Select Mailbox or Mail-enabled User** dialog box. Use this dialog box to select the recipient you want to add as a manager of the group, and then click **OK**.

     Click  to remove the selected manager from the dynamic distribution group.
   - **Notes** Use this box to view or modify administrative notes about the group. These notes are also visible in Outlook. When a user views the properties of the group in Outlook, the notes will be displayed on the **General** tab.

6. Use the **Filter** tab to modify the recipient filter for the group:
   - **Select the recipient container where you want to apply this filter** This box is populated with the OU that you selected when you created the dynamic distribution group. To specify a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. A dynamic distribution group contains all recipients that are in the specified OU and any other OUs under it.
   - Select the recipient types you want to include. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:

     Users with Exchange mailboxes Select this check box if you want to include users that have mailboxes. Users that have Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.

     Users with external e-mail addresses Select this check box if you want to include users that have external e-mail addresses.

Users that have external e-mail accounts have user domain accounts in Active Directory, but use e-mail accounts that are external to the organization. This enables them to be included in the global address list (GAL) and added to distribution lists.
Resource mailboxes Select this check box if you want to include Exchange resource mailboxes. Resource mailboxes allow you to administer company resources through a mailbox, such as a conference room or company vehicle.
Contacts with external e-mail addresses Select this check box if you want to include contacts that have external e-mail addresses. Contacts that have external e-mail accounts do not have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.
Mail-enabled groups Select this check box if you want to include security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

7. Use the **Conditions** tab to define any optional conditions to further restrict the recipients that are included in this dynamic distribution group.
   - **Step 1: Select conditions** Use this section to select one or more conditions. If you don't want to set any conditions for the list, don't select any of the check boxes.
   - **Step 2: Edit the conditions by selecting an underlined value** If you select any conditions in Step 1, each condition you select will append to the definition. For example, if you selected the **Recipient is in a State or Province** check box, you'll see the **in the specified State or Province(s)** condition in Step 2.

     For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.

     Important:
     The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.
   - **Preview** Click this button to view the recipients that will be included, based on the conditions that you specified.

     Note:
     If you want to specify conditions other than the ones available on this tab, you must use the Exchange Management Shell to create a custom query for the dynamic distribution group. Keep in mind that the filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell. For more information about recipient filters, see Creating Filters in Recipient Commands.

8. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.
   - **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:

     SMTP Address This is the default address type. Click this

button and use the corresponding dialog box to add an SMTP address.
EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
-  Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:
  This button is enabled when an address other than the external e-mail address is selected.

- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

9. Use the **Advanced** tab to view or change the advanced group settings, such as the expansion server and delivery report options.
   - **Simple display name** Use this box to view or modify the simple display name for the group. The **Display name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode. The simple display name field accepts only ASCII characters.
   - **Set expansion server** For each message that is sent to the dynamic distribution group, Exchange must access the full membership list to route

the message to all recipients. This process is known as *distribution group expansion*. Use this box and corresponding **Browse** button to select a Hub Transport server in your Exchange organization that will be responsible for expanding the membership list for this group

Expansion of very large dynamic distribution groups is a resource intensive process. If it occurs on a production server, it may impact mail flow. To avoid any production impact, you may want to specify expansion servers for very large groups.

- **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.

  After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.
- **Send out-of-office message to originator** Select this check box to allow Out of Office messages from group members to be sent to the message sender. If this check box is selected, users who send messages to the group will receive Out of Office replies from any member that has an Out of Office rule turned on.

  Clear this check box to prevent Out of Office replies from group members to be sent to the message sender.
- **Send delivery reports to group manager** Click this button to send non-delivery reports (NDRs) to only the group manager.
- **Send delivery reports to message originator** Click this button to send NDRs to the message sender.
- **Do not send delivery reports** Click this button to prevent the sending of NDRs.

10. Use the **Mail Flow Settings** tab to configure message size or message delivery restrictions for the dynamic distribution group. To view or change a mail flow setting, select the setting from the list, and then click **Properties**.
    - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. Use this dialog box to configure the maximum message size in kilobytes (KB) that users are allowed to send to this group.

      If a message larger than the specified size is sent to the group, the message will be returned to the sender with a descriptive error message.

      In the **Message Size Restrictions** dialog box, select the **Maximum message size (in KB)** check box to set the maximum size for messages that can be received by this group. Use the corresponding box to specify the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB.

      Clear the **Maximum message size (in KB)** check box to remove the size restrictions for receiving messages.
    - **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

      All senders Click this button to allow the group to accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.

      Only senders in the following list Click this button to specify that the group can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all

recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.
Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the group. By default, this check box is selected for dynamic distribution groups. This prevents external senders from sending messages to dynamic distribution groups.
No Senders Click this button to specify that the group will not reject messages from any senders in the Exchange organization. This button is selected by default.
Senders in the following list Click this button to specify that the group will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

Use the Shell to configure dynamic distribution group properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

This example changes the *MaxSendSize* property to 20MB and sets the *ModerationEnabled* property to `$True`:

```
Set-DynamicDistributionGroup "Seattle Employees" -MaxSendSize 20MB -ModerationEna
```

This example adds a second SMTP e-mail address and changes the group manager to John.

```
Set-DynamicDistributionGroup -Identity "Seattle Employees" -ManagedBy 'mail.conto
```

For detailed syntax and parameter information, see Set-DynamicDistributionGroup

Managing Distribution Groups

1.8.3.10.12 Configure Dynamic Distribution Groups in a Hybrid Deployment

Configure Dynamic Distribution Groups in a Hybrid Deployment

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-23*

In a hybrid deployment environment between Microsoft Exchange Online and on-premises Microsoft Exchange organizations, the Microsoft Online Services Directory Synchronization Tool (DirSync) cannot be used to synchronize dynamic distribution groups to Exchange Online. Therefore, mailboxes that have been moved to Exchange Online cannot send mail to dynamic distribution lists. To work around this issue, create a contact in Exchange Online for the dynamic distribution list, and then grant permissions so that only authenticated senders can submit messages to the new contact.

Looking for other management tasks related to Managing Distribution Groups? Check out Managing Distribution Groups.

Looking for more information about hybrid deployments? Check out Hybrid Deployments.

Prerequisites

- Hybrid deployment between an on-premises Exchange organization and Exchange Online.

Enable Exchange Online users to send mail to a dynamic distribution list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

Consider the scope of the dynamic distribution group before the hybrid deployment and before the mailboxes were moved to Exchange Online. If the scope included only mailboxes, the scope must be expanded to include mail users and mail contacts. To do this, follow these steps:

1. On an on-premises Exchange server, start the Exchange Management Console (EMC).
2. In the console tree, navigate to Recipient Configuration. Beneath that, navigate to Distribution Group.
3. In the results pane, click the dynamic distribution group that you want to configure.
4. In the Action pane, click **Properties**.
5. On the **Filter** tab, select **The following specific types**, and then click to select the **Users with Exchange mailboxes** and the **Users with external e-mail addresses** check boxes.
6. Click **Apply**. Then, click **OK**.

To create a contact in Exchange Online to represent the dynamic distribution group, follow these steps:

1. Sign in to Outlook Web App on the Office 365 tenant by using a service administrator account.
2. Click **Options**, and then click **See all options**.
3. Click **Manage Myself**, and then click **Manage Organization**.
4. Click **Users and Groups**, and then click **External Contacts**.
5. Click **New**, and then type the contact details.
6. In the **External e-mail address** box, type the mail address of the Dynamic Distribution group that was created on the on-premises Exchange server.
7. Click **Save**.

Exchange Online users can now select the dynamic distribution group from the global address list (GAL). When they do, messages will be delivered to the members of the group as defined by the settings for the group.

For More Information

Configure Dynamic Distribution Group Properties

Create a Dynamic Distribution Group

Exchange Hybrid Deployment and Migration with Office 365

1.8.3.10.13 Mail-Enable or Mail-Disable a Distribution Group

Mail-Enable or Mail-Disable a Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can mail-enable or mail-disable a distribution group. By default, distribution groups are mail-enabled when created.

Looking for additional management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the EMC to mail-enable a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the action pane, click **New Distribution Group**. The New Distribution Group wizard appears.
3. On the **Introduction** page, click **Existing Group**, and then click **Browse**.
4. In **Select Group**, select the group that you want to mail-enable, and then click **OK**.
5. On the **Group Information** page, in the **Alias** box, type the name of the alias for the group. The alias can't exceed 64 characters and must be unique in the forest.

   Note:

   The **Name** and **Name (pre-Windows 2000)** boxes are read-only and can't be modified at this time. If you want to modify these names, use the **Group Information** tab in the distribution group's properties.

6. On the **New Distribution Group** page, review the **Configuration Summary**. To make any configuration changes, click **Back**. To mail-enable the group, click **New**.
7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the EMC to mail-disable a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the group that you want to mail-disable.
3. In the action pane, under the group name, click **Disable**.
4. A warning appears confirming that you want to mail-disable the group. Click **Yes**.

Use the Shell to mail-enable a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example mail-enables the security group Schema Admins. When you mail-enable a group, you must specify the alias, display name, and primary SMTP address.

```
Enable-DistributionGroup -Identity "Schema Admins" -Alias "SchemaAdmins" -Display
```

For detailed syntax and parameter information, see Enable-DistributionGroup.

Use the Shell to mail-disable a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

After you disable a distribution group, you can remove it from the global address list (GAL), without removing it from Active Directory. The Active Directory group object still exists, but the distribution group will be unable to send or receive mail.

This example disables the distribution group Employee Garage Sales.

```
Disable-DistributionGroup -Identity "Employee Garage Sales"
```

For detailed syntax and parameter information, see Disable-DistributionGroup.

1.8.3.10.14 Mail-Enable or Mail-Disable a Security Group

Mail-Enable or Mail-Disable a Security Group

Mailbox > Managing Mailbox Servers > Managing Distribution Groups >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Security groups are used to grant access permissions to resources in Active Directory. If you mail-enable the security group, you can send e-mail to all members of that group. For example, if you create a security group that gives members access to the computers in a specific server lab, you may want to send mail to that group to notify them of a power outage in the lab.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the EMC to mail-enable a security group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the action pane, click **New Distribution Group**. The New Distribution Group wizard appears.
3. On the **Introduction** page, click **Existing Group**, and then click **Browse**.
4. In the **Select Group** dialog box, select the security group that you want to mail-enable, and then click **OK**.

   Note:

   If the security group that you want to mail-enable doesn't appear in the list, you may need to change the recipient scope. For more information, see Change the Recipient Scope.

5. Click **Next**.
6. On the **Group Information** page, complete the following fields:
   - **Name** This read-only field shows the security group's display name. If you want to modify this name, use the **General** tab in **<Security group> Properties**.
   - **Name (pre-Windows 2000)** This read only field shows the name for the group that's compatible with legacy versions of Windows (prior to the release of Windows 2000 Server).
   - **Alias** Use this box to type an alias for the security group. The alias can't exceed 64 characters and must be unique in the forest.
7. Click **Next**.
8. On the **New Distribution Group** page, review the **Configuration Summary**. To make any configuration changes, click **Back**. To mail-enable the security group, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the EMC to mail-disable a security group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution**

Group.
2. In the result pane, select the security group that you want to mail-disable.
3. In the action pane, under the group name, click **Disable**.
4. A warning appears confirming that you want to mail-disable the group. Click **Yes**.

Use the Shell to mail-enable a security group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example mail-enables the Server Lab 222 security group.

```
Enable-DistributionGroup -Identity "Server Lab 222"
```

Note:
You may need to change the recipient scope to access security groups. For more information, see Change the Recipient Scope.

For detailed syntax and parameter information, see Enable-DistributionGroup.

Use the Shell to mail-disable a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

After you disable a distribution group, you can remove it from the global address list (GAL), without removing it from Active Directory. The Active Directory group object still exists, but the distribution group will be unable to send or receive mail.

This example disables the distribution group Employee Garage Sales.

```
Disable-DistributionGroup -Identity "Employee Garage Sales"
```

For detailed syntax and parameter information, see Disable-DistributionGroup.

Other Tasks

After you mail-enable the security group, you may also want to:

- Add a Member to a Distribution Group
- Remove a Distribution Group Member

Manage the Members of Distribution Groups

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-03-07*

Microsoft Exchange Server 2010 provides a new feature to manage distribution groups. This feature lets your users join existing groups, manage some of the properties of groups that they own, manage their membership in groups that they own, and even create and remove groups.

Manage Distribution Groups

Microsoft Exchange Server 2010 now offers users the ability to manage distribution groups with more control than that provided by Microsoft Office Outlook 2007. This new feature lets your users join existing groups, manage some of the properties of groups that they own, manage membership in groups that they own, and even create and remove groups.

By default, this feature is turned off. To turn on this feature, use the Exchange Control Panel (ECP) to assign the **MyDistributionGroups RBAC** role to the **Default Role Assignment Policy**.

Although some customers want their users to have the ability to create and remove distribution groups on this role, the control that is offered by this new feature may be more than you want to provide the users on your network.

For example, you may want to modify the functionality of this feature to meet any of the following goals:

- Let users manage distribution groups they own.
- Not let users be able to create distribution groups.
- Not let users be able to remove distribution groups, including those that they own.

To help you change the functionality of the new feature, use the ManageGroupManagementRole.ps1 script. This script is available from the TechNet Script Center. To use this script, follow these steps:

1. Obtain the script by visiting the following TechNet Script Center Web site: Manage-GroupManagementRole.ps1.
2. Copy the contents of the script to a text file on the computer on which you want to run it, and then save the file by using the following filename: **Manage-GroupManagementRole.ps1**.
3. At an Exchange PowerShell command prompt, run the following command: **Manage-Groupmanagmentrole.ps1 -creategroup –removegroup**.

This combination of switches makes the changes that are described in the example mentioned earlier. When the script is finished running, your users will be able to manage distribution groups, but not create or remove them. When you run the script, the script performs the following actions:

1. Creates a new RBAC role that is a child of the MyDistributionGroups Role.
   Removes the **remove-distributiongroup** cmdlet and the **new-distributiongroup** cmdlet from the role that you just created.
   Assigns the new role to the Default Role Assignment Policy.

For more information about how to use this script, examine the contents of the script file.

Or, run the script without switches. Each step that the script takes is documented in the script. You can extract from the script just what you require to change the functionality of the manage distribution groups feature. The script is designed to be flexible. If you run the script by using the default settings, you get a new role and a new role assignment.

How to Use Groups to Manage Groups in Exchange 2010

In Exchange 2010, distribution groups cannot be managed by groups; only individual users can manage groups. This behavior differs from Microsoft Exchange Server 2003, in which you use groups to manage a distribution group. In Exchange 2003, group ownership is handled at a different level. If you move mailboxes from Exchange 2003 to Exchange 2010, members of a group that managed a distribution group in Exchange 2003 can no longer modify the group in Exchange 2010.

The Set-DistributionGroupOwners.ps1 script lets you work around this changed behavior. The script enables you to simulate group ownership of a distribution group in Exchange 2010.

You can run the script in the following modes, depending on the switches that you use together with the script.

- Mode 1: Set Ownership for a particular distribution group. Modifications to the **ManagedBy** attribute are not set at this time. Instead, the script modifies a custom attribute to obtain the information it will require later to set the ManagedBy **attribute**.
- Mode 2: Modify the **ManagedBy** attribute of a specific distribution group so that the members of either a security group or a distribution group can manage the group.
- Mode 3: Automate the process. This mode is designed to be run as a scheduled task and to make sure that individual members of a group have ownership of the distribution group that they are set to own. Use this mode if you prefer to automate the process and, perhaps, run it nightly to find any changes to security group and distribution group membership.

Important:

Windows Server 2008 R2 is required to run the Set-DistributionGroupOwners.ps1 script. The script does not have to be run on a server that's running Exchange Server. However, the Exchange management tools must be installed on the computer on which you run the script.

To run the Set-DistributionGroupOwners.ps1 script, follow these steps:

1. Visit the Script Center, and then download Set-DistributionGroupOwners.txt from the following Web page: Set-DistributionGroupOwners.
2. Change the file name extension from **.txt** to **.ps1**. The filename should now be **Set-DistributionGroupOwners.ps1**.
3. By default, the script populates the **CustomAttribute5** field by using the Distinguished Name (DN) of the group. The DN is specified in the **ManagedBy** attribute of the distribution group that you want to manage. You can change the default behavior to use one of the 15 custom attributes in the default schema. Determine which custom attribute works in your environment. To change the custom attribute, follow these steps:
   3.a. Open the Set-DistributionGroupOwners.ps1 file in Notepad.
   3.b. Locate the following text: **$dn_storage = "CustomAttribute5"**.
   3.c. Change **CustomAttribute5** to the custom attribute that you want to use.
   3.d. Save and then close the Set-DistributionGroupOwners.ps1 file.
4. Determine which of the following modes you want to use to run the script.
   4.a. **Mode 1 - Set Ownership of a Group** In this mode, run the script

together with the *–DistributionGroup* and *–GroupOwner* parameters. Specify the distribution group (-DistributionGroup) and the group that you want to manage it (-GroupOwner). This resets the DN of the owning group (as specified in *–GroupOwner*) to the custom attribute for the Distribution Group (as specified in *–DistributionGroup*).

4.b. **Mode 2 - Modify the ManagedBy attribute for one Group** Mode 2 or Mode 3 don't work until you set the value of the customer attribute to the DN of the owning group. If you have already run the Script in Mode 1, Mode 2 configures the *ManagedBy* attribute for a single group. To run the script in Mode 2, specify only the *–DistributionGroup* parameter, and list the DL that you want to have processed.

4.c. **Mode 3 – Run the Script as a Scheduled Task to look all new modifications to Group Ownership** When you run the script without switches, the script searches the directory in Active Directory Domain Services for all groups that have the defined custom attribute set to a DN. Then, it processes all the groups as in Mode 2. The script is designed to be run in this mode as either a one-off kind of operation for which you know updates are needed or as a scheduled task to keep everything in sync. A key point is that when the script populates the **ManagedBy** attribute, it overwrites the existing values by using the current members of the owning group.

For more information about custom attributes, see Understanding Custom Attributes.

For more information about managing distribution groups, see Managing Distribution Groups.

1.8.3.10.16 Remove a Distribution Group

Remove a Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove a distribution group from Microsoft Exchange and Active Directory. To disable a distribution group without removing the Active Directory object, see Mail-Enable or Mail-Disable a Distribution Group.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the EMC to remove a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the distribution group that you want to remove.
3. In the action pane, under the name of the distribution group, click **Remove**.
4. A warning appears confirming that you want to remove the distribution group. Click **Yes**.

Use the Shell to remove a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example removes the distribution group Temporary Staff.

```
Remove-DistributionGroup -Identity "Temporary Staff"
```

When prompted, type **Y** to confirm the removal of the distribution group.

For detailed syntax and parameter information, see Remove-DistributionGroup.

1.8.3.10.17 Remove a Distribution Group Member

Remove a Distribution Group Member

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove members from a distribution group by using the EMC or the Shell.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Use the EMC to remove a member from a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the distribution group from which you want to remove a recipient.
3. In the action pane, under the distribution group name, click **Properties**.
4. In **<Distribution Group> Properties**, on the **Members** tab, click the recipient you want to remove, and then click  .
5. Click **OK**.

Use the Shell to remove a member from a distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

This example removes the user adam@contoso.com from the distribution group Marketing

Managers.

```
Remove-DistributionGroupMember -Identity "Marketing Managers" -Member adam@contos
```

When prompted, type **Y** to confirm the removal.

For detailed syntax and parameter information, see Remove-DistributionGroupMember.

1.8.3.10.18 Stop Automatic Conversion of Universal Distribution Groups to Universal Security Groups

Stop Automatic Conversion of Universal Distribution Groups to Universal Security Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Universal distribution groups and universal security groups are groups of recipients created to expedite the mass sending of e-mail messages and other information. However, unlike universal distribution groups, universal security groups can also be used to assign permissions.

In Microsoft Exchange, only Active Directory objects that have security principals can be used to grant permission to a public folder or to a mailbox folder. However, it's possible for a Microsoft Outlook user to use a universal distribution group to grant permission to a public folder or to a mailbox folder. In this case, the universal distribution group is automatically converted to a universal security group by the Microsoft Exchange Information Store service. This is the default behavior in Exchange Server 2010 and Exchange Server 2007.

You can modify this behavior to prevent the automatic conversion of universal distribution groups to universal security groups. The **msExchDisableUDGConversion** attribute of your Exchange organization object in Active Directory is used to control how the Microsoft Exchange Information Store service responds to requests for conversion of universal distribution groups to universal security groups. The following are the acceptable values for the **msExchDisableUDGConversion** attribute:

- **0** If the attribute is set to 0, or if it isn't configured, universal distribution groups are automatically converted to universal security groups when they're used to grant permissions to public folders or mailbox folders.
- **1** If the attribute is set to 1, Outlook can't request the conversion. However, Exchange system processes can still convert a universal distribution group to a universal security group.
- **2** If the attribute is set to 2, automatic conversions can't occur.

This topic explains how to use Active Directory Service Interfaces (ADSI) Edit to modify the **msExchDisableUDGConversion** attribute to prevent the automatic conversion of universal distribution groups to universal security groups.

Use ADSI Edit to stop the automatic conversion of universal distribution groups to universal security groups

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

1. Start ADSI Edit.
2. In the console tree, expand **Configuration Container**.

   Note:
   If you don't see **Configuration Container**, you'll need to connect to it. From the **Action** menu, click **Connect to**. In **Connection Settings**, select **Configuration** from the **Select a well known Naming Context** list, and then click **OK**.

3. Expand **CN=Configuration,DC=<domain>,DC=<domain extension>**. For example, if your Exchange organization is in the contoso.com forest, this folder name would be **CN=Configuration,DC=contoso,DC=com**.
4. Expand **CN=Services**.
5. Expand **CN=Microsoft Exchange**.
6. Right-click **CN=<Exchange organization name>**, and then click **Properties**.
7. In the **Attributes** list, select **msExchDisableUDGConversion**, and then click **Edit**.

   Note:
   If you can't find this property in the list, you'll need to turn on the ability to view optional settings. On the **Attribute Editor** tab, click **Filter**, and then, under **Show attributes**, select **Optional**.

8. In **Integer Attribute Editor**, in the **Value** box, type **2**, and then click **OK**.
9. Click **Apply**.
10. Click **OK**.

For More Information

For detailed steps about disabling automatic conversion of universal distribution groups to universal security groups in Exchange Server 2003 and Exchange 2000 Server, see Microsoft Knowledge Base article 843587, How to stop automatic conversion of universal distribution groups to universal security groups in Exchange 2000 and in Exchange 2003.

1.8.3.10.19 Turn Off User's Ability to Create Distribution Groups

Turn Off User's Ability to Create Distribution Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, all users in your Microsoft Exchange Server 2010 organization can create and manage distribution groups from their e-mail client. There are several ways to turn off a user's ability to create or manage distribution groups:

- Create an assignment policy and assign it to the users who shouldn't be allowed to create or manage distribution groups.
- Remove the My Distribution Groups and the My Distribution Group Membership roles from the default management role assignment policy.

The procedures in this topic assume that you haven't changed the name of the My Distribution Groups and My Distribution Group Membership management roles.

Looking for other management tasks related to distribution groups? Check out Managing Distribution Groups.

Prerequisites

Read Understanding Management Role Assignment Policies.

Use the Shell to create a role assignment policy to apply to specific users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to create a role assignment policy to apply to specific users.

You can create a policy that doesn't contain the My Distribution Group and My Distribution Group Membership roles and apply that role to specific users in your organization. Those users won't be able to create or manage distribution groups.

1. Create a role assignment policy. This example creates the policy No Distribution Group Management.

```
New-RoleAssignmentPolicy "No Distribution Group Management"
```

2. Use a variable to get all of the roles assigned to the default role assignment policy.

```
$Roles = Get-ManagementRoleAssignment -RoleAssignee "Default Role Assi
```

Note:
The default role assignment policy that's installed with Exchange 2010 is named Default Role Assignment Policy. If you change the name of that policy or if you have a different default policy, you can locate the default policy by running the following command.

```
Get-RoleAssignmentPolicy | Where { $_.IsDefault -eq $True }
```

3. Add all of the roles assigned to the default assignment policy to the new role assignment policy, excluding the ones that contain the word distribution.

```
$Roles | Where {$_.Role -NotLike "*Distribution*" } | New-ManagementRo
```

4. Apply the No Distribution Group Management assignment policy to the appropriate users. This example applies the No Distribution Group Management role assignment policy to all mailboxes that have the *CustomAttribute1* value set to Contract Employee.

```
Get-Mailbox -Filter {CustomAttribute1 -eq "Contract Employee"} | Set-M
```

For detailed syntax and parameter information, see the following topics:

- Get-Mailbox
- Set-Mailbox
- Get-RoleAssignmentPolicy
- New-RoleAssignmentPolicy

Use the Shell to remove the My Distribution Groups and the My Distribution Groups Membership roles from the default management role

assignment policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:
You can't use the EMC to remove the My Distribution Groups and the My Distribution Group Membership roles from the default management role assignment policy.

Removing the My Distribution Groups and My Distribution Group Membership roles from the default role assignment policy is the easiest way to remove this permission from most users in your organization. However, this doesn't affect recipients who have been assigned a different role assignment policy.

Note:
By creating a default role assignment policy, you can save the master settings and create additional policies from it.

1. Create a role assignment policy. This example creates the policy No Distribution Group Management.

```
New-RoleAssignmentPolicy "No Distribution Group Management"
```

2. Use a variable to get all of the roles assigned to the Default Role Assignment Policy.

```
$Roles = Get-ManagementRoleAssignment -RoleAssignee "Default Role Assi
```

Note:
The default role assignment policy that's installed with Exchange 2010 is named Default Role Assignment Policy. If you change the name of that policy or if you have a different default policy, you can locate the default policy by running the following command.

```
Get-RoleAssignmentPolicy | Where { $_.IsDefault -eq $True }
```

3. Add all of the roles assigned to the default assignment policy to the new role assignment policy, excluding the ones that contain the word distribution.

```
$Roles | Where {$_.Role -NotLike "*Distribution*" } | New-ManagementRo
```

4. Make the new role assignment policy the default policy so that it will apply to all users in the organization.

```
Set-RoleAssignmentPolicy "No Distribution Group Management" -IsDefault
```

5. Rename the old default role assignment policy something more appropriate. This example renames it Old_Default Role Assignment Policy.

```
Set-RoleAssignmentPolicy "Default Role Assignment Policy" -Name "Old_D
```

For detailed syntax and parameter information, see the following topics:

- Get-RoleAssignmentPolicy
- Set-RoleAssignmentPolicy
- New-RoleAssignmentPolicy

1.8.3.10.20 View Members of a Dynamic Distribution Group

View Members of a Dynamic Distribution Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Dynamic distribution groups are distribution groups whose membership is based on specific recipient filters rather than a defined set of recipients. Microsoft Exchange Server 2010 provides precanned filters to make it easier to create recipient filters for dynamic distribution groups. A *precanned filter* is a commonly used filter that you can use to meet a variety of recipient-filtering criteria. You can specify the recipient types you want to include in a dynamic distribution group. Additionally, you can also specify a list of conditions that the recipients must meet. You can use both the EMC and the Shell to preview the list of recipients for a dynamic distribution group that uses precanned filters.

You can also specify conditions based on recipient fields other than what the precanned filters provide. To do this, you must use the Shell to create a custom query for the dynamic distribution group. Filter and condition settings for dynamic distribution groups that have custom recipient filters can be managed only by using the Shell.

Looking for other management tasks related to dynamic distribution groups? Check out Managing Distribution Groups.

Use the EMC to preview the list of members for a dynamic distribution group that uses precanned filters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Distribution Group**.
2. In the result pane, select the dynamic distribution group for which you want to preview the list of members.
3. In the action pane, under the dynamic distribution group name, click **Properties**.
4. In **<Dynamic distribution group> Properties**, click the **Conditions** tab.
5. Click **Preview**.

Use the Shell to preview the list of members of a dynamic distribution group

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Dynamic distribution groups" entry in the Mailbox Permissions topic.

This example returns the list of members for the dynamic distribution group Marketing Department. The first command stores the dynamic distribution group object in the variable `$MarketingDepartment`. The second command uses the **Get-Recipient** cmdlet to list the recipients that match the criteria defined for the dynamic distribution group.

```
$MarketingGroup = Get-DynamicDistributionGroup "Marketing Group"
Get-Recipient -RecipientPreviewFilter $MarketingGroup.RecipientFilter -Organizati
```

For detailed syntax and parameter information, see Get-DynamicDistributionGroup and Get-Recipient.

1.8.3.11 Managing E-Mail Address Policies

Managing E-Mail Address Policies

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-16*

Apply an E-Mail Address Policy

Create an E-Mail Address Policy

Create an E-Mail Address Policy By Using Recipient Filters

Change E-Mail Address Policy Priorities

Edit an E-Mail Address Policy

Remove an E-Mail Address Policy

View the Members of an E-Mail Address Policy by Using the Exchange Management Shell

1.8.3.11.1 Apply an E-Mail Address Policy

Apply an E-Mail Address Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

E-mail address policies generate the primary and secondary e-mail addresses for your recipients (which include users, contacts, and groups) so they can receive and send e-mail. After you create an e-mail address policy, you need to apply it to the intended recipients for the policy to take effect.

Note:

Although this topic shows you how to use the Apply E-Mail Address Policy wizard to apply an e-mail address policy, the New E-Mail Address Policy and the Edit E-Mail Address Policy wizards also allow you to apply the policy as you create or edit it.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Prerequisites

You can't edit e-mail address policies that were created in the Shell with a recipient filter. For more information, see Create an E-Mail Address Policy By Using Recipient Filters.

What Do You Want to Do?

- Use the EMC to apply an e-mail address policy
- Use the Shell to apply an e-mail address policy

Use the EMC to apply an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **E-Mail Address Policies** tab, and then select the e-mail address policy that you want to apply.
3. In the action pane, click **Apply**.
4. On the **Introduction** page, complete the following fields:
   - **Apply the e-mail address policy** Select one of the following schedule settings to specify when the e-mail address policy should be applied:
     Immediately Select this option to apply the e-mail address policy immediately.
     At the following time Select this option and use the corresponding lists to specify a time to apply the e-mail address policy.
   - **Cancel tasks that are still running after (hours)** Select this check box and use the corresponding text box to specify how long the e-mail address policy task will run. The default is 8 hours.
5. On the **Apply E-Mail Address Policy** page, review your configuration settings. Click **Apply** to apply the e-mail address policy. Click **Back** to make configuration changes.

   Note:
   Although the process begins when you click **Apply**, you may have to wait several hours for the process to complete and the e-mail address policy to be applied.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to apply an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

This example applies the e-mail address policy Marketing.

```
Update-EmailAddressPolicy -Identity Marketing
```

Note:
Although running the **Update-EmailAddressPolicy** cmdlet starts the update process, you may have to wait several hours for the process to complete and the e-mail address policy to be applied.

For syntax and parameter information, see Update-EmailAddressPolicy.

For More Information

Understanding E-Mail Address Policies

Edit an E-Mail Address Policy

1.8.3.11.2 Create an E-Mail Address Policy

Create an E-Mail Address Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

For a recipient to receive or send e-mail messages, the recipient must have an e-mail address. E-mail address policies generate the primary and secondary e-mail addresses for your recipients (which include users, contacts, and groups) so they can receive and send e-mail.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Prerequisite

Before an SMTP address domain can be used in an e-mail address policy, you must configure an accepted domain. For more, see Understanding Accepted Domains.

What Do You Want to Do?

- Use the EMC to create an e-mail address policy
- Use the Shell to create an e-mail address policy

Use the EMC to create an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the action pane, click **New E-mail Address Policy**.
3. On the **Introduction** page, complete the following fields to define the recipient scope:

- **Name** Use this text box to create the display name for the new e-mail address policy. The name can contain as many as 64 characters but cannot include wildcard characters.
- **Select the recipient container where you want to apply this filter** Click **Browse** to open the **Select Organizational Unit** dialog box. Specify an organizational unit (OU), and then click **OK**. The recipient container filters the recipients that the e-mail address policy will affect based upon their location in Active Directory.
- Select the recipient types you want to include in the policy. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:

  Users with Exchange mailboxes Select this check box if you want your e-mail address policy to apply to users with Exchange 2010, Exchange 2007, or Exchange 2003 mailboxes. Users with Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.

  Users with external e-mail addresses Select this check box if you want your e-mail address policy to apply to users with external e-mail addresses. Users with external e-mail accounts have user domain accounts in Active Directory, but use e-mail accounts that are external to the organization. This enables them to be included in the global address list (GAL) and added to distribution lists.

  Resource mailboxes Select this check box if you want your e-mail address policy to apply to Exchange resource mailboxes. Resources mailboxes allow you to administer company resources through a mailbox, such as a conference room or company vehicle.

  Contacts with external e-mail addresses Select this check box if you want your e-mail address policy to apply to contacts with external e-mail addresses. Contacts with external e-mail accounts do not have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.

  Mail-enabled groups Select this check box if you want your e-mail address policy to apply to security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

4. On the **Conditions** page, compete the following fields to further filter the recipients who will be affected by this e-mail address policy:

   Step 1: Select condition(s) Use this section to select one or more conditions for your e-mail address policy. If you don't want to set any conditions for the policy, don't select any of the check boxes. Select from the following conditions:

   - **Recipient is in a State or Province** Select this check box if you want the e-mail address policy to include only recipients from specific states or provinces. This information is contained on the **Address and Phone** tab in the recipient's properties.
   - **Recipient is in a Department** Select this check box if you want the e-mail address policy to include only recipients in specific departments. This information is contained on the **Organization** tab in the recipient's properties.
   - **Recipient is in a Company** Select this check box if you want the e-mail address policy to include only recipients in specific companies. This information is contained on the **Organization** tab in the recipient's properties.

Note:
The **State or Province**, **Department**, and **Company** conditions are based on attributes that are applicable only to mailboxes, mail users, and mail contacts. These conditions do not apply to mail-enabled distribution groups. If you configure any of these conditions for an e-mail address policy, you will in effect be excluding all mail-enabled distribution groups.

- **Custom Attribute equals Value** There are 15 custom attributes for each recipient. There is a separate condition for each custom attribute. If you want the e-mail address policy to include only recipients that have a specific value set for a specific custom attribute, select the check box that corresponds to that custom attribute.

Step 2: Edit the conditions by selecting an underlined value If you select any conditions in Step 1, each condition you select will append to the definition of the e-mail address policy. For example, if you selected the **Recipient is in a State or Province** check box in Step 1, you will see **in the specified State or Province(s)** condition in Step 2.
For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.
If you click an underlined value for the **State or Province**, **Department**, or **Company** conditions, a dialog box appears in which you can specify the values for the condition. To create values for the condition, use the following buttons in the dialog box:

- **Add** Enter a value in the text box and click **Add**. You can add more than one value, but you cannot enter duplicate values.
- **Edit** To modify an existing value, select it from the list, and then click **Edit**.
- To remove an existing value, select it from the list, and then click .

If you click an underlined value for a custom attribute condition, a dialog box appears in which you can specify the value for the condition. You can specify a single value for each custom attribute. Type the value in the text box and click **OK**.

Important:
The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.

Preview Click this button to view the recipients that will be contained in the e-mail address policy, based on the conditions that you specified.

5. On the **E-Mail Addresses** page, specify an e-mail address for your e-mail address policy.
   - **Add** Click **Add** to add a new e-mail address for the policy. Use the drop-down box to select from the following address types:

     SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address. The following settings are available:
     ?Select the **E-mail address local part** check box and use the corresponding options to configure how the local part of the SMTP e-mail address will appear. The local part of an e-mail address is the name that appears before the at sign (@). If you clear the check box, the local part uses the recipient's alias.
     ?Click **Select the accepted domain for the e-mail address** and then click **Browse** to select the e-mail address domain to which this e-mail address policy applies. You can also create additional e-mail address policies if your organization receives mail for multiple domains, or if your default domain is used strictly for

internal purposes and you use a different external mail domain.
?Click **Specify the custom fully qualified domain name (FQDN) for the e-mail address**, and then type the FQDN for the domain part of the e-mail address that appears after the at sign (@). This FQDN must match an accepted domain.
Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to a mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.

6. On the **Schedule** page, complete the following fields:
   - **Apply the e-mail address policy** Select one of the following options to specify when the e-mail address policy should be applied.
     Do not apply Click this button to create the e-mail address policy without applying it to the mailboxes. For more information, see Apply an E-Mail Address Policy.
     Immediately Click this button to apply the e-mail address policy as soon as the e-mail address policy is created.
     At the following time Click this button and use the corresponding lists to specify a time to apply the new e-mail address policy.
   - **Cancel tasks that are still running after (hours)** Select this check box and use the corresponding text box to specify how long the new e-mail address policy task will run. The default is 8 hours.

7. On the **New E-Mail Address Policy** page, review your configuration settings. Click **New** to create the e-mail address policy. Click **Back** to make configuration changes.

8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
9. Click **Finish** to close the wizard.

Use the Shell to create an e-mail address

policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

This example creates a e-mail address policy that includes mailbox users in the Southeast offices who will have e-mail addresses that include their last name combined with the first two letters of their first name.

```
New-EmailAddressPolicy -Name "southeast offices" -IncludedRecipients MailboxUsers
```

Understanding E-Mail Address Policies

Apply an E-Mail Address Policy

Edit an E-Mail Address Policy

1.8.3.11.3 Create an E-Mail Address Policy By Using Recipient Filters

Create an E-Mail Address Policy By Using Recipient Filters

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to create an e-mail address policy by using recipient filters. To learn more about e-mail address policies, see Understanding E-Mail Address Policies.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Prerequisites

- Before an SMTP address domain can be used in an e-mail address policy, you must configure an accepted domain. For information about configuring accepted domains, see Understanding Accepted Domains.
- To use the *RecipientFilter* parameter to create a custom filter, you must specify a string for the filter. The Shell uses OPath for the filtering syntax. OPath is a querying language designed to query object data sources. For more information about the OPath filtering syntax, see Creating Filters in Recipient Commands.

Important:

If you use a recipient filter to create or edit an e-mail address policy, you can't use the EMC to edit the e-mail address policy. You must use the **Set-EmailAddressPolicy** cmdlet in the Shell. For detailed syntax and parameter information, see Set-EmailAddressPolicy.

Use the Shell to create an e-mail address

policy by using recipient filters

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to create an e-mail address policy by using recipient filters.

To create an e-mail address policy by using recipient filters, use the following syntax.

```
New-EmailAddressPolicy -Name <String> -RecipientFilter <String>
```

This example creates an e-mail address policy that applies to all executives and for which the local part of the e-mail address consists of the first two letters of their first name and their entire last name.

```
New-EmailAddressPolicy -Name 'Execs' -EnabledEmailAddressTemplates 'SMTP:%2g%s@co
```

For detailed syntax and parameter information, see New-EmailAddressPolicy.

1.8.3.11.4 Change E-Mail Address Policy Priorities

Change E-Mail Address Policy Priorities

Mailbox > Managing Mailbox Servers > Managing E-Mail Address Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Change Priority** dialog box to change the priority of your e-mail address policies.

When you create an e-mail address policy in the Exchange Management Console (EMC), or when you create a policy in the Exchange Management Shell and don't define the priority, by default, the new e-mail address policy will be assigned a priority of 1. However, if you already specified a priority for the policy, subsequent policies that you create will be assigned a lower priority.

For example, let's say you already have two e-mail address policies, and you used the EMC or the Shell to assign them priorities of 1 and 2**.** If you create another policy, it will automatically be assigned a priority of 3. However, let's say you have two policies, and you used the EMC or the Shell to specify that one of them is priority 1, but the other policy was assigned a default priority of 2 when it was created. In this case, the next policy you create will, by default, become the priority 2 policy. The previous priority 2 policy will be assigned a priority of 3.

Note:
You can't change the priority of the Default Policy. The Default Policy's priority will always be "Lowest".

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

What Do You Want to Do?

- Use the EMC to change the priority of an e-mail address policy

- Use the Shell to change the priority of an e-mail address policy

Use the EMC to change the priority of an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **E-Mail Address Policies** tab, and then select the e-mail address policy for which you want to change the priority.
3. In the action pane, click **Change Priority**.

   Note:
   This action is available only when you have more than one e-mail address policy (not including the default policy).

4. In **Change E-mail Address Policy Priority**, type the priority number for the e-mail address policy.

   Note:
   You can't change the priority to a level higher than the number of e-mail address policies you currently have in your organization.

5. Click **OK**.

Use the Shell to change the priority of an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

This example changes the priority of the e-mail address policy Conference Rooms to priority 5.

Note:
You can't change the priority to a level higher than the number of e-mail address policies you currently have in your organization.

```
Set-EmailAddressPolicy -Identity "Conference Rooms" -Priority 5
```

For More Information

Understanding E-Mail Address Policies

Edit an E-Mail Address Policy

1.8.3.11.5 Edit an E-Mail Address Policy

Edit an E-Mail Address Policy

Mailbox > Managing Mailbox Servers > Managing E-Mail Address Policies >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

E-mail address policies generate the primary and secondary e-mail addresses for your recipients (which include users, contacts, and groups) so they can receive and send e-mail. You can use the Edit E-mail Address Policy wizard to modify the settings of a policy.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Caution

You can't use the EMC to edit an e-mail address policy if the policy was created by using one of the following methods:

- **Exchange Server 2003** If this is an Exchange Server 2003 e-mail address policy, you must use Exchange System Manager in Exchange 2003 to edit this object or upgrade the object to an Exchange 2010 object. For more information, see Upgrade Custom LDAP Filters to OPATH Filters.
- **Exchange Management Shell** Some e-mail address policy settings that you can set in the Shell cannot be managed in the EMC. If this is an e-mail address policy that was created or edited by using the Shell, use the Shell to edit this policy.

What Do You Want to Do?

- Use the EMC to edit an e-mail address policy
- Use the Shell to edit an e-mail address policy

Use the EMC to edit an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **E-mail Address Policies** tab, and then select the policy you want to edit.
3. In the action pane, click **Edit**.
4. On the **Introduction** page, edit the following fields to define the recipient scope:
   - **Name** This box contains the display name of the e-mail address policy that you specified when it was created. You can modify the name. The name can contain as many as 64 characters but cannot include wildcard characters.
   - **Select the recipient container where you want to apply the filter** If you want to specify a different recipient container, click **Browse** to open the **Select Organizational Unit** dialog box. Specify an organizational unit (OU), and then click **OK**. The recipient container filters the recipients that the e-mail address policy will affect based upon their location in Active Directory.
   - Select the recipient types you want to include in the policy. You can select **All recipient types** or **The following specific types**. If you select **The following specific types**, you can select one or more of the following recipient types:

     Users with Exchange mailboxes Select this check box if you want your e-mail address policy to apply to users who have Exchange 2010, Exchange Server 2007, or Exchange Server

2003 mailboxes. Users with Exchange mailboxes are those that have a user domain account and a mailbox in the Exchange organization.
Users with external e-mail addresses Select this check box if you want your e-mail address policy to apply to users who have external e-mail addresses. Users with external e-mail accounts have user domain accounts in the Active Directory directory service, but use e-mail accounts that are external to the organization. This enables them to be included in the global address list (GAL) and added to distribution lists.
Resource mailboxes Select this check box if you want your e-mail address policy to apply to Exchange resource mailboxes. Resource mailboxes let you administer company resources through a mailbox, such as a conference room or a company vehicle.
Contacts with external e-mail addresses Select this check box if you want your e-mail address policy to apply to contacts with external e-mail addresses. Contacts with external e-mail accounts do not have user domain accounts in Active Directory, but the external e-mail address is available in the GAL.
Mail-enabled groups Select this check box if you want your e-mail address policy to apply to security groups or distribution groups that have been mail-enabled. Mail-enabled groups are similar to distribution groups. E-mail messages that are sent to a mail-enabled group account will be delivered to several recipients.

5. On the **Conditions** page, edit the following fields to further filter the recipients who will be affected by this e-mail address policy:
Step 1: Select condition(s) Use this section to set one or more conditions for your e-mail address policy. If you don't want to set any conditions for the policy, don't select any of the check boxes.
You can select from the following conditions:
   - **Recipient is in a State or Province** Select this check box if you want the e-mail address policy to include only recipients from specific states or provinces. This information is contained on the **Address and Phone** tab in the recipient's properties.
   - **Recipient is in a Department** Select this check box if you want the e-mail address policy to include only recipients in specific departments. This information is contained on the **Organization** tab in the recipient's properties.
   - **Recipient is in a Company** Select this check box if you want the e-mail address policy to include only recipients in specific companies. This information is contained on the **Organization** tab in the recipient's properties.

Note:
The **State or Province**, **Department**, and **Company** conditions are based on attributes that are applicable only to mailboxes, mail users, and mail contacts. These conditions do not apply to mail-enabled distribution groups. If you configure any of these conditions for an e-mail address policy, you will in effect be excluding all mail-enabled distribution groups.

   - **Custom Attribute equals Value** There are 15 custom attributes for each recipient. There is a separate condition for each custom attribute. If you want the e-mail address policy to include only recipients that have a specific value set for a specific custom attribute, select the check box that corresponds to that custom attribute.

Step 2: Edit the conditions by selecting an underlined value If you select any conditions in Step 1, each condition you select will append to the definition of the e-mail address policy. For example, if you selected the

Recipient is in a State or Province check box in Step 1, you will see **in the specified State or Province(s)** condition in Step 2.
For each condition, click the underlined term to create your condition. By default, the underlined term for new conditions will read **specified**. After you edit the condition, the underlined term will change to the value that you specified.
If you click an underlined value for the **State or Province**, **Department**, or **Company** conditions, a dialog box appears in which you can specify the values for the condition. To create values for the condition, use the following buttons in the dialog box:

- **Add** Enter a value in the text box and click **Add**. You can add more than one value, but you cannot enter duplicate values.
- **Edit** To modify an existing value, select it from the list, and then click **Edit**.
- To remove an existing value, select it from the list, and then click .

If you click an underlined value for a custom attribute condition, a dialog box appears in which you can specify the value for the condition. You can specify a single value for each custom attribute. Type the value in the text box and click **OK**.

Important:

The values that you enter in these dialog boxes must exactly match those that appear in the recipient's properties. For example, if you enter **Washington** in the **Specify State or Province** dialog box, but the **Address and Phone** tab in the recipient's properties lists the state as **WA**, the condition will not be met.

Preview Click this button to view the recipients that will be contained in the e-mail address policy, based on the conditions that you specified.

6. On the **E-Mail Addresses** page, specify an e-mail address for your e-mail address policy.
   - **Add** Click **Add** to add a new e-mail address for the policy. Use the drop-down box to select from the following address types:
     SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address. The following settings are available:
     ?Select the **E-mail address local part** check box and use the corresponding options to configure how the local part of the SMTP e-mail address will appear. The local part of an e-mail address is the name that appears before the at sign (@). If you clear the check box, the local part uses the recipient's alias.
     ?Click **Select the accepted domain for the e-mail address** and then click **Browse** to select the e-mail address domain to which this e-mail address policy applies. You can also create additional e-mail address policies if your organization receives mail for multiple domains, or if your default domain is used strictly for internal purposes and you use a different external mail domain.
     ?Click **Specify the custom fully qualified domain name (FQDN) for the e-mail address**, and then type the FQDN for the domain part of the e-mail address that appears after the at sign (@). This FQDN must match an accepted domain.
     Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

     Note:

     With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.
   - **Edit** Click this button to modify the selected e-mail address.
   - **Set as Reply** Click this button to set your selected address as the "reply

to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.

This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.

If an e-mail address policy in your Exchange organization applies to a mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.

7. On the **Schedule** page, complete the following fields:
   - **Apply the e-mail address policy** Select one of the following schedule settings to specify when the e-mail address policy should be applied:
     Do not apply Click this button to update the e-mail address policy without applying it to the intended recipients.
     Immediately Select this option to apply the e-mail address policy as soon as the e-mail address policy is edited.
     At the following time Select this option and use the corresponding lists to specify a time to apply the e-mail address policy.
   - **Cancel tasks that are still running after (hours)** Select this check box and use the corresponding text box to specify how long the e-mail address policy task will run. The default is 8 hours.

8. On the **Edit E-Mail Address Policy** page, review your configuration settings. Click **Edit** to apply your changes to the e-mail address policy. Click **Back** to make any configuration changes.

   Note:
   Although the process begins when you click **Edit**, you may have to wait several hours for the process to complete and the e-mail address policy to be applied.

9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
10. Click **Finish** to close the wizard.

Use the Shell to edit an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

This example edits the e-mail address policy South East Offices that currently includes recipients in Georgia, Alabama, and Louisiana to also include recipients in Texas.

```
Set-EmailAddressPolicy -Identity "South East Offices" -ConditionalStateorProvince
```

Note:
Although the e-mail address policy is already applied to recipients in Georgia, Alabama, and Louisiana, you must include them in the parameter because the parameter overwrites values; it doesn't append values to existing ones.

For More Information

Understanding E-Mail Address Policies

Managing E-Mail Address Policies

1.8.3.11.6 Remove an E-Mail Address Policy

Remove an E-Mail Address Policy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to remove an e-mail address policy. By default, Exchange contains an e-mail address policy that specifies the recipient's alias as the local part of the e-mail address and uses the default accepted domain. The local part of an e-mail address is the name that appears before the "at" sign (@).This e-mail address policy applies to all users in the organization. You can't remove this e-mail address policy.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Note:
If you remove an e-mail address policy that's used by recipients as the primary e-mail address policy, and no other e-mail address policies have been configured for recipients, the default e-mail address policy will be used.

Use the EMC to remove an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Hub Transport**.
2. In the result pane, click the **E-mail Address Policies** tab, and then select the e-mail address policy that you want to remove.
3. In the action pane, click **Remove**.
4. A warning appears. Click **Yes** to confirm that you want to remove the e-mail address policy.

Use the Shell to remove an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry in the Mailbox Permissions

topic.

To remove an e-mail address policy, use the following syntax.

```
Remove-EmailAddressPolicy -Identity <EmailAddressPolicyIdParameter>
```

This example removes the e-mail address policy South East Offices.

```
Remove-EmailAddressPolicy -Identity "South East Offices"
```

Type **Y** to confirm that you want to remove the e-mail address policy, and then press ENTER.

For detailed syntax and parameter information, see Remove-EmailAddressPolicy.

1.8.3.11.7 View the Members of an E-Mail Address Policy by Using the Exchange Management Shell

View the Members of an E-Mail Address Policy by Using the Exchange Management Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Exchange, you can view the members of an e-mail address policy by using the Edit E-Mail Address Policy wizard or New E-Mail Address Policy wizard in the EMC. However, if you used the Shell to create the policy, you can't use the EMC to view the members. Instead, you must use the **Get-Recipient** cmdlet in the Shell. For more information about how to use the EMC to view the members of an e-mail address policy, see Edit an E-Mail Address Policy.

Looking for other management tasks related to e-mail address policies? Check out Managing E-Mail Address Policies.

Use the Shell to view members of an e-mail address policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "E-mail address policies" entry and the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. This example finds the GUID of an e-mail address policy Tokyo Division.

```
Get-EmailAddressPolicy -Identity "Tokyo Division" | fl GUID
```

2. This example lists the members of an e-mail address policy by using the GUID of the e-mail address policy Tokyo Division.

```
Get-Recipient -Filter {PoliciesIncluded -like '{82025f12-8000-4d5e-805
```

For detailed syntax and parameter information, see Get-Recipient.

1.8.3.12 Managing Exchange Search

Managing Exchange Search

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-16*

Default Filters for Exchange Search

Disable or Enable Exchange Search

Diagnose Exchange Search Issues

Reseed the Search Catalog

1.8.3.12.1 Default Filters for Exchange Search

Default Filters for Exchange Search

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

In Microsoft Exchange Server 2010, Exchange Search includes a number of default filters to index different types of message attachments. You can also install filters to index additional file types.

When managing or using Exchange Search and the features that depend on it (such as Multi-Mailbox Search), consider the following factors:

- **Unsearchable items** When Exchange Search can't index a particular file type for any reason (for example, if a filter isn't installed), the search for the file type fails.
- **Safe lists** Certain file types don't contain any indexable data and therefore aren't indexed. These file types are indicated by a null filter entry in the registry. Items with an attachment type for which a null filter exists aren't searched and aren't returned as unsearchable items.

This topic includes the default filters and safe list filters that are installed on an Exchange 2010 Mailbox server. It also shows you how to use the Shell to retrieve.

Looking for other management tasks related to Exchange Search? Check out Managing Exchange Search.

Default Filters

The following table lists the default search filters installed on an Exchange 2010 Mailbox server. You can retrieve the list of default filters on a Mailbox server from the following registry location:

HKLM\SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\Filters

File extension

.ascx
.asm

Default Safe List Filters

The following table lists the default safe list filters that are installed on an Exchange 2010 Mailbox server. Exchange Search doesn't index file types for which a safe list filter exists. You can retrieve the safe list filters from the following registry location:

HKLM\SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\NullFilters

File extension
.aif
.aifc
.aiff

Use the Shell to retrieve default and safe

list filters

You can use the **Get-ChildItem** cmdlet to retrieve registry keys. This is particularly useful when you need to retrieve a large number of registry keys, such as the list of default and safe list search filters.

This example retrieves the list of default search filters used by Exchange Search on an Exchange 2010 Mailbox server.

```
Get-ChildItem HKLM:SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\Filters | Forma
```

This example retrieves the list of safe list filters for file types that aren't indexed by Exchange Search on an Exchange 2010 Mailbox server.

```
Get-ChildItem HKLM:SOFTWARE\Microsoft\ExchangeServer\v14\MSSearch\NullFilters | F
```

For detailed syntax and parameter information, see Get-ChildItem.

1.8.3.12.2 Disable or Enable Exchange Search

Disable or Enable Exchange Search

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-15*

By default, Exchange Search is enabled for all new mailbox databases and does not require additional configuration. However, if you want to stop Exchange Search from indexing mailbox content, you can disable it for individual mailbox databases or for an entire Mailbox server.

Caution:

Disabling Exchange Search impacts the functionality and performance of the full-text searches that are performed by your users using Outlook in online mode, Outlook Live, or on Windows Mobile devices.
The Discovery feature in Exchange 2010 also relies on Exchange Search. If you disable Exchange Search for a mailbox database or for a Mailbox server, Discovery won't return any messages from the database or server. For more information, see Understanding Multi-Mailbox Search.

Note:

You can enable or disable Exchange Search for servers or mailbox databases, but not for individual mailbox users.

What Do You Want to Do?

- Disable or enable Exchange Search for a mailbox database
- Disable or enable Exchange Search for a Mailbox server

Disable or enable Exchange Search for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Exchange Search" entry in the Mailbox Permissions topic.

This command disables Exchange Search for a mailbox database named EXCH01:

```
Set-MailboxDatabase "Mailbox Database (EXCH01)" -IndexEnabled $false
```

This command enables Exchange Search for a mailbox database named EXCH01:

```
Set-MailboxDatabase "Mailbox Database (EXCH01)" -IndexEnabled $true
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

Disable or enable Exchange Search for a Mailbox server

To disable or enable Exchange Search for a Mailbox server, you must disable and stop or enable and start the Microsoft Exchange Search Indexer service. You can use either the Services console or the Shell to do this.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Manage Exchange Search Indexer service on a Mailbox server" entry in the Mailbox Permissions topic.

Use the Services console

1. Navigate to **Start** > **Administrative Tools** > **Services**.
2. In the **Services** details pane, right-click the **Microsoft Exchange Search Indexer** service, and then select **Properties**.
3. On the **General** tab, in the **Startup type** list, select **Disabled** to disable the service or **Automatic** to start it automatically.

   Note:
   The startup type impacts the service the next time an attempt is made to start it, either automatically after the server is restarted or by manually starting the service. In the next step, the service is stopped or started manually.

4. Click **Stop** to stop the service or **Start** to start the service.

Use the Shell

The following examples stop and disable the Microsoft Exchange Search Indexer service.

```
Stop-Service MSExchangeSearch
Set-Service MSExchangeSearch -StartupType Disabled
```

The following examples configure the Exchange Search Indexer service to start automatically and then start the service.

```
Set-Service MSExchangeSearch -StartupType Automatic
Start-Service MSExchangeSearch
```

1.8.3.12.3 Diagnose Exchange Search Issues

Diagnose Exchange Search Issues

Mailbox > Managing Mailbox Servers > Managing Exchange Search >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Exchange Search indexes mailboxes and supported attachments in Exchange mailboxes. With increasing volumes of e-mail, increasing mailbox sizes and storage quotas, provisioning of personal archive mailboxes for users, and the introduction of Multi-Mailbox Search for performing discovery searches, Exchange Search is a critical component of the Mailbox servers in your Microsoft Exchange Server 2010 organization. Issues with Exchange Search can affect user productivity and impact Multi-Mailbox Search functionality.

To learn more about Exchange Search, see Understanding Exchange Search.

Looking for management tasks related to managing Exchange Search? See Managing Exchange Search.

Using the Test-ExchangeSearch Cmdlet

Step 5 of the procedure in this topic describes running the **Test-ExchangeSearch** cmdlet to help diagnose Exchange Search issues. You can use the **Test-ExchangeSearch** cmdlet to test Exchange Search functionality for a Mailbox server, a mailbox database, or a specific mailbox. The cmdlet delivers a test message to the specified mailbox (or to a database's system mailbox if a mailbox isn't specified), and then performs a search to determine whether the message is indexed, including the time taken to index it. Under normal conditions, Exchange Search indexes a message within about 10 seconds of the message being created or delivered to a mailbox. The test message is automatically deleted after the test.

Exchange 2010 includes the following enhancements to the **Test-ExchangeSearch** cmdlet:

- The *Mailbox* parameter has been added to the standard output.
- When you specify a server name, the cmdlet simultaneously tests all mailbox databases on the Mailbox server. For databases that are replicated to other Mailbox servers in a database availability group (DAG), if you run the command on a Mailbox server that doesn't contain the active database copy, the test is automatically performed against the server that contains the active database copy.
- When you use the cmdlet with the *MonitoringContext* parameter, it provides additional data that can be used by monitoring software such as Microsoft System Center Operations Manager 2007.
- When you use the cmdlet with the *Verbose* switch, the cmdlet returns detailed results and status for every step, and additional diagnostic information to help you troubleshoot issues related to search.

For detailed syntax and parameter information, see Test-ExchangeSearch.

Retrieving Unsearchable Items

You can use the **Get-FailedContentIndexDocuments** cmdlet to retrieve a list of unsearchable mailbox items that couldn't be successfully indexed by Exchange Search. You can run the cmdlet against a Mailbox server, a mailbox database, or a specific mailbox. The cmdlet returns details about each item that couldn't be searched. There are several reasons why a mailbox item can't be searched; for example, an e-mail message includes an attachment file type for which a search filter isn't installed. If a search filter for that file type is available, you can install it on your Exchange servers.

Important:

Search filters provided by Microsoft are tested and supported by Microsoft. We recommend that you test any third-party search filters in a test environment before installing them on Exchange servers in a production environment.

Note:
Messages that contain an attachment file format that's listed on the safe list aren't returned in the list of unsearchable items. For more details, see "Exchange Search and Attachments" in Understanding Exchange Search.

For detailed syntax and parameter information, see Get-FailedContentIndexDocuments.

Diagnose Exchange Search Issues

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Search" entry in the Mailbox Permissions topic.

1. **Check service state** Is the Microsoft Exchange Search Indexer (MSExchangeSearch) service started on the Mailbox server? If yes, go to Step 2. If no, use the Services MMC snap-in to verify that the MSExchangeSearch service is running as follows:
   1.a.Click **Start**, point to **Administrative Tools**, and then click **Services**.
   1.b.In **Services**, verify that the **Status** for the **Microsoft Exchange Search Indexer** service is listed as **Started**.
2. **Check mailbox database configuration** Is the *IndexEnabled* parameter set to true for the user's mailbox database? If yes, go to Step 3. If no, run the following command in the Shell to verify that the *IndexEnabled* flag is set to true.

   ```
   Get-MailboxDatabase | Format-Table Name,IndexEnabled
   ```

   For detailed syntax and parameter information, see Get-MailboxDatabase.
3. **Check mailbox database crawl state** Has the Exchange database been crawled? If yes, go to Step 4. If no, use Reliability and Performance Monitor to check the **Full Crawl Mode Status** counter of the **MSExchange Search Indices** performance object. Perform the following steps:
   3.a.Open Reliability and Performance Monitor (perfmon.exe).
   3.b.In the console tree, under **Monitoring Tools**, click **Performance Monitor**.
   3.c.In the Performance Monitor pane, click **Add** (green plus sign).
   3.d.In **Add Counters**, in the **Select counters from computer** list, select the server on which the mailbox database you want to monitor is located.
   3.e.In the unlabeled box below the **Select counters from computer** list, select the **MSExchange Search Indices** performance object.
   3.f.In the **Instances of selected object** box, select the instance for the user's mailbox database.
   3.g.Click **Add**, and then click **OK**.
   In the Performance Monitor pane, the **MSExchange Search Indices** performance object is listed in the **Object** column, and its various counters are listed in the **Counter** column. View the **Full Crawl Mode Status** counter. When the database is still being crawled, it has a value of **1**. When the crawl is complete, the value is **0**.
   To view other relevant search counters, use the preceding Steps a though g to add the following performance objects:
   3.h.**MSExchange Search Indexer**
   3.i.**MSFTESQL-Exchange:Catalogs**
   3.j.**MSFTESQL-Exchange:FD**
   3.k.**MSFTESQL-Exchange:Indexer**
   3.l.**MSFTESQL-Exchange:Service**
   For information about using Performance Monitor, see Performance and Reliability Monitoring Step-by-Step Guide for Windows Server 2008
4. **Check the database copy indexing health** Is the content index healthy? Use the **Get-MailboxDatabaseCopyStatus** cmdlet to check the content indexing health for a database copy.

   ```
   Get-MailboxDatabaseCopyStatus | Format-Table Identity,ActiveDatabaseCo
   ```

   For detailed syntax and parameter information, see Get-

MailboxDatabaseCopyStatus.

5. **Run the Test-ExchangeSearch cmdlet** If the mailbox database has already been crawled, you can run the **Test-ExchangeSearch** cmdlet for the mailbox database or for a specific mailbox.

```
Test-ExchangeSearch -Identity AlanBrewer@contoso.com
```

For detailed syntax and parameter information, see Test-ExchangeSearch.

6. **Check the Application event log** Using Event Viewer or the Shell, check the Application event log for search-related error messages. Check the **Source: MSExchangeSearch Indexer** and **msftesql-Exchange** events. For more information, follow the link in the event log entry.
7. **Restart the Microsoft Exchange Search Indexer service** Use the Services MMC snap-in or the Shell to stop and then restart the Microsoft Exchange Search Indexer (MSExchangeSearch) service:
   7.a.Click **Start**, point to **Administrative Tools**, and then click **Services**.
   7.b.In **Services**, right-click **Microsoft Exchange Search Indexer**, and then click **Stop**. After the service is stopped, right-click the service again, and then click **Start**.
8. **Reseed the search catalog** In some cases, such as when the search catalog is corrupted, you may need to reseed the catalog. When a search catalog needs to be reseeded, Exchange Search notifies you by logging entries in the Application event log. For more information about reseeding the Search catalog, see Reseed the Search Catalog.

1.8.3.12.4 Reseed the Search Catalog

Reseed the Search Catalog

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If the content index catalog for a mailbox database copy gets corrupted, you may need to reseed the catalog. Corrupted content indexes are indicated in the Application event log by the following event.

Event ID	Level	Source	Details
123	Error	ExchangeStoreDB	At *<timestamp>* the Microsoft Exchange Information Store Database *<identity>* copy on this server experienced a corrupted search catalog. Consult the event log on the server for other "ExchangeStoreDb" and "MSExchange Search Indexer" events for more specific information about the failure. Reseeding the

			catalog is recommended via the 'Update-MailboxDatabaseCopy' task.

Note:
If the mailbox database copy is the only copy, Exchange Search must create a new content index catalog. You can use the `ResetSearchIndex.ps1` script to do this.

Looking for other management tasks related to Exchange Search? Check out Managing Exchange Search.

Reseed the content index catalog from any source

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Search" entry in the Mailbox Permissions topic.

This example reseeds the content index catalog for the database copy DB1 on Mailbox server MBX1 from any source server that has a copy of the database.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1 -CatalogOnly
```

For detailed syntax and parameter information, see Update-MailboxDatabaseCopy.

Reseed the content index catalog from a specific source

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Search" entry in the Mailbox Permissions topic.

This example reseeds the content index catalog for the database copy DB1 on Mailbox server MBX1 from Mailbox server MBX2, which also has a copy of the database.

```
Update-MailboxDatabaseCopy -Identity DB1\MBX1 -SourceServer MBX2 -CatalogOnly
```

For detailed syntax and parameter information, see Update-MailboxDatabaseCopy.

1.8.3.12.5 Error Codes for Exchange Search Failed Documents

Error Codes for Exchange Search Failed Documents

Mailbox > Managing Mailbox Servers > Managing Exchange Search >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-30*

When Exchange Search fails to index a document, the document is treated as a *failed document*. When you use the Get-FailedContentIndexDocuments cmdlet to retrieve a list of failed documents, an error code is returned for each failed document.

The following table lists the error codes, error messages, and associated metadata for

errors that occur when Exchange Search fails to index a document.

Error Code	Severity	Symbolic Name	Message
0x0DA5	Warning	GTHR_E_SINGLE_THREADED_EMBEDDING	The system attempted to load a filter marked as apartment from an embedded component in a multi-threaded filter daemon. The document will be retried in a single-threaded filter daemon. Since multithreaded filtering is more efficient, try to obtain the version of the filter that is multi-threaded.
0x0D16	Warning	GTHR_E_FILTER_NOT_FOUND	A filter for the document cannot be created, likely because it isn't installed. Install the corresponding filter for this document format to index this file.
0x120D	Warning	PRTH_E_MIME_EXCLUDED	The URL is excluded because its content type (multipart/x-mixed-replace) is not supported.
0x120E	Warning	PRTH_E_CANT_TRANSFORM_EXTERNAL_ACL	Search was unable to convert the Access Control List of the crawled store into a Windows NT Access Control List. Make sure local information is not used in the store.
0x1217	Warning	PRTH_E_LOAD_FAILED	Loading Protocol handler failed.
0x1218	Warning	PRTH_E_INIT_FAILED	Initializing Protocol handler failed.
0x3600	Warning	FTE_E_CATALOG_ALREADY_MOUNTED	A catalog is already mounted with this name, so another can't be mounted.
0x3601	Warning	FTE_E_CATALOG_NOT_FOUND	The specified catalog was not found in the

			current list of mounted catalogs.
0x3603	Warning	FTE_E_PIPE_NOT_CONNECTED	The named pipe used to communicate with the filter daemon has not been connected.
0x3604	Warning	FTE_E_ADMIN_BLOB_CORRUPT	The configuration data given to the MSFTESQL service is corrupt.
0x3605	Warning	FTE_E_FILTER_SINGLE_THREADED	The system attempted to load an apartment threading model filter marked in a multi-threaded filter daemon. The document will be retried in a single-threaded filter daemon process. Since multithreaded filtering is more efficient, try to obtain the version of the filter that is multi-threaded.
0x3606	Warning	FTE_E_ERROR_WRITING_REGISTRY	The value cannot be set, because the object was already deleted or was not initialized properly. Make sure the object reference is still valid, increase the registry size, or recreate the catalog configuration.
0x3607	Warning	FTE_E_PROJECT_SHUTDOWN	An internal interface is being used after the corresponding catalog has been shutdown. The operation will be aborted.
0x3608	Warning	FTE_E_PROJECT_NOT_INITALIZED	An internal interface is being used prior to being initialized. The operation will be aborted.
0x3609	Warning	FTE_E_PIPE_DATA_CORRUPTED	Data transferred between the MSFTESQL service and a filter daemon process is corrupted.

			This is an internal error.
0x3610	Warning	FTE_E_URB_TOO_BIG	This is an internal error: The URB has exceeded the maximum size.
0x3611	Warning	FTE_E_INVALID_DOCID	This is an internal error: Document IDs should be greater than 0 and less than or equal to 0x7FFFFCCf.
0x3612	Warning	FTE_E_PAUSE_EXTERNAL	An external status change has put the catalog in a paused state.
0x3613	Warning	FTE_E_REJECTED_DUE_TO_PROJECT_STATUS	A status change is occurring or the project is in a force paused state, so MSFTESQL cannot accept input at this time.
0x3614	Warning	FTE_E_FD_DID_NOT_CONNECT	The MSFTEFD process was launched but did not connect with the MSFTESQL service.
0x3616	Warning	FTE_E_PROGID_REQUIRED	This is an internal error: Initialization of the datasink is incorrect. At least one protocol handler PROGID is required.
0x3617	Warning	FTE_E_STATIC_THREAD_INVALID_ARGUMENTS	This is an internal error: A static thread has gotten invalid arguments and will force batches to be aborted and retried.
0x3618	Warning	FTE_E_CATALOG_ALREADY_EXISTS	A catalog already exists with this name, so another can be created or mounted.
0x3619	Success	FTE_S_RESOURCES_STARTING_TO_GET_LOW	The Full Text Engine's input queue is getting full. This batch has been accepted for processing. This success code is intended to help pause input until the queue is less full.

0x361A	Warning	FTE_E_PATH_TOO_LONG	A file path exceeds the maximum limit for paths in Windows, so it can't be used.
0x361B	Warning	FTE_INVALID_ADMIN_CLIENT	Access is denied to the caller of this administration interface.
0x361C	Warning	FTE_E_COM_SIGNATURE_VALIDATION	Signature validation cannot be performed on modules loaded by COM, so the object will not be created. The object is likely a filter, wordbreaker, stemmer, or protocol handler.
0x361D	Warning	FTE_E_AFFINITY_MASK	The processor affinity mask is invalid.
0x3621	Warning	FTE_E_EXCEEDED_MAX_PLUGINS	The maximum number of plug-ins has been exceeded, so a new plug-in can't be loaded.
0x3622	Success	FTE_S_BEYOND_QUOTA	The Full Text Engine's input queue is full. This batch has been accepted for processing; however, the Full Text Engine will soon go into a forced paused state until the queue is less full.
0x3624	Warning	FTE_E_DUPLICATE_OBJECT	An object could not be inserted because it was a duplicate of an existing object. The object may be a catalog or other named entity.
0x3625	Success	FTE_S_REDUNDANT	This transaction was superseded by a subsequent transaction, so it will not be completed.
0x3626	Warning	FTE_E_REDUNDANT_TRAN_FAILURE	The transaction that superseded this one ended in error.
0x3627	Warning	FTE_E_DEPENDENT_TRAN_FAILED_TO_PERSIST	The transaction that superseded this one ended in error.

0x3628	Warning	FTE_E_FD_SHUTDOWN	This is an internal error: This request cannot be completed because the Filter Daemon has been shutdown.
0x3629	Warning	FTE_E_CATALOG_DOES_NOT_EXIST	The catalog does not exist, so the operation can't be performed.
0x362A	Warning	FTE_E_NO_PLUGINS	There are no plug-in components in the indexing pipeline, so the data collected will not be used.
0x362B	Success	FTE_S_STATUS_CHANGE_REQUEST	The project state has changed or is changing due to a status change request.
0x362D	Warning	FTE_E_ANOTHER_STATUS_CHANGE_IS_ALREADY_ACTIVE	A status change is active on another thread. Since only one status change is allowed at a time this request can't be handled.
0x362E	Success	FTE_S_RESUME	This is an internal error: The project will be resumed.
0x362F	Warning	FTE_E_NOT_PROCESSED_DUE_TO_PREVIOUS_ERRORS	A previous error prevented further processing of the batch.
0x3630	Warning	FTE_E_FD_TIMEOUT	The filter daemon process MSFTEFD timed out for an unknown reason. This may indicate a bug in a filter, wordbreaker, or protocol handler.
0x3631	Warning	FTE_E_RESOURCE_SHUTDOWN	This is an internal error: This activity is no longer valid because the resource is shutdown.
0x3632	Warning	FTE_E_INVALID_PROPERTY	The property specified is invalid.
0x3633	Warning	FTE_E_NO_MORE_PROPERTIES	There are no more properties.

0x3634	Warning	FTE_E_UNKNOWN_PLUGIN	The plug-in specified is not known likely because it isn't loaded, so the operation can't succeed. Only specify plug-ins that are loaded.
0x3635	Warning	FTE_E_LIBRARY_NOT_LOADED	The performance monitor library could not be loaded.
0x3636	Warning	FTE_E_PERFMON_FULL	There are no more slots available for this performance monitor instance
0x1600	CoError	QUERY_E_FAILED	Call failed for unknown reason.
0x1601	CoError	QUERY_E_INVALIDQUERY	Invalid parameter.
0x1602	CoError	QUERY_E_INVALIDRESTRICTION	The query restriction could not be parsed.
0x1605	CoError	QUERY_E_ALLNOISE	A clause of the query contained only ignored words.
0x1606	CoError	QUERY_E_TOOCOMPLEX	The query was too complex to be executed.
0x1607	CoError	QUERY_E_TIMEDOUT	The query exceeded its execution time limit.
0x160C	CoError	QUERY_S_NO_QUERY	The catalog is in a state where indexing continues, but queries are not allowed.
0x160D	CoError	QUERY_E_ALLNOISE_AND_NO_RELDOC	A clause of the query contained only ignored words and all the relevant documents specified are not found.
0x160E	CoError	QUERY_E_NO_RELDOC	All the relevant documents specified in the query are not found.
0x160F	CoError	QUERY_E_ALLNOISE_AND_NO_RELPROP	A clause of the query contained only ignored words and no data is found in the

			relevant documents under the specified property(ies).
0x1613	CoError	QUERY_E_INVALID_DOCUMENT_IDENTIFIER	The document identifier specified is not valid.
0x1614	CoError	QUERY_E_INCORRECT_VERSION	The server version is older and cannot handle this query
0x1618	CoError	QUERY_E_UPGRADEINPROGRESS	Queries are disabled due to catalog upgrade. Try your query again in a few minutes.
0x1680	Success	FDAEMON_W_WORDLISTFULL	Wordlist has reached maximum size. Additional documents should not be filtered.
0x1681	CoError	FDAEMON_E_LOWRESOURCE	The system is running out of one of more resources needed for filtering, usually memory.
0x1682	CoError	FDAEMON_E_FATALERROR	A critical error occurred during document filtering. Consult system administrator.
0x1683	CoError	FDAEMON_E_PARTITIONDELETED	Documents not stored in content index because partition has been deleted.
0x1684	CoError	FDAEMON_E_CHANGEUPDATEFAILED	Documents not stored in content index because update of changelist failed.
0x1685	Success	FDAEMON_W_EMPTYWORDLIST	Final wordlist was empty.
0x1686	CoError	FDAEMON_E_WORDLISTCOMMITFAILED	Commit of wordlist failed. Data not available for query.
0x1688	CoError	FDAEMON_E_TOOMANYFILTEREDBLOCKS	During document filtering the limit on buffers has been exceeded.
0x1730	CoError	FILTER_E_TOO_BIG	File is too large to filter.
0x1733	Success	FILTER_S_CONTENTSCAN_DELAYED	A content scan of the disk needs to be

			scheduled for execution later.
0x1734	CoFail	FILTER_E_CONTENTINDEXCORRUPT	The content index is corrupt. A content scan will to be scheduled after chkdsk or autochk is run.
0x1735	Success	FILTER_S_DISK_FULL	The disk is getting full.
0x1736	CoError	FILTER_E_ALREADY_OPEN	A file is already open. Cannot open another one while a file is open.
0x1738	CoError	FILTER_E_IN_USE	The document is in use by another process.
0x173D	CoError	FILTER_E_OFFLINE	The document is offline.
0x173E	CoError	FILTER_E_PARTIALLY_FILTERED	The document was too large to filter in its entirety. Portions of the document were not emitted.
0x1781	Success	LANGUAGE_S_LARGE_WORD	Word larger than maximum length. May be truncated by word sink.
0x1783	CoError	WBREAK_E_BUFFER_TOO_SMALL	Buffer too small to hold composed phrase.
0x1784	CoError	LANGUAGE_E_DATABASE_NOT_FOUND	Language database/ cache file could not be found.
0x1785	CoError	WBREAK_E_INIT_FAILED	Initialization of word breaker failed.
0x1800	CoFail	CI_CORRUPT_DATABASE	The content index is corrupt.
0x1801	CoFail	CI_CORRUPT_CATALOG	The content index meta data is corrupt.
0x1802	CoFail	CI_INVALID_PARTITION	The content index partition is invalid.
0x1805	CoFail	CI_OUT_OF_INDEX_IDS	The content index is out of index ids.
0x1806	CoFail	CI_NO_CATALOG	There is no catalog.
0x1807	CoFail	CI_CORRUPT_FILTER_	The filter buffer is

		BUFFER	corrupt.
0x1808	CoFail	CI_INVALID_INDEX	The index is invalid.
0x1809	CoFail	CI_PROPSTORE_INCONSISTENCY	Inconsistency in property store detected.
0x180B	CoError	CI_E_NOT_INITIALIZED	The object is not initialzed.
0x180F	CoError	CI_E_INVALID_STATE	The object is not in a valid state.
0x1811	CoError	CI_E_DISK_FULL	The disk is full and the specified operation cannot be done.
0x1812	CoError	CI_E_SHUTDOWN	The request could not be completed because the process and/or catalog are being shutdown
0x1818	CoError	CI_E_UPDATES_DISABLED	A document update was rejected because updates were disabled.
0x181B	CoError	CI_E_SHARING_VIOLATION	A sharing or locking violation caused a failure.
0x181C	CoError	CI_E_LOGON_FAILURE	A logon permission violation caused a failure.
0x181E	CoError	CI_E_STRANGE_PAGEORSECTOR_SIZE	Page size is not an integral multiple of the sector size of the volume where index is located.
0x181F	CoError	CI_E_TIMEOUT	Service is too busy.
0x1820	CoError	CI_E_NOT_RUNNING	Service is not running.
0x1828	CoError	CI_E_CONFIG_DISK_FULL	The disk has reached its configured space limit.
0x182D	CoFail	CI_E_CORRUPT_FWIDX	The forward index is corrupt.
0x182E	CoFail	CI_E_DIACRITIC_SETTINGS_DIFFER	Catalog was created with different diacritic settings.
0x182F	CoFail	CI_E_INVALID_THESAURUS_FILE	The thesaurus file is invalid.

0x1830	CoFail	CI_E_THESAURUS_FILE_BOM_MISSING	Unicode byte order mark (0xFEFF) missing at the beginning of thesaurus file.
0x170b	CoError	FILTER_E_PASSWORD	File was not filtered due to password protection.
0x170C	CoError	FILTER_E_UNKNOWNFORMAT	The document format is not recognized by the filter.

1.8.3.13 Managing Hierarchical Address Books

Managing Hierarchical Address Books

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-06-22*

Configure Hierarchical Address Books

1.8.3.13.1 Configure Hierarchical Address Books

Configure Hierarchical Address Books

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can configure a hierarchical address book (HAB), which is a feature in Microsoft Exchange Server 2010 and the Microsoft Outlook 2010 Address Book. With a HAB, users can browse recipients in their Exchange organization by using an organizational hierarchy. To learn more about HABs, see Understanding Hierarchical Address Books.

Prerequisites

- Read Understanding Hierarchical Address Books. You should understand if a HAB is appropriate for your Exchange organization.
- Understand how organizational units (OUs), groups, users, and contacts are currently configured in your Exchange organization.
- Understand the cmdlets and associated parameters in the following table, which are required to configure a HAB.

Cmdlet	Parameter
Set-OrganizationConfig	*HierarchicalAddressBookRoot*
Set-Group	*IsHierarchicalGroup* *SeniorityIndex* *PhoneticDisplayName*

Set-User	*SeniorityIndex* *PhoneticDisplayName*
Set-Contact	*SeniorityIndex* *PhoneticDisplayName*

Use the Shell to enable a hierarchical address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable a HAB. However, after you enable a HAB, you can use the EMC to manage the membership of the groups in the organizational hierarchy.

For this example, an OU called HAB will be created for the HAB. The name of the domain for the Exchange 2010 organization is Contoso-dom, and Contoso,Ltd will be the name of the top-level organization in the hierarchy (the *root organization*). Subordinate groups named Corporate Office, Product Support Organization, and Sales & Marketing Organization will be created as child organizations under Contoso,Ltd. Additionally, the groups Human Resources, Accounting Group, and Administration Group will be created as child organizations under Corporate Office.

For detailed information about creating distribution groups, see Create a Distribution Group.

1. Create an OU named HAB in the Contoso organization. You can use Active Directory Users and Computers or type the following at a command prompt.

   Note:
   Alternatively, you can use an existing OU in your Exchange forest.

   ```
   dsadd ou "OU=HAB,DC=Contoso-dom,DC=Contoso,DC=com"
   ```

   Note:
   For details, see Create a New Organizational Unit.

2. Create the root distribution group Contoso,Ltd for the HAB.

   Note:
   For the purposes of this topic, the Shell example is provided. However, you can also use the EMC to create a distribution group. For details, see Create a Distribution Group.

   ```
   New-DistributionGroup -Name "Contoso,Ltd" -DisplayName "Contoso,Ltd" -
   ```

3. Designate Contoso,Ltd as the root organization for the HAB.

   ```
   Set-OrganizationConfig -HierarchicalAddressBookRoot "Contoso,Ltd"
   ```

4. Create distribution groups for the other tiers in the HAB. For this example, you would create the following groups: Corporate Office, Product Support Organization, Sales & Marketing Organization, Human Resources, Accounting Group, and Administration Group. This example creates the distribution group Corporate Office.

   Note:
   For the purposes of this topic, the Shell example is provided. However, you can also use the EMC to create distribution groups. For details, see Create a Distribution Group.

```
New-DistributionGroup -Name "Corporate Office" -DisplayName "Corporate
```

5. Designate each of the groups as members of the HAB. For this example, you would designate the following groups as being hierarchical groups: Contoso,Ltd, Corporate Office, Product Support Organization, Sales & Marketing Organization, Human Resources, Accounting Group, and Administration Group. This example designates the distribution group Contoso,Ltd as a member of the HAB.

```
Set-Group -Identity "Contoso,Ltd" -IsHierarchicalGroup $true
```

6. Add each of the subordinate groups as members of the root organization. For this example, distribution groups Corporate Office, Product Support Organization, and Sales & Marketing Organization, are added as members of the root organization Contoso,Ltd in the HAB. This example adds the Corporate Office distribution group as a member of the Contoso,Ltd root distribution group.

Note:
This example uses the alias of the distribution groups.

```
Add-DistributionGroupMember -Identity "ContosoRoot" -Member "Corporate
```

7. Add each of the groups that are subordinate to the distribution group Corporate Office as members of the group. For this example, distribution groups Human Resources, Accounting Group, and Administration Group, are added as members of the distribution group Corporate Office. This example adds the Human Resources distribution group as a member of the Corporate Office distribution group.

Note:
This example uses the alias of the distribution groups and assumes the Human Resources distribution group alias is HumanResources.

```
Add-DistributionGroupMember -Identity "CorporateOffice" -Member "Human
```

8. Add users to the groups in the HAB. For this example, David Hamilton (SMTP address DHamilton@contoso.com) is an existing user in the OU Contoso-dom.Contoso.com/Users and will be added to the group Corporate Office. Repeat this step to add other users to groups in the HAB.

```
Add-DistributionGroupMember -Identity "CorporateOffice" -Member "DHami
```

9. Set the *SeniorityIndex* parameter for groups in the HAB. For this example, the Corporate Office group contains three child groups: Human Resources, Accounting Group, and Administration Group. Instead of having the groups listed in ascending alphabetical order, which is the default, the preferred sorting will be Human Resources (*SeniorityIndex* = 100), Accounting Group (*SeniorityIndex* = 50), and then Administration Group (*SeniorityIndex* = 25). This example sets the *SeniorityIndex* parameter for the Human Resources group to 100.

```
Set-Group -Identity "Human Resources" -SeniorityIndex 100
```

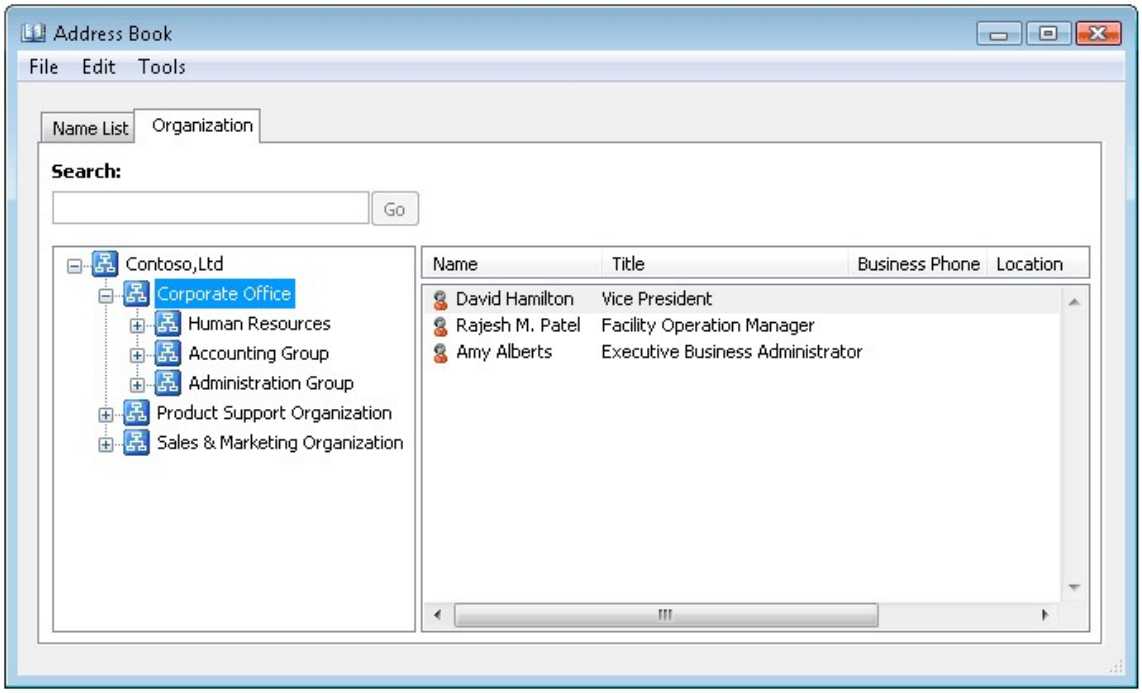
Note:
The *SeniorityIndex* parameter is a numerical value used to sort groups or users in descending numerical order in a HAB. If the *SeniorityIndex* parameter isn't set or is equal for two or more users, the HAB sorting order uses the *PhoneticDisplayName* parameter value to list the users in ascending alphabetical order. If the *PhoneticDisplayName* value isn't set, the HAB sorting order defaults to the *DisplayName* parameter value and lists the users in ascending alphabetical order.

10. Set the *SeniorityIndex* parameter for users in the HAB groups. For this example, the Corporate Office group contains three users: Amy Alberts, David Hamilton, and Rajesh M. Patel. Instead of having the users listed in ascending alphabetical order by default, the preferred sorting will be David

Hamilton (*SeniorityIndex* = 100), Rajesh M. Patel (*SeniorityIndex* = 50), and then Amy Alberts (*SeniorityIndex* = 25). This example sets the *SeniorityIndex* parameter for the user David Hamilton to 100.

```
Set-User -Identity "DHamilton@contoso.com" -SeniorityIndex 100
```

After completing the preceding steps, the HAB will be visible in Outlook 2010. To view the HAB, open Outlook 2010 and click **Address Book**. The HAB is displayed on the **Organization** tab, similar to the following figure.



After the HAB is created, you can use the EMC to manage the membership of the groups in the organizational hierarchy. However, you must use the Shell to modify the *SeniorityIndex* parameter for any new groups or users.

For detailed syntax and parameter information, see the following:

- New-DistributionGroup
- Set-OrganizationConfig
- Set-Group
- Add-DistributionGroupMember
- Set-User

Use the Shell to disable a hierarchical address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Distribution groups" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to disable a HAB.

This example disables the root organization used for the HAB.

```
Set-OrganizationConfig -HierarchicalAddressBookRoot $null
```

Note:
This command doesn't delete the root organization or child groups used in the HAB structure or reset the *SeniorityIndex* values for groups or users. It only prevents the HAB from being displayed in Outlook 2010. To enable the HAB with the same configuration settings again, you only need to enable the root organization again.

For detailed syntax and parameter information, see Set-OrganizationConfig.

1.8.3.14 Managing Mail Contacts and Mail Users

Managing Mail Contacts and Mail Users

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-18*

1.8.3.14.1 Create a Mail Contact

Create a Mail Contact

Mailbox > Managing Mailbox Servers > Managing Mail Contacts and Mail Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Mail contacts are mail-enabled Active Directory objects that contain information about people or organizations that exist outside your Exchange organization. Each mail contact has an external e-mail address.

Looking for other management tasks related to mail contacts? Check out Managing Mail Contacts and Mail Users.

Prerequisite

If you want to create a new mail contact in a domain that is different than the one in which your Exchange servers reside, you must first prepare that domain for Exchange 2010. To learn more about preparing a domain for Exchange 2010, see Prepare Active Directory and Domains.

What Do You Want to Do?

- Use the EMC to create a mail contact
- Use the Shell to create a mail contact

Use the EMC to create a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Mail Contact**.
3. On the **Introduction** page, under **Create a mail contact for**, select one of the following options.
   - **New contact** This button is selected by default. Click this button to create and mail-enable a new contact. If you click this button, you'll need to provide the required account information for the contact on the **Contact Information** page of this wizard.
   - **Existing contact** Click this button to mail-enable an existing contact in Active Directory. Click **Browse** to open the **Select Contact** dialog box. This dialog box displays a list of all contacts in the forest that aren't mail-enabled. Select the contact that you want, and then click **OK** to return to the wizard.
4. If you selected **New Contact** in Step 3, complete the following fields on the **Contact Information** page. Otherwise skip to Step 5:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name** Use this box to type the contact's first name. This field is optional.
   - **Initials** Use this box to type the contact's initials. This field is optional.
   - **Last name** Use this box to type the contact's last name. This field is optional.
   - **Name** Use this box to type a name for the contact. This is the name that's listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this field. The name can't exceed 64 characters.
   - **Alias** Use this box to type a unique alias (64 characters or less) for the contact. This field is required.
   - **External e-mail address** To specify the external e-mail address, perform one of the following tasks:

     To specify a SMTP e-mail address, click **Edit**. In the **SMTP**

address dialog box, type the SMTP e-mail address.

Note:
Exchange validates SMTP addresses for proper formatting. If your entry is inconsistent with the SMTP format, an error message will be displayed when you click **OK**.

To specify a custom e-mail address, click the arrow next to **Edit**, and then click **Custom Address**. In the **Custom Address** dialog box, use the **E-mail address** box to type the e-mail address and the **E-mail type** box to specify the e-mail type. For example, you can specify an X.400, GroupWise, or Lotus Notes address.

5. On the **New Mail Contact** page, review your configuration settings. To make changes, click **Back**. To create the new mail contact, click **New**. Click **Cancel** to close the wizard without creating the new mail contact.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to close the wizard.

Use the Shell to create a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

This example creates a mail contact for Ted Bremer.

```
New-MailContact -Name "Ted Bremer" -ExternalEmailAddress ted@tailspintoys.com -Or
```

This example mail-enables an existing contact named David.

```
Enable-MailContact -Identity David -ExternalEmailAddress David@thirdcoffee.com
```

Managing Mail Contacts and Mail Users

1.8.3.14.2 Create a Mail User

Create a Mail User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Mail users are similar to mail contacts. Both have external e-mail addresses and both contain information about people outside your Exchange Server 2010 organization that can be displayed in the global address list (GAL) and other address lists. However, unlike

a mail contact, a mail user has Active Directory logon credentials and can access resources.

Looking for other management tasks related to mail users? Check out Managing Mail Contacts and Mail Users.

Prerequisite

If you want to create a mail user in a domain that is different than the one in which your Exchange servers reside, you must first prepare that domain for Exchange 2010. To learn more about preparing a domain for Exchange 2010, see Prepare Active Directory and Domains.

What Do You Want to Do?

- Use the EMC to create a mail user
- Use the Shell to create a mail user

Use the EMC to create a mail user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail users" entry in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Mail User**.
3. On the **Introduction** page, select the type of user that you want to create or mail-enable.
   - **New user** This button is selected by default. Click this button to create a new user account for the mail user. This allows you to provision the user account and mail-enable it simultaneously.
     If you click this button, you'll need to provide the required user account information on the **User Information** page of this wizard.
   - **Existing user** Click this button to mail-enable an existing user account in Active Directory. Click **Browse** to open the **Select User** dialog box. This dialog box displays a list of user accounts in the forest that aren't mail-enabled or don't have Exchange mailboxes. Select the user account you want, and then click **OK** to return to the wizard.
4. If you selected **New User** in Step 3, complete the following fields on the **User Information** page. Otherwise skip to Step 5:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name** Use this box to type the user's first name. This field is optional.
   - **Initials** Use this box to type the user's middle initials. This field is optional.
   - **Last name** Use this box to type the user's last name. This field is optional.

- **Name** Use this box to type a name for the user. This is the name that's listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this field. The name can't exceed 64 characters.

  User logon name (User Principal Name) Use this box to type the name that the user will use to log on to the mailbox. The user logon name consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides. This name can't exceed 1,024 characters and must be unique in the forest.
- **User logon name (pre-Windows 2000)** Use this box to type the name for the user that is compatible with the legacy versions of Microsoft Windows (prior to the release of Windows 2000 Server). This field is automatically populated based on the **User logon name (User Principal Name)** field. This name can't exceed 20 characters and must not contain any of the following characters: **\/ []:|<> + = ; ? , ***.
- **Password** Use this box to type the password for the user.

  Note:
  Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you are creating the user account.
- **Confirm password** Use this box to confirm the password that you typed in the **Password** box.
- **User must change password at next logon** Select this check box if you want the user to reset the password when they first logon to the mailbox.

  If you select this check box, at first logon, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.

5. On the **Mail Settings** page, complete the following fields:
   - **Alias** Use this text box to type the alias of the user. The alias can't exceed 64 characters and must be unique in the forest.
   - **External e-mail address** To specify the external e-mail address, perform one of the following tasks:

     To specify a SMTP e-mail address, click **Edit**. In the **SMTP address** dialog box, type the SMTP e-mail address.

     Note:
     Exchange validates SMTP addresses for proper formatting. If your entry is inconsistent with the SMTP format, an error message will be displayed when you click **OK**.

     To specify a custom e-mail address, click the arrow next to **Edit**, and then click **Custom Address**. In the **Custom Address** dialog box, use the **E-mail address** box to type the e-mail address and the **E-mail type** box to specify the e-mail type. For example, you can specify an X.400, GroupWise, or Lotus Notes address.

6. On the **New Mail User** page, review your configuration settings. To make changes, click **Back**. To create the new mail user, click **New**. Click **Cancel** to close the wizard without creating the new mail contact.

7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task

fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a mail user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail users" entry in the Mailbox Permissions topic.

This example creates the mail user Ted Bremer with the external e-mail address ted@tailspintoys.com.

```
New-MailUser -Name Ted -FirstName Ted -LastName Bremer -ExternalEmailAddress ted@
```

For More Information

Understanding Recipients

Configure Mail User Properties

1.8.3.14.3 Configure Mail Contact Properties

Configure Mail Contact Properties

Mailbox > Managing Mailbox Servers > Managing Mail Contacts and Mail Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Mail contacts are mail-enabled Active Directory objects that contain information about people or organizations that exist outside your Exchange organization. Each mail contact has an external e-mail address. You can use the **<Mail Contact> Properties** dialog box to configure settings for a mail-enabled contact.

Looking for other management tasks related to mail contacts? Check out Managing Mail Contacts and Mail Users.

What Do You Want to Do?

- Use the EMC to configure mail contact properties
- Use the Shell to configure mail contact properties

Use the EMC to configure mail contact properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

Properties specific to a mail user are controlled by the **Set-MailContact** cmdlet. The EMC allows you to set additional properties, and the permissions may vary depending on the feature that you're configuring. The permissions listed above grant permission to edit all of the properties of the **<Mail Contact> Properties** dialog box.

1. In the console tree, navigate to **Recipient Configuration** > **Mail Contact**.
2. In the result pane, select the mail contact that you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to modify the display name, alias, and custom attributes.
   - **Display name** Use this unlabeled box at the top of the page to view or change the display name.
   - **Organizational unit** This field displays the organizational unit (OU) that contains the user account.
   - **Modified** This read-only field displays the last date and time that a configuration change was made to the recipient.
     Configuration changes made through any other method, such as the through the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.
   - **Alias** Use this box to view or change the recipient's alias. The alias can't exceed 64 characters and must be unique in the forest. One of the reasons why the alias field must be unique is because it's used to generate the SMTP address in a default installation.
   - **Use MAPI rich text format** Select one of the following options from the corresponding list:
     Never If you select this option, messages sent to this recipient will be converted to plain text.
     Always If you select this option, messages sent to this recipient will be in the MAPI rich text format (RTF).
     Use Default Settings If you select this option, messages sent to this recipient will be sent in either MAPI RTF or plain text, depending on the settings of the client computer from which the message is sent.
   - **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.
     After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.
   - **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**.

5. Use the **Contact Information** tab to modify the following fields.
   - **First name** Use this box to modify the contact's first name.
   - **Initials** Use this box to modify the contact's middle initials.
   - **Last name** Use this box to modify the contact's last name.
   - **Name** Use this box to modify the contact's directory name. This is the name that is listed in Active Directory.
   - **Simple display name** Use this box to modify the contact's simple display name. This field accepts only ASCII characters.
     The **Display name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode.
   - **Web page** Use this box to modify the contact's Web page address.
   - **Notes** Use this box to modify administrative notes about the contact.
     These notes are also visible in Outlook. When a user views the recipient's properties in Outlook, the notes will be displayed on the **Phone/Notes** tab.

6. Use the **Address and Phone** tab to view or modify the following fields:

- **Street address** Use this box to view or change the recipient's street.
- **City** Use this box to view or change the city where the recipient is located.
- **State/Province** Use this box to view or change the state or province where the recipient is located.

  You can use the **State/Province** field as a condition for dynamic distribution groups and e-mail address policies. If you plan to use this field as a condition, you must devise and follow a consistent naming convention to ensure accurate results for dynamic distribution groups and e-mail address policies.
- **ZIP/Postal code** Use this box to view or change the ZIP code or the postal code where the recipient is located.
- **Country/region** Use this list to view or change the country or region where the recipient is located.
- **Business** Use this box to view or change the recipient's business phone number.
- **Pager** Use this box to view or change the recipient's pager number.
- **Fax** Use this box to view or change the recipient's fax number.
- **Home** Use this box to view or change the recipient's home phone number.
- **Mobile** Use this box to view or change the recipient's mobile phone number.

7. Use the **Organization** tab to view or change the information about the recipient's role in your organization.
   - **Title** Use this box to view or change the recipient's title.
   - **Company** Use this box to view or change the company for which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Department** Use this box to view or change the department in which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Office** Use this box to view or change the office location for the recipient.
   - **Manager** Select this check box if you want to specify this recipient's manager. By specifying the manager for each recipient in your organization, you can create a virtual organization chart that is accessible from e-mail clients such as Outlook.

     Click **Browse** to open the **Select Recipient User or Contact** dialog box. Select the recipient's manager, and then click **OK** to return to the property page.
   - **Direct Reports** Use this box to view the list of mailbox users and contacts that are managed by this recipient. This field is read-only and is populated automatically when this recipient is designated as a manager for another recipient.

8. Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

9. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.
   - **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:

     SMTP Address This is the default address type. Click this

button and use the corresponding dialog box to add an SMTP address.
EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
- Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:
  This button is enabled when an address other than the external e-mail address is selected.

- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

10. Use the **Mail Flow Settings** tab to configure message size or message delivery restrictions for the contact.
    - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. In this dialog box, select the **Maximum message size (in KB)** check box to set the maximum size for messages that can be received by this recipient. Use the corresponding text box to specify the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB. If a message larger than the specified size is sent to the recipient, the message will be returned to the sender with a descriptive error message.
    - **Message Delivery Restrictions** Select this setting and then click

Properties to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.

Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.

No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.

Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

Use the Shell to configure mail contact properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

This example sets the contact John Peoples' external e-mail address to john@contoso.com.

```
Set-MailContact -Identity "John Peoples" -ExternalEmailAddress "john@contoso.com"
```

Managing Mail Contacts and Mail Users

1.8.3.14.4 Configure Mail User Properties

Configure Mail User Properties

Mailbox > Managing Mailbox Servers > Managing Mail Contacts and Mail Users >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-24*

Mail users are similar to mail contacts. Both have external e-mail addresses and both contain information about people outside your Exchange organization that can be displayed in the global address list (GAL) and other address lists. However, unlike a mail contact, a mail user has Active Directory logon credentials and can access resources.

Properties specific to a mail user are controlled by the **Set-MailUser** cmdlet. You can use the EMC to set additional properties, but the permissions may vary depending upon the feature that you're configuring.

Looking for other management tasks related to mail users? Check out Managing Mail Contacts and Mail Users.

What Do You Want to Do?

- Use the EMC to configure mail user properties
- Use the Shell to configure mail user properties

Use the EMC to configure mail user properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipient Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mail Contact**.
2. In the result pane, select the mail user that you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to modify the display name, alias, and custom attributes.
   - **Display name** Use this unlabeled box at the top of the page to view or change the display name.
   - **Organizational unit** This field displays the organizational unit (OU) that contains the user account.
   - **Modified** This read-only field displays the last date and time that a configuration change was made to the recipient.
     Configuration changes made through any other method, such as the through the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.
   - **Alias** Use this box to view or change the recipient's alias. The alias can't exceed 64 characters and must be unique in the forest. One of the reasons why the alias field must be unique is because it's used to generate the SMTP address in a default installation.
   - **Use MAPI rich text format** Select one of the following options from the corresponding list:
     Never If you select this option, messages sent to this recipient will be converted to plain text.
     Always If you select this option, messages sent to this recipient will be in the MAPI rich text format (RTF).
     Use Default Settings If you select this option, messages sent to this recipient will be sent in either MAPI RTF or plain text, depending on the settings of the client computer from which the message is sent.
   - **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address

lists that are defined in your Exchange organization.

After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.

- **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**.

5. Use the **User Information** tab to modify the following fields.
   - **First name** Use this box to modify the recipient's first name.
   - **Initials** Use this box to modify the recipient's middle initials.
   - **Last name** Use this box to modify the recipient's last name.
   - **Name** Use this box to modify the recipient's directory name. This is the name that's listed in Active Directory.
   - **Simple display name** Use this box to modify the recipient's simple display name. The simple display name field accepts only ASCII characters.

     In Exchange 2010, the **Display name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode.
   - **Web page** Use this box to modify the recipient's Web page address.
   - **Notes** Use this box to modify administrative notes about the recipient.

     These notes are also visible in Outlook. When a user views the recipient's properties in Outlook, the notes will be displayed on the **Phone/Notes** tab.

6. Use the **Address and Phone** tab to view or modify the following fields:
   - **Street address** Use this box to view or change the recipient's street.
   - **City** Use this box to view or change the city where the recipient is located.
   - **State/Province** Use this box to view or change the state or province where the recipient is located.

     You can use the **State/Province** field as a condition for dynamic distribution groups and e-mail address policies. If you plan to use this field as a condition, you must devise and follow a consistent naming convention to ensure accurate results for dynamic distribution groups and e-mail address policies.
   - **ZIP/Postal code** Use this box to view or change the ZIP code or the postal code where the recipient is located.
   - **Country/region** Use this list to view or change the country or region where the recipient is located.
   - **Business** Use this box to view or change the recipient's business phone number.
   - **Pager** Use this box to view or change the recipient's pager number.
   - **Fax** Use this box to view or change the recipient's fax number.
   - **Home** Use this box to view or change the recipient's home phone number.
   - **Mobile** Use this box to view or change the recipient's mobile phone number.

7. Use the **Organization** tab to view or change the information about the recipient's role in your organization.
   - **Title** Use this box to view or change the recipient's title.
   - **Company** Use this box to view or change the company for which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Department** Use this box to view or change the department in which the

recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.

- **Office** Use this box to view or change the office location for the recipient.
- **Manager** Select this check box if you want to specify this recipient's manager. By specifying the manager for each recipient in your organization, you can create a virtual organization chart that is accessible from e-mail clients such as Outlook.

  Click **Browse** to open the **Select Recipient User or Contact** dialog box. Select the recipient's manager, and then click **OK** to return to the property page.
- **Direct Reports** Use this box to view the list of mailbox users and contacts that are managed by this recipient. This field is read-only and is populated automatically when this recipient is designated as a manager for another recipient.

8. Use the **Account** tab to modify the logon names for the Active Directory domain service user account that is associated with the recipient:
   - **User logon name (User Principal Name)** The user logon name consists of a user name and a suffix. Use this box to type the user name that the user will use to log on to the Active Directory domain. The user logon name cannot exceed 1,024 characters and must be unique in the forest.

     Use the corresponding drop-down list to select the suffix for this user. Typically, the suffix is the Active Directory domain name in which the user account resides. To view or change the list of available domain suffixes in your forest, use Active Directory Domains and Trusts. In the Active Directory Domains and Trusts console tree, right-click **Active Directory Domains and Trusts**, and then click **Properties**. In the property page, use the **UPN suffixes** tab to view the list of available domain suffixes in the forest.
   - **User logon name (pre-Windows 2000)** Use this box to type a user name that is compatible with legacy versions of Windows (prior to the release of Windows 2000 Server). The user logon name for a version of Windows earlier than Windows 2000 Server can't exceed 20 characters and can't contain any of the following characters: **\/ [] : | <> + = ; ? , ***.

     When the user account is first created, this field is automatically populated based on the **User logon name (User Principal Name)** field.
   - **User must change password at next logon** Select this check box if you want the user to change the password at next logon. The user won't be able to log on until the password is successfully changed.

9. Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

10. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.
    - **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:

      SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address.

EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:
With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
-  Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:
  This button is enabled when an address other than the external e-mail address is selected.

- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

11. Use the **Mail Flow Settings** tab to configure message size or message delivery restrictions for the mail user.
    - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. In this dialog box, select the **Maximum message size (in KB)** check box to set the maximum size for messages that can be received by this recipient. Use the corresponding text box to specify the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB. If a message larger than the specified size is sent to the recipient, the message will be returned to the sender with a descriptive error message.
    - **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.
Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.
No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.
Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

Use the Shell to configure mail user properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipient Permissions" section in the Mailbox Permissions topic.

This example sets the e-mail address outside of the organization to which mail-enabled user John Peoples' e-mail is sent.

```
Set-MailUser john -ExternalEmailAddress john@tailspintoys.com
```

This example sets the maximum size of messages that John Peoples is allowed to receive to 10 MB.

```
Set-MailUser -Identity john -MaxReceiveSize '10 MB'
```

Understanding Recipients

Managing Mail Contacts and Mail Users

1.8.3.14.5 Disable E-Mail for a Mail Contact

Disable E-Mail for a Mail Contact

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable e-mail for an existing mail contact object in Active Directory by removing its Exchange attributes.

Important:

There are two types of mail contacts in Microsoft Exchange Server 2010: mail contacts and mail forest contacts. Mail forest contacts are read-only recipient objects that are updated only through Microsoft Identity Integration Server (MIIS) or a similar custom synchronization. You can't remove or modify a mail forest contact by using the EMC or the Shell.

Looking for other management tasks related to managing mail contacts and mail users? Check out Managing Mail Contacts and Mail Users.

Use the EMC to disable e-mail for a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mail Contact**.
2. In the result pane, select the mail contact that you want to disable.
3. In the action pane, under the name of the mail contact, click **Disable**.
4. In the warning appears verifying that you want to disable e-mail for the mail contact. Click **Yes**.

Use the Shell to disable e-mail for a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

This example disables e-mail for the mail contact Ellen Adams.

```
Disable-MailContact -Identity "Ellen Adams" -DomainController Domain.Contoso.com
```

For detailed syntax and parameter information, see Disable-MailContact.

1.8.3.14.6 Disable Mail for a Mail-Enabled User

Disable Mail for a Mail-Enabled User

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can disable mail for a mail-enabled user. This task removes all the Exchange attributes from the user object in Active Directory. However, it doesn't remove the user from Active Directory.

Looking for other management tasks related to managing mail contacts and mail users? Check out Managing Mail Contacts and Mail Users.

Use the EMC to disable mail for a mail-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail users" entry in the Mailbox Permissions topic.

1. In the console tree, expand **Recipient Configuration**, and then click **Mail Contact**.
2. In the result pane, select the mail user for which you want to disable mail.
3. In the action pane, under the name of the mail user, click **Disable**.
4. A warning appears verifying that you want to disable mail for the user. Click **Yes**.

Use the Shell to disable mail for a mail-enabled user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail users" entry in the Mailbox Permissions topic.

This example disables mail for the mail-enabled user John.

```
Disable-MailUser john@contoso.com
```

When prompted, type **Y** to confirm the disabling of the mail user.

For detailed syntax and parameter information, see Disable-MailUser.

1.8.3.14.7 Mail-Enable an Existing Contact

Mail-Enable an Existing Contact

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can mail-enable an existing contact object in Active Directory by populating its Exchange attributes (such as the contact's alias and external e-mail address).

Note:

This procedure doesn't create a mail contact in Active Directory.

Looking for other management tasks related to managing mail contacts and mail users? Check out Managing Mail Contacts and Mail Users.

Use the EMC to mail-enable an existing

mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

1. In the console tree, expand **Recipient Configuration**, and then click **Mail Contact**.
2. In the action pane, click **New Mail Contact**. The New Mail Contact wizard appears.
3. On the **Introduction** page, click **Existing contact**, and then click **Browse**.
4. In **Select Contact**, select the contact that you want to mail-enable, click **OK**, and then click **Next**.
5. On the **Contact Information** page, complete the following fields:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name** This read-only box displays the first name of the contact.
   - **Initials** This read-only box displays the initials of the contact.
   - **Last name** This read-only box displays the last name of the contact.
   - **Name** This read-only box displays the name of the contact that's listed in Active Directory. This name may be different than the first and last names.
   - **Alias** Use this box to type a unique alias (64 characters or less) for the contact. This field is required.
   - **External e-mail address** To specify the external e-mail address, perform one of the following tasks:

     To specify an SMTP e-mail address, click **Edit**. In the **SMTP address** dialog box, type the SMTP e-mail address.

     Note:

     Exchange validates SMTP addresses for proper formatting. If your entry is inconsistent with the SMTP format, an error message is displayed when you click **OK**.

     To specify a custom e-mail address, click the arrow next to **Edit**, and then click **Custom Address**. In the **Custom Address** dialog box, use the **E-mail address** box to type the e-mail address and the **E-mail type** box to specify the e-mail type. For example, you can specify an X.400, GroupWise, or Lotus Notes address.
6. On the **New Mail Contact** page, review your configuration settings. To make changes, click **Back**. To create the mail-enabled contact, click **New**. Click **Cancel** to close the wizard without mail-enabling the contact.
7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to mail-enable an existing mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

This example mail-enables the existing mail contact Ellen Adams.

```
Enable-MailContact -Identity EllenAdams -ExternalEmailAddress EllenAdams@Contoso.
```

For detailed syntax and parameter information, see Enable-MailContact.

1.8.3.14.8 Mail-Enable Multiple Existing Contacts

Mail-Enable Multiple Existing Contacts

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can mail-enable existing contact objects in Active Directory by populating their Exchange attributes (such as the contact's alias and external e-mail address).

Note:

This procedure doesn't create new contacts in Active Directory.

To mail-enable existing contacts, at a minimum you must provide external e-mail addresses. When mail-enabling several contacts in bulk, it's easier to first export the list of contacts to a .csv file, and then add the external e-mail addresses to the .csv file by using a text editor such as Notepad, or a spreadsheet application such as Microsoft Office Excel. You can then use the updated .csv file in your bulk mail-enabling operation.

Looking for other management tasks related to managing mail contacts and mail users? Check out Managing Mail Contacts and Mail Users.

Use the Shell to mail-enable multiple existing contacts

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to mail-enable multiple existing contacts.

1. This example exports the list of existing contacts in your organization that aren't mail-enabled to the .csv file ContactsList.

   ```
   Get-Contact | Out-File "C:\ContactsList.CSV"
   ```

   The resulting .csv file will be similar to the following:

   ```
   #TYPE System.Management.Automation.PSCustomObject,
   Name
   Kim Abercrombie
   Don Funk
   Sanjay Patel
   ```

```
Amy Strande
...
```

2. For each contact, add a column heading and the external e-mail addresses to the .csv file. The updated .csv file should look similar to the following:

```
#TYPE System.Management.Automation.PSCustomObject,
Name,ExternalAddress
Kim Abercrombie,Kim@contoso.com
Don Funk,Don@fabrikam.com
Sanjay Patel,Sanjay@fabrikam.com
Amy Strande,Amy@contoso.com
...
```

3. This example imports and uses the data in the .csv file so you can mail-enable the contacts in bulk.

```
Import-CSV "C:\ContactsList.CSV" | ForEach-Object {Enable-MailContact
```

For detailed syntax and parameter information, see Get-Contact or Enable-MailContact.

1.8.3.14.9 Remove a Mail Contact

Remove a Mail Contact

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove an existing mail contact from Active Directory.

Important:

There are two types of mail contacts in Microsoft Exchange Server 2010: mail contacts and mail forest contacts. Mail forest contacts are read-only recipient objects that are updated only through Microsoft Identity Integration Server (MIIS) or a similar custom synchronization. You can't remove or modify a mail forest contact by using the EMC or the Shell.

Looking for other management tasks related to managing mail contacts and mail users? Check out Managing Mail Contacts and Mail Users.

Use the EMC to remove a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

1. In the console tree, expand **Recipient Configuration**, and then click **Mail Contact**.
2. In the result pane, click the mail contact that you want to remove.
3. In the action pane, under the name of the mail contact, click **Remove**.
4. In the warning that asks if you're sure you want to remove the mail contact, click **Yes**.

Use the Shell to remove a mail contact

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mail contacts" entry in the Mailbox Permissions topic.

This example removes the mail contact Ellen Adams.

```
Remove-MailContact -Identity "Ellen Adams" -DomainController Contoso.Domain.Com
```

For detailed syntax and parameter information, see Remove-MailContact.

1.8.3.15 Managing Mailbox Databases

Managing Mailbox Databases

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-30*

Create a Mailbox Database

Mount a Database

Dismount a Database

Remove a Mailbox Database

Maintain Mailbox Databases

Modify a Database Size Limit

Move the Database Path

Configure Mailbox Database Properties

1.8.3.15.1 Create a Mailbox Database

Create a Mailbox Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can create a mailbox database, which is a unit of granularity where mailboxes are created and stored. A mailbox database is stored as an Exchange database (.edb) file.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

Prerequisites

Sufficient disk space exists to create the database. For more information, see Mailbox Server Storage Design.

What Do You Want to Do?

- Use the EMC to create a mailbox database

- Use the Shell to create a mailbox database

Use the EMC to create a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Mailbox Database**. The New Mailbox Database wizard appears.
3. On the **Introduction** page, complete the following fields:
   - **Mailbox database name** Use this box to type a name for the new mailbox database. The name can contain up to 64 characters but can't include the following characters: \ / " = , ;.
   - **Browse** Click this button to locate the server on which to create the database. Select the server, and then click **OK**.
4. On the **Set Paths** page, complete the following fields:
   - **Database file path** This box displays the default path to the database file. You can change the location by typing a new path.
   - **Log folder path** This box displays the default path to the log folder. You can change the location by typing a new path.
   - **Mount this database** Select this check box if you want to mount this database. Mounting a database puts it online, making its data available to users.
5. On the **New Mailbox Database** page, click **New** to create the mailbox database.
6. On the **Completion** page, confirm whether the new mailbox database was created successfully. A status of **Completed** indicates that the wizard completed the task successfully. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to complete the wizard. The new mailbox database appears on the **Database Management** tab.

Use the Shell to create a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

This example creates the mailbox database MailboxDatabase01 and specifies where to create the .edb database file.

```
New-MailboxDatabase -Name "MailboxDatabase01" -EdbFilePath D:\DatabaseFiles\Mailb
```

This example creates the mailbox database MailboxDatabase01 and specifies where to create the .edb database file and the log folder path.

```
New-MailboxDatabase -Name "MailboxDatabase01" -EdbFilePath D:\DatabaseFiles\Mailb
```

This example mounts the newly created database MailboxDatabase01.

```
Mount-Database -Identity "MailboxDatabase01"
```

For detailed syntax and parameter information, see New-MailboxDatabase and Mount-Database.

1.8.3.15.2 Mount a Database

Mount a Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the EMC or the Shell to mount a mailbox database on a computer that has the Microsoft Exchange Server 2010 Mailbox server role installed.

Note:
You can mount a database only if the Microsoft Exchange Information Store service is running.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

What Do You Want to Do?

- Use the EMC to mount a database
- Use the Shell to mount a database

Use the EMC to mount a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, select the server on which the database is located.
3. In the work pane, select the mailbox database that you want to mount.
4. In the action pane, click **Mount Database**.
5. Verify that the status indicated in the **Status** column has changed from **Dismounted** to **Mounted**.

Use the Shell to mount a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

This example uses the **Mount-Database** command to mount the database MyDatabase.

```
Mount-Database "MyDatabase"
```

For detailed syntax and parameter information, see Mount-Database.

1.8.3.15.3 Dismount a Database

Dismount a Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Exchange Management Console or the Shell to dismount a mailbox database on a computer that has the Microsoft Exchange Server 2010 Mailbox server role installed.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

What Do You Want to Do?

- Use the EMC to dismount a database
- Use the Shell to dismount a database

Use the EMC to dismount a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, select the server on which the mailbox or public folder database is located.
3. In the work pane, select the database that you want to dismount.
4. In the action pane, click **Dismount Database**.
5. A warning appears asking if you want to dismount the database. Click **Yes**.

Use the Shell to dismount a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

This example uses the **Dismount-Database** command to dismount the database MyDatabase.

```
Dismount-Database "MyDatabase"
```

Note:

You can dismount a database only if the Microsoft Exchange Information Store service is running.

1.8.3.15.4 Remove a Mailbox Database

Remove a Mailbox Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Exchange Management Console or the Shell to remove a mailbox database.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

What Do You Want to Do?

- Use the EMC to remove a mailbox database
- Use the Shell to remove a mailbox database

Use the EMC to remove a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the work pane, expand the mailbox database you want to remove.
3. In the action pane, click **Remove**.
4. A warning appears asking if you're sure you want to remove the mailbox database. Click **Yes**.
5. When the dialog box appears stating that the database was removed successfully, note the location of the Exchange database (.edb) file. If you want to remove this file from the hard drive, you must remove it manually. Click **OK**.

Use the Shell to remove a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

This example uses the **Remove-MailboxDatabase** command to remove the database MyDatabase.

```
Remove-MailboxDatabase -Identity "MyDatabase"
```

1. When you are prompted about whether you're sure that you want to perform the action, type **Y**.
2. When the dialog box appears stating that the database was removed successfully, note the location of the Exchange database (.edb) file. If you want to remove this file from the hard drive, you must remove it manually.

For detailed syntax and parameter information, see Remove-MailboxDatabase.

1.8.3.15.5 Maintain Mailbox Databases

Maintain Mailbox Databases

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use several tools to maintain your mailbox database. The following sections describe how to use these tools to ensure that your mailbox databases continue to operate efficiently. These tools help to reduce the administrative database maintenance tasks that you had to perform in previous versions of Exchange.

Looking for other management tasks related to managing mailbox databases? Check out Managing Mailbox Databases.

Use performance counters to monitor online defragmentation

In Microsoft Exchange Server 2010, the following performance counters for monitoring the behavior of database defragmentation have been added for use with Performance Monitor:

- **MSExchange Database ==> Instances \ Defragmentation tasks** Shows the background database defragmentation tasks currently executing.
- **MSExchange Database ==> Defragmentation Tasks completed/Sec** Shows the number of background database defragmentation tasks completing execution per second.
- **MSExchange Database ==> Defragmentation Tasks Discarded** Shows the background database defragmentation tasks that couldn't be registered.
- **MSExchange Database ==> Defragmentation Tasks Pending** Shows the background database defragmentation tasks currently pending.
- **MSExchange Database ==> Instances \ Defragmentation Tasks Scheduled/Sec** Shows the background database defragmentation tasks scheduled for execution per second.

These are informational performance counters to show the performance of the database and aren't required to be part of the daily maintenance of your database.

You can also enable extended Extensible Storage Engine (ESE) performance counters to further help with monitoring your databases. For more information, see How to Enable Extended ESE Performance Counters.

Use the EMC to set the maintenance schedule for a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

You can use the EMC to set the maintenance schedule for a database or allow 24x7 database maintenance. Online defragmentation no longer runs only during the maintenance window as it did in Exchange Server 2007. Instead, it's performed continuously as data is read from and written to the database. For more information, see New Exchange Core Store Functionality.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, click the mailbox database for which you want to set the maintenance schedule.
3. In the action pane, under the name of the database, click **Properties**. The **<Database Name> Properties** dialog box appears.
4. On the **Maintenance** tab, select the **Enable background database maintenance (24 x 7 ESE scanning)** check box, and then click **Customize** to

select a predefined schedule or to create a customized schedule.
5. Click **OK** to save your changes.

Use the Shell to set the maintenance schedule for a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

This example sets the database schedule for the mailbox database MailboxDatabase1 on Server01 to run between 02:00 and 03:00 on Sundays and Wednesdays.

```
Set-MailboxDatabase -Identity "Server01\MailboxDatabase1" -MaintenanceSchedule "S
```

This example mounts the database in 24 x 7 background check-summing mode.

```
Set-MailboxDatabase -BackgroundDatabaseMaintenance $true -Identity <dbname>
```

When set to `$false`, the database will be mounted without the 24x7 checksum mode and will perform the ESE checksum maintenance during the online maintenance period that you selected.

For detailed syntax and parameter information, see Set-MailboxDatabase.

For more information about database maintenance, see the "Database Maintenance" section in New Exchange Core Store Functionality.

1.8.3.15.6 Modify a Database Size Limit

Modify a Database Size Limit

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-20*

You can use Registry Editor to modify a database size limit in Microsoft Exchange Server 2010. The default database size limit for Exchange 2010 Standard Edition is 1024 gigabytes (GB). There is no default database size limit for the Exchange 2010 Enterprise Edition. The Exchange store checks any database size limits periodically and dismounts a database when the size limit is reached. You can modify the database size limit by adding or changing a value in the registry.

Note:
When you change this setting, this change is propagated to all servers that host a copy of this database.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

Use Registry Editor to Modify a Database Size Limit

If you change the size limit of your Exchange databases, you may want to evaluate your

Exchange database backup and restore plan. Specifically, if you increase the size limit of the Exchange databases, test your backup and recovery operations using the new database size limits to make sure that you can still meet your service level agreements (SLAs).

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Start Registry Editor (regedit).
2. Locate the following registry subkey:
   HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchangeIS\<Server Name>\Private-<database GUID>

   Note:

   You can get the GUID of a database by running the following command in the Exchange Management Shell: `Get-MailboxDatabase -Identity "<database name>" | Format-Table Name, GUID`
3. If the **Database Size Limit in GB** DWORD exists for the subkey, change its value to the desired size in gigabytes.
4. If the **Database Size Limit in GB** DWORD doesn't exist for the subkey, create a new DWORD with that name, and then set its value to the desired size in gigabytes.

For more information about managing databases, see Managing Mailbox Databases.

To learn more about Registry Editor, see Registry Editor overview.

1.8.3.15.7 Move the Database Path

Move the Database Path

Mailbox > Managing Mailbox Servers > Managing Mailbox Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-04-24*

You can move the mailbox database path on a server that is running Microsoft Exchange Server 2010. To set a new path to the location of a database, and to move the related files to that location, you can use the EMC or the Exchange Management Shell.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

Prerequisites

To perform the move operation, you must temporarily dismount the database. This makes the database inaccessible to all users. If the database is currently dismounted, it isn't remounted upon completion.

What Do You Want to Do?

- Use the EMC to move the mailbox database path
- Use the Shell to move the mailbox database path

Use the EMC to move the mailbox database path

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the database you want to configure.
3. In the work pane, click M**ove Database Path**.
4. In the Move Database Path wizard, under **Database paths**, click **Move** to move the database path to the default location. You can change the location for the database file path by editing the **Database file path** field. You can change the location for the log folder path by editing the **Log folder path** text field.
5. View the status of the move operation. The wizard moves the database file path and the log folder path to the new location. Click **Back** to make configuration changes.
6. On the **Completion** page, confirm whether the move process completed successfully. A status of **Completed** indicates that the wizard completed the task successfully. A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to complete the Move Database Path wizard.

Note:

After the database is moved, the Indexing service maintains a lock on the Catalog files. Before you can delete these files from the old location, you must restart the Microsoft Exchange Search Indexer service.

Use the Shell to move the mailbox database path

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Database permissions" entry in the Mailbox Permissions topic.

This example uses the **Move-DatabasePath** command to set a new path for the mailbox database specified by the GUID.

```
Move-DatabasePath -Identity a0ec9f03-12a9-4e40-9310-43f9105fd4d2 -EdbFilePath C:\
```

For detailed syntax and parameter information, see Move-DatabasePath.

Note:

After the database is moved, the Indexing service maintains a lock on the Catalog files. Before you can delete these files from the old location, you must restart the Microsoft Exchange Search Indexer service.

Configure Mailbox Database Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

In Microsoft Exchange Server 2010, each mailbox database has its own properties that you can configure. These properties include mounting, dismounting, and moving a database path.

Looking for other management tasks related to mailbox databases? Check out Managing Mailbox Databases.

What Do You Want to Do?

- Use the EMC to configure mailbox database properties
- Use the Shell to configure mailbox database properties

Use the EMC to configure mailbox database properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, on the **Database Management** tab, select the database you want to configure.
3. In the action pane, under the database name, click **Properties**.
4. Use the **General** tab to view status about the mailbox database, including the mailbox database path, last backup, and mailbox database status:
   - **Database path** This read-only field displays the full path to the Exchange database (.edb) file for the selected mailbox database. To view the entire path, you may have to click the path and use the Right Arrow key. You can't use this field to change the path. To change the location of the database files, close **Properties**, right-click the database, and then click **Move Database Path**. You can also change the location by using the Move-DatabasePath cmdlet.
   - **Last full backup** This read-only field displays the date and time of the last complete backup of the mailbox database.
   - **Last incremental backup** This read-only field displays the date and time of the last incremental backup of the mailbox database.
   - **Status** This read-only field displays whether the mailbox database is mounted or dismounted.
   - **Mounted on server** This read-only field displays which server the database is mounted on.
   - **Master** This read-only field displays the master server for the mailbox database. The Mailbox server that hosts the active copy of a database is referred to as the mailbox database master. For more information, see Managing Mailbox Database Copies.
   - **Master type** This read-only field displays the type of mailbox database master.
   - **Modified** This read-only field displays the date and time the database was last modified.

- **Servers hosting a copy of this database** This read-only field displays the other servers that have a copy of this database.

5. Use the **Maintenance** tab to configure mailbox database settings, including specifying a journal recipient, setting a maintenance schedule, and mounting the database at startup:
   - **Journal Recipient** Select this check box to enable transport journaling of e-mail. To learn more, see Understanding Journaling.
   - **Maintenance schedule** Use this list to select one of the preset maintenance schedules. You can also configure a custom schedule. To configure a custom schedule, click **Customize**.
   - **Enable background database maintenance (24 x 7 ESE scanning)** Select this check box to enable online database scanning, which runs continuously in the background. Online database scanning performs a checksum calculation of the database and performs operations that allow Exchange to scan for lost space on the database and recover it. If you select this check box, Exchange scans the database no more than one time per day and will issue a warning event if it can't finish scanning the database in a seven day period. For more information, see Maintain Mailbox Databases.
   - **Don't mount this database at startup** Select this check box to prevent Exchange from mounting this mailbox database when it starts.
   - **This database can be overwritten by a restore** Select this check box to allow the mailbox database to be overwritten during a restore process.
   - **Enable circular logging** Select this check box to enable circular logging. For more information about circular logging, see Understanding the Exchange 2010 Store.

6. Use the **Limits** tab to specify the storage limits, the warning message interval, and the deletion settings for a mailbox database:
   - **Issue warning at (MB)** Select this check box to automatically warn mailbox users that their mailbox is approaching its storage limit. To specify the storage limit, select the check box, and then specify in kilobytes (KB) how much content can be stored in the mailbox before a warning e-mail message is sent to the mailbox users. You can enter a value from 0 through 2,097,151 megabytes (MB) (2.0 terabytes).
   - **Prohibit send at (MB)** Select this check box to prevent users from sending new e-mail messages after the size of their mailbox reaches the specified limit. To specify this limit, select the check box, and then type the size of the mailbox in MB at which you want to prohibit the sending of new e-mail messages and notify the user. You can enter a value from 0 through 2,097,151 MB (2.0 terabytes).
   - **Prohibit send and receive at (MB)** Select this check box to prevent users from sending and receiving e-mail messages after their mailbox size reaches the specified limit. To specify this limit, select the check box, and then type the size of the mailbox in MB at which you want to prohibit the sending and receiving of e-mail messages and notify the user. You can enter a value from 0 through 2,097,151 MB (2.0 terabytes).
   - **Warning message interval** Use this list to specify the time at which mailboxes are scanned for compliance with the storage limits that you set. To configure a custom time, click **Customize**.
   - **Keep deleted items for (days)** Use this box to set the number of days that deleted items are retained in a mailbox. You can enter a value from 0 through 24,855 days.
   - **Keep deleted mailboxes for (days)** Use this box to set the number of days that deleted mailboxes are retained. You can enter a value from 0 through 24,855 days.
   - **Don't permanently delete items until the database has been backed up** Select this check box to prevent mailboxes and e-mail messages from

being deleted until after the mailbox database has been backed up.

7. Use the **Client Settings** tab to view and select the default public folder database and the offline address book (OAB) for the mailbox:
   - **Default public folder database** This box shows the location of the default public folder database. The public folder database stores public folder data, OAB information, and free/busy information for Microsoft Exchange Server 2003 and earlier versions. To change the location of the default public folder database, click **Browse** and select a new location.
   - **Offline address book** This box shows the location of the OAB. To change the location of the OAB, click **Browse**, and then select a new location.

Use the Shell to configure mailbox database properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

This example sets the length of time that deleted items are retained. If a particular mailbox has its own item retention set, that value is used instead of this value, which is set on the mailbox database.

```
Set-MailboxDatabase "Mailbox Database01" -DeletedItemRetention 7.00:00:00
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

1.8.3.15.9 Turn Off Exchange Store Time-Out Detection

Turn Off Exchange Store Time-Out Detection

Mailbox > Managing Mailbox Servers > Managing Mailbox Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

An indication of an unhealthy Exchange store is that threads are either deadlocked or are otherwise not making progress. If there are more than five threads on a single mailbox, ten threads on a single database, or twenty threads on a single server that haven't progressed in one minute, a time-out is reported on the server. The performance counters that indicate time-outs are:

- RPC Request Timeout Detected on Mailbox
- RPC Request Timeout Detected on Database
- RPC Request Timeout Detected on Server

The Exchange store also writes the following events to the server under the MSExchangeIS source:

- **Event 10025** Reports a time-out on the Exchange server
- **Event 10026** Reports a time-out on the database
- **Event 10027** Reports a time-out on an individual mailbox

If the time-out is detected on a single mailbox, the mailbox is potentially considered to be poisoned and is handled similarly to a failure by increasing the **CrashCount** property. This action makes the mailbox susceptible to being quarantined. Therefore, you may want to turn off Exchange store time-out detection for Mailbox servers that regularly have a large number of threads operating against them.

Use the Registry to turn off Exchange store time-out detection

Caution:

Incorrectly editing the registry can cause serious problems that may require you to reinstall your operating system. Problems resulting from editing the registry incorrectly may not be able to be resolved. Before editing the registry, back up any valuable data.

1. Open Registry Editor (regedit).
2. Navigate to the following subkey:
   \\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSExchangeIS\<Server Name>
3. Right-click the *<Server Name>*, point to **New**, and then click **DWORD (32-bit) Value**. The new DWORD value displays in the results pane.
4. Rename the key to **DisableTimeoutDetection**, and then press Enter.
5. Right-click **DisableTimeoutDetection**, and then click **Modify**.
6. Change the **Value data** to **1**.
7. Click **OK**.

Manage Database Log Growth by Using the Troubleshoot-DatabaseSpace.ps1 Script in the Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The **Troubleshoot-DatabaseSpace.ps1** script is used by Microsoft System Center Operations Manager 2007 to detect and correct any excess log growth or Microsoft Exchange database (.edb) file growth that, if unchecked, may cause database downtime. By default, System Center Operations Manager 2007 runs the script every 15 minutes. However, you can use Task Scheduler to configure and run this script to monitor database log and file growth.

Note:

A script must be run from the folder in which it resides. By default, scripts installed with Exchange 2010 are installed at C:\Program Files\Microsoft\Exchange Server\V14\Scripts. The Shell doesn't load scripts automatically. To run a script from the local file, you must precede all scripts with "**.**" For example, to run the SampleScript.ps1 script, type `.\SampleScript.ps1`. To run a script and specify the default installation path, type `"C:\Program Files\Microsoft\Exchange Server\V14\Scripts\SampleScript.ps1"`. For more information, see Scripting with the Exchange Management Shell.

The **Troubleshoot-DatabaseSpace.ps1** script performs the following actions:

1. Keeps track of log generation rate for the highest log generators per database. This helps determine which users are logging too heavily and potentially causing space issues.
2. Keeps track of the available disk space for both the database and the log files. If either of these is within a configurable threshold of being full, further action must be taken.
3. Keeps track of the log generation rate. If it appears that the disk is going to run out of space within the value specified by the *HourThreshold* parameter (based on the log generation rate), further action must be taken.

   Note:

   To avoid critical issues, make sure the value for the *HourThreshold* parameter is large enough to give you time to react during normal business hours while enough free space is available. If drives are filling up faster than the value specified, immediate action must be taken to protect the disk.

4. If all of the preceding conditions are fulfilled, the script determines the list of top 25 users who accessed the database during the last one-hour period. The script then quarantines the top high-usage mailboxes for which the sum of the log generation rate is greater than the difference between the current generation rate and the sustainable generation rate that would allow tiding over the configurable time threshold. These users are quarantined for six hours, during which they won't have access to e-mail.
5. If the troubleshooter is unsuccessful at dropping the log generation rate to below the threshold level, it will write out events that translate into health model alerts. At this point, the script removes the database from provisioning by running the Set-MailboxDatabase cmdlet with the *ExcludeFromProvisioning* parameter set to `$true` against the specified database. You may need to move mailboxes to a new server to rebalance space.
6. If the troubleshooter quarantines more than 10 users, this indicates a systemic issue, which you need to follow up on. The health model will trigger an urgent alert from this condition.

The default settings used in the **Troubleshoot-DatabaseSpace.ps1** script are defined in the **StoreTSConstants.ps1** script.

Looking for other management tasks related to databases? Check out Managing Mailbox Databases.

Use the Troubleshoot-DatabaseSpace.ps1 script

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

The following parameter syntax set and table lists the parameters that you can use to move specific mailboxes.

```
Troubleshoot-DatabaseSpace.ps1 -MailboxDatabaseName <DatabaseID> [-PercentEdbFree
Troubleshoot-DatabaseSpace.ps1 -Server <ServerID> [-PercentEdbFreeSpaceThreshold
```

Parameter	Required	Description
MailboxDatabaseName	Required	The *MailboxDatabaseName* parameter specifies the mailbox database on which you're monitoring the log growth. This parameter accepts the following

		values: • GUID • Distinguished name (DN) • Database name **Note:** You can't use this parameter in conjunction with the *Server* parameter.
Server	Required	The *Server* parameter specifies the Mailbox server on which you're monitoring the log growth for all mailbox databases. **Note:** You can't use this parameter in conjunction with the *MailboxDatabaseName* parameter.
HourThreshold	Optional	The *HourThreshold* parameter specifies the number of hours you can wait until running out of space. The default value is 12 hours.
MonitoringContext	Optional	The *MonitoringContext* parameter specifies whether the results of the command include monitoring events to be written in the regular Application logs in Event Viewer and in the Operations log. If you don't specify this value, the Operations logs will be written to the following location in Event Viewer: **Event Viewer** > **Application and Services Logs** > **Microsoft-Exchange-Troubleshooters/ Operational**. You don't have to specify a value for this parameter.
PercentEdbFreeSpaceThreshold	Optional	The *PercentEdbFreeSpaceThreshold* parameter specifies the percentage of disk space for the .edb file at which Exchange should begin quarantining users. For example, if you specify 10 percent, Exchange will begin quarantining the heaviest users when the command detects that the hard drive will run out of space due to growth of the .edb file within the time specified in the *HourThreshold* parameter. The default value for this parameter is 25 percent.
PercentLogFreeSpaceThre	Optional	The *PercentLogFreeSpaceThreshold* parameter specifies the percentage of

shold		disk space for the log files at which Exchange should begin quarantining users. For example, if you specify 10 percent, Exchange will begin quarantining the heaviest users when the command detects that the hard drive will run out of space due to log growth within the time specified in the *HourThreshold* parameter. The default value for this parameter is 25 percent.
Quarantine	Optional	The *Quarantine* parameter specifies that heavy users will be quarantined. If you don't specify this parameter, users won't be quarantined. You don't need to specify a value for this parameter.

Example

This example shows how to run the **Troubleshoot-DatabaseSpace.ps1** script with the following settings:

- The warnings are set at 10 percent free space in the volume containing the database logs and 10 percent free space in the database file and the volume containing it.
- The hour threshold is set at 5 hours.

With these settings, if the troubleshooter determines that the free space on the hard drive will be at 10 percent or less capacity within 5 hours, it will quarantine the heaviest users.

```
.\Troubleshoot-databasespace.ps1 -server MBX01 -PercentLogFreeSpace 10 -PercentED
```

Note:

This example shows how to run the command manually once. To produce the data that the troubleshooter needs to effectively monitor your server or database, you must run this command several times at regular intervals. We recommend that you use the Task Scheduler in the Microsoft Windows operating system to set up this task. For more information, see Task Scheduler Overview.

View the log growth troubleshooter output

In Event Viewer, the results of the **Troubleshoot-DatabaseSpace.ps1** script will be available in the following location: **Event Viewer** > **Application and Services Logs** > **Microsoft-Exchange-Troubleshooters/Operational**.

For example, the following represents output from event ID 5101. This output would be returned if the script ran successfully without errors.

```
The database space troubleshooter finished on volume D:\ for database MBD01, no problems were detected.

EDB drive free space: 151938752512 B

Log drive free space: 151845265408 B
```

EDB free space threshold: 10%

Log free space threshold: 10%

Hour threshold: 12 Hrs

Current growth rate: 314572800 B/Hr

The following table displays the event ID, the description of the event, and if necessary, the action to take.

Note:
The descriptions in this table are examples of the information that may be included in these events.

Event ID	Description	Action
5100	The database space troubleshooter started on volume D:\ for database MBD01.	Informational only. No action is required.
5101	The database space troubleshooter finished on volume D:\ for database MBD01. No problems were detected.	Informational only. No action is required.
5400	The database space troubleshooter finished on volume D:\ for database MBD01. The database is over the free space threshold. Users were quarantined to avoid running out of space.	Warning event: Continue monitoring. Users will be quarantined for six hours and won't be able to access their mailboxes.
5401	The database space troubleshooter finished on volume D:\ for database MBD01. The database is under the free space threshold, but not growing at an unusual rate. No action was taken.	Warning event: Continue monitoring.
5410	The database space troubleshooter quarantined mailbox f3bb8007-b6d1-45f5-b748-211d66fa43f6 in database MBD01.	Warning event: This event will be created when event 5400 is created. Continue monitoring.
5700	The database space troubleshooter finished on volume D:\ for database MBD01. The database is over the free space threshold and continues to grow. Manual intervention is required.	This error event indicates that the database space is over the free space threshold. Run the Microsoft Exchange Server User Monitor tool (Exmon) to track users or services that are creating excessive log

		growth. For details, see Microsoft Exchange Server User Monitor.
5701	The database space troubleshooter detected a low space condition on volume D:\ for database MBD01. Provisioning for this database has been disabled. Free space for this database is less than 10 percent.	This error event indicates that the database has been removed from provisioning. In this case, the script runs the Set-MailboxDatabase cmdlet with the *ExcludeFromProvisioning* parameter set to `$true` against the specified database. When the database space problem is resolved, you must manually turn provisioning back on for the mailbox database. You may need to move mailboxes to a new server to rebalance space.
5702	The database space troubleshooter has detected a critically low space condition on volume D:\ for database MBD01. Provisioning for this database has been disabled. Free space for this database is less than 10 percent.	This error event indicates that the database has been removed from provisioning because resources are critically low. In this case, the script runs the Set-MailboxDatabase cmdlet with the *ExcludeFromProvisioning* parameter set to `$true` against the specified database. When the database space problem is resolved, you must manually turn provisioning back on for the mailbox database. You may need to move users to a new database to rebalance space.

1.8.3.15.11 Manage Database Latencies by Using the Troubleshoot-DatabaseLatency.ps1 Script in the Shell

Manage Database Latencies by Using the Troubleshoot-DatabaseLatency.ps1 Script in the Shell

Mailbox > Managing Mailbox Servers > Managing Mailbox Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The **Troubleshoot-DatabaseLatency.ps1** script is used by Microsoft System Center Operations Manager 2007 to detect and correct high latencies on a database. You can create a scheduled task by using Task Scheduler to run this script. Database latencies can be caused by a number of issues, including the following problems:

- **Disk latencies due to a bad disk** Disks with very high read or write latencies can be caused by a bad disk if the latencies persist over long periods of time.
- **Domain controller latencies** A domain controller may exhibit long latencies in responding to LDAP search queries.
- **High user workload** A single user (or set of users) conducting heavy operations can result in database latencies.

The **Troubleshoot-DatabaseLatency.ps1** script performs the following actions:

1. Checks whether database latencies are above the latency threshold (as specified by the *LatencyThreshold* parameter). The default is 70 milliseconds (ms).
2. Checks whether the disk's transfers-per-second rate is less than the DiskReadRateThreshold performance counter and whether the disk's seconds-per-transfer rate is greater than the DiskReadLatencyThreshold performance counter. If this is the case, the script determines that the disk must be replaced because it's under low-load conditions but is exhibiting high latencies.
3. Checks whether a single user is using more than one thread over the last 10 minute period for longer than the value specified by the *TimeInServerThreshold* parameter. If this is the case, the user is likely contributing to the high latencies, and, as a result, the user's mailbox is quarantined. The user's mailbox is quarantined for six hours, during which the user won't have access to e-mail.

The default settings used in the **Troubleshoot-DatabaseLatency.ps1** script are defined in the **StoreTSConstants.ps1** script.

Note:

A script must be run from the folder in which it resides. By default, scripts installed with Exchange 2010 are installed at C:\Program Files\Microsoft\Exchange Server\V14\Scripts. The Shell doesn't load scripts automatically. To run a script from the local file, you must precede all scripts with "**.**" For example, to run the SampleScript.ps1 script, type `.\SampleScript.ps1`. To run a script and specify the default installation path, type `"C:\Program Files\Microsoft\Exchange Server\V14\Scripts\SampleScript.ps1"`. For more information, see Scripting with the Exchange Management Shell.

Use the Troubleshoot-DatabaseLatency.ps1 script

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

The following parameter syntax set and table lists the parameters that you can use to detect and troubleshoot database latency issues.

```
Troubleshoot-DatabaseLatency.ps1 -MailboxDatabaseName <DatabaseID> [-LatencyThres
```

Parameter	Required	Description

MailboxDatabaseName	Required	The *MailboxDatabase* parameter specifies the mailbox database on which you're monitoring the database latency. This parameter accepts the following values: • GUID • Distinguished name (DN) • Database name
LatencyThreshold	Optional	The *LatencyThreshold* parameter specifies the amount of time in ms that the database can be idle before it's considered to be latent. The default value is 70 ms.
MonitoringContext	Optional	The *MonitoringContext* parameter specifies whether the results of the command are written in the Application event log. If you don't specify this value, the event logs are written to the following location in Event Viewer: **Event Viewer** > **Application and Services Logs** > **Microsoft** > **Microsoft-Exchange-Troubleshooters/Operational**. You don't have to specify a value with this parameter.
Quarantine	Optional	The *Quarantine* parameter specifies that heavy users who are contributing to the high latencies will be quarantined. If you don't specify this parameter, users won't be quarantined. You don't have to specify a value with this parameter.
TimeInServerThreshold	Optional	The *TimeInServerThreshold* parameter specifies how much time (in seconds) that any user activity for which the Exchange store uses a thread can be spent per minute for a single mailbox before the mailbox is considered hazardous to the health of the database. The number of seconds is measured by aggregating the time that all threads working on behalf of the mailbox (during the period reported by the Get-StoreUsageStatistics cmdlet) spend inside the Exchange store. The number of seconds of work per minute is calculated by dividing this aggregate number by the period

		reported by the **Get-StoreUsageStatistics** cmdlet (by default 10 minutes). For example, if you set this parameter to 80 seconds, and a single user uses more than one thread for longer than 80 seconds in a 10 minute period, an event error is returned. If you specify the *Quarantine* parameter, the event error is returned, and the user's mailbox is also quarantined for six hours. The default value is 200 seconds.

Example

This example shows how to run the **Troubleshoot-DatabaseLatency.ps1** script with the following settings:

- The *LatencyThreshold* parameter is set to 100 ms. If the database is latent for more than 100 ms, an error is returned.
- The *TimeInServerThreshold* parameter is set to 80 seconds. If a single user uses more than one thread for longer than 80 seconds in a 10 minute period, that user is quarantined.

```
.\Troubleshoot-DatabaseLatency.ps1 -MailboxDatabaseName MBD01 -LatencyThreshold 1
```

Note:

This example shows how to run the command manually once. To produce the data that the troubleshooter needs to effectively monitor your databases, you must run this command at regular intervals. We recommend that you use the Task Scheduler in the Microsoft Windows operating system to set up this task. For more information, see Task Scheduler Overview.

View the database latency troubleshooter output

In Event Viewer, the results of the **Troubleshoot-DatabaseLatency.ps1** script are available in the following location: **Event Viewer** > **Application and Services Logs** > **Microsoft** > **Microsoft-Exchange-Troubleshooters/Operational**.

For example, the following represents output from event ID 5111. This output would be returned if the script ran successfully without errors.

```
The database latency troubleshooter has detected that the current latency of 1 ms for database MBD01 is within the threshold of 100 ms.
```

The following table displays the event ID, the description of the event, and, if necessary, the action to take.

Note:

The descriptions in this table are examples of the information that may be included in these events.

Event ID	Description	Action
5110	The database latency troubleshooter started on	Informational only. No action is required.

	database MBD01.	
5111	The database latency troubleshooter has detected that the current latency of 30 ms for database MBD01 is within the threshold of 70 ms.	Informational only. No action is required.
5411	The database latency troubleshooter quarantined user f3bb8007-b6d1-45f5-b748-211d66fa43f6 on database MBD01 due to unusual activity in the mailbox. If the problem persists, manual intervention will be required.	Warning event: Continue monitoring.
5412	The database latency troubleshooter identified a problem with user f3bb8007-b6d1-45f5-b748-211d66fa43f6 on database MBD01 due to unusual activity in the mailbox. The user wasn't quarantined because the *Quarantine* parameter wasn't specified. If the problem persists, manual intervention will be required.	Warning event: Continue monitoring.
5710	The database latency troubleshooter detected that disk latencies are abnormal for database MBD01. You need to replace the disk.	Error event: You need to replace the disk. Contact your hardware manufacturer for replacement instructions.
5712	The database latency troubleshooter detected high RPC average latencies for database MBD01 but was unable to determine a cause. Manual intervention is required.	Error event: The cause of the latency couldn't be determined. You should create a dump file and analyze it to determine the cause of the issue. For Windows Vista, Windows 7, or Windows Server 2008, see How to Create a user-mode process dump file. For Windows Server 2003 or earlier, see How to use the Userdump.exe tool to create a dump file.

1.8.3.16 Managing Mailbox Import and Export Requests

Managing Mailbox Import and Export Requests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-08*

1.8.3.16.1 Add the Mailbox Import Export Role to a Role Group

Add the Mailbox Import Export Role to a Role Group

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

By default, the Mailbox Import Export management role isn't included in any of the built-in role groups, such as the Organization Management role group. To import or export mailbox data, you need to add the Mailbox Import Export management role to a role group.

You can add the Mailbox Import Export management role to a role group with no scope between the role and the role group. When you do this, the implicit read and implicit write scopes of the role apply. For details about how to add the Mailbox Import Export management role to a role group with a predefined scope, see Add a Role to a Role Group.

Looking for other management tasks related to importing and exporting mailbox data? Check out Managing Mailbox Import and Export Requests.

Prerequisites

- Because you can't add roles to built-in role groups, you need to create a role group to which you can add the Mailbox Import Export management role. For detailed instructions, see Create a Role Group.
- Read the following topics:
  - Understanding Management Role Groups
  - Understanding Management Role Assignments
  - Understanding Management Role Scopes
- Be aware that role assignments are additive. This means that all the roles are added together when they're evaluated. If two roles are assigned to a user and one role contains a cmdlet but the other doesn't, the cmdlet is still available to the user.
- By default, role assignments, including the Organization Management role, don't grant the ability (called *role delegation*) to assign roles to other users. Role delegation is an advanced task. To enable a user to assign roles to other role groups, see Delegate Role Assignments.

Use the Shell to add the Mailbox Import Export role to a role group with no scope

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Role groups" entry in the Role Management Permissions topic.

Note:

You can't use the EMC to add the Mailbox Import Export management role to a role group with no scope.

This example assigns the Mailbox Import Export management role to the Enterprise Support security group.

```
New-ManagementRoleAssignment -Name "Import Export_Enterprise Support" -SecurityGr
```

For detailed syntax and parameter information, see New-ManagementRoleAssignment.

Other Tasks

After you add the Mailbox Import Export management role to a role group, you may also want to:

- Add Members to a Role Group
- Change the Scope of Role Assignments to a Role Group
- Create a Mailbox Import Request
- Create a Mailbox Export Request

1.8.3.16.2 Create a Mailbox Export Request

Create a Mailbox Export Request

Mailbox > Managing Mailbox Servers > Managing Mailbox Import and Export Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-11-21*

A mailbox export request is a process of exporting mailbox or archive data to a .pst file. You can create more than one mailbox export request per mailbox, and each request must have a unique name. Microsoft Exchange automatically generates up to 10 unique names for a mailbox. To create more than 10 export requests for a mailbox, you must specify a unique name when you create the request.

Note:
Although you can create multiple export requests per mailbox at one time, you can create only one request at a time per .pst file. This is because the .pst file is locked as *in-use* when the request begins to run.

Alternatively, you can remove existing export requests by using the **Remove-MailboxExportRequest** cmdlet, and then start the new request by using `MailboxExportX` as the default value for the *Name* parameter (where *X* equals 0–9). For more information, see Remove a Mailbox Export Request.

Note:
You can't use the Exchange Management Console (EMC) to create a mailbox export request. You must use the Exchange Management Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Note:
When you use the **New-MailboxExportRequest** cmdlet to export a mailbox to a .pst file, the .pst file can be opened only by using Microsoft Outlook 2010 or a later version.

Prerequisites

To export a mailbox or archive, you must first create a network shared folder. You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox. For more information, see Set Permissions for Shared Folders.

Use the Shell to export a user's primary mailbox to a .pst file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example exports Ayla Kol's primary mailbox to a .pst file on the network shared folder PSTFileShare on server MBX-01.

Note:
The command doesn't create directories. If you specify a directory that doesn't exist, the command fails.

```
New-MailboxExportRequest -Mailbox AylaKol -FilePath \\MBX-01\PSTFileShare\Ayla_Re
```

For detailed syntax and parameter information, see New-MailboxExportRequest.

Use the Shell to export a user's personal archive to a .pst file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example exports Kweku's archive to a .pst file on the network shared folder PSTFileShare.

```
New-MailboxExportRequest -Mailbox Kweku -IsArchive -FilePath "\\SERVER01\PSTFileS
```

For detailed syntax and parameter information, see New-MailboxExportRequest.

Use the Shell to export data from a user's mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example exports Tony's messages that were received before January 1, 2010, and contain the words "company" and "profit" in the message body.

For more information about how to use the *ContentFilter* parameter, see Filterable Properties for the -ContentFilter Parameter.

```
New-MailboxExportRequest -Mailbox Tony -ContentFilter {(body -like "*company*") -
```

For detailed syntax and parameter information, see New-MailboxExportRequest.

Use the Shell to export data from a well-known folder

Well-known folders are mailbox folders known by a specific name, regardless of the folder's name in another language. For example, #Inbox# denotes the Inbox folder even if it's localized in Turkish as Gelen Kutusu. Well-known folders include the following types:

- Inbox
- SentItems
- DeletedItems
- Calendar
- Contacts
- Drafts

- Journal
- Tasks
- Notes
- JunkEmail
- CommunicationHistory
- Voicemail
- Fax
- Conflicts
- SyncIssues
- LocalFailures
- ServerFailures

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example exports all messages from Kweku's Inbox to the .pst file LitigationHold.

```
New-MailboxExportRequest -Mailbox Kweku -IncludeFolders "#Inbox#" -FilePath \\PST
```

For detailed syntax and parameter information, see New-MailboxExportRequest.

Other Tasks

After you export mailboxes or archives, you may also want to:

- View Mailbox Export Request Properties
- Remove a Mailbox Export Request

1.8.3.16.3 Create a Mailbox Import Request

Create a Mailbox Import Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A mailbox import request is a process of importing mailbox data from a .pst file into a mailbox or archive. You can create more than one mailbox import request per mailbox, and each request must have a unique name. Microsoft Exchange automatically generates up to 10 unique names for a mailbox. However, to create more than 10 import requests for a mailbox, you need to specify a unique name when creating the request.

Note:

Although you can create multiple import requests per mailbox at one time, you can create only one request at a time per .pst file. This is because the .pst file is locked as *in-use* when the request begins to run.

Alternatively, you can remove existing import requests by using the **Remove-**

MailboxImportRequest cmdlet, and then start the new request by using `MailboxImportX` as the default value for the *Name* parameter (where *X* equals 0–9). For more information, see Remove a Mailbox Import Request.

Note:
You can't use the Exchange Management Console (EMC) to create a mailbox import request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to import a .pst file into a user's primary mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example imports a recovered .pst file into Ayla's primary mailbox. Only data in the .pst file's Inbox is imported. The data is imported into the RecoveredFiles folder of Ayla's target mailbox.

```
New-MailboxImportRequest -Mailbox Ayla -FilePath \\SERVER01\PSTFiles\Recovered.ps
```

For detailed syntax and parameter information, see New-MailboxImportRequest.

Use the Shell to import a .pst file into a user's archive

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example imports a .pst file into Kweku's archive folder. The *TargetRootFolder* parameter isn't specified. Therefore, content is merged into existing folders, and folders are created if they don't already exist in the target folder structure.

```
New-MailboxImportRequest -Mailbox Kweku -IsArchive -FilePath \\SERVER01\PSTFiles\
```

For detailed syntax and parameter information, see New-MailboxImportRequest.

Use the Shell to import multiple .pst files

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

You need to grant read/write permission to the group Exchange Trusted Subsystem to

the network share where you'll export or import mailboxes. If you don't grant this permission, you'll receive an error message stating that Exchange is unable to establish a connection to the target mailbox.

This example imports all the .pst files in a shared folder. Each .pst file is named after a corresponding user's alias. The command creates an import request for all the .pst files and imports the data into the matching mailbox.

```
Dir \\SERVER01\PSTshareRO\Recovered\*.pst | %{ New-MailboxImportRequest -Name Rec
```

For detailed syntax and parameter information, see New-MailboxImportRequest.

1.8.3.16.4 Configure Mailbox Export Request Properties

Configure Mailbox Export Request Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create a mailbox export request, the request could possibly fail (for example, if the bad item limit is exceeded). If the request fails, you can edit the properties of the mailbox export request to increase the bad item limit. After the mailbox export request is initiated, you can edit the settings until it reaches a status of Completed.

Note:

You can't use the Exchange Management Console (EMC) to change the properties of an export request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to change the bad item limit of a single mailbox export request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example changes the mailbox export request Ayla\MailboxExport to accept up to 10 corrupted mailbox items.

```
Set-MailboxExportRequest -Identity "Ayla\MailboxExport" -BadItemLimit 10
```

For detailed syntax and parameter information, see Set-MailboxExportRequest.

Use the Shell to change the properties of multiple mailbox export requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example finds all mailbox export requests that have a status of Failed, changes the

bad item limit to accept up to five corrupted mailbox items, and then gives the requests a batch name of BadItemLimitTo5.

```
Get-MailboxExportRequest -Status Failed | Set-MailboxExportRequest -BadItemLimit
```

For detailed syntax and parameter information, see Get-MailboxExportRequest and Set-MailboxExportRequest.

1.8.3.16.5 Configure Mailbox Import Request Properties

Configure Mailbox Import Request Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create a mailbox import request, the request could possibly fail (for example, if the bad item limit is exceeded). If the request fails, you can edit the properties of the mailbox import request to increase the bad item limit. After the mailbox import request is initiated, you can edit the settings until it reaches a status of Completed.

Note:

You can't use the Exchange Management Console (EMC) to change the properties of an import request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to change the bad item limit of a single mailbox import request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example changes the mailbox import request Kweku\Import to accept up to five corrupted mailbox items.

```
Set-MailboxImportRequest -Identity "Kweku\Import" -BadItemLimit 5
```

For detailed syntax and parameter information, see Set-MailboxImportRequest.

Use the Shell to change the properties of multiple mailbox import requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example finds all mailbox import requests that have a status of Suspended, and then gives the requests a batch name of April14.

```
Get-MailboxImportRequest -Status Suspended | Set-MailboxImportRequest -BatchName
```

For detailed syntax and parameter information, see Get-MailboxImportRequest and Set-MailboxImportRequest.

1.8.3.16.6 Suspend a Mailbox Export Request

Suspend a Mailbox Export Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can suspend a mailbox export request any time after the request is created, but before the request reaches the status of Completed. You can resume the request by using the Resume-MailboxExportRequest cmdlet.

Note:
You can't use the Exchange Management Console (EMC) to suspend an export request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to suspend a mailbox export request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example suspends the mailbox export request Ayla\MailboxExport.

```
Suspend-MailboxExportRequest -Identity "Ayla\MailboxExport"
```

For detailed syntax and parameter information, see Suspend-MailboxExportRequest.

Use the Shell to suspend multiple mailbox export requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example suspends all mailbox export requests in progress by using the **Get-MailboxExportRequest** cmdlet to retrieve all requests that have a status of `InProgress`, and then pipelines the output to the **Suspend-MailboxExportRequest** cmdlet with the suspend comment "Resume after 10 P.M."

```
Get-MailboxExportRequest -Status InProgress | Suspend-MailboxExportRequest -Suspe
```

For detailed syntax and parameter information, see Get-MailboxExportRequest and Suspend-MailboxExportRequest.

Other Tasks

After you suspend the mailbox export request, you may also want to resume it. For detailed steps, see Resume a Mailbox Export Request.

1.8.3.16.7 Suspend a Mailbox Import Request

Suspend a Mailbox Import Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can suspend a mailbox import request any time after the request is created, but before the request reaches the status of Completed. You can resume the request by using the Resume-MailboxImportRequest cmdlet.

Note:
You can't use the Exchange Management Console (EMC) to suspend an import request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to suspend a mailbox import request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example suspends the mailbox import request Ayla\MailboxImport.

```
Suspend-MailboxImportRequest -Identity "Ayla\MailboxImport"
```

For detailed syntax and parameter information, see Suspend-MailboxImportRequest.

Use the Shell to suspend multiple mailbox import requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example suspends all mailbox import requests in progress by using the **Get-MailboxImportRequest** cmdlet to retrieve all requests that have a status of `InProgress`, and then pipelines the output to the **Suspend-MailboxImportRequest** cmdlet with the suspend comment "Resume after 10 P.M."

```
Get-MailboxImportRequest -Status InProgress | Suspend-MailboxImportRequest -Suspe
```

For detailed syntax and parameter information, see Get-MailboxImportRequest and Suspend-MailboxImportRequest.

Other Tasks

After you suspend the mailbox import request, you may also want to resume it. For detailed steps, see Resume a Mailbox Import Request.

1.8.3.16.8 Resume a Mailbox Export Request

Resume a Mailbox Export Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can resume a mailbox export request that has a status of Suspended or Failed.

Note:
You can't use the Exchange Management Console (EMC) to resume an export request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to resume a mailbox export request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example resumes the mailbox export request Kweku\Export.

```
Resume-MailboxExportRequest -Identity Kweku\Export
```

For detailed syntax and parameter information, see Resume-MailboxExportRequest.

Use the Shell to resume multiple mailbox export requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example resumes all mailbox export requests that have a status of Failed.

```
Get-MailboxExportRequest -Status Failed | Resume-MailboxExportRequest
```

For detailed syntax and parameter information, see Get-MailboxExportRequest and Resume-MailboxExportRequest.

1.8.3.16.9 Resume a Mailbox Import Request

Resume a Mailbox Import Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can resume a mailbox import request that has a status of Suspended or Failed.

Note:
You can't use the Exchange Management Console (EMC) to resume an import request. You must use the shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to resume a mailbox import request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example resumes the mailbox import request Kweku\MailboxImport.

```
Resume-MailboxImportRequest -Identity Kweku\MailboxImport
```

For detailed syntax and parameter information, see Resume-MailboxImportRequest.

Use the Shell to resume multiple mailbox import requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example resumes all mailbox import requests that have a status of Failed.

```
Get-MailboxImportRequest -Status Failed | Resume-MailboxImportRequest
```

For detailed syntax and parameter information, see Get-MailboxImportRequest and Resume-MailboxImportRequest.

1.8.3.16.10 View Mailbox Import Request Properties

View Mailbox Import Request Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A mailbox import request is the process of importing mailbox data from a .pst file to a

mailbox or archive. You can view the properties of a mailbox import request, or you can view the statistics. The properties provide you with basic information about the status of a mailbox import request. The statistics provide you with detailed information that can be used for troubleshooting purposes.

The search criteria for the **Get-MailboxImportRequest** and **Get-MailboxImportRequestStatistics** cmdlets is a Boolean **And** statement. If you use multiple parameters, you can narrow your search and reduce your search results.

Note:
You can't use the Exchange Management Console (EMC) to view the properties of a mailbox import request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to view mailbox import request properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example returns the default information about the status of the ongoing mailbox import request Tony\Recovered. By default, the type of information returned includes the name of the request, the mailbox for which the request is being performed, and the status of the request.

```
Get-MailboxImportRequest -Identity "Tony\Recovered"
```

This example returns detailed information about the status of the ongoing mailbox import request Tony\Recovered by using the *IncludeReport* parameter and by pipelining the results to the **Format-List** command.

```
Get-MailboxImportRequest -Identity "Tony\Recovered" -IncludeReport | Format-List
```

This example returns the information about mailbox import requests that have a status of In Progress for mailboxes or archives that reside on database DB01.

```
Get-MailboxImportRequest -Status InProgress -Database DB01
```

This example returns information about mailbox import requests in the ImportingDB1PSTs batch that have a status of Completed.

```
Get-MailboxImportRequest -BatchName "ImportingDB1PSTs" -Status Completed
```

This example returns all mailbox import requests that have the name Recovered and have a status of Suspended.

```
Get-MailboxImportRequest -Name "Recovered" -Suspend $true
```

For detailed syntax and parameter information, see Get-MailboxImportRequest.

Get-MailboxImportRequest Output

By default, the **Get-MailboxImportRequest** cmdlet returns the name of the request, the alias of the target mailbox, and the status of the request. The following table lists the information that's returned if you pipeline the **Format-List** command.

Value	Description
FilePath	This value specifies the file path of the .pst

	file from which data is being exported.
TargetDatabase	This value specifies the database that contains the mailbox or archive to which the .pst file is being imported.
Mailbox	This value specifies the user whose mailbox or archive is being imported.
Name	This value specifies the name of the mailbox import request.
RequestGUID	This value specifies the GUID of the mailbox import request.
RequestQueue	This value specifies the database on which the Microsoft Exchange Mailbox Replication service (MRS) stores the detailed status of the mailbox import request.
Flags	This value specifies flags that the cmdlet automatically sets when creating the mailbox import request.
BatchName	This value specifies a batch name. If you didn't provide a batch name, this field is blank.
Status	This value specifies the status of the request.
Suspend	This value specifies whether the request was created to be automatically suspended before completion.
Direction	This value specifies whether the request is a push or a pull. For mailbox import requests, this value is always `Pull`.
RequestStyle	This value specifies whether the request is `IntraOrg` or `CrossOrg`. For Exchange Server 2010 Service Pack 1 (SP1), this value is always `IntraOrg`.
Identity	This value specifies the identity of the mailbox import request.

Use the Shell to view mailbox import request statistics

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example returns the default statistics for the mailbox import request for Tony Smith. By default, the type of information returned includes the name of the request, the mailbox for which the request is being performed, and the status of the request.

```
Get-MailboxImportRequestStatistics -Identity Tony\MailboxImport
```

This example returns additional information about the mailbox import request

LitigationHold for Ayla's mailbox by using the *IncludeReport* parameter and by pipelining the results to the **Format-List** command.

```
Get-MailboxImportRequestStatistics -Identity Ayla\LitigationHold -IncludeReport |
```

This example returns detailed statistics for the mailbox import request Tony\MailboxImport and exports the report to a .csv file.

```
Get-MailboxImportRequestStatistics -Identity Tony\MailboxImport | Export-CSV \\SE
```

This example returns additional information for all the mailbox import requests that have a status of Failed by using the *IncludeReport* parameter, and then saves the information to the text file AllImportReports.txt.

```
Get-MailboxImportRequest -Status Failed | Get-MailboxImportRequestStatistics -Inc
```

For detailed syntax and parameter information, see Get-MailboxImportRequestStatistics and Get-MailboxImportRequest.

Get-MailboxImportRequestStatistics Output

By default, the **Get-MailboxImportRequestStatistics** cmdlet returns the name of the request, the status of the request, the alias of the target mailbox, and the percentage completed. The following table lists the information that's returned if you pipeline the **Format-List** command.

Value	Description
Name	This value specifies the name of the request.
Status	This value specifies the status of the request.
StatusDetail	This value specifies more detailed status information about the request.
Flags	This value specifies flags that the cmdlet automatically sets when creating the mailbox import request.
RequestStyle	This value specifies whether the request is `IntraOrg` or `CrossOrg`. For Exchange 2010 SP1, this value is always `IntraOrg`.
Suspend	If set to `$true`, this value specifies whether an administrator suspended this request or whether the request failed.
FilePath	This value specifies a file path from where the .pst file is imported.
TargetAlias	This value specifies the alias of the target mailbox.
TargetIsArchive	This value specifies whether the .pst file is being imported into an archive.
TargetExchangeGuid	This value specifies the GUID of the target mailbox or archive.
TargetRootFolder	This value specifies the name of the root folder in the mailbox's or archive's hierarchy

	to which data is imported. If this value is blank, data is imported to the folder Top of Information Store.
TargetDatabase	This value specifies the target database to which the .pst file is being imported.
IncludeFolders	This value specifies the list of folders to include during the import. If this value is blank, no folders were specified when the request was created, and all folders will be imported to the mailbox or archive (unless the *ExcludeFolders* parameter is used to exclude specific folders).
ExcludeFolders	This value specifies the list of folders to exclude during the import. If this value is blank, no folders were specified when the request was created, and all folders will be imported to the mailbox or archive (unless the *IncludeFolders* parameter is used to include specific folders).
ExcludeDumpster	This value specifies whether the Recoverable Items folder was excluded when the request was created.
ConflictResolutionOption	This value specifies the action for MRS to take if there are matching messages in the target and source folders.
AssociatedMessagesCopyOption	This value specifies whether the associated messages are copied when the request is processed. Associated messages are special messages that contain hidden data with information about rules, views, and forms.
BatchName	This value specifies a batch name. If you don't provide a batch name, this field is blank.
BadItemLimit	This value specifies the number of bad items that MRS will skip if the request encounters corrupted messages.
BadItemsEncountered	This value specifies the number of corrupted messages encountered by the command. If the *BadItemsEncountered* value is greater than the *BadItemLimit* value, the request fails.
QueuedTimestamp	This value specifies the date and time at which the request was initiated to MRS.
StartTimestamp	This value specifies the date and time at which the import started being processed by MRS.
LastUpdateTimeStamp	This value specifies the date and time at which the last change was made to the request. The change could have been made

	by an administrator or by MRS.
CompletionTimeStamp	This value specifies the date and time at which the request completed.
SuspendedTimeStamp	This value specifies the date and time at which the request was suspended. If the request wasn't suspended, this value is blank.
OverallDuration	This value specifies the amount of time it took to complete the request. If the request is in a Failed state, this value specifies the amount of time between the request being initiated and the request failing. If the request hasn't completed, this value specifies the amount of time between the request being initiated and the **Get-MailboxImportRequestStatistics** cmdlet being run.
TotalSuspendedDuration	This value specifies the amount of time the request was in the Suspended state.
TotalFailedDuration	This value specifies the amount of time the request was in the Failed state.
TotalQueuedDuration	This value specifies the amount of time the request was in the Queued state.
TotalInProgressDuration	This value specifies the amount of time the request was in the In Progress state.
TotalStalledDueToHADuration	This value specifies the amount of time the request was stalled due to high availability.
TotalTransientFailureDuration	This value specifies the amount of time that the request was stalled due to a transient failure, such as a database failure or network connectivity issues.
MRSServerName	This value specifies the name of the Client Access server that processed the request.
EstimatedTransferSize	This value specifies the file size that was imported or the file size that MRS expects to import if the mailbox import request is in the In Progress state.
EstimatedTransferItemCount	This value specifies the number of items that were imported or the number of items that MRS expects to import if the request is in the In Progress state.
BytesTransferred	This value specifies the number of bytes that have been transferred.
BytesTransferredPerMinute	This value specifies the average number of bytes that have been transferred per minute.
ItemsTransferred	This value specifies the number of items that

	have been transferred.
PercentComplete	This value specifies the percentage of the request that has been completed.
PositionInQueue	If the request hasn't started, this value specifies the request's position in the queue.
FailureCode	If there was a failure, this value specifies the failure code.
FailureType	If there was a failure, this value specifies the failure type.
Message	If there was a failure, this value specifies the failure message. This value can also specify the suspend comment.
FailureTimestamp	If the request failed, this value specifies the date and time at which the request failed.
IsValid	This value specifies whether the mailbox import request was valid.
ValidationMessage	If the mailbox import request wasn't valid, this value specifies the reason.
RequestGUID	This value specifies the GUID of the mailbox import request.
RequestQueue	This value specifies the database on which MRS stores the detailed status of the mailbox import request.
Identity	This value specifies the identity of the request.
Report	If you specified the *IncludeReport* parameter when using the **Get-MailboxImportRequest** cmdlet, this value specifies information that can be used to troubleshoot the request.

1.8.3.16.11 View Mailbox Export Request Properties

View Mailbox Export Request Properties

Mailbox > Managing Mailbox Servers > Managing Mailbox Import and Export Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A mailbox export request is the process of exporting mailbox or archive data to a .pst file. You can view the properties of an export request, or you can view the statistics. The properties provide you with basic information about the status of an export request. The statistics provide you with detailed information that can be used for troubleshooting purposes.

Note:

You can't use the Exchange Management Console (EMC) to view the properties of a mailbox export request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

View Export Request Properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example returns the default information about the status of the ongoing export request Tony\DB01toPST. By default, the type of information includes the name of the request, the mailbox for which the request is being performed, and the status of the request.

```
Get-MailboxExportRequest -Identity "Tony\DB01toPST"
```

This example returns additional information about the status of the ongoing export request Tony\DB01toPST by pipelining the results to the **Format-List** command.

```
Get-MailboxExportRequest -Identity "Tony\DB01toPST" | Format-List
```

This example returns information about export requests that have a status of In Progress and are exporting data from a mailbox or archive that resides on database DB01.

```
Get-MailboxExportRequest -Status InProgress -Database DB01
```

This example returns information about export requests in the Attachment_CompanyReport batch that have a status of Completed.

```
Get-MailboxExportRequest -BatchName "Attachment_CompanyReport" -Status Completed
```

This example returns all export requests that have the name DB01toPST and have a status of Suspended.

```
Get-MailboxExportRequest -Name "DB01toPST" -Suspend $true
```

For detailed syntax and parameter information, see Get-MailboxExportRequest.

Get-MailboxExportRequest Output

By default, the **Get-MailboxExportRequest** cmdlet returns the name of the request, the mailbox for which the request is being performed, and the status of the request. The following table lists the information that's returned if you pipeline the **Format-List** command:

Value	Description
FilePath	This value specifies file path where the .pst file will be exported.
SourceDatabase	This value specifies the database that contains the mailbox or archive that's being exported.
Mailbox	This value specifies the user whose mailbox or archive is being exported.
Name	This value specifies the name of the export request.
RequestGUID	This value specifies the GUID of the export

	request.
RequestQueue	This value specifies the database on which the Microsoft Exchange Mailbox Replication service (MRS) stores the detailed status of the export request.
Flags	This value specifies flags that the cmdlet automatically sets when creating the export request.
BatchName	This value specifies a batch name. If you didn't provide a batch name, this field will be blank.
Status	This value specifies the status of the request.
Suspend	This value specifies if the request was created to be automatically suspended before completion.
Direction	This value specifies if the request is a push or a pull. For export requests, this value is always `Push`.
RequestStyle	This value specifies if the request is `IntraOrg` or `CrossOrg`. For Exchange 2010 SP1, this value is always `IntraOrg`.
Identity	This value specifies the identity of the export request.

View Export Request Statistics

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example returns the default export request statistics for Tony\MailboxExport. By default, the type of information returned includes the name of the request, the mailbox for which the request is being performed, and the status of the request.

```
Get-MailboxExportRequestStatistics -Identity Tony\MailboxExport
```

This example returns additional information about the export request Tony\MailboxExport by using the *IncludeReport* parameter and by pipelining the results to the **Format-List** command.

```
Get-MailboxExportRequestStatistics -Identity Tony\MailboxExport -IncludeReport |
```

This example returns detailed statistics for the export request Tony\MailboxExport and exports the report to a .csv file.

```
Get-MailboxExportRequestStatistics -Identity Tony\MailboxExport | Export-CSV \\Ex
```

This example returns additional information for all the export requests that have a status of Failed by using the *IncludeReport* parameter, and then saves the information to the text file AllExportReports.txt.

```
Get-MailboxExportRequest -Status Failed | Get-MailboxExportRequestStatistics -Inc
```

For detailed syntax and parameter information, see Get-MailboxExportRequestStatistics and Get-MailboxExportRequest.

Get-MailboxExportRequestStatistics Output

By default, the **Get-MailboxExportRequestStatistics** cmdlet returns the name of the request, the status of the request, the alias of the source mailboxes, and the percentage completed. The following table lists the information that's returned if you pipeline the **Format-List** command:

Value	Description
Name	This value specifies the name of the request.
Status	This value specifies the status of the request.
StatusDetail	This value specifies more detailed status information about the request.
Flags	This value specifies flags that the cmdlet automatically sets when creating the export request.
RequestStyle	This value specifies if the request is `IntraOrg` or `CrossOrg`. For Exchange 2010 SP1, this value is always `IntraOrg`.
Suspend	If set to `true`, this value specifies whether an administrator suspended this request or if the request failed.
FilePath	This value specifies file path from where the .pst file is exported.
SourceAlias	This value specifies the alias of the source mailbox.
SourceExchangeGuid	This value specifies the GUID of the source mailbox or archive.
SourceRootFolder	This value specifies the name of the root folder in the mailbox's or archive's hierarchy from which the data is exported. If this value is blank, the data is exported from the folder "Top of Information Store".
IncludeFolders	This value specifies the list of folders to include during the export. If this value is blank, no folders were specified when the request was created and all folders will be exported (unless the *ExcludeFolders* parameter is used to exclude specific folders).
ExcludeFolders	This value specifies the list of folders to exclude during the export. If this value is blank, no folders were specified when the request was created and all folders will be exported (unless the *IncludeFolders* parameter is used to include specific folders).

ExcludeDumpster	This value specifies if the Recoverable Items folder was excluded when the request was created.
ConflictResolutionOption	This value specifies the action for MRS to take if there are matching messages in the target and source folders.
AssociatedMessagesCopyOption	This value specifies whether the associated messages are copied when the request is processed. Associated messages are special messages that contain hidden data with information about rules, views, and forms.
BatchName	This value specifies a batch name. If you don't provide a batch name, this field will be blank.
ContentFilter	This value specifies the OPATH content filter used to search for message content. For more information, see Filterable Properties for the -ContentFilter Parameter.
ContentFilterLanguage	This value specifies the language used in the content filter string searches.
BadItemLimit	This value specifies the number of bad items that MRS will to skip if the request encounters corrupted messages.
BadItemsEncountered	This value specifies the number of corrupted messages encountered by the command. If the number of *BadItemsEncountered* is greater than the *BadItemLimit*, the request will fail.
QueuedTimeStamp	This value specifies the time at which the request was initiated to MRS.
StartTimestamp	This value specifies the date and time at which the export started being processed by MRS.
LastUpdateTimeStamp	This value specifies the date and time at which the last change was made to the request. The change could have been made by an administrator or by MRS.
CompletionTimeStamp	This value specifies the date and time at which the request completed.
SuspendedTimeStamp	This value specifies the date and time at which the request was suspended. If the request wasn't suspended, this value will be blank.
OverallDuration	This value specifies the amount of time it took to complete the request. If the request is in a Failed state, this value specifies the amount of time between the request being initiated and the request failed. If the request hasn't completed, this value

	specifies the amount of time between the request being initiated and the **Get-MailboxExportRequestStatistics** cmdlet being run.
TotalSuspendedDuration	This value specifies the amount of time the request was in the Suspended state.
TotalFailedDuration	This value specifies the amount of time the request was in the Failed state.
TotalQueuedDuration	This value specifies the amount of time the request was in the queued state.
TotalInProgressDuration	This value specifies the amount of time the request was in the In Progress state.
TotalStalledDueToHADuration	This value specifies the amount of time the request was stalled due to high availability.
TotalTransientFailureDuration	This value specifies the amount of time the request was in the Stalled state due to a transient database failure.
MRSServerName	This value specifies the name of the Client Access server that processed the request.
EstimatedTransferSize	This value specifies the file size that was exported or MRS expects to export if the export request is still in progress.
EstimatedTransferItemCount	This value specifies the number of items that were exported or that MRS expects to export if the request is in the In Progress state.
BytesTransferred	This value specifies the number of bytes that have been transferred.
BytesTransferredPerMinute	This value specifies the average number of bytes that have been transferred per minute.
ItemsTransferred	This value specifies the number of items that have been transferred.
PercentComplete	This value specifies the percentage of the request that has been completed.
PositionInQueue	If the request hasn't started, this value specifies the request's position in the queue.
FailureCode	If there was a failure, this value specifies the failure code.
FailureType	If there was a failure, this value specifies the failure type.
Message	If there was a failure, this value specifies the failure message. This value can also specify the suspend comment.

FailureTimestamp	If the request failed, this value specifies the date and time at which the request failed.
IsValid	This value specifies if the export request was valid.
ValidationMessage	If the export request wasn't valid, this value specifies the reason.
RequestGUID	This value specifies the GUID of the export request.
RequestQueue	This value specifies the database on which MRS stores the detailed status of the export request.
Identity	This value specifies the identity of the request.
Report	If you specified the *IncludeReport* parameter when using the **Get-MailboxExportRequest** cmdlet, this value specifies information that can be used to troubleshoot the request.

1.8.3.16.12 Remove a Mailbox Import Request

Remove a Mailbox Import Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Completed mailbox import requests aren't cleared automatically. You can remove fully or partially completed mailbox import requests by using the **Remove-MailboxImportRequest** cmdlet.

Note:
If you remove a partially completed mailbox import request, the request is removed from the Microsoft Exchange Mailbox Replication service (MRS) job queue. Any import progress made before the removal won't be reverted back.

Note:
You can't use the Exchange Management Console (EMC) to remove an import request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to remove a mailbox import request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example removes the mailbox import request Ayla\MailboxImport.

```
Remove-MailboxImportRequest -Identity "Ayla\MailboxImport"
```

This example cancels a mailbox import request by using the *RequestGuid* parameter for a mailbox or archive on MBXDB01.

Note:
You should use the *RequestGuid* parameter only for debugging or troubleshooting purposes.

```
Remove-MailboxImportRequest -RequestQueue MBXDB01 -RequestGuid 25e0eaf2-6cc2-4353
```

For detailed syntax and parameter information, see Remove-MailboxImportRequest.

Use the Shell to remove multiple mailbox import requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example removes all mailbox import requests that have a status of Completed.

```
Get-MailboxImportRequest -Status Completed | Remove-MailboxImportRequest
```

For detailed syntax and parameter information, see Get-MailboxImportRequest and Remove-MailboxImportRequest.

1.8.3.16.13 Remove a Mailbox Export Request

Remove a Mailbox Export Request

Mailbox > Managing Mailbox Servers > Managing Mailbox Import and Export Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Completed mailbox export requests aren't cleared automatically. You can remove fully or partially completed mailbox export requests by using the **Remove-MailboxExportRequest** cmdlet.

Note:
If you remove a partially completed mailbox export request, content already exported isn't removed from the .pst file. If you want to start a new mailbox export request to the same file and start with an empty .pst file, you must rename or delete the previous .pst file.

Note:
You can't use the Exchange Management Console (EMC) to remove an export request. You must use the Shell.

Looking for other management tasks related to mailbox import or export requests? Check out Managing Mailbox Import and Export Requests.

Use the Shell to remove a mailbox export

request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example removes the mailbox export request Ayla\MailboxExport.

```
Remove-MailboxExportRequest -Identity "Ayla\MailboxExport"
```

This example cancels a mailbox export request by using the *RequestGuid* parameter for a mailbox or archive on MBXDB01.

Note:

You should use the *RequestGuid* parameter only for debugging or troubleshooting purposes.

```
Remove-MailboxExportRequest -RequestQueue MBXDB01 -RequestGuid 25e0eaf2-6cc2-4353
```

For detailed syntax and parameter information, see Remove-MailboxExportRequest.

Use the Shell to remove multiple mailbox export requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Import Export" entry in the Mailbox Permissions topic.

This example removes all mailbox export requests that have a status of Completed.

```
Get-MailboxExportRequest -Status Completed | Remove-MailboxExportRequest
```

For detailed syntax and parameter information, see Get-MailboxExportRequest and Remove-MailboxExportRequest.

1.8.3.17 Managing Repair Requests

Managing Repair Requests

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-16*

Create a Mailbox Repair Request

View Mailbox Repair Request Entries in Event Viewer

Create a Public Folder Database Repair Request

Create a Mailbox Repair Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Use the **New-MailboxRepairRequest** cmdlet to detect and repair mailbox corruptions. You can run this command against a specific mailbox or against a mailbox database. While this task is running, mailbox access is disrupted for the mailbox being repaired. If you're running this command against a mailbox database, only the mailbox being repaired is disrupted. All other mailboxes in the database remain operational.

Note:
You can't perform these procedures in the Exchange Management Console (EMC). You must use the Shell.

The **New-MailboxRepairRequest** cmdlet detects and repairs the following types of mailbox corruptions:

- Search folder corruptions (using the `SearchFolder` value of the *CorruptionType* parameter)
- Aggregate counts on folders that aren't reflecting correct values (using the `AggregateCounts` value of the *CorruptionType* parameter)
- Views on folders that aren't returning the correct content (using the `FolderView` value of the *CorruptionType* parameter)
- Provisioned folders that are incorrectly pointing into parent folders that aren't provisioned (using the `ProvisionedFolder` value of the *CorruptionType* parameter)

To avoid any performance problems, Exchange enforces limits on the number of simultaneous repair requests that can be submitted per server. Only one request can be active for a database-level repair; up to 100 requests can be active for a mailbox-level repair per server.

Note:
After you start the repair request, it can't be stopped unless you dismount the database. For more information, see Dismount a Database.

Looking for other management tasks related to creating a mailbox repair request? Check out Managing Repair Requests.

New-MailboxRepairRequest Output

When you run the **New-MailboxRepairRequest** cmdlet, the following output is displayed:

- **RepairTaskID** This value specifies a unique identifier for the repair task.
- **Mailbox** This value specifies the mailbox being repaired. If you specified a database-level repair, this value is blank.
- **Database** This value specifies the database that contains the mailbox being repaired.
- **Server** This value specifies the Mailbox server hosting the active copy of the database that contains the mailbox being repaired.

Use the Shell to detect corruptions and repair a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox repair request" entry in the Mailbox Permissions topic.

This example detects and repairs the folder view for the mailbox tony@contoso.com.

```
New-MailboxRepairRequest -Mailbox tony@contoso.com -CorruptionType FolderView
```

For detailed syntax and parameter information, see New-MailboxRepairRequest.

Use the Shell to detect corruptions and repair a set of mailboxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox repair request" entry in the Mailbox Permissions topic.

This example detects and repairs all corruption types for mailboxes that have CustomAttribute2 set to Repair Required.

```
Get-Mailbox -Filter {CustomAttribute2 -like "Repair Required"} | New-MailboxRepai
```

For detailed syntax and parameter information, see Get-Mailbox and New-MailboxRepairRequest.

Use the Shell to detect corruptions for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox repair request" entry in the Mailbox Permissions topic.

This example detects and reports only on `ProvisionedFolder` and `SearchFolder` corruption issues in Ayla Kol's mailbox. This command doesn't repair the mailbox.

```
New-MailboxRepairRequest -Mailbox ayla -CorruptionType ProvisionedFolder,SearchFo
```

For detailed syntax and parameter information, see New-MailboxRepairRequest.

Use the Shell to repair all mailboxes in a database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox repair request" entry in the Mailbox Permissions topic.

This example detects and repairs the corruption type `AggregateCounts` for the mailbox database MBX-DB01.

```
New-MailboxRepairRequest -Database MBX-DB01 -CorruptionType AggregateCounts
```

For detailed syntax and parameter information, see New-MailboxRepairRequest.

Other Tasks

After you perform these procedures, you may also want to see which mailboxes had corruptions and were repaired. For details, see View Mailbox Repair Request Entries in Event Viewer.

1.8.3.17.2 View Mailbox Repair Request Entries in Event Viewer

View Mailbox Repair Request Entries in Event Viewer

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-29*

After you run the New-MailboxRepairRequest cmdlet, you can use Event Viewer to view the details of the request.

This topic lists the events that are logged and also provides steps for creating a custom view in Event Viewer in which you can view the repair request events.

Event IDs for Mailbox Repair Requests

The events are logged in Event Viewer under the **MSExchangeIS Mailbox Store** source. The following event IDs are logged for repair requests.

Event ID	Description
10044	The mailbox repair request failed for provisioned folders. This event ID is created in conjunction with event ID 10049.
10045	The database repair request failed for provisioned folders. This event ID is created in conjunction with event ID 10049.
10046	The provisioned folders repair request completed successfully.
10047	A mailbox-level repair request started.
10048	The mailbox or database repair request completed successfully.
10049	The mailbox or database repair request failed because Exchange encountered a problem with the database or another task is running against the database. To fix this issue, perform the following steps: 1. Run the command again. 2. If the problem persists, run Eseutil (Exchange Server Database Utilities) to check the drive for errors. 3. Run the Microsoft Exchange Troubleshooting Assistant v1.1 (ExTRA) with the **tagISINTEG** property. Save the ExTRA log trace information and then contact Microsoft support

<table>
<tr><td></td><td>services.</td></tr>
<tr><td>10050</td><td>The database repair request couldn't run against the database because the database doesn't support the corruption types specified in the command. This issue can occur when you run the command from a server that's running a later version of Exchange than the database you're scanning.</td></tr>
<tr><td>10051</td><td>The database repair request was cancelled because the database was dismounted.</td></tr>
<tr><td>10059</td><td>A database-level repair request started.</td></tr>
<tr><td>10062</td><td>Corruption was detected. View the repair log details to see what the corruption type was and if it was repaired.

The following is an example of the information you would get if the repair request detected and repaired a mailbox with event ID 10062.

Corruptions detected during online integrity check for request 321c88e0-0ad2-4e15-b93b-197a94efd1bd

Mailbox:C51AB7C3-9EB7-40C9-AAC6-953FD084AF59

Database:MBD01
<table>
<tr><th>Corruption</th><th>Is fixed</th><th>FID</th><th>Resolution</th></tr>
<tr><td>Folder Backlinks</td><td>Yes</td><td>1c7c-BC72D267870102</td><td>Update</td></tr>
<tr><td>Folder Aggregate Count</td><td>Yes</td><td>1c7c-BC72D267870102</td><td>Update</td></tr>
</table>
</td></tr>
</table>

Looking for other management tasks related to mailbox repair requests? Check out Managing Repair Requests.

Use Event Viewer to create a custom view for mailbox repair requests

1. Open **Event Viewer**.
2. In the console tree, click **Event Viewer**
3. On the **Action** menu, click **Create Custom View**.
4. In **Create Custom View**, click **By source**, and then, in the **Event sources** list, select **MSExchangeIS Mailbox Store**.
5. In the box labeled **<All Event IDs>**, add the event IDs for the repair request events that you want to see. For example if you want to see all of the events, enter **10044,10045,01146,10047,10048,10049,10050,10051,10059,10062**.
6. Click **OK**.
7. In **Save Filter to Custom View**, type the name of the view. For example, **Mailbox Repair Events**.

8. Click **OK**.
9. The view is created in the **Custom Views** node of the Event Viewer console tree.

1.8.3.17.3 Create a Public Folder Database Repair Request

Create a Public Folder Database Repair Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **New-PublicFolderDatabaseRepairRequest** cmdlet to detect and fix replication issues in a public folder database. While the request is running, only access to the public folder being repaired is disrupted. All other public folders are available.

Note:
After you start the repair request, you can't stop it unless you dismount the database. For more information, see Dismount a Database.

Looking for other management tasks related to repair requests? Check out Managing Repair Requests.

New-PublicFolderDatabaseRepairRequest Output

When you run the **New-PublicFolderDatabaseRepairRequest** cmdlet, the following output is displayed:

- **RequestID** This value specifies a unique identifier for the repair request.
- **Database** This value specifies the public folder database on which the repair is being made.
- **Server** This value specifies the Mailbox server hosting the public folder database being repaired.

Use the Shell to create a public folder database repair request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the" Public folder database repair request" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to create a public folder database repair request.

This example detects and repairs replication issues in public folder database PFDB01.

```
New-PublicFolderDatabaseRepairRequest -Database PFDB01 -CorruptionType ReplState
```

This example only detects and reports replication issues in public folder database PFDB02. No issues are repaired.

```
New-PublicFolderDatabaseRepairRequest -Database PFDB02 -CorruptionType ReplState
```

For detailed syntax and parameter information, see New-PublicFolderDatabaseRepairRequest.

1.8.3.18 Managing Meeting Items

Managing Meeting Items

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-17*

Enable or Disable the Automatic Processing of Meeting Messages

Enable or Disable the Automatic Removal of Older Versions of Meeting Messages

1.8.3.18.1 Enable or Disable the Automatic Processing of Meeting Messages

Enable or Disable the Automatic Processing of Meeting Messages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can enable or disable the Calendar Attendant function to process meeting messages for a user. A *meeting message* is any meeting item used in the meeting workflow to update calendar items.

By default, the Calendar Attendant performs the following actions on a user's calendar:

- Updates the time of the meeting on an attendee's calendar after receiving an update from the organizer.
- Updates the attendee's response on the organizer's calendar after receiving a response from the attendee.

For more information about how to disable the automatic removal of older meeting messages on a per-user basis in Microsoft Office Outlook Web App, see "Automatic Processing" in Calendar Tab.

Looking for other management tasks related to meeting items? Check out Managing Meeting Items.

Use the Shell to enable automatic processing of meeting messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar processing" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable automatic processing of meeting messages.

This example enables the automatic processing of meeting messages for Ellen Adam's mailbox.

```
Set-CalendarProcessing -Identity "Ellen Adams" -AutomateProcessing AutoUpdate
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

Use the Shell to disable automatic processing of meeting messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar processing" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to disable automatic processing of meeting messages.

This example disables the automatic processing of meeting messages for Kevin's mailbox.

```
Set-CalendarProcessing -Identity "Kevin" -AutomateProcessing:None
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

1.8.3.18.2 Enable or Disable the Automatic Removal of Older Versions of Meeting Messages

Enable or Disable the Automatic Removal of Older Versions of Meeting Messages

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, the Calendar Attendant removes older versions of meeting messages (such as meeting requests, cancellations, and updates) delivered to recipients' Inboxes. Removing these items helps reduce the number of meeting messages that users have to manage.

When the Calendar Attendant performs this task, the following actions occur:

- Out-of-date meeting updates are deleted.
- Redundant meeting responses that don't contain text are deleted.
- Meeting messages that contain text (for example, responses with additional text or attachments) are preserved.

For example, Tony sends a meeting request to Ayla, and Ayla tentatively accepts the meeting. Tony receives a meeting message stating that Ayla has tentatively accepted the meeting. Ayla later declines the meeting. Tony receives the newer e-mail message stating that Ayla has declined the meeting. The Calendar Attendant moves the older, tentative meeting message into Tony's Deleted Items folder.

For more information about how to disable the automatic removal of older meeting messages on a per-user basis in Microsoft Office Outlook Web App, see "Automatic

Processing" in Calendar Tab.

Looking for other management tasks related to meeting items? Check out Managing Meeting Items.

Use the Shell to disable automatic removal of meeting messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar processing" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to disable automatic removal of meeting messages.

This example disables the process by setting the *RemoveOldMeetingMessages* parameter to `false` for Ayla Kol's mailbox.

```
Set-CalendarProcessing -Identity "Ayla Kol" -RemoveOldMeetingMessages $false
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

Use the Shell to enable automatic removal of meeting messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar processing" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable automatic removal of meeting messages.

This example enables the process by setting the *RemoveOldMeetingMessages* parameter to `true` for Tony Smith's mailbox.

```
Set-CalendarProcessing -Identity "Tony Smith" -RemoveOldMeetingMessages $true
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

1.8.3.19 Managing Move Requests

Managing Move Requests

Troubleshooting Mailbox Moves

1.8.3.19.1 Create a Local Move Request

Create a Local Move Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A move request is the process of moving a mailbox from one mailbox database to another. A local move request is a mailbox move that occurs within a single forest. For more information, see Understanding Move Requests.

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), mailboxes and personal archive mailboxes can reside on separate databases. Using the move request functionality, you can move the primary mailbox and the associated archive to the same database or to separate ones. For more information about personal archive mailboxes, see Understanding Personal Archives.

Note:
If you're moving a mailbox from an Exchange 2003 database, the mailbox move will be offline.

Note:
To view all move requests in a multiple-domain environment in the Exchange Management Console, the recipient scope needs to be modified to view the entire forest. For more information, see Change the Recipient Scope.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

What Do You Want to Do?

- Use the EMC to create a local move request
- Use the Shell to create a local move request

Use the EMC to create a local move

request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select one or more mailboxes that you want to move.
3. In the action pane, click **New Local Move Request**.

4. On the **Introduction** page, configure the following settings:
   - **A new move request will be placed for the following mailboxes** This box displays the mailboxes that you selected in the result pane. If you want to add or remove mailboxes, click **Cancel**, and then make the changes in the result pane.
   - **Target mailbox database** Click **Browse** to open the **Select Mailbox Database** dialog box. Use this dialog box to select the mailbox database to which you want to move the mailboxes. Click **OK** to return to the wizard.

     If the mailbox has an archive associated with it, the following options are displayed:

     Move only the user mailbox Click this button if you want to move only the user's primary mailbox to the new database. This is selected by default.

     Move only the archive mailbox Click this button if you want to move only the user's archive mailbox to the new database.

     Move both the mailbox and the archive Click this button if you want to move both the user's primary mailbox and the associated archive mailbox to the new database.

5. On the **Move Settings** page, specify how you want to manage corrupted messages:
   - **Skip the mailbox** Click this button to specify that mailboxes containing corrupted messages won't be moved. We recommend selecting this option.
   - **Skip the corrupted messages** Click this button to move the mailbox, but not to move any corrupted messages. If you select this option, you need to set the **Maximum number of messages to skip**. We recommend selecting this option only if the move request failed in a previous attempt.
   - **Maximum number of messages to skip** If you select **Skip the corrupted messages**, use this list to specify a number from **1** through **50**.

     Note:

     If you specify a value higher than 50, the task will fail, and you need to use the Shell to create the move request. For details, see Move a user's primary mailbox and allow a large bad item limit later in this topic.

   - **Suspend this move when it is ready to complete** Select this check box to suspend the move request before the completion stage begins. You can resume the move request at a later time. For details, see Complete or Resume a Move Request.

   Note:

   You can use this feature only for online mailbox moves and when moving mailboxes from Exchange 2007 and Exchange 2010 mailbox databases. You can't use this feature for offline moves or when moving from Exchange 2003 mailbox databases.

6. On the **New Local Move Request** page, review your configuration settings. Click **New** to create the move request. Click **Back** to make changes.

7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task

successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a local move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Test whether a mailbox is ready to move

This example uses the *WhatIf* switch to test whether Tony Smith's mailbox is ready to move to the new database DB01 and if there are any errors within the command. When you use the *WhatIf* switch, the system performs checks on the mailbox. If the mailbox isn't ready to move, you receive an error.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -TargetDatabase DB01 -WhatIf
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a local move request

This example moves Tony Smith's mailbox to the new database DB01. If Tony's mailbox has an associated archive, it's also moved to the same database.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -TargetDatabase DB01
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a batch move request

This example creates a batch move request for all mailboxes on the database DB01 and moves them to the database DB02 with the *BatchName* parameter value DB01toDB02.

```
Get-Mailbox -Database DB01 | New-MoveRequest -TargetDatabase DB02 -BatchName "DB0
```

For detailed syntax and parameter information, see Get-Mailbox and New-MoveRequest.

Create a move request that suspends before completion

This example creates a move request that's suspended after the initial content is moved, but before the mailbox is locked down and switched over to the new location.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -TargetDatabase DB01 -Suspend
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a move request processed by a specific server

This example creates a move request processed by the Client Access server CAS1.contoso.com, which has the Microsoft Exchange Mailbox Replication service installed.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -TargetDatabase DB01 -MRSServ
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a suspended move requests

This example creates a batch move request that's suspended for all mailboxes on database DB01. Run this command if you want to create the move request during business hours, and then resume at a later time, when e-mail traffic is low.

```
Get-Mailbox -Database DB01 | New-MoveRequest -TargetDatabase DB02 -BatchName "26A
```

For detailed syntax and parameter information, see Get-Mailbox and New-MoveRequest.

Move only a user's primary mailbox

This example moves only Tony Smith's primary mailbox to DB01. The archive isn't moved.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -PrimaryOnly -TargetDatabase
```

For detailed syntax and parameter information, see New-MoveRequest.

Move only an archive mailbox

This example moves only Tony Smith's archive mailbox to DB03. The primary mailbox isn't moved.

```
New-MoveRequest -Identity 'tony@alpineskihouse.com' -ArchiveOnly -ArchiveTargetDa
```

For detailed syntax and parameter information, see New-MoveRequest.

Move a user's primary mailbox and archive mailbox to separate databases

This example moves Ayla's primary mailbox and archive mailbox to separate databases. The primary database is moved to DB01, and the archive is moved to DB03.

```
New-MoveRequest -Identity 'ayla@humongousinsurance.com' -TargetDatabase DB01 -Arc
```

For detailed syntax and parameter information, see New-MoveRequest.

Move a user's primary mailbox and allow a large bad item limit

This example moves Kweku's primary mailbox to mailbox database DB01 and sets the bad item limit to 100. To set a large bad item limit, you must use the *AcceptLargeDataLoss* parameter.

```
New-MoveRequest -Identity 'Kweku' -PrimaryOnly -TargetDatabase "DB01" -BadItemLim
```

For detailed syntax and parameter information, see New-MoveRequest.

Other Tasks

After you move the mailboxes, you may also want to:

- View Move Request Properties
- Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010
- Complete or Resume a Move Request

1.8.3.19.2 Complete or Resume a Move Request

Complete or Resume a Move Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can complete a move request that failed or was suspended.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Prerequisites

Before you can complete a move request, it must have a move request status of **Suspended**, **Automatically suspended**, or **Failed**. For more information, see Suspend Move Requests.

Use the EMC to complete a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Move Requests**.
2. In the result pane, select one or more mailboxes that have a move request status of **Failed**, **Suspended**, or **Automatically suspended**.
3. In the action pane, click **Complete Move Request**.
4. In **Complete Move Request**, confirm that you want to complete the move request by clicking **Yes**.

Use the Shell to complete a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

This example completes the move request for Tony Smith's mailbox.

```
Resume-MoveRequest -Identity "Tony@contoso.com"
```

This example resumes any failed move requests.

```
Get-MoveRequest -MoveStatus Failed | Resume-MoveRequest
```

This example resumes any move requests that have the suspend comment "Resume after 10 P.M."

```
Get-MoveRequest -MoveStatus Suspended | Get-MoveRequestStatistics |Where {$_.Mess
```

For detailed syntax and parameter information, see the following topics:

- Resume-MoveRequest
- Get-MoveRequest
- Get-MoveRequestStatistics

1.8.3.19.3 Configure Move Request Properties

Configure Move Request Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you create a move request, the request could fail due to bad item limit errors or rule

limit errors. If the move request fails because of those errors, you can edit the move request settings to increase the bad item limit or to ignore rule limit errors. After the move request is initiated, you can edit it until it has a status of Completed.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Use the Shell to change the bad item limit

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to change the bad item limit.

This example changes the move request for Ayla's mailbox to accept up to five corrupted mailbox items.

```
Set-MoveRequest -Identity "Ayla" -BadItemLimit 5
```

For detailed syntax and parameter information, see Set-MoveRequest.

Use the Shell to ignore rule limit errors

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to ignore rule limit errors.

This example ignores rule limit errors by not moving any rules associated with Tony's mailbox.

```
Set-MoveRequest -Identity "Tony" -IgnoreRuleLimitErrors $true
```

For detailed syntax and parameter information, see Set-MoveRequest.

1.8.3.19.4 Move Mailboxes by Using the MoveMailbox.ps1 Script in the Shell

Move Mailboxes by Using the MoveMailbox.ps1 Script in the Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Similar to the **Move-Mailbox** cmdlet in Microsoft Exchange Server 2007, the MoveMailbox.ps1 script provides a synchronous management experience for moving mailboxes. By default, scripts are installed at C:\Program Files\Microsoft\Exchange Server

\V14\Scripts.

Note:
You can use this script for local moves only. You can't use this script for remote (cross-forest) moves. For information about remote mailbox moves, see Prepare Mailboxes for Cross-Forest Move Requests.

MoveMailbox.ps1 performs the following tasks:

1. Creates a local move request.
2. Waits for the mailbox move to complete.
3. Clears the move request after it completes.

MoveMailbox.ps1 includes two parameter sets. The first parameter set moves a single mailbox, or you can pipeline mailboxes into the command. The second parameter set moves all mailboxes hosted on a specified database, or you can pipeline database objects into the command to move all mailboxes that reside on those mailbox databases.

Note:
The Shell doesn't load scripts automatically. You must precede all scripts with "**.**" For example, to run the MoveMailbox.ps1 script, type `.\MoveMailbox.ps1`.

For more information about using and writing scripts, see Scripting with the Exchange Management Shell.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Using MoveMailbox.ps1 to move specific mailboxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

The following parameter syntax set and table lists the parameters that you can use to move specific mailboxes.

```
MoveMailbox.ps1 -Identity <Object> -DatabaseMap <Hashtable> -TargetDatabase <Obje
```

Parameter	Required	Description
DatabaseMap	Required	The *DatabaseMap* parameter specifies the map between the databases you're moving to and from. Use this parameter if you're using the pipelining method to identify the mailboxes you're moving to. The *DatabaseMap* parameter requires the following: • Use the following syntax: `@{"<SourceDatabase>"="<TargetDatabase>"}` • The *SourceDatabase* name must match the database name as reported by the Get-Mailbox cmdlet. • You can include multiple database maps. Separate multiple maps with a semicolon (;), for example,

		@{"DB1"="DBA";"DB2"="DBB"} **Note:** You can't use this parameter in conjunction with the *TargetDatabase* parameter. If you're pipelining the command, and a user matches the identity in the Get-Mailbox cmdlet but doesn't match the source database in the *DatabaseMap* cmdlet, that user's mailbox will be skipped.
Identity	Required	The *Identity* parameter specifies the identity of the mailbox that you want to move. This parameter accepts the following values: • ADObjectID • Alias • Distinguished name (DN) • *Domain\Account* • GUID • LegacyExchangeDN • SmtpAddress • User principal name (UPN) **Note:** You can pipeline the *Identity* parameter by using the **Get-Mailbox** cmdlet.
TargetDatabase	Required	The *TargetDatabase* parameter specifies the identity of the database that you're moving the mailbox to. This parameter accepts the following values: • GUID • Distinguished name (DN) • *Server\database name* • Database name **Note:** You can't use this parameter in conjunction with the *DatabaseMap* parameter.
AutoSuspend	Optional	The *AutoSuspend* switch specifies whether to suspend the move request before it reaches the status of `CompletionInProgress`. After the move is suspended, it has a status of `AutoSuspended`. If you use this parameter, you must complete the move by using the Resume-MoveRequest cmdlet.
BadItemLimit	Optional	The *BadItemLimit* parameter specifies the number of bad items to skip if the move request encounters corruption in the mailbox. Use the value 0 if you

		don't want to skip bad items. Use the value -1 to skip an unlimited number of bad items. The valid input range for this parameter is from -1 through 2,147,483,647. The default value is 0. We recommend that you keep the default value 0 and only change the *BadItemLimit* parameter value if the move request fails.
DomainController	Optional	The *DomainController* parameter specifies the fully qualified domain name (FQDN) of the domain controller that writes this configuration change to Active Directory.
PollInterval	Optional	The *PollInterval* parameter specifies, in seconds, the amount of time to wait before checking if a move request is completed. For example, if the *PollInterval* is set to 180, the MoveMailbox.ps1 script will check the move requests status every 3 minutes to see if the move has the status of Completed. The default time is 10 seconds.
StartBatchSize	Optional	The *StartBatchSize* parameter specifies how often to start mailbox moves for load balancing purposes. The parameter applies only when moving multiple mailboxes at one time. For example, if this parameter is set to 10 and you're moving 15 mailboxes, the script will invoke the **New-MoveRequest** cmdlet when it sees that 10 mailboxes are being moved to the same target database.

Examples

EXAMPLE 1

This example moves the mailboxes that begin with "ay". If these mailboxes reside on the mailbox database DB1, this example uses the *DatabaseMap* parameter to move them to mailbox database DBA. If these mailboxes reside on DB2, this example moves them to mailbox database DBB.

```
Get-Mailbox ay* | .\MoveMailbox.ps1 -DatabaseMap @{"DB1"="DBA";"DB2"="DBB"}
```

EXAMPLE 2

This example moves Tony Smith's mailbox to DB2.

```
.\MoveMailbox.ps1 -Identity "Tony@Contoso.com" -TargetDatabase "DB2"
```

Using MoveMailbox.ps1 to move mailboxes homed on a specific database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

The following parameter syntax set and table lists the parameters that will move mailboxes based on the database.

```
MoveMailbox.ps1 -MailboxDatabase <Object> [-DatabaseMap <Hashtable>] [-TargetData
```

Parameter	Required	Description
MailboxDatabase	Required	The *MailboxDatabase* parameter specifies the mailbox database from which you're moving mailboxes. This parameter accepts the following values: • GUID • Distinguished name (DN) • *Server\database name* • Database name **Note:** You can't use this parameter in conjunction with the *DatabaseMap* parameter.
AutoSuspend	Optional	The *AutoSuspend* switch specifies whether to suspend the move request before it reaches the status of `CompletionInProgress`. After the move is suspended, it has a status of `AutoSuspended`. If you use this parameter, you must complete the move by using the Resume-MoveRequest cmdlet.
BadItemLimit	Optional	The *BadItemLimit* parameter specifies the number of bad items to skip if the move request encounters corruption in the mailbox. Use the value 0 if you don't want to skip bad items. Use the value -1 to skip an unlimited number of bad items. The valid input range for this parameter is -1 to `2,147,483,647`. The default value is 0. We recommend that you keep the default value 0 and only change the *BadItemLimit* parameter value if the move request fails.
DatabaseMap	Optional	The *DatabaseMap* parameter specifies the map between the databases you're moving to and from. Use this parameter if you're using the pipelining method to identify the mailboxes you're moving to. The *DatabaseMap* parameter requires the following: • Use the following syntax: `@{"<SourceDatabase>"="<TargetDatabase>"}` • The *SourceDatabase* name must match the database name as reported by the

		Get-Mailbox cmdlet. • You can include multiple database maps. Separate multiple maps with a semicolon (;), for example, @{"DB1"="DBA";"DB2"="DBB"} **Note:** You can't use this parameter in conjunction with the *TargetDatabase* parameter. If you're pipelining the command, and a user matches the identity in the Get-Mailbox cmdlet but doesn't match the source database in the *DatabaseMap* cmdlet, that user's mailbox will be skipped.
DomainController	Optional	The *DomainController* parameter specifies the fully qualified domain name (FQDN) of the domain controller that writes this configuration change to Active Directory.
PollInterval	Optional	The *PollInterval* parameter specifies, in seconds, the amount of time to wait before checking if a move request is completed. For example, if the *PollInterval* is set to 180, the MoveMailbox.ps1 script will check the move requests status every 3 minutes to see if the move has the status of Completed. The default time is 10 seconds.
StartBatchSize	Optional	The *StartBatchSize* parameter specifies how often to start mailbox moves for load balancing purposes. The parameter applies only when moving multiple mailboxes at one time. For example, if this parameter is set to 10 and you're moving 15 mailboxes, the script will invoke the **New-MoveRequest** cmdlet when it sees that 10 mailboxes are being moved to the same target database.
TargetDatabase	Optional	The *TargetDatabase* parameter specifies the identity of the database that you're moving the mailbox to. This parameter accepts the following values: • GUID • Distinguished name (DN) • *Server\database name* • Database name **Note:** You can't use this parameter in conjunction with the *DatabaseMap*

		parameter.

Examples

EXAMPLE 1

This example moves all mailboxes that reside on mailbox database DB1 to database DB2.

```
.\MoveMailbox.ps1 -MailboxDatabase DB1 -TargetDatabase DB2
```

EXAMPLE 2

This example uses the **Get-MailboxDatabase** cmdlet to retrieve all mailbox database objects whose mailbox database begins with "DB1", and then pipelines the result to the MoveMailbox.ps1 script.

```
Get-MailboxDatabase DB1* | .\MoveMailbox.ps1 -DatabaseMap @{"DB10"=DBA;"DB11"="DB
```

1.8.3.19.5 Clear or Remove Move Requests

Clear or Remove Move Requests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When a move request reaches a status of **Completed** or **Completed with warning**, you must clear the move request to remove the **InTransit** flag from the mailbox. You won't be able to move the mailbox again until you clear the previous move request. To learn more about the **Completed with warning** status, see Troubleshooting Mailbox Moves.

In addition, you can remove a move request that's in progress. When you remove a move request in progress, mailbox replication stops, and the replica is deleted from the target database. If you remove the move request and later decide to move the mailbox, you must start the move request process at the beginning.

Note:
To view all move requests in a multiple-domain environment in the Exchange Management Console, the recipient scope needs to be modified to view the entire forest. For more information, see Change the Recipient Scope.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Use the EMC to clear a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Move Request**.
2. In the result pane, select a recipient that has a **Move Request Status** of **Completed** or **Completed with warning**.

   Note:
   You can select multiple recipients in the result pane.

3. In the action pane, click **Clear Move Request**.
4. A warning message appears confirming that you want to clear the move request. Click **Yes**.

Use the EMC to remove a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Move Request**.
2. In the result pane, select a recipient that has a **Move Request Status** of **Automatically Suspended**, **In Progress**, **Queued**, or **Completing**.

   Note:
   You can select multiple recipients in the result pane.

3. In the action pane, click **Remove Move Request**.
4. A warning appears confirming that you want to remove the move request. Click **Yes**.

Use the Shell to clear or remove a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

This example clears the move request from all mailboxes that have a status of Completed.

```
Get-MoveRequest -MoveStatus Completed | Remove-MoveRequest
```

This example removes the move request for Ayla's mailbox.

```
Remove-MoveRequest -Identity 'Ayla@humongousinsurance.com'
```

For detailed syntax and parameter information, see Remove-MoveRequest or Get-MoveRequest.

Other Tasks

After you clear the move request, you can no longer view move request statistics for those mailboxes. For information about how to view the move history for a mailbox, see View Move Request Properties.

1.8.3.19.6 Suspend Move Requests

Suspend Move Requests

Mailbox > Managing Mailbox Servers > Managing Move Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the **Suspend-MoveRequest** cmdlet to suspend a move request any time after the move request is created, but before it reaches the status of CompletionInProgress, Completing, or Completed. You can also automatically suspend a move request by using the **New-MoveRequest** cmdlet with the *SuspendWhenReadyToComplete* parameter.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Use the Shell to suspend a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to suspend a move request.

This example suspends a move request for Tony Smith's mailbox and includes the suspend comment "Move suspended per user request. Do not resume until Sunday."

```
Suspend-MoveRequest -Identity 'Tony@humongousinsurance.com' -SuspendComment "Move
```

This example suspends all move requests that have the target database DB02 and includes the suspend comment "Pending final approval."

```
Get-MoveRequest -TargetDatabase DB02 | Suspend-MoveRequest -SuspendComment "Pendi
```

For detailed syntax and parameter information, see Suspend-MoveRequest and Get-MoveRequest.

Use the Shell to automatically suspend a move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

This example automatically suspends a move request when the request reaches a status of ReadyToComplete.

```
New-MoveRequest -Identity Ayla@alpineskihouse.com -TargetDatabase DB05 -SuspendWh
```

For detailed syntax and parameter information, see New-MoveRequest.

1.8.3.19.7 View Move Request Properties

View Move Request Properties

Mailbox > Managing Mailbox Servers > Managing Move Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A move request is the process of moving a mailbox from one mailbox database to another. After starting the move request process, you must wait until the Microsoft Exchange Mailbox Replication service replicates the mailbox from the source database to the target database, and the move request status is **Completed** or **Completed with warning**.

During this waiting period, you can view the move request status by using the EMC or the **Get-MoveRequest** cmdlet in the Shell. (For a more detailed report, you can run the **Get-MoveRequestStatistics** cmdlet with the *IncludeReport* parameter.)

After the move request is complete, you can view the move history of the completed move request by running the **Get-MailboxStatistics** cmdlet with the *IncludeMoveHistory*

parameter. You can also get the complete move request report by running the **Get-MailboxStatistics** cmdlet with the *IncludeMoveReport* parameter. Use this information to troubleshoot any errors or failures that may have occurred during the move.

Note:
Move requests won't display in the result pane of the **Move Request** node until they're in the **Queued** status.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

What Do You Want to Do?

- Use the EMC to view the status of an in-progress or completed move request
- Use the Shell to view the status of an in-progress move request
- Use the Shell to view a completed move request report

Use the EMC to view the status of an in-progress or completed move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Move Request**.

   Note:
   If you have multiple forests in the EMC, you need to navigate to the target forest's **Move Request** node.

2. In the result pane, select a move request.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view the following information about the move request:
   - **Move request status** This read-only field displays one of the following move request statuses:

     Automatically Suspended This status specifies that the move is ready to complete, but that the move request was suspended when it was created. This can be done either by selecting the **Suspend this move when it is ready to complete** check box in the EMC or by specifying the *SuspendWhenReadyToComplete* switch in the Shell. You can resume the move request by using the **Resume-MoveRequest** cmdlet or by using the **Complete Move Request** action in the action pane. For more information, see Complete or Resume a Move Request.

     Completed This status specifies that the move request was completed successfully without any warnings.

     Completed with warning This status specifies that the move request completed, but that there were warnings. For more information, see Troubleshooting Mailbox Moves.

     Completion in progress This status specifies that the mailbox is in its final stages of being moved. If the move was an online move, at this point, the user's mailbox may become unavailable.

     Failed This status specifies that the move request has failed. To view the message that describes why the move failed, click **View** located next to the **Failed Message** field.

     In progress This status specifies that the move is still in progress. If this is an online mailbox move, the user can still

access the mailbox. If this is an offline mailbox move, the user's mailbox is unavailable.
Queued This status specifies that the move has been queued and is waiting to be picked up by the Microsoft Exchange Mailbox Replication service.
Ready to complete This status specifies that the move is ready to complete. You need to manually complete the move. For more information, see Complete or Resume a Move Request.
Suspended This status specifies that the move was suspended by using the **Suspend-MoveRequest** cmdlet. You can resume the move request by using the **Resume-MoveRequest** cmdlet or by using the **Complete Move Request** action in the action pane. For more information, see Complete or Resume a Move Request.

- **Percent complete** This field displays the completion percentage for the move request.
- **Duration** This field displays how long it took the move to complete.
- **Mailbox size** This field displays the size of the mailbox being moved.
- **Number of corrupted items** This field displays the number of corrupted items detected during the move.
- **Source database** This field displays the database from which the mailbox is being moved.
- **Target database** This field displays the database to which the mailbox is being moved.
- **Last updated time** This field displays the date and time at which the last change was made to the request. The change could've been made by an administrator or by the Microsoft Exchange Mailbox Replication service (MRS).
- **Suspend this move when it is ready to complete** If the move has the move request status of **In Progress** or **Queued**, you can select this check box, and then click **Apply** to suspend the move when it's ready to complete. You can then manually complete the move request at a later time. For more information, see Complete or Resume a Move Request. If you select this check box, a **Suspended Comment** appears on the **Details** tab.

5. Use the **Details** tab to view the following information about the move request:
   - **Remote host name** If you're moving the mailbox across Exchange forests, this field displays the fully qualified domain name (FQDN) of the remote host. If this is a local move, this field is blank.
   - **Move request server name** This field displays the FQDN of the Client Access server that processed the move request.
   - **Source version** This field displays the version of Exchange on which the source database resides.
   - **Target version** This field displays the version of Exchange on which the target database resides.
   - **Move request queued time** This field displays the time the move request was queued. The time may not be the same as the time the move request was created.
   - **Queued duration** This field displays the amount of time the move request remained in the **Queued** status.
   - **Move request start time** This field displays the time at which the move request began.
   - **Move request completion time** This field displays the time at which the move request completed. If the move request isn't completed, this field is blank.
   - **Suspended time** This field displays the time at which the request was suspended. If the request wasn't suspended, this field is blank.

- **Suspended comment** This field displays the comment added by the administrator who suspended the move request. By default, if the move request was set to be suspended before completion, the comment includes the following text:

  Informational: The move request for mailbox <mailbox GUID> is ready to complete and has been automatically suspended because the SuspendWhenReadyToComplete parameter is set to $true

6. Use the **Log** tab to view the move request log. Click **View** to display the log. The move request log can be used for debugging purposes if a move request fails or is having transient issues. You can press Ctrl+C to copy the contents of the log file.

Use the Shell to view the status of an in-progress move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

This example retrieves the status of the ongoing move for Tony Smith's mailbox (tony@contoso.com).

```
Get-MoveRequest -Identity 'tony@contoso.com'
```

This example retrieves the status of ongoing moves for user mailboxes in the Marketing department.

```
Get-User -Filter {Department -like 'Marketing'} | Get-MoveRequest
```

This example retrieves the status of ongoing mailbox moves to the target database DB05.

```
Get-MoveRequest -MoveStatus InProgress -TargetDatabase DB05
```

This example retrieves the status for completed move requests in the FromDB01toDB02 batch that had warnings.

```
Get-MoveRequest -BatchName "FromDB01ToDB02" -MoveStatus CompletedWithWarning
```

For detailed syntax and parameter information, see Get-MoveRequest or Get-User.

Use the Shell to view a completed move request report

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

This example uses the *IncludeMoveHistory* parameter to retrieve the move history of a completed move request for Tony Smith's mailbox.

```
Get-MailboxStatistics -Identity tony@contoso.com -IncludeMoveHistory
```

This example uses the *IncludeMoveReport* parameter to retrieve a detailed move report for a failed move request of Ayla Kol's mailbox.

```
Get-MailboxStatistics -Identity ayla@contoso.com -IncludeMoveReport
```

For detailed syntax and parameter information, see Get-MailboxStatistics.

Other Tasks

After the move is complete, you may also want to clear the move requests from the result pane of the EMC. For detailed instructions, see Clear or Remove Move Requests.

If the move failed, you may also want to troubleshoot the move to determine the cause of the failure. For more information, see Troubleshooting Mailbox Moves.

1.8.3.19.8 Test Mailbox Replication Service Health

Test Mailbox Replication Service Health

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The Microsoft Exchange Mailbox Replication service (MRS) runs on Client Access servers. You can test MRS health to make sure that MRS is running and that it responds to a remote procedure call (RPC) ping check. Use this procedure to troubleshoot problems that occur when moving mailboxes.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Use the Shell to test MRS health

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to test MRS health.

This example tests the health of MRS on all Client Access servers.

```
Get-ClientAccessServer | Test-MRSHealth
```

This example tests the health of MRS on the Client Access server CAS01.

```
Test-MRSHealth -Identity CAS01
```

This example tests the health of MRS on the Client Access server CAS02 and also includes monitoring events and performance counters in the results. The results are then exported to the .xml file CAS02_MRSHealth.xml.

```
Test-MRSHealth -Identity CAS02 -MonitoringContext $true | Export-CliXml "C:\CAS02
```

For detailed syntax and parameter information, see Get-ClientAccessServer or Test-MRSHealth.

Throttling the Mailbox Replication Service

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-13*

The Mailbox Replication Service (MRS), which resides on all Microsoft Exchange Server 2010 Client Access servers, is the service responsible for moving mailboxes, importing and exporting .pst files, and restoring disabled and soft-deleted mailboxes.

Because MRS performs several tasks, you can throttle it to maintain the overall health of your Exchange organization. Although each instance of MRS has its own configuration settings, each instance of MRS is aware of the tasks that other instances of MRS are processing. MRS throttling is controlled by the configuration file MSExchangeMailboxReplication.exe.config. By default, this configuration file is located on all Client Access servers in the same folder where Exchange is installed: *<Exchange Installation Path>*\Program Files\Microsoft\Exchange Server\V14\Bin\MSExchangeMailboxReplication.exe.config.

Note:

When you open the configuration file, you can find the minimum, maximum, and default values for the configuration settings in the section titled **! Mailbox Replication Service configuration**.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Throttle MRS

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Text editor" entry in the Client Access Permissions topic.

1. Navigate to *<Exchange Installation Path>*\Program Files\Microsoft\Exchange Server\V14\Bin**.**
2. Open the MSExchangeMailboxReplication.exe.config file using a text editor such as Notepad.
3. Navigate to the **MRSConfiguration** section. You can edit the following properties:
   - **MaxRetries** This property specifies the maximum number of times MRS will attempt to perform a task after encountering a transient failure. You can specify a value from 0 through 1000. The default value is 60.
   - **MaxCleanupRetries** This property specifies the number of times that MRS should attempt to clean up a task. If the maximum number of attempts is reached, the task fails. You can specify a value from 0 through 100. The default value is 5.
   - **MaxStallRetryPeriod** This property specifies the maximum duration for which MRS pauses while waiting for the Microsoft Exchange Information Store service to bring the target mailbox database into compliance with its configured data redundancy constraints. If the Microsoft Exchange Information Store service reports that the mailbox database is unhealthy, MRS will pause. If the maximum time is reached, the task fails. You can specify a value from 00:00:10 (10 seconds) through 05:00:00 (5 hours). The default value is 00:15:00 (15 minutes).
   - **RetryDelay** This property specifies the amount of time MRS will wait before it attempts to perform a task again after a transient failure. You can specify a value from 00:00:10 (10 seconds) through 00:30:00 (30 minutes). The default value is 00:00:30 (30 seconds).

- **MaxMoveHistoryLength** This property specifies the maximum number of move histories to maintain in the mailbox. You can specify a value from 0 through 100. The default value is 2 move histories per mailbox.
- **MaxActiveMovesPerSourceMDB** This property specifies the total number of tasks MRS can perform that involve the mailbox database as a data source. Types of tasks include moving mailboxes located on the database, exporting mailbox data from mailboxes located on the database, and restoring mailbox data from the database. You can specify a value from 0 through 100. The default value is 5 concurrent tasks.
- **MaxActiveMovesPerTargetMDB** This property specifies the total number of tasks MRS can perform that involve the mailbox database as a data target. Types of tasks include moving mailboxes to the database, importing mailbox data into a mailbox located on the database, and restoring mailbox data to a mailbox located on the database. You can specify a value from 0 through 100. The default value is 2 concurrent tasks.
- **MaxActiveMovesPerSourceServer** This property specifies the total number of tasks MRS can perform that include the server as a data source. You can specify a value from 0 through 1000. The default value is 50 concurrent moves.
- **MaxActiveMovesPerTargetServer** This property specifies the total number of tasks MRS can perform that involve the server as a data target. You can specify a value from 0 through 1000. The default value is 5 concurrent moves.
- **MaxTotalMovesPerMRS** This property specifies the total number of tasks that a single instance of MRS can perform at a time. You can specify a value from 0 through 1000. The default value is 100 concurrent moves.
- **FullScanMoveJobsPollingPeriod** This property specifies how often each instance of MRS scans for new tasks. You can specify a value from 00:03:00 (3 minutes) through 1.00:00:00 (1 day). The default value is 00:10:00 (10 minutes).

In addition to the preceding properties, you can also configure the following properties. However, you should only change these settings when directed by support personnel.

- **MinimumTimeBeforePickingJobsFromSameDatabase**
- **ServerCountsNotOlderThan**
- **MRSAbandonedMoveJobDetectionTime**
- **BackoffIntervalForProxyConnectionLimitReached**
- **DataGuaranteeCheckPeriod**
- **DataGuaranteeTimeout**
- **DataGuaranteeLogRollDelay**
- **MailboxLockoutTimeout**
- **MailboxLockoutRetryInterval**
- **EnableDataGuaranteeCheck**
- **DisableMrsProxyCompression**
- **DisableMrsProxyBuffering**
- **MinBatchSize**
- **MinBatchSizeKB**

4. Make sure any changes you make are also applied to the MSExchangeMailboxReplication.exe.config file on all other Client Access servers.

1.8.3.19.10 Managing Remote Move Requests

Managing Remote Move Requests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-09-02*

Create a Remote Move Request That has Exchange 2010 in Both Forests

Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

Prepare Mailboxes for Cross-Forest Move Requests

Prepare Mailboxes for Cross-Forest Moves Using the Prepare-MoveRequest.ps1 script in the Shell

Prepare Mailboxes for Cross-Forest Moves Using Sample Code

Start the MRSProxy Service on a Remote Client Access Server

1.8.3.19.10.1 Create a Remote Move Request That has Exchange 2010 in Both Forests

Create a Remote Move Request That has Exchange 2010 in Both Forests

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Remote mailbox moves are also known as cross-forest mailbox moves. Microsoft Exchange Server 2010 supports two types of remote mailbox moves:

- **Remote mailbox moves that have Exchange 2010 in both forests** In this scenario, one forest is an Exchange 2010 forest, and the other forest has at least one Exchange 2010 Client Access server. You can use the Exchange Management Console (EMC) or the Exchange Management Shell to perform these mailbox moves.
- **Remote mailbox moves with a legacy Exchange forest** In this scenario, one forest contains Exchange 2010, and the other forest contains Exchange Server 2003 Service Pack 2 (SP2), Exchange Server 2007 SP3, or a combination of both. No Exchange 2010 Client Access server is installed in the legacy forest. You can't use the EMC to perform these mailbox moves. You must use the Shell. For more information, see Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010.

When you move Exchange 2003 mailboxes, the mailbox move is offline. During the move, the users won't be able to access their mailboxes. When you move Exchange 2007 SP2 mailboxes or Exchange 2010 mailboxes, the move is online, and the users can access their mailboxes during the move.

While performing remote mailbox moves, the Microsoft Exchange Mailbox Replication service (MRS) maintains the Send As and Receive As permissions. MRS maps the trustee to the matching user in the destination forest. This functionality relies on the destination

forest having all recipient objects being represented and having their corresponding **msExchMailboxGUID** attributes stamped.

Important:
Maintaining permissions may not be possible in split permission deployments. This is because in split permission deployments the **ExchangeTrustedSubsystem** group attribute isn't included in the Exchange Windows Permissions security group.

MRS also uses the **msExchMailboxGUID** attribute to attempt to maintain mailbox and mailbox folder permissions. MRS maps the permissions to point to the matching user in the destination forest. The security identifiers (SIDs) in the access control entries (ACEs) are replaced. If a SID isn't mapped, the permissions aren't maintained.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Prerequisites

For the complete list of prerequisites to move mailboxes across forests, see Prepare Mailboxes for Cross-Forest Move Requests.

What Do You Want to Do?

- Use the EMC to create a remote move request
- Use the Shell to create a remote move request

Use the EMC to create a remote move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

If the source forest is an Exchange 2007 or Exchange 2003 forest, the administrator performing the move must have the following remote credentials on the Exchange 2007 server:

- Exchange Server Administrator role
- Exchange Recipient Administrator role

Important:
You can't move mailboxes by using the EMC if the source forest doesn't have at least one Exchange 2010 Client Access server installed. Instead, you must use the Shell to perform the task. For more information, see Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox** of the remote forest.

   Note:
   All remote moves need to be initiated from the target forest.

2. In the result pane, select one or more mailboxes that you want to move.
3. In the action pane, click **New Remote Move Request**.
4. On the **Introduction** page, view the mailboxes that you selected in the result pane. If you want to remove or add recipients, click **Cancel**, and then make the changes in the result pane.

   Note:

The option to select a target database from the EMC isn't available. A target database is automatically selected. For more information about how database automatic selection is determined, see Understanding Move Requests.

5. On the **Connection Configurations** page, view or specify the following settings:
   - **Source Forest** This read-only field displays the source forest on which the mailboxes that you're moving reside.
   - **Target Forest** Select the target forest from the list. This field is populated with the forests that have been added to the EMC. If this field is blank, see View Local Forest Properties for information about how to add forests.
   - **FQDN of the Microsoft Exchange Mailbox Replication Service proxy server in the source forest** Type the fully qualified domain name (FQDN) for the server on which the MRS proxy resides. This is a Client Access server in the remote forest, for example, CAS01.contoso.com.
   - **Use the following source forest's credential** To move mailboxes across forests, you must supply the credentials of a recipient administrator who has permission to move mailboxes from the source forest:
     User Name Type the domain name and password of a recipient administrator who has permission to move mailboxes from the source forest.
     Password Type the administrator's password.

6. On the **Move Settings** page, specify the following settings:
   - **Target Delivery Domain** Type the FQDN of the external e-mail address created in the source forest for the mail-enabled user when the move request is complete, for example, the FQDN of the target forest. Mail-enabled users must have a proxy address that has this FQDN as the SMTP domain of the address. At move completion, this proxy address is stamped as the mail-enabled user's external e-mail address in the source forest to ensure that mail flow will return to the new mailbox.
   - **Archive Domain** Type the FQDN of the domain on which the archive will reside.
   - **Target Database** Type the name of the target database in the remote forest.

7. On the **New Remote Move Request** page, review the settings for this remote move request, and then click **New**.

8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a remote move request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

If the source forest is an Exchange 2007 or Exchange 2003 forest, the administrator performing the move must have the following remote credentials on the Exchange 2007 or Exchange 2003 server:

- Exchange Server Administrator role

- Exchange Recipient Administrator role

Test whether a mailbox is ready to move across forests

This example uses the *WhatIf* switch to test whether a mailbox is ready to move across forests and whether any errors are within the command. When you use the *WhatIf* switch, the system performs checks on the mailbox. If the mailbox isn't ready, an error is returned. This command is run on the target forest.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -Remote -TargetDatabase D
```

For detailed syntax and parameter information, see New-MoveRequest or Get-Credential.

Move a mailbox from a remote forest

This example moves Tony Smith's mailbox into the forest where the command is run. When the move is completed, the new **ExternalEmailAddress** property in the source forest will be Tony's proxy address with the SMTP domain mail.contoso.com.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -Remote -TargetDatabase D
```

For detailed syntax and parameter information, see New-MoveRequest.

Move a mailbox to a remote forest

This example pushes Tony Smith's mailbox to the remote forest. Use this command when you initiate the move from the source forest. When initiating moves from the source forest, you must use the *RemoteTargetDatabase* parameter to specify the database that you're moving the mailbox to. When the move is complete, the new **ExternalEmailAddress** property in the source forest will be Tony's proxy address with the SMTP domain mail.contoso.com.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -Remote -RemoteTargetData
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a batch move request

This example creates a batch move request for all mailboxes in the source forest on the database DB01 and moves them to the target database DB02 in the target forest with the *BatchName* parameter value HumongousDB01ToContosoDB02.

Note:

By creating a batch, you can create a tag that identifies the mailboxes being moved. Each mailbox is moved individually when an MRS instance becomes available to perform the move. You can then filter searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -Database DB01 | New-MoveRequest -Remote -RemoteHostName 'CAS01.humo
```

For detailed syntax and parameter information, see Get-MailUser or New-MoveRequest.

Create a move request that suspends before completion

This example creates a remote move request for all mailboxes on the target forest that begin with the letter a. The request will be suspended after all the initial content is moved, but before the mailbox is locked down and switched over to the new location.

Note:

You can use the *SuspendWhenReadyToComplete* parameter only for online mailbox moves and when moving mailboxes from Exchange 2007 and Exchange 2010 mailbox databases. You can't use this parameter for offline moves or when moving from Exchange 2003 mailbox databases.

The move request will then need to be resumed by using the **Resume-MoveRequest** cmdlet.

Note:
By creating a batch, you can create a tag that identifies the mailboxes being moved. Each mailbox is moved individually when an MRS instance becomes available to perform the move. You can then filter searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -Anr a* | New-MoveRequest -Remote -RemoteHostName 'CAS01.humongousin
```

For detailed syntax and parameter information, see Get-MailUser or New-MoveRequest.

Create a move request processed by a specific server

This example creates a move request processed by the specific Client Access server CAS1.contoso.com, which has MRS installed.

Note:
The *MRSServer* parameter is reserved for debugging purposes. Use this parameter only if directed by support personnel. If you use this parameter and the specified server isn't functional, this move request isn't processed.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteHostName 'CAS01.hu
```

For detailed syntax and parameter information, see New-MoveRequest.

Create a suspended move request

This example creates a batch move request that's suspended for all mailboxes in the target forest where the *CustomAttribute1* parameter is set to Monday. You may want to run this command if you want to create the move request now, and then resume it in the evening, when e-mail traffic is low.

Note:
By creating a batch, you can create a tag that identifies the mailboxes being moved. Each mailbox is moved individually when an MRS instance becomes available to perform the move. You can then filter searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -Filter {CustomAttribute1 -eq 'Monday'} | New-MoveRequest -RemoteHos
```

For detailed syntax and parameter information, see Get-MailUser or New-MoveRequest.

1.8.3.19.10.2 Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

Managing Mailbox Servers > Managing Move Requests > Managing Remote Move Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Remote mailbox moves are also known as cross-forest mailbox moves. There are two types of remote mailbox moves that Microsoft Exchange Server 2010 supports:

- **Remote mailbox moves with a legacy Exchange forest** In this scenario, one forest contains Exchange 2010 and the other forest contains Exchange Server 2003 Service Pack 2 (SP2), Exchange Server 2007 SP2, or a combination of both. There is no Exchange 2010 Client Access server installed in the legacy forest. You must use the Shell to perform these mailbox moves.
- **Remote mailbox moves that have Exchange 2010 in both forests** In this

scenario, one forest contains Exchange 2010 and the other forest has at least one Exchange 2010 Client Access server. You can use the EMC or the Shell to perform these mailbox moves. For more information, see Create a Remote Move Request That has Exchange 2010 in Both Forests.

When you move Exchange 2003 mailboxes to Exchange 2010, the mailbox move will be offline. During the move, users won't be able to access their mailboxes. When you move Exchange 2007 SP2 mailboxes to Exchange 2010, the move will be online, and users can access their mailboxes during the move.

To perform remote legacy move requests, you must supply the following information in the command:

- Identity of the mail-enabled user
- *RemoteLegacy* switch
- Fully qualified domain name (FQDN) of the remote global catalog server
- FQDN of the external e-mail address that's created in the source forest for the mail-enabled user when the move request is complete
- Target database when moving mailboxes to Exchange 2010 or remote target database when moving mailboxes from Exchange 2010 to the remote legacy database

While performing remote mailbox moves, the Microsoft Exchange Mailbox Replication service (MRS) uses the **msExchMailboxGUID** attribute to find matching users, thereby maintaining the Send As and Receive As permissions. MRS then maps the trustee to the matching user in the destination forest.

Important:

Maintaining permissions may not be possible in split-permission deployments. The **ExchangeTrustedSubsystem** attribute isn't included in the Exchange Windows Permissions security group.

MRS also uses the **msExchMailboxGUID** attribute to attempt to maintain mailbox and mailbox folder permissions. MRS then maps the permissions to point to the matching user in the destination forest.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Prerequisites

For the complete list of prerequisites to move mailboxes across forests, see Prepare Mailboxes for Cross-Forest Move Requests.

Use the Shell to create remote legacy move requests

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to create remote legacy move requests.

In addition to the permissions listed previously, the administrator performing the move must have the following remote credentials on the Exchange 2003 or Exchange 2007 server:

- Exchange Server Administrator role
- Exchange Recipient Administrator role

Note:
The following examples use the *RemoteCredential* parameter. This parameter requires the creation and passing of a credential object. This credential object is created by using the **Get-Credential** cmdlet. For more information, see Get-Credential.

Move a mailbox from a remote legacy forest

This example moves Tony Smith's mailbox into the Exchange 2010 forest from an Exchange 2007 SP2 or Exchange 2003 SP2 forest. When the move is complete, the new *ExternalEmailAddress* in the source forest will be Tony's proxy address with the SMTP domain mail.contoso.com.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteLegacy -TargetData
```

Move a mailbox to a remote legacy forest

This example moves Tony Smith's mailbox to the remote forest. Use this command when you initiate the move from the source Exchange 2010 forest. When initiating moves from the source forest, you must use the *RemoteTargetDatabase* parameter to specify the database that you're moving the mailbox to. When the move is complete, the new *ExternalEmailAddress* in the source forest will be Tony's proxy address with the SMTP domain mail.contoso.com.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteLegacy -RemoteTarg
```

Create a remote legacy batch move request

This example creates a batched move request for all mailboxes in the source forest that have **CustomAttribute2** set to Washington and moves them to the target database DB02 in the target forest with the *BatchName* parameter value Washington_HumongousToContoso.

Note:
Creating a batch move request allows you to create a tag that identifies which mailboxes are being moved. When an MRS instance becomes available to perform the move, each mailbox will be moved individually. You can then filter in searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -Filter {CustomAttribute2 -eq "Washington"} | New-MoveRequest -Remot
```

Create a remote legacy move request that suspends before completion

This example creates a remote move request for all mailboxes that begin with the letter 'a' in the target forest. The request will be suspended after the initial content is moved, but before the mailbox is locked down and switched over to the new location.

Note:
You can use the *SuspendWhenReadyToComplete* parameter only for online mailbox moves and when moving mailboxes from Exchange 2007 and Exchange 2010 mailbox databases. You can't use this parameter for offline moves or when moving from Exchange 2003 mailbox databases.

The move request will then need to be resumed by using the **Resume-MoveRequest** cmdlet.

Note:
Only online moves can be suspended by using the *SuspendWhenReadyToComplete* parameter.

Note:
Creating a batch move request allows you to create a tag that identifies which mailboxes are being moved. When an MRS instance becomes available to perform the move, each mailbox will be moved individually. You can then filter in searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -ANR a* | New-MoveRequest -RemoteLegacy -RemoteGlobalCatalog 'GC01.h
```

Create a remote legacy move request that's processed by a specific server

This example creates a move request that's processed by the Client Access server CAS1.contoso.com, which has MRS installed.

Note:

The *MRSServer* parameter is reserved for debugging purposes. Use this parameter only if directed by support personnel. If you use this parameter and the specified server isn't functional, the move request won't be processed.

```
New-MoveRequest -Identity 'tony@humongousinsurance.com' -RemoteLegacy -RemoteGlob
```

Create a suspended remote legacy move request

This example creates a batch move request that's suspended for all mailboxes in the target forest where **CustomAttribute1** is set to Monday. You may want to run this command if you want to create the move request now and then resume it in the evening, when e-mail traffic is low.

Note:

Creating a batch move request allows you to create a tag that identifies which mailboxes are being moved. When an MRS instance becomes available to perform the move, each mailbox will be moved individually. You can then filter in searches using the *BatchName* parameter in the **Get-MoveRequest** and **Get-MoveRequestStatistics** cmdlets.

```
Get-MailUser -Filter {CustomAttribute1 -eq 'Monday'} | New-MoveRequest -RemoteLeg
```

For More Information

For detailed syntax and parameter information, see the following cmdlet reference topics:

- New-MoveRequest
- Get-MailUser
- Get-MoveRequest
- Get-MoveRequestStatistics

1.8.3.19.10.3 Prepare Mailboxes for Cross-Forest Move Requests

Prepare Mailboxes for Cross-Forest Move Requests

Managing Mailbox Servers > Managing Move Requests > Managing Remote Move Requests >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Microsoft Exchange Server 2010 supports remote mailbox moves via the **New-MoveRequest** cmdlet. To move a mailbox from an Exchange Server 2010, Exchange Server 2007, or Exchange Server 2003 forest to another Exchange 2010 forest, the Exchange 2010 target forest must contain a valid mail-enabled user with a specified set of Active Directory attributes. (Exchange 2010 doesn't support moving an Exchange 2000 Server mailbox.) If there is at least one Exchange 2010 Client Access server deployed in the forest, the forest is considered an Exchange 2010 forest.

To prepare for the mailbox move, you must create mail-enabled users with the required attributes in the target forest. Here are two recommended approaches to creating mail-enable users with the necessary attributes:

- If you deployed Microsoft Identity Lifecycle Manager (ILM) for cross-forest

global address list (GAL) synchronization, the recommended approach to creating the mail-enabled user is to use Service Pack 1 (SP1) for ILM 2007 Feature Pack 1 (FP1). We've created sample code that you can use to learn how to customize ILM to synchronize the source mailbox user and target mail user.
For more information, including how to download the sample code, see Prepare Mailboxes for Cross-Forest Moves Using Sample Code.

- If you created the target mail user using an Active Directory tool other than ILM/MIIS, use the **Update-Recipient** cmdlet with the *Identity* parameter to run the Address List service to generate the **LegacyExchangeDN** for the target mail user. We have created a sample Windows PowerShell script that reads from and writes to Active Directory and calls the **Update-Recipient** cmdlet. For more information about using the sample script, see Prepare Mailboxes for Cross-Forest Moves Using the Prepare-MoveRequest.ps1 script in the Shell.

After creating the target mail user, you can then run the **New-MoveRequest** cmdlet to move the mailbox to the target Exchange 2010 forest.

For more information about remote move requests, see the following topics:

- Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010
- Create a Remote Move Request That has Exchange 2010 in Both Forests
- New-MoveRequest

For more information about remote mailbox moves and remote legacy moves, see Understanding Move Requests.

The remainder of this topic describes the Active Directory mail user attributes that are required for a mailbox move. These attributes are configured for you when you use either the code or script to prepare for the mailbox move. However, you can manually copy these attributes using an Active Directory editor.

Active Directory User Attributes Required for a Mailbox Move

To support a remote mailbox move, the mail user object in the target Exchange 2010 forest must have the Active Directory attributes that are described in this section:

- Mandatory attributes
- Optional attributes
- Linked attributes
- Linked user attributes
- Resource mailbox attributes
- Additional attributes

Mandatory Attributes

The following table lists the minimum set of attributes that need to be configured in ILM on the target mail user for the **New-MoveRequest** cmdlet to function correctly.

Mail user's attributes

Mail user's Active Directory attributes	Action
displayName	Copy the corresponding attribute of the source mailbox or generate a new value.
Mail	Directly copy the corresponding attribute of the source mailbox.
mailNickname	Copy the corresponding attribute of the

	source mailbox or generate a new value.
msExchArchiveGUID and msExchArchiveName	Directly copy the corresponding attribute of the source mailbox. Attributes are only available if the source mailbox is Exchange 2010.
msExchMailboxGUID	Directly copy the corresponding attribute of the source mailbox.
msExchRecipientDisplayType	-2147483642 (decimal) //equivalent to 0x80000006 (hex).
msExchRecipientTypeDetails	128 (decimal) /0x80 (hex).
msExchUserCulture	Directly copy the corresponding attribute of the source mailbox.
msExchVersion	44220983382016 (decimal).
cn	Copy the corresponding attribute of the source mailbox or generate a new value.
proxyAddresses	Copy source mailbox's **proxyAddresses** attribute. Additionally, copy source mailbox's **LegacyExchangeDN** as an X500 address in the **proxyAddresses** attribute of the target mail user. **Note:** The **proxyAddresses** of the source mailbox user must contain an SMTP address that matches the authoritative domain of the target forest. This allows the **New-MoveRequest** cmdlet to correctly select the **targetAddress** of the source mail-enabled user (converted from the source mailbox user after the mailbox move request is complete) to ensure that mail routing is still functional.
sAMAccountName	Copy the corresponding attribute of the source mailbox or generate a new value. Ensure that the value is unique within the target forest domain that the target mail user belongs to.
targetAddress	Set to an SMTP address in the **proxyAddresses** attribute of the source mailbox. This SMTP address must belong to the authoritative domain of the source forest.
userAccountControl	Constant: 514 //equivalent to 0x202, ACCOUNTDISABLE | NORMAL_ACCOUNT.
userPrincipalName	Copy the corresponding attribute of the source mailbox or generate a new value. Because the mail user is logon disabled, this **userPrincipalName** isn't used.

Optional Attributes

It isn't mandatory that the following attributes are configured for the **New-MoveRequest** cmdlet to function correctly; however, synchronizing them provides a better end-to-end user experience after moving the mailbox. Because the GAL in the target forest displays this target mail user, you should set the following GAL-related attributes.

GAL-related attributes

Mail user's Active Directory attributes	Action
c	Directly copy the corresponding attribute of the source mailbox.
co	Directly copy the corresponding attribute of the source mailbox.
countryCode	Directly copy the corresponding attribute of the source mailbox.
company	Directly copy the corresponding attribute of the source mailbox.
department	Directly copy the corresponding attribute of the source mailbox.
facsimileTelephoneNumber	Directly copy the corresponding attribute of the source mailbox.
givenName	Directly copy the corresponding attribute of the source mailbox.
homePhone	Directly copy the corresponding attribute of the source mailbox.
info	Directly copy the corresponding attribute of the source mailbox.
initials	Directly copy the corresponding attribute of the source mailbox.
l	Directly copy the corresponding attribute of the source mailbox.
mobile	Directly copy the corresponding attribute of the source mailbox.
msExchAssistantName	Directly copy the corresponding attribute of the source mailbox.
msExchHideFromAddressLists	Directly copy the corresponding attribute of the source mailbox.
otherHomePhone	Directly copy the corresponding attribute of the source mailbox.
otherTelephone	Directly copy the corresponding attribute of the source mailbox.
pager	Directly copy the corresponding attribute of the source mailbox.
physicalDeliveryOfficeName	Directly copy the corresponding attribute of the source mailbox.

postalCode	Directly copy the corresponding attribute of the source mailbox.
sn	Directly copy the corresponding attribute of the source mailbox.
st	Directly copy the corresponding attribute of the source mailbox.
streetAddress	Directly copy the corresponding attribute of the source mailbox.
telephoneAssistant	Directly copy the corresponding attribute of the source mailbox.
telephoneNumber	Directly copy the corresponding attribute of the source mailbox.
title	Directly copy the corresponding attribute of the source mailbox.

Linked Attributes

A linked attribute is an Active Directory attribute that references other Active Directory objects in the local forest. You can't directly copy the linked attribute values from a mailbox in the source forest to a mail user in the target forest. First, you must find the Active Directory objects in the source forest that the source mailbox attribute refers to. Then, you must find the corresponding Active Directory objects in the target forest for the above-mentioned Active Directory object in the source forest. And finally, set the target mail user's attribute to refer to the Active Directory objects in the target forest.

Linked attributes

Mail User's Active Directory attributes	Action
altRecipient	Correspond to the source mailbox's **altRecipient** attribute.
deliverAndRedirect	Directly copy the corresponding attribute of the source mailbox. This attribute is a Boolean value that should be set along with **altRecipient**.
Manager (and its backlinks)	Correspond to the source mailbox's manager attribute.
MemberOf (backlinks)	This is the backlink of group member attribute.
publicDelegates (and its backlinks)	Correspond to the source mailbox's **publicDelegates** attribute.

Linked User Attributes

If you want to move a mailbox to an Exchange 2010 resource forest, the mailbox in the resource forest is considered a *linked mailbox*. In this scenario, you need to create a linked mail user in the (target) resource forest. To create a linked mail user, you need to set the attributes shown in the following table.

Linked mail user attributes

Mail user's Active Directory attributes	Action
msExchMasterAccountHistory	Directly copy the corresponding attribute of the source mailbox.

msExchMasterAccountSid	If the source mailbox has **msExchMasterAccountSid**, copy it. Otherwise, copy the source mailbox's **objectSid**.
msExchRecipientDisplayType	Constant:-1073741818 (decimal) // equivalent to *unsigned* 0xC0000006.

Note:
A linked mailbox can only be created if there's forest trust between the source forest and target forest.

If the source object is disabled and the **msExchMasterAccountSid** attribute is set to self (resource mailbox, shared mailbox), don't stamp anything on the target user.

If the source object is disabled and the **msExchMasterAccountSid** attribute isn't set, the mailbox is invalid.

If the source object is enabled and the **msExchMasterAccountSid** attribute is set, the mailbox is invalid.

Resource Mailbox Attributes

If you want to move a resource mailbox to an Exchange 2010 forest, you need to set the attributes shown in the following table on the target mail user.

Resource mailbox attributes

Mail user's Active Directory attributes	Action

msExchRecipientDisplayType	If the source mailbox is a conference room:
	• **Constant** -2147481850 (decimal) // equivalent to *unsigned* 0x80000706.
	
	If the source mailbox is an equipment mailbox:
	• **Constant** -2147481594 (decimal) // equivalent to *unsigned* 0x80000806.

msExchResourceCapacity	Directly copy the corresponding attribute of the source mailbox.
msExchResourceDisplay	Directly copy the corresponding attribute of the source mailbox.
msExchResourceMetaData	Directly copy the corresponding attribute of the source mailbox.
msExchResourceSearchProperties	Directly copy the corresponding attribute of the source mailbox.

Additional Attributes

In Exchange 2007, the **Move-Mailbox** cmdlet also copied the attributes shown in the following table when moving a mailbox. You can optionally copy these attribute if required by your organization.

Resource mailbox attributes

Mail User's Active Directory attributes	Description
comment	Directly copy the corresponding attribute of the source mailbox.

deletedItemFlags	Directly copy the corresponding attribute of the source mailbox.
delivContLength	Directly copy the corresponding attribute of the source mailbox.
departmentNumber	Directly copy the corresponding attribute of the source mailbox.
description	Directly copy the corresponding attribute of the source mailbox.
division	Directly copy the corresponding attribute of the source mailbox.
employeeID	Directly copy the corresponding attribute of the source mailbox.
employeeNumber	Directly copy the corresponding attribute of the source mailbox.
employeeType	Directly copy the corresponding attribute of the source mailbox.
extensionAttribute1-15	Directly copy the corresponding attribute of the source mailbox.
homePostalAddress	Directly copy the corresponding attribute of the source mailbox.
internationalISDNNumber	Directly copy the corresponding attribute of the source mailbox.
ipPhone	Directly copy the corresponding attribute of the source mailbox.
language	Directly copy the corresponding attribute of the source mailbox.
lmPwdHistory	Directly copy the corresponding attribute of the source mailbox.
localeID	Directly copy the corresponding attribute of the source mailbox.
mAPIRecipient	Directly copy the corresponding attribute of the source mailbox.
middleName	Directly copy the corresponding attribute of the source mailbox.
msDS-PhoneticCompanyName	Directly copy the corresponding attribute of the source mailbox.
msDS-PhoneticDepartment	Directly copy the corresponding attribute of the source mailbox.
msDS-PhoneticDisplayName	Directly copy the corresponding attribute of the source mailbox.
msDS-PhoneticFirstName	Directly copy the corresponding attribute of the source mailbox.

msDS-PhoneticLastName	Directly copy the corresponding attribute of the source mailbox.
msExchBlockedSendersHash	Directly copy the corresponding attribute of the source mailbox.
msExchELCExpirySuspensionEnd	Directly copy the corresponding attribute of the source mailbox.
msExchELCExpirySuspensionStart	Directly copy the corresponding attribute of the source mailbox.
msExchELCMailboxFlags	Directly copy the corresponding attribute of the source mailbox.
msExchExternalOOFOptions	Directly copy the corresponding attribute of the source mailbox.
msExchMessageHygieneFlags	Directly copy the corresponding attribute of the source mailbox.
msExchMessageHygieneSCLDeleteThreshold	Directly copy the corresponding attribute of the source mailbox.
msExchMessageHygieneSCLJunkThreshold	Directly copy the corresponding attribute of the source mailbox.
msExchMessageHygieneSCLQuarantineThreshold	Directly copy the corresponding attribute of the source mailbox.
msExchMessageHygieneSCLRejectThreshold	Directly copy the corresponding attribute of the source mailbox.
msExchMDBRulesQuota	Directly copy the corresponding attribute of the source mailbox.
msExchPoliciesExcluded	Directly copy the corresponding attribute of the source mailbox.
msExchSafeRecipientsHash	Directly copy the corresponding attribute of the source mailbox.
msExchSafeSendersHash	Directly copy the corresponding attribute of the source mailbox.
msExchUMSpokenName	Directly copy the corresponding attribute of the source mailbox.
otherFacsimileTelephoneNumber	Directly copy the corresponding attribute of the source mailbox.
otherIpPhone	Directly copy the corresponding attribute of the source mailbox.
otherMobile	Directly copy the corresponding attribute of the source mailbox.
otherPager	Directly copy the corresponding attribute of the source mailbox.
preferredDeliveryMethod	Directly copy the corresponding attribute of the source mailbox.

personalPager	Directly copy the corresponding attribute of the source mailbox.
personalTitle	Directly copy the corresponding attribute of the source mailbox.
photo	Directly copy the corresponding attribute of the source mailbox.
pOPCharacterSet	Directly copy the corresponding attribute of the source mailbox.
pOPContentFormat	Directly copy the corresponding attribute of the source mailbox.
postalAddress	Directly copy the corresponding attribute of the source mailbox.
postOfficeBox	Directly copy the corresponding attribute of the source mailbox.
primaryInternationalISDNNumber	Directly copy the corresponding attribute of the source mailbox.
primaryTelexNumber	Directly copy the corresponding attribute of the source mailbox.
showInAdvancedViewOnly	Directly copy the corresponding attribute of the source mailbox.
street	Directly copy the corresponding attribute of the source mailbox.
terminalServer	Directly copy the corresponding attribute of the source mailbox.
textEncodedORAddress	Directly copy the corresponding attribute of the source mailbox.
thumbnailLogo	Directly copy the corresponding attribute of the source mailbox.
thumbnailPhoto	Directly copy the corresponding attribute of the source mailbox.
url	Directly copy the corresponding attribute of the source mailbox.
userCert	Directly copy the corresponding attribute of the source mailbox.
userCertificate	Directly copy the corresponding attribute of the source mailbox.
userSMIMECertificate	Directly copy the corresponding attribute of the source mailbox.
wWWHomePage	Directly copy the corresponding attribute of the source mailbox.

Prepare Mailboxes for Cross-Forest Moves Using the Prepare-MoveRequest.ps1 script in the Shell

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-20*

Microsoft Exchange Server 2010 supports an online mailbox move using the **New-MoveRequest** cmdlet. You can move a mailbox from a source Exchange forest to a target Exchange 2010 forest.

To run the **New-MoveRequest** cmdlet, a mail user must exist in the target Exchange forest, and the mail user must have a minimum set of required Active Directory attributes.

The sample Windows PowerShell script described in this topic supports this task by synchronizing mailbox users from an Exchange 2010, Exchange Server 2007, or Exchange Server 2003 source forest to Exchange 2010 target forests as mail-enabled users. The script copies the Active Directory attributes of the mailbox users in the source forest to the target forest, and then uses the **Update-Recipient** cmdlet to turn the target objects into mail-enabled users.

For more information about using and writing scripts, see Scripting with the Exchange Management Shell. For more information about preparing for cross-forest moves, see Prepare Mailboxes for Cross-Forest Move Requests.

Looking for other management tasks related to remote move requests? Check out Managing Remote Move Requests.

Prerequisites

- Locate the script in the following location: Program Files\Microsoft\Exchange Server\V14\Scripts.
- To run the sample script, you need the following:
  - A source forest running Exchange 2010, Exchange 2007, or Exchange 2003, where the mailbox currently resides.
  - A target forest with Exchange 2010 installed, where the mailbox will be moved to.

Use the Prepare-MoveRequest.ps1 script to prepare mailboxes for cross-forest moves

Run the script from the Shell on a server role running Exchange 2010 in the target Exchange 2010 forest. The script copies the mailbox attributes from the source forest.

To assign a specific authentication credential for the remote forest domain controller, you must first run the Windows PowerShell **Get-Credential** cmdlet and store the user input in

a temporary variable. When you run the **Get-Credential** cmdlet, the cmdlet asks for the user name and password of the account used during authentication with the remote forest domain controller. You can then use the temporary variable in the Prepare-MoveRequest.ps1 script. For more information about the **Get-Credential** cmdlet, see Get-Credential.

Note:
Make sure that you use two separate credentials for the local forest and the remote forest when calling this script.

First, run the following commands to get the local forest and remote forest credentials.

```
$LocalCredentials = Get-Credential
$RemoteCredentials = Get-Credential
```

Then, run the following commands to pass the credential information to the *LocalForestCredential* and *RemoteForestCredential* parameters in the Prepare-MoveRequest.ps1 script.

```
Prepare-MoveRequest.ps1 -Identity JohnSmith@Fabrikan.com -RemoteForestDomainContr
```

The following table describes the parameter set for the script.

Parameter set of the Prepare-MoveRequest.ps1 script

Parameter	Required	Description
Identity	Required	The *Identity* parameter uniquely identifies a mailbox in the source forest. Identity can be any of the following: • Common name (CN) • Alias • **proxyAddress** property • **objectGuid** property • **DisplayName** property
RemoteForestCredential	Required	The *RemoteForestCredential* parameter specifies the administrator who has permissions to copy data from the source forest Active Directory.
RemoteForestDomainController	Required	The *RemoteForestDomainController* parameter specifies a domain controller in the source forest where the mailbox resides.
DisableEmailAddressPolicy	Optional	The *DisableEmailAddressPolicy* parameter specifies whether the Email Address Policy (EAP) should be disabled when creating a **MailUser** object in the target forest. When you specify this parameter, the EAP in the target forest won't be applied. **Note:** When you specify this parameter, the **MailUser** object won't have e-mail address mapping in the local forest domain stamped. This is usually

		stamped by the EAP.
LinkedMailUser	Optional	The *LinkedMailUser* switch specifies whether to create a linked MailUser in the local forest for the mailbox user in the remote forest. If the switch is provided, the script creates a target **MailUser** object linked to the source mailbox. If the switch is omitted, the script creates a regular target **MailUser** object. For more information, see Create a Linked Mailbox.
LocalForestCredential	Optional	The *LocalForestCredential* parameter specifies the administrator with permissions to write data to the target forest Active Directory. We recommend that you explicitly specify this parameter to avoid Active Directory permission issues. If the remote forest and the local forest have a trusted relationship configured, don't use a user account from the remote forest as the local forest credential, even though the remote user account may have permission to modify Active Directory in the local forest.
LocalForestDomainController	Optional	The *LocalForestDomainController* parameter specifies a domain controller in the target forest where the mail-enabled user will be created. We recommend that you specify this parameter to avoid possible domain controller replication delay issues in the local forest that could occur if a random domain controller is selected.
MailboxDeliveryDomain	Optional	The *MailboxDeliveryDomain* parameter specifies an authoritative domain of the source forest so that the script can select the correct source mailbox user's **proxyAddress** property as the target mail-enabled user's **targetAddress** property. By default, the primary SMTP address of the source mailbox user is set as the **targetAddress** property of the target mail-enabled user.
OverWriteLocalObject	Optional	The *OverWriteLocalObject* parameter is used for users created by the Active Directory Migration Tool. The

		properties are copied from the existing mail contact to the newly created mail user. However, after this copy, the script also copies the properties from the source forest user to the newly created mail user.
TargetMailUserOU	Optional	The *TargetMailuserOU* parameter specifies the organizational unit (OU) under which the target mail-enabled user will be created.
UseLocalObject	Optional	The *UseLocalObject* parameter specifies whether to convert the existing local object to the required target mail-enabled user if the script detects an object in the local forest that conflicts with the to-be-created mail-enabled user.

Examples

This section contains several examples of how you can use the Prepare-MoveRequest.ps1 script.

Example 1

This example provisions a single linked mail-enabled user in the local forest, when there is forest trust between the remote forest and local forest.

First, run the following commands to get the local forest and remote forest credentials.

```
$LocalCredentials = Get-Credential
$RemoteCredentials = Get-Credential
```

Then, run the following command to pass the credential information to the *LocalForestCredential* and *RemoteForestCredential* parameters in the Prepare-MoveRequest.ps1 script.

```
Prepare-MoveRequest.ps1 -Identity JamesAlvord@Contoso.com -RemoteForestDomainCont
```

Example 2

This example supports pipelining if you supply a list of mailbox identities.

First, run the following command.

```
$UserCredentials = Get-Credential
```

Then, run the following command to pass the credential information to the *RemoteForestCredential* parameter in the Prepare-MoveRequest.ps1 script.

```
"IanP@Contoso.com", "JoeAn@Contoso.com" | Prepare-MoveRequest.ps1 -RemoteForestDo
```

Example 3

You can generate a CSV file containing a list of mailbox identities from the source forest, which allows you to pipe the content of this file into the script to bulk create the target mail-enabled users.

For example, the content of the CSV file can be:

Identity

Ian@contoso.com

John@contoso.com

Cindy@contoso.com

This example calls a CSV file to bulk create the target mail-enabled users.

First, run the following command to get the remote forest credentials.

```
$UserCredentials = Get-Credential
```

Then, run the following command to pass the credential information to the *RemoteForestCredential* parameter in the Prepare-MoveRequest.ps1 script.

```
Import-Csv Test.csv | Prepare-MoveRequest.ps1 -RemoteForestDomainController DC001
```

Script Behavior per Target Object

This section describes how the script performs in relation to the following scenarios for target objects:

- Duplicate target mail-enabled object
- Mail-enabled user
- Mail-enabled contact
- **LegacyExchangeDN** attribute

Duplicate Target Mail-Enabled Object

When the script attempts to create a target mail-enabled user from the source mailbox user, and it detects a duplicate local mail-enabled object, it uses the following logic:

- If the source mailbox user's **masterAccountSid** attribute equals any target object's **objectSid** or **masterAccountSid** attribute:
  - If the target object isn't mail-enabled, the script returns an error because the script doesn't support converting an object that isn't mail-enabled to a mail-enabled user.
  - If the target object is mail-enabled, the target object is a duplicate.
- If an address in the source mailbox user's **proxyAddress** properties (smtp/x500 only) equals an address in a target object's **proxyAddress** properties (smtp/x500 only), the target object is a duplicate.

The script prompts the user about the duplicate objects.

If the target mail-enabled object is a mail-enabled user or contact, which is most likely created by a cross-forest (Identity Lifecycle Management 2007 Service Pack 1-based) global address list (GAL) synchronization deployment, the user can run the script again with the *UseLocalObject* parameter to use the target mail-enabled object for mailbox migration.

Mail-Enabled User

If the target object is a mail-enabled user, the script copies the following attributes from the source mailbox user to the target mail-enabled user:

- **msExchMailboxGUID**
- **msExchArchiveGUID**
- **msExchArchiveName**

If the *LinkedMailUser* parameter is set, the script copies the source **objectSid**/**masterAccountSid** attribute.

Mail-Enabled Contact

If the target object is a mail-enabled contact, the script deletes the existing contact and copies all its attributes to a new mail-enabled user. The script also copies the following attributes from the source mailbox user:

- **msExchMailboxGUID**
- **msExchArchiveGUID**
- **msExchArchiveName**
- **sAMAccountName**
- **userAccountControl** (set to 514 //equivalent to 0x202, ACCOUNTDISABLE | NORMAL_ACCOUNT)
- **userPrincipalName**

If the *LinkedMailUser* parameter is set, the script copies the source **objectSid**/ **masterAccountSid** attribute.

LegacyExchangeDN Attribute

When the **Update-Recipient** cmdlet is called to convert the target object into a mail-enabled user, a new **LegacyExchangeDN** attribute is generated for the target mail-enabled user. The script copies the **LegacyExchangeDN** attribute of the target mail-enabled user as an x500 address to the **proxyAddress** properties of the source mailbox user. This action ensures the correct resolution of recipients when messages are sent between the source and target forests.

1.8.3.19.10.5 Prepare Mailboxes for Cross-Forest Moves Using Sample Code

Prepare Mailboxes for Cross-Forest Moves Using Sample Code

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-02-02*

Microsoft Exchange Server 2010 supports an online mailbox move using the **New-MoveRequest** cmdlet in the Exchange Management Shell. You can move a mailbox from a source Exchange forest to a target Exchange 2010 forest. To run **New-MoveRequest**, a mail user must exist in the target Exchange forest and the mail user must have a minimum set of required Active Directory attributes.

You can create the required mail user in the target Exchange forest by customizing your Microsoft Identity Lifecycle Manager (ILM) 2007 deployment. The ILM-based rules extension sample code described in this topic demonstrates how to customize your current ILM deployment to create the required mail-enabled users in the target Exchange 2010 forest.

For more information about preparing for cross-forest moves, including descriptions of the required Active Directory attributes, see Prepare Mailboxes for Cross-Forest Move Requests.

Prerequisites

- Download the sample code from the Prepare for Online Mailbox Move page in the Microsoft Download Center.
- To run the sample code, you need ILM 2007 Feature Pack 1 SP1. To download the feature pack, see Microsoft Knowledge Base article 977791, Service Pack 1 (build 3.3.1139.2) is available for Identity Lifecycle Manager 2007 Feature Pack 1.
- You also need the following:

- A source forest running Exchange 2003, Exchange 2007 or Exchange 2010, where the mailbox currently resides

  Note:
  Exchange 2010 doesn't support moving an Exchange 2000 mailbox.

- A target forest with Exchange 2010 installed, where the mailbox will be moved to

- To connect to the Exchange 2010 target forest, you must have the appropriate permission to call the **UpdateRecipient** cmdlet. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Contents of Sample Code

In Microsoft Visual Studio 2008, open Microsoft.Exchange.Sample.OneWayGALSync.sln to view the sample code. The sample code includes the following:

- Microsoft.MetadirectoryServicesEx.dll is the binary file that is shipped with ILM 2007 FP1 SP1 under "\Program Files\Microsoft Identity Integration Server\Bin \Assemblies". It's referenced by the sample code.
- OneWaySync.xml is referenced by the sample code.
- The ILMServerConfig folder contains the ILM configuration files for the source management agent (MA), target MA, and the ILM Metaverse (MV).
- Microsoft.Exchange.Sample.OneWayGALSync.MARules.dll and Microsoft.Exchange.Sample.OneWayGALSync.MVRules.dll (built from the sample code) are under "\obj\Debug"

Install the ILM sample code

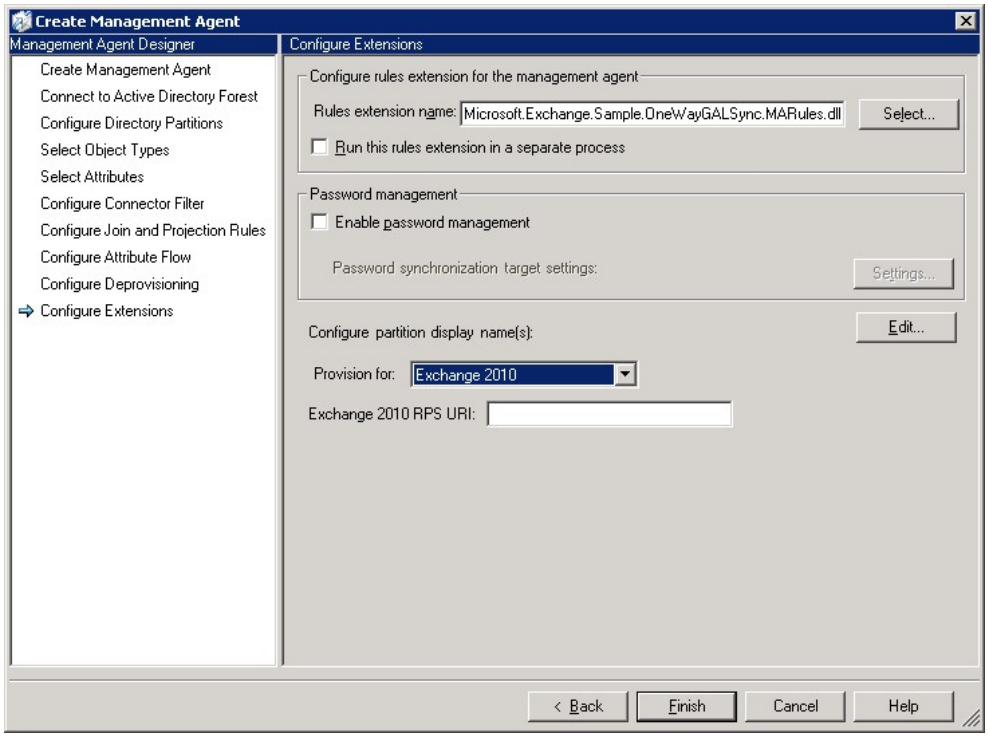
1. On the ILM server, copy the following to \Program Files\Microsoft Identity Integration Server\Extensions:
   - OneWaySync.xml
   - Microsoft.Exchange.Sample.OneWayGALSync.MARules.dll
   - Microsoft.Exchange.Sample.OneWayGALSync.MVRules.dll
2. Edit the file OneWaySync.xml that you copied to the ILM Extensions folder in step 1 to specify the distinguishedName (DN) of the TargetOU container in the target Exchange forest in which you want to create the mail users. You can use LDP.exe or ADSIEdit.exe to browse for the TargetOU container if you don't know what its name is.

   Note:
   If you're using this sample together with ILM GalSync 2007 exclude this container from the list of containers managed by GalSync2007.

3. On the ILM Identity Manager Console, go to **File** > **Import Server Configuration** to import the ILM server configuration from the folder ILMServerConfig. This action will import two Active Directory Management Agents along with the Metaverse schema and the provisioning rule.

   Note:
   During the import, you must provide the forest name and credentials and match the partitions of the imported Active Directory Management Agent (ADMA) to the partition name in your configuration for both the source and target ADMAs.

4. For the ADMA to support the Exchange 2010 target forest, on the **Create Management Agent** page, on the **Configure Extensions** pane, select **Exchange 2010** in the **Provision for** drop-down and then enter the remote Windows PowerShell URI of an Exchange 2010 Client Access server in **Exchange 2010 RPS URI**.



5. On the ILM Identity Manager Console on the **Create Management Agent** pane, open the **Properties** for the Source Forest Management Agent. Select the **Configure Directory Partitions** wizard, and then click **Containers** to select the container that will contain the mailboxes you will be moving to the target forest. Clear the selections for all other containers, that is, scope the management agent to only manage this one container. Similarly, for the target forest MA, select the container to which mail-enabled user's will be provisioned, that is, the TargetOU specified in step 2.

Note:
If you're using this sample together with ILM GalSync 2007, exclude both of these containers from the list of containers managed by GalSync 2007.

6. Perform an initial Full Import (stage only) on the target MAs so that ILM can discover the TargetOU specified in step 2.

Create Mail User in Target Exchange Forest

Now that you've installed the sample code, use the following procedure to create the required mail user in the target Exchange forest so that **New-MoveRequest** can be run to perform an online mailbox move.

1. In the source forest, use the Exchange Management Console to create mailbox users in the container selected in step 4 of "Install the ILM sample code". You can also use Active Directory Users and Computers to move existing mailbox users to the container.
2. Perform Delta Import and Delta Sync run on the source MA to discover the mailboxes added to the source container, and provision mail users to the target MA.
3. Perform Export run on the target MA to export the mail users provisioned in step 1 to the target Active Directory.
4. Perform Delta Import on the target MA to confirm the changes exported in step 2.
5. In the target forest, open the Exchange Management Shell and use the

New-MoveRequest cmdlet to move mailboxes from the source forest.

For more information related to the preceding steps, see the following topics:

- Prepare Mailboxes for Cross-Forest Move Requests
- Create a Remote Move Request That has Exchange 2010 in Both Forests
- Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

1.8.3.19.10.6 Start the MRSProxy Service on a Remote Client Access Server

Start the MRSProxy Service on a Remote Client Access Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2013-01-22*

The Mailbox Replication Proxy (MRSProxy) service is installed on every Microsoft Exchange Server 2010 Client Access server. MRSProxy helps to facilitate cross-forest move requests and runs on the remote forest's Exchange 2010 Client Access server. However, MRSProxy is disabled by default.

Note:

All Client Access servers in the Network Load Balancing (NLB) array must have MRSProxy started. When you create a remote move request, and specify the fully qualified domain name (FQDN) of the *RemoteHostName* parameter, the load balancers that share the same name space as the FQDN you specified can direct the move request to any of the Client Access servers in that array. If you don't have MRSProxy started on one of the Client Access servers, and a move request is directed to that server, the move request fails. For more information about the NLB array, see "Availability Service Network Load Balancing" in Understanding the Availability Service.

Looking for other management tasks related to move requests? Check out Managing Move Requests.

Use the Shell to Enable MRSProxy in the Remote Forest

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Exchange Web Services virtual directory settings" entry in the Client Access Permissions topic.

This example enables MRSProxy on the Exchange Web Services (EWS) default Web site. It also modifies the maximum number of simultaneous connections that an MRSProxy instance accepts by changing the value to 50. The default value is 100.

```
Set-WebServicesVirtualDirectory -Identity "EWS (Default Web Site)" -MRSProxyEnabl
```

1.8.3.19.10.7 Modify the Maximum Number of Recipients to Display in the Result Pane

Modify the Maximum Number of Recipients to Display in the Result Pane

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Maximum Number of Recipients to Display** dialog box to specify how many recipients you want to display in the result pane of the Exchange Management Console (EMC).

By default, a maximum of 1,000 recipients is displayed. Increasing this value can be beneficial in large environments. However, increasing the value also increases the time it takes to display the results. Depending on the size of your organization, it may also have a performance impact on the domain controller to which you are connected.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipients Permissions" section in the Mailbox Permissions topic.

1. In the EMC console tree, click **Recipient Configuration**.
2. In the action pane, click **Modify the Maximum Number of Recipients to Display**.
3. In the **Maximum number of recipients to display** box, type the number of recipients that you want to display in the result pane. The number must be between 1 and 100,000.
4. Click **OK**.

1.8.3.20 Managing Offline Address Books

Managing Offline Address Books

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

1.8.3.20.1 Add or Remove an Address List from an Offline Address Book

Add or Remove an Address List from an Offline Address Book

[This topic is in progress.]

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to add or remove an address list from an offline address book (OAB). By default, there is an OAB named the Default Offline Address Book that contains the global address list (GAL). OABs are generated based on the address lists that they contain. To create custom OABs that users can download, you can add or remove address lists from OABs.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Note:

The changes to the address list aren't available for client download until after the OAB in which the address list resides has been generated. For more information, see Update the Offline Address Book.

Use the EMC to add or remove an address list from an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then click the OAB that you want to edit.
3. In the action pane, click **Properties**.
4. In **<Offline Address Book Name> Properties**, click the **Address Lists** tab.
5. To add an address list to the OAB or remove an address list from the OAB, select the **Include the following address lists** check box, and then perform one of the following tasks:
   - Click **Add** to select one or more address lists to add to the OAB. You can select one or multiple address lists.
   - Click **Remove** ( ) to remove the selected address list from the OAB.
6. Click **Apply** to save your changes without closing, or click **OK** to save your changes and close **<Offline Address Book Name> Properties**.

Use the Shell to add or remove an address

list from an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

To add an address list to an OAB, use the following syntax.

```
Set-OfflineAddressBook -Identity <OfflineAddressBookIdParameter> -AddressLists <A
```

When using the *AddressLists* parameter, any address lists that currently exist will be overwritten. You must include existing address lists when you use the *AddressLists* parameter to continue to generate those address lists in your OAB. This example, in which you have AddressList1 and AddressList2, adds AddressList3.

```
Set-OfflineAddressBook -Identity "My OAB" -AddressLists AddressList1,AddressList2
```

To remove an address list from an OAB, omit that address list from the list of addresses. This example, in which you have AddressList1, AddressList2, and AddressList3, removes AddressList3.

```
Set-OfflineAddressBook -Identity "My OAB" -AddressLists AddressList1,AddressList2
```

For detailed syntax and parameter information, see Set-OfflineAddressBook.

1.8.3.20.2 Change the Default Offline Address Book

Change the Default Offline Address Book

Mailbox > Managing Mailbox Servers > Managing Offline Address Books >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

By default, when you install the Mailbox server role, a Web-based default offline address book (OAB) named Default Offline Address Book is created. You can set any OAB in your Exchange organization as the default OAB. This new default OAB is associated with all newly created mailbox databases. You can have only one default OAB in your organization. If you delete the default OAB, Microsoft Exchange doesn't automatically assign another OAB as the default. You must manually designate another OAB as the default.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Use the EMC to change the default offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then click the OAB that you want to set as the default OAB.
3. In the action pane, click **Set as Default**. A warning appears. Click **Yes** to

confirm that you want to set this OAB as the default OAB.

Use the Shell to change the default offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

To change the default OAB, use the following syntax.

```
Set-OfflineAddressBook -Identity <OfflineAddressBookIdParameter> -IsDefault <$tru
```

This example sets the OAB named My OAB as the default OAB.

```
Set-OfflineAddressBook -Identity "My OAB" -IsDefault $true
```

1.8.3.20.3 Create an Offline Address Book

Create an Offline Address Book

Mailbox > Managing Mailbox Servers > Managing Offline Address Books >

[This topic is in progress.]

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

An offline address book (OAB) in Exchange Server 2010 is a copy of an address book that has been downloaded so that an Outlook user can access the information it contains while disconnected from the server. Exchange administrators can choose which address books are made available to users who work offline, and they can also configure the method by which the address books are distributed (Web-based distribution or public folder distribution).

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

What Do You Want to Do?

- Use the EMC to create an OAB
- Use the Shell to create an OAB with web-based distribution
- Use the Shell to create an OAB with public folder distribution

Use the EMC to create an OAB

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Offline Address Book**.
3. On the **Introduction** page, complete the following fields:
   - **Name** Use this box to provide a name for the OAB.
   - **Offline address book generation server** Click **Browse** to specify the location where the OAB generation server will be located. The OAB generation server is the Mailbox server on which the OABs are generated.

- **Include the default Global Address List** The OAB is a snapshot of the Active Directory information that's available in the GAL. Select this check box to include the default GAL in the OAB.
- **Include the following address lists** Select this check box to add address lists to or remove address lists from the OAB.
  Click **Add** to open the **Select Address List** dialog box. Use this dialog box to select one or more address lists to add to the OAB.
  Click  to remove the selected address list from the OAB.

4. On the **Distribution Points** page, complete the following fields:
   - **Enable Web-based distribution** Select this check box to distribute the OAB from selected virtual directories. Web-based distribution is the distribution method by which Outlook 2007 or later clients that are working offline or through a dial-up connection access OABs. Clients will download the OAB over HTTPS from the virtual directory you specify.
     Click **Add** to open the **Select OAB Virtual Directory** dialog box. Use this dialog box to add virtual directories from which to distribute the OAB.
     Click  to delete the Web-based distribution point.
   - **Enable public folder distribution** Select this check box to enable public folder distribution. Public folder distribution is the distribution method by which Outlook 2003 or earlier clients that are working offline or through a dial-up connection access OABs.

5. On the **New Offline Address** Book page, review your configuration settings. Click **New** to create the OAB or click **Back** to make changes. Click **Cancel** to close the wizard without creating a new OAB.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** the close the wizard.

Use the Shell to create an OAB with web-based distribution

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

This example creates the OAB New OAB that uses Web-based distribution for Outlook 2007 or later clients on SERVER01 by using the default virtual directory.

```
New-OfflineAddressBook -Name "New OAB" -AddressLists "\Default Global Address Lis
```

Use the Shell to create an OAB with public folder distribution

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

This example creates the OAB Legacy OAB that uses public folder distribution for Outlook 2003 SP1 and Outlook 98 Service Pack 2 (SP2) clients on SERVER01.

```
New-OfflineAddressBook -Name "Legacy OAB" -AddressLists "Default Global Address L
```

Note:
If you configure OABs to use public folder distribution, but your organization doesn't have any public folder infrastructure, an error will be returned. For more information, see Managing Public Folders.
For detailed syntax and parameter information, see New-OfflineAddressBook.

For More Information

Understanding Offline Address Books

Configure Offline Address Book Properties

Configure Offline Address Book Distribution Properties

1.8.3.20.4 Configure Offline Address Book Properties

Configure Offline Address Book Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-17*

An offline address book (OAB) in Exchange Server 2010 is a copy of an address book that's been downloaded so that an Outlook user can access the information it contains while disconnected from the server. Exchange administrators can choose which address books are made available to users who work offline, and they can also configure the method by which the address books are distributed (Web-based distribution or public folder distribution).

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

What Do You Want to Do?

- Use the EMC to configure OAB properties
- Use the Shell to configure OAB properties

Use the EMC to configure OAB properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then select the offline address book that you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view OAB properties and to set the update interval for the OAB.

- **Name** This unlabeled box at the top of the tab displays the OAB name. You can modify this name.
- **Generation server** This read-only field displays the OAB generation server. The OAB generation server is the Mailbox server on which the OABs are generated. If you want to specify a different generation server, use the **Move-OfflineAddressBook** cmdlet with the *Server* parameter. For more information, see Move-OfflineAddressBook.
- **Default offline address book** This read-only field displays a **True** or **False** status to indicate whether the selected OAB is the default OAB. If this isn't the default OAB, and you want to set it as the default, right-click the OAB in the result pane, and then click **Set as Default**.
- **Modified** This read-only field displays the last date and time that the OAB was modified.
- **Update Schedule** This list displays the time and interval for the regularly scheduled update.

  To customize the schedule, select **Use Custom Schedule** from the list, and then click **Customize** to open the **Schedule** dialog box and specify the schedule you want.

5. Use the **Address Lists** tab to select the address lists you want to include in the OAB. If you want to include a global address list (GAL) other than the default GAL, you must use the Shell.
   - **Include the default Global Address List** Select this check box to include the default GAL in the OAB.
   - **Include the following address lists** Select this check box to add address lists to or remove address lists from the OAB.

     Click **Add** to select one or more address lists to add to the OAB.

     Click  to remove the selected address list from the OAB.

6. Use the **Distribution** tab to specify the client support and OAB distribution points for the OAB.

   Client Support Select the OAB version that will be generated for the version of Outlook that is used by your Exchange organization. If you have more than one version of Outlook in your organization, you can select one or more of the following versions:
   - **Outlook 98 SP1 or earlier (Version 2)**
   - **Outlook 98 SP2 or later (Version 3)**
   - **Outlook 2003 SP2 or later (Version 4)**

   If you don't select one of the **Client Support** options, Version 4 will be generated.

   Distribution Points OAB distribution is the method by which the OAB can be accessed by users when they are working remotely or over a dial-up connection. To distribute the OAB, administrators can use Web-based distribution, public folder distribution, or both. An OAB distribution point is the HTTP Web address or public folder where client computers can download an OAB.

   You can select one or both of the following check boxes:
   - **Enable Web-based distribution** Select this check box to enable Web-based distribution. Web-based distribution is the distribution method by which Outlook 2007 or later clients that are working offline or through a dial-up connection access the OAB. With Web-based distribution, a Client Access server will contain an OAB virtual directory for Web distribution purposes.

     Click **Add** to specify the virtual directory or directories from which you want to distribute the OAB.

     Click  to remove the selected virtual directory from the OAB.
   - **Enable public folder distribution** Select this check box to enable public folder distribution. Public folder distribution is the distribution method by which Outlook 2003 or earlier clients that are working offline or through a

dial-up connection access OABs.

Use the Shell to configure OAB properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

This example modifies the time and date at which the OAB generation occurs for the OAB My OAB.

```
Set-OfflineAddressBook -Identity "My OAB" -Schedule "Sun.1:15 AM-Sun.1:30 AM"
```

Note:
The *Schedule* parameter takes the following format and must include a range: Weekday.Hour:Minute[AM/PM]-Weekday.Hour:Minute[AM/PM].

For More Information

Understanding Offline Address Books

Configure Offline Address Book Distribution Properties

1.8.3.20.5 Provision Recipients for Offline Address Book Downloads

Provision Recipients for Offline Address Book Downloads

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

If you use multiple offline address books (OABs) in your organization, there are several ways to specify which recipients download which OABs:

- **Per mailbox database** You can use the EMC or the Shell to provision recipients for OAB downloads by linking a mailbox database to a public folder database (for Microsoft Outlook 2003 clients), to a default OAB (for Office Outlook 2007 and Outlook 2010 clients), or both.
- **Per recipient** You can use the **Set-Mailbox** cmdlet in the Shell to specify which OAB is downloaded by linking the OAB directly to a recipient's mailbox. You can't specify the public folder database at the per-recipient level.
- **Per multiple recipients** You can use a pipelined command in the Shell to specify the OAB that multiple recipients download, based on common attributes.
- **Per address book policy** You can assign an address book policy (ABP) to a mailbox user's account to specify which OAB is downloaded to a recipient's mailbox. If you assign an ABP to a user account that already has an OAB assigned, the OAB that is explicitly assigned to the mailbox will take precedence. For more information, see Assign an Address Book Policy to a Mail User.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Provision recipients for OAB downloads

by linking their mailbox database to a public folder database or to a default OAB

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

Use the EMC

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab, and then select the mailbox database you want.
3. In the action pane, click **Properties**.
4. In **<Mailbox Database Name>** **Properties**, on the **Client Settings** tab, use the following boxes to select the default public folder database, the default OAB, or both:
   - **Default public folder database** This box displays the location of the default public folder database. The public folder database stores public folder data, OAB information, and free/busy information for Outlook 2003 and earlier clients. To change the location of the default public folder database, click **Browse**.
   - **Offline address book** This box displays the location of the OAB that this database uses as the default OAB for Outlook 2007 and Outlook 2010 clients. To change the OAB, click **Browse**.
5. Click **Apply** to save your changes without closing, or click **OK** to save your changes and close **<Mailbox Database Name> Properties**.

Use the Shell

To specify the public folder database and OAB, use the following syntax.

```
Set-MailboxDatabase -Identity <DatabaseIdParameter> -OfflineAddressBook <OfflineA
```

This example sets up the Web-based distribution of My OAB for the default mailbox database.

```
Set-MailboxDatabase -Identity "Mailbox Database" -OfflineAddressBook "My OAB"
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

Use the Shell to specify which OAB will be downloaded by linking the OAB directly to a recipient's mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to complete this procedure.

To specify which OAB is downloaded by linking the OAB directly to a recipient's mailbox, use the following syntax.

```
Set-Mailbox -Identity <MailboxIDParameter> -OfflineAddressBook <OfflineAddressBoo
```

Note:

The *Identity* parameter identifies the mailbox and can take the following values: GUID, ADObjectID, distinguished name (DN), *domain**account*, user principal name (UPN), LegacyExchangeDN, SmtpAddress, and alias.

This example specifies that the user Kim will download the OAB My OAB.

```
Set-Mailbox -Identity Kim -OfflineAddressBook "My OAB"
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to specify the OAB that multiple recipients will download

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to complete this procedure.

To specify the OAB that multiple recipients download, use the following syntax.

```
Get-User -Filter <String> | Set-Mailbox -OfflineAddressBook <OfflineAddressBookId
```

This example specifies that all user mailboxes in the United States for the Contoso company download the OAB Contoso United States.

```
Get-User -ResultSize Unlimited -Filter { Company -eq "Contoso" -and RecipientType
```

Note:
For more information about using filters to limit the scope of a command, see Creating Filters in Recipient Commands.

For detailed syntax and parameter information, see Get-User and Set-Mailbox.

1.8.3.20.6 Remove an Offline Address Book

Remove an Offline Address Book

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to remove an offline address book (OAB).

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Note:
After you remove an OAB that's linked to a user or to a mailbox database, the recipient will download the default OAB until you assign a new OAB for that user. If you remove the default OAB, you must assign a different OAB as the default OAB. For instructions about how to change the default OAB, see Change the Default Offline Address Book.

Use the EMC to remove an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then click the OAB that you want to remove.
3. In the action pane, click **Remove**. A warning appears. Click **Yes** to confirm that you want to remove the OAB.

Use the Shell to remove an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

To remove an OAB, use the following syntax.

```
Remove-OfflineAddressBook -Identity <OfflineAddressBookIdParameter>
```

This example removes an OAB named My OAB.

```
Remove-OfflineAddressBook -Identity "My OAB"
```

Type **Y** to confirm that you want to remove the OAB, and then press ENTER.

For detailed syntax and parameter information, see Remove-OfflineAddressBook.

1.8.3.20.7 Update the Offline Address Book

Update the Offline Address Book

Mailbox > Managing Mailbox Servers > Managing Offline Address Books >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the EMC or the Shell to update an offline address book (OAB). After you create an OAB or modify OAB settings, the changes aren't available to users until the OAB generation (OABGen) process has completed.

For information about how to create OABs, see Create an Offline Address Book.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Use the EMC to update an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then click the OAB that you want to update.
3. In the action pane, click **Update**.
4. A warning appears. Click **Yes** to update the OAB.

Use the Shell to update an offline address book

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

To update an OAB, use the following syntax.

```
Update-OfflineAddressBook -Identity <OfflineAddressBookIdParameter>
```

This example updates the OAB named My OAB.

```
Update-OfflineAddressBook -Identity "My OAB"
```

For detailed syntax and parameter information, see Update-OfflineAddressBook.

1.8.3.20.8 Create an Offline Address Book Virtual Directory

Create an Offline Address Book Virtual Directory

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

You can use the Shell to create an offline address book (OAB) virtual directory.

The OAB virtual directory is the distribution point used by the Web-based distribution method of the OAB. By default, when Microsoft Exchange Server 2010 is installed, a new virtual directory named OAB is created in the default internal Web site in Internet Information Services (IIS). If you have client-side users that connect to Microsoft Outlook from outside your organization's firewall, you can add an external Web site. Alternatively, when you run the **New-OABVirtualDirectory** cmdlet in the Shell, a new virtual directory named OAB is created in the default IIS Web site on the local Exchange server.

Although Web-based distribution is enabled by default and doesn't require further configuration, we recommend that you enable Secure Sockets Layer (SSL) for the OAB distribution point. For more information, see Require SSL for Offline Address Book Distribution.

Creating an OAB virtual directory isn't a common task. Exchange allows for one OAB virtual directory named OAB, and you should create an OAB virtual directory only if there is a problem with the existing OAB virtual directory, and the previous OAB virtual directory was removed. For more information, see Remove, Re-Create, and Reconnect an Offline Address Book Virtual Directory.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Important:
Before you create an OAB virtual directory, make sure that your users are aware of the changes you are making. This procedure may interrupt the OAB downloading process for your users.

Prerequisites

- The local Exchange server has the Client Access server role installed.
- There is a default IIS Web site, for example, /w3svc/1/root.
- A virtual directory named OAB doesn't already exist.

Use the Shell to create an OAB virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "OAB virtual directory" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to create an OAB virtual directory.

To create an OAB virtual directory with all of the default settings, you can run the **New-OABVirtualDirectory** cmdlet without any parameters. Use the following procedure to create an OAB virtual directory with custom settings.

Note:
When creating an OAB virtual directory, we recommend that you have SSL enabled.

To create an OAB virtual directory, use the following syntax.

```
New-OABVirtualDirectory -DomainController <Fqdn> -ExternalUrl <Url> -InternalUrl
```

This example creates an OAB virtual directory on the Client Access server named CAS_SERVER01 that has SSL enabled and an external URL.

```
New-OABVirtualDirectory -RequireSSL $true -ExternalURL "https://www.contoso.com/O
```

After you create a new OAB virtual directory, you must edit the settings on each OAB that uses Web-based distribution to reconnect to the OAB virtual directory. For more information, see Configure Offline Address Book Properties.

For detailed syntax and parameter information, see New-OABVirtualDirectory.

1.8.3.20.9 Configure Offline Address Book Distribution Properties

Configure Offline Address Book Distribution Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

For each offline address book (OAB) distribution point in Exchange Server 2010, you can configure two URLs—an internal URL that can be accessed only from your internal corporate network and an external URL that can be accessed from the Internet.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

What Do You Want to Do?

- Use the EMC to view or configure OAB distribution properties
- Use the Shell to configure OAB distribution properties

Use the EMC to view or configure OAB distribution properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address book distribution" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Server Configuration** > **Client Access**.
2. In the result pane, select the Client Access server you want.
3. In the work pane, click the **Offline Address Book Distribution** tab, and then select the OAB distribution point you want to configure.
4. In the action pane, click **Properties**.
5. Use the **General** tab to view information about the OAB and to configure the polling interval.
   - **Server** This read-only field displays the name of the server that hosts the OAB.
   - **Path** This read-only field displays the path to the location where the OAB is stored.
   - **Modified** This read-only field displays the date and time when the last configuration change was made to this OAB distribution point.
   - **Polling interval (minutes)** Use this box to configure your polling interval (in minutes). The distribution point will use this interval to poll for updated OAB files. The default setting is eight hours (480 minutes).
6. Use the **URLs** tab to view and modify the URLs to which users connect to download OAB updates.
   - **Internal URL** Use this box to type the URL that Outlook users on the corporate network can use to download OAB updates.
   - **External URL** Use this box to type the URL that Outlook users can use to download OAB updates from the Internet.

Use the Shell to configure OAB distribution properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address book distribution" entry in the Mailbox Permissions topic.

This example sets the polling interval for OAB distribution on the OAB virtual directory OAB (Default Web Site) to six hours.

```
Set-OABVirtualDirectory "OAB (Default Web Site)" -PollInterval 360
```

This example sets the external distribution point to https://contoso.com/OAB for the

default OAB virtual directory OAB (Default Web Site).

```
Set-OABVirtualDirectory "OAB (Default Web Site)" -ExternalUrl https://contoso.com
```

For More Information

Understanding Offline Address Books

1.8.3.20.10 Move the Offline Address Book Generation Process to Another Server

Move the Offline Address Book Generation Process to Another Server

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Offline address book (OAB) generation is the process by which Exchange creates and updates the OAB. When OAB generation occurs, Exchange generates new OAB files, compresses the files, and then places the files on a local share.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Cautions

- If you use Web-based distribution, the Client Access server replicates the files. If you use public folder distribution, the OAB generation process places the files directly in one of the public folders, and then the Exchange store replication copies the data to other public folder distribution points.
- Client computers that are running Outlook periodically check for and download OAB updates. For information about how to modify when OAB generation occurs, see Configure Offline Address Book Properties.
- If your organization contains Exchange Server 2003 servers, you can generate the OAB from an Exchange 2003 server provided that public folder distribution is enabled. However, if you generate the OAB from an Exchange 2003 server, you will lose the following functionality:
  - Japanese phonetic display name
  - Japanese phonetic surname
  - Japanese phonetic given name
  - Japanese phonetic company name
  - Japanese phonetic department name
  - PR_DISPLAY_TYPE_EX, which is used by Office Outlook 2007 and later to render the correct icon for objects that are replicated across the forest.

What Do You Want to Do?

- Use the EMC to move OAB generation to another server
- Use the Shell to move OAB generation to another server

Use the EMC to move OAB generation to

another server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "OAB virtual directories" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Offline Address Book** tab, and then select the OAB for which you want to move the generation to a new server.
3. In the action pane, click **Move**.
4. On the **Move Offline Address Book** page, click **Browse** to open the **Select Mailbox Server** dialog box. Select the server to which you want to move the OAB generation process, and then click **OK**.
5. Click **Move** to move the OAB generation process to the new server.
6. View the status of the move operation. The wizard will move the generation of your OAB to the new server and copy the existing files for the OAB to the new server. Click **Back** to make configuration changes.
7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
8. Click **Finish** to close the wizard.

Use the Shell to move OAB generation to another server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "OAB virtual directories" entry in the Mailbox Permissions topic.

This example moves the OAB generation process to SERVER01 for the OAB MyOAB.

```
Move-OfflineAddressBook -Identity "My OAB" -Server SERVER01
```

For detailed syntax and parameter information, see Move-OfflineAddressBook.

For More Information

Understanding Offline Address Books

1.8.3.20.11 Remove, Re-Create, and Reconnect an Offline Address Book Virtual Directory

Remove, Re-Create, and Reconnect an Offline Address Book Virtual Directory

Mailbox > Managing Mailbox Servers > Managing Offline Address Books >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to remove, re-create, and then reconnect an offline address book (OAB) virtual directory. The OAB virtual directory is the distribution point used by the Web-based distribution method of the OAB. By default, when Microsoft Exchange Server 2010 is installed, a virtual directory named OAB is created in the default internal Web site in Internet Information Services (IIS).

When you remove an OAB virtual directory, the OABs that use Web-based distribution will lose their connection to the OAB virtual directory. After you re-create the virtual directory, you must edit the settings on each OAB that uses Web-based distribution to reconnect to the OAB virtual directory. For information about how to edit OAB settings, see Configure Offline Address Book Properties.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Important:

Before you remove, re-create, and reconnect an OAB virtual directory, make sure that your users are aware of the changes. These procedures may interrupt the OAB downloading process for your users.

Use the Shell to remove, re-create, and reconnect an OAB virtual directory

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Offline address books" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to remove an OAB virtual directory.

1. To get the default OAB virtual directory's settings, run the following command.

```
Get-OABVirtualDirectory -Identity "OAB (Default Web Site)" | fl | Out-
```

2. Record the settings for the *PollInterval*, *OfflineAddressBooks*, *RequireSSL*, *Path*, *InternalURL*, and *ExternalURL* parameters.
3. To delete the default OAB virtual directory, run the following command.

```
Remove-OABVirtualDirectory -Identity "OAB (Default Web Site)"
```

4. Type **Y** to confirm that you want to remove the OAB virtual directory, and then press ENTER. If the OAB virtual directory that you are removing has OABs connecting to it, you will receive another warning indicating that you must designate another OAB virtual directory.
5. Create an OAB virtual directory that has the same settings as the OAB that you removed, except the settings for the *OfflineAddressBooks* parameter. You will reconnect the OABs in the next step. For instructions about how to create an OAB virtual directory, see Create an Offline Address Book Virtual Directory.
6. Reconnect any OABs that use the Web-based distribution method to the new OAB virtual directory. For instructions about how to reconnect OABs to a virtual directory, see Configure Offline Address Book Properties.

For detailed syntax and parameter information, see Remove-OABVirtualDirectory.

Require SSL for Offline Address Book Distribution

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use Internet Information Services (IIS) Manager and the Shell to configure the virtual directory to use Secure Sockets Layer (SSL) for an offline address book (OAB). By default, when you install the Client Access server role on a computer running Microsoft Exchange Server 2010, a virtual directory named OAB is created on the default IIS Web site on the Exchange server.

When SSL is enabled, both SSL and unencrypted requests to the OAB virtual directory are allowed. You can disallow unencrypted requests by performing the procedures detailed later in this topic.

Looking for other management tasks related to OABs? Check out Managing Offline Address Books.

Prerequisites

- To learn more about the various security and authentication related options that are available, we recommend that you first read Securing Client Access Servers.
- After you obtain a valid SSL certificate to use with the Client Access server on the OAB default Web site or on the Web site where you host your OAB virtual directory, you should test SSL connectivity by issuing an HTTPS request. Using your browser, type the following URL in the address bar: **https://<server name>/**. The request should return your server's home page. You can configure the Web site to require SSL. You can also enable SSL for one or more Web sites hosted by the Client Access server. For more information, see Securing Client Access Servers.

Step 1: Use Internet Information Services 7 Manager to set up the default Web site for OAB to require SSL

To perform this procedure, you must be a member of the Administrators group on the local computer.

1. Click **Start**, point to **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.
2. In the console tree of **Internet Information Services (IIS) 7 Manager**, expand the Client Access server on which you are going to configure IIS.
3. Expand **Sites**, expand **Default Web Site**, and then click **OAB**.
4. In the result pane, double-click **SSL Settings**.
5. In the **SSL Settings** property page, select the **Require SSL** check box, and then select the **Require 128-bit SSL** check box.
6. In the action pane, click **Apply**.

Step 2: Use the Shell to set up the OAB virtual directory to require SSL

verification and to use an SSL-enabled external Web site

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "OAB virtual directory" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to set up the OAB virtual directory to require SSL verification and to use an SSL-enabled external Web site.

To set up the OAB virtual directory to require SSL verification and to use an SSL-enabled external Web site, use the following syntax.

```
Set-OABVirtualDirectory -Identity <VirtualDirectoryIdParameter> -RequireSSL <$tru
```

This example requires SSL for the OAB default Web site with an external URL for the Contoso company.

```
Set-OABVirtualDirectory -Identity "OAB (Default Web Site)" -RequireSSL $true -Ext
```

For detailed syntax and parameter information, see Set-OABVirtualDirectory.

1.8.3.21.1 Change the Default Public Folder Database for a Mailbox Database

Change the Default Public Folder Database for a Mailbox Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Each mailbox database is configured with a default public folder database. MAPI client applications, such as Microsoft Outlook, open a connection to the default public folder database and perform all hierarchy-based operations against the server that contains that database. These operations include viewing public folders, creating and deleting public folders, and querying for the location of public folder content.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to change the default public folder database for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, select the mailbox database for which you want to change the default public folder database.
3. In the action pane, under the mailbox database name, click **Properties**.
4. In **<Mailbox Database Name> Properties**, click the **Client Settings** tab.
5. Next to the **Default public folder database** box, click **Browse**.
6. In **Select Public Folder Database**, select the public folder database from the list of public folder databases, and then click **OK**.
7. Click **OK**.

Use the Shell to change the default public folder database for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox database" entry in the Mailbox Permissions topic.

This example sets the public folder database PublicFolderDB1 as the default public folder database for the mailbox database Mailbox Database.

```
Set-MailboxDatabase -Identity "Mailbox Database" -PublicFolderDatabase "PublicFol
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

1.8.3.21.2 Create a Public Folder

Create a Public Folder

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. Public folders are hierarchically organized, stored in dedicated databases, and can be replicated between Exchange servers.

When you create a public folder, the only required attribute is the folder name. After the folder has been created, you can edit the public folder to configure other folder properties. For more information, see Configure Public Folder Properties.

Caution:

By default, a public folder inherits the settings of its parent folder, including the permissions settings.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Prerequisite

You can't create public folders until you have created a public folder database. For detailed instructions, see Create a Public Folder Database.

What Do You Want to Do?

- Use the EMC to create a public folder
- Use the Shell to create a public folder

Note:

You can also create public folders by using a client program such as Outlook.

Use the EMC to create a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, navigate to **Default Public Folders**, and then select the parent public folder for the public folder you want to create.
4. In the action pane, click **New Public Folder**.
5. On the **Introduction** page, complete the following fields:

- **Name** Use this box to type the name of the new public folder.
- **Path** Use this read-only box to verify the path to the public folder. If this box displays a backslash (****), the public folder that you are creating will be a top-level public folder.

Note:
To change the path, close the wizard, and then, in the Public Folder Management Console, select the public folder under which you want to create this public folder, and start the wizard again.

6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to close the wizard.

Use the Shell to create a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example creates a public folder in the root of the public folder tree on the closest Mailbox server that has a public folder database.

```
New-PublicFolder -Name "My Public Folder"
```

Note:
If you don't specify a server, the cmdlet checks if the local server is an Exchange 2007 or later Mailbox server that has a public folder database. If it is, the public folder is created locally. If it isn't, Exchange finds the closest (by site cost) Exchange 2007 or later Mailbox server that has a public folder database on which to create the public folder.

This example creates the public folder Pending in the existing public folder Legal on the Mailbox server My Server.

```
New-PublicFolder -Name "Pending" -Path \Legal -Server "My Server"
```

For syntax and parameter information, see New-PublicFolder.

Other Tasks

After you create a public folder, you may also want to:

- Mail-Enable a Public Folder
- Configure Public Folder Properties

For More Information

Understanding Public Folders

Managing Public Folders

1.8.3.21.3 Configure Public Folder Properties

Configure Public Folder Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Public folders in Exchange Server 2010 are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. Public folders are hierarchically organized, stored in dedicated databases, and can be replicated between Exchange servers.

Note:
By default, a public folder inherits the settings of its parent folder, including the permissions settings.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

What Do You Want to Do?

- Use the EMC to configure public folder properties
- Use the EMC to overwrite child public folder settings with the parent public folder settings
- Use the Shell to configure public folder properties

Use the EMC to configure public folder properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the console tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want, and then, in the action pane, click **Properties**.
5. Use the **General** tab to view the properties of a public folder or to change the public folder's name.
   - **Name** Use this unlabeled box to view or modify the display name for the public folder.
   - **Path** This read-only field displays the path to the public folder.
   - **Total items** This read-only field displays the number of items in the public folder.
   - **Size (KB)** This read-only field displays the public folder's size in kilobytes (KB).
   - **Public folder database** This read-only field displays the name of the public folder database that contains this public folder.
   - **Modified** This read-only field displays the last date and time a configuration change was made.

     Note:
     Configuration changes made through any other method, such as

the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.

- **Maintain per-user read and unread information for this folder** Select this check box to allow the user to see if a public folder message has been read or unread in Outlook.

6. Use the **Statistics** tab to view the number of associated items in a public folder, the total size of associated and deleted items, the owner and contact count, and the last time the public folder was accessed.
   - **Associated items** This read-only field displays the number of associated items in a public folder. Associated items include rules configured on the public folder, categories that are set on posts in a public folder, and more.
   - **Total size of associated items (KB)** This read-only field displays the size, in kilobytes, of the associated items in a public folder.
   - **Total size of deleted items (KB)** This read-only field displays the size, in kilobytes, of the deleted items in a public folder. The size of a public folder's deleted items is calculated independently of the public folder size displayed on the **General** tab.
   - **Owner count** This read-only field displays the number of owners specified on a public folder.
   - **Contact count** This read-only field displays the number of contacts specified on a public folder.
   - **Last access time** This read-only field displays the last time the public folder was accessed.

7. Use the **Replication** tab to view and set the content replication schedule and to specify the databases on which the public folder content will be replicated. To learn more, see Understanding Public Folder Replication.
   - **Replicate content to these public folder databases**

     Add Click this button to open the **Select Public Folder Database** dialog box. Use this dialog box to specify which public folder databases this public folder should be replicated to. Select the public folder database, and then click **OK**.

      Select a database from the list, and then click this button to remove it from the replication list.
   - **Use public folder database replication schedule** Select this check box to use the replication schedule that is set on the public folder database. This check box is selected by default. To manually set the replication schedule, clear this check box and then select from the options in the corresponding list. If you select **Use Custom Schedule**, click **Customize** to open the **Schedule** dialog box, and then specify the times that you want replication to occur.
   - **Local replica age limit (days)** Use this text box to specify the age limit for items in this public folder. Items that have reached the specified age limit are deleted.

8. Use the **Limits** tab to view or configure storage quotas, deleted item retention, and age limits for the public folder.

   Storage quotas
   - **Use database quota defaults** Select this check box to use the public folder database quota limits on which the public folder resides. If you clear this check box, the **Issue warning at (KB)**, **Prohibit post at (KB)**, and **Maximum item size (KB)** check boxes are made available.
   - **Issue warning at (KB)** Select this check box to automatically warn public folder owners that the public folder is approaching its storage limit.

     To specify this limit, select the check box, and then specify the size of the public folder in kilobytes (KB) at which you want to prohibit posting. You can enter a value between 0 and 2,147,483,647 KB (2.1 terabytes).

- **Prohibit post at (KB)** Select this check box to prevent posting to the public folder after the size of the folder reaches the specified limit.
  To specify this limit, select the check box, and then specify the size of the public folder in KB at which you want to prohibit posting. You can enter a value between 0 and 2,147,483,647 KB (2.1 terabytes).
- **Maximum item size (KB)** Select this check box to limit the maximum size of items that users can post to the public folder.
  To specify the size, select the check box, and then specify the maximum size of items in KB that users can post to the public folders. You can enter a value between 0 and 2,097,151 KB.

Deleted item retention

- **Use database retention defaults** Select this check box to use the public folder database item retention limits on which this public folder resides. If you clear this check box, the **Retain deleted items for (days)** check box is made available.
- **Retain deleted items for (days)** Select this check box to set the number of days that deleted items are retained in a public folder. You can enter a value between 0 and 24,855 days.

Age limits

- **Use database age defaults** Select this check box to use the public folder database age limits on which this public folder resides. If you clear this check box, the **Age limit for replicas (days)** check box is made available.
- **Age limit for replicas (days)** Select this check box to limit the age of the public folder. Use the corresponding text box to specify the age limit in days. Replicas of this public folder are automatically deleted when the age limit is exceeded. You can enter a value between 0 and 24,855 days.

9. Use the **Permissions** tab to add user permissions to or remove user permissions from the selected public folder.
   - **Add** Click this button to add a user. After you add the user, you must select the permissions you want them to have.
   -  Click this button to remove a user's permissions to the public folder.
   - **Permission Level** Use this list and the associated check boxes to assign permissions to the selected user. For more information about the permissions and the level of access that each one grants, see the "Client User Access Rights and Roles" section of Understanding Public Folder Permissions.

10. (This tab appears only for mail-enabled public folders.)
    Use the **Exchange General** tab to view and configure the general settings of a mail-enabled public folder.
    - **Alias** Use this box to view or modify the alias for the mail-enabled public folder.
    - **Display name** Use this box to view or modify the display name for the public folder. This is the name that the public folder displays in the global address list (GAL).
    - **Simple display name** Use this box to view or modify the simple display name for the mail-enabled public folder. This field accepts only ASCII characters.
      The **Display name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older client applications may not support Unicode characters. If the system that is displaying the public folder doesn't support Unicode characters, the simple display name can be used. For more information about Unicode characters, see Unicode.
    - **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.

After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.

- **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**. To learn more, see Understanding Custom Attributes.

11.(This tab appears only for mail-enabled public folders.)
Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.

- **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:
  SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address.
  EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
  Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

  Note:
  With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
-  Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:
  This button is enabled when an address other than the external e-mail address is selected.

- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

12.(This tab appears only for mail-enabled public folders.)
Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

13.(This tab appears only for mail-enabled public folders.)
Use the **Mail Flow Settings** tab to configure delivery options and message size or message delivery restrictions for the mail-enabled public folder.

- **Delivery Options** Select this setting and then click **Properties** to open the **Delivery Options** dialog box. Use this dialog box to configure the following settings:
  Send on behalf Click **Add** to open the **Select Mailbox or Mail-Enabled User** dialog box. Use this dialog box to grant a recipient the permissions to send e-mail on behalf of the selected public folder. Click  to remove a recipient from the list.
  Forward to Select this check box, and then click **Browse** to open the **Select Recipient** dialog box. Use this dialog box to select a recipient to whom you want to forward all e-mail messages that are sent to this public folder.
  Deliver message to both forwarding address and mailbox If you selected the **Forward to** check box, you can select this check box to specify that e-mail messages be delivered to both the public folder and to the forwarding address.
- **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. In this dialog box, use the **Maximum message size (in KB)** check boxes to set the maximum size for messages that can be sent and received by this recipient. Use the corresponding text boxes to type the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB. If a message larger than the specified size is sent to the recipient, the message will be returned to the sender with a descriptive error message.
- **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:
  All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.
  Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.
No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.
Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

Use the EMC to overwrite child public folder settings with the parent public folder settings

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder client permissions" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, double-click **Public Folder Management Console**.
3. In the public folder tree of the Public Folder Management Console, expand **Default Public Folders**, and then click the parent public folder of the public folder you want to configure.
4. In the result pane, click the public folder you want to configure.
5. In the action pane, click **Manage Settings**.
6. On the **Introduction** page, click **Overwrite Settings** to override the child public folder settings with the selected parent public folder settings. You can overwrite the age limits, keep per-user read/unread state, replicas, and replication schedule. This option is available only if the public folder that you're modifying has one or more child public folders.
7. On the **Select Settings** page, select the settings to overwrite. For more information about the settings you can configure, see Configure Public Folder Properties.
   - **Age limits** Select this check box to copy the selected public folder's age limits to the child public folders.
   - **Keep per user read/unread state** Select this check box to copy the selected public folder's per-user read/unread settings to the child public folders. This setting allows users to see if a public folder message has been read or unread in Microsoft Outlook.
   - **Replicas** Select this check box to copy the selected public folder's replica settings to the child public folders.
   - **Replication schedule** Select this check box to copy the selected public folder's replication schedule to the child public folders.
8. On the **Overwrite Settings** page, review your configuration settings. Click **Overwrite** to overwrite the child public folder settings with the selected public folder. Click **Back** to make configuration changes.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

10.Click **Finish** to close the wizard.

Use the Shell to configure public folder properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Use the **Set-MailPublicFolder** cmdlet to configure public folder properties.

This example sets the primary SMTP address of the public folder Sales to MyMailPublicFolder@contoso.com.

```
Set-MailPublicFolder -Identity "\Sales" -PrimarySmtpAddress MyMailPublicFolder@co
```

Note:
You cannot change the primary SMTP e-mail address if the *EmailAddressEnabled* parameter is set to true.

This example disables the e-mail address policy of the mail-enabled public folder Sales.

```
Set-MailPublicFolder -Identity "\Sales" -EmailAddressEnabled $False
```

This example assigns a value (string) to the first custom attribute of the mail-enabled public folder Sales.

```
Set-MailPublicFolder -Identity "\Sales" -CustomAttribute1 "This string is the val
```

This example sets a 200 megabyte (MB) size limit for the mail-enabled public folder Sales, after which the folder can no longer send e-mail messages.

```
Set-MailPublicFolder -Identity "\Sales" -SendStorageQuota 200MB
```

Understanding Recipients

Mail-Enable a Public Folder

Managing Public Folders

1.8.3.21.4 Configure Public Folder Referrals

Configure Public Folder Referrals

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Public folder referrals have an associated *cost number*. The numbers range from 1 through 100. This cost number is used to optimize message flow. Specifically, e-mail messages are routed according to lowest cost number. If two or more routes are available with the same cost, the load is distributed as equally as possible between them. This cost is also used to calculate the most appropriate route that the client application (such as Microsoft Outlook) can use to access public folders on remote servers.

The maximum public folder referral cost that you can set for a public folder database is 100. However, by setting the maximum referral cost for a server to 100, the server may still be used for referrals. If you want to decrease the chances of the server being used for referrals, you should work with your domain administrator or enterprise administrator to configure site link costs.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to configure public folder referrals

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, select the public folder database that you want to modify.
3. In the action pane, under the name of the public folder database, click **Properties**.
4. In **<Public Folder Database> Properties**, click the **Public Folder Referral** tab.
5. To specify that Exchange uses the cost data from the Active Directory site to compute the connection cost for public folder referrals, click **Use Active Directory site costs**. This is the default option.

   Note:

   If the custom list contains public folder referrals and you click **Use Active Directory sites costs**, the list is unavailable and is cleared when this tab is refreshed.

6. To create a custom public folder referrals list and the associated costs, click **Use custom list**, click **Add**, and then perform following steps:
   6.a. Click **Browse**.
   6.b. In **Select Referral Server**, select the Mailbox server on which a public folder database resides, and then click **OK**.

   Note:

   You can't select a server that's already in the list of servers that appear in the **Name** column on the **Public Folder Referral** tab, nor can you select the server on which the specified public folder database resides.

   6.c. In the **Cost** box, assign a cost number from **1** through **100**, and then click **OK**. The number 1 represents the lowest cost, which means that Exchange routing is more likely to use this as the replica server. The number 100 represents the highest cost, which means that Exchange routing is less likely to use this as the replica server.
7. To add additional servers to the referral list, on the **Public Folder Referral** tab, click **Add**, and then repeat Steps a through c.
8. Click **OK** to close **<Public Folder Database> Properties**.

Use the Shell to configure public folder referrals

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

This example configures public folder referrals.

```
Set-PublicFolderDatabase -Identity "Server1\PublicFolderDatabase01" -UseCustomRef
```

Note:
The *CustomReferralServerList* parameter accepts an array in the following format: **serverID:cost**. Separate multiple servers with a comma.

For detailed syntax and parameter information, see Set-PublicFolderDatabase.

1.8.3.21.5 Configure Public Folder Replication

Configure Public Folder Replication

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to configure public folder replication and to set the public folder replication schedule for a specific public folder. For information about how to configure the public folder replication schedule for a public folder database, see Set the Replication Schedule for a Public Folder Database.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to configure public folder replication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder replication" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the public folder tree, click or expand **Default Public Folders**, and then select the parent public folder of the public folder that you want to configure.

   Note:
   To configure replication for the offline address book (OAB) or for Schedule+ free and busy information, expand **System Public Folders**, and then click **OFFLINE ADDRESS BOOK** or **SCHEDULE+ FREE BUSY**.
5. In the result pane, select the public folder for which you want to configure replication.
6. In the action pane, click **Properties.**
7. In **<Public Folder> Properties**, click the **Replication** tab.
8. To add a public folder database to the list of replicas, click **Add**.
9. In **Select Public Folder Database**, select the public folder database on which to replicate the public folder, and then click **OK**.
10. By default, Exchange uses the replication schedule set on the public folder database. To create a custom replication schedule for the public folder, clear the **Use public folder database replication schedule** check box and use the

following settings in the corresponding list:

- **Never Run** The public folder is not replicated.
- **Always Run** The replication process is initiated during the replication interval set for the public folder database.
- **Run every hour** The replication process is initiated every hour.
- **Run every 2 hours** The replication process is initiated every 2 hours.
- **Run every 4 hours** The replication process is initiated every 4 hours.
- **Use Custom Schedule** The replication process uses the customized schedule that you create in Step 12.

11. To create a customized schedule, click **Customize**.

Note:
If you want to use a customized schedule, you must select **Use Custom Schedule** from the interval list.

12. To set the schedule, click the time grid in the **Schedule** dialog box. Public folder replication will run during the time slots that you specify. You can select the same time slot every day by clicking a column header for a specific time slot. You can select an entire day by clicking the name of that day.

Note:
The default time slot for the grid is one hour. For finer control, you can change the schedule grid to 15 minute intervals by clicking **15 minute**. Scheduled intervals must be at least 15 minutes apart.

13. Click **OK** to close the **Schedule** dialog box.
14. To specify the age limit for items in this public folder, type the number of days in the **Local replica age limit (days)** box. Items that have reached the age limit are deleted.
15. Click **OK** to close **<Public Folder> Properties** and to save your changes.

Use the Shell to configure public folder replication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder replication" entry in the Mailbox Permissions topic.

This example sets the public folder My Public Folder so that it doesn't use the default replication schedule of the public folder database and replicates to PFDatabase02 on Server02 and PFDatabase03 on Server03.

```
Set-PublicFolder "\My Public Folder" -UseDatabaseReplicationSchedule: $False -Rep
```

This example sets a public folder so that it always uses the default replication schedule of the public folder database.

```
Set-PublicFolder "\My Public Folder" -ReplicationSchedule Always
```

This example sets a public folder so that it replicates only during the weekend.

```
Set-PublicFolder \MyPublicFolder -ReplicationSchedule "Saturday.12:00 AM-Monday.1
```

Note:
The public folder replication schedule uses the format: "Weekday.Hour:Minute [AM/PM]-Weekday.Hour:Minute [AM/PM]"

For detailed syntax and parameter information, see Set-PublicFolder.

1.8.3.21.6 Mail-Disable a Public Folder

Mail-Disable a Public Folder

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to mail-disable a public folder.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to mail-disable a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the public folder tree, click or expand **Default Public Folders**, and then if any public folders are displayed in the result pane, select the parent folder of the public folder that you want to mail-disable.
5. In the result pane, select the public folder that you want to mail-disable.
6. In the action pane, click **Mail Disable**. A warning dialog box appears.
7. Click **Yes** to confirm that you want to mail-disable the public folder.
8. To indicate that this is a mail-disabled public folder, the icon for the public folder changes.
   Mail-disabled public folders are represented by the following icon.
   
   Mail-enabled public folders are represented by the following icon.
   

Use the Shell to mail-disable a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example mail-disables the public folder My Public Folder.

```
Disable-MailPublicFolder -Identity "\My Public Folder"
```

This example mail-disables the public folder My Public Folder on the server Server01.

```
Disable-MailPublicFolder -Identity "\My Public Folder" -Server "Server01"
```

For detailed syntax and parameter information, see Disable-MailPublicFolder.

1.8.3.21.7 Mail-Enable a Public Folder

Mail-Enable a Public Folder

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Shell or the Exchange Management Console (EMC) to mail-enable public folders.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Important:

To ensure that users can send e-mail messages to a mail-enabled public folder, the public folder must have at least the *CreateItems* access right granted to the Anonymous account.

Use the EMC to mail-enable a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the public folder tree, click or expand **Default Public Folders**, and then if any public folders are displayed in the result pane, select the parent folder of the public folder that you want to mail-enable.
5. In the result pane, select the public folder that you want to mail-enable.
6. In the action pane, click **Mail Enable**.
7. To indicate that this is a mail-enabled public folder, the icon for the public folder changes.
   Mail-enabled public folders are represented by the following icon.

Public folders that aren't mail-enabled are represented by the following icon.

Use the Shell to mail-enable a public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example mail-enables the public folder My Public Folder.

```
Enable-MailPublicFolder -Identity "\My Public Folder"
```

This example mail-enables the public folder My Public Folder on the server Server01.

```
Enable-MailPublicFolder -Identity "\My Public Folder" -Server "Server01"
```

Note:

If you don't specify a server, the cmdlet checks whether the local server is an Exchange Mailbox server that contains a public folder database. If it is, the public folder is created

locally. If it isn't, Exchange finds the closest (by site cost) Exchange Mailbox server that has a public folder database on which to create the public folder.

This example mail-enables the public folder My Public Folder, but hides the folder from address lists.

```
Enable-MailPublicFolder -Identity "\My Public Folder" -HiddenFromAddressListsEnab
```

For detailed syntax and parameter information, see Enable-MailPublicFolder.

1.8.3.21.8 Managing Public Folder Databases

Managing Public Folder Databases

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-14*

1.8.3.21.8.1 Create a Public Folder Database

Create a Public Folder Database

Managing Mailbox Servers > Managing Public Folders > Managing Public Folder Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. A public folder database is a database that stores public folders, indexes their contents, and assists in the replication of the folders with other servers. A public folder database is stored as an Exchange database (.edb) file.

Important:

Before you perform this procedure, be aware that a server can contain only one public folder database.

Looking for other management tasks related to public folder databases? Check out Managing Public Folder Databases.

What Do You Want to Do?

Use the EMC to create a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the action pane, click **New Public Folder Database**.
3. On the **Introduction** page, complete the following fields:
   - **Public folder database name** Use this box to type the name of the new public folder database.
   - **Server name** This box lets you specify where to create the public folder database. To specify a location click **Browse** to open the **Select Mailbox Server** dialog box. Use this dialog box to select the server where you want to create the public folder database, and then click **OK**.
4. On the **Set Paths** page, complete the following fields:
   - **Database file path** This box is automatically populated with the default path to the database file. To specify a different location or file name, type the location in the box.
   - **Log folder path** This box is automatically populated with the default path to the database log files. To specify a different location, type the location in the box.
   - **Mount this database** Select this check box to mount the database immediately after it is created.
5. On the **New Public Folder Database** page, review your configuration settings. Click **New** to create the public folder database. Click **Back** to make changes. Click **Cancel** to close the wizard without creating the public folder database.
6. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.
7. Click **Finish** to close the wizard.

Use the Shell to create a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

Use the **New-PublicFolderDatabase** cmdlet to create a new public folder database. When you create a new public folder database, you must specify the server on which to

create it. If you don't specify the public folder database file path, database file name, or the database log file path, the following default values are used:

- **Public folder database and filename** <installation location>\V14 \Mailbox\<database name>\<database name>.edb
- **Public folder database log file path** <installation location>\V14 \Mailbox\<database name>

By default, public folder databases are dismounted when created. You must mount the database manually after it's created by using the **Mount-Database** cmdlet.

This example creates the public folder database Public Folders on the server SERVER01 with the default database locations.

```
New-PublicFolderDatabase "Public Folders" -Server SERVER01
```

This example mounts the database Public Folders.

```
Mount-Database "Public Folders"
```

To specify database and database log locations you can use the *EdbFilePath* and *LogFilePath* parameters respectively. This example creates the public folder database Support on the server SERVER02 with alternate database and log locations.:

```
New-PublicFolderDatabase Support -Server SERVER02 -EdbFilePath E:\Databases\Suppo
```

This example mounts the database Support.

```
Mount-Database Support
```

Understanding Public Folders

View or Configure Public Folder Database Properties

1.8.3.21.8.2 View or Configure Public Folder Database Properties

View or Configure Public Folder Database Properties

Managing Mailbox Servers > Managing Public Folders > Managing Public Folder Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Public folders are designed for shared access and provide an easy and effective way to collect, organize, and share information with other people in your workgroup or organization. A public folder database is a database that stores public folders, indexes their contents, and assists in the replication of the folders with other servers. A public folder database is stored as an Exchange database (.edb) file.

Looking for other management tasks related to public folder databases? Check out Managing Public Folder Databases.

What Do You Want to Do?

- Use the EMC to view or configure public folder database properties

- Use the Shell to configure public folder database properties
- Use the Shell to view public folder database properties

Use the EMC to view or configure public folder database properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab, and then select the public folder database you want to configure.
3. In the action pane, click **Properties**.
4. Use the **General** tab to view or configure the properties of a public folder database, to change its name, and to customize its maintenance schedule.
   - **Name** This unlabeled box at the top of the tab displays the name of the public folder database. You can modify this name.
   - **Database path** This read-only field displays the full path to the Exchange database (.edb) file for the selected public folder database. To view the entire path, you may have to click the path and use the RIGHT ARROW key.
     You cannot use this field to change the path. To change the location of the database files, close **Properties**, right-click the public folder database, and then click **Move Database Files**. You can also change the location by using the Move-DatabasePath cmdlet in the Exchange Management Shell.
   - **Last full backup** This read-only field displays the date and time of the last complete backup of the public folder database.
   - **Last incremental backup** This read-only field displays the date and time of the last incremental backup of the public folder database.
   - **Status** This read-only field displays whether the public folder database is mounted or dismounted.
     For information about how to mount or dismount a database, see the following topics:
     Mount a Database
     Dismount a Database
   - **Modified** This read-only field displays the last date and time that the public folder database was modified.
   - **Maintenance schedule** Use this list to select one of the preset maintenance schedules.
     You can also configure a custom schedule. To configure a custom schedule, in the **Maintenance schedule** list, select **Use Custom Schedule**, and then click **Customize**.
   - **Enable background database maintenance (24 x7 ESE scanning)** Select this check box to enable background database maintenance. If you select this check box, the Extensible Storage Engine (ESE) performs the database maintenance, and the public folder database reads the object during database mount and initializes the database to perform the background database maintenance. If you don't select this check box, the public folder database reads the object during database mount and initializes the database without the option to perform the background database maintenance.
   - **Don't mount this database at startup** Select this check box to prevent Exchange from mounting this public folder database when it starts.
   - **This database can be overwritten by a restore** Select this check box to allow the public folder database to be overwritten during a restore process.
   - **Enable circular logging** Click this check box to enable circular logging.

Circular logging overwrites and reuses a single log file after the data it contains has been written to the database. Circular logging is disabled by default. By enabling circular logging, you reduce drive storage space requirements. However, you can't recover anything more recent than the last full (normal) backup because the transaction logs no longer contain all the transactions that were completed since the last backup. Therefore, in a normal production environment, circular logging isn't recommended.

5. Use the **Replication** tab to specify the public folder database replication interval and the replication message size limit.
   - **Replication interval** Use this list to set the interval at which replication of public folders or content updates may occur.
     To schedule a custom replication interval, select **Use Custom Schedule** from the list, and then click **Customize**. Use the **Schedule** dialog box to customize the replication schedule, and then click **OK** to return to the **Replication** tab.
   - **Replication interval for "Always Run" (minutes)** If you set the replication interval to **Always Run**, this box displays the time interval (in minutes) during which replication of public folders or contents may occur. You can modify this interval. The value range is from 1 through 2,147,483,647 minutes.
   - **Replication message size limit (KB)** This box displays the size limit in kilobytes (KB) of a replication message. Small items may be aggregated into a single replication message that can be as large as this setting, but items larger than this setting are replicated with messages larger than this size. You can modify this size limit. The value range is from 1 through 2,097,151 KB.

6. Use the **Limits** tab to specify the storage limits, warning message interval, deletion settings, and age limits for all public folders in the selected public folder database.
   - **Issue warning at (MB)** Select this check box to automatically warn public folder owners that the public folder is approaching its storage limit.
     To specify the storage limit, select the check box, and then specify in megabytes (MB) how much content can be stored in the public folder before a warning e-mail message is sent to the folder's owner. You can enter a value from 0 through 2,097,151 MB (2.0 terabytes)
   - **Prohibit post at (MB)** Select this check box to prevent posting to the public folders in the database after the size of folder reaches the specified limit.
     To specify this limit, select the check box, and then specify the size of the public folder in megabytes (MB) at which you want to prohibit posting. You can enter a value from 0 through 2,097,151 MB (2.0 terabytes)
   - **Maximum item size (MB)** Select this check box to limit the maximum size of items that users can post to the public folders in the database.
     To specify the size, select the check box, and then specify the maximum size of items in megabytes (MB) that users can post to the public folders. You can enter a value from 0 through 2,097,151 MB (2.0 terabytes)
     Warning message interval Use this list to display the interval at which you want warning messages to be generated. To select one of the default intervals, click the list, and then select one of the following:
     Run daily at midnight
     Run daily at 1:00 AM
     Run daily at 2:00 AM
     Use Custom Schedule
     If you select **Use Custom Schedule**, you must click **Customize**

to set the schedule.

- **Keep deleted items for (days)** Use this box to set the numbers of days that deleted items are retained in a public folder. You can enter a value between 0 and 24,855 days.
- **Don't permanently delete items until the database has been backed up** Select this check box to prevent items from being permanently deleted until after the public folder database is backed up.
- **Age limit for all folders in this public folder database (days)** Select this check box to limit the age of all folders in this public folder database. Use the text box to specify the age limit in days. You can enter a value between 0 and 24,855 days.

7. Use the **Public Folder Referral** tab to configure the folder replica that will be accessed by the client application. To learn more, see Understanding Public Folder Referrals.
   - **Use Active Directory site costs** Click this button to specify that Exchange uses the cost data from the Active Directory site to compute the connection cost for public folder referrals. This is the default option.

     Note:
     If the custom list contains public folder referrals, and you click **Use Active Directory site costs**, the list is unavailable and is cleared when this tab is refreshed.

   - **Use custom list** Click this button to create a custom list of public folder referrals and the associated costs.

     When you click **Use custom list**, the following features are made available:

     Note:
     If you click **Use Active Directory site costs**, these features are unavailable.

     Add Click this button to open the **Server Referral Cost** dialog box.
     Click **Browse** to open the **Select Referral Server** dialog box. Use this dialog box to select the referral server from the list of available servers that contain a public folder database and click OK.
     In the **Cost** box, assign a cost number between **1** and **100**. The number **1** represents the lowest cost, which means that Exchange routing is more likely to use this as the replica server. The number **100** represents the highest cost, which means that Exchange routing is less likely to use this as the replica server.
     Edit Select a server from the list, and then click this button to edit a public folder referral. This button is disabled if no servers are listed in the custom list.
      Click this button to remove a public folder referral from the custom list. This button is disabled if no servers are listed in the custom list.

Use the Shell to configure public folder database properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

This example changes the size of the maximum post that can be stored in the Sales public folder database to 1 GB and issues a warning when the post size reaches 900 MB.

```
Set-PublicFolderDatabase  Sales -IssueWarningQuota 900MB -ProhibitPostQuota 1GB
```

This example sets the database maintenance schedule on PFDB01 to run daily from 02:00 (2:00 A.M.) until 06:00 (6:00 A.M.).

```
Set-PublicFolderDatabase -Identity 'PFDB01'-MaintenanceSchedule 'Sun.2:00 AM-Sun.
```

This example sets the deleted items retention on the public folder database PFDB01 to 10 days.

```
Set-PublicFolderDatabase -Identity 'PFDB01' -DeletedItemRetention '10.00:00:00'
```

This example prevents the deleted items in the public folder database PFDB01 from being permanently deleted until after the database has been backed up.

```
Set-PublicFolderDatabase -RetainDeletedItemsUntilBackup $true -Identity 'PFDB01'
```

For syntax and parameter information, see Set-PublicFolderDatabase.

Use the Shell to view public folder database properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder databases" entry in the Mailbox Permissions topic.

Use the **Get-PublicFolderDatabase** cmdlet to view the properties of a public folder database. This command returns all the public folder databases in your organization.

```
Get-PublicFolderDatabase
```

To view all of the properties of a single public folder database, you can pipe the results of the **Get-PublicFolderDatabase** cmdlet to the **Format-List** cmdlet. This example gets the properties of the public folder database Support.

```
Get-PublicFolderDatabase Support | Format-List
```

For syntax and parameter information, see Get-PublicFolderDatabase.

1.8.3.21.8.3 Move Public Folder Content from One Public Folder Database to Another Public Folder Database

Move Public Folder Content from One Public Folder Database to Another Public Folder Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use scripts to move public folders to a different database or server.

Looking for other management tasks related to public folder databases? Check out Managing Public Folder Databases.

Use the MoveAllReplicas.ps1 script to move all public folder content from one server to another server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

To move all public folders in a public folder database on one server to a public folder database on another server, use the MoveAllReplicas.ps1 script. This script replaces a server with a new server in the replication list for all public folders, including system folders. For more information about using public folder scripts, see Scripts for Managing Public Folders in the Exchange Management Shell.

This example moves all public folder content from Server01 to Server02.

```
.\MoveAllReplicas.ps1 -Server Server01 -NewServer Server02
```

Use the ReplaceReplicaOnPFRecursive.ps1 script to move replicas in a public folder subtree to another server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

To move all the replicas of a public folder subtree from one server to another server, use the ReplaceReplicaOnPFRecursive.ps1 script. This script adds a new server to the replication list for a public folder and all the folders within that hierarchy. If the server is already listed in the replication list for a folder, nothing is changed for that folder. For more information about using public folder scripts, see Scripts for Managing Public Folders in the Exchange Management Shell.

This example moves the public folder replica Legal and all the folders within that hierarchy from Server01 to Server02.

```
.\ReplaceReplicaOnPFRecursive.ps1 -TopPublicFolder "\Legal" -ServerToAdd Server02
```

1.8.3.21.8.4 Remove Multiple Public Folders from a Public Folder Database

Remove Multiple Public Folders from a Public Folder Database

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to remove all the public folders from a public folder database.

This procedure removes all the user and system public folders from a public folder database. If you only want to remove one public folder from a public folder database, see Remove Public Folders. This procedure is required if you are removing the last public folder

database in your Exchange organization. For detailed instructions about how to remove public folder databases, see Remove Public Folder Databases.

Caution:
The **Remove-PublicFolder** cmdlet removes the public folder data from all servers in your organization. If you only want to remove data from one server, use the **Set-PublicFolder** cmdlet with the *Replicas* parameter. For more information, see Set-PublicFolder.

Looking for other management tasks related to public folder databases? Check out Managing Public Folder Databases.

Use the Shell to delete user public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to delete user public folders.

This example removes all user public folders.

```
Get-PublicFolder -Server <server containing the public folder database> "\" -Recu
```

For detailed syntax and parameter information, see Get-PublicFolder and Remove-PublicFolder.

Use the Shell to delete system public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to delete system public folders.

This example removes all system public folders.

```
Get-PublicFolder -Server <server containing the public folder database> "\Non_Ipm
```

For detailed syntax and parameter information, see Get-PublicFolder and Remove-PublicFolder.

1.8.3.21.8.5 Remove Public Folder Databases

Remove Public Folder Databases

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can remove a public folder database using the steps in this procedure. Links to detailed topics will help you complete the task.

The process for removing a public folder database requires several steps. Because this process is different if you're removing the last public folder database in your organization, consider the following scenarios before you begin:

- **Removing a public folder database from a Mailbox server** If you want to remove a public folder database from a Mailbox server, you must first move the data within the public folder database to a public folder database on another server, and then you remove the public folder database.
- **Removing the last public folder database from the organization** If you want to remove the last public folder database in your organization, you must first make sure that your organization doesn't contain any servers running Microsoft Exchange Server 2003 or earlier versions.

Caution:

If you remove the last public folder database, only users who are running Microsoft Office Outlook 2007 or later versions, or who are running Microsoft Office Outlook Web App, will be able to connect to your Exchange organization.

Important:

Don't remove the last public folder database if your organization uses public folders to distribute organizational forms or to replicate free/busy information to or from another Exchange organization.

Migrating public folders from Exchange 2003 to Exchange Server 2010? If so, you can use either Exchange System Manager in Exchange 2003 or the Exchange Management Console (EMC) in Exchange 2010 to move Exchange 2003 public folders to an Exchange 2010 server.

Looking for other management tasks related to public folder databases? Check out Managing Public Folder Databases.

Remove a public folder database from a Mailbox server

To remove a public folder database from a Mailbox server, perform the following steps.

Note:

If you have a mixed Exchange 2003 or Exchange Server 2007 and Exchange 2010 organization, we recommend that you perform these procedures against an Exchange 2010 server. For more information about performing public folder management tasks in mixed environments, see Understanding Public Folders.

Step 1: Delete unnecessary public folders

You can't delete a public folder database that contains data. To remove data from a public folder database, delete any unnecessary public folders. For detailed instructions, see Remove Public Folders. To determine which public folders are unnecessary, see View Public Folder Item Statistics.

Step 2: Move the public folder replicas to another server

After you delete any unnecessary public folders, you must move the remaining folder replicas in that database to a public folder database on another server.

Note:

Depending on the number of public folders, the amount of information in the database, and the replication interval, this process may take several hours to complete.

For detailed instructions, see Move Public Folder Content from One Public Folder Database to Another Public Folder Database.

Important:
Don't remove the public folder database until public folder replication has completed.

Step 3: Associate mailbox databases with another default public folder database

If the public folder database you're removing is being used as the default public folder database by any mailbox databases, you must configure another public folder database as the default public folder database.

This example identifies the public folder databases associated with all mailbox databases.

```
Get-MailboxDatabase | ft Name,PublicFolderDatabase
```

For more information about how to change the default public folder database, see Change the Default Public Folder Database for a Mailbox Database.

Step 4: Remove the public folder database

Note:
If you successfully perform Step 1 through Step 4 and you receive an error message stating that the public folder database can't be removed because it contains replicas, you may need to wait several hours for public folder replication to finish.

Use the EMC to remove a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. Click the **Database Management** tab.
3. In the result pane, select the public folder database that you want to remove.
4. In the action pane, click **Remove**. A message appears confirming that you want to remove the database. Click **Yes**.

   Note:
   If you haven't moved the public folder replicas to another server, or if you haven't removed all the public folders in the public folder database, you'll receive an error stating that the public folder database can't be removed because it contains public folder replicas.

5. A warning appears, indicating that the database was successfully removed and reminding you to manually remove the database file. The default location for these files is <Exchange Installation Path>\V14\Mailbox\<*public folder database name*>.

Use the Shell to remove a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. This example removes a public folder database named PFDB01:

   ```
   Remove-PublicFolderDatabase -Identity "PFDB01"
   ```

   Note:
   If you haven't moved the public folder replicas to another server, or if you haven't removed all the public folders in the public folder database, you'll receive an error stating that the public folder database can't be removed because it contains public folder replicas.

2. A message appears asking you to confirm that you want to perform this action. Enter **Y**.
3. A warning appears, indicating that the database was removed and reminding you to manually remove the database file. The default location for these files is <*Exchange installation path*>\v14\Mailbox\<*public folder database name*>.

Step 5: Delete the public folder database files manually

When you remove a public folder database, the Exchange database (.edb) file for the database and other files associated with the database aren't automatically deleted. You must delete the public folder database files manually. The default location for these files on an Exchange 2010 server is *<Exchange installation path>*\v14\Mailbox*<public folder database name>*. The default location for these files on an Exchange 2007 server is C:\Program Files\Microsoft\ExchangeServer\Mailbox*<storage group name>**<public folder database name>*.

Remove the last public folder database from an organization

To remove the last public folder database from an organization, perform the following steps.

Note:

If you have a mixed Exchange 2003 or Exchange 2007 and Exchange 2010 organization, we recommend that you perform these procedures against an Exchange 2010 server. For more information about performing public folder management tasks in mixed environments, see Understanding Public Folders.

Step 1: Verify that no OABs in your organization are configured for public folder distribution

If any offline address books (OABs) are configured for public folder distribution, you can't remove the last public folder database in your organization. For instructions about how to reconfigure OABs, see Managing Offline Address Books.

Step 2: Remove all public folders from the public folder database

You can't delete a public folder database that contains data. To remove data from a public folder database, delete any unnecessary public folders. For detailed instructions about how to remove all the public folders in a public folder database, see Remove Multiple Public Folders from a Public Folder Database.

Step 3: Remove the last public folder database

Note:

If you successfully perform Step 1 and Step 2 and you receive an error message stating that the public folder database can't be removed because it contains replicas, repeat Step 2 of the procedure Remove Multiple Public Folders from a Public Folder Database. In addition, you can verify that all public folders have been removed by running the **Get-PublicFolderStatistics** cmdlet. For more information about this cmdlet, see Get-PublicFolderStatistics.

Use the EMC to remove a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. Click the **Database Management** tab.
3. In the result pane, select the public folder database that you want to remove.
4. In the action pane, click **Remove**. A message appears confirming that you want to remove the database. Click **Yes**.

Note:

If you haven't moved the public folder replicas to another server, or if you haven't removed all the public folders in the public folder database, you'll receive an error stating that the public folder database can't be removed because it contains public folder replicas.

5. A warning appears, indicating that the database was successfully removed and reminding you to manually remove the database file. The default location for these files is <Exchange Installation Path>\V14\Mailbox*<public folder database name>*.

Use the Shell to remove a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. This example removes a public folder database named PFDB01:

```
Remove-PublicFolderDatabase -Identity "PFDB01"
```

Note:
If you haven't moved the public folder replicas to another server, or if you haven't removed all the public folders in the public folder database, you'll receive an error stating that the public folder database can't be removed because it contains public folder replicas.

2. A message appears asking you to confirm that you want to perform this action. Enter **Y**.
3. A warning appears, indicating that the database was removed and reminding you to manually remove the database file. The default location for these files is *<Exchange installation path>*\v14\Mailbox*<public folder database name>*.

Step 4: Delete the public folder database files manually

When you remove a public folder database, the Exchange database (.edb) file for the database and other files associated with the database aren't automatically deleted. You must delete the public folder database files manually. The default location for these files on an Exchange 2010 server is *<Exchange installation path>*\v14\Mailbox*<public folder database name>*. The default location for these files on an Exchange 2007 server is C:\Program Files\Microsoft\ExchangeServer\Mailbox*<storage group name>**<public folder database name>*.

Note:
When the last public folder database in the organization is removed, the default public folder database for all mailbox databases is automatically set to null.

1.8.3.21.8.6 Set the Replication Schedule for a Public Folder Database

Set the Replication Schedule for a Public Folder Database

Managing Mailbox Servers > Managing Public Folders > Managing Public Folder Databases >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

After you determine which public folders you want to replicate and the databases on which they will be replicated, you can set the public folder database replication schedule. By default, public folder replication is scheduled to run every 15 minutes. You can select precanned replication intervals, or you can create a custom schedule. For more information about how to configure the list of public folder databases to which public folders will replicate, see Configure Public Folder Replication.

This topic shows you how to use the Exchange Management Console (EMC) or the Exchange Management Shell to set the public folder replication schedule for a public folder database.

Looking for other management tasks related to managing public folder databases? Check out Managing Public Folder Databases.

Use the EMC to set the replication schedule for a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder replication" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, click the **Database Management** tab, and then click the public folder database you want to configure.
3. In the action pane, click **Properties**.
4. In **<Public Folder Database> Properties**, click the **Replication** tab.
5. In the **Replication interval** list, the following options are available:
   - **Always Run** The replication process is initiated during the replication interval that's specified in the **Replication interval for "Always Run" (minutes)** box.
   - **Never Run** The public folder database isn't replicated.
   - **Run every hour** The replication process is initiated every hour.
   - **Run every 2 hours** The replication process is initiated every 2 hours.
   - **Run every 4 hours** The replication process is initiated every 4 hours.
   - **Use Custom Schedule** The replication process uses the customized schedule that you create in Step 8.
6. Click **Customize** to create a customized schedule.

   Note:
   If you use a customized schedule, you must select **Use Custom Schedule** from the **Replication interval** list.

7. To set the schedule, click the time grid in the **Schedule** dialog box. Public folder replication will run during the time slots that you specify. You can select the same time slot every day by clicking a column header for a specific time slot. You can select an entire day by clicking the name of that day.

   Note:
   The default time slot for the grid is one hour. For finer control, you can change the schedule grid to 15 minute intervals by clicking **15 minute**. Scheduled intervals must be at least 15 minutes apart.

8. Click **OK** to close the **Schedule** dialog box.
9. Click **OK** to close the **<Public Folder Database> Properties** dialog box and to save your changes.

Use the Shell to set the replication schedule for a public folder database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder replication" entry in the Mailbox Permissions topic.

This example creates a customized public folder replication schedule for the public folder database PFDatabase that resides on Server01.

```
Set-PublicFolderDatabase -Identity "Server01\PFDatabase" -ReplicationSchedule "Su
```

For detailed syntax and parameter information, see Set-PublicFolderDatabase.

1.8.3.21.9 Remove Public Folders

Remove Public Folders

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to remove a public folder. To help determine which public folders should be removed, see View Public Folder Item Statistics.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Caution:

The **Remove-PublicFolder** cmdlet removes the public folder data from all servers in your organization. If you only want to remove data from one server, use the **Set-PublicFolder** cmdlet with the *Replicas* parameter. For more information, see Set-PublicFolder.

Use the EMC to remove public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the console tree, expand **Default Public Folders**, and then select the parent public folder of the public folder that you want to remove.
5. In the result pane, select the public folder that you want to remove.
6. In the action pane, click **Remove**. A warning appears. Click **Yes** to confirm that you want to remove the public folder.

Use the Shell to remove public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example removes the public folder My Public Folder.

```
Remove-PublicFolder -Identity "\My Public Folder"
```

This example removes the public folder My Public Folder and specifies the server from which to remove it.

```
Remove-PublicFolder -Identity "\My Public Folder" -Server "My Server"
```

This example tests the previous command without making any modifications.

```
Remove-PublicFolder -Identity "\My Public Folder" -WhatIf
```

This example removes the public folder My Public Folder and all of its subfolders because the command runs recursively.

```
Remove-PublicFolder -Identity "\My Public Folder" -Recurse: $True
```

For detailed syntax and parameter information, see Remove-PublicFolder.

1.8.3.21.10 Resume Public Folder Content Replication

Resume Public Folder Content Replication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to resume public folder content replication.

You need to resume public folder content replication if public folder content replication has stopped or if you have suspended replication due to a configuration error pertaining to the replication of the public folder hierarchy. If you suspend replication due to a configuration error, you must first correct the error, and then let the change replicate throughout the public folder hierarchy.

For more information about how to suspend public folder content replication, see Suspend Public Folder Content Replication.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the Shell to resume public folder content replication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder replication" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to resume public folder content replication.

This command resumes public folder content replication.

```
Resume-PublicFolderReplication
```

For detailed syntax and parameter information, see Resume-PublicFolderReplication.

1.8.3.21.11 Scripts for Managing Public Folders in the Exchange Management Shell

Scripts for Managing Public Folders in the Exchange Management Shell

See Also

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-29*

Running scripts in the Exchange Management Shell can make public folder administration faster and easier by automating complex or frequently performed tasks. You can use scripts that are installed with Microsoft Exchange Server 2010 and described in this topic (as well as other scripts), or you can write your own scripts.

Note:
The Shell doesn't load scripts automatically. You must precede all scripts with **.** (a period, followed by a backslash). For example, to run the AggregatePFData.ps1 script, type **.\AggregatePFData.ps1**.

The collection of Shell scripts described in this topic is installed, by default, at <*Exchange Installation Path*>\v14\ Server\Scripts.

For more information about using and writing scripts, see Scripting with the Exchange Management Shell.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Administrative Scripts

The following table lists the administrative scripts included with Exchange 2010.

Task	Script	Description
Add a server to the replication list.	AddReplicaToPFRecursive.ps1	This script adds a new server to the replication list for a public folder and all the folders beneath it in the hierarchy. If the server is already listed in the replication list for a folder, nothing is changed for that folder. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that has a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **ServerToAdd** (Required) This parameter specifies the server identity to add to the replica list. This server must contain a

		public folder database.
Aggregate data across all public folder replicas.	AggregatePFData.ps1	This script aggregates and captures information collected from the following cmdlets: • **Get-PublicFolderItemStatistics** • **Get-PublicFolderStatistics** • **Get-PublicFolder** The following information is aggregated at the public folder level, and not at the item level: • Last user access and last user modification times • Owner of the public folder • Other properties such as MailEnabled, HasRules, ItemCount, FolderType, HasModerator, and TotalItemSize This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Public Folder** (Required) This parameter specifies the identity of the public folder. For more information, see View Public Folder Item Statistics.
Remove a server from the replication list.	RemoveReplicaFromPFRecursive.ps1	This script removes a server from the replication list for a public folder and all the folders beneath it in the hierarchy. If the server isn't listed in the replication list for a folder, nothing is changed for that folder. If the server is the only server on the replication list, the list isn't changed. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that has a public folder database. If you don't use the *Server* parameter to

		specify a server, the script defaults to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **ServerToRemove** This parameter specifies the server identity to remove from the replica list. This server must have a public folder database.
Replace a server in the replication list.	MoveAllReplicas.ps1	This script replaces a server with a new server in the replication list for all public folders, including system folders. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Required) This parameter specifies the server to remove. This server must be an Exchange Mailbox server that contains a public folder database. • **NewServer** (Required) This parameter specifies the identity of the server to add to the replica list. This server must contain a public folder database.
Replace a server in the replication list with a new server.	ReplaceReplicaOnPFRecursive.ps1	This script replaces a server with a new server in the replication list for a public folder and all the folders beneath it in the hierarchy. If the server that you want to remove isn't listed in the replication list for a particular folder, nothing is changed for that folder. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that contains a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults to the local server. • **TopPublicFolder**

		(Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **ServerToRemove** This parameter specifies the server identity to remove from the replica list. This server must contain a public folder database. •

User Management Scripts

The following table lists the user management scripts included with Exchange 2010.

Task	Script	Description
Add a user to the client permissions list.	AddUsersToPFRecursive.ps1	This script adds a user and that user's permissions to the client permissions list for a public folder and all the folders beneath it in the hierarchy. If the user is already listed in the client permissions list for a folder, the user's permissions are updated to the new set specified in the script. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that contains a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **User** (Required) This parameter specifies the identity of the user to whom to add client permissions. • **Permissions** (Required) This parameter specifies the client permissions to apply to the user.
Replace a user with a new user in the client	ReplaceUserWithUserOnPFRecursive.ps1	This script replaces a user with a new user in the client permissions list for a

permissions list.		public folder and all the folders beneath it in the hierarchy. Existing permissions for the first user are retained. Public folders that don't contain permissions for the user aren't modified. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that has a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **UserOld** (Required) This parameter specifies the identity of the user from whom to remove client permissions. • **UserNew** (Required) This parameter specifies the identity of the user to whom to add client permissions.
Replace a user's permissions.	ReplaceUserPermissionOnPFRecursive.ps1	This script replaces the permissions of a user in the client permissions list for a public folder with a new set of permissions. It also replaces the permissions for all the folders in the hierarchy beneath that folder. Public folders that don't contain permissions for the user aren't modified. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that contains a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults

		to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **User** (Required) This parameter specifies the identity of the user for whom to replace client permissions. • **Permissions** (Required) This parameter specifies the client permissions to apply to the user.
Remove a user from the client permissions list.	RemoveUserFromPFRecursive.ps1	This script removes a user from the client permissions list for a public folder and from all the folders beneath it in the hierarchy. This script accepts the following parameters: • **Help** This parameter displays the Help file for the script. • **Server** (Optional) This parameter specifies the server to operate against. This server must be an Exchange Mailbox server that contains a public folder database. If you don't use the *Server* parameter to specify a server, the script defaults to the local server. • **TopPublicFolder** (Required) This parameter specifies the identity of the folder at the top of the public folder tree. • **User** (Required) This parameter specifies the identity of the user from whom to remove client permissions. **Note:** The users Default and Anonymous can't be removed from the permissions list. Any attempt to do so effectively replaces their permissions with None.

Managing Public Folders
Exchange Management Shell

1.8.3.21.12 Set the Size Limit for Public Folder Replication Messages

Set the Size Limit for Public Folder Replication Messages

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When you modify a public folder or its contents, the database that contains the replica of the public folder that was changed sends a descriptive e-mail message to the other public folder databases that host a replica of the public folder. To reduce traffic on your network, Exchange includes information about multiple changes in one e-mail message. The amount of information included in these messages depends on the size limit you set for replication messages. If any message exceeds the specified size limit, that message is sent as a separate replication message.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to set the size limit for public folder replication messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Organization Configuration** > **Mailbox**.
2. In the result pane, select the public folder database you want to configure.
3. In the action pane, click **Properties**.
4. In **<Public Folder Database> Properties**, click the **Replication** tab.
5. In the **Replication message size limit (KB)** box, type the message size limit. The value range is from 1 through 2,097,151 kilobytes (KB). The default message size is 300 KB.
6. Click **OK** to close the **<Public Folder Database> Properties** dialog box and to save your changes.

Use the Shell to set the size limit for public folder replication messages

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folder" entry in the Mailbox Permissions topic.

This example sets the public folder replication message size limit to 500 KB for the public folder database PFDatabase that resides on Server01.

```
Set-PublicFolderDatabase -Identity "Server01\PFDatabase" -ReplicationMessageSize
```

For detailed syntax and parameter information, see Set-PublicFolderDatabase.

1.8.3.21.13 Suspend Public Folder Content Replication

Suspend Public Folder Content Replication

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to suspend the replication of public folder content.

Note:
Suspending public folder replication applies only to content replication. Hierarchical replication will continue normally.

If you experience a configuration error pertaining to the replication of the public folder hierarchy, you must suspend the replication of public folder content and correct the error. You can resume the replication of public folder content after you have fixed the error, and then let the change replicate throughout the public folder hierarchy. For more information about how to resume public folder replication, see Resume Public Folder Content Replication.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the Shell to suspend public folder content replication

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to suspend public folder content replication.

This command suspends content replication.

```
Suspend-PublicFolderReplication
```

For detailed syntax and parameter information, see Suspend-PublicFolderReplication.

1.8.3.21.14 Update a Public Folder Hierarchy

Update a Public Folder Hierarchy

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console or the Exchange Management Shell to update a public folder hierarchy.

Perform this procedure to synchronize the public folder hierarchy from one server to the other servers on which public folder replicas exist. This procedure is helpful in cases

where the public folder hierarchy on one server is different from the public folder hierarchy on other servers in your organization.

Note:

In Microsoft Exchange Server 2003, this procedure is known as *manually replicating the public folder*.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Caution:

Performing this procedure only allows the server running Exchange to begin any outstanding replication actions. The process may take several hours to complete.
Because factors not controlled by replication can prevent the hierarchy from becoming immediately synchronized, performing this procedure doesn't ensure that the public folder hierarchy will be completely synchronized.
This procedure only updates the public folder hierarchy. It doesn't update public folder content. For instructions about how to update public folder content, see Update Public Folders.

Use the EMC to update a public folder hierarchy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the public folder tree, click the **Public Folders - <Server Name>** node.
5. In the action pane, click **Update Hierarchy**.

Use the Shell to update a public folder hierarchy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example updates the public folder hierarchy on the server Server01.

```
Update-PublicFolderHierarchy -Server "Server01"
```

For detailed syntax and parameter information, see Update-PublicFolderHierarchy.

1.8.3.21.15 Update Public Folders

Update Public Folders

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to update the public folder content in a specified public folder's replication list.

For more information about how to update the public folder hierarchy, see Update a Public Folder Hierarchy.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the EMC to update public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

1. In the console tree, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**. The Public Folder Management Console appears.
4. In the public folder tree, click or expand **Default Public Folders**, and then if any public folders are displayed in the result pane, select the parent folder of the public folder that you want to update.
5. In the result pane, click the public folder that you want to update.
6. In the action pane, click **Update Content**.

Use the Shell to update public folders

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

This example updates the folders in the replication list of the public folder My Public Folder that resides on the server My Server.

```
Update-PublicFolder "\My Public Folder" -Server "My Server"
```

Note:

The *Server* parameter specifies the identity of a Mailbox server with a public folder database that's the source of the replication.

For detailed syntax and parameter information, see Update-PublicFolder.

1.8.3.21.16 View Public Folder Item Statistics

View Public Folder Item Statistics

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can view the following information about items within a specific public folder:

- Type of item
- Subject
- Last user modification time
- Last user access time
- Creation time

- Attachments
- Message size

You can use this information to make decisions about what actions to take for your public folders, such as which public folders to delete. For example, you may want to delete a public folder if the items haven't been accessed for over two years, or you may want to convert a public folder that's being used as a document repository to another client access application.

Looking for other management tasks related to public folders? Check out Managing Public Folders.

Use the Shell to view item statistics for a specific public folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to view item statistics for a specific public folder.

This example returns default statistics for all items in the public folder Pamphlets under the \Marketing\2010 path. Default information includes item identity, creation time, and subject.

```
Get-PublicFolderItemStatistics -Identity "\Marketing\2010\Pamphlets"
```

This example returns additional information about the items within the public folder Pamphlets, such as subject, last modification time, creation time, attachments, message size, and the type of item by piping the results of the **Get-PublicFolderItemStatistics** cmdlet to the **Format-List** cmdlet.

```
Get-PublicFolderItemStatistics -Identity "\Marketing\2010\Pamphlets" | Format-Lis
```

For detailed syntax and parameter information, see Get-PublicFolderItemStatistics.

Use the Shell to export the output of the Get-PublicFolderItemStatistics cmdlet to a .csv file

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to export the output of the **Get-PublicFolderItemStatistics** cmdlet to a .csv file.

This example exports the output of the **Get-PublicFolderItemStatistics** cmdlet to the PFItemStats.csv file that includes the following information for all items within the public folder \Marketing\Reports:

- Subject of the message (Subject)
- Date and time that the item was last modified (LastModificationTime)
- Whether the item has attachments (HasAttachments)
- Type of item (ItemType)
- Size of the item (MessageSize)

```
Get-PublicFolderItemStatistics -Identity "\Marketing\Reports" | Select Subject,La
```

For detailed syntax and parameter information, see Get-PublicFolderItemStatistics.

Use AggregatePFData.ps1 to aggregate public folder statistics across all replicas

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

The AggregatePFData.ps1 script aggregates and captures information collected from three cmdlets:

- **Get-PublicFolderItemStatistics**
- **Get-PublicFolderStatistics**
- **Get-PublicFolder**

The following information is aggregated at the public folder level, and not at the item level:

- Last user access and last user modification times
- Owner of the public folder
- Properties such as MailEnabled, HasRules, ItemCount, FolderType, HasModerator, and TotalItemSize

This example returns the aggregated data from the public folder Pamphlets under the \Marketing\2008 path.

Note:

The Shell doesn't load scripts automatically. You must precede all scripts with a period followed by a backslash (.\) For example, to run the AggregatePFData.ps1 script, type `.\AggregatePFData.ps1`. For more information, see Scripting with the Exchange Management Shell.

```
.\AggregatePFData.ps1 -Publicfolder "\Marketing\2008\Pamphlets"
```

1.8.3.21.17 View Public Folder Statistics

View Public Folder Statistics

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to retrieve statistics about a public folder, such as the display name, creation time, last user modified time, last user access, and item size. You can use this information to make decisions about deleting or keeping public folders.

You can also use the **Get-PublicFolderItemStatistics** cmdlet and the **AggregatePFDAta.ps1** script to view additional information about public folders and their contents. For more information, see View Public Folder Item Statistics.

Looking for other management tasks related to managing public folders? Check out Managing Public Folders.

Use the Shell to retrieve public folder statistics

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to retrieve public folder statistics.

This example returns the statistics for the public folder Marketing with a piped command to format the list.

```
Get-PublicFolderStatistics -Identity \Marketing | fl
```

Note:
The value for the *Identity* parameter must include the path. For example, if the public folder Marketing existed under the parent folder Business, you would provide the following value: \Business\Marketing

For detailed syntax and parameter information, see Get-PublicFolderStatistics.

1.8.3.21.18 Create an Organizational Forms Library

Create an Organizational Forms Library

Mailbox > Managing Mailbox Servers > Managing Public Folders >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

An organizational forms library is a repository for forms generally accessed by all users in a company. Forms are templates that help users to enter and view information. For example, a standard supply request form can be stored in an organizational forms library. Provided that you granted all users permissions to the library, all users in your organization can access the forms within the library.

An organizational forms library is a special type of public folder listed only under the NON_IPM_SUBTREE systems folder. You can have only one organizational forms library for each language in your organization.

You can add a form to the organizational forms library when you want to use the same custom form in more than one public folder. This library is frequently used for e-mail message forms because they typically aren't based on a specific public folder. When you publish a form, you can maintain only a single published form.

Important:
By default, the organizational forms library isn't required for Microsoft Exchange Server 2010 to operate correctly. Create the organizational forms library only if you must support custom forms already developed or if a third-party application requires the library.

Looking for other management tasks related to managing public folders? Check out Managing Public Folders.

Step 1: Create a public folder for the organizational forms library Public Folder

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Public folders" entry in the Mailbox Permissions topic.

Use the Shell to create the public folder for the organization forms library

This example creates the public folder for the organizational forms library in the EFORMS REGISTRY branch of your public folder hierarchy.

```
New-PublicFolder -Path "\NON_IPM_SUBTREE\EFORMS REGISTRY" -Name "Organizational F
```

For detailed syntax and parameter information, see New-PublicFolder.

Use the Public Folder Management Console to create the public folder for the organizational forms library

1. In the console tree of the EMC, click **Toolbox**.
2. In the result pane, click **Public Folder Management Console**.
3. In the action pane, click **Open Tool**.
4. In the public folder tree of the Public Folder Management Console, expand **System Public Folders**, and then click **EFORMS REGISTRY**.
5. In the action pane, click **New Public Folder**.
6. On the **Introduction** page, complete the following fields:
   - **Name** Use this box to type the name of the new public folder, for example, **Organizational Forms Library**.
   - **Path** Use this read-only box to verify the path to the public folder. The path should read: **\Non_IPM_SUBTREE\EFORMS REGISTRY**.
7. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Step 2: Use the ExFolders tool to add the PR_URL_NAME property to the organizational forms library

To perform this procedure, the ExFolders tool (ExFolders.exe) must exist in the *<Exchange Installation Path>*\V14\Bin directory. You can download the tool from one of the following locations:

- If you're running Exchange 2010 Service Pack 1 (SP1), see ExFolders tool (Compatible with Exchange 2010 SP1 version).
- If you're running the release to manufacturing (RTM) version of Exchange 2010, see ExFolders tool (Compatible with Exchange 2010 RTM version).

After the download, be sure to copy the ExFolders.exe file to the *<Exchange Installation Path>*\V14\Bin directory.

To perform this procedure, you must have administrative permissions to the public folders you're modifying. For more information, see Understanding Public Folder Permissions.

1. Navigate to the **<Exchange Installation Path>\V14\Bin** directory, and then double-click **ExFolders.exe**.

Note:
You must run the ExFolders tool from an Exchange 2010 server. You can't run it from a workstation as you could with the PFDAVAdmin tool. To learn more about the ExFolders tool, see the Exchange Server Team Blog article Exchange, Meet ExFolders.

2. In the ExFolders management console, navigate to **File** > **Connect**.
3. In **Connect**, click **Public Folders**.
4. Next to the **Global Catalog** box, click **Select**, and then select a global catalog server you want to use.
5. Next to the **Database(s)** box, click **Select**, select the public folder database you want to use, and then click **OK**. A public folder hierarchy will appear in the ExFolders console tree.
6. Expand **System Folders**, expand **EFORMS REGISTRY**, right-click the public folder you created for the organizational forms library, and then click **Property Editor**.
7. On the **Property** menu, click **Add Property To View**.
8. In **Add Property To View**, type **0x6707001E**, and then click **OK**.
9. Sort the **Name** column to find the **PR_URL_NAME** property you just added.
10. Right-click **PR_URL_NAME**, and then click **Edit Value**.
11. In the **Value** box, type **/NON_IPM_SUBTREE/EFORMS REGISTRY**, and then click **OK**.
12. Close the ExFolders tool.

Step 3: Use MAPI Editor (Mfcmapi.exe) to add the PR_EFORMS_LOCALE_ID property to the organizational forms library

To perform this procedure, you must use the Microsoft Exchange Server MAPI Editor (MFCMAPI) tool on a computer that's running the 64-bit version of Microsoft Outlook 2010. To download MFCMAPI, see Microsoft Exchange Server MAPI Editor.

1. In MFCMAPI, on the **Session** menu, click **Logon and Display Store Table**.

Note:
If this is your first time using MAPI Editor, you're prompted to create a profile.

2. On the **MDB** menu, click **Open Public Folder Store**, and then click **OK**. The Public Folder Management Console appears.
3. In the console tree, expand **Public Root**, expand **NON_IPM_SUBTREE**, expand **EFORMS REGISTRY**, and then click the public folder that you created for the organizational forms library.
4. In the result pane, in the **Property Name(s)** column, click the **PR_URL_NAME** property.
5. On the **Property Pane** menu, click **Modify 'Extra' Properties**.
6. In **Extra Properties**, click **Add**.
7. In **Property Tag Editor**, click **Select Property Tag**.
8. In **Property Selector**, click **PR_EFORMS_LOCALE_ID**, and then click **OK**.
9. Click **OK** to close **Property Tag Editor**, and then click **OK** to close **Extra Properties**.
10. To verify that the property was added, in the Public Folder Management Console, locate the newly created **PR_EFORMS_LOCALE_ID** property in the **Property Name(s)** column. A red exclamation point (!) is displayed as its icon.
11. Double-click **PR_EFORMS_LOCALE_ID** to open **Property Editor**.
12. In the **Unsigned Decimal** box, type the desired locale ID, and then click **OK**. For example, type **1033** for English, **1040** for Italian, and so on.

Note:
For more information about determining the locale ID, see languagecode

Field.

13.Close MFCMAPI.

Other Tasks

After you create the organizational forms library, you may also want to:

- Use the Set-PublicFolder cmdlet to set storage limits.
- Use the following cmdlets to set permissions for each user:
  - Add-PublicFolderClientPermission
  - Add-PublicFolderAdministrativePermission

1.8.3.22 Managing Recoverable Items

Managing Recoverable Items

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-05-24*

Enable Single Item Recovery for a Mailbox

Configure Deleted Item Retention and Recoverable Items Quotas

Perform Single Item Recovery

Get Recoverable Items Folder Statistics

Clean Up the Recoverable Items Folder

1.8.3.22.1 Enable Single Item Recovery for a Mailbox

Enable Single Item Recovery for a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Exchange Management Shell to enable single item recovery on a mailbox.

Looking for other management tasks related to recovery items? Check out Managing Recoverable Items.

Use the Shell to enable recoverable items

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Retention and legal holds" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to enable recoverable items.

This example uses the **Set-Mailbox** command to enable single item recovery and sets the number of days that deleted items are retained.

```
Set-Mailbox -Identity MBX01 -SingleItemRecoveryEnabled $True -RetainDeletedItemsF
```

Note:
By default, the mailbox uses the deleted item retention settings of the mailbox database, but you can override the default can be overridden by setting it at the mailbox level for specific mailboxes.

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.22.2 Configure Deleted Item Retention and Recoverable Items Quotas

Configure Deleted Item Retention and Recoverable Items Quotas

Mailbox > Managing Mailbox Servers > Managing Recoverable Items >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

When a user deletes items from the Deleted Items default folder by using the Delete, Shift+Delete, or **Empty Deleted Items Folder** actions, the items are moved to the **Recoverable Items\Deletions** folder. The duration that deleted items remain in this folder is based on the deleted item retention settings configured for the mailbox database or the mailbox. By default, a mailbox database is configured to retain deleted items for 14 days, and the Recoverable Items warning quota and Recoverable Items quota are set to 20 gigabytes (GB) and 30 GB respectively.

Note:
Before the retention time for deleted items elapses, Microsoft Outlook and Microsoft Office Outlook Web App users can recover deleted items by using the Recover Deleted Items feature. To learn more about these features, see the "Recover deleted items" topic for Outlook or Outlook Web App.

You can use the Shell to configure deleted item retention settings and Recoverable Items quotas for a mailbox or mailbox database. These values are ignored when a mailbox is placed on litigation hold.

Note:
You can't use the EMC to configure deleted item retention and recoverable items quotas.

To learn more about deleted item retention, the Recoverable Items folder, and litigation hold, see the following topics:

- Understanding Recoverable Items
- Understanding Litigation Hold

Looking for other management tasks related to recoverable items? Check out Managing Recoverable Items.

Use the Shell to configure deleted item

retention for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Retention and legal holds" entry in the Mailbox Permissions topic.

This example configures April Stewart's mailbox to retain deleted items for 30 days.

```
Set-Mailbox -Identity - "April Stewart" -RetainDeletedItemsFor 30
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to configure Recoverable Items quotas for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Retention and legal holds" entry in the Mailbox Permissions topic.

This example configures a Recoverable Items warning quota of 12 GB and a Recoverable Items quota of 15 GB for April Stewart's mailbox.

```
Set-Mailbox -Identity "April Stewar"t -RecoverableItemsWarningQuota 12GB -Recover
```

Note:

To configure a mailbox to use different Recoverable Items quotas than the mailbox database in which it resides, you must set the *UseDatabaseQuotaDefaults* parameter to `$false`.

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to configure deleted item retention for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Retention and legal holds" entry in the Mailbox Permissions topic.

This example configures a deleted item retention period of 10 days for the mailbox database MDB2.

```
Set-MailboxDatabase -Identity MDB2 -DeletedItemRetention 10
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

Use the Shell to configure Recoverable Items quotas for a mailbox database

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Retention and legal holds" entry in the Mailbox Permissions topic.

This example configures a Recoverable Items warning quota of 15 GB and a Recoverable

Items quota of 20 GB on mailbox database MDB2.

```
Set-MailboxDatabase -Identity MDB2 -RecoverableItemsWarningQuota 15GB -Recoverabl
```

For detailed syntax and parameter information, see Set-MailboxDatabase.

1.8.3.22.3 Perform Single Item Recovery

Perform Single Item Recovery

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Single item recovery provides an additional layer of protection so that you can recover items accidentally deleted by a user or by automated processes such as the Managed Folder Assistant. Single item recovery simplifies recovery and reduces recovery time because you can recover items without recovering an entire mailbox or mailbox database from backup media.

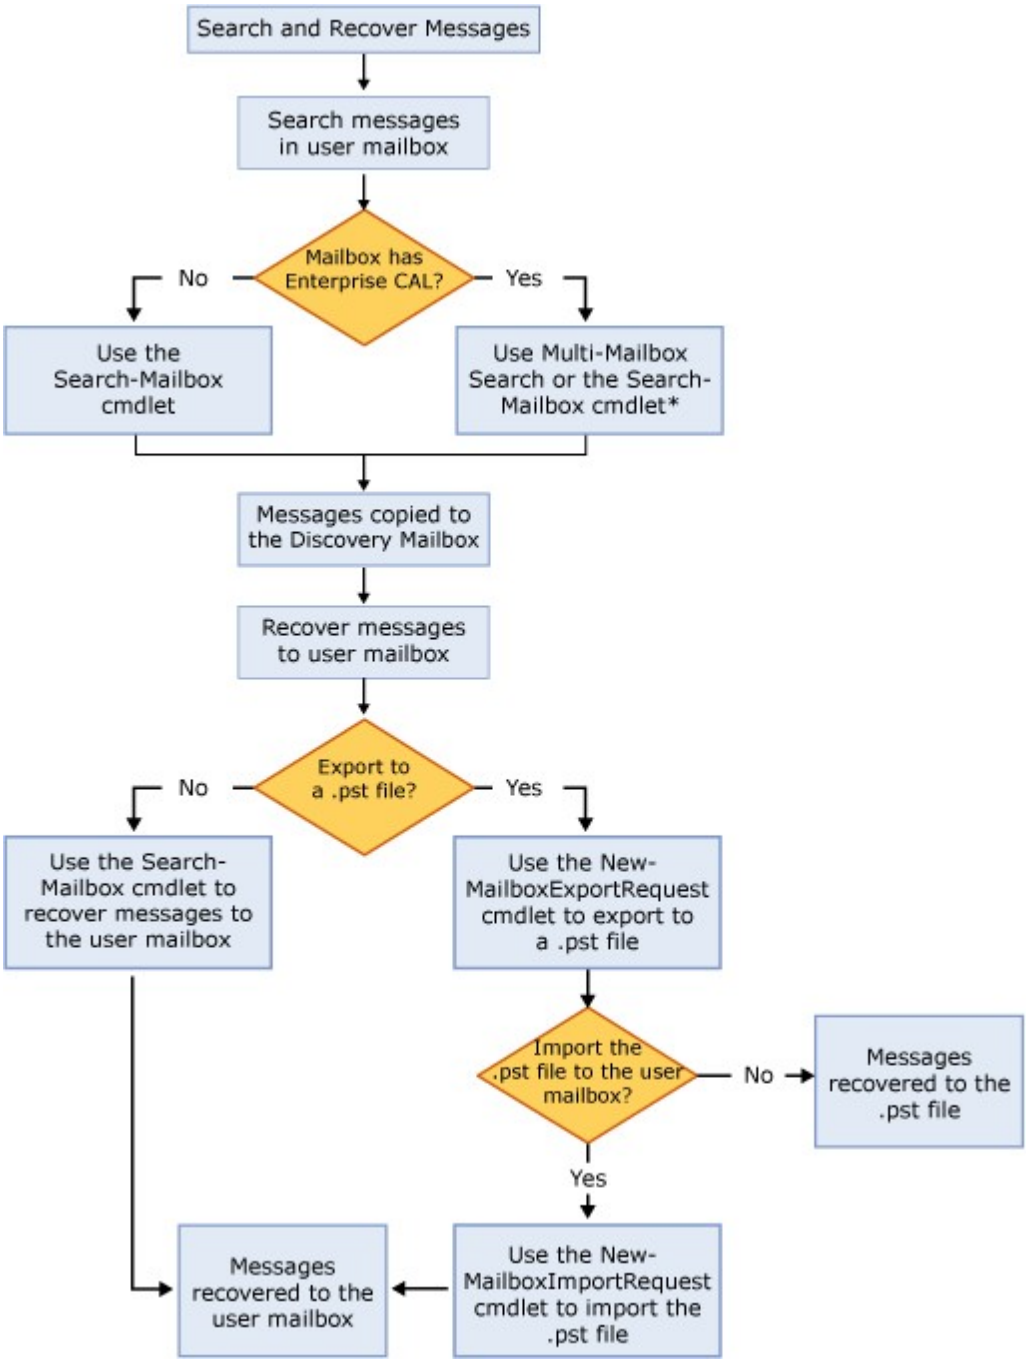
Note:

In addition to using this procedure to search for and recover deleted items (which are moved to the Recoverable Items\Purges folder if either single item recovery or litigation hold is enabled), you can also use this procedure to search for items residing in other folders in the mailbox and to delete items from the source mailbox (also known as *search and destroy*). For details, see Use Mailbox Search to Delete Messages.

The method you use to search for and recover missing items depends on the client access license (CAL) for the mailbox you're searching. If the mailbox has an enterprise CAL, you can use the Multi-Mailbox Search feature in the Exchange Control Panel (ECP) or the **New-MailboxSearch** cmdlet in the Shell. These features also allow you to search multiple mailboxes simultaneously.

You can also use the **Search-Mailbox** cmdlet in the Shell to search for and recover missing items. If the mailbox has a standard CAL, this is the only method you can use. If you use this cmdlet, you can search only one mailbox at a time.

The following flowchart illustrates the different methods available for performing single item recovery.



To search for and recover items, you must have the following information:

- **Source mailbox** This is the mailbox being searched.
- **Target mailbox** This is the discovery mailbox in which messages will be recovered. Exchange Setup creates a default discovery mailbox. If required, you can create additional discovery mailboxes. For details, see Create a Discovery Mailbox.

Note:

When using the **Search-Mailbox** cmdlet, you can also specify a target mailbox that isn't a discovery mailbox. However, you can't specify the same mailbox as the source and target mailbox.

- **Search criteria** Criteria include sender or recipient, or keywords (words or phrases) in the message.

The process consists of two steps:

1. **Search** Searching for the missing items and recovering them to a discovery mailbox.
2. **Restore** Restoring the items to the user's mailbox or a .pst file.

Looking for other management tasks related to recoverable items? Check out Managing Recoverable Items.

Prerequisites

Before the item you want to recover is deleted, single item recovery must be enabled for a mailbox. For details, see Enable Single Item Recovery for a Mailbox.

Step 1: Search for and recover missing items

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Multi-Mailbox Search" entry in the Messaging Policy and Compliance Permissions topic.

Note:
You can't use the EMC to search for and recover missing items.

The first step in the recovery process is to search for messages in the source mailbox. Use one of the following methods to search a user mailbox and copy messages to a discovery mailbox.

Use the Shell

This example searches for messages in April Stewart's mailbox that meet the following criteria:

- Sender: Ken Kwok
- Keyword: Seattle

```
Search-Mailbox "April Stewart" -SearchQuery "from:'Ken Kwok' AND seattle" -Target
```

Note:
When using the **Search-Mailbox** cmdlet, you can scope the search by using the *SearchQuery* parameter to specify a query formatted using Advanced Query Syntax (AQS). You can also use the *SearchDumpsterOnly* switch to search only items in the dumpster.

For detailed syntax and parameter information, see Search-Mailbox.

Use Multi-Mailbox Search in the ECP

For details about how to perform a Multi-Mailbox Search in the ECP, see Multi-Mailbox Searches.

Step 2: Restore recovered items

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Multi-Mailbox Search" entry in the Messaging Policy and Compliance Permissions topic.

Note:
You can't use the EMC to restore recovered items.

After messages have been recovered to a discovery mailbox, you can restore them to the user's mailbox by using the **Search-Mailbox** cmdlet. You can also use the **New-MailboxExportRequest** and **New-MailboxImportRequest** cmdlets to export the messages to or import the messages from a .pst file.

Use the Shell to restore messages

This example restores messages to April Stewart's mailbox and deletes them from the Discovery Search Mailbox.

```
Search-Mailbox "Discovery Search Mailbox" -SearchQuery "from:'Ken Kwok' AND seatt
```

For detailed syntax and parameter information, see Search-Mailbox.

Use the Shell to export and import messages from a .pst file

In Microsoft Exchange Server 2010 Service Pack 1 (SP1), you can export messages from and import messages to .pst files without requiring the installation of Microsoft Outlook. To learn more about mailbox import and export, see Understanding Mailbox Import and Export Requests.

This example uses the following settings to export messages from the folder April Stewart Recovery in the Discovery Search Mailbox to a .pst file:

- **Mailbox** Discovery Search Mailbox
- **Source folder** April Stewart Recovery
- **ContentFilter** april travel plans
- **PST file path** \\MYSERVER\HelpDeskPst\AprilStewartRecovery.pst

```
New-MailboxExportRequest -Mailbox "Discovery Search Mailbox" -SourceRootFolder "A
```

For detailed syntax and parameter information, see New-MailboxExportRequest.

This example uses the following settings to import messages from a .pst file to the folder Recovered By Helpdesk in April Stewart's mailbox:

- **Mailbox** April Stewart
- **Target folder** Recovered By Helpdesk
- **PST file path** \\MYSERVER\HelpDeskPst\AprilStewartRecovery.pst

```
New-MailboxImportRequest -Mailbox "April Stewart" -TargetRootFolder "Recovered By
```

For detailed syntax and parameter information, see New-MailboxImportRequest.

1.8.3.22.4 Get Recoverable Items Folder Statistics

Get Recoverable Items Folder Statistics

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Recoverable Items folder contains items deleted by Microsoft Outlook and Microsoft Office Outlook Web App users or by the Mailbox Assistant. The duration that deleted items remain in this folder is based on the deleted item retention settings configured for the mailbox database or the mailbox. By default, a mailbox database is configured to retain deleted items for 14 days, and the Recoverable Items warning quota and Recoverable Items quota are set to 20 gigabytes (GB) and 30 GB respectively. However, if litigation hold is enabled for the mailbox, the Recoverable Items folder can accumulate deleted items beyond the specified retention period and can also maintain different versions of

modified mailbox items.

When the Recoverable Items folder reaches the Recoverable Items warning quota, a warning event is logged in the Application event log. If the mailbox isn't on litigation hold, items are then removed on a first in, first out (FIFO) basis. However, if the mailbox is on litigation hold, the mailbox is never emptied and upon reaching the Recoverable Items quota, mailbox functionality is impacted.

Therefore, it's important to monitor the event log for alerts generated when mailboxes reach the Recoverable Items quotas. You can also use this procedure to report statistics for the Recoverable Items folder, particularly for mailboxes placed on litigation hold.

To learn more, see the following topics:

- Understanding Recoverable Items
- Understanding Litigation Hold

Looking for other management tasks related to recoverable items? Check out Managing Recoverable Items.

Use the Shell to get Recoverable Items folder statistics for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox folders" entry in the Mailbox Permissions topic.

Note:

You can't use the Exchange Management Console (EMC) to get Recoverable Items folder statistics for a mailbox.

This example gets folder statistics for Soumya Singhi's Recoverable Items folder and displays the output in a list format.

```
Get-MailboxFolderStatistics -Identity "Soumya Singhi" -FolderScope RecoverableIte
```

This example gets folder statistics for Soumya Singhi's Recoverable Items folder and displays the folder name, folder path, number of items in the folder, and folder size in a table format.

```
Get-MailboxFolderStatistics -Identity "Soumya Singhi" -FolderScope RecoverableIte
```

For detailed syntax and parameter information, see Get-MailboxFolderStatistics.

Use the Shell to get Recoverable Items folder statistics for all mailboxes on litigation hold

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox folders" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to get Recoverable Items folder statistics for all mailboxes on litigation hold.

This example retrieves a list of all mailboxes placed on litigation hold and retrieves mailbox folder statistics for the Recoverable Items folder and its subfolders for each

mailbox. The **Identity** (mailbox folder identity) and the **FolderAndSubfolderSize** properties are displayed in a table format.

```
Get-Mailbox -ResultSize Unlimited -Filter {LitigationHoldEnabled -eq $true} | Get
```

For detailed syntax and parameter information, see Get-Mailbox and Get-MailboxFolderStatistics.

Other Tasks

After you get Recoverable Items folder statistics for a mailbox, you may also want to:

- Configure Deleted Item Retention and Recoverable Items Quotas
- Clean Up the Recoverable Items Folder

1.8.3.22.5 Clean Up the Recoverable Items Folder

Clean Up the Recoverable Items Folder

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The Recoverable Items folder (known in earlier versions of Exchange as the dumpster) exists to protect from accidental or malicious deletions and to facilitate discovery efforts commonly undertaken before or during litigation or investigations. To learn more about the Recoverable Items folder, see Understanding Recoverable Items.

How you clean up a mailbox's Recoverable Items folder depends on whether the mailbox is placed on litigation hold or had single item recovery enabled:

- If a mailbox isn't placed on litigation hold or doesn't have single item recovery enabled, you can simply delete items from the Recoverable Items folder. After being deleted, you can't use single item recovery to recover the items.
- If the mailbox is placed on litigation hold or has single item recovery enabled, it's important to preserve the mailbox data until the litigation hold is removed or single item recovery is disabled. Therefore, you need to perform more detailed steps to clean up the Recoverable Items folder.

To learn more about litigation hold and single item recovery, see Understanding Litigation Hold or "Single Item Recovery" inUnderstanding Recoverable Items.

Looking for other management tasks related to recoverable items? Check out Managing Recoverable Items.

Prerequisites

Because incorrectly cleaning up the Recoverable Items folder can result in data loss, it’s important that you're familiar with the Recoverable Items folder and the impact of removing its contents. Before performing this procedure, we recommend that you review the information in Understanding Recoverable Items.

Use the Shell to delete items from the Recoverable Items folder for mailboxes that aren't placed on litigation hold or don't have single item recovery enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Delete mailbox content" entry in the Messaging Policy and Compliance Permissions topic.

Note:
You can't use the EMC to delete items from the Recoverable Items folder for mailboxes that aren't placed on litigation hold or don't have single item recovery enabled.

This example permanently deletes items from Gurinder Singh's Recoverable Items folder and also copies the items to the GurinderSingh-RecoverableItems folder in the Discovery Search Mailbox (a discovery mailbox created by Exchange Setup).

```
Search-Mailbox -Identity "Gurinder Singh" -SearchDumpsterOnly -TargetMailbox "Dis
```

Note:
To delete items from the mailbox without copying them to another mailbox, use the preceding command without the *TargetMailbox* and *TargetFolder* parameters.

For detailed syntax and parameter information, see Search-Mailbox.

Use the Shell to clean up the Recoverable Items folder for mailboxes that are placed on litigation hold or have single item recovery enabled

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Delete mailbox content" entry in the Messaging Policy and Compliance Permissions topic.

Note:
You can't use the EMC to clean up the Recoverable Items folder for mailboxes placed on litigation hold or have single item recovery enabled.

If a mailbox reaches its Recoverable Items quota, we recommend that you raise the quota and not delete items from the folder. You can also monitor events in the Application log related to the Recoverable Items warning quota and take necessary actions (such as raising the quota or investigating dumpster growth for mailboxes that reach the warning quota).

If storage constraints or similar issues prevent you from raising the Recoverable Items quota, and you need to delete messages from the Recoverable Items folder of a mailbox on litigation hold or has single item recovery enabled, we recommend that you first copy data from the user's Recoverable Items folder to another mailbox. If you're deleting items due to storage constraints on one volume, you can copy items to a mailbox located on a volume that has adequate storage.

This procedure copies items from Gurinder Singh's Recoverable Items folder to the

GurinderSingh-RecoverableItems folder in the Discovery Search Mailbox. Before you copy and delete items from the Recoverable Items folder, you must first perform several steps to make sure items aren't deleted from the Recoverable Items folder. After you copy items to a discovery or backup mailbox and clean up the folder, you can revert to the mailbox's previous settings.

1. Retrieve the following quota settings. Be sure to note the values so you can revert to these settings after cleaning up the Recoverable Items folder:
   - *RecoverableItemsQuota*
   - *RecoverableItemsWarningQuota*
   - *ProhibitSendQuota*
   - *ProhibitSendReceiveQuota*
   - *UseDatabaseQuotaDefaults*
   - *RetainDeletedItemsFor*
   - *UseDatabaseRetentionDefaults*

   Note:

   If the *UseDatabaseQuotaDefaults* parameter is set to `$true`, the previous quota settings aren't applied. The corresponding quota settings configured on the mailbox database are applied, even if individual mailbox settings are populated.

   ```
   Get-Mailbox "Gurinder Singh" | Format-List RecoverableItemsQuota, Reco
   ```

2. Retrieve the mailbox access settings for the mailbox. Be sure to note these settings for later.

   ```
   Get-CASMailbox "Gurinder Singh" | Format-List EwsEnabled, ActiveSyncEn
   ```

3. Retrieve the current size of the Recoverable Items folder. Note the size so you can raise the quotas in Step 6.

   ```
   Get-MailboxFolderStatistics "Gurinder Singh" -FolderScope RecoverableI
   ```

4. Retrieve the current Managed Folder Assistant work cycle configuration. Be sure to note the setting for later.

   ```
   Get-MailboxServer "My Mailbox Server" | Format-List Name,ManagedFolder
   ```

5. Disable client access to the mailbox to make sure no changes can be made to mailbox data for the duration of this procedure.

   ```
   Set-CASMailbox "Gurinder Singh" -EwsEnabled $false -ActiveSyncEnabled
   ```

6. To make sure no items are deleted from the Recoverable Items folder, increase the Recoverable Items quota, increase the Recoverable Items warning quota, and set the deleted item retention period to a value higher than the current size of the user's Recoverable Items folder. This is particularly important for preserving messages for mailboxes placed on litigation hold. We recommend raising these settings to twice their current size.

   ```
   Set-Mailbox "Gurinder Singh" -RecoverableItemsQuota 50Gb -RecoverableI
   ```

7. Disable the Managed Folder Assistant on the Mailbox server.

   ```
   Set-MailboxServer MyMailboxServer -ManagedFolderWorkCycle $null
   ```

   Important:

   If the mailbox resides on a mailbox database in a database availability group (DAG), you must disable the Managed Folder Assistant on each DAG member that hosts a copy of the database. If the database fails over to another server, this prevents the Managed Folder Assistant on that server from deleting mailbox data.

8. Disable single item recovery and remove the mailbox from litigation hold.

   ```
   Set-Mailbox "Gurinder Singh" -SingleItemRecoveryEnabled $false -Litiga
   ```

Important:
After you run this command, it may take up to one hour to disable single item recovery or litigation hold. We recommend that you perform the next step only after this period has elapsed.

9. Copy items from the Recoverable Items folder to a folder in the Discovery Search Mailbox and delete the contents from the source mailbox.

```
Search-Mailbox -Identity "Gurinder Singh" -SearchDumpsterOnly -TargetM
```

If you need to delete only messages that match specified conditions, use the *SearchQuery* parameter to specify the conditions. This example deletes messages that have the string "Your bank statement" in the **Subject** field.

```
Search-Mailbox -Identity "Gurinder Singh" -SearchQuery "Subject:'Your
```

Note:
It isn't required to copy items to the Discovery Search Mailbox. You can copy messages to any mailbox. However, to prevent access to potentially sensitive mailbox data, we recommend copying messages to a mailbox that has access restricted to authorized records managers. By default, access to the default Discovery Search Mailbox is restricted to members of the Discovery Management role group. For details, see Understanding Multi-Mailbox Search.

10. If the mailbox was placed on litigation hold or had single item recovery enabled earlier, enable these features again.

```
Set-Mailbox "Gurinder Singh" -SingleItemRecoveryEnabled $true -Litigat
```

Important:
After you run this command, it may take up to one hour to enable single item recovery or litigation hold. We recommend that you enable the Managed Folder Assistant and allow client access (Steps 11 and 12) only after this period has elapsed.

11. Revert the following quotas to the values noted in Step 1:
    - *RecoverableItemsQuota*
    - *RecoverableItemsWarningQuota*
    - *ProhibitSendQuota*
    - *ProhibitSendReceiveQuota*
    - *UseDatabaseQuotaDefaults*
    - *RetainDeletedItemsFor*
    - *UseDatabaseRetentionDefaults*

    In this example, the mailbox is removed from retention hold, the deleted item retention period is reset to the default value of 14 days, and the Recoverable Items quota is configured to use the same value as the mailbox database. If the values you noted in Step 1 are different, you must use the preceding parameters to specify each value and set the *UseDatabaseQuotaDefaults* parameter to `$false`. If the *RetainDeletedItemsFor and UseDatabaseRetentionDefaults* parameters were previously set to a different value, you must also revert them to the values noted in Step 1.

```
Set-Mailbox "Gurinder Singh" -RetentionHoldEnabled $false -RetainDelet
```

12. Enable the Managed Folder Assistant by setting the work cycle back to the value you noted in Step 4. This example sets the work cycle to one day.

```
Set-MailboxServer MyMailboxServer -ManagedFolderWorkCycle 1
```

13. Enable client access.

```
Set-CASMailbox -ActiveSyncEnabled $true -EwsEnabled $true -MAPIEnabled
```

For detailed syntax and parameter information, see the following topics:

- Get-Mailbox
- Get-CASMailbox

- Get-MailboxFolderStatistics
- Get-MailboxServer
- Set-CASMailbox
- Set-Mailbox
- Set-MailboxServer
- Search-Mailbox

Other Tasks

After you clean up the Recoverable Items folder, you may also want to:

- Enable Single Item Recovery for a Mailbox
- Configure Deleted Item Retention and Recoverable Items Quotas

1.8.3.23 Managing Resource Mailboxes and Scheduling

Managing Resource Mailboxes and Scheduling

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-30*

Create a Room or Equipment Mailbox

Create or Remove Custom Resource Properties

Configure Custom Resource Properties for a Resource Mailbox

Configure the Automated Booking Policies for a Resource Mailbox

Customize the Response Message for Resource Scheduling

Enable or Disable Automatic Booking on a Resource Mailbox

List Available Resource Mailboxes and Their Properties

Remove Full Access Permissions from a Resource Mailbox Schedule

Set a Delegate on a Resource Mailbox

Set Full Access Permissions to a Resource Mailbox Schedule

Add Resource Mailboxes to an Address List

1.8.3.23.1 Add Resource Mailboxes to an Address List

Add Resource Mailboxes to an Address List

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Exchange Management Shell to add a resource mailbox to an address list. Only the global address list (GAL) contains all of the recipient types. The All Rooms address list, which is one of the default address lists included with Exchange, contains only resource mailboxes that are the Recipient Display type **ConferenceRoomMailbox** or **SyncedConferencRoomMailbox**.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the Shell to add resource mailboxes to an address list

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Address lists" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to add resource mailboxes to an address list.

None of the default address lists installed with Exchange include equipment mailboxes. This example changes the name of the address list Resource Rooms to Rooms and Equipment and sets the *IncludedRecipients* parameter to ResourceMailboxes, which includes room and equipment mailboxes.

```
Set-AddressList -Identity "Resource Rooms" -Name "Rooms and Equipment" -IncludedR
```

For detailed syntax and parameter information, see Set-AddressList.

1.8.3.23.2 Create a Room or Equipment Mailbox

Create a Room or Equipment Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *room mailbox* is a resource mailbox assigned to a meeting location, such as a conference room, auditorium, or training room. An *equipment mailbox* is a resource mailbox assigned to a resource that's not location specific, such as a portable computer, projector, microphone, or a company car. You can use the Exchange Management Console (EMC) and the Exchange Management Shell to create a room or equipment mailbox.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to create a room or equipment mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration**.

2. In the action pane, click **New Mailbox**.
3. On the **Introduction** page, click **Room Mailbox** or **Equipment Mailbox**, and then click **Next**.
4. On the **User Type** page, click **New user**, and then click **Next**.
5. On the **Mailbox Information** page, complete the following fields:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name**, **Initials**, and **Last name** Because this mailbox will be used as a resource, it isn't necessary to complete these fields.
   - **Name** Type a name for the user. This is the name that's listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this field. The name can't exceed 64 characters.
   - **User logon name (User Principal Name)** Type the name that the user will use to log on to the mailbox. The user logon name consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides.
   - **User logon name (pre-Windows 2000)** Type the name for the user that's compatible with the legacy versions of Microsoft Windows (prior to the release of Windows 2000 Server). This field is automatically populated based on the **User logon name (User Principal Name)** field. This field is required.
   - **Password** Type the password that the user must use to log on to his or her mailbox.

     Note:
     Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you are creating the user account.
   - **Confirm password** To confirm, type the password that you typed in the **Password** box.
   - **User must change password at next logon** Select this check box if you want the user to reset the password when the user first logs on to the mailbox.

     If you select this check box, at first logon, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.
6. On the **Mailbox Settings** page, complete the following fields:
   - **Alias** Type an alias for the mailbox. The alias can't exceed 64 characters and must be unique in the forest.
   - **Specify the mailbox database rather than using a database automatically selected** Select this check box to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name. Select the mailbox database you want to use, and then click **OK**. This is an optional

field.

- **Managed folder mailbox policy** Select this check box to specify a managed folder mailbox policy for the mailbox. A managed folder mailbox policy is a logical grouping of managed folders. When a managed folder mailbox policy is applied to a user's mailbox, all the managed folders linked to the policy are deployed in a single operation, thereby making the deployment of messaging records management (MRM) easier. To learn more, see Understanding Managed Folders.

  Click **Browse** to open the **Select Managed Folder Mailbox Policy** dialog box. Use this dialog box to select the managed folder mailbox policy to be associated with this mailbox. This is an optional field.

  Note:
  Managed custom folders are a premium feature of MRM. Mailboxes with policies that include managed custom folders require an Exchange Server Enterprise client access license (CAL).

- **Exchange ActiveSync mailbox policy** Select this check box to specify an Exchange ActiveSync mailbox policy for the mailbox. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. To learn more, see Understanding Exchange ActiveSync Mailbox Policies.

  Click **Browse** to open the **Select ActiveSync Mailbox Policy** dialog box. Use this dialog box to select the policy that you want associated with this mailbox. This is an optional field.

7. (Optional) On the **Archive Settings** page, select the **Create an archive mailbox for this account** check box if you want to link an online archive to the mailbox. If you create an archive mailbox for the mailbox, mailbox items will be moved automatically from the primary user mailbox to the archive, based on the default retention policy settings or those you define. To learn more, see Understanding Personal Archives.

   Note:
   Due to the small size of a resource mailbox, we recommend that you don't create an archive for a resource mailbox.

8. On the **New Mailbox** page, review your configuration settings. To make any configuration changes, click **Back**. To create the mailbox, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a room mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example creates a room mailbox with the following configuration:

- The resource mailbox resides on Mailbox Database 1.
- The mailbox's name is ConfRoom1 and the name will display in the global address list (GAL) as ConfRoom1.
- The mailbox is in the Conference Rooms organizational unit.
- The user principal name (UPN) is ConfRoom1@contoso.com.
- The *Room* switch specifies that this mailbox will be created as a room mailbox.

```
New-Mailbox -database "Mailbox Database 1" -Name ConfRoom1 -OrganizationalUnit "C
```

For detailed syntax and parameter information, see New-Mailbox.

Use the Shell to create an equipment mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example creates an equipment mailbox with the following configuration:

- The equipment mailbox resides on Mailbox Database 1.
- The equipment's name is DVDPlayer01 and the name will display in the GAL as DVDPlayer01.
- The mailbox is in the Equipment organizational unit.
- The UPN is DVDPlayer01@contoso.com.
- The *Equipment* switch specifies that this mailbox will be created as an equipment mailbox.

```
New-Mailbox -Database "Mailbox Database 1" -Name DVDPlayer01 -OrganizationalUnit
```

For detailed syntax and parameter information, see New-Mailbox.

Other Tasks

After the room or equipment mailbox is created, we recommend that you perform additional configuration tasks based on the needs of your organization. For example, you can configure resource scheduling policies or assign delegates for the mailbox. For details, see Managing Resource Mailboxes and Scheduling.

1.8.3.23.3 Create or Remove Custom Resource Properties

Create or Remove Custom Resource Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to create or remove custom resource properties by modifying the resource configuration of your Exchange organization.

Custom resource properties are features for room or equipment mailboxes. You can indicate that a resource has a specific feature by assigning the corresponding custom resource property to that resource mailbox.

Important:

Custom resource properties can't include spaces.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the Shell to add custom resource

properties to the resource schema

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to add custom resource properties to the resource schema.

This example creates three custom resource properties for room mailboxes and two custom resource properties for equipment mailboxes. This example also demonstrates two methods for adding new custom resource properties. The syntax of both commands can be used interchangeably.

1. Use the following command to read the current resource configuration and store it in a temporary variable called `$ResourceConfiguration`.

```
$ResourceConfiguration = Get-ResourceConfig
```

2. Use the following commands to create the custom properties AV, TV, and Whiteboard for room mailboxes.

Note:
This example assumes that some of the meeting rooms in your organization have audio-visual equipment, TV, or whiteboards. It also assumes that you want to differentiate the rooms that have the specified features from others that don't.

```
$ResourceConfiguration.ResourcePropertySchema+=("Room/AV")
$ResourceConfiguration.ResourcePropertySchema.Add("Room/TV")
$ResourceConfiguration.ResourcePropertySchema+=("Room/Whiteboard")
```

3. Use the following commands to create the custom properties Car and Van for equipment mailboxes.

Note:
This example assumes that your organization uses equipment mailboxes to track the scheduling of company vehicles, and you plan to use the custom resource properties to specify the vehicle type.

```
$ResourceConfiguration.ResourcePropertySchema.Add("Equipment/Car")
$ResourceConfiguration.ResourcePropertySchema+=("Equipment/Van")
```

4. Use the following commands to update the resource configuration of your organization by using the modified resource property schema.

```
Set-ResourceConfig -ResourcePropertySchema $ResourceConfiguration.Reso
```

For detailed syntax and parameter information, see Get-ResourceConfig and Set-ResourceConfig.

Use the Shell to remove custom resource properties from the resource schema

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example removes two of the custom resource properties for room mailboxes that were created in the previous procedure. The commands also demonstrate two methods for removing a custom resource property. The syntax of both commands can be used interchangeably.

1. Use the following command to read the current resource configuration and store it in a temporary variable called $ResourceConfiguration.

```
$ResourceConfiguration = Get-ResourceConfig
```

2. Use the following commands to remove the custom properties AV and TV from room mailboxes.

```
$ResourceConfiguration.ResourcePropertySchema-=("Room/AV")
$ResourceConfiguration.ResourcePropertySchema.Remove("Room/TV")
```

3. Use the following commands to update the resource configuration of your organization by using the modified resource property schema.

```
Set-ResourceConfig -ResourcePropertySchema $ResourceConfiguration.Reso
```

For detailed syntax and parameter information, see Get-ResourceConfig and Set-ResourceConfig

Other Tasks

After you create custom resource properties, you may also want to assign them to a resource mailbox. For detailed steps, see Configure Custom Resource Properties for a Resource Mailbox.

1.8.3.23.4 Configure Custom Resource Properties for a Resource Mailbox

Configure Custom Resource Properties for a Resource Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *resource mailbox* is a mailbox that represents conference rooms and company equipment. Resource mailboxes can be included as resources in meeting requests, providing a simple and efficient way to manage the scheduling of resources for your organization.

There are two types of resource mailboxes: room and equipment. *Room mailboxes* are assigned to a meeting location such as a conference room, auditorium, or training room. *Equipment mailboxes* are assigned to a resource that isn't location specific, such as a portable computer projector, microphone, or company car.

Custom resource properties can help users select the most appropriate room or equipment by providing additional information about the resource. For example, you can create a custom property for room mailboxes called AV. You can add this property to all rooms that have audio-visual equipment. This allows users to identify which conference rooms have audio-visual equipment available.

Note:

For every custom resource property you create in your organization, you must specify to which resource mailbox type it applies (room or equipment). When you are managing a resource mailbox, you can assign only those custom resource properties that apply to that specific resource mailbox type. For example, if you are configuring a room mailbox, you can assign only the custom resource properties that apply to room mailboxes.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Prerequisites

Before you can assign custom resource properties to a room or equipment mailbox, you must first create these properties by modifying the resource configuration of your Exchange organization. For detailed instructions, see Create or Remove Custom Resource Properties.

Use the EMC to add or remove custom resource properties for a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox that you want to configure.
3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. In **<Resource Mailbox Name> Properties**, click the **Resource General** tab.
5. Under **Resource custom properties**, perform the following tasks:
   - To add a custom resource property, click **Add**. The **Select Resource Custom Property** dialog box opens. This dialog box displays a list of all custom resource properties defined in your Exchange organization for the specific resource type. Select the custom resource properties you want to assign to this mailbox, and then click **OK**.
   - To remove a custom resource property, select the property you want to remove, and then click  .
6. Click **OK**.

Use the Shell to add custom resource properties to a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example adds the resource property AV to the room mailbox Conference Room 1. This example also overwrites any existing custom resource properties on the mailbox.

```
Set-Mailbox -Identity "Conference Room 1" -ResourceCustom ("AV")
```

This example adds the custom resource properties TV and Whiteboard to the room mailbox Conference Room 1. This example adds the Whiteboard custom property and preserves any existing custom resource properties on the mailbox. This example also demonstrates the two acceptable syntaxes for adding a custom resource property.

```
$ResourceMailbox = Get-Mailbox -Identity "Conference Room 1"
$ResourceMailbox.ResourceCustom+=("TV")
$ResourceMailbox.ResourceCustom.Add("whiteboard")
Set-Mailbox -ResourceCustom $ResourceMailbox.ResourceCustom.Add
```

For detailed syntax and parameter information, see Get-Mailbox and Set-Mailbox.

Use the Shell to remove custom resource

properties from a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example removes the custom resource properties AV and TV from the room mailbox Conference Room 1. This example also demonstrates the two acceptable syntaxes for removing a custom resource property.

```
$ResourceMailbox = Get-Mailbox -Identity "Conference Room 1"
$ResourceMailbox.ResourceCustom-=("AV")
$ResourceMailbox.ResourceCustom.Remove("TV")
Set-Mailbox -Identity "Converence Room 1" $ResourceMailbox.ResourceCustom.Remove
```

For detailed syntax and parameter information, see Get-Mailbox and Set-Mailbox.

1.8.3.23.5 Configure the Automated Booking Policies for a Resource Mailbox

Configure the Automated Booking Policies for a Resource Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-08-28*

A meeting organizer can send a meeting request to any resource mailbox, which includes conference room and equipment mailboxes. Depending on the scheduling role membership of the meeting organizer, this meeting request can be automatically approved or declined.

In some cases, the meeting request requires special handling to determine if the meeting organizer can schedule a conference room. In this case, an acknowledgement is sent to the meeting organizer, and the request is kept in the resource mailbox or forwarded to a delegate.

Meeting requests sent to the resource mailbox are categorized as one of the following:

- **In-policy meeting requests** These meeting requests don't violate any of the resource scheduling options.
- **Out-of-policy meeting requests** These meeting requests violate one or more of the resource scheduling options. For example, one reason a meeting request is considered out-of-policy is because of a conflict with an existing resource reservation.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to specify which users can send meeting requests to resource mailboxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox

Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox that you want to configure.
3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. On the **Resource In-Policy Requests** tab, configure the following settings:
   - **All Users** Select this option to allow all users to submit requests within the resource policy's configuration.
   - **Selected recipients** Select this option to specify who can submit requests within the resource policy's configuration. If you select this option, you need to click **Add** to select the recipients. You can also remove selected recipients by clicking **Remove**.
5. On the **Resource Out-of-Policy Requests** tab, specify the users who can submit out-of-policy requests. Users who can submit out-of-policy requests won't have their request denied, but the requests will require approval by one of the resource's delegates. Configure the following settings:
   - **All users** Select this option to allow all users who submit resource requests that don't meet the resource policy's configuration.
   - **Selected recipients** Select this option to add specific users who are allowed to submit out-of-policy requests. If you select the **Selected recipients** option, you need to click the **Add** button to select the recipients. You can also remove selected recipients by clicking **Remove**.

Use the Shell to specify which users can send meeting requests to resource mailboxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

To control who can schedule a resource, use the following parameters with the **Set-CalendarProcessing** cmdlet:

- *AllBookInPolicy*
- *AllRequestInPolicy*
- *AllRequestOutOfPolicy*
- *BookInPolicy*
- *RequestInPolicy*
- *RequestOutOfPolicy*
- *ProcessExternalMeetingMessages*

Note:

When *AllRequestInPolicy* and *AllRequestOutOfPolicy* are both set to True, only out-of-policy requests are forwarded to delegates. Exchange Server automatically accepts in-policy requests, and does not forward the policy requests to a delegate.

This example allows the Calendar Attendant to approve in-policy requests from all users for the room mailbox 5th Floor Conference Room.

```
Set-CalendarProcessing -Identity "5th Floor Conference Room" -AutomateProcessing
```

This example allows all users to submit in-policy requests to the room mailbox 5th Floor Conference Room, but the request is still subject to approval by a delegate.

```
Set-CalendarProcessing -Identity "5th Floor Conference Room" -AutomateProcessing
```

This example allows the Calendar Attendant to accept out-of-policy requests from Alan Brewer to the room mailbox Room222. The request is still subject to approval by a delegate.

```
Set-CalendarProcessing -Identity "Room222" -AutomateProcessing AutoAccept -Reques
```

This example allows a list of users to submit in-policy meeting requests to the equipment mailbox Car54.

```
Set-CalendarProcessing -Identity "Car54" -AutomateProcessing AutoAccept -BookInPo
```

This example rejects meeting requests from any user who isn't a member of the Exchange organization.

```
Set-CalendarProcessing -Identity "Room222" -ProcessExternalMeetingMessages $false
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

Other Tasks

After you specify which users can send meeting requests to resource mailboxes, you may also want to set a delegate on a resource mailbox. For detailed steps, see Set a Delegate on a Resource Mailbox.

1.8.3.23.6 Customize the Response Message for Resource Scheduling

Customize the Response Message for Resource Scheduling

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can create a custom response message that's included in the Accept, Decline, or Acknowledge messages sent back to a meeting organizer.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to customize the response message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox you want to configure.
3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. In **<Resource Mailbox Name> Properties**, click the **Resource Information** tab.
5. Select the **Add additional text** check box to customize the message the requester receives when the meeting has been accepted, declined, or acknowledged. In the **Additional Text** field, type the custom message. For example, type **All requests for Car 54 are subject to approval**.

Use the Shell to customize the response

message

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

This example sends a response message for all requests made to the equipment mailbox for Car 54.

```
Set-CalendarProcessing -Identity "Car 54" -AddAdditionalResponse:$true  -Addition
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

1.8.3.23.7 Enable or Disable Automatic Booking on a Resource Mailbox

Enable or Disable Automatic Booking on a Resource Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

The *Resource Booking Attendant* can accept or decline resource requests based upon policies that you create. If the Resource Booking Attendant is enabled, it uses the booking policies to determine if incoming requests will be accepted or declined. If the Resource Booking Attendant is disabled, the resource mailbox's delegate must accept or decline all requests. For more information about booking policies, see Configure the Automated Booking Policies for a Resource Mailbox.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to enable or disable automatic booking on a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox that you want to configure.
3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. In **<Resource Mailbox Name> Properties**, on the **Resource General** tab, do one of the following:
   - To enable the Resource Booking Attendant, select the **Enable the Resource Booking Attendant** check box. This allows the Resource Booking Attendant to process resource requests and cancellations automatically.
   - To disable the Resource Booking Attendant, clear the **Enable the Resource Booking Attendant** check box.
5. Click **Apply** to apply the changes, or click **OK** to apply the changes and close the dialog box.

Use the Shell to enable automatic booking

on a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

This example enables the Resource Booking Attendant for the resource mailbox Room 222 by setting the *AutomateProcessing* parameter to **AutoAccept**. With this setting enabled, the Resource Booking Attendant will use the booking policies to determine if incoming requests will be accepted or declined.

```
Set-CalendarProcessing "Room 222" -AutomateProcessing AutoAccept
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

Use the Shell to disable automatic booking on a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

This example disables the Resource Booking Attendant for the resource mailbox Car 54 by setting the *AutomateProcessing* parameter to **AutoUpdate**. With this setting enabled, the Resource Booking Attendant is disabled, but the Calendar Attendant is still enabled.

```
Set-CalendarProcessing "Car 54" -AutomateProcessing AutoUpdate
```

For detailed syntax and parameter information, see Set-CalendarProcessing.

Other Tasks

After you enable automatic booking on a resource mailbox, you may also want to configure the policies for accepting or declining requests. For detailed steps, see Configure User and Resource Mailbox Properties.

1.8.3.23.8 List Available Resource Mailboxes and Their Properties

List Available Resource Mailboxes and Their Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *resource mailbox* is a mailbox that represents conference rooms and company equipment. Resource mailboxes can be included as resources in meeting requests, providing a simple and efficient way to utilize resources for an organization. By default, the user account associated with a resource mailbox is disabled.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to list available resource mailboxes and their properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, click **Create Filter**.
3. Use the drop-down lists to create a filter that displays the resource mailboxes you want:
   - If you want to display conference room mailboxes, select **Recipient Type Details**, select **Equals**, and then select **Conference Room Mailbox**.
   - If you want to display equipment mailboxes, select **Recipient Type Details**, select **Equals**, and then select **Equipment Mailbox**.
4. Click **Apply Filter** to display the results.

Use the Shell to list available resource mailboxes and their properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

This example lists available room mailboxes.

```
Get-Mailbox -RecipientTypeDetails RoomMailbox
```

This example lists available equipment mailboxes.

```
Get-Mailbox -RecipientTypeDetails EquipmentMailbox
```

For detailed syntax and parameter information, see Get-Mailbox.

1.8.3.23.9 Publish Free/Busy Information for More Than Two Months in Exchange 2010

Publish Free/Busy Information for More Than Two Months in Exchange 2010

Mailbox > Managing Mailbox Servers > Managing Resource Mailboxes and Scheduling >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-03*

This topic explains how to configure Microsoft Exchange Server 2010 so that published Free/Busy information for a mailbox is displayed for more than a two-month period. To do this, you must configure the registry on the server that is running both Microsoft Exchange and Resource Booking Attendant.

By default, Microsoft Office Outlook displays the Free/Busy information for a mailbox for a two-month period. If you want to display Free/Busy information for a longer period, you must add the **Excdo\Parameters** subkey to the registry, and then add the value for the period in which you want to display Free/Busy information. After you make this change, restart the Internet Information Services (IIS) Admin service and the Microsoft Exchange

System Attendant service.

To change the amount of Free/Busy information that is displayed for mailboxes

1. Start Registry Editor.
2. Expand the following subkey:
   HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft
3. Right-click **Microsoft**, point to **New**, and then click **Key**.
4. Type **Excdo**, and then press ENTER to name the new key.
5. Right-click **Excdo**, point to **New**, and then click **Key**.
6. Type **Parameters**, and then press ENTER to name the new subkey.
7. Right-click **Parameters**, point to **New**, and then click **DWORD (32-bit) Value**.
8. Type **FBPublishMonths**, and then press ENTER to name the new value.
9. Right-click **FBPublishMonths**, and then click **Modify**.
10. Click Decimal. Then, in the **Value data** box, type the number of months for which you want to publish Free/Busy information. For example, if you want to publish Free/Busy data for four months, type **4** in the **Value data** box.
11. Click **OK**, and then exit Registry Editor.
12. Restart the IIS Admin service and the Microsoft Exchange System Attendant service. To do this, type the following commands at a command prompt, and then press ENTER after each command:
    iisreset
    net stop msexchangesa && net start msexchangesa

For More Information

For more information about managing resource mailboxes or scheduling, see Managing Resource Mailboxes and Scheduling.

1.8.3.23.10 Remove Full Access Permissions from a Resource Mailbox Schedule

Remove Full Access Permissions from a Resource Mailbox Schedule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to remove Full Access permissions from a resource mailbox schedule. A *resource mailbox* is a mailbox that represents conference rooms and company equipment and is used for conference room or equipment scheduling. The user account associated with a resource mailbox is disabled.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the Shell to remove Full Access permissions from a resource mailbox schedule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to remove Full Access permissions from a resource mailbox schedule.

This example removes Tony's permissions to access the resource mailbox Car 54.

```
Remove-MailboxPermission -AccessRights FullAccess -Identity "Car 54" -User Tony@c
```

For detailed syntax and parameter information, see Remove-MailboxPermission.

1.8.3.23.11 Set a Delegate on a Resource Mailbox

Set a Delegate on a Resource Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can set a delegate on a resource mailbox to control the scheduling options for that resource mailbox and to have all requests forwarded to the delegate.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the EMC to set a delegate on a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox that you want to configure.
3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. In **<Resource Mailbox Name> Properties**, click the **Resource Policy** tab.
5. Under **Specify delegates of this mailbox**, perform the following tasks:
   - To add a resource delegate, click **Add**, and then select the recipient.
   - To remove a resource delegate, select the delegate, and then click **Remove**.
6. If you want to forward all meeting requests to the delegates listed, select the **Forward meeting requests to delegates** check box.
7. Click **Apply** to save your changes, or click **OK** to save your changes and close the dialog box.

Use the Shell to set a delegate on a resource mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Resource Mailbox Configuration Permissions" section in the Mailbox Permissions topic.

This example uses the primary SMTP address for Ed, Ayla, and Tony to set them as the delegates for the resource mailbox Room222

```
Set-CalendarProcessing -Identity "Room222" -ResourceDelegates "ed@contoso.com","a
```

Note:
Don't run this cmdlet on a user mailbox. This causes the user's mail to be forwarded to the assigned delegate.

For detailed syntax and parameter information, see Set-CalendarProcessing.

1.8.3.23.12 Set Full Access Permissions to a Resource Mailbox Schedule

Set Full Access Permissions to a Resource Mailbox Schedule

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can use the Shell to set Full Access permissions to a resource mailbox schedule. A *resource mailbox* is a mailbox that represents conference rooms and company equipment and is used for conference room or equipment scheduling. The user account associated with a resource mailbox is disabled.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Use the Shell to set Full Access permissions to a resource mailbox schedule

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Permissions and delegation" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to set Full Access permissions to a resource mailbox schedule.

This example grants Tony Full Access permissions to Car54's schedule.

```
Add-MailboxPermission -AccessRights FullAccess -Identity Car54 -User Tony
```

For detailed syntax and parameter information, see Add-MailboxPermission.

1.8.3.23.13 Upgrade Exchange 2003 Auto Accept Agent-Based Resource Mailboxes to Exchange 2010

Upgrade Exchange 2003 Auto Accept Agent-Based Resource Mailboxes to Exchange 2010

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *resource mailbox* is a mailbox that represents conference rooms and company equipment. Resource mailboxes are used for conference room or equipment scheduling. The Auto Accept agent is an Exchange store event sink that automatically processes meeting requests for resource mailboxes. In Microsoft Exchange Server 2003, you must use the Auto Accept agent for resource mailboxes. Because Exchange Server 2010 supports automatic booking for resource mailboxes, the Auto Accept agent isn't required.

Upgrading Exchange 2003 Auto Accept agent-based resource mailboxes to Exchange 2010 involves the following steps:

1. Unregister the Exchange 2003 Auto Accept agent-based resource mailboxes from the Exchange 2003 store.
2. Move the resource mailboxes from the Exchange 2003 server to an Exchange 2010 Mailbox server.
3. Convert the Exchange 2003 Auto Accept agent-based mailbox to an Exchange 2010 resource mailbox.
4. Configure automated processing for the Exchange 2010 resource mailbox.

Looking for other management tasks related to resource mailboxes? Check out Managing Resource Mailboxes and Scheduling.

Step 1: Use a command prompt to unregister the Exchange 2003 Auto Accept agent

To perform this procedure, the account you use must be an Exchange Admin account and have Local Administrator rights.

From a Command Prompt window on an Exchange 2003 computer, use the following example to unregister the Exchange 2003 Auto Accept agent-based resource mailboxes from the Exchange 2003 store.

```
cscript RegisterMailbox.vbs /u /m:"Room2@Fabrikam.Contoso.com"
```

This script is located in the Auto Accept agent installation directory (usually %Program Files%\Exchsrvr\Agents\AutoAccept).

Step 2: Use the EMC or the Shell to move the mailbox to an Exchange 2010 Mailbox server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox moves" entry in the Mailbox Permissions topic.

You can use the EMC or the Shell to move the Auto Accept agent-based resource mailboxes from the Exchange 2003 server to an Exchange 2010 Mailbox server. For detailed instructions, see the following topics:

- Create a Local Move Request
- Create a Remote Move Request That has Exchange 2010 in Both Forests
- Create a Remote Legacy Move Request Where One of the Forests Doesn't Have Exchange 2010

Step 3: Use the Shell to convert the Auto

Accept agent-based mailbox to an Exchange 2010 resource mailbox

After you move the Exchange 2003 resource mailbox to Exchange 2010, it's considered a shared mailbox. You must convert the shared mailbox to an Exchange 2010 resource mailbox.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to convert the Auto Accept agent-based mailbox.

This example converts the mailbox Room222 to a room mailbox.

```
Set-Mailbox Room222 -Type Room
```

For more information, see Convert a Mailbox.

Step 4: Use the Shell to configure automatic processing of the Exchange 2010 resource mailbox

After you convert the mailbox to an Exchange 2010 resource mailbox, you may want to configure the resource mailbox to automate the processing of meeting requests.

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Calendar processing" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure automatic processing of resource mailboxes.

This example configures the automatic processing of the room mailbox Room222 to approve in-policy requests from all users.

```
Set-CalendarProcessing -Identity Room222 -AutomateProcessing AutoAccept -AllBookI
```

For more information, see the following topics:

- Enable or Disable Automatic Booking on a Resource Mailbox
- Configure the Automated Booking Policies for a Resource Mailbox

1.8.3.24 Managing User Mailboxes

Managing User Mailboxes

Exchange Server 2010 > Mailbox > Managing Mailbox Servers >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-07-16*

1.8.3.24.1 Add an E-Mail Address for a User Mailbox

Add an E-Mail Address for a User Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to add an e-mail address for a user mailbox.

Looking for other management tasks related to managing user mailboxes? Check out Managing User Mailboxes.

Use the EMC to add an e-mail address for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox for which you want to add an e-mail address.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<User Mailbox > Properties**, click the **E-Mail Addresses** tab.
5. To create an e-mail address, under **E-mail Addresses**, click the arrow next to **Add** and select from the following address types:
   - **SMTP Address** This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address.
   - **EUM Address** An Exchange Unified Messaging (EUM) address is used by Unified Messaging (UM) servers to locate UM-enabled users within a Microsoft Exchange Server 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.
   - **Custom Address** Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

   Note:
   With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.
6. Click **Apply**, and then click **OK**.

Use the Shell to add an e-mail address for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example shows how to add an additional address to the user john@contoso.com. For more information about adding and removing values from multivalued properties, see Modifying Multivalued Properties.

```
Set-Mailbox john@contoso.com -EmailAddresses @{add="john@northamerica.contoso.com
```

For detailed syntax and parameter information, see Set-Mailbox or Get-Mailbox.

1.8.3.24.2 Change the Languages for a User Mailbox

Change the Languages for a User Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to change the languages for a user mailbox.

In Microsoft Exchange Server 2010, you can specify multiple languages for a mailbox, in order of preference. Several Exchange components display information to a mailbox user in the preferred language, if that language is supported. These components include quota messages, non-delivery reports (NDRs), the Microsoft Office Outlook Web App user interface, and Unified Messaging (UM) voice prompts.

Note:
For Exchange Server 2003, the language for quota messages and NDRs wasn't determined by the Exchange server. Instead, the language for these messages was determined by the language setting on the Outlook client computer used to view the NDR. To make sure that users who migrated from Exchange 2003 or earlier versions continue to receive these messages in their preferred language, set the language to match the language settings configured on their Outlook client computer.

The language for a mailbox can be set by using the *Languages* parameter of the **Set-Mailbox** cmdlet. An acceptable value for this parameter is a combination of an ISO 639 two-letter lowercase culture code associated with a language and an ISO 3166 two-letter uppercase subculture code associated with a country or region. To learn more about culture codes and to view a complete list of acceptable values, see CultureInfo Class in the MSDN Library.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the Shell to change the languages for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "User mailboxes users" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to change the languages for a user mailbox.

This example sets the language for the user Katarina Larsson to Finnish.

```
Set-Mailbox -Identity "Katarina Larsson" -Languages "fi-FI"
```

Note:
This command overwrites any existing languages for the mailbox.

This example adds the language Turkish to the user mailbox Cigdem Akin without overwriting any existing languages.

```
$Mailbox = Get-Mailbox -Identity "Cigdem Akin"
$Mailbox.Languages += "tr-TR"
Set-Mailbox -Identity "Cigdem Akin" $Mailbox.languages
```

For detailed syntax and parameter information, see Set-Mailbox.

Create a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-12-16*

Mailboxes are the most common recipient type used by information workers in an Exchange organization. Each mailbox is associated with an Active Directory user account. The user can use the mailbox to send and receive messages, and to store messages, appointments, tasks, notes, and documents. You can also create mailboxes for resources such as meeting rooms and equipment. Mailboxes are the primary messaging and collaboration tools for the users in your organization. To learn more about mailboxes, see Understanding Recipients.

Looking for other management tasks related to mailboxes? See Managing User Mailboxes.

What Do You Want to Do?

- Use the EMC to create a mailbox
- Use the Shell to create a single new mailbox
- Use the Shell to mail-enable existing users
- Use the Shell to create a linked mailbox

Use the EMC to create a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox users" entry in the Mailbox Permissions topic.

If you want to create mailboxes for new users, you'll have to use this wizard for each new user mailbox; you can't use the wizard to create multiple user mailboxes. However, you can use the wizard to create multiple mailboxes for existing users.

Note:

If you create mailboxes for multiple existing users, you must create mailboxes of the same type.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Mailbox**.

3. On the **Introduction** page, select one of the following options:
   - **User Mailbox** Click this button to create a mailbox that is owned by a user to send and receive e-mail messages. User mailboxes can't be used for resource scheduling.

     The Active Directory account that is associated with user mailboxes must reside in the same forest as the Exchange server. To use an account in a trusted forest, select **Linked Mailbox**.
   - **Room Mailbox** Click this button to create a mailbox that will be used as a location resource for scheduling meetings. Room mailboxes can be included in meeting requests as resources and can be configured to automatically process incoming requests.

     If you create a new user account for the room mailbox in Active Directory, it will be disabled. If you plan to associate the room mailbox with an existing account, you must select a disabled account.
   - **Equipment Mailbox** Click this button to create a mailbox that will be used

as a resource for scheduling meetings. Equipment mailboxes can be included in meeting requests as resources and can be configured to automatically process incoming requests.

As a best practice, create mailboxes for shared meeting equipment, such as projectors or audio equipment, which can be moved to different meeting rooms.

If you create a new user account for the equipment mailbox in Active Directory, it will be disabled. If you plan to associate the equipment mailbox with an existing account, you must select a disabled account.

- **Linked Mailbox** Click this button to create a user mailbox that is accessed by a user in a separate, trusted forest. You must still create a user account in the forest in which Exchange Server resides. This is required to create the necessary Active Directory object for storing the mailbox information.

  Linked mailboxes might be necessary for organizations that choose to deploy Exchange in a resource forest. The resource forest scenario allows an organization to centralize Exchange in a single forest, while allowing access to the Exchange organization with user accounts in one or more trusted forests.

  Note:
  You cannot create linked mailboxes for multiple existing users. You can only use this wizard to create one linked mailbox at a time.

4. On the **User Type** page, select one of the following options:
   - **New User** Click this button to simultaneously create a new user in Active Directory and mail-enable the user.

     If you click this button, you'll need to provide the required user account information on the **User Information** page of this wizard.
   - **Existing users** Click this button to mail-enable one or more existing users.

     Click **Add** to open the **Select User** dialog box. This dialog box displays a list of user accounts in the forest that aren't mail-enabled or don't have Exchange mailboxes. Select the user accounts you want to mail-enable, and then click **OK** to return to the wizard.

     To remove a user from the list, select the user name, and then click  .

5. If you selected **New User** in Step 4, complete the following fields on the **User Information** page. Otherwise skip to Step 6:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name** Use this box to type the first name of the user. This field is optional.
   - **Initials** Use this box to type the initials of the user. This field is optional.
   - **Last name** Use this box to type the last name of the user. This field is optional.
   - **Name** Use this box to type a name for the user. This is the name that's

listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this field. The name can't exceed 64 characters.

Note:
In Exchange 2010, the mailbox's alias is generated based on the Name property. Invalid characters in the name will be replaced with a question mark (?) when the alias is generated.

- **User logon name (User Principal Name)** Use this box to type the name that the user will use to log on to the mailbox. The user logon name consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides.
- **User logon name (pre-Windows 2000)** Use this box to type the name for the user that is compatible with the legacy versions of Microsoft Windows (prior to the release of Windows 2000 Server). This field is automatically populated based on the **User logon name (User Principal Name)** field. This field is required.
- **Password** Use this box to type the password that the user must use to log on to his or her mailbox. This box won't be available if you're creating a room, equipment, or linked mailbox.

Note:
Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you are creating the user account.

- **Confirm password** Use this box to confirm the password that you typed in the **Password** box. This box won't be available if you're creating a room, equipment, or linked mailbox.
- **User must change password at next logon** Select this check box if you want the user to reset the password when they first logon to the mailbox. This box won't be available if you're creating a room, equipment or linked mailbox.

  If you select this check box, at first logon, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.

6. On the **Mailbox Settings** page, complete the following fields:
   - **Alias** This field is automatically populated with the text that you specified in the **Name** box. If you're creating a new user, or if you selected a single existing user to mail-enable, you can modify the alias for the mailbox. If you're mail-enabling more than one existing user, you can't specify a value for this field. The alias can't exceed 64 characters and must be unique in the forest.
   - **Specify the mailbox database rather than using a database automatically selected** Select this check box to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name. Select the mailbox database you want to use, and then click **OK**. This is an optional field.
   - **Retention policy** Select this check box to specify a retention policy for the mailbox. Retention policies allow you to group one or more retention tags and apply them to mailboxes to enforce message retention settings. A mailbox can't have more than one retention policy. To learn more, see Understanding Retention Tags and Retention Policies.

     Click **Browse** to open the **Select Retention Policy** dialog box.

Use this dialog box to select the retention policy to be associated with this mailbox. This is an optional field.

- **Exchange ActiveSync mailbox policy** Select this check box to specify an Exchange ActiveSync mailbox policy for the mailbox. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. To learn more, see Understanding Exchange ActiveSync Mailbox Policies.

  Click **Browse** to open the **Select ActiveSync Mailbox Policy** dialog box. Use this dialog box to select the policy that you want associated with this mailbox. This is an optional field.
- **Address book policy** Select this check box to specify an address book policy (ABP) for the mailbox. ABPs contain a GAL, an offline address book (OAB), a room list, and a set of address lists. When assigned to mailbox users, an ABP provides them with access to a customized GAL in Outlook and Outlook Web App. To learn more, see Understanding Address Book Policies.

  Click **Browse** to open the **Select Address Book Policy** dialog box. Use this dialog box to select the policy that you want associated with this mailbox.

7. On the **Archive Settings** page, complete the following fields:

Note:
This page isn't available if you're creating a room, equipment, or linked mailbox.

- **Don't create an archive** Click this button if you don't want to create an archive for the mailbox.
- **Create a local archive** Click this button to create a personal (also known as a *local* or *on-premises* archive) for the mailbox.

  If you create a personal archive, mailbox items will be moved automatically from the primary mailbox to the archive, based on the default retention policy settings or those you define. If you click this button, the following settings are available:

  Select a specific mailbox database rather than having one selected automatically Select this check box and then click **Browse** to select a database that resides in the local forest. To learn more, see Understanding Personal Archives.
- **Create a remote hosted archive** Click this button to create a cloud-based archive. To create a cloud-based archive, you must first configure Exchange Online Archiving. For details, see Configure Exchange Online Archiving. If you've already configured Exchange Online Archiving, click **Browse** to select the domain name of the cloud-based organization. To learn more, see Understanding Exchange Online Archiving.

8. If you selected **Linked Mailbox** in Step 3, complete the following fields on the **Master Account** page. Otherwise skip to Step 9.
   - **Trusted forest or domain** Click **Browse** to open the **Select Trusted Forest or Domain** dialog box. Use this dialog box to select the forest or domain that contains the master account, and then click **OK**. This enables the **Browse** button for the **Linked domain controller** field.
   - **Use the following Windows user account to access linked domain controller** To access the domain controller in the trusted forest or domain, you can use credentials other than the ones with which you are currently logged on. If you want to specify a different user account, select this check box, and then use the **User name** and **Password** boxes to type your credentials.
   - **Linked domain controller** Click **Browse** to open the **Select Domain Controller** dialog box. Use this dialog box to select the linked domain controller that you want to use, and then click **OK**. Selecting a valid linked domain controller enables the **Browse** button for **the Linked master account** field.

- **Linked master account** Click **Browse** to open the **Select Master Account** dialog box. Use this dialog box to select the user account that you want to use as the master account for the linked mailbox, and then click **OK**.

9. On the **New Mailbox** page, review your configuration settings. To make any configuration changes, click **Back**. To create the new mailbox, click **New**.

10. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a single mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox users" entry in the Mailbox Permissions topic.

This example creates a mailbox for the user Chris Ashton with the following details:

- The mailbox's alias is Chris
- The user's first name is Chris and the last name is Ashton
- The name and display name is Chris Ashton
- The user principal name (UPN) is ChrisAshton@contoso.com
- The mailbox will be created in the Users container of the organizational unit

```
New-Mailbox -Alias chris -Name "Chris Ashton" -FirstName Chris -LastName Ashton -
```

This example creates a mailbox for the 3rd floor conference room with the following details:

- The room mailbox's alias is 3rdfloorconf
- The first name is 3rd Floor and the last name is Conference Room
- The name and display name is 3rdFloor Conference Room
- The UPN is 3rdfloorconf@contoso.com
- The mailbox will be created in the Room container of the organizational unit

```
New-Mailbox -Alias 3rdfloorconf -Name "3rd Floor Conference Room" -FirstName "3rd
```

For syntax and parameter information, see New-Mailbox.

Use the Shell to mail-enable existing users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox users" entry in the Mailbox Permissions topic.

This example mail-enables the user john@contoso.com on the database Sales

```
Enable-Mailbox john@contoso.com -Database Sales
```

You can also use the **Enable-Mailbox** cmdlet to mail-enable multiple users. You can do this by piping the results of the **Get-User** cmdlet to the **Enable-Mailbox** cmdlet. When you run the **Get-User** cmdlet, you must return only users that aren't already mail-enabled. To do this, you need specify the value User with the *RecipientTypeDetails* parameter. You can also limit the results returned by using the *Filter* parameter to request only users that meet the criteria you specify. You then pipe the results to the **Enable-Mailbox** cmdlet.

For example, this command mail-enables users who aren't already mail-enabled and that contain the text "Contoso" in the Company user field.

```
Get-User -RecipientTypeDetails User -Filter { Company -Eq 'Contoso' } | Enable-Ma
```

For syntax and parameter information, see Enable-Mailbox and Get-User.

For more information about pipelining, see Pipelining.

Use the Shell to create a linked mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox User" entry in the Mailbox Permissions topic.

When you create a linked mailbox, you must use the *LinkedMasterAccount* parameter to specify the account in the account forest. You must also use the *LinkedDomainController* parameter to specify the domain controller of the account domain you want to contact and the *LinkedCredential* parameter to specify the credentials that allow access to the account domain. For example, this command creates a mailbox for the user John Peoples and links the mailbox to John's account on the domain controller DC01fabrikam.

```
New-Mailbox -Database "Mailbox Database 1" -Name "John Peoples" -LinkedDomainCont
```

For syntax and parameter information, see New-Mailbox.

1.8.3.24.4 Create a Mailbox for an Existing User

Create a Mailbox for an Existing User

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to create a mailbox for an existing user. After you mailbox-enable an existing user on a specified Mailbox server, the user can send and receive e-mail messages.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to create a mailbox for an existing user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "User mailboxes" entry in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration**.
2. In the action pane, click **New Mailbox**.
3. On the **Introduction** page, click **User Mailbox**, and then click **Next**.
4. On the **User Type** page, click **Existing user**, and then click **Add**.
5. In **Select User**, select the user for whom you want to create a mailbox, and then click **OK**.
6. Click **Next**.

7. On the **Mailbox Settings** page, complete the following fields:
   - **Alias** Use this box to type the alias for the user mailbox. If the user logon name contains any characters that aren't valid for the alias field, they will be replaced by underscore characters (_). The alias can't exceed 64 characters and must be unique in the forest. If you're creating mailboxes for multiple existing users, this box will be unavailable and will display the following message: **An alias will be automatically generated for each new mailbox**.
   - **Specify the mailbox database rather than using a database automatically selected** Select this check box to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by server name. Select the mailbox database you want to use, and then click **OK**. This is an optional field.
   - **Managed folder mailbox policy** Select this check box to specify a managed folder mailbox policy for the mailbox. A managed folder mailbox policy is a logical grouping of managed folders. When a managed folder mailbox policy is applied to a user's mailbox, all the managed folders linked to the policy are deployed in a single operation, thereby making the deployment of messaging records management (MRM) easier. To learn more, see Understanding Managed Folders.

     Click **Browse** to open the **Select Managed Folder Mailbox Policy** dialog box. Use this dialog box to select the managed folder mailbox policy to be associated with this mailbox. This is an optional field.

     Note:
     Managed custom folders are a premium feature of MRM. Mailboxes with policies that include managed custom folders require an Exchange Server Enterprise client access license (CAL).
   - **Exchange ActiveSync mailbox policy** Select this check box to specify a Microsoft Exchange ActiveSync mailbox policy for the mailbox. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. To learn more, see Understanding Exchange ActiveSync Mailbox Policies.

     Click **Browse** to open the **Select ActiveSync Mailbox Policy** dialog box. Use this dialog box to select the policy that you want associated with this mailbox. This is an optional field.
8. On the **New Mailbox** page, review the **Configuration Summary**. This summary contains information about the options you have selected for the mailbox. To make changes to these options, click **Back**. To create the new mailbox, click **New**.
9. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a mailbox for an existing user

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "User mailboxes" entry in the Mailbox Permissions topic.

This example creates a mailbox for the existing user John in the contoso.com domain.

```
Enable-Mailbox john@contoso.com -Database "MyServer\Mailbox Database"
```

For detailed syntax and parameter information, see Enable-Mailbox.

Other Tasks

After you create a mailbox, you may want to:

- Configure Anti-Spam Features on a Mailbox
- Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder
- Configure Storage Quotas for a Mailbox
- Restrict the Number of Recipients per Message
- Configure resource mailbox settings (if this is a resource mailbox). For more information about the different configuration options on a resource mailbox, see Managing Resource Mailboxes and Scheduling.

1.8.3.24.5 Create a Linked Mailbox

Create a Linked Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A linked mailbox is a mailbox associated with an external account. The resource forest scenario is an example of when you would want to associate a mailbox with an external account. In a resource forest scenario, user objects in the Exchange forest have mailboxes, but the user objects are disabled for logon. You must associate these disabled user accounts in the Exchange forest with enabled user objects in the external accounts forest.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to create a linked mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration**.
2. In the action pane, click **New Mailbox**.
3. On the **Introduction** page, click **Linked Mailbox**, and then click **Next**.
4. On the **User Type** page, click **New User**.

   Note:

   Every mailbox must have a user account associated with it. However, the user account that will access the linked mailbox doesn't exist in the forest where Exchange is deployed. Therefore, a disabled user account that exists in the same forest as Exchange must be created and associated with each linked mailbox, which is the new user account to which this wizard page is referring.

5. Click **Next**.

6. On the **User Information** page, complete the following fields. These fields are for the disabled user account that will be associated with the linked mailbox, and not for the actual user account in the remote forest that will be accessing the mailbox:
   - **Specify the organizational unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope). If the recipient scope is set to the forest, the default value is set to the **Users** container in the Active Directory domain that contains the computer on which the Exchange Management Console is running. If the recipient scope is set to a specific domain, the **Users** container in that domain is selected by default. If the recipient scope is set to a specific OU, that OU is selected by default. To select a different OU, click **Browse** to open the **Select Organizational Unit** dialog box. This dialog box displays all OUs in the forest that are within the specified scope. Select the desired OU, and then click **OK**. To learn more about recipient scopes, see Understanding Recipient Scope.
   - **First name** Use this box to type the first name of the user. This field is optional.
   - **Initials** Use this box to type the initials of the user. This field is optional.
   - **Last name** Use this box to type the last name of the user. This field is optional.
   - **Name** Use this box to type a name for the user. This is the name that's listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must still type a name in this field. The name can't exceed 64 characters.
   - **User logon name (User Principal Name)** Use this box to type the name that the user will use to log on to the mailbox. The user logon name consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides.
   - **User logon name (pre-Windows 2000)** Use this box to type the name for the user that's compatible with the legacy versions of Microsoft Windows (prior to the release of Windows 2000 Server). This field is automatically populated based on the **User logon name (User Principal Name)** field. This field is required.
   - **Password** Use this box to type the password that the user must use to log on to his or her mailbox.

     Note:
     Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you're creating the user account.

   - **Confirm password** Use this box to confirm the password that you typed in the **Password** box.
   - **User must change password at next logon** Select this check box if you want the user to reset the password when first logging on to the mailbox. If you select this check box, at first logon, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.
7. Click **Next**.
8. On the **Mailbox Settings** page, complete the following fields:
   - **Alias** Use this box to type an alias for the mailbox. The alias can't exceed 64 characters and must be unique in the forest.
   - **Specify the mailbox database rather than using a database automatically selected** Select this check box to specify a mailbox database instead of allowing Exchange to select a database for you. Click **Browse** to open the **Select Mailbox Database** dialog box. This dialog box lists all the mailbox databases in your Exchange organization. By default, the mailbox databases are sorted by name. You can also click the title of the corresponding column to sort the databases by storage group name or

server name. Select the mailbox database you want to use, and then click **OK**. This is an optional field.

- **Managed folder mailbox policy** Select this check box to specify a managed folder mailbox policy for the mailbox. A managed folder mailbox policy is a logical grouping of managed folders. When a managed folder mailbox policy is applied to a user's mailbox, all the managed folders linked to the policy are deployed in a single operation, thereby making the deployment of messaging records management (MRM) easier. To learn more, see Understanding Managed Folders.

  Click **Browse** to open the **Select Managed Folder Mailbox Policy** dialog box. Use this dialog box to select the managed folder mailbox policy to be associated with this mailbox. This is an optional field.

  Note:
  Managed custom folders are a premium feature of MRM. Mailboxes with policies that include managed custom folders require an Exchange Server Enterprise client access license (CAL).

- **Exchange ActiveSync mailbox policy** Select this check box to specify a Microsoft Exchange ActiveSync mailbox policy for the mailbox. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. To learn more, see Understanding Exchange ActiveSync Mailbox Policies.

  Click **Browse** to open the **Select ActiveSync Mailbox Policy** dialog box. Use this dialog box to select the policy that you want associated with this mailbox. This is an optional field.

9. Click **Next**.
10. On the **Master Account** page, complete the following fields:
    - **Trusted forest or domain** Click **Browse** to open the **Select Trusted Forest or Domain** dialog box. Use this dialog box to select the forest or domain that contains the master account, and then click **OK**. This enables the **Browse** button for the **Linked domain controller** field.
    - **Use the following Windows user account to access linked domain controller** To access the domain controller in the trusted forest or domain, you can use credentials other than the ones with which you are currently logged on. If you want to specify a different user account, select this check box, and then use the **User name** and **Password** boxes to type your credentials.
    - **Linked domain controller** Click **Browse** to open the **Select Domain Controller** dialog box. Use this dialog box to select the linked domain controller that you want to use, and then click **OK**. Selecting a valid linked domain controller enables the **Browse** button for **the Linked master account** field.
    - **Linked master account** Click **Browse** to open the **Select Master Account** dialog box. Use this dialog box to select the user account that you want to use as the master account for the linked mailbox, and then click **OK**.
11. Click **Next**.
12. On the **New Mailbox** page, review the **Configuration Summary**. To change the configuration, click **Back**. To create the new linked mailbox, click **New**.
13. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
    - A status of **Completed** indicates that the wizard completed the task successfully.
    - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a linked mailbox

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example creates a linked mailbox for John Peoples. The fabrikam domain is in the accounts forest. The user account fabrikam\Admin01 is used to access the linked domain controller.

```
New-Mailbox -Database "Mailbox Database 1" -Name "John Peoples" -LinkedDomainCont
```

For detailed syntax and parameter information, see New-Mailbox.

1.8.3.24.6 Create a Remote Mailbox

Create a Remote Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the New Remote Mailbox wizard to create a mail-enabled user in your Microsoft Exchange Server 2010 on-premises organization with an associated mailbox in the cloud-based service.

A remote mailbox consists of a mail-enabled user that exists in the on-premises Active Directory and an associated mailbox that exists in the cloud-based service. When you create a new remote mailbox, the mail-enabled user is created in your on-premises Active Directory. Then, directory synchronization, if it's configured, automatically synchronizes this new user object to the cloud-based service which then converts it to a user mailbox. You can create remote mailboxes as regular user mailboxes or as resource mailboxes for meeting rooms and equipment.

Directory synchronization and mail flow should be configured correctly for a mailbox to be created in the service. Creation of the mailbox in the service isn't immediate and depends on the directory synchronization schedule.

To learn more about remote mailboxes, see Understanding Recipients.

Looking for other management tasks related to remote mailboxes? See Managing User Mailboxes.

Use the EMC to create a remote mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote mailboxes" entry in the Mailbox Permissions topic.

If you want to create remote mailboxes, you'll have to use this wizard for each remote mailbox. You can't use the wizard to create multiple remote mailboxes.

1. In the console tree, click **Recipient Configuration**.
2. In the action pane, click **New Remote Mailbox**.
3. On the **Introduction** page, select one of the following options:
   - **User Mailbox** Click this button to create a remote mailbox in the cloud-based service that is owned by a user to send and receive e-mail messages. User remote mailboxes can't be used for resource scheduling.
   - **Room Mailbox** Click this button to create a remote mailbox in the cloud-based service that will be used as a location resource for scheduling

meetings. Room remote mailboxes can be included in meeting requests as resources and can be configured to automatically process incoming requests.

- **Equipment Mailbox** Click this button to create a remote mailbox in the cloud-based service that will be used as a resource for scheduling meetings. Equipment remote mailboxes can be included in meeting requests as resources and can be configured to automatically process incoming requests.

  As a best practice, create mailboxes for shared meeting equipment, such as projectors or audio equipment, which can be moved to different meeting rooms.

4. On the **User Information** page, complete the following fields:
   - **Specify the on-premises organization unit rather than using a default one** Select this check box to select an organizational unit (OU) other than the default (which is the recipient scope).
   - **First name** Use this box to type the first name of the user. This field is optional.
   - **Initials** Use this box to type the initials of the user. This field is optional.
   - **Last name** Use this box to type the last name of the user. This field is optional.
   - **Name** Use this box to type a name for the user. This is the name that's listed in Active Directory. By default, this box is populated with the names you enter in the **First name**, **Initials**, and **Last name** boxes. If you didn't use those boxes, you must type a name in this field. The name can't exceed 64 characters.
   - **User logon name (User Principal Name)** Use this box to type the name that the user will use to log on to the remote mailbox. The user logon name consists of a user name and a suffix. Typically, the suffix is the domain name in which the user account resides. This field is required.
   - **Password** Use this box to type the password that the user must use to log on to his or her remote mailbox.

     Note:
     Make sure that the password you supply complies with the password length, complexity, and history requirements of the domain in which you are creating the user account.

   - **Confirm password** Use this box to confirm the password that you typed in the **Password** box.
   - **User must change password at next logon** Select this check box if you want the user to reset the password when they first log on to the remote mailbox.

     If you select this check box, at first logon, the new user will be prompted with a dialog box in which to change the password. The user won't be allowed to perform any tasks until the password is successfully changed.

5. On the **Archive Mailbox** page, select the **Add an archive mailbox** check box if you want to link an archive mailbox to the remote mailbox in the cloud-based service. The archive mailbox is also created in the cloud-based service. If you create an archive mailbox for the remote mailbox, mailbox items will be moved automatically from the primary user mailbox to the archive, based on the default retention policy settings or those settings that you define. To learn more, see Understanding Personal Archives.

6. On the **New Remote Mailbox** page, review your configuration settings. To make any configuration changes, click **Back**. To create the new remote mailbox, click **New**.

7. On the **Completion** page, review the following, and then click **Finish** to close

the wizard:

- A status of **Completed** indicates that the wizard completed the task successfully.
- A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to create a single remote mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote mailboxes" entry in the Mailbox Permissions topic.

This example creates a mail-enabled user in the on-premises Active Directory and an associated remote mailbox in the cloud-based service for the user Chris Ashton with the following details:

- The remote mailbox's alias is Chris.
- The user's first name is Chris and the last name is Ashton.
- The name and display name is Chris Ashton.
- The user principal name (UPN) is ChrisAshton@contoso.com.
- The mail-enabled user will be created in the Users container of the on-premises organizational unit.

```
New-RemoteMailbox -Alias chris -Name "Chris Ashton" -FirstName Chris -LastName As
```

Because the *RemoteRoutingAddress* parameter isn't specified, Exchange calculates the SMTP address of the remote mailbox in the cloud-based service automatically. This assumes mail flow has been configured between the on-premises organization and the cloud-based service. This example also assumes that directory synchronization has been configured.

This example creates a mailbox for the third floor conference room with the following details:

- The room remote mailbox's alias is 3rdfloorconf.
- The first name is 3rd Floor and the last name is Conference Room.
- The name and display name is 3rdFloor Conference Room.
- The UPN is 3rdfloorconf@contoso.com.
- The mail-enabled user will be created in the Room container of the on-premises organizational unit.

```
New-RemoteMailbox -Alias 3rdfloorconf -Name "3rdFloor Conference Room" -FirstName
```

Because the *RemoteRoutingAddress* parameter isn't specified, Exchange calculates the SMTP address of the remote mailbox in the cloud-based service automatically. This assumes mail flow has been configured between the on-premises organization and the cloud-based service. This example also assumes that directory synchronization has been configured.

Use the Shell to mail-enable existing users

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote mailboxes" entry in the Mailbox Permissions topic.

This example mail-enables the on-premises user john@contoso.com and creates an associated remote mailbox in the cloud-based service.

```
Enable-Mailbox john@contoso.com
```

You can also use the **Enable-RemoteMailbox** cmdlet to mail-enable multiple users and create their remote mailboxes in the cloud-based service. You can do this by piping the results of the **Get-User** cmdlet to the **Enable-RemoteMailbox** cmdlet. When you run the **Get-User** cmdlet, you must return only users that aren't already mail-enabled. To do this, specify the value User with the *RecipientTypeDetails* parameter. You can also limit the results returned by using the *Filter* parameter to request only users that meet the criteria you specify. You then pipe the results to the **Enable-RemoteMailbox** cmdlet.

For example, this command mail-enables users who aren't already mail-enabled and that contain the text "Contoso" in the Company user field.

```
Get-User -RecipientTypeDetails User -Filter { Company -Eq 'Contoso' } | Enable-Re
```

Because the *RemoteRoutingAddress* parameter isn't specified, Exchange calculates the SMTP address of the remote mailboxes in the cloud-based service automatically. This assumes mail flow has been configured between the on-premises organization and the cloud-based service. These examples also assume that directory synchronization has been configured.

For more information about pipelining, see Pipelining.

Other Tasks

View or Configure Remote Mailbox Properties

1.8.3.24.7 View or Configure Remote Mailbox Properties

View or Configure Remote Mailbox Properties

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Properties** dialog box to configure the settings for the remote mailboxes in your Microsoft Exchange Server 2010 organization.

A remote mailbox consists of a mail-enabled user that exists in the on-premises Active Directory and an associated mailbox that exists in the cloud-based service. When you create a new remote mailbox, the mail-enabled user is created in your on-premises Active Directory. Then, directory synchronization, if it's configured, automatically synchronizes this new user object to the cloud-based service and is converted to a user mailbox. You can create remote mailboxes as regular user mailboxes or as resource mailboxes for meeting rooms and equipment.

Directory synchronization and mail flow should be configured correctly for a mailbox to be created in the service. Creation of the mailbox in the service isn't immediate and depends on the directory synchronization schedule.

To learn more about remote mailboxes, see Understanding Recipients.

Looking for other management tasks related to remote mailboxes? See Managing User Mailboxes.

Use the EMC to view or configure remote mailbox properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote mailboxes" section in the Mailbox Permissions topic.

Properties specific to a remote mailbox are controlled by the **Set-RemoteMailbox** cmdlet. The EMC allows you to set additional properties and the permissions may vary depending upon the feature that you're configuring. The permissions listed above grant permission to edit all the properties of the **< Remote Mailbox> Properties** dialog box.

1. In the console tree, navigate to **Recipient Configuration** > **Mail Contact**.
2. In the result pane, select the remote mailbox you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to view or modify the following settings:
   - **Display name** Use this unlabeled box at the top of the page to view or change the display name.
   - **On-Premises organizational unit** This read-only field displays the on-premises organizational unit (OU) that contains the mail-enabled user.
   - **Modified** This read-only field displays the last date and time that a configuration change was made to the remote mailbox.
     Configuration changes made through any other method, such as the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.
   - **Alias** Use this text box to view or change the remote mailbox's alias. The alias can't exceed 64 characters and must be unique in the forest.
   - **Use MAPI rich text format** Select one of the following options from the corresponding list:
     Never If you select this option, messages sent to this recipient are converted to plain text.
     Always If you select this option, messages sent to this recipient are in the MAPI rich text format (RTF).
     Use Default Settings If you select this option, messages sent to this recipient are sent in either MAPI RTF or plain text, depending on the settings of the client computer from which the message is sent.
   - **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.
     After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.
   - **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**. To learn more, see Understanding Custom Attributes.

5. Use the **User Information** tab to modify the following fields.
   - **First name** Use this box to modify the recipient's first name.
   - **Initials** Use this box to modify the recipient's middle initials.
   - **Last name** Use this box to modify the recipient's last name.
   - **Name** Use this box to modify the recipient's directory name. This is the name that's listed in Active Directory.
   - **Simple display name** Use this box to modify the recipient's simple display name. The simple display name field accepts only ASCII characters.
     In Exchange 2010, the **Display name** field (located on the

General tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode.

- **Web page** Use this box to modify the recipient's Web page address.
- **Notes** Use this box to modify administrative notes about the recipient. These notes are also visible in Outlook. When a user views the recipient's properties in Outlook, the notes will be displayed on the **Phone/Notes** tab.

6. Use the **Address and Phone** tab to view or modify the following fields:
   - **Street address** Use this box to view or change the recipient's street.
   - **City** Use this box to view or change the city where the recipient is located.
   - **State/Province** Use this box to view or change the state or province where the recipient is located. You can use the **State/Province** field as a condition for dynamic distribution groups and e-mail address policies. If you plan to use this field as a condition, you must devise and follow a consistent naming convention to ensure accurate results for dynamic distribution groups and e-mail address policies.
   - **ZIP/Postal code** Use this box to view or change the ZIP code or the postal code where the recipient is located.
   - **Country/region** Use this list to view or change the country or region where the recipient is located.
   - **Business** Use this box to view or change the recipient's business phone number.
   - **Pager** Use this box to view or change the recipient's pager number.
   - **Fax** Use this box to view or change the recipient's fax number.
   - **Home** Use this box to view or change the recipient's home phone number.
   - **Mobile** Use this box to view or change the recipient's mobile phone number.

7. Use the **Organization** tab to view or change the information about the recipient's role in your organization.
   - **Title** Use this box to view or change the recipient's title.
   - **Company** Use this box to view or change the company for which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Department** Use this box to view or change the department in which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Office** Use this box to view or change the office location for the recipient.
   - **Manager** Select this check box if you want to specify this recipient's manager. By specifying the manager for each recipient in your organization, you can create a virtual organization chart that is accessible from e-mail clients such as Outlook. Click **Browse** to open the **Select Recipient User or Contact** dialog box. Select the recipient's manager, and then click **OK** to return to the property page.
   - **Direct Reports** Use this box to view the list of mailbox users and contacts that are managed by this recipient. This field is read-only and is populated automatically when this recipient is designated as a manager for another recipient.

8. Use the **Account** tab to modify the logon names for the Active Directory domain service user account that is associated with the recipient:
   - **User logon name (User Principal Name)** The user logon name consists

of a user name and a suffix. Use this box to type the user name that the user will use to log on to the Active Directory domain. The user logon name cannot exceed 1,024 characters and must be unique in the forest.

Use the corresponding drop-down list to select the suffix for this user. Typically, the suffix is the Active Directory domain name in which the user account resides. To view or change the list of available domain suffixes in your forest, use Active Directory Domains and Trusts. In the Active Directory Domains and Trusts console tree, right-click **Active Directory Domains and Trusts**, and then click **Properties**. In the property page, use the **UPN suffixes** tab to view the list of available domain suffixes in the forest.

- **User logon name (pre-Windows 2000)** Use this box to type a user name that is compatible with legacy versions of Windows (prior to the release of Windows 2000 Server). The user logon name for a version of Windows earlier than Windows 2000 Server can't exceed 20 characters and can't contain any of the following characters: **\/ [] : | <> + = ; ? , ***.

  When the user account is first created, this field is automatically populated based on the **User logon name (User Principal Name)** field.
- **User must change password at next logon** Select this check box if you want the user to change the password at next logon. The user won't be able to log on until the password is successfully changed.

9. Use the **Mail Flow Settings** tab to configure delivery options and message size or message delivery restrictions for the remote mailbox.
   - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. In this dialog box, use the **Maximum message size (in KB)** check boxes to set the maximum size for messages that can be sent and received by this recipient. Use the corresponding text boxes to type the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB. If a message larger than the specified size is sent to the recipient, the message will be returned to the sender with a descriptive error message.
   - **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

     All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.

     Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

     Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.

     No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.

     Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of

senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

10. Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

11. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the remote mailbox. You can modify the existing addresses or create additional ones. Each remote mailbox must have at least one primary STMP address that is internal to your Exchange organization and one remote routing address. The remote routing address should contain the SMTP address of the mail-enabled user's associated remote mailbox in the cloud-based service.
    - **Add** Click **Add** to add a new e-mail address for this recipient. Use the drop-down box to select from the following address types:
      SMTP Address This is the default address type. Click this button, and use the corresponding dialog box to add an SMTP address.
      Custom Address Click this button, and use the corresponding dialog box to add a custom address (for example, fax or X.400).

      Note:
      With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.
    - **Edit** Click this button to modify the selected e-mail address.
    - **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.
      This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.
      If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
    - **Set as Routing Address** Click **Set as Routing Address** to designate the selected e-mail address as the remote routing address for the recipient.

      Note:
      This button is enabled when an address other than the remote routing address is selected.
    - **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your

organization. This box is selected by default.

Use the Shell to configure remote mailbox properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Remote mailboxes" section in the Mailbox Permissions topic.

This example shows how to change the type of the Resource1 remote mailbox to `Equipment`.

```
Set-RemoteMailbox Resource1 -Type Equipment
```

This example uses the **Get-RemoteMailbox** command to find all the mailboxes in the Marketing on-premises organizational unit, and then uses the **Set-RemoteMailbox** command to configure these remote mailboxes. The custom maximum send and receive message sizes are set to 10 MB. You can use this command to configure a specific set of mailboxes to have larger or smaller message size limits than other mailboxes in the organization.

```
Get-RemoteMailbox -OnPremisesOrganizationalUnit "Marketing" | Set-RemoteMailbox -
```

This example sets the MailTip translation in French and Chinese.

```
Set-RemoteMailbox JohnD@contoso.com -MailTipTranslations ("FR: C'est la langue fr
```

1.8.3.24.8 Configure Anti-Spam Features on a Mailbox

Configure Anti-Spam Features on a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can use the Shell to configure anti-spam features on a mailbox. All messages that come into the Exchange organization from the Internet are filtered by the anti-spam agents that are enabled on the Edge Transport server. As the messages are filtered, metadata is added to the messages.

Legitimate messages that haven't been filtered are delivered to the recipient's mailbox.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Prerequisites

Before you perform these procedures, review Understanding Anti-Spam and Antivirus Functionality to confirm that you understand the general strategy for configuring all anti-spam agents so that they work together efficiently for your organization.

Use the Shell to configure anti-spam features on mailboxes

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to configure anti-spam features on mailboxes.

You use the following parameters to configure anti-spam features with the **Set-Mailbox** cmdlet:

- *AntispamBypassEnabled*
- *RequireSenderAuthenticationEnabled*
- *SCLDeleteEnabled*
- *SCLDeleteThreshold*
- *SCLJunkEnabled*
- *SCLJunkThreshold*
- *SCLQuarantineEnabled*
- *SCLQuarantineThreshold*
- *SCLRejectEnabled*
- *SCLRejectThreshold*

Note:
With the exception of the junk e-mail settings, the spam confidence level (SCL) settings on the mailbox are the same as the settings that you apply on the Content Filter agent. The content filtering settings are applied to the organization. The mailbox settings are applied to the individual mailbox user. The mailbox settings override the organization-wide content filtering settings.
The *SCLDeleteEnabled*, *SCLJunkEnabled*, *SCLQuarantineEnabled*, and *SCLRejectEnabled* parameters have three possible values: `$true`, `$false`, and `$null`. If a parameter has the value of `$true` or `$false`, that parameter overrides the settings on the Content Filter agent. If the setting is `$null`, the settings on the Content Filter agent are applied.

Use the Shell to configure anti-spam features on a single mailbox

To configure all the anti-spam settings on a mailbox, use the following syntax.

```
Set-Mailbox -Identity <MailboxIdParameter> -AntispamBypassEnabled <$true | $false
```

This example configures John Peoples' mailbox to bypass all the anti-spam filters and to have messages that meet or exceed an SCL Junk E-mail folder threshold of 5 delivered to his Junk E-mail folder in Microsoft Outlook.

```
Set-Mailbox -Identity John -AntispamBypassEnabled $true -SCLJunkEnabled $true -SC
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to configure anti-spam features on multiple mailboxes by using a piped command

To configure all the anti-spam settings on multiple mailboxes by using a piped command, use the following syntax.

```
Get-Mailbox | Set-Mailbox
```

This example enables the SCL quarantine threshold with a value of 7 on all mailboxes in the Users container in the Contoso.com domain.

```
Get-Mailbox -OrganizationalUnit Contoso.com\Users | Set-Mailbox -SCLQuarantineEna
```

For detailed syntax and parameter information, see Set-Mailbox.

Use the Shell to configure anti-spam

features for all mailboxes in your organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Anti-spam features" entry in the Transport Permissions topic.

Note:

You can't use the EMC to configure anti-spam features for all mailboxes in your organization.

To configure all the anti-spam features on multiple mailboxes by using the **Set-OrganizationConfig** cmdlet, use the following syntax.

```
Set-OrganizationConfig -SCLJunkThreshold <Int32>
```

This example sets the organization's junk e-mail threshold to 5.

```
Set-OrganizationConfig -SCLJunkThreshold 5
```

For detailed syntax and parameter information, see Set-OrganizationConfig.

1.8.3.24.9 Configure Deleted Mailbox and Disabled Personal Archive Retention

Configure Deleted Mailbox and Disabled Personal Archive Retention

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you delete a mailbox or disable a personal archive, the mailbox or archive is kept in the mailbox database for a specified period of time. When that time expires, the mailbox database maintenance permanently deletes the mailbox or personal archive. By default, mailbox databases are configured to retain mailboxes and personal archives for 30 days. Before the time expires, mailboxes and personal archives are in a disconnected state. You can reconnect them by associating them with an existing user.

For more information, see the following topics:

- Connect or Restore a Disabled Mailbox
- Connect a Disconnected Personal (On-Premises) or Cloud-Based Archive

Looking for other management tasks related to mailboxes? Check out Managing User Mailboxes.

Use the Shell to configure deleted mailbox and disabled personal archive retention

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure deleted mailbox and disabled personal archive retention.

This example changes the mailbox retention to 45 days for the mailbox database MBX01.

```
Set-MailboxDatabase -Identity MBX01 -MailboxRetention 45
```

Note:

To specify a value for the *MailboxRetention* parameter, enter it as a time span: dd.hh:mm:ss where d = days, h = hours, m = minutes, and s = seconds.

For detailed syntax and parameter information, see Set-MailboxDatabase.

1.8.3.24.10 Configure Mail Forwarding

Configure Mail Forwarding

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to configure mail forwarding for a mailbox.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to configure mail forwarding for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, right-click the mailbox for which you want to configure mail forwarding, and then click **Properties**.
3. In **<Mailbox> Properties**, on the **Mail Flow Settings** tab, click **Delivery Options**, and then click **Properties**.
4. Select the **Forward to** check box, and then click **Browse**.
5. In **Select Recipient**, select the recipient to whom you want to forward messages, and then click **OK**.

   Note:

   By default, the dialog box displays all recipients that are in the current recipient scope specified in the **Recipient Configuration** node. To learn more about the recipient scope and its impact on the recipient work center, see Understanding Recipient Scope.

6. If you want incoming messages to be delivered to the mailbox as well as to the forwarding address you specified, select the **Deliver message to both forwarding address and mailbox** check box. Clear this check box to forward all incoming messages without retaining copies in the mailbox.
7. Click **OK** to return to **<Mailbox> Properties**.

Use the Shell to configure mail forwarding for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example forwards all mail for John Smith's mailbox to sara@contoso.com.

```
Set-Mailbox -Identity "John Smith" -ForwardingAddress "sara@contoso.com"
```

This example delivers mail to John Smith's mailbox and at the same time forwards all mail for John Smith's mailbox to sara@contoso.com.

```
Set-Mailbox -Identity "John Smith" -ForwardingAddress "sara@contoso.com" -Deliver
```

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.24.11 Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder

Configure Message Size Limits for a Mailbox or a Mail-Enabled Public Folder

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to configure message size limits for a mailbox-enabled user or a mail-enabled public folder.

Keep in mind that there are other settings in an Exchange organization that determine the maximum message size a mailbox can send and receive (for example, the maximum message size configured on a Hub Transport server). To learn more about the message size restrictions in Microsoft Exchange Server 2010, including their scope and the order of precedence, see Understanding Message Size Limits.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to configure message size limits

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. For mailboxes, perform the following steps:
   1.a. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
   1.b. In the result pane, select the mailbox for which you want to configure message size limits.
   1.c. In the action pane, under the mailbox name, click **Properties**.
   1.d. In **<Mailbox User> Properties**, click the **Mail Flow Settings** tab.
   1.e. Select **Message Size Restrictions**, and then click **Properties**.

1.f.Proceed to Step 3.

2. For mail-enabled public folders, perform the following steps:
   2.a.In the console tree, click **Toolbox**.
   2.b.In the result pane, click **Public Folder Management Console**, and then in the action pane, click **Open Tool**. The Public Folder Management Console appears.
   2.c.In the console tree, expand **Default Public Folders**, and then click the public folder that you want to configure. If the public folder you want to configure is a top-level public folder, click **Default Public Folders**.
   2.d.In the result pane, select the public folder for which you want to configure message size limits.
   2.e.In the action pane, under the public folder name, click **Properties**.
   2.f.In **<Public Folder> Properties**, click the **Mail Flow Settings** tab.
   2.g.Select **Message Size Restrictions**, and then click **Properties**.
   2.h.Proceed to Step 3.
3. In the **Message Size Restrictions** dialog box, select the **Maximum message size (in KB)** check boxes to set the maximum size for messages that can be sent and received by the mailbox or public folder. Use the corresponding text boxes to type the maximum message size allowed in kilobytes (KB). The message size must be from 0 through 2,097,151 KB. If a message larger than the specified size is sent to the mailbox or public folder, the message will be returned to the sender with a descriptive error message. Click **OK** to return to the **Mail Flow Settings** tab.
4. Click **OK**.

Use the Shell to configure message size limits

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section and the "Public folders" entry in the Mailbox Permissions topic.

This example sets both the sending and receiving message sizes for the mailbox of user John Smith to 10 megabytes (MB).

```
Set-Mailbox -Identity "John Smith" -MaxSendSize 10mb -MaxReceiveSize 10mb
```

This example sets both the sending and receiving message sizes for the mail-enabled public folder Accounting Department to 10 MB.

```
Set-MailPublicFolder -Identity "\Accounting Department" -MaxSendSize 10mb -MaxRec
```

For detailed syntax and parameter information, see Set-Mailbox or Set-MailPublicFolder.

1.8.3.24.12 Configure Storage Quotas for a Mailbox

Configure Storage Quotas for a Mailbox

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) or the Exchange Management Shell to configure mailbox storage quotas for a mailbox. Storage quotas allow administrators to control the size of mailboxes and manage the growth of mailbox

databases.

Note:
Storage quotas can also be configured on a per-database basis. The quotas configured for a mailbox database apply to all mailboxes in that database, unless the mailbox is configured to not use mailbox database defaults. For details, see Configure Mailbox Database Properties.

When a mailbox size reaches or exceeds a specified storage quota limit, Exchange sends a descriptive notification to the mailbox owner.

Important:
The message associated with the **Issue warning** quota won't be sent to the user unless the value of the quota is greater than 50% of the value specified in the **Prohibit send** quota. For example, if you set the **Prohibit send** quota to 8 MB, you must set the **Issue warning** quota to at least 4 MB. If you don't, the **Issue warning** quota message won't be sent.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to configure storage quotas for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox user for whom you want to configure storage quotas.
3. In the action pane, under the mailbox user's name, click **Properties**.
4. In **<Mailbox User Name> Properties**, click the **Mailbox Settings** tab.
5. Click **Storage Quotas**, and then click **Properties**.
6. In **Storage Quotas**, clear the **Use mailbox database defaults** check box, and then complete the following fields:
   - **Issue warning at (KB)** Use this check box and use the corresponding text box to specify the maximum storage limit in kilobytes (KB) before a warning is issued to the mailbox user. The value range is from 0 through 2,147,483,647 KB. If the mailbox size reaches or exceeds the value specified, Exchange sends a warning message to the mailbox user.
   - **Prohibit send at (KB)** Use this check box and use the corresponding text box to specify a *prohibit send* limit in KB for the mailbox. The value range is from 0 through 2,147,483,647 KB. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the mailbox user from sending new messages and displays a descriptive error message.
   - **Prohibit send and receive at (KB)** Use this check box and use the corresponding text box to specify a *prohibit send and receive* limit in KB for the mailbox. The value range is from 0 through 2,147,483,647 KB. If the mailbox size reaches or exceeds the specified limit, Exchange prevents the mailbox user from sending new messages and won't deliver any new messages to the mailbox. Any messages sent to the mailbox are returned to the sender with a descriptive error message.
7. Click **OK** to return to the **Mailbox Settings** tab.
8. Click **OK**.

Use the Shell to configure storage quotas

for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example sets the warning, prohibit send, and prohibit send and receive limits for John Smith's mailbox to 200 megabytes (MB), 250 MB, and 280 MB respectively.

Note:

To make sure that the custom settings for the mailbox are used rather than the mailbox database defaults, you must set the *UseDatabaseQuotaDefaults* parameter to `$false`.

```
Set-Mailbox -Identity jsmith@contoso.com -IssueWarningQuota 209715200 -ProhibitSe
```

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.24.13 Configure User and Resource Mailbox Properties

Configure User and Resource Mailbox Properties

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-10-26*

Mailboxes are the most common recipient type used by information workers in an Exchange organization. Each mailbox is associated with an Active Directory user account. The user can use the mailbox to send and receive messages, and to store messages, appointments, tasks, notes, and documents. You can also use mailboxes for resources such as meeting rooms and equipment. Mailboxes are the primary messaging and collaboration tools for the users in your organization. To learn more about mailboxes, see Understanding Recipients.

Looking for other management tasks related to mailboxes? See Managing User Mailboxes.

What Do You Want to Do?

- Use the EMC to view or configure user mailbox properties
- Use the EMC to configure resource mailbox properties
- Use the Shell to configure user mailbox properties

Use the EMC to view or configure user mailbox properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipient Permissions" section in the Mailbox Permissions topic.

Properties specific to a mailbox user are controlled by the **Set-Mailbox** cmdlet. The EMC allows you to set additional properties and the permissions may vary depending upon the feature that you're configuring. The permissions listed above grant permission to edit all of the properties of the **< User Mailbox> Properties** dialog box.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.

2. In the result pane, select the user or resource mailbox you want to configure.
3. In the action pane, click **Properties**.

4. Use the **General** tab to view or modify the following settings:
   - **Display name** Use this unlabeled box at the top of the page to view or change the display name.
   - **Organizational unit** This read-only field displays the organizational unit (OU) that contains the user account.
   - **Last logged on by** This read-only field displays the Active Directory user that last logged on to the mailbox.

     Note:
     To obtain the information that's displayed in this field, the Exchange Management Console (EMC) queries the mailbox database that hosts the mailbox. If the EMC is unable to communicate with the Exchange store that contains the mailbox database, this field will be blank. This field will also be blank if no user has logged on to the mailbox since the Microsoft Exchange Information Store service was last started.

   - **Total items** This read-only field displays the total number of items in the mailbox.

     Note:
     To obtain the information that's displayed in this field, the EMC queries the mailbox database that hosts the mailbox. If the EMC is unable to communicate with the Exchange store that contains the mailbox database, this field will be blank.

   - **Size (KB)** This read-only field displays the total size of the mailbox in kilobytes (KB).

     Note:
     To obtain the information that's displayed in this field, the EMC queries the mailbox database that hosts the mailbox. If the EMC is unable to communicate with the Exchange store that contains the mailbox database, this field will be blank.

   - **Mailbox database** This read-only field displays the name of the storage group and mailbox database that host the mailbox.
   - **Archive database** This read-only field displays the name of the mailbox database that host the archive mailbox. If an archive doesn't exist for the mailbox, this field will be blank.
   - **Modified** This read-only field displays the last date and time that a configuration change was made to the user mailbox.
     Configuration changes made through any other method, such as the Exchange Management Shell or Active Directory Service Interfaces (ADSI) Edit, will also update this field.
   - **Alias** Use this text box to view or change the user's alias. The alias cannot exceed 64 characters and must be unique in the forest. One of the reasons why the alias must be unique is because it is used to generate the SMTP address in a default installation.
   - **Hide from Exchange address lists** Select this check box to prevent the recipient from appearing in the global address list (GAL) and other address lists that are defined in your Exchange organization.
     After you select this check box, users in your Exchange organization can still send messages to the recipient by using the e-mail address.
   - **Custom Attributes** Click this button to open the **Custom Attributes** dialog box. You can specify up to 15 custom attributes for the recipient. To specify the custom attribute values, use the corresponding boxes, and then click **OK**. To learn more, see Understanding Custom Attributes.

5. Use the **User Information** tab to modify the following fields.
   - **First name** Use this box to modify the recipient's first name.
   - **Initials** Use this box to modify the recipient's middle initials.
   - **Last name** Use this box to modify the recipient's last name.
   - **Name** Use this box to modify the recipient's directory name. This is the name that's listed in Active Directory.
   - **Simple display name** Use this box to modify the recipient's simple display name. The simple display name field accepts only ASCII characters.
     In Exchange 2010, the **Display name** field (located on the **General** tab) can contain Unicode characters. However, third-party applications and older clients may not support Unicode characters. If the system that is displaying the recipient properties doesn't support Unicode characters, you can use the simple display name. For more information about Unicode characters, see Unicode.
   - **Web page** Use this box to modify the recipient's Web page address.
   - **Notes** Use this box to modify administrative notes about the recipient.
     These notes are also visible in Outlook. When a user views the recipient's properties in Outlook, the notes will be displayed on the **Phone/Notes** tab.

6. Use the **Address and Phone** tab to view or modify the following fields:
   - **Street address** Use this box to view or change the recipient's street.
   - **City** Use this box to view or change the city where the recipient is located.
   - **State/Province** Use this box to view or change the state or province where the recipient is located.
     You can use the **State/Province** field as a condition for dynamic distribution groups and e-mail address policies. If you plan to use this field as a condition, you must devise and follow a consistent naming convention to ensure accurate results for dynamic distribution groups and e-mail address policies.
   - **ZIP/Postal code** Use this box to view or change the ZIP code or the postal code where the recipient is located.
   - **Country/region** Use this list to view or change the country or region where the recipient is located.
   - **Business** Use this box to view or change the recipient's business phone number.
   - **Pager** Use this box to view or change the recipient's pager number.
   - **Fax** Use this box to view or change the recipient's fax number.
   - **Home** Use this box to view or change the recipient's home phone number.
   - **Mobile** Use this box to view or change the recipient's mobile phone number.

7. Use the **Organization** tab to view or change the information about the recipient's role in your organization.
   - **Title** Use this box to view or change the recipient's title.
   - **Company** Use this box to view or change the company for which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Department** Use this box to view or change the department in which the recipient works. You can use this field to create recipient conditions for dynamic distribution groups, e-mail address policies, or address lists.
   - **Office** Use this box to view or change the office location for the recipient.
   - **Manager** Select this check box if you want to specify this recipient's manager. By specifying the manager for each recipient in your organization, you can create a virtual organization chart that is accessible from e-mail clients such as Outlook.
     Click **Browse** to open the **Select Recipient User or Contact** dialog box. Select the recipient's manager, and then click **OK** to

return to the property page.

- **Direct Reports** Use this box to view the list of mailbox users and contacts that are managed by this recipient. This field is read-only and is populated automatically when this recipient is designated as a manager for another recipient.

8. Use the **Account** tab to modify the logon names for the Active Directory domain service user account that is associated with the recipient:
   - **User logon name (User Principal Name)** The user logon name consists of a user name and a suffix. Use this box to type the user name that the user will use to log on to the Active Directory domain. The user logon name cannot exceed 1,024 characters and must be unique in the forest.
     Use the corresponding drop-down list to select the suffix for this user. Typically, the suffix is the Active Directory domain name in which the user account resides. To view or change the list of available domain suffixes in your forest, use Active Directory Domains and Trusts. In the Active Directory Domains and Trusts console tree, right-click **Active Directory Domains and Trusts**, and then click **Properties**. In the property page, use the **UPN suffixes** tab to view the list of available domain suffixes in the forest.
   - **User logon name (pre-Windows 2000)** Use this box to type a user name that is compatible with legacy versions of Windows (prior to the release of Windows 2000 Server). The user logon name for a version of Windows earlier than Windows 2000 Server can't exceed 20 characters and can't contain any of the following characters: **\/ [] : | <> + = ; ? , ***.
     When the user account is first created, this field is automatically populated based on the **User logon name (User Principal Name)** field.
   - **User must change password at next logon** Select this check box if you want the user to change the password at next logon. The user won't be able to log on until the password is successfully changed.

9. Use the **Mail Flow Settings** tab to configure delivery options and message size or message delivery restrictions for the mailbox.
   - **Delivery Options** Select this setting and then click **Properties** to open the **Delivery Options** dialog box. Use this dialog box to configure the following settings:
     Send on behalf Click **Add** to open the **Select Mailbox or Mail-Enabled User** dialog box. Use this dialog box to grant a recipient the permissions to send e-mail on behalf of the selected mailbox. Click  to remove a recipient from the list.
     Forward to Select this check box, and then click **Browse** to open the **Select Recipient** dialog box. Use this dialog box to select a recipient to whom you want to forward all e-mail messages that are sent to this mailbox.
     Deliver message to both forwarding address and mailbox If you selected the **Forward to** check box, you can select this check box to specify that e-mail messages be delivered to both the mailbox and to the forwarding address.
     Maximum Recipients Select this check box to limit the number of recipients to which this mailbox can send e-mail messages at one time.
   - **Message Size Restrictions** Select this setting and then click **Properties** to open the **Message Size Restrictions** dialog box. In this dialog box, use the **Maximum message size (in KB)** check boxes to set the maximum size for messages that can be sent and received by this recipient. Use the corresponding text boxes to type the maximum message size allowed (in KB). The message size must be between 0 and 2,097,151 KB. If a message larger than the specified size is sent to the recipient, the message will be

returned to the sender with a descriptive error message.

- **Message Delivery Restrictions** Select this setting and then click **Properties** to open the **Message Delivery Restrictions** dialog box. Use this dialog box to configure the following settings:

  All senders Click this button to specify that the recipient can accept messages from all senders. This includes senders in both your Exchange organization and external senders. This button is selected by default. This option includes external users only if you clear the **Require that all senders are authenticated** check box. If you select this check box, messages from external users will be rejected.

  Only senders in the following list Click this button to specify that the recipient can accept messages only from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now**.

  Require that all senders are authenticated Select this check box to prevent anonymous users from sending messages to the recipient.

  No senders Click this button to specify that the recipient will not reject messages from any senders in the Exchange organization. This button is selected by default.

  Senders in the following list Click this button to specify that the recipient will reject messages from a specified set of senders in your Exchange organization. Click **Add** to open the **Select Recipient** dialog box. This dialog box displays a list of all recipients in the Active Directory forest. Select the recipients you want, and then click **OK**. You can also search for a specific recipient by typing its name in the **Search** box and then clicking **Find Now.**

10. Use the **Mailbox Features** tab to view or modify the following mailbox features:
    - **Outlook Web App** This feature is enabled by default. Click **Disable** to disable this feature for the mailbox. Click **Properties**, and then use the corresponding property page to add an Outlook Web App mailbox policy to the user's mailbox. Outlook Web App enables access to an Exchange mailbox from a Web browser. To learn more, see Understanding Outlook Web App Mailbox Policies.
    - **Exchange ActiveSync** This feature is enabled by default. Click **Disable** to disable this feature for the mailbox. Click **Properties**, and then use the corresponding property page to apply an Exchange ActiveSync mailbox policy to the user's mailbox. Exchange ActiveSync enables access to an Exchange mailbox from a mobile device. To learn more, see Understanding Exchange ActiveSync Mailbox Policies.
    - **Unified Messaging** This feature is disabled by default. To enable Unified Messaging (UM) for the mailbox, in the EMC result pane, select the mailbox, and then, in the action pane, click **Enable Unified Messaging**. For details, see Enable a User for Unified Messaging.

      If UM is enabled, click **Properties** and use the corresponding property page to configure UM settings for the user. For details see View or Configure the Properties of a UM-Enabled User.
    - **MAPI** This feature is enabled by default. Click **Disable** to disable this feature for the mailbox. MAPI enables access to an Exchange mailbox from a MAPI client such as Outlook. There is no property page available for this feature.
    - **POP3** and **IMAP4** These features are enabled by default. Click **Disable** to

disable these features for the mailbox. Click **Properties**, and then use the corresponding property pages to specify the MIME format of messages that are retrieved from the server.

- **Archive** If an archive doesn't exist for the mailbox, this feature is disabled . To enable an archive for this mailbox, in the EMC result pane, select the mailbox and then, in the action pane, click **Enable Archive**. If an archive does exist for the mailbox, click **Properties**, and then use the corresponding property page to specify a name for the archive associated with this mailbox. For more information, see Enable a Personal (On-Premises) or Cloud-Based Archive for an Existing Mailbox.

11. Use the **Calendar Settings** tab to modify the Calendar Attendant settings for this mailbox. The Calendar Attendant processes meeting requests as they come in, even if users are not currently logged on by means of a client such as Outlook. Meetings are automatically placed on the calendar as "Tentative" so timeslots won't be overbooked. You can use the Calendar Attendant to accept and decline requests for users.

Note:
This tab isn't displayed for resource mailboxes. To configure calendar settings for resource mailboxes, see Use the EMC to configure resource mailbox properties later in this topic.

- **Enable the Calendar attendant** Select this check box to enable the Calendar Attendant or clear the check box to disable it. It is enabled by default. When Calendar Attendant is enabled, the following settings are made available:

  Remove meeting forward notifications to the Deleted Items folder If you select this check box, meeting forwarding notifications are moved to the Deleted Items folder after they are processed by the Calendar Attendant. This setting is disabled by default.

  Remove old meeting requests and responses If you select this check box, the Calendar Attendant removes old and redundant updates and responses. This setting is enabled by default.

  Mark new meeting requests as Tentative If you select this check box, incoming meeting requests are marked as "Tentative" on the calendar. If you don't select this check box, pending requests are marked as "Free". This setting is enabled by default.

  Process meeting requests and responses originating outside the Exchange organization If you select this check box, the Calendar Attendant will process meeting requests that originate outside the Exchange organization. This setting is disabled by default.

12. Use the **Member Of** tab to view a list of the groups to which this recipient belongs. Some of these groups may not be mail-enabled. Mail-enabled groups will have an envelope icon next to them. You can't use this tab to modify membership information. The recipient may match the criteria for one or more dynamic distribution groups in your organization. However, dynamic distribution groups aren't displayed on this tab because their membership is calculated each time they are used. For more information, see Managing Distribution Groups.

13. Use the **E-Mail Addresses** tab to configure the e-mail addresses for the recipient. You can modify the existing addresses or create additional ones. Each recipient must have at least one primary STMP address that is internal to your Exchange organization and one external address.

- **Add** Click **Add** to add a new e-mail address for this recipient. Use the

drop-down box to select from the following address types:

SMTP Address This is the default address type. Click this button and use the corresponding dialog box to add an SMTP address.

EUM Address This address type is available only for user mailboxes. It's not available for mail users, mail contacts, distribution groups, or mail-enabled public folders. An EUM (Exchange Unified Messaging) address is used by Unified Messaging servers to locate UM-enabled users within an Exchange 2010 organization. EUM addresses contain the extension number and the UM dial plan for the UM-enabled user. Click this button and use the corresponding dialog box to add an EUM address.

Custom Address Click this button and use the corresponding dialog box to add a custom address (for example, fax or X.400).

Note:

With the exception of X.400 addresses, Exchange doesn't validate custom addresses for proper formatting. You must make sure that the custom address you specify complies with the format requirements for that address type.

- **Edit** Click this button to modify the selected e-mail address.
-  Click this button to remove the selected e-mail address.
- **Set as Reply** Click this button to set your selected address as the "reply to" address. A recipient can have multiple e-mail addresses for a specific address type. This allows the recipient to receive messages that are addressed to any one of these e-mail addresses. However, a single address must be used for any messages that are sent by the recipient. If a recipient has multiple e-mail addresses, the primary address is used for any messages sent by the recipient.

  This button is available only when an address other than the primary address is selected. Primary addresses for each address type are displayed in bold type.

  If an e-mail address policy in your Exchange organization applies to this mailbox, the **Set as Reply** setting will be controlled by that policy. To change the primary address for a specific address type, you must clear the **Automatically update e-mail addresses based on e-mail address policy** check box.
- **Set as External** This button is available only for mail users and mail contacts. It's not available for user mailboxes, distribution groups, or mail-enabled public folders. Click **Set as External** to designate the selected e-mail address as the external e-mail address for the recipient.

  Note:

  This button is enabled when an address other than the external e-mail address is selected.
- **Automatically update e-mail addresses based on e-mail address policy** Select this check box to have the recipient's e-mail addresses automatically updated based on changes made to e-mail address policies in your organization. This box is selected by default.

14. Use the **Mailbox Settings** tab to configure the following settings for this mailbox.
    - **Messaging Records Management** Select this setting and then click **Properties** to open the **Messaging Records Management** dialog box. Use this dialog box to configure the following settings:

      Apply Retention Policy Select this check box and then click **Browse** to select a retention policy for the mailbox. To learn more about retention policies, see Understanding Retention Tags and Retention Policies.

Halt Retention Policy during this period Select this check box to place the mailbox on retention hold, and then use the **Start Date** and **End Date** settings to specify a timeframe for the retention hold. To learn more about retention holds, see Understanding Retention Tags and Retention Policies.
Enable Litigation Hold Select this check box to place the mailbox on litigation hold. Litigation hold preserves deleted mailbox items and records changes made to mailbox items. Deleted items and all instances of changed items are returned in a discovery search. To learn more about Litigation Hold, see Understanding Litigation Hold.
Messaging Records Management Description URL Use this box to enter the location of a Web page or document that contains more information about the litigation hold or retention hold policies in your organization. The URL is displayed in the Backstage area of Microsoft Outlook 2010. This makes it easier for users to access linked Help documents, and may reduce calls to your Help desk or Legal department by answering common questions.
Comments Use this field to type a comment that you want to be displayed to the mailbox user in the Backstage view of Microsoft Outlook 2010.

- **Sharing** Select this setting and then click **Properties** to open the **Sharing** dialog box. Use this dialog box to set the sharing policy for this mailbox. For more information, see Apply a Sharing Policy to Mailboxes.
- **Storage Quotas** Select this setting and then click **Properties** to open the **Storage Quotas** dialog box. Use this dialog box to set the storage quotas for this mailbox. For more information, see Configure Storage Quotas for a Mailbox.
- **Archive Quota** Select this setting and then click **Properties** to open the **Archive Quota** dialog box. Use this dialog box to set the archive quotas for this mailbox. If archiving isn't enabled for this mailbox, the **Properties** button will be unavailable. For more information, see Configure Archive Quotas for a Personal (On-Premises) Archive.
- **Role Assignment Policy** Select this setting and then click **Properties** to open the **Role Assignment Policy** dialog box. Use this dialog box to apply a role assignment policy for this user. Click **Browse** to view the available role assignment policies. For more information, see Change the Assignment Policy on a Mailbox.
- **Address book policy** Select this setting and then click **Properties** to open the **Address Book Policy** dialog box. Use this dialog box to apply an address book policy (ABP) for this mailbox. Click **Browse** to open the **Select Address Book Policy** dialog box. Use this dialog box to select the policy you want associated with this mailbox. To learn more, see Understanding Address Book Policies.

Use the EMC to configure resource mailbox properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipient Permissions" section in the Mailbox Permissions topic.

In addition to the properties listed in the previous section, resource mailboxes have specific settings that you can configure by using the EMC. For more information about how to configure resource mailboxes by using the Shell, see Configure Custom Resource Properties for a Resource Mailbox.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the resource mailbox that you want to configure.

3. In the action pane, under the name of the resource mailbox, click **Properties**.
4. Use the **Resource General** tab to configure general settings for the resource mailbox:
   - **Resource capacity** Use this box to specify the capacity of this resource. For example, if this is a room resource, specify the maximum occupancy of the room.
   - **Resource custom properties** Use this box to specify custom resource properties that can be searched by users. In Outlook, the properties appear in the **Description** column when users select the **All Rooms** address book.
   - **Enable the Resource Booking Attendant** Select this check box to allow the Resource Booking Attendant to process resource requests and cancellations automatically.

     Note:
     If you don't select this check box, the settings that you configure on the **Resource Policy** tab, the **Resource In-Policy Requests** tab, and the **Resource Out-of-Policy Requests** tab aren't enabled.
5. Use the **Resource Policy** tab to specify under which conditions the resource mailbox automatically accepts requests:
   - **Allow conflict meeting requests** Select this check box to allow conflicting meeting requests to be scheduled by the Resource Booking Attendant.
   - **Allow repeating meetings** Select this check box to allow repeating or recurring meetings to be scheduled.
   - **Allow scheduling only during working hours** Select this check box to allow scheduling for the resource to occur during working hours. Users can set working hours either by using Outlook or Outlook Web App. Administrators can set working hours by using the **Set-MailboxCalendarConfiguration** cmdlet on the resource mailbox.
   - **Reject repeating meetings that have an end date beyond the booking window** Select this check box to allow the Resource Booking Attendant to reject recurring meeting requests that are outside of the resources booking window.
   - **Booking window (days)** Use this box to specify the number of days that the room can be booked in advance. For example, if the booking window is set for 90 days and a request is received for scheduling the resource 4 months from today's date, the Resource Booking Attendant rejects the request.
   - **Maximum duration (minutes)** Use this box to specify the maximum number of minutes that the resource can be scheduled for.
   - **Maximum conflict instances** Use this box to specify the maximum number of conflicts allowed for recurring meetings. If the number of instances for a recurring meeting in conflict exceeds this number, the recurring meeting request is declined.
   - **Conflict percentage allowed** Use this box to specify the conflict percentage threshold from recurring meetings. If the percentage of instances of a recurring meeting that conflicts with other meetings exceeds the threshold, the recurring meeting request is denied.
   - **Specify delegates of this mailbox** Click **Add** to add delegates who can control the scheduling options for the resource mailbox. Click **Remove** to remove delegates from this resource mailbox.
   - **Forward meeting requests to delegates** Select this check box to forward all meeting requests to the delegates.
6. Use the **Resource Information** tab to specify the meeting information that appears in the resource's calendar:
   - **Delete attachments** Select this check box to remove attachments from all incoming requests.
   - **Delete comments** Select this check box to remove comments from all

incoming requests.

- **Delete the subject** Select this check box to remove the subject of all incoming requests.
- **Delete non-calendar items** Select this check box to remove non-calendar items from all incoming requests.
- **Add the organizer's name to the subject** Select this check box to specify whether the resource requestor's name is added to the subject of the request.
- **Remove the private flag on an accepted meeting** Select this check box to remove the private flag for all incoming requests.
- **Send organizer information when a meeting request is declined because of conflicts** Select this check box to send the meeting organizer information regarding a denied request.
- **Customize the response message that organizers will receive** Select the **Add additional text** check box to customize the message that the requester receives when the meeting has been declined, and then type the additional information in the **Additional text** field.
- **Mark pending requests as Tentative on the calendar** Select this checkbox to specify that all pending requests are marked as Tentative in the resource's calendar. The delegate can then accept or deny the request as needed.

7. Use the **Resource In-Policy Requests** tab to specify users who are allowed to submit requests within the resource policy's configuration:
   - **Specify users who are allowed to submit in-policy meeting requests that will be automatically approved** Click **All users** or **Selected recipients**. If you click **Selected recipients**, you need to click **Add** to select the recipients. You can also remove selected recipients by clicking **Remove**.
   - **Specify who can submit in-policy meeting requests that are subject to approval by a resource mailbox delegate** Click **All users** or **Selected recipients**. If you click **Selected recipients**, you need to click **Add** to select the recipients. You can also remove selected recipients by clicking **Remove**.
8. Use the **Resource Out-of-Policy Requests** tab to specify the users who are allowed to submit out-of-policy requests. Users who have permission to submit out-of-policy requests won't have their request denied, but the requests require approval by one of the resource's delegates:
   - **All users** Click this button to allow all users to submit resource requests that don't meet the resource policy's configuration.
   - **Selected recipients** Click this button to select specific users who can submit out-of-policy requests.

Use the Shell to configure user mailbox properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Provisioning Recipient Permissions" section in the Mailbox Permissions topic.

This example shows how to forward John Peoples' e-mail messages to Jose De Oliveira's (jose@contoso.com) mailbox.

```
Set-Mailbox -Identity John -DeliverToMailboxAndForward $true -ForwardingAddress j
```

This example uses the **Get-Mailbox** command to find all the mailboxes in the Marketing organizational unit, and then uses the **Set-Mailbox** command to configure these mailboxes. The custom warning, prohibit send, and prohibit send and receive limits are set to 200 megabytes (MB), 250 MB, and 280 MB respectively, and the mailbox database's default limits are ignored. This command can be used to configure a specific set of mailboxes to have larger or smaller limits than other mailboxes in the organization.

```
Get-Mailbox -OrganizationalUnit "Marketing" | Set-Mailbox -IssueWarningQuota 2097
```

This example uses the **Get-User** command to find all users in the Customer Service department, and then uses the **Set-Mailbox** command to change the maximum message size for sending messages to 2 MB.

```
Get-User -Filter "Department -eq 'Customer Service'" | Set-Mailbox -MaxSendSize 2
```

This example sets the MailTip translation in French and Chinese.

```
Set-Mailbox JohnD@contoso.com -MailTipTranslations ("FR: C'est la langue français
```

1.8.3.24.14 Convert a Mailbox

Convert a Mailbox

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

This topic explains how to use the Exchange Management Shell to convert a mailbox to a different type of mailbox. You can convert the following:

- User mailbox to shared mailbox
- User mailbox to resource mailbox
- Shared mailbox to user mailbox
- Shared mailbox to resource mailbox
- Resource mailbox to user mailbox
- Resource mailbox to shared mailbox

You can't use this procedure to convert a user mailbox to a linked mailbox or a linked mailbox to a user mailbox. For instructions about how to convert to a linked mailbox, see Convert Linked Mailboxes.

A scenario in which you may want to convert a mailbox is if you have moved resource mailboxes from Exchange Server 2003 to Exchange Server 2010. In Exchange 2003, you use shared mailboxes to represent resources. When you move these mailboxes to Exchange 2010, they will be Exchange 2010 shared mailboxes. You must convert them from Exchange 2010 shared mailboxes to Exchange 2010 resource mailboxes so that they will have all the properties of Exchange 2010 resource mailboxes.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the Shell to convert a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to convert a mailbox.

This example converts the shared mailbox ConfRoom1to a room mailbox.

```
Set-Mailbox ConfRoom1 -Type Room
```

You can use the following values for the *Type* parameter:

- Regular
- Room
- Equipment
- Shared

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.24.15 Convert Linked Mailboxes

Convert Linked Mailboxes

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A *linked mailbox* is a mailbox that's associated with an external account. The resource forest scenario is an example of when you would want to associate a mailbox with an external account. In a resource forest scenario, user objects in the Exchange forest have mailboxes, but the user objects are disabled for logon. You must associate these mailbox objects in the Exchange forest with enabled user objects in the external accounts forest.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the Shell to convert a mailbox to a linked mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to convert a mailbox to a linked mailbox.

1. To disconnect the mailbox object in the Exchange store from the user object in Active Directory, use this example.

```
Disable-Mailbox -Identity User1
```

2. To create a credential object, run the following command.

```
$cred = Get-Credential
```

   You will be prompted for credentials. Specify an account that has permissions to access the domain controller in the forest where the user account resides. Use the *LinkedDomainController* parameter to specify the domain controller. This domain controller obtains security information for the account to which you are linking the mailbox object.

3. To reconnect the mailbox object in the Exchange store to an external user object, use this example.

```
Connect-Mailbox -Identity User1 -Database "Mailbox Database" -LinkedDo
```

For detailed syntax and parameter information, see Disable-Mailbox or Connect-Mailbox.

Use the Shell to convert a linked mailbox to a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to convert a linked mailbox to a user mailbox.

This example converts Kweku's mailbox from a linked mailbox to a non-linked user mailbox by setting the *LinkedMasterAccount* parameter to `null`.

Important:
Performing this procedure on a linked mailbox removes all permissions on the mailbox, such as Send As, Full Access, folder permissions, and calendar delegation.

```
Set-User -Identity kweku@fabrikam.com -LinkedMasterAccount $null
```

For detailed syntax and parameter information, see Set-User.

1.8.3.24.16 Disable a Mailbox

Disable a Mailbox

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to disable the mailbox of an existing Active Directory user object in Microsoft Exchange Server 2010. This task removes all the Exchange attributes from the user object in Active Directory. Based on the deleted items retention policy, the Exchange store will retain mailbox data for the user object.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to disable a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox that you want to disable.
3. In the action pane, under the name of the mailbox, click **Disable**.
4. A warning appears asking, **Are you sure you want to disable 'mailbox name'?** Click **Yes** to disable the mailbox.

Use the Shell to disable a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient provisioning permissions" section in the Mailbox

Permissions topic.

This example disables the mailbox for john@contoso.com.

```
Disable-Mailbox john@contoso.com
```

For detailed syntax and parameter information, see Disable-Mailbox.

1.8.3.24.17 Enable or Disable MAPI for a User Mailbox

Enable or Disable MAPI for a User Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to enable or disable MAPI for a user mailbox.

Looking for other management tasks related to managing user mailboxes? Check out Managing User Mailboxes.

Use the EMC to enable or disable MAPI for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access user settings" entry in the Client Access Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the user mailbox for which you want to enable or disable MAPI.
3. In the action pane, under the user mailbox name, click **Properties**.
4. In **< User Mailbo > Properties**, on the **Mailbox Features** tab, click **MAPI**, and then click either **Enable** or **Disable**.
5. Click **OK**.

Use the Shell to enable or disable MAPI for a user mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Client Access user settings" entry in the Client Access Permissions topic.

This example enables MAPI for the user John.

```
Set-CASMailbox -Identity John -MAPIEnabled $true
```

This example disables MAPI for the user John.

```
Set-CASMailbox -Identity John -MAPIEnabled $false
```

For detailed syntax and parameter information, see Set-CASMailbox.

1.8.3.24.18 Remove a Mailbox

Remove a Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to remove a mailbox. When you remove a mailbox, you disconnect the mailbox from its associated user account and remove the user from Active Directory. The mailbox is retained in the mailbox database for a specified amount of time. By default, Exchange retains the disconnected mailbox for 30 days. You can reconnect the mailbox to its user account before the specified amount of time expires. For more information, see Understanding Disconnected Mailboxes.

If you want to permanently remove a mailbox, including the associated user account in Active Directory, you must use the Shell.

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the EMC to remove a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, navigate to **Recipient Configuration** > **Mailbox**.
2. In the result pane, select the mailbox you want to remove.
3. In the action pane, under the name of the mailbox, click **Remove**.
4. A warning appears asking, **Are you sure you want to remove 'mailbox name'?** Click **Yes** to remove the mailbox.

Use the Shell to remove a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example removes the mailbox for user John from John's user account and also deletes the user account.

```
Remove-Mailbox -Identity contoso\john
```

Use the Shell to permanently remove a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example permanently deletes the mailbox and the user account for John.

```
Remove-Mailbox -Identity contoso\john -Permanent
```

For detailed syntax and parameter information, see Remove-Mailbox.

1.8.3.24.19 Restrict the Number of Recipients per Message

Restrict the Number of Recipients per Message

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

You can restrict the number of recipients per message at the following levels in your Exchange organization:

- Mailbox
- Organization
- Connector (for Receive connectors only)
- Transport server

Generally, it's a best practice to configure this setting at a higher level and use the mailbox-level configuration for exceptions only. For more information about the levels at which you can configure this restriction, as well as a list of default values, see Understanding Message Size Limits.

Looking for other management tasks related to managing user mailboxes? Check out Managing User Mailboxes.

Caution:

Active Directory also has a global limit for the maximum number of recipients per message. This global limit is separate from the limits that can be managed by using the EMC or the Shell. This global limit is used in Microsoft Exchange Server 2003, but it also has an effect in Exchange Server 2010. If the global limit in Active Directory and the organization-level limit in Exchange 2010 are in conflict, the smaller of the two is used as the effective limit.
To modify the global limit in Active Directory, you must use Exchange System Manager (in Exchange 2003) or ADSI Edit.

Use the Shell to restrict the number of recipients per message for the entire Exchange organization

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:

You can't use the EMC to perform this task.

This example restricts the number of recipients per message to 1,000 for your Exchange organization.

```
Set-TransportConfig -MaxRecipientEnvelopeLimit 1000
```

For detailed syntax and parameter information, see Set-TransportConfig.

Use the Shell to restrict the number of recipients per message on a Receive connector

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Receive connectors" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

This example restricts the number of recipients per message to 300 for messages received through the Receive connector Contoso Receive Connector.

```
Set-ReceiveConnector -Identity "Contoso Receive Connector" -MaxRecipientsPerMessa
```

For detailed syntax and parameter information, see Set-ReceiveConnector.

Use the Shell to restrict the number of recipients per message on a transport server

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Hub Transport server" entry in the Transport Permissions topic.

Note:
You can't use the EMC to perform this task.

This example restricts the number of recipients per message to 200 for messages processed by the Hub Transport server Server01:

```
Set-TransportServer -Identity "Server01" -PickupDirectoryMaxRecipientsPerMessage
```

For detailed syntax and parameter information, see Set-TransportServer.

Note:
This restriction applies only to messages submitted by using the Pickup directory on an Edge Transport or Hub Transport server. For more information about the Pickup directory, see Understanding the Pickup and Replay Directories.

Use the EMC to restrict the number of recipients per message for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the mailbox for which you want to restrict the number of recipients per message.
3. In the action pane, under the mailbox name, click **Properties**.
4. In **<Mailbox> Properties**, on the **Mail Flow Settings** tab, select **Delivery Options** from the list of mail flow settings, and then click **Properties**.

5. In **Delivery Options**, select the **Maximum recipients** check box, and then, in the corresponding text box, type the maximum number of recipients that can receive a message from the mailbox.
6. Click **OK** to return to the **Mail Flow Settings** tab.

Use the Shell to restrict the number of recipients per message for a mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example restricts the number of recipients per message to 100 for the mailbox user John Smith.

```
Set-Mailbox -Identity "John Smith" -RecipientLimits 100
```

For detailed syntax and parameter information, see Set-Mailbox.

1.8.3.24.20 Update a Recipient's Address and Phone Information

Update a Recipient's Address and Phone Information

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

This topic explains how to use the Exchange Management Console (EMC) and the Exchange Management Shell to update a recipient's address and phone information. The changes you make to the recipient objects also update Active Directory and the address book.

Looking for other management tasks related to managing user mailboxes? Check out Managing User Mailboxes.

Use the EMC to update a recipient's address and phone information

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

1. In the console tree, click **Recipient Configuration**.
2. In the result pane, select the recipient you want to modify.
3. In the action pane, under the recipient's name, click **Properties**.
4. In **<Recipient> Properties**, on the **Address and Phone** tab, update the address and phone information.
5. Click **Apply**, and then click **OK**.

Use the Shell to update a recipient's address and phone information

You need to be assigned permissions before you can perform this procedure. To see what

permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example configures the phone number and address for the user john@contoso.com.

```
Set-User -Identity john@contoso.com -Phone "(425) 555-0100" -StreetAddress "4567
```

For detailed syntax and parameter information, see Set-User.

1.8.3.24.21 View Logon Statistics

View Logon Statistics

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

The **Get-LogonStatistics** cmdlet retrieves logon information so you can view users or services currently connecting to your Microsoft Exchange Server 2010 servers. Logon statistics include information such as user name, logon time, last access time, and client version.

When you run the cmdlet from a Mailbox server, you don't have to use any parameters. In this case, the cmdlet returns the logon statistics for all mailboxes on all databases on the local server.

Note:

Users who log on to their mailboxes using Microsoft Office Outlook Web App aren't connected continuously to the Mailbox server. An Outlook Web App client connects to the server, performs tasks, and then disconnects from the server. Therefore, you may see few or no logon statistics for Outlook Web App, even if users are logged on to the client.

Because the **Get-LogonStatistics** cmdlet provides a quick snapshot of the connections to Exchange at one specific time, you may want to create a script that runs in Windows Task Scheduler to capture additional data, so you can analyze server and database usage over a specified period of time.

Note:

Running the **Get-LogonStatistics** cmdlet too often may significantly affect the CPU load on the Client Access server.

For more information, see the following topics:

- Scripting with the Exchange Management Shell
- Task Scheduler Overview

Looking for other management tasks related to user mailboxes? Check out Managing User Mailboxes.

Use the Shell to view logon statistics

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to view logon statistics.

This example returns logon statistics for all users connected to the server MBXSVR01.

```
Get-LogonStatistics -Server MBXSVR01
```

This example returns logon statistics for a specific user with the SMTP address tony@contoso.com.

```
Get-LogonStatistics -Identity tony@contoso.com
```

This example returns logon statistics for all users who reside on the mailbox database MDB01.

```
Get-LogonStatistics -Database MDB01
```

This example returns all logon statistics for all processes and mailboxes currently logged on and groups the statistics by the session ID.

```
Get-LogonStatistics | Group SessionId
```

For detailed syntax and parameter information, see Get-LogonStatistics.

Logon Statistics Output

By default, the **Get-LogonStatistics** cmdlet returns the `UserName`, `ServerName`, `LogonTime`, and `LastAccessTime` values for each user or process that has logon statistics. The following table lists the information returned if you pipeline the output of the **Get-LogonStatistics** cmdlet to the **Format-List** cmdlet.

Logon statistics output

Value	Description
`AdapterSpeed`	This value is always blank.
`ApplicationId`	This value specifies the type of client application making the connection.
`ClientIPAddress`	If provided by the client application, this value specifies the IP address of the client computer from which the user or service is accessing Exchange.
`ClientMode`	This value is always `ExchangeServer`, because the client application connects through the Microsoft Exchange RPC Client Access service or some other Exchange service.
`ClientName`	This value specifies the name of the Exchange server initiating the connection.
`ClientVersion`	This value specifies the version of the client application accessing Exchange.
`CodePage`	This value specifies the code page that the client application is using to log on. For more information, see Code Pages.
`CurrentOpenAttachments`	This value specifies how many open attachments there were when the **Get-LogonStatistics** cmdlet was run.
`CurrentOpenFolders`	This value specifies how many open folders

	there were when the **Get-LogonStatistics** cmdlet was run.
CurrentOpenMessages	This value specifies how many open messages there were when the **Get-LogonStatistics** cmdlet was run.
DatabaseName	This value specifies the name of the mailbox database in which the mailbox resides.
FolderOperationCount	This value is always 0.
FullMailboxDirectoryName	This value specifies the full name of the mailbox directory.
FullUserDirectoryName	This value specifies the full user directory name of the account to which this mailbox belongs.
HostAddress	If provided by the client application, this value specifies the IP address of the host server from which the user or service is accessing Exchange.
Identity	This value specifies the distinguished name of the mailbox or service connecting to Exchange.
IsValid	This value specifies whether the command was valid.
LastAccessTime	This value specifies the last time an action was performed using that logon.
Latency	This value is always 0.
LocaleID	This value specifies the language locale of the mailbox.
LogonTime	This value specifies the time and date at which the user or service created the specific logon.
MACAddress	If provided by the client application, this value specifies the MAC address of the network node from which the user or service logged on to Exchange.
MapiIdentity	This value specifies the distinguished name of the mailbox or service connecting to Exchange.
MessagingOperationCount	This value is always 0.
OriginatingServer	This value specifies the fully qualified domain name (FQDN) of the server.
ProgressOperationCount	This value is always 0.
RPCCallsSucceeded	This value is always 0.
ServerName	This value specifies the name of the server

	on which the mailbox resides.
SessionID	This value specifies the unique identity of the session used to identify logons that come from the same session.
StreamOperationCount	This value is always 0.
TableOperationCount	This value is always 0.
TotalOperationCount	This value is always 0.
TransferOperationCount	This value is always 0.
UserName	This value specifies the user name of the mailbox.
Windows2000Account	This value specifies the user name of the account accessing the mailbox. For example, if the mailbox user shared a calendar with other users, this value specifies the name of the users who logged on to view the calendar.

1.8.3.24.22 Managing Disconnected Mailboxes

Managing Disconnected Mailboxes

Mailbox > Managing Mailbox Servers > Managing User Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-11-16*

1.8.3.24.22.1 Connect or Restore a Disabled Mailbox

Connect or Restore a Disabled Mailbox

Managing Mailbox Servers > Managing User Mailboxes > Managing Disconnected Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

A *disconnected mailbox* is a mailbox object in the Exchange store that isn't associated with an Active Directory user account.

There are two types of disconnected mailboxes:

- **Disabled mailboxes** When a mailbox is disconnected or removed by using the **Disable-Mailbox** or **Remove-Mailbox** cmdlet, Exchange retains the deleted mailbox, and the mailbox is switched to a disabled state. With disabled mailboxes, you can recover mailbox data without having to restore the entire mailbox database. Disabled mailboxes are retained in the mailbox database until the deleted mailbox retention period expires or until the mailbox is permanently deleted.
- **Soft-deleted mailboxes** When mailboxes are moved from a Microsoft Exchange Server 2010 Service Pack 1 (SP1) database to any other database, Exchange doesn't fully delete the mailbox from the source database upon completion of the move. Instead, the mailbox in the source mailbox database is switched to a *soft-deleted* state. With soft-deleted mailboxes, you can use the **MailboxRestoreRequest** cmdlet set to access mailbox data during a mailbox restore operation. Soft-deleted mailboxes are retained in the source database until either the deleted mailbox retention period expires or until the **Remove-StoreMailbox** cmdlet is used to purge the mailbox. For more information, see Restore a Soft-Deleted Mailbox.

Disabled mailboxes remain in the Exchange database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disabled mailboxes are retained for 30 days. During this retention period, a disabled mailbox can be recovered by connecting it to a new or existing Active Directory user account.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

What Do You Want to Do?

- Use the EMC to connect a disabled mailbox
- Use the Shell to connect a disabled mailbox
- Use the Shell to restore a disabled mailbox

Use the EMC to connect a disabled mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

Only disconnected mailboxes that have a disabled status are displayed in the EMC. Soft-deleted mailboxes aren't displayed.

1. In the console tree, navigate to **Recipient Configuration** > **Disconnected Mailbox**.
2. In the result pane, select the disabled mailbox that you want to reconnect.
3. In the action pane, click **Connect**.
4. On the **Introduction** page, select one of the following to specify the mailbox type for the mailbox you're connecting:

- **User Mailbox** Click this button to connect the mailbox as a mailbox owned by a user to send and receive e-mail messages. User mailboxes can't be used for resource scheduling.

  The Active Directory account associated with a user mailbox must reside in the same forest as the Exchange server. To use an account in a trusted forest, select **Linked Mailbox**.
- **Room Mailbox** or **Equipment Mailbox** Click one of these buttons to connect the mailbox as a mailbox that will be used as a location resource for scheduling meetings (room mailbox) or a shared resource (equipment mailbox) that isn't location specific. Room and equipment mailboxes can be included in meeting requests as resources and can be configured to automatically process incoming requests.

  Note:
  You can connect a room or equipment mailbox only to a disabled user account. Therefore, the **Select Recipient** dialog box that you use to select a user account on the **Mailbox Settings** page of this wizard will display only a list of disabled user accounts in the Active Directory forest.
- **Linked Mailbox** Click this button to connect the mailbox as a user mailbox that's accessed by a user in a separate, trusted forest. To store the mailbox information, you must select a user account in the forest in which the Exchange server resides.

  Linked mailboxes might be required for organizations that choose to deploy Exchange in a resource forest. Using the resource forest scenario, you can centralize Exchange in a single forest, while allowing access to the Exchange organization with user accounts in one or more trusted forests.

5. On the **Mailbox Settings** page, configure the following settings:
   - **Matching User** Click this button to have Exchange locate a matching user object in Active Directory. Click **Browse** to open the **Select User** dialog box. If Exchange locates a matching user, it will appear in this dialog box. Select the user, and then click **OK**.

     If Exchange can't find a matching user, you must click **Existing User**. To locate a user account that matches the mailbox object, Exchange uses the **LegacyExchangeDN** and **DisplayName** attributes of the Exchange store mailbox object.
   - **Existing User** Click this button if you want to connect the mailbox to a user other than the matching user. Click **Browse** to see a list of users available in Active Directory. The list contains only users that don't have an associated mailbox.

     Note:
     If you're connecting a room, equipment, or linked mailbox, the **Select User** dialog box displays only users that are disabled in Active Directory. If you're connecting a user mailbox, the **Select User** dialog box displays only users that are enabled in Active Directory.
   - **Alias** Use this box to type an alias for the mailbox.
   - **Retention Policy** Select this check box to assign a retention policy to the mailbox. Click **Browse** to select a policy from a list of available retention policies. For more information, see Understanding Messaging Records Management.
   - **Exchange ActiveSync mailbox policy** Select this check box to assign a Microsoft Exchange ActiveSync policy to the mailbox. Click **Browse** to select a policy from a list of available Exchange ActiveSync policies. For more information, see Understanding Exchange ActiveSync Mailbox Policies.

6. If you're connecting a linked mailbox, use the **Master Account** page to

configure the following settings for the mailbox:

- **Trusted forest or domain** Click **Browse** to open the **Select Forest** dialog box. Select the forest that contains the master account, and then click **OK**. This enables the **Browse** button next to the **Linked domain controller** check box.
- **Use the following Window user account to access linked domain controller** Select this check box if you want to specify a different user account. To access the domain controller in the linked forest, you can use a user account other than the one you're currently logged on as. Select the **User name** and **Password** check boxes to type the credentials of the user account.
- **Linked domain controller** Click **Browse** to open the **Select Domain Controller** dialog box. Select the domain controller you want, and then click **OK**. Selecting a valid linked domain controller enables the **Browse** button next to the **Linked master account** check box.
- **Linked master account** Click **Browse** to open the **Select Master Account** dialog box. Select the user account that you want to use as the master account, and then click **OK**.

7. On the **Connect Mailbox** page, review your configuration settings. Click **Connect** to associate the disconnected mailbox with the Active Directory user that you selected on the **Mailbox Settings** page. Click **Back** to make configuration changes.

8. On the **Completion** page, review the following, and then click **Finish** to close the wizard:
   - A status of **Completed** indicates that the wizard completed the task successfully.
   - A status of **Failed** indicates that the task wasn't completed. If the task fails, review the summary for an explanation, and then click **Back** to make any configuration changes.

Use the Shell to connect a disabled mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example connects the mailbox for John Evans that resides on the mailbox database MBXDB02. In addition, this command bypasses the messaging records management (MRM) policy warnings for e-mail clients using versions of Microsoft Outlook earlier than Microsoft Office Outlook 2007.

```
Connect-Mailbox -Identity "John Evans" -Database "MBXDB02" -User "John Evans" -Ma
```

This example connects a linked mailbox.

```
Connect-Mailbox -Identity "John Evans" -Database "MBXDB02" -LinkedDomainControlle
```

This example connects an equipment mailbox for CAR001 that resides on the database MBXResourceDB.

```
Connect-Mailbox -Identity "CAR001" -Database "MBXResourceDB" -Equipment -User "CA
```

This example connects a room mailbox for a conference room (ConfRm212) that resides on the database MBXResourceDB.

```
Connect-Mailbox -Identity "ConfRm212" -Database "MBXResourceDB" -Room -User "Conf
```

For detailed syntax and parameter information, see Connect-Mailbox.

Use the Shell to restore a disabled mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to restore a disabled mailbox.

Note:
To create a restore request, you must use the `DisplayName`, `LegacyDN`, or `MailboxGUID` values to identify the disabled mailbox.

1. Use the **Get-MailboxStatistics** cmdlet to find the display name, legacy distinguished name (DN), or mailbox GUID of the disabled mailbox. This example returns the `LegacyDN`, `DisplayName`, `MailboxGUID`, and `DisconnectReason` values for all mailboxes on mailbox database MBD01 that have a disconnect reason of `Disabled`.

```
Get-MailboxStatistics -Database MBD01 | Where { $_.DisconnectReason -e
```

2. Use the **New-MailboxRestoreRequest** cmdlet to create the restore request. This example restores the disabled mailbox that has the mailbox GUID 1d20855f-fd54-4681-98e6-e249f7326ddd on mailbox database MDB01 to the target mailbox Ayla. This example assumes that the legacy DN of the target mailbox matches the legacy DN of the source mailbox.

```
New-MailboxRestoreRequest -SourceDatabase "MDB01" -SourceStoreMailbox
```

   This example restores the disabled mailbox Tony Smith to the target mailbox tony@contoso.com on the target mailbox database MDB01. The *AllowLegacyDNMismatch* parameter is used so the source mailbox can be restored to a mailbox that doesn't have the same legacy DN value.

```
New-MailboxRestoreRequst -SourceDatabase "MDB01" -SourceStoreMailbox "
```

For detailed syntax and parameter information, see the following topics:

- Get-MailboxStatistics
- New-MailboxRestoreRequest

Other Tasks

After the mailbox is connected, we recommend that you configure anti-spam features. For detailed steps, see Configure Anti-Spam Features on a Mailbox.

1.8.3.24.22.2 Restore a Soft-Deleted Mailbox

Restore a Soft-Deleted Mailbox

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

A disconnected mailbox is a mailbox object in the Exchange store that isn't associated with an Active Directory user account. Disconnected mailboxes remain in the Exchange database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disconnected mailboxes are retained for 30 days. During this retention period, a mailbox can be recovered by connecting it to a new or existing Active Directory user account.

There are two types of disconnected mailboxes:

- **Soft-deleted mailboxes** When mailboxes are moved from a Microsoft Exchange Server 2010 Service Pack 1 (SP1) database to any other database, Exchange doesn't fully delete the mailbox from the source database upon completion of the move. Instead, the mailbox in the source mailbox database is switched to a *soft-deleted* state. With soft-deleted mailboxes, you can use the **MailboxRestoreRequest** cmdlet set to access mailbox data during a mailbox restore operation. Soft-deleted mailboxes are retained in the source database until either the deleted mailbox retention period expires or until the **Remove-StoreMailbox** cmdlet is used to purge the mailbox.
- **Disabled mailboxes** When a mailbox is disconnected or removed using the **Disable-Mailbox** or **Remove-Mailbox** cmdlet, Exchange retains the deleted mailbox, and the mailbox is switched to a disabled state. With disabled mailboxes, you can recover mailbox data without having to restore the entire mailbox database. Disabled mailboxes are retained in the mailbox database until the deleted mailbox retention period expires or until the mailbox is permanently deleted. For more information, see Connect or Restore a Disabled Mailbox.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to restore a soft-deleted mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to restore a soft-deleted mailbox.

Note:
To create a restore request, you must use the `DisplayName`, `LegacyDN`, or `MailboxGUID` values to identify the soft-deleted mailbox.

1. Use the **Get-MailboxStatistics** cmdlet to find the display name, legacy distinguished name (DN), or mailbox GUID of the soft-deleted mailbox. This example returns the `DisplayName`, `LegacyDN`, `MailboxGUID`, and `DisconnectReason` values for all mailboxes on mailbox database MBD01 that have a disconnect reason of `SoftDeleted`.

```
Get-MailboxStatistics -Database MBD01 | Where { $_.DisconnectReason -e
```

2. Use the **New-MailboxRestoreRequest** cmdlet to create the restore request. This example restores the source mailbox that has the display name Ayla on mailbox database MBD01 to Ayla's mailbox.

```
New-MailboxRestoreRequest -SourceDatabase "MBD01" -SourceStoreMailbox
```

For detailed syntax and parameter information, see Get-MailboxStatistics or New-MailboxRestoreRequest.

Use the Shell to restore a soft-deleted mailbox to a user's archive mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:
You can't use the EMC to restore a soft-deleted mailbox to a user's archive mailbox.

This example restores the source mailbox that has the mailbox GUID 1d20855f-fd54-4681-98e6-e249f7326ddd on mailbox database MBD01 to Tony's archive mailbox.

```
New-MailboxRestoreRequest -SourceDatabase "MBD01" -SourceStoreMailbox 1d20855f-fd
```

For detailed syntax and parameter information, see New-MailboxRestoreRequest.

Other Tasks

After you initiate the restore request, you may also want to:

- View Restore Request Properties and Statistics
- Remove a Restore Request

1.8.3.24.22.3 View Restore Request Properties and Statistics

View Restore Request Properties and Statistics

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Mailbox restore requests are used to restore disconnected mailboxes. A disconnected mailbox is a mailbox object in the Exchange store that isn't associated with an Active Directory user account. Disconnected mailboxes remain in the Exchange database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disconnected mailboxes are retained for 30 days. During this retention period, a mailbox can be recovered by connecting it to a new or existing Active Directory user account.

You can view the properties of a mailbox restore request, or you can view the statistics. The properties provide you with basic information about the status of a mailbox restore request. The statistics provide you with detailed information that can be used for troubleshooting purposes.

The search criteria for the **Get-MailboxRestoreRequest** and **Get-MailboxRestoreRequestStatistics** cmdlets is a Boolean **And** statement. If you use multiple parameters, you can narrow your search and reduce your search results.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to view mailbox restore request properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailboxes" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to view mailbox restore request properties.

This example returns the status of the restore request Ayla\MailboxRestore using the *Identity* parameter.

```
Get-MailboxRestoreRequest -Identity "Ayla\MailboxRestore"
```

This example returns additional information about the status of the second restore request for the target mailbox with the display name Kweku by pipelining the command to the **Format-List** cmdlet.

```
Get-MailboxRestoreRequest -Identity "Kweku\MailboxRestore1" | Format-List
```

This example returns the status of restore requests being restored from the source database MBD01.

```
Get-MailboxRestoreRequest -SourceDatabase MBD01
```

This example returns all restore requests named RestoreToMBD01 that have been suspended.

```
Get-MailboxRestoreRequest -Name "RestoreToMBD01" -Suspend $true
```

For detailed syntax and parameter information, see Get-MailboxRestoreRequest.

Get-MailboxRestoreRequest Output

Be default, the **Get-MailboxRestoreRequest** cmdlet returns the name of the request, the target mailbox to which data is being restored, and the status of the request. The following table lists the information returned if you pipeline the cmdlet to the **Format-List** cmdlet.

Value	Description
SourceDatabase	Specifies the database that contains the disconnected mailbox being restored.
TargetDatabase	Specifies the database that contains the mailbox or archive to which the mailbox is being restored.
TargetMailbox	Specifies the mailbox into which data is being restored.
Name	Specifies the name of the request.
RequestGuid	Specifies the GUID of the request.
RequestQueue	Specifies the database on which the Microsoft Exchange Mailbox Replication service (MRS) stores the detailed status of the request.
Flags	Specifies flags that the cmdlet automatically

	sets when creating the request.
BatchName	Specifies a batch name. If you didn't provide a batch name, this field is blank.
Status	Specifies the status of the request.
Suspend	Specifies whether the request was created to be automatically suspended before completion.
Direction	Specifies whether the request is a push or a pull. For mailbox restore requests, this value is always Pull.
RequestStyle	Specifies whether the request is IntraOrg or CrossOrg. For Microsoft Exchange Server 2010 Service Pack 1 (SP1), this value is always IntraOrg.
OrganizationID	If the request is performed in a multi-tenant organization, this value specifies the identity of the organization on which the request is performed.
Identity	Specifies the identity of the request. This identity is a combination of the target mailbox name and the request name.
IsValid	Specifies whether the mailbox restore request is valid.

Use the Shell to view mailbox restore request statistics

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailboxes" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to view mailbox restore request statistics.

This example returns the default statistics for the restore request Tony\MailboxRestore1. By default, the information returned includes name, mailbox, status, and percentage complete.

```
Get-MailboxRestoreRequestStatistics -Identity Tony\MailboxRestore1
```

This example returns the statistics for Tony Smith's mailbox and exports the report to a .csv file.

```
Get-MailboxRestoreRequestStatistics -Identity Tony\MailboxRestore | Export-CSV \\
```

This example returns additional information about the restore request for Tony Smith's mailbox using the *IncludeReport* parameter and pipelining the results to the **Format-List** cmdlet.

```
Get-MailboxRestoreRequestStatistics -Identity Tony\MailboxRestore -IncludeReport
```

This example returns default statistics for a restore request being processed by the

instance of MRS running on the Client Access server CAS01. This command returns only information for restore requests currently being processed by an instance of MRS. If the Client Access server is finished processing all restore requests, no information is returned. This command is for debugging purposes and should only be performed if requested by support personnel.

```
Get-MailboxRestoreRequestStatistics -MRSInstance CAS01.contoso.com
```

This example returns additional information for all restore requests that have a status of `Failed` using the *IncludeReport* parameter, and then saves the information to the file AllRestoreReports.txt in the location where the command is being run.

```
Get-MailboxRestoreRequest -Status Failed | Get-MailboxRestoreRequestStatistics -I
```

For detailed syntax and parameter information, see Get-MailboxRestoreRequestStatistics and Get-MailboxRestoreRequest.

Get-MailboxRestoreRequestStatistics Output

By default, the Get-MailboxRestoreRequestStatistics cmdlet returns the name of the request, the status of the request, the alias of the target mailbox, and the percentage completed. The following table lists the information returned if you pipeline the cmdlet to the **Format-List** cmdlet.

Value	Description
`Name`	Specifies the name of the request.
`Status`	Specifies the status of the request.
`StatusDetail`	Specifies more details about the request status. For example, if the `Status` value returns `InProgress`, the `StatusDetail` value would return the specific stages for the `InProgress` status, such as `CreatingFolderHierarchy` and `CopyingMessages`.
`SyncStage`	Specifies how far along the request is through the restore process.
`Flags`	Specifies flags that the cmdlet automatically sets when creating the mailbox restore request.
`RequestStyle`	Specifies whether the request is `IntraOrg` or `CrossOrg`. For Exchange 2010 SP1, this value is always `IntraOrg`.
`Direction`	Specifies whether the request is a push or a pull. For mailbox restore requests, this value is always `Pull`.
`Protect`	Reserved for Microsoft internal use only.
`Suspend`	Specifies whether the restore request is suspended. This value is `true` in the following scenarios: • MRS stopped or is in the process of stopping the request due to a failure. • An administrator suspended the request.
`SourceExchangeGuid`	Specifies the GUID of the source mailbox from which data is being restored.

SourceRootFolder	Specifies the name of the root folder in the source mailbox's hierarchy from which data is being restored. If this value is blank, data is restored from the folder Top of Information Store.
SourceVersion	Specifies the version of Exchange running on the database in which the source mailbox is located.
SourceDatabase	Specifies the name of the database on which the source mailbox is located.
MailboxRestoreFlags	Specifies that the mailbox being restored is either Disabled or Soft-Deleted.
TargetAlias	Specifies the alias of the target mailbox.
TargetIsArchive	Specifies whether the mailbox is being restored into an archive.
TargetExchangeGuid	Specifies the GUID of the target mailbox or archive.
TargetRootFolder	Specifies the name of the root folder in the mailbox's or archive's hierarchy to which data is being restored. If this value is blank, data is restored to the folder Top of Information Store.
TargetVersion	Specifies the version of Exchange running on the Mailbox server on which the target database is mounted.
TargetDatabase	Specifies the name of the database on which the target mailbox is located.
TargetMailboxIdentity	Specifies the identity of the target mailbox.
IncludeFolders	Specifies the list of folders to include during the restore. If this value is blank, no folders were specified when the request was created, and all folders will be restored to the mailbox or archive (unless the *ExcludeFolders* parameter is used to exclude specific folders).
ExcludeFolders	Specifies the list of folders to exclude during the restore. If this value is blank, no folders were specified when the request was created, and all folders will be restored to the mailbox or archive (unless the *IncludeFolders* parameter is used to include specific folders).
ExcludeDumpster	Specifies whether the Recoverable Items folder was excluded when the request was created.
ConflictResolutionOption	Specifies the action for MRS to take if there are matching messages in the target and source folders.
AssociatedMessagesCopyOption	Specifies whether the associated messages are copied when the request is processed. Associated messages are special messages that contain hidden data with information about rules, views, and forms.

BatchName	Specifies a batch name. If you don't provide a batch name, this field is blank.
BadItemLimit	Specifies the number of bad items that MRS will skip if the request encounters corrupted messages.
BadItemsEncountered	Specifies the number of corrupted messages encountered by the command. If the *BadItemsEncountered* value is greater than the *BadItemLimit* value, the request fails.
QueuedTimeStamp	Specifies the date and time at which the request was initiated to MRS.
StartTimeStamp	Specifies the date and time at which the restore request started being processed by MRS.
LastUpdateTimeStamp	Specifies the date and time at which the last change was made to the request. The change may have been made by an administrator or by MRS.
SuspendTimeStamp	Specifies the date and time at which the request was suspended.
OverallDuration	Specifies the amount of time it took to complete the request. If the request is in a `Failed` state, this value specifies the amount of time between the request being initiated and the request failing. If the request isn't complete, this value specifies the amount of time between the request being initiated and the **Get-MailboxRestoreRequestStatistics** cmdlet being run.
TotalSuspendedDuration	Specifies the amount of time the request was in the `Suspended` state.
TotalFailedDuration	Specifies the amount of time the request was in the `Failed` state.
TotalQueuedDuration	Specifies the amount of time the request was in the `Queued` state.
TotalInProgressDuration	Specifies the amount of time the request was in the `In Progress` state.
TotalStalledDueToHADuration	Specifies the amount of time the request was stalled due to high availability.
MRSServerName	Specifies the name of the Client Access server that processed the request.
EstimatedTransferSize	Specifies the file size that was restored or the file size that MRS expects to restore if the request is in the `In Progress` state.
EstimatedTransferItemCount	Specifies the number of items that were restored or the number of items that MRS expects to restore if the request is in the `In Progress` state.
BytesTransferred	Specifies the total number of bytes that have been

	transferred.
BytesTransferredPerMinute	Specifies the average number of bytes that have been transferred per minute.
ItemsTransferred	Specifies the number of items that have been transferred.
PercentComplete	Specifies the percentage of the request that has been completed.
PositionInQueue	If the request hasn't started, this value specifies the request's position in the queue.
FailureCode	If there is a failure, this value specifies the failure code.
FailureType	If there is a failure, this value specifies the failure type.
FailureSide	If there is a failure, this value specifies whether the failure occurred on the target mailbox or the source mailbox.
Message	If there is a failure, this value specifies the failure message. This value can also specify the suspend comment.
FailureTimestamp	If the request failed, this value specifies the date and time at which the request failed.
FailureContext	If the request failed, this value specifies information about the action being performed at the time of failure.
IsValid	Specifies whether the request was valid.
ValidationMessage	If the request isn't valid, this value specifies the reason.
OrganizationID	If the request is performed in a multi-tenant organization, this value specifies the identity of the organization in which the request is performed.
RequestGuid	Specifies the GUID of the request.
RequestQueue	Specifies the database on which MRS stores the detailed status of the request.
Identity	Specifies the identity of the request.
Report	If you used the *IncludeReport* parameter, this value specifies information that can be used to troubleshoot the request.

1.8.3.24.22.4 Configure Restore Request Properties

Configure Restore Request Properties

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Mailbox restore requests are used to restore disconnected mailboxes. A disconnected mailbox is a mailbox object in the Exchange store that isn't associated with an Active Directory user account. Disconnected mailboxes remain in the Exchange database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disconnected mailboxes are retained for 30 days.

If a restore request fails, you can change the request's properties to recover from the failure.

Looking for other management tasks related to disconnected mailboxes or restore requests? Check out Managing Disconnected Mailboxes.

Use the Shell to configure restore request properties

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailboxes" entry in the Mailbox Permissions topic.

Note:

You can't use the EMC to configure restore request properties.

This example specifies that the restore request MailboxRestore1 for Ayla's mailbox skips 10 corrupted mailbox items.

```
Set-MailboxRestoreRequest -Identity "Ayla\MailboxRestore1" -BadItemLimit 10
```

This example specifies that the restore request MailboxRestore1 for Kweku's mailbox skips 100 corrupted items. Because the *BadItemLimit* value is greater than 50, the *AcceptLargeDataLoss* parameter must be specified.

```
Set-MailboxRestoreRequest -Identity "Kweku\MailboxRestore1" -BadItemLimit 100 -Ac
```

For detailed syntax and parameter information, see Set-MailboxRestoreRequest.

Other Tasks

After you configure the restore request's settings, you may also want to resume the restore request. For details, see Resume a Restore Request.

1.8.3.24.22.5 Suspend a Restore Request

Suspend a Restore Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

You can suspend a restore request any time after the request was created but before the request reaches the status of `Completed`. You can resume the restore request using the Resume-MailboxRestoreRequest cmdlet.

Looking for other management tasks related to restore requests or disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to suspend a restore request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailboxes" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to suspend a restore request.

This example suspends the restore request MailboxRestore1 for Ayla's mailbox.

```
Suspend-MailboxRestoreRequest -Identity Ayla\MailboxRestore1
```

This example suspends all restore requests in progress by first retrieving all requests that have a status of `InProgress`, and then pipelining output to the **Suspend-MailboxRestoreRequest** cmdlet and including the suspend comment "Resume after 10:00 PM."

```
Get-MailboxRestoreRequest -Status InProgress | Suspend-MailboxRestoreRequest -Sus
```

For detailed syntax and parameter information, see Suspend-MailboxRestoreRequest and Get-MailboxRestoreRequest.

Other Tasks

After you suspend a restore request, you may also want to resume the request. For details, see Resume a Restore Request.

1.8.3.24.22.6 Resume a Restore Request

Resume a Restore Request

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Use the **Resume-MailboxRestoreRequest** cmdlet to resume a restore request that was previously suspended or failed.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to resume a restore request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

This example resumes the restore request kweku\RestoreFromDB01

```
Resume-MailboxRestoreRequest -Identity "kweku\RestoreFromDB01"
```

This example resumes any restore request that has a status of Failed.

```
Get-MailboxRestoreRequest -Status Failed | Resume-MailboxRestoreRequest
```

For detailed syntax and parameter information, see the following topics:

- Resume-MailboxRestoreRequest
- Get-MailboxRestoreRequest

Other Tasks

After you resume the restore request, you may also want to view the properties of the restore request. For details, see View Restore Request Properties and Statistics.

1.8.3.24.22.7 Remove a Restore Request

Remove a Restore Request

Managing Mailbox Servers > Managing User Mailboxes > Managing Disconnected Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Mailbox restore requests are used to restore disconnected mailboxes. A disconnected mailbox is a mailbox object in the Exchange store that isn't associated with an Active Directory user account. Disconnected mailboxes remain in the Exchange database for the duration specified in the deleted mailbox retention settings for the mailbox database. By default, disconnected mailboxes are retained for 30 days.

You can use the **Remove-MailboxRestoreRequest** cmdlet to remove a partially completed restore request. If you remove the restore request after mailbox data begins to move to the target mailbox, the mailbox data that is moved remains in the target mailbox.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to remove a restore request

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Recipient Provisioning Permissions" section in the Mailbox Permissions topic.

Note:

You can't use the EMC to restore a mailbox.

This example removes the restore request Ayla\MailboxRestore1.

```
Remove-MailboxRestoreRequest -Identity "Ayla\MailboxRestore1"
```

This example removes all restore requests that have the status of Completed.

```
Get-MailboxRestoreRequest -Status Completed | Remove-MailboxRestoreRequest
```

This example cancels the restore request by using the *RequestGuid* parameter for a request stored on MBXDB01. The parameter set that requires the *RequestGuid* and *RequestQueue* parameters is used only for Microsoft Replication Service debugging purposes. You should use this parameter set only if instructed by Microsoft Customer Service and Support.

```
Remove-MailboxRestoreRequest -RequestQueue MBXDB01 -RequestGuid 25e0eaf2-6cc2-435
```

For detailed syntax and parameter information, see the following topics:

- Remove-MailboxRestoreRequest
- Get-MailboxRestoreRequest

1.8.3.24.22.8 Permanently Delete a Disconnected Mailbox

Permanently Delete a Disconnected Mailbox

Managing Mailbox Servers > Managing User Mailboxes > Managing Disconnected Mailboxes >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

When you use the **Remove-StoreMailbox** cmdlet to purge a disconnected mailbox and all its contents from the mailbox database, the data loss is permanent. There are two types of disconnected mailboxes: soft-deleted and disabled. When running the cmdlet, you must specify one of these types. If the type you specify doesn't match the actual type of the disconnected mailbox, the command fails.

To learn more about disconnected mailboxes, see Understanding Disconnected Mailboxes.

Note:
You can run the **Remove-StoreMailbox** cmdlet only against disconnected mailboxes. If you attempt to run the cmdlet against an active mailbox, the cmdlet fails, and an error is returned. For details about how to permanently delete an active mailbox, see "Use the Shell to permanently remove a mailbox" in Remove a Mailbox.

Looking for other management tasks related to disconnected mailboxes? Check out Managing Disconnected Mailboxes.

Use the Shell to permanently delete a disconnected mailbox

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Disconnected mailboxes" entry in the Mailbox Permissions topic.

Note:
You can't use the EMC to permanently delete a disconnected mailbox.

This example permanently deletes the soft-deleted mailbox for Ayla from mailbox database MBD01.

```
Remove-StoreMailbox -Database MBD01 -Identity Ayla -MailboxState SoftDeleted
```

This example permanently deletes all soft-deleted mailboxes from mailbox database MBD01.

```
Get-MailboxStatistics -Database MBD01 | where {$_.DisconnectReason -eq "SoftDelet
```

This example permanently deletes the disabled mailbox with the GUID 2ab32ce3-fae1-4402-9489-c67e3ae173d3 from mailbox database MBD01.

```
Remove-StoreMailbox -Database MBD01 -Identity "2ab32ce3-fae1-4402-9489-c67e3ae173
```

For detailed syntax and parameter information, see Remove-StoreMailbox and Get-MailboxStatistics.

1.8.4 Securing Mailbox Servers

Securing Mailbox Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-19*

This topic summarizes the security-related options available for a computer running Microsoft Exchange Server 2010 that has the Mailbox server role installed. By default, HTTP, Microsoft Exchange ActiveSync, POP3, and IMAP4 communication between the Mailbox servers and other Exchange server roles, domain controllers, and global catalog servers is encrypted.

Make sure that your Mailbox servers aren't accessible to the Internet. Also, the Mailbox server role in Exchange 2010 includes security improvements to the Exchange store. For information about these improvements, see Understanding the Exchange 2010 Store.

1.8.5 Troubleshooting Mailbox Servers

Troubleshooting Mailbox Servers

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-31*

After the Mailbox server role is installed on an Exchange 2010 server, you may have to test the server's functionality or solve problems related to mailbox connectivity. The following topics can help you troubleshoot common errors and test that your Mailbox server is configured correctly:

- Troubleshooting Mailbox Moves
- Autodiscover won't work with OABs in Active Directory forest that contains a single-label domain name

- "Task Mount-Database throwing terminating exception" Error Occurs When You Try to Mount a Database
- The Log Generation Number is Not Reset if You Delete the Physical Files in an Exchange Server 2010 Database
- Event IDs 1121 and 5000 Are Logged When You Try to Start the Information Store Service

1.8.5.1 Autodiscover won't work with OABs in Active Directory forest that contains a single-label domain name

Autodiscover won't work with OABs in Active Directory forest that contains a single-label domain name

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2011-11-08*

If you try to use the Autodiscover feature in Exchange Server 2007 together with offline address books (OABs) in an Active Directory forest that contains a single-label domain name, Autodiscover won't work as expected.

Single-label DNS names are DNS names that don't contain a suffix, such as .com, .corp, .net, or .org. For example, Contoso instead of Contoso.com.

This issue occurs because Outlook assumes that the default e-mail address policy would map to a publicly resolvable name. To send mail over the Internet, SMTP domains in an e-mail address policy must resolve to one of the top-level domains supported by RFCs (for example, the top-level domain names described in RFC 1591 - Domain Name System Structure and Delegation). Outlook requires that the proxy addresses defined in the e-mail address policy contain at least two levels of hierarchy in the name. Specifically, the addresses must contain at least one dotted suffix that's acceptable by Outlook. The following list includes examples of names that Outlook considers valid:

- contoso.com
- contoso.eu
- contoso.test

Note:

Although, Outlook considers contoso.test to be a valid domain name, it isn't publicly resolvable according to RFC standards because there is no top-level domain called "test" on the Internet. However, such a domain name could be used to route internal e-mail only. Recipients couldn't receive mail for that domain from outside the company.

What can I do to fix this?

To maintain your second-level domain (SLD), the proxy addresses in your default e-mail address policy must include at least two levels of hierarchy (for example, Fname.Lname@contoso.com).

Depending on your organization's structure, run one or both of the following commands:

- **Mixed Exchange 2003 and Exchange 2007 organization**
  - If the e-mail address policy (called a Recipient Policy in Exchange 2003) exists on an Exchange 2003 server, the policy won't have the OPATH filtering syntax. In this case, run Command 1 followed by Command 2.

- If the e-mail address policy exists on an Exchange 2007 server, run only Command 2.

- **Pure Exchange 2007 or Exchange 2010 organization** Run only Command 2.

Command 1

```
Set-EmailAddressPolicy "Default Policy" -IncludedRecipients AllRecipients
```

Command 2

```
Set-EmailAddressPolicy "Default Policy" -EnabledPrimarySMTPAddressTemplate "%g.%s
```

For detailed syntax and parameter information, see Set-EmailAddressPolicy.

1.8.5.2 Event IDs 1121 and 5000 Are Logged When You Try to Start the Information Store Service

Event IDs 1121 and 5000 Are Logged When You Try to Start the Information Store Service

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-10-30*

This topic provides information about how to troubleshoot an issue in which the Microsoft Exchange Information Store service does not start in Exchange Server 2010. Looking for other management tasks related to Microsoft Exchange Information Store service? Check out Managing Mailbox Servers.

When you try to start the Exchange Information Store, you receive the following error message:

> Windows could not start the Microsoft Exchange Information Store on Local Computer. For more information, review the System Event Log. If this is a non-Microsoft service, contact the service vendor, and refer to service-specific error code 0.

When this error occurs, events that resemble the following may be recorded in the Application log in Event Viewer.

Event ID 1121

> Event Type: Error
>
> Event Source: MSExchangeIS
>
> Event Category: General
>
> Description: Error 0x8004010f connecting to the Microsoft Active Directory.

Event ID 5000

> Event Type: Error
>
> Event Source: MSExchangeIS

Event Category: General

Description: Unable to initialize the Microsoft Exchange Information Store service. - Error 0x8004010f.

This issue may occur if the **Default Policy** item was deleted from the **E-mail Address Policies** tab, and if it was replaced by a custom e-mail address policy. By default, Exchange Server 2010 is hard-coded to search for the default recipient policy when the Information Store starts.

To resolve this issue, use Active Directory Service Interfaces (ADSI) Edit to change the value of the **msExchPolicyOrder** attribute to **2147483647** for a custom e-mail address policy.

ADSI Edit can be run from a client computer or a server. The computer does not have to be a member of a domain, but the user must have the rights to view and edit the Active Directory directory service domain to which the user is connecting. For more information about how to use ADSI Edit, see ADSI Edit (adsiedit.msc).

To change one of your custom e-mail address policies to a default policy

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the Mailbox server configuration entry in the Mailbox Permissions topic.

1. Install ADSI Edit if it is not already installed on the computer that is running Exchange Server 2010.
2. Start ADSI Edit. To do this, click **Start**, click **Run**, type **adsiedit.msc** in the text box, and then click **OK**.
3. Expand the following container:**CN= Recipient Policies\CN=<Organization>\CN= Microsoft Exchange\CN= Services\CN= Configuration\DC=<Domain Name>\DC=com**
4. Right-click the e-mail address policy that you want to change to the default policy, and then click **Properties**.
5. In the **Attribute** column, locate the **purportedSearch** attribute, and then verify that the value in the **Value** column is **(mailNickname=*)**. If the value is incorrect, follow these steps:
   5.a.Click **purportedSearch**, and then click **Edit**.
   5.b.Click **Clear**, type **(mailNickname=*)** in the **Value** box, and then click **OK**.
6. In the **Attribute** list, click the **msExchPolicyOrder** attribute, and then click **Edit**.
7. Click **Clear**, type **2147483647** in the **Value** box, and then click **OK**.
8. Click **OK**, and then close ADSI Edit.
9. Restart the Exchange Mailbox server.

Understanding the Exchange 2010 Store

Overview of Services Installed by Exchange Setup

1.8.5.3 Reclaim Space When the .edb File Size Grows Too Large

Reclaim Space When the .edb File Size Grows Too Large

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-10-25*

The .edb file of a database may grow too large for its volume in Microsoft Exchange Server 2010. If this occurs, you must take the following actions:

- Move mailboxes from the problem Exchange mailbox database to mailbox databases that have more space.
- Remove the problem mailbox database.

As an optional third step, you can re-create the original database, and then restore some of the mailboxes to it.

To resolve this issue, follow these steps.

Important:

Contact Microsoft Customer Service and Support for help to complete this procedure. For more information, see the Contact us website.

Prerequisites

- Verify that all copies of the database are in a healthy state. To do this, run the following command:
  - **Get-MailboxDatabaseCopyStatus (Get-MailboxDatabase | ? {$_.EdbFilePath -eq $pathToEDBdatabaseFile})**

  For more information, see Monitoring High Availability and Site Resilience.
- In Exchange Management Shell, run the following commands to determine whether mailboxes exist on the databases:
  - **Set-ADServerSettings -ViewEntireForest $True**
  - **Get-Mailbox -Database "<Database_ID>"**

  If the mailboxes do exist, see the Create a Local Move Request topic to move the mailboxes to databases that have more space.

Warning:

This process can permanently delete data. Make sure that there no mailboxes exist on the affected database before you go to the next step.

Use the shell to reclaim space when the edb file size has grown too large

You need to be assigned permissions before you can perform this procedure. To see what permissions you need, see the "Mailbox databases" entry in the Mailbox Permissions topic.

1. Open Exchange Management Shell.
2. Note the configured properties of the affected database and database copies. See the Configure Mailbox Database Copy Properties topic for the properties that will have to be reset when the database copies are re-created.
3. Follow the instructions in the Remove a Mailbox Database Copy topic to remove all passive copies of the database.

   Note:

As mentioned in the "Remove a Mailbox Database Copy" topic, circular logging must be disabled when you remove the last passive database copy. If circular logging is enabled, run the following cmdlet to disable it for the database: **Set-MailboxDatabase "<Database_Identity>" –CircularLoggingEnabled $false**

4. Run the following cmdlet to unmount the database: **Dismount-Database "<Database_Identity>"**When you are prompted, type **a** to confirm the action.
5. Run the following cmdlet to remove the mailbox database: **Remove-MailboxDatabase "<Database_Identity>"**When you are prompted, type **a** to confirm the action.
6. Manually delete the .edb file and log files of this database from all servers that contained database copies. Also, manually delete the .edb file and log files from all servers that contain a copy of the database that you are removing.
7. Follow the instructions in the Create a Mailbox Database topic to re-create this database.
8. Run the following cmdlet to mount the empty database: **Remove-MailboxDatabase "<Database_Identity>"**.
9. Manually delete the edb and log files of this database from all servers that contained database copies.
10. Follow the instructions in the Create a Mailbox Database topic to re-create this database.
11. Run the following cmdlet to mount the empty database: **Mount-Database "<Database_Identity>" -Force**
12. Follow the instructions in the Add a Mailbox Database Copy topic to re-create all the database copies you removed in step 2. Use the properties that you noted in step 2.
13. If Circular Logging was disabled in step 3, run the following cmdlet to enable Circular Logging: **Set-MailboxDatabase "<Database_Identity>" -CircularLoggingEnabled $true**. For more information about circular logging, see the "Circular Logging" entry in the Understanding the Exchange 2010 Store topic.
14. Move some mailboxes back to this database.

Validation

To validate the database, follow these steps.

1. Run the following cmdlet to verify the health of all copies of this database: **Get-MailboxDatabaseCopyStatus "<Database_Identity>"**
2. Run the following cmdlet to verify that the database can replicate changes to all servers that contain database copies: **Test-ReplicationHealth <Each_Server_With_A_Copy_Of_The_Database>**
3. Run the following cmdlet to verify the health of all servers that contain database copies: **Test-MAPIConnectivity <Server_With_The_Mounted_Copy_Of _The_Database>**

Managing Mailbox Databases

Managing Mailbox Database Copies

1.8.5.4 "Task

"Task Mount-Database throwing terminating exception" Error Occurs When You Try to Mount a Database

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2011-08-12*

When you try to mount a database in Microsoft Exchange Server 2010, you may receive the following error message:

Task Mount-Database throwing terminating exception when processing record of index 0. Exception: System.InvalidOperationException: The database object MB11DB1' in Active Directory has been corrupted and is in an inconsistent state: The servers of the database are null.

If this error occurs, you can use database portability to resolve the problem.

How can I fix the problem?

To resolve this problem, use database portability to move an Exchange 2010 mailbox database between Exchange 2010 Mailbox servers in the same organization. For more information about how to do this, see Move a Mailbox Database Using Database Portability.

1.8.5.5 The Log Generation Number is Not Reset if You Delete the Physical Files in an Exchange Server 2010 Database

The Log Generation Number is Not Reset if You Delete the Physical Files in an Exchange Server 2010 Database

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2011-09-09*

The current log generation does not reset in a Microsoft Exchange Server 2010 cluster database if you do the following:

- You delete the physical files in the cluster database
- You leave the objects in Active Directory directory service
- You do not delete the files in the cluster database

The system tracks the current log generation as part of the logic to maintain the loss calculation. This number is not reset by deleting the files.

To resolve this issue, an administrator must use the **Move-ActiveMailboxDatabase** cmdlet together with the *MountDialOverride* parameter to complete a lossless move of the active database to the cluster database. The value of the current log generation is determined again based on the available files. Then, the value is saved.

More information

For more information about the **Move-ActiveMailboxDatabase** cmdlet, see Move-ActiveMailboxDatabase.

1.8.5.6 Troubleshooting Mailbox Moves

Troubleshooting Mailbox Moves

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-23*

Troubleshooting content will be made available as issues arise. If there's a troubleshooting issue you'd like us to document, click **Click to Rate and Give Feedback** at the top of this topic and send us feedback. Include as much detail as you can, including any relevant error codes, error descriptions, or event IDs.

Legend

FC	Failure code
ID	Event ID source and number

General steps for troubleshooting mailbox moves

1. If the move request didn't complete, view the Move Request Statistics. For more information, see the section "Use the Shell to view the status of an in-progress move request" in View Move Request Properties.
2. If the move request completed with errors, view the move report. For more information, see the section "Use the Shell to view a completed move request report" in View Move Request Properties.
3. View the Event log on the Client Access server running the instance of the Microsoft Exchange Mailbox Replication service that's processing the failed move request.
4. Step 4 - If you still can't determine the problem, use the Exchange Management Console or the Exchange Management Shell to increase the diagnostic logging levels on the Client Access server for the **Mailbox Move** and **Service** categories of the **MSExchange Mailbox Replication** service. Then resume the failed move request. For details about how to modify the diagnostic logging level, see Manage Diagnostic Logging Levels.

Problems with cross forest\remote move requests

If you're experiencing errors when moving mailboxes across forests, it's possible that the target forest hasn't been properly prepared. For details, see Prepare Mailboxes for Cross-Forest Move Requests.

Corrupted item limit reached (FC: -2147467259 | ID: MSExchange Mailbox

Replication 1100)

Problem

The move request fails because the mailbox has more corrupted items than the move request is configured to skip.

Diagnosis

The move request fails, and the **Get-MoveRequestStatistics** cmdlet returns the following error:

Failure code	Message
-2147467259	Error: This mailbox exceeded the maximum number of corrupted items that were specified for this move request.

The following Event log entry appears on the Client Access server on which the move request was initiated:

Log Name	Application
Source	MSExchange Mailbox Replication
Date	10/26/2009 2:47:17 PM
Event ID	1100
Task Category	Mailbox Move
Level	Error
Keywords	Classic
User	N/A
Computer	CAS01.fabrikam.com
Description	Mailbox move for 'fabrikam.com/Users/TonySmith' (de278a9f-33eb-49f9-950a-070db3323715) has failed. Error code: -2147467259 This mailbox exceeded the maximum number of corrupted items that were specified for this move request.

Resolution

1. Use the Set-MoveRequest cmdlet to increase the *BadItemLimit* threshold. For details, see Configure Move Request Properties.
2. Resume the failed move request. For details, see Complete or Resume a Move Request.

Rules in source mailbox's Inbox folder are larger than 32 KB

Problem

The move request fails when you attempt to move a mailbox from Exchange 2010 to

Exchange 2003 because the size of the rules in the Exchange 2010 mailbox exceeds the size of the rules that's allowed in Exchange 2003 (32 KB).

Diagnosis

When you attempt to move the mailbox, you receive an error similar to the following:

```
Mailbox 'fabrikam.com/Users/tonysmith' could not be moved because rules in source
    + CategoryInfo          : InvalidArgument: (mbx2:MailboxOrMailUserIdParameter
```

Resolution

1. Run the Set-MoveRequest cmdlet with the *IgnoreRuleLimitErrors* parameter. For details, see Configure Move Request Properties.
2. Resume the move request. For details, see Complete or Resume a Move Request.

Note:

End users will need to re-create their rules.

The mailbox dumpster size exceeds the target quota

Problem

The recoverable items quota for the mailbox being moved has exceeded the target quota. This error occurs when you're moving mailboxes from Exchange 2003 or Exchange 2007 to Exchange 2010.

Diagnosis

When you try to move the mailbox, you receive an error similar to the following:

```
Mailbox dumpster size 713 MB (747,659,085 bytes) exceeds target quota 500 MB (524
    + CategoryInfo          : InvalidArgument: (xxxxx/xxxx/xxxx/xxxx:MailboxOrMai
```

Resolution

Move requests don't support moving an Exchange 2003 or Exchange 2007 dumpster to Exchange 2010. However, the move request will still compare the dumpster size between the two product versions. To fix this issue, perform the following steps.

1. Increase the recoverable items quota for the target mailbox database by using the Set-MailboxDatabase cmdlet with the *RecoverableItemsQuota* parameter. For details, see Configure Deleted Item Retention and Recoverable Items Quotas.
2. Resume the failed move request. For details, see Complete or Resume a Move Request.
3. When the move request is complete, return the recoverable items quota to its original size.

MapiExceptionMdbOffline error (FC: -2147467259 | ID: MSExchange Mailbox Replication 1100)

Problem

While the move was in progress, the source or target mailbox database went offline. By default, the Microsoft Exchange Mailbox Replication service (MRS) will attempt to reconnect with the offline database for 30 minutes. If the database doesn't come online within that time, the move will fail. For more information about how to change the MRS connection rate, see Understanding Move Requests.

Diagnosis

The move request fails, and when you run the Get-MoveRequestStatistics cmdlet, you

receive the following error:

Failure code	Message
-2147467259	Error: MapiExceptionMdbOffline: Unable to open entry ID. (hr=0x80004005, ec=1142)

Also, the Client Access server that was processing the move request will log an event similar to the following:

Log Name	Application
Source	MSExchange Mailbox Replication
Date	10/27/2009 10:30:02 AM
Event ID	1100
Task Category	Mailbox Move
Level	Error
Keywords	Classic
User	N/A
Computer	CAS01.fabrikam.com
Description	Mailbox move for 'fabrikam.com/Users/TonySmith' (8dfd4b3b-8147-4e1b-b86f-5d00799abbf3) has failed. Error code: -2147467259 MapiExceptionMdbOffline: Unable to open entry ID. (hr=0x80004005, ec=1142)

Resolution

1. Mount the mailbox database. For details, see Mount a Database.
2. Resume the move request. For details, see Complete or Resume a Move Request.

No available healthy database copies (FC: -2147220223 | ID: MSExchange Mailbox Replication 1100)

When the target database is a replicated database in a database availability group (DAG), MRS regularly checks the replication health of the target database. High availability infrastructure verifies the current replication health against the configured throttling behavior for high availability mailbox moves (as specified by the *DataMoveReplicationConstraint* parameter) for the target database. Depending on the results, MRS will either continue with the move or wait. If the target database isn't healthy for five minutes, MRS will fail. For details about how to change the MRS connection rate, see Understanding Move Requests.

Diagnosis

The move request fails when you run the Get-MoveRequestStatistics cmdlet and the output file returns an error similar to the following:

Failure Code	Message

-2147220223	Error: Move for mailbox '/o=First Organization/ou=Exchange Administrative Group (FYDIBOHF23SPDLT)/cn=Recipients/cn=MBX1' is stalled because DataMoveReplicationConstraint is not satisfied for the database 'mdb1' (agent MailboxDatabaseReplication). Failure Reason: Database 1541069d-2976-4f40-afb1-569ed323de0b does not satisfy constraint SecondCopy. There are no available healthy database copies.

Also, the Client Access server that was processing the move request will log an event similar to the following:

Log Name	Application
Source	MSExchange Mailbox Replication
Date	10/27/2009 10:30:02 AM
Event ID	1100
Task Category	Mailbox Move
Level	Error
Keywords	Classic
User	N/A
Computer	MBX01.fabrikam.com
Description	Mailbox move for 'MBX01.fabrikam.com/Users/MBX1' (214dbbab-bb93-4954-a593-515dcc200e7c) has failed. Error code: -2147220223 Move for mailbox '/o=First Organization/ou=Exchange Administrative Group (FYDIBOHF23SPDLT)/cn=Recipients/cn=MBX1' is stalled because DataMoveReplicationConstraint is not satisfied for the database 'mdb1' (agent MailboxDatabaseReplication). Failure Reason: Database 1541069d-2976-4f40-afb1-569ed323de0b does not satisfy constraint SecondCopy. There are no available healthy database copies.

Resolution

To resolve this issue, try the following options:

- Remove the move request and then move the mailbox to a healthy target database. For details, see Clear or Remove Move Requests.
- Resolve the issue with the target database's replication and resume the move request. For more information, see Understanding High Availability and Site Resilience.
- Update the *DataMoveReplicationConstraint* parameter on the Set-MailboxDatabase cmdlet for the target database to reflect its current state (if

the constraint that's specified is the wrong constraint). For details, see Configure Mailbox Database Properties.

Certificates are too large or too many

Problem

The user has too many certificates on the mailbox account or the certificates are too large. The maximum number of certificates should be under 1 MB.

Diagnosis

When you attempt to create a move request, you receive an error similar to the following:

```
The call to 'net.tcp:// cas01.fabrikam.com/Microsoft.Exchange.MailboxReplicationS
Error details: The maximum message size quota for incoming messages (262144) has
    + CategoryInfo          : NotSpecified: (0:Int32) [New-MoveRequest], MailboxR
```

Resolution

1. Start Active Directory Users and Computers.
2. On the **View** menu, click **Advanced Features**.
3. In the console tree, expand the domain you want, and then click **Users**.
4. In the details pane, right-click the user, and then click **Properties**.
5. In **<User Name> Properties**, on the **Published Certificates** tab, select the certificate that you want to delete, and then click **Remove**. Repeat this process until you have removed enough certificates.
6. Resume the move request. For details, see Complete or Resume a Move Request.

There aren't any available servers running the Mailbox Replication Service.

Problem

The Microsoft Exchange Mailbox Replication (MSExchangeMailboxReplication) service must be running on at least one Client Access server in the local Active Directory site.

Diagnosis

When you try to create a move request, you receive the following error:

```
There are no available servers that are running the Mailbox Replication Service.
    + CategoryInfo          : NotSpecified: (0:Int32) [New-MoveRequest], MailboxR
```

Resolution

Start the Microsoft Exchange Mailbox Replication Service on at least on Client Access server. For details about how to start the service, see Start, stop, pause, resume, or restart a service.

The Microsoft Exchange Mailbox Replication Service fails to start (ID: MSExchange Mailbox Replication 1010)

Problem

The Microsoft Exchange Mailbox Replication (MSExchangeMailboxReplication) service fails to start.

Diagnosis

The event log on the Client Access server that was processing the request logs the following event:

Provider [Name]	MSExchange Mailbox Replication
Event ID	1010
[Qualifiers]	49156
Level	4
Task	1
Keywords	0x80000000000000
TimeCreated [SystemTime]	2009-07-22T20:53:26.000Z
Channel	Application
Computer	CAS01.fabrikam.com
EventData	System.ServiceModel.CommunicationException: The TransportManager failed to listen on the supplied URI using the NetTcpPortSharing service: failed to start the service because it is disabled. An administrator can enable it by running 'sc.exe config NetTcpPortSharing start= demand'.. ---> System.InvalidOperationException: Cannot start service NetTcpPortSharing on computer '.'. ---> System.ComponentModel.Win32Exception: The service cannot be started, either because it is disabled or because it has no enabled devices associated with it --- End of inner exception stack trace --- at System.ServiceProcess.ServiceController.Start(String[] args) at System.ServiceModel.Channels.SharedConnectionListener.SharedListenerProxy.HandleServiceStart(Boolean isReconnecting) --- End of inner exception stack trace --- at System.ServiceModel.Channels.SharedConnectionListener.SharedListenerProxy.HandleServiceStart(Boolean isReconnecting) at System.ServiceModel.Channels.SharedConnectionListener.SharedListenerProxy.Open(Boolean isReconnecting) at System.ServiceModel.Channels.SharedConnectionListener.StartListen(Boolean isReconnecting) at System.ServiceModel.Channels.SharedTcpTransportManager.OnOpenInternal(Int32 queueId, Guid token) at System.ServiceModel.Channels.SharedTcpTransportManager.OnOpen() at System.ServiceModel.Channels.TransportManager.Open(TransportChannelListener channelListener) at System.ServiceModel.Channels.TransportManagerContainer.Open(SelectTransportManagersCallback selectTransportManagerCallback) at

	System.ServiceModel.Channels.ConnectionOrientedTransportChannelListener.OnOpen (TimeSpan timeout) at System.ServiceModel.Channels.TcpChannelListener`2.OnOpen(TimeSpan timeout) at System.ServiceModel.Channels.CommunicationObject.Open(TimeSpan timeout) at System.ServiceModel.Dispatcher.ChannelDispatcher.OnOpen(TimeSpan timeout) at System.ServiceModel.Channels.CommunicationObject.Open(TimeSpan timeout) at System.ServiceModel.ServiceHostBase.OnOpen(TimeSpan timeout) at System.ServiceModel.Channels.CommunicationObject.Open(TimeSpan timeout) at Microsoft.Exchange.MailboxReplicationService.MailboxReplicationServiceImpl.OnStartInternal(String[] args) in c:\E14\sources\sources\dev\mrs\src\ServiceHost\ServiceImpl.cs:line 227

Resolution

1. At the command prompt, Type the following:

```
C:\>sc.exe config NetTcpPortSharing start= auto
```

Note:
In the above command, there's a space before `auto`.

2. Start the Microsoft Exchange Mailbox Replication service on at least on Client Access server. For details about how to start the service, see Start, stop, pause, resume, or restart a service.
3. Resume the failed move request. For details, see Complete or Resume a Move Request.

MRSProxy isn't running in the source forest

Problem

When performing remote move requests, the Mailbox Replication Proxy (MRSProxy) service must be running on all Client Access servers in the source forest. By default, MRSProxy is disabled.

Diagnosis

When you attempt to create a move request, you receive an error similar to the following:

```
Service 'net.tcp://bl20102ca002.contoso.com/Microsoft.Exchange.MailboxReplication
    + CategoryInfo          : NotSpecified: (0:Int32) [New-MoveRequest], MailboxR
```

Resolution

1. Start the MRSProxy service on all Client Access servers in the source forest. For details, see Start the MRSProxy Service on a Remote Client Access Server.
2. Resume the failed move request. For details, see Complete or Resume a Move Request.

Move request can't be cleared after it's completed

Problem

The move request completes, but has the status of **Completed With Warning**. You are unable to clear the move request because the Microsoft Exchange Mailbox Replication (MSExchangeMailboxReplication) service couldn't reset the **InTransit** flag from the destination mailbox. If this flag isn't removed, end users won't be able to log on to their mailboxes.

Diagnosis

When you run the Get-MoveRequestStatistics with the *IncludeMoveHistory* parameter, the move report returns an error similar to the following:

```
Failed to reset the destination mailbox after the move.
When you run Test-MAPIConnectivity for this mailbox, it will fail with the follow
Error      : [Microsoft.Exchange.Data.Storage.MailboxInTransitException]: Cannot
```

Resolution

1. Start a new move request for the mailbox. For details, see Create a Local Move Request or Create a Remote Move Request That has Exchange 2010 in Both Forests.
2. Remove the move request as soon as it reaches the status of **In Progress**. For details, see Clear or Remove Move Requests.

1.8.6 Performance Counter Reference for Mailbox Servers

Performance Counter Reference for Mailbox Servers

Exchange Server 2010 > Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-03-19*

Ensuring that servers running Microsoft Exchange Server 2010 are operating reliably is a key objective for messaging operations. An important part of Exchange 2010 operations is monitoring the Exchange components to understand the health state of servers and server roles. For more information about mailbox performance counters, see the following topics:

- Mailbox Server Counters
- Performance and Scalability Counters and Thresholds

1.8.7 Error and Event Reference for Mailbox Servers

Error and Event Reference for Mailbox Servers

Exchange Server 2010 > Mailbox >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-05-01*

Microsoft Exchange Server 2010 Mailbox components, features, and services generate Error events to let you effectively troubleshoot and monitor Mailbox servers.

Event Viewer is a Microsoft Management Console (MMC) snap-in that enables you to browse and manage event logs. You can also gather information about hardware and software problems, and monitor Microsoft Windows security events. Although Event Viewer isn't a Microsoft Exchange component, Event Viewer is useful when you troubleshoot problems with Exchange 2010 server roles. For more information, see Event Viewer. For more information about Exchange 2010 event logs, look for "MSExchange" event logs in the Event Viewer on your Exchange 2010 server.

Mailbox Errors and Events

The following Mailbox errors and events are grouped according to the Mailbox feature areas.

- ADAccess Errors and Events
- ApplicationLogic Errors and Events
- Common Errors and Events
- Control Panel Errors and Events
- ExchangeStoreDB Errors and Events
- MonitoringCorrelation Errors and Events
- MSExchangeAL Errors and Events
- MSExchangeFDS Errors and Events
- MSExchangeIS Errors and Events
- MSExchangeRepl Errors and Events
- MSExchangeRPC Errors and Events
- MSExchangeSA Errors and Events
- MSExchangeSetup Errors and Events
- OAB Maintenance Errors and Events
- Progress Manager Errors and Events
- Search Indexer Errors and Events

1.8.7.1 ADAccess Errors and Events

ADAccess Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates MSExchange ADAccess events in Event Viewer so that you can troubleshoot and verify the ADAccessfeatures, and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

ADAccessfeatures Errors and Events

The following table provides a list of the ADAccessfeatures errors and events.

Event ID	Category	Event type	Value or description
MSExchange	Topology	Warning	Process %1 (PID=%

ADAccess 2077			2). Exchange Active Directory Provider could not find any domain controller servers in either the local site '%3' or the following sites: %4
MSExchange ADAccess 2098	General	Warning	Process %1 (PID=%2). DSAccess performed disaster cleanup for the lock %3.
MSExchange ADAccess 2389	LDAP	Warning	Process %1 (PID=%2). A request to Directory Server %3 did not return a result within %4 seconds and is being abandoned. The search will be retried if possible. The search that failed has the following characteristics: Base DN=%5, Filter=%6, Scope=%7.
MSExchange ADAccess 2392	LDAP	Warning	Process %1 (PID=%2). DSAccess did not register an Active Directory shutdown notification with the local server, error 0x%3 (%4). To speed up the shutdown process, manually stop the Exchange services before you shut down the server.
MSExchange ADAccess 2601	General	Warning	Process %1 (PID=%2). When initializing a remote procedure call (RPC) to the Microsoft Exchange Active Directory Topology service, Exchange could not retrieve the SID for account %3 - Error code=%4. The Microsoft Exchange Active Directory Topology service will continue starting with limited permissions.
MSExchange ADAccess 2106	Topology	Warning	Process %1 (PID=%2). Exchange Active

			Directory Provider failed to obtain DNS records for forest %3. DNS Priority and Weight for the Global Catalog servers in this forest will be set to the default values %4 (priority) and %5 (weight).
MSExchange ADAccess 2124	Topology	Warning	Process %1 (PID=%2). Domain controller %3 was not found when DNS was queried for the service location (SRV) resource records for domain %4 The query was for the SRV record for %5 The following domain controllers were identified by the query:%6 Common causes of this error include the following: - The DNS SRV records required to locate a domain controller for the domain are not registered in DNS. These records are registered with a DNS server automatically when a domain controller is added to a domain. They are updated by the domain controller at set intervals. This computer is configured to use DNS servers with following IP addresses:%7 - One or more of the following zones do not include delegation to its child zone:%8 For information about correcting this problem, %9%10
MSExchange ADAccess 2114	Topology	Error	Process %1 (PID=%2). Topology discovery failed, error 0x%3 (%4). Look up the Lightweight

			Directory Access Protocol (LDAP) error code specified in the event description. To do this, use Microsoft Knowledge Base article 218185, "Microsoft LDAP Error Codes." Use the information in that article to learn more about the cause and resolution to this error. Use the Ping or PathPing command-line tools to test network connectivity to local domain controllers.
MSExchange ADAccess 2500	Site Update	Error	Process %1 (PID=%2). The site monitor API could not start - Call=%3 Error code=%4. Try to resolve this event by restarting the computer that is running Exchange. If this event reoccurs, review the Application log and System log for any corresponding Warning or Error events.
MSExchange ADAccess 2089	Configuration	Warning	Process %1 (PID=%2). The configuration domain controller specified in the registry (%3) was not found in the Sites container in the Active Directory. Exchange Active Directory Provider will select the configuration domain controller from the list of available domain controllers.
MSExchange ADAccess 2123	Topology	Warning	Process %1 (PID=%2). Exchange Active Directory Provider is unable to connect to the Domain Controller %3 although its service location (SRV)

			resource record was found in the DNS The query was for the SRV record for %4 The following domain controllers were identified by the query:%5 Common causes of this error include: - Host (A) records that map the name of the domain controller to its IP addresses are missing or contain incorrect addresses. - Domain controllers registered in DNS are not connected to the network or are not running. For information about correcting this problem, %6%7
MSExchange ADAccess 2139	Topology	Error	Process %1 (PID=%2). Active Directory topology could not be discovered in {0} seconds. Review the Application log for related Warning or Error events. Use the Ping or PathPing command-line tools to test network connectivity to local domain controllers. Run the Dcdiag command line tool to test domain controller health.
MSExchange ADAccess 2156	Validation	Error	Process %1 (PID=%2). Recipient object %3 read from %4 failed validation. A data validation exception will be given. Set event logging level for Validation category to Expert to get additional events about each failure.
MSExchange ADAccess 2060	Topology	Warning	Process %1 (PID=%2). No Global Catalog server was found in the local site %3.

			Exchange Active Directory Provider will try to find Global Catalog servers in other sites.
MSExchange ADAccess 2049	LDAP	Warning	Process %1 (PID=%2). An asynchronous LDAP call failed - Server=%3 Error code=%4 (%8). Base DN=%5, Filter=%6, Scope=%7.
MSExchange ADAccess 2118	Topology	Error	Process %1 (PID=%2). Error DNS_ERROR_RCODE_SERVER_FAILURE (0x%3) occurred when DNS was queried for the service location (SRV) resource record used to locate a domain controller for domain %4 The query was for the SRV record for %5 Common causes of this error include the following: - The DNS servers used by this computer contain incorrect root hints. This computer is configured to use DNS servers with following IP addresses:%6 - One or more of the following zones contains incorrect delegation:%7 For information about correcting this problem, %8%9
MSExchange ADAccess 2090	Configuration	Warning	Process %1 (PID=%2). The configuration domain controller specified in the registry (%3) is unreachable. Exchange Active Directory Provider will select the configuration domain controller from the list of available domain controllers.
MSExchange	Topology	Warning	Process %1 (PID=%

ADAccess 2112			2). The Exchange computer %3 does not have Audit Security Privilege on the domain controller %4. This domain controller will not be used by Exchange Active Directory Provider.
MSExchange ADAccess 2138	Configuration	Error	Process %1 (PID=%2). Exchange Active Directory Provider received a request to connection to domain controller %3 but that domain controller is not available. Use the Ping or PathPing command-line tools to test network connectivity to local domain controllers. Run the Dcdiag command line tool to test domain controller health.
MSExchange ADAccess 2053	Cache	Error	Process %1 (PID=%2). Internal error - A hash table that stores DSAccess information is damaged and cannot be used. This event may be caused because of internal memory issues. You may be able to resolve this event by restarting the Microsoft Exchange Active Directory Topology service. If the error persists, restart the Exchange server that logged this event.
MSExchange ADAccess 2137	configuration	Error	Process %1 (PID=%2). Exchange Active Directory Provider could not read attribute %3 from Root DSE of server %4. This issue must be resolved in order to allow Exchange Active

			Directory Provider to correctly operate.
MSExchange ADAccess 2066	LDAP	Warning	Process %1 (PID=%2). An LDAP Notify call failed - Server=%3 Error code=%4 (%8). Base DN=%5, Filter=%6, Scope=%7.
MSExchange ADAccess 2121	Topology	Warning	Process %1 (PID=%2). Exchange Active Directory Provider is unable to connect to any domain controller in domain %3 although DNS was successfully queried for the service location (SRV) resource record used to locate a domain controller for that domain. The query was for the SRV record for %4 The following domain controllers were identified by the query:%5 Common causes of this error include: - Host (A) records that map the name of the domain controller to its IP addresses are missing or contain incorrect addresses. - Domain controllers registered in DNS are not connected to the network or are not running. For information about correcting this problem, %6%7
MSExchange ADAccess 2159	Validation	Error	Process %1 (PID=%2). Configuration object %3 read from %4 failed validation and will be excluded from the result set. Set event logging level for Validation category to Expert to get additional events about each failure.
MSExchange	Cache	Error	Process %1 (PID=%

ADAccess 2054			2). A cache hash table that stores DSAccess information ran out of memory. This event can be caused by internal memory issues. You may be able to resolve this event by restarting the Microsoft Exchange Active Directory Topology service. If the error persists, restart the Exchange server that logged this event.
MSExchange ADAccess 2152	General	Error	Process %1 (PID=%2). An remote procedure call (RPC) request to the Microsoft Exchange Active Directory Topology service failed with error %3 (%4). Make sure that the Remote Procedure Call (RPC) service is running. In addition, make sure that the network ports that are used by RPC are not blocked by a firewall.
MSExchange ADAccess 2130	Topology	Error	Process %1 (PID=%2). Exchange Active Directory Provider could not find an available domain controller in domain %3. This event may be caused by network connectivity issues or configured incorrectly DNS server. This event may also occur if you have not configured correctly your multiple Active Directory sites.
MSExchange ADAccess 2101	topology	Warning	Process %1 (PID=%2). The configuration domain controller specified in a call to SetConfigDCName (%3) is unreachable. Exchange Active

			Directory Provider will select the configuration domain controller from the list of available domain controllers.
MSExchange ADAccess 2100	Topology	Warning	Process %1 (PID=%2). The configuration domain controller specified in a call to SetConfigDCName (%3) was not found in the Sites container in the Active Directory. Exchange Active Directory Provider will select the configuration domain controller from the list of available domain controllers.
MSExchange ADAccess 2600	General	Error	Process %1 (PID=%2). DSAccess could not initiate a remote procedure call (RPC) - Call=%3 Error code=%4.
MSExchange ADAccess 2050	General	Error	Process %1 (PID=%2). The shared memory heap could not be created. This may be caused if physical memory limits have been exceeded. It may also be caused if too many other processes are running DSAccess. You may be able to resolve this error by restarting the Exchange server that logged this event.
MSExchange ADAccess 2069	Topology	Error	Process %1 (PID=%2). Exchange Active Directory Provider couldn't find any Global Catalog servers in either the local site '%3' or the following sites: %4
MSExchange ADAccess 2502	Site Update	Error	Process %1 (PID=%2). The site monitor API could not update the msExchServerSite

			attribute in Active Directory. You must update this attribute to reflect new site name where this Exchange server is installed - Call=%3 Error code=%4.
MSExchange ADAccess 2075	Configuration	Error	Process %1 (PID=%2). DSAccess could not discover the Fully Qualified Domain Name (FQDN) of local server with Exception %3. The local name that was used to look up the server is %4. This event may be caused by an incorrectly configured DNS server. It may also occur if the local server was renamed but DNS records were not updated. To resolve this error, see "Troubleshooting DNS servers" in the Microsoft Windows Server TechCenter. In addition, if the name of the server that logged this event was changed, make sure that the computer was restarted.
MSExchange ADAccess 2091	Configuration	Warning	Process %1 (PID=%2). The domain controller specified in the registry (%3) was not found in the Sites container in Active Directory. Exchange Active Directory Provider will not use this server as a domain controller or global catalog.
MSExchange ADAccess 2104	Topology	Error	Process %1 (PID=%2). Topology discovery failed due to LDAP_SERVER_DOWN error. This event can occur if one or more domain controllers in

			local or all domains become unreachable because of network problems. Use the Ping or PathPing command line tools to test network connectivity to local domain controllers. Run the Dcdiag command line tool to test domain controller health.
MSExchange ADAccess 2086	Topology	Warning	Process %1 (PID=%2). No Domain Controller server was found in the local site %3. Exchange Active Directory Provider will try to find Domain Controller servers in other sites.
MSExchange ADAccess 2155	Validation	Error	Process %1 (PID=%2). Configuration object %3 read from %4 failed validation. DataValidationException will be thrown. Set event logging level for Validation category to Expert to get additional events about each failure.
MSExchange ADAccess 2105	Topology	Warning	Process %1 (PID=%2). Exchange Active Directory Provider failed to obtain DNS records for domain %3. DNS Priority and Weight for the Domain Controllers in this domain will be set to the default values %4 (priority) and %5 (weight).
MSExchange ADAccess 2056	Cache	Error	Process %1 (PID=%2). An internal memory cache error occurred. A record that was not valid was used with the cache hash table. This event can be caused by internal memory issues. You may be able to resolve this

			event by restarting the Microsoft Exchange Active Directory Topology service. If the error persists, restart the Exchange server that logged this event.
MSExchange ADAccess 2107	Topology	Error	Process %1 (PID=%2). Exchange Active Directory Provider failed to obtain an IP address for DS server %3, error %4 (%5). This host will not be used as a DS server by Exchange Active Directory Provider.
MSExchange ADAccess 2119	Topology	Error	Process %1 (PID=%2). Error DNS_ERROR_RCODE_NAME_ERROR (0x%3) occurred when DNS was queried for the service location (SRV) resource record used to locate a domain controller for domain %4 The query was for the SRV record for %5 Common causes of this error include the following: - The DNS SRV records required to locate a domain controller for the domain are not registered in DNS. These records are registered with a DNS server automatically when a domain controller is added to a domain. They are updated by the domain controller at set intervals. This computer is configured to use DNS servers with following IP addresses:%6 - One or more of the following zones do not include delegation to its child zone:%7 For information about correcting this

			problem, %8%9
MSExchange ADAccess 2501	Site update	Error	Process %1 (PID=%2). The site monitor API was unable to verify the site name for this Exchange computer - Call=%3 Error code=%4. Make sure that Exchange server is correctly registered on the DNS server.
MSExchange ADAccess 2076	Configuration	Error	Process %1 (PID=%2). The 'PreloadBaseDNs' and 'PreloadFilters' registry keys do not contain the same number of entries. 'PreloadBaseDNs' contains %3 strings and 'PreloadFilters' contains %4 strings. Only the first %5 preload filters will be used. Each entry in PreloadBaseDNs registry key must match an entry in PreloadFilters registry key. To resolve this error, make sure that number of entries in PreloadBaseDNs registry key equals the number of entries in PreloadFilters registry key.
MSExchange ADAccess 2122	Topology	Error	Process %1 (PID=%2). Error 0x%3 occurred when DNS was queried for the service location (SRV) resource record used to locate a domain controller for domain %4 The query was for the SRV record for %5 For information about correcting this problem, %6%7
MSExchange ADAccess 2110	LDAP	Error	Process %1 (PID=%2). Could not bind to DS server %3, error %4 (%6) at port %5.

MSExchange ADAccess 2067	General	Error	Process %1 (PID=%2). Error %3 occurred, code 0x%4. Callstack 0x%5 0x%6 0x%7 0x%8 0x%9 0x%10 0x%11 0x%12
MSExchange ADAccess 2097	General	Error	Process %1 (PID=%2). The Preload Filters registry key '%3' for the DN '%4' could not be parsed. The error is %5 (%6). This filter will not be used. To resolve this error, make sure that filter specified in PreloadFilters registry key is valid. For more information, see Microsoft Knowledge Base article 250572, "XCON: Preloading and the DSAccess Cache."
MSExchange ADAccess 2160	Validation	Warning	Process %1 (PID=%2). Recipient object %3 read from %4 failed validation and will be excluded from the result set. Set event logging level for Validation category to Expert to get additional events about each failure.
MSExchange ADAccess 2055	Cache	Error	Process %1 (PID=%2). An internal memory cache error occurred. A hash table iterator is no valid. This event can be caused by internal memory issues. You may be able to resolve this event by restarting the Microsoft Exchange Active Directory Topology service. If the error persists, restart the Exchange server that logged this event.
MSExchange ADAccess 2061	LDAP	Warning	Process %1 (PID=%2). An LDAP search call to Directory

			Server %3 failed - Error code=%4 (%8). Base DN=%5, Filter= %6, Scope=%7.
MSExchange ADAccess 2116	Topology	Warning	Process %1 (PID=% 2). The domain controller %3 is running Windows %4 %5. Exchange Active Directory Provider requires that domain controllers are running Windows Server 2003 Service Pack 1 or later versions of Windows.
MSExchange ADAccess 2190	Topology	Error	Process %1 (PID=% 2). Exchange Topology could not be discovered. Reason: %3.
MSExchange ADAccess 2051	General	Error	Process %1 (PID=% 2). The maximum allowed number of processes are using the DSAccess memory cache. No more processes can use the API. Try to resolve this event by restarting the Microsoft Exchange Active Directory Topology service. If the error persists, restart the Exchange server that logged this event.
MSExchange ADAccess 2120	Topology	Warning	Process %1 (PID=% 2). Error ERROR_TIMEOUT (0x %3) occurred when DNS was queried for the service location (SRV) resource record used to locate a domain controller for domain %4 The query was for the SRV record for %5. The DNS servers used by this computer for name resolution are not responding. This computer is configured to use DNS

			servers with the following IP addresses:%6. Verify that this computer is connected to the network, that these are the correct DNS server IP addresses, and that at least one of the DNS servers is running. For information about correcting this problem, %7%8
MSExchange ADAccess 2058	Cache	Information	Process %1 (PID=%2). The specified record key does not exist in the cache hash table.
MSExchange ADAccess 2059	Cache	Warning	Process %1 (PID=%2). The last record in the cache hash table was found.
MSExchange ADAccess 2068	General	Information	Process %1 (PID=%2). DSAccess initialized successfully.
MSExchange ADAccess 2070	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider lost contact with domain controller %3. Error was 0x%4 (%6) (%5). Exchange Active Directory Provider will attempt to reconnect with this domain controller when it is reachable.
MSExchange ADAccess 2074	LDAP	Information	Process %1 (PID=%2). A search or read to Directory Server %3 returned object '%4' which has attribute '%5' with too many values to return in a single search. If possible, reduce the number of values in this attribute to allow normal operation.
MSExchange ADAccess 2078	General	Information	Process %1 (PID=%2). DSAccess is shutting down.

MSExchange ADAccess 2081	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider will use the servers from the following list: Domain Controllers:%3 Global Catalogs:%4 The Configuration Domain Controller is set to %5.
MSExchange ADAccess 2082	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider has detected that the following Domain Controller servers in the local site '%3' became reachable and is using them: %4
MSExchange ADAccess 2083	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider has detected that the following Global Catalog servers in the local site '%3' became reachable and is using them: %4
MSExchange ADAccess 2084	Topology	Warning	Process %1 (PID=%2). No Domain Controller server is up in the local site '%3'. Exchange Active Directory Provider will use the following out of site Domain Controller servers: %4
MSExchange ADAccess 2085	Topology	Information	Process %1 (PID=%2). No Global Catalog server is up in the local site '%3'. Exchange Active Directory Provider will use the following out of site global catalog servers: %4
MSExchange ADAccess 2088	Configuration	Information	Process %1 (PID=%2). The value of %3 specified in the registry must be in the range of %4 - %5, and it was %6. Using the default

			value of %7.
MSExchange ADAccess 2092	Configuration	Information	Process %1 (PID=%2). Exchange Active Directory Provider will use Domain Controllers specified in the registry.
MSExchange ADAccess 2094	Configuration	Information	Process %1 (PID=%2). Registry key 'SYSTEM \CurrentControlSet \Services \MSExchange ADAccess\Diagnostics' is missing. Exchange Active Directory Provider cannot get a list of event log categories. Only events of level 'None' will be logged.
MSExchange ADAccess 2095	Topology	Information	Process %1 (PID=%2). The Configuration Domain Controller has been changed from %3 to %4.
MSExchange ADAccess 2096	Configuration	Information	Process %1 (PID=%2). Exchange Active Directory Provider will use the Configuration Domain Controller (%3) specified in the registry.
MSExchange ADAccess 2102	Topology	Error	Process %1 (PID=%2). All Domain Controller Servers in use are not responding: %3
MSExchange ADAccess 2103	Topology	Warning	Process %1 (PID=%2). All Global Catalog Servers in forest %3 are not responding: %4
MSExchange ADAccess 2093	Configuration	Information	Process %1 (PID=%2). Exchange Active Directory Provider will use Global Catalogs specified in the registry.
MSExchange ADAccess 2099	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider will

			use the Configuration Domain Controller (%3) specified in a call to SetConfigDCName.
MSExchange ADAccess 2111	LDAP	Error	Process %1 (PID=%2). Received LDAP error 0x%3 (%5) from Directory Server %4 due to Kerberos ticket timeout.
MSExchange ADAccess 2113	Topology	Information	Process %1 (PID=%2). Exchange Server %3 now has Audit Security Privilege on Domain Controller %4.
MSExchange ADAccess 2115	LDAP	Error	Process %1 (PID=%2). Exchange Active Directory Provider needs to close a connection to the Domain Controller %3 due to error 0x%4 (%5).
MSExchange ADAccess 2117	General	Information	Process %1 (PID=%2). Impersonated account %3 is calling into Exchange Active Directory Provider with the following callstack: %4 %5 %6 %7 %8 %9 %10 %11
MSExchange ADAccess 2125	Cache	Warning	Process %1 (PID=%2). An attribute on object %3 is too large to be cached. Requested size was %4, maximum cacheable is %5. Performance may be degraded.
MSExchange ADAccess 2127	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider detected that Active Directory server %3 is reachable again via port %4.
MSExchange ADAccess 2128	Configuration	Information	Process %1 (PID=%2). Object %3 was not found on the Domain Controller %4. This may indicate a

			replication or permission issue.
MSExchange ADAccess 2129	Topology	Information	Process %1 (PID=%2). Exchange Active Directory Provider needs a Domain Controller in domain %3. Found server %4.
MSExchange ADAccess 2131	LDAP	Information	Process %1 (PID=%2). Opening new connection to server %3 at port %4. Connection pool: %5.
MSExchange ADAccess 2132	LDAP	Information	Process %1 (PID=%2). Closing connection to the server %3 at port %4.
MSExchange ADAccess 2133	LDAP	Warning	Process %1 (PID=%2). An LDAP %3 operation succeeded but took %4 milliseconds - Server=%5. Base DN=%6, Filter=%7, Scope=%8.
MSExchange ADAccess 2134	LDAP	Information	Process %1 (PID=%2). Exchange Active Directory Provider received change notification for '%3'.
MSExchange ADAccess 2136	Configuration	Information	Process %1 (PID=%2). Exchange Active Directory Provider found multiple records for %3. Locate and fix the affected recipients to resume mail flow.
MSExchange ADAccess 2141	General	Information	Process %1 (PID=%2). Process preferred topology changed. Preferred Domain Controllers: %3 Preferred Global Catalog: %4 Preferred Configuration Domain Controller: %5
MSExchange ADAccess 2142	Topology	Error	Process %1 (PID=%2). Topology discovery failed, error

			0x%3.
MSExchange ADAccess 2143	Topology	Warning	Process %1 (PID=%2). Error occurred when getting server from domain Distinguished Name: %3. ADAM topology provider is not available. Please make sure Microsoft Exchange ADAM service is started.
MSExchange ADAccess 2150	Topology	Information	Process %1 (PID=%2). The following Active Directory servers are going to be used in connection pools of this process: Domain Controllers: %3 Global Catalogs: %4 Configuration Domain Controller: %5. Topology Version %6, Topology provider: %7.
MSExchange ADAccess 2151	General	Information	Process %1 (PID=%2). Microsoft.Exchange.Data.Directory.dll is loaded successfully.
MSExchange ADAccess 2154	LDAP	Information	Process %1 (PID=%2). Attribute %3 of '%4' had %5 values and required ranged read operations on Directory Server %6.
MSExchange ADAccess 2157	Validation	Warning	Process %1 (PID=%2). Configuration object %3 read from %4 failed validation. A partially valid object will be returned. Set the event logging level for Validation category to Expert to get additional events about each failure.
MSExchange ADAccess 2158	Validation	Information	Process %1 (PID=%2). Recipient object %3 read from %4 failed validation. A partially valid object will be returned. Set event logging level for

			Validation category to Expert to get additional events about each failure.
MSExchange ADAccess 2191	Exchange Topology	Information	Process %1 (PID=%2). Two servers with the same fully qualified domain name have been detected. Only %3 will be considered and %4 will be ignored.
MSExchange ADAccess 2390	LDAP	Information	Process %1 (PID=%2). DSAccess registered an Active Directory shutdown notification on the local server.
MSExchange ADAccess 2393	LDAP	Information	Process %1 (PID=%2). DSAccess failed to register an Active Directory shutdown notification with the local server because the local server does not support shutdown notifications. To expedite the shutdown process, manually shut down Exchange services before shutting down the server.
MSExchange ADAccess 2394	LDAP	Error	Process %1 (PID=%2). An LDAP search call returned a referral - Server=%3 Error code=%4 (%8). Base DN=%5, Filter=%6, Scope=%7.
MSExchange ADAccess 2402	Exchange Topology	Information	Process %1 (PID=%2). Server %3 is not assigned to any site. This can be caused by incorrect configuration of subnets or sites or by replication latency. Server will not be used.
MSExchange ADAccess 2452	General	Information	Process %1 (PID=%2). Impersonated account %3 is calling

			into Exchange Active Directory Provider and allowed.
MSExchange ADAccess 2453	General	Information	Process %1 (PID=%2). Function %3 failed indicating that the remote procedure call (RPC) server is temporarily unavailable - Error code=%4.
MSExchange ADAccess 2503	Site update	Information	Process %1 (PID=%2). Site monitor updated msExchServerSite in Active Directory. New site: %3 Old site: %4
MSExchange ADAccess 2602	General	Error	Process %1 (PID=%2). Failed to flush Kerberos ticket for local system account - Error code=%3. Microsoft Exchange Active Directory Topology service could not update token to have Exchange Servers group membership (SID: %4). This may be caused by replication latency. Wait for replication to complete and try again.
MSExchange ADAccess 2800	General	Information	Process %1 (PID=%2). The Microsoft Exchange Active Directory Topology Service has started successfully.
MSExchange ADAccess 2801	General	Information	Process %1 (PID=%2). The Microsoft Exchange Active Directory Topology Service has stopped successfully.
MSExchange ADAccess 2802	Topology	Information	Process %1 (PID=%2). %3 is a read-only domain controller. Exchange Active Directory Provider requires that domain controllers are not

			read-only.
MSExchange ADAccess 2901	General	Information	Process %1 (PID=%2). Default throttling policy for organization '%3' is missing.
MSExchange ADAccess 2902	General	Information	Process %1 (PID=%2). Multiple default throttling policies found for organization '%3'.
MSExchange ADAccess 2903	General	Information	Process %1 (PID=%2). Unable to initialize throttling performance counters. The exception was: '%3'
MSExchange ADAccess 2904	General	Information	Process %1 (PID=%2). Failed to read throttling policy with ID '%3'. The exception was: '%4'
MSExchange ADAccess 2905	General	Information	Process %1 (PID=%2). Dynamic distribution group %3 read from %4 is not valid.%5.
MSExchange ADAccess 2913	General	Information	Process %1 (PID=%2). Coudn't find a global address list for user '%3' (SID='%4')
MSExchange ADAccess 2914	General	Information	Process %1 (PID=%2). Deleted throttling policy was referenced. Id: '%3'.
MSExchange ADAccess 2920	General	Information	Process %1 (PID=%2). Component: %3. Unable to initialize resource health performance counters. Exception: '%4'
MSExchange ADAccess 2927	General	Information	Process %1 (PID=%2).The concurrency controller for resource '%3' detected that a thread stayed in the overflow queue for more than %4 milliseconds, which is a warning that the resource might be unhealthy.

MSExchange ADAccess 2929	General	Information	Process %1 (PID=%2).The concurrency controller for resource '%3' detected that the overflow queue has reached its warning limit of %4.
MSExchange ADAccess 2934	General	Information	Process %1 (PID=%2). The recipient full sync page token for tenant '%3' has been cleared from storage.
MSExchange ADAccess 2935	General	Information	Process %1 (PID=%2) Component %3. Encountered a timeout while trying to access remote performance counter '%4'. Remote server might be unresponsive.
MSExchange ADAccess 2936	General	Information	Process %1 (PID=%2) Component %3. Encountered an exception while trying to read remote performance counter '%4'. Exception: '%5'.
MSExchange ADAccess 2937	Validation	Information	Process %1 (PID=%2). Object [%3]. Property [%4] is set to value [%5], it is pointing to the Deleted Objects container in Active Directory. This property should be fixed as soon as possible.
MSExchange ADAccess 2938	General	Information	Process %1 (PID=%2).The Concurrency controller detected that Resource '%3' reached its concurrency limit and therefore the resource is set to unhealthy
MSExchange ADAccess 2939	General	Information	Process %1 (PID=%2). Unable to find UM Allowed CountryList. Id: '%3'.

1.8.7.2 ApplicationLogic Errors and Events

ApplicationLogic Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Application Logic events in Event Viewer so that you can troubleshoot and verify the MSExchangeApplicationLogic features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchangeApplicationLogic Errors and Events

The following table provides a list of the Application Logic errors and events.

Event ID	Category	Event type	Value or description
MSExchangeApplicationLogic 1002	TextMessaging	Error	Process %1 (ID %2) failed to load text messaging hosting data file %3. Failure details: %4
MSExchangeApplicationLogic 1003	TextMessaging	Information	Process %1 (ID %2) successfully loaded the text messaging hosting data files.

1.8.7.3 Common Errors and Events

Common Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Exchange Common errors and events in Event Viewer so that you can troubleshoot and verify the Common features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Common Errors and Events

The following table provides a list of the Common errors and events.

Event ID	Category	Event type	Value or description
MSExchange Common 205	General	Error	No DNS servers could be retrieved from network adapter %1. Check if the computer is connected to a network and Get-NetworkConnectionInfo returns any results.
MSExchange Common 579	General	Error	Removal of privileges from process "%1" (PID=%2, LABEL=%3) failed with error code %4.
MSExchange Common 6003	Logging	Error	%1: Failed to create the log directory: %2 because of the error: %3. Logs will not be generated until the problem is corrected.
MSExchange Common 6004	Logging	Error	%1: Failed to write logs because of the error: %2.

1.8.7.4 Control Panel Errors and Events

Control Panel Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates MSExchange Control Panel events in Event Viewer so that you can troubleshoot and verify the Exchange Control Panel features and services. Event Viewer tracks the following kinds of events in the given order based on importance:

- Error events
- Warning events
- Informational events

MSExchange Control Panel Errors and Events

The following table provides a list of the MSExchange Control Panel errors and events.

Event ID	Category	Event type	Value or description
MSExchange Control Panel 20	General	Error	The Web management interface couldn't find a mailbox for user '%

			1' and will let the user continue to site '%2'. This is expected for objects of type MailUser.
MSExchange Control Panel 30	Proxy	Error	Current User: '% 1'Client Access server "%2" tried to proxy Web management traffic to Client Access server "%3" and received the following error for "%4":%5
MSExchange Control Panel 26	Proxy	Error	Current User: '% 1'Client Access server "%2" tried to proxy Web management traffic to Client Access server "%3". This failed because the Outlook Web App registry key "AllowInternalUntrustedCerts" is set to "0", but no certificate trusted by "%2" was available for the Secure Sockets Layer (SSL) encryption of the proxy connection.
MSExchange Control Panel 28	Proxy	Error	Current User: '% 1'Client Access server "%2" tried to proxy Web management traffic to Client Access server "%3". This failed because one of the following configuration problems was encountered:1. "%3" has been set to use "http://" (not using SSL) instead of "https://" (using SSL). You can modify this by setting the InternalUrl parameter of the Web management virtual directory that this proxy traffic is going to. You can set that parameter using the Set-EcpVirtualDirectory cmdlet in the

			Exchange Management Shell.2. The destination virtual directory returned an HTTP 403 error code. This usually means it's not configured to accept SSL access. You can change this configuration by using Internet Services Manager on the Client Access server "%3".If you don't want this proxy connection to use SSL, set the registry key "AllowProxyingWithoutSSL" on this Client Access server and set the InternalUrl and SSL settings for the Web management virtual directory that this proxy traffic is going to accordingly.
MSExchange Control Panel 4	General	Warning	Current user: '%1'Request for URL '%2' failed with the following error:%3
MSExchange Control Panel 19	Redirect	Error	The Web management interface couldn't redirect user '%1' from site '%2' to site '%3' and will let the user continue to the original site. The possible causes are: There are no Client Access servers on the destination site with major version equal to '%4' or the Client Access server doesn't have an external URL.
MSExchange Control Panel 5	General	Warning	Current user: '%1'Web service call '%2' failed with the following error:%3
MSExchange Control Panel 31	General	Error	Can't determine if the current user "%1" is enabled for the RBAC role "%2". Error: "%3"

MSExchange Control Panel 27	Proxy	Error	Current User: '%1'Client Access server "%2" tried to proxy Web management traffic to Client Access server "%3". This failed because "%3" couldn't verify that the Active Directory account "%2" used to authenticate has the necessary access rights to send Web management proxy traffic. Verify in the IIS Manager that Windows Authentication is enabled in the internal 'ECP' virtual directory and that 'Get-EcpVirtualDirectory' reports 'WindowsAuthentication' as 'True' in the internal server '%3'.
MSExchange Control Panel 29	Proxy	Error	Current User: '%1'Client Access server "%2" tried to proxy Web management traffic to Client Access server "%3" but the target service wasn't available. Verify that "%2" has network connectivity with "%3", "%3" has the HTTP driver, the IIS service and IIS sites started, the "MSExchangeECPAppPool" is running, and firewall settings aren't blocking Web traffic.

1.8.7.5 ExchangeStoreDB Errors and Events

ExchangeStoreDB Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-08-10*

Microsoft Exchange Server 2010 generates ExchangeStoreDB events in Event Viewer so that you can troubleshoot and verify the ExchangeStoreDB features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

ExchangeStoreDB Errors and Events

The following table provides a list of the ExchangeStoreDB error and events.

Event ID	Category	Event type	Value or description
ExchangeStoreDB 230	Database recovery	Error	At '%8' the copy of database '%1' on this server encountered a serious I/O error that may have affected all copies of the database. The error returned by Suspend-MailboxDatabaseCopy was '%7'. Consult the event log on the server for other "ExchangeStoreDb" or "msexchangerepl" events for more specific information about the failure. All data should be immediately moved out of this database.
ExchangeStoreDB 129	Database recovery	Warning	At '%8' the Exchange store database '%1' copy on this server encountered an error. For more detail about this failure, consult the Event log on the server for other "ExchangeStoreDb" or "msexchangerepl" events. Page patching was initiated to restore the page.
ExchangeStoreDB 134	Database recovery	Error	At '%8' the Microsoft Exchange Information Store Database '%1' copy on this server encountered a serious I/O error. A

			lost write was detected. Page patching was initiated to restore the page. Consult the event log on the server for other "ExchangeStoreDb" or "msexchangerepl" events for more specific information about the failure.
ExchangeStoreDB 130	Database recovery	Warning	At '%8', the copy of database '%1' on this server encountered an error that it was able to repair. For specific information that may help identify the failure, consult the Event log on the server for other "ExchangeStoreDb" or "MSExchangeRepl" events. The Microsoft Exchange Replication service will automatically attempt to retry the operation.
ExchangeStoreDB 137	Database recovery	Error	At '%8' the copy of database '%1' on this server encountered a serious I/O error that may have affected all copies of the database. Consult the event log on the server for other "ExchangeStoreDb" or "msexchangerepl" events for more specific information about the failure. All data should be immediately moved out of this database. The passive database copy has been suspended.
ExchangeStoreDB 219	Database recovery	Warning	At '%8' database copy '%1' on this server appears to have a greater load than it can support.To help identify the

			specific issue, consult the Event log on the server for other storage and "ExchangeStoreDb" events. Service recovery was not attempted.
ExchangeStoreDB 119	Database recovery	Warning	At '%8' database copy '%1' on this server appears to have a greater load than it can support. Consult the Event log on the server for other storage and "ExchangeStoreDb" events that may identify the specific issue. Recovery was not attempted.
ExchangeStoreDB 123	Database recovery	Error	At '%8' the Microsoft Exchange Information Store Database '%1' copy on this server experienced a corrupted search catalog. Consult the event log on the server for other "ExchangeStoreDb" and "MSExchange Search Indexer" events for more specific information about the failure. Reseeding the catalog is recommended via the 'Update-MailboxDatabaseCopy' task.
ExchangeStoreDB 136	Database recovery	Error	At '%8' the copy of database '%1' on this server encountered a serious I/O error that may have affected all copies of the database. Consult the event log on the server for other "ExchangeStoreDb" or "msexchangerepl" events for more specific information about the failure. All

			data should be immediately moved out of this database.

1.8.7.6 MonitoringCorrelation Errors and Events

MonitoringCorrelation Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Monitoring Correlation events in Event Viewer so that you can troubleshoot and verify the MonitoringCorrelation features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MonitoringCorrelation Errors and Events

The following table provides a list of the Monitoring Correlation errors and events.

Event ID	Category	Event type	Value or description
MSExchangeMonitoringCorrelation 713	General	Error	%1
MSExchangeMonitoringCorrelation 714	General	Error	%1
MSExchangeMonitoringCorrelation 715	General	Warning	%1
MSExchangeMonitoringCorrelation 717	General	Warning	%1
MSExchangeMonitoringCorrelation 718	General	Warning	%1
MSExchangeMonitoringCorrelation 719	General	Warning	%1
MSExchangeMonitoringCorrelation 716	General	Warning	%1

1.8.7.7 MSExchangeAL Errors and Events

MSExchangeAL Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Exchange Address List events in Event Viewer so that you can troubleshoot and verify the Address List Service features and services. Event Viewer tracks the following kinds of events in the given order based on importance:

- Error events
- Warning events
- Informational events

MSExchangeAL Errors and Events

The following table provides a list of the MSExchangeAL errors and events.

Event ID	Category	Event type	Value or description
MSExchangeAL 8363	Error	Error	Microsoft Exchange failed to initialize Directory Service Access (DSAccess) with error 0x%1. Proxy address calculation services will not be available on the local Exchange server. %2
MSExchangeAL 8325	Error	Error	The service can't work properly because Email Address Policy '%1' has an invalid filter rule (PurportedSearch). The error is '%2'. Use the Exchange Management Console to correct this problem. New users, contacts, and groups won't be fully provisioned until this is fixed. %3
MSExchangeAL 8326	Error	Error	The address list '%1' has an invalid filter rule (PurportedSearch). The error is '%2'. No directory entries will belong to this address list until you correct this problem in the Exchange Management

			Console. %3
MSExchangeAL 8229	Error	Error	Unsupported or unloadable policy group: '%1'. %2
MSExchangeAL 8358	Error	Error	Microsoft Exchange couldn't read the registry key '%1' under 'HKLM\%2' because the value is not a DWORD.
MSExchangeAL 8364	Error	Error	Directory Service Access (DSAccess) failed to provide a domain controller to use to read configuration with error 0x%1. Proxy address calculation services will not be available on the local Exchange server. %2
MSExchangeAL 8213	Error	Error	Couldn't find an accessible writable domain controller for domain '%1'. %2
MSExchangeAL 8142	Error	Error	The service threw an unexpected exception.
MSExchangeAL 8115	Error	Error	The Win32 API call '%1' returned an error. The service could not be initialized. Make sure that the operating system was installed properly.
MSExchangeAL 8331	Error	Error	The service threw an unexpected exception which was caught at %1(%2)
MSExchangeAL 8252	Error	Error	Could not search under entry '%1' on directory %2. Cannot access Address List information. %3
MSExchangeAL 8359	Error	Error	The Recipient Update Service is slow to start because of network issues. The service will continue to retry until it successfully restarts. Until that time, not all

			Recipient Update Service features will be available.
MSExchangeAL 8114	Error	Error	The service could not be initialized because the necessary entry point '%1' could not be found in the file %2. Make sure that the operating system was installed properly.
MSExchangeAL 8063	Error	Error	Could not read the root entry on directory '%1'. Cannot access configuration information. %2
MSExchangeAL 8357	Error	Error	The search '%1' under entry '%2' failed with error code '%3'. Microsoft Exchange cannot access schema information. %4
MSExchangeAL 8362	Error	Error	Microsoft Exchange couldn't read the forest GUID from %1. Proxy address calculation services will not be available on the local Exchange server. %2
MSExchangeAL 8260	Error	Error	Could not open LDAP session to directory '%1' using local service credentials. Cannot access Address List configuration information. Make sure the server '%1' is running. %2
MSExchangeAL 8284	Error	Error	The Recipient Update Service could not find the Address List Root which is located in the Exchange Service entry under the attribute addressBookRoots. This might have been caused by a permissions problem. %1

MSExchangeAL 8144	Error	Error	The service threw an out of memory exception.

1.8.7.8 MSExchangeFDS Errors and Events

MSExchangeFDS Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Microsoft Exchange File Distribution service events in Event Viewer so that you can troubleshoot and verify the Microsoft Exchange File Distribution features and services. Event Viewer tracks the following kinds of events in the given order based on importance:

- Error events
- Warning events
- Informational events

Microsoft Exchange File Distribution Errors and Events

The following table provides a list of the Microsoft Exchange File Distribution errors and events.

Event ID	Category	Event type	Value or description
MSExchangeFDS 1007	General	Error	Process %1 (PID=%2). Unhandled exception occurred in worker thread %3. Exception message: %4 Current synchronization task is aborted.
MSExchangeFDS 1018	General	Warning	Process %1 (PID=%2). Failed to connect to remote server %3. The remote server may be down, or its Server service may not be running.
MSExchangeFDS 1001	FileReplication	Error	Process %1 (PID=%2). Manifest file %3 for Offline Address Book file set %4 is corrupted. Quitting current file synchronization operation.

MSExchangeFDS 1012	General	Warning	Process %1 (PID=%2). Active Directory contains invalid value for PollInterval attribute of OAB Virtual Directory object. The valid value range is 0-71582. The upper range limit value is used instead.
MSExchangeFDS 1017	General	Error	Process %1 (PID=%2). %3
MSExchangeFDS 1020	General	Error	Process %1 (PID=%2). Failed to copy file %3 to directory %4, the error: %5.
MSExchangeFDS 1016	General	Error	Process %1 (PID=%2). %3
MSExchangeFDS 1014	General	Error	Process %1 (PID=%2). Failed to read from metabase. Metabase object %3 can not be found. OAB synchronization suspended.
MSExchangeFDS 1005	FileReplication	Warning	Process %1 (PID=%2). %3 operation has failed for %4. Exception message: %5 Current file synchronization operation has ended
MSExchangeFDS 1010	FileReplication	Warning	Process %1 (PID=%2). Failed to read security descriptor from Active Directory for Offline Address Book %3. Synchronization task for this object is aborted.
MSExchangeFDS 1003	General	Warning	Process %1 (PID=%2). Temporarily unable to read configuration data for object %3 (%4). Will wait for %5 seconds and retry.
MSExchangeFDS 1021	General	Information	Process %1 (PID=%2). Could not find directory %3. This is

			normal if it has never been generated. Otherwise, make sure this directory and share has read permission for "Exchange Servers" group.
MSExchangeFDS 1002	General	Warning	Process %1 (PID=%2). Manifest file %3 for dial plan %4 is corrupted. The current file synchronization operation will be aborted.
MSExchangeFDS 1011	General	Warning	Process %1 (PID=%2). Active Directory contains invalid configuration object, validation error is "%3". Will wait for %4 seconds and retry.
MSExchangeFDS 1022	General	Information	Process %1 (PID=%2). Could not find file %3. This is normal if it has never been generated. Otherwise, make sure this file has read permission for "Exchange Servers" group.
MSExchangeFDS 1015	General	Error	Process %1 (PID=%2). Failed to read property %3 from metabase object %4. OAB synchronization suspended.
MSExchangeFDS 1019	General	Error	Process %1 (PID=%2). Failed to copy file %3 to directory %4, destination directory does not exist.
MSExchangeFDS 1013	General	Error	Process %1 (PID=%2). Remote file %3 not found. Current synchronization task aborted.
MSExchangeFDS 1006	FileReplication	Warning	Process %1 (PID=%2). %3 operation has failed for %4 to %5. Exception message:

			%6 Current file synchronization operation has ended.

1.8.7.9 MSExchangeIS Errors and Events

MSExchangeIS Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates Exchange Information Store events in Event Viewer so that you can troubleshoot and verify the MSExchangeIS features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchangeIS Errors and Events

The following table provides a list of Exchange Information Store errors and events.

Event ID	Category	Event type	Value or description
MSExchangeIS 10023	Error	Error	The mailbox for %1 (GUID %2) has exceeded the maximum Recoverable Items Quota. Items cannot be deleted from this mailbox. The mailbox owner should be notified about the condition of the mailbox as soon as possible. Please remove items from Recoverable Items or increase the Recoverable Items Quota to restore functionality.
MSExchangeIS 9506	Error	Error	Out of memory
MSExchangeIS 9693	Error	Error	Failed to create a new named property for database "%1" because the number of named properties reached the quota limit for MAPI protocol (%2). User

			attempting to create the named property: "%3" Named property GUID: %4 Named property name/id: "%5"
MSExchangeIS 1088	Error	Error	The database could not be started because the distinguished name (DN) %2 of mailbox database "%3" does not match the DN of directory %1. The database may have been restored to a computer that is in an organization or site different from the original database.
MSExchangeIS 5000	Error	Error	Unable to initialize the Microsoft Exchange Information Store service. %1 - Error %2.
MSExchangeIS 9667	Error	Error	Failed to create a new named property for database "%1" because the number of named properties reached the quota limit (%2). User attempting to create the named property: "%3" Named property GUID: %4 Named property name/id: "%5"
MSExchangeIS 9643	Information	Information	Process termination function %1 was called by a function in module %2; some parameters and their values were %3. A significant section of the call stack is in the data section.
MSExchangeIS 9786	Warning	Warning	The database engine has consumed %1% of the "%2" resource (%3 used out of a maximum of %4) for database '%5'.
MSExchangeIS 9673	Error	Error	An exception with

			code %1 was thrown in module %2; some parameters and their values were %3. A significant section of the call stack is in the data section.
MSExchangeIS 9691	Error	Error	Status %1 registering RPC protocol "%2" endpoint="%3". This may be expected, depending on the machine configuration.
MSExchangeIS 1121	Error	Error	Error %1 connecting to Active Directory.
MSExchangeIS 1184	Error	Error	Cannot start the Microsoft Exchange Information Store. Error retrieving local host information. Please make sure that your server's TCP/IP networking software is properly configured.
MSExchangeIS 5003	Error	Error	Unable to initialize the Information Store service because the clocks on the client and server are skewed. This may be caused by a time change either in the client or the server, and may require a reboot of that computer. Verify that your domain is properly configured and is currently online.
MSExchangeIS 9509	Error	Error	Out of file handles
MSExchangeIS 9688	Error	Error	Exchange store '%1': The logical size of this database (the logical size equals the physical size of the .edb file minus the logical free space) is %2 GB. This database size is approaching the size limit of %3 GB. If the logical

			database size exceeds the maximum size limit, it will be dismounted on a regular basis.
MSExchangeIS 9659	Error	Error	The Microsoft Exchange Information Store encountered an unexpected exception %1 at address %2 while processing a request for user %3.
MSExchangeIS 10024	Error	Error	The mailbox for %1 (GUID %2) has exceeded the Recoverable Items Warning Quota. Please remove items from Recoverable Items or increase the Recoverable Items Warning Quota and Recoverable Items Quota. If the Recoverable Items Quota is exceeded, the user will be unable to delete items from the mailbox.
MSExchangeIS 5002	Error	Error	Unable to initialize the Microsoft Exchange Information Store service. Out of memory.

1.8.7.10 MSExchangeRepl Errors and Events

MSExchangeRepl Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Replication service errors and events in Event Viewer so that you can troubleshoot and verify the Exchange Replication service features and services. Event Viewer tracks the following kinds of events in the given order, based

on importance:

- Error events
- Warning events
- Informational events

MSExchangeRepl Errors and Events

The following table provides a list of Exchange Replication service errors and events.

Event ID	Category	Event type	Value or description
MSExchangeRepl 4038	Service	Warning	The Cluster service health check failed.%nMailbox server: %1%nError: %2
MSExchangeRepl 2120	Service	Warning	The Microsoft Exchange Replication service failed to start the HTTP listener. The error was %1
MSExchangeRepl 2017	Exchange VSS Writer	Error	The Microsoft Exchange Replication service VSS Writer initialization failed with error %1. The Exchange VSS Writer is not loaded.
MSExchangeRepl 2092	Action	Error	Database: %1%nMailbox server: %2%n%nDatabase %1 won't be mounted because the number of lost logs was greater than the amount specified by the AutoDatabaseMountDial.%n* The log file generated before the switchover or failover was: %3%n* The log file successfully replicated to this server was: %4%n* AutoDatabaseMountDial is set to: %5%n%nAttempts to copy the log files from the source server were unsuccessful. Error: %6
MSExchangeRepl 3175	Service	Warning	The Microsoft Exchange Replication service failed to start the Active Manager RPC server.

MSExchangeRepl 2069	Service	Error	The Microsoft Exchange Replication service is unable to remove log file %2 for %1 because the file is in use or because of insufficient permissions. The database copy status will be set to Failed. Error: %3
MSExchangeRepl 4040	Service	Warning	Active Manager health check failed.% nMailbox server: % 1%nMessage: %2
MSExchangeRepl 4108	Service	Warning	The Microsoft Exchange Replication service failed to clean up file '%2', which was used for an incremental reseed of database '%1'. Error: %3
MSExchangeRepl 4044	Service	Information	Database availability group members up health check failed.% nMailbox server: % 1%nMessage: %2
MSExchangeRepl 2055	Service	Error	The Microsoft Exchange Replication service failed to create a temporary log file for %1 when %2. Service recovery was not attempted.
MSExchangeRepl 4109	Service	Warning	The Microsoft Exchange Replication service failed to clean up files under '%1' for database '%2'. Error: %3
MSExchangeRepl 4051	Service	Error	Quorum group health check failed.% nMailbox server: % 1%nMessage: %2
MSExchangeRepl 2135	Service	Error	The Microsoft Exchange Replication service failed to start the Tasks RPC server. This may be due to insufficient permissions in Active Directory.

MSExchangeRepl 4046	Service	Error	Database availability group network health check failed.% nNetwork: %1% nError: %2
MSExchangeRepl 4049	Service	Warning	File share quorum health check failed.% nMailbox server: % 1%nMessage: %2
MSExchangeRepl 4053	Service	Warning	The Tasks RPC listener health check failed.%nMailbox server: %1% nMessage: %2
MSExchangeRepl 4055	Service	Warning	HttpListener health check has failed.% nMailbox Server: % 1%nSpecific Message: %2
MSExchangeRepl 2001	Service	Warning	The Microsoft Exchange Replication service has started.

1.8.7.11 MSExchangeRPC Errors and Events

MSExchangeRPC Errors and Events

Exchange Server 2010 > Mailbox > Error and Event Reference for Mailbox Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Exchange RPC events in Event Viewer so that you can troubleshoot and verify the Exchange RPC features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Exchange RPC Errors and Events

The following table provides a list of MSExchangeRPC errors and events.

Event ID	Category	Event type	Value or description
MSExchangeRPC 1000	General	Information	The Microsoft Exchange RPC service

			has started successfully and is now ready to accept logons to private mailboxes.
MSExchangeRPC 1006	General	Information	Starting MSExchangeRPC service. Process ID %1. %2 %3.
MSExchangeRPC 1020	General	Information	The Microsoft Exchange RPC service has started successfully and is now ready to accept sign-ins to public folders.

1.8.7.12 MSExchangeSA Errors and Events

MSExchangeSA Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates Exchange System Attendant service events in Event Viewer so that you can troubleshoot and verify the System Attendant features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Exchange System Attendant Errors and Events

The following table provides a list of MSExchangeSA errors and events.

Event ID	Category	Event type	Value or description
MSExchangeSA 9371	Error	Error	OABGen encountered an error while generating the differential downloads of address list '%1'. The offline address book has not been updated so clients will not be able to download the current set of changes. Check other logged events

			to find the cause of this error. - %2
MSExchangeSA 9376	Error	Error	OABGen failed to create the '%1' directory. The directory name syntax is incorrect. The offline address book name cannot include certain characters ('/', '\', ':', '?', '"', '<', '>', or '|'). The offline address book won't be published. - %2
MSExchangeSA 9126	Error	Error	OABGen encountered error %1 while calculating the offline address book for address list '%2'. This offline address book won't be available for client download. - %3.
MSExchangeSA 9373	Error	Error	OABGen detected that the file '%1' is corrupted or missing. This indicates data tampering or disk problems. Restore files in this folder from the recent backup or clean up folder content and force a full OAB generation. - %2
MSExchangeSA 9385	Error	Error	Microsoft Exchange System Attendant failed to read the membership of the universal security group '%1'; the error code was '%2'. The problem might be that the Microsoft Exchange System Attendant does not have permission to read the membership of the group. If this computer is not a member of the group '%1', you should manually stop all Microsoft Exchange services, run the task 'add-

			ExchangeServerGroup Member,' and then restart all Microsoft Exchange services.
MSExchangeSA 9397	Error	Error	OALGen failed to retrieve the CMS name. OAB generation will not be performed.
MSExchangeSA 2033	Error	Error	Unable to generate a unique '%1' e-mail address type for '%2'.
MSExchangeSA 9301	Error	Error	Failed to generate offline address book %1, error '%2'
MSExchangeSA 2030	Error	Error	Unable to find the e-mail address '%1' in the directory. Error '% 2'.
MSExchangeSA 9157	Error	Error	Microsoft Exchange System Attendant does not have sufficient rights to read Exchange configuration objects in Active Directory. Wait for replication to complete and then check to make sure that the computer account is a member of the "Exchange Servers" and "Exchange Install Domain Servers" security groups.
MSExchangeSA 9152	Information	Information	Microsoft Exchange System Attendant reported an error '% 1' in its DS Monitoring thread.
MSExchangeSA 2025	Error	Error	Unable to generate the e-mail address. Address type '%1' is not valid.
MSExchangeSA 9408	Error	Error	OABGen failed to load the OAB version 4 manifest file '%1'. This may indicate data tampering or disk problems. Restore files in this folder from

			the recent backup or clean up folder content and force a full OAB generation. - %2
MSExchangeSA 9368	Error	Error	OABGen could not flush the file '%2' to the disk (error %1). The offline address book is not going to be published to the distribution point. - %3
MSExchangeSA 2027	Error	Error	Unable to generate the e-mail address. Unable to load address module '%1' for address type '%2'. Error %3.
MSExchangeSA 9370	Warning	Warning	OALGen encountered error %1 while updating the time stamp of the '%2' file. - %3
MSExchangeSA 2013	Error	Error	An error occurred adding replica of naming context '%1' to server '%2' from server '%3'. %4
MSExchangeSA 2038	Error	Error	Unable to create directory '%1'.
MSExchangeSA 9153	Information	Information	Microsoft Exchange System Attendant reported an error '%1' when setting DS notification.
MSExchangeSA 9390	Error	Error	OALGen failed to find the OAB version 4 manifest file '%1'. This is normal if it is the first time this offline address list has been published to the file system. Check other logged events to see if this is a serious error.
MSExchangeSA 9175	Error	Error	The MAPI call '%1' failed with the following error: %2
MSExchangeSA 9386	Warning	Warning	OALGen is configured to generate version 2

			or version 3 OAB files for offline address book '%1' but there is no public folder server available. OAB versions prior to version 4 require a public folder server and cannot be generated at this time. Please ensure that a public folder server with a replica of the Offline Address Book system folder is online and mounted, or disable all OAB versions other than version 4.
MSExchangeSA 9186	Warning	Warning	Microsoft Exchange System Attendant has detected that the local computer '%1' is not a member of group '%2'. System Attendant is going to add the local computer into the group. The current members of the group are '%3'.
MSExchangeSA 9384	Error	Error	OALGen only supports alphanumeric and space characters on the offline address name. The offline address list is not going to be published. - %1
MSExchangeSA 9187	Error	Error	Microsoft Exchange System Attendant failed to add the local computer as a member of the DS group object '%1'. Please stop all Exchange services, add the local computer into the group manually and restart all the services.
MSExchangeSA 9149	Information	Information	Microsoft Exchange System Attendant failed to start Exchange server '%1'.

			Error code '%2'.
MSExchangeSA 9367	Error	Error	OABGen could not copy file '%2' to '%3' (error %1). The offline address book is not going to be published to the distribution point. - %4
MSExchangeSA 2037	Error	Error	The file version of '%1' installed on the local server is not current. Unable to locate a correct version on any server in the site.
MSExchangeSA 9391	Error	Error	OALGen failed to read the OAB version 4 manifest from folder '%1'.
MSExchangeSA 9396	Error	Error	OALGen is running on an SCC cluster node which does not have the registry value '%1\%2\%3' or it is set to a non-existing path. OAB generation will not be performed.
MSExchangeSA 9392	Error	Error	OABGen is unable to read file information for file '%1'. This might indicate permission problems. - %2
MSExchangeSA 9315	Error	Error	Exchange detected that "%1" is not the correct version required to run Exchange System Manager or Exchange Server 2003. This may cause failures in Exchange System Manager, affect availability of your server, or both. For more information, see Microsoft Knowledge Base article Microsoft does not support installing Exchange Server components and Outlook on the same computer.

MSExchangeSA 1005	Error	Error	Unexpected error %1 occurred.
MSExchangeSA 9364	Warning	Warning	OABGen received error %1 while trying to delete file '%2'. This is not a fatal problem and the offline address list will be normally posted to the distribution point. - %3
MSExchangeSA 9317	Error	Error	Failed to register Service Principal Name for %1; error code was %2.
MSExchangeSA 9150	Informational	Information	Microsoft Exchange System Attendant failed to stop Exchange server '%1'. Error code '%2'.
MSExchangeSA 9393	Warning	Warning	The directory object for this computer has the serverRole attribute set to 1 (indicating a Front End server). This will be ignored.
MSExchangeSA 9369	Error	Error	OABGen encountered an error while publishing the OAB files to the distribution point '% 1'. Check other logged events to see more information about the problem. - %2
MSExchangeSA 9363	Error	Error	OALGen failed to download the files currently in offline address list '%1'. The offline address list is going to be generated without the previous differential files. - %2
MSExchangeSA 2034	Error	Error	Unable to generate an e-mail address. The '%1' address type was returned by address generation DLL '%2'.

MSExchangeSA 9340	Warning	Warning	A new parent Legacy Exchange DN container value '%1' was found during generation of the differential update file for offline address list '%2'. This will force clients using this offline address list to do a full download of the offline address list. - %3
MSExchangeSA 9154	Informational	Information	DSAccess returned an error '%1' on DS notification. Microsoft Exchange System Attendant will reset DS notification later.
MSExchangeSA 2031	Error	Error	An e-mail address of type '%1' couldn't be generated. Success was indicated, but no e-mail address was returned.
MSExchangeSA 9005	Error	Error	The OABGEN.DLL is required but cannot be loaded, error '%1'.
MSExchangeSA 9398	Error	Error	OALGen is running on a passive cluster node. OAB generation will not be performed.
MSExchangeSA 9320	Warning	Warning	OABGen could not generate full details for some entries in the offline address list for address list '%1'. To see which entries are affected, set event logging for the offline address list generator to at least medium.
MSExchangeSA 1008	Error	Error	Unable to move mailbox '%1'. Error: %2
MSExchangeSA 2035	Error	Error	The e-mail address description object in the Microsoft Exchange directory for the '%1' address type on '%2' machines is missing.

MSExchangeSA 9395	Warning	Warning	OALGen is running on CCR cluster node which does not have registry value '%1\%2\%3' or it is not set to this node name. OAB generation will not be performed.
MSExchangeSA 9394	Warning	Warning	OALGen failed to open directory '%1' as the OAB V4 publishing point. The default location under the Exchange install path will be used.
MSExchangeSA 1004	Informational	Information	%1 failed to start.
MSExchangeSA 9375	Error	Error	OABGen failed to create the '%1' directory. The directory name is invalid. The offline address book name cannot be a device name ('prn', 'aux', etc). The offline address book is not going to be published. - %2
MSExchangeSA 9321	Error	Error	OABGen could not generate full details for entry '%1' in address list '%2' because the total size of the details information is greater than 64 kilobytes. - %3
MSExchangeSA 9151	Informational	Information	Microsoft Exchange System Attendant failed while restarting its internal services: '%1'.
MSExchangeSA 1031	Error	Error	One of the System Attendant's task is blocked. Function: %1
MSExchangeSA 9300	Error	Error	Failed to generate offline address book, error '%1'
MSExchangeSA 1038	Error	Error	Microsoft Exchange System Attendant was unable to find

			the Exchange server object named '%1' in Active Directory. All known domain controllers were checked for this object.
MSExchangeSA 5017	Error	Error	An attempt was made to use the Cluster RPC interface without proper permissions.
MSExchangeSA 9387	Error	Error	OALGen failed to read the OAB version 4 property list from registry key '%1'. The registry value must be a binary value and the number of bytes must be a multiple of 4. The version 4 OAB files will not be generated until this is corrected.
MSExchangeSA 2029	Error	Error	Unable to generate e-mail addresses because no valid e-mail address types were specified.
MSExchangeSA 9130	Error	Error	OABGen could not create a message to post in the public folder for address list '%3'. MAPI component '%1' encountered error '%2'. - %4
MSExchangeSA 9389	Error	Error	The task failed to correctly generate RUS information [Proxies, Addresslists, Policies included] for this object, error '%1'.
MSExchangeSA 9001	Error	Error	The ABV DG dll is required but cannot be loaded, error '%1'.
MSExchangeSA 9360	Error	Error	OABGen encountered an error while generating the %1 file for version 2 and 3 differential downloads of address list '%2'. The offline address book has not been updated so

			clients will not be able to download the current set of changes. Check other logged events to find the cause of this error. If the cause of the problem was intentional or cannot be resolved, OABGen can be forced to post a full offline address book by creating the DWORD registry key 'HKEY_LOCAL_MACHINE\%3\%4' and setting it to 1 on this server. When OABGen next generates the offline address book, clients will perform a full OAB download. After that time, the registry key should be removed to prevent further full downloads. - %5
MSExchangeSA 9002	Error	Error	The ABV DG service failed to start, error '%1'.
MSExchangeSA 9094	Error	Error	The MAD Free Busy dll is missing or failed to start properly, error '%1'.
MSExchangeSA 1000	Informational	Information	%1 is starting. Microsoft Exchange Server System Attendant, service startup complete, version %2 (build %3).
MSExchangeSA 9006	Informational	Information	Microsoft Exchange System Attendant is loading '%1'.
MSExchangeSA 9007	Informational	Information	Microsoft Exchange System Attendant is initializing '%1'.
MSExchangeSA 9008	Informational	Information	Microsoft Exchange System Attendant is starting '%1'.
MSExchangeSA 9012	Informational	Information	Microsoft Exchange System Attendant is binding to domain

			controller '%1'.
MSExchangeSA 9013	Informational	Information	Microsoft Exchange System Attendant is being started for Exchange server '%1'.
MSExchangeSA 9014	Informational	Information	Microsoft Exchange System Attendant has been successfully started for Exchange server '%1'.

1.8.7.13 MSExchangeSetup Errors and Events

MSExchangeSetup Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-05-14*

Microsoft Exchange Server 2010 generates Exchange Setup events in Event Viewer so that you can troubleshoot and verify the MSExchangeSetup features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

Exchange Setup Errors and Events

The following table provides a list of MSExchangeSetup errors and events.

Event ID	Category	Event type	Value or description
MSExchangeSetup 1002	Error	Error	Exchange Server component %1 failed. Error: %2
MSExchangeSetup 1	Informational	Information	Microsoft Exchange Setup
MSExchangeSetup 1000	Informational	Information	Exchange Setup (build %1) was started.
MSExchangeSetup 1001	Informational	Information	Exchange Setup (build %1) completed successfully.
MSExchangeSetup	Informational	Information	During installation,

1003			Exchange Setup modified the WebSvcExtRestrictionList metabase key. The WebSvcExtRestrictionList metabase key contains a list of .dll files that are either allowed or denied access to run on your server. Exchange setup has added and allowed the following .dll files and extension groups to run: %1 Parts of Microsoft Exchange require this modification to work properly.
MSExchangeSetup 1004	Informational	Information	During uninstall, Exchange Setup did not disable the following Web Service Extensions: %1

1.8.7.14 OAB Maintenance Errors and Events

OAB Maintenance Errors and Events

Exchange Server 2010 > Mailbox > Error and Event Reference for Mailbox Servers >

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates OAB Maintenance events in Event Viewer so that you can troubleshoot and verify the OAB Maintenance features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

OAB Maintenance Errors and Events

The following table provides a list of OAB Maintenance errors and events.

Event ID	Category	Event type	Value or description
MSExchange OAB Maintenance 1001	General	Information	The OAB Maintenance servicelet is starting.
MSExchange OAB Maintenance 1002	General	Information	The OAB Maintenance Servicelet caught an exception of type %1:

			"%2". A Watson report will be sent, and the servicelet will be re-started.
MSExchange OAB Maintenance 1003	General	Information	The OAB Maintenance Servicelet caught an exception of type %1: "%2". The task did not complete successfully.
MSExchange OAB Maintenance 2001	Orphaned OAB Recovery	Information	The server responsible for performing the OAB recovery scan is %1.
MSExchange OAB Maintenance 2002	Orphaned OAB Recovery	Information	Because this server is not the one responsible for performing the OAB recovery scan, the task is exiting.
MSExchange OAB Maintenance 2003	Orphaned OAB Recovery	Information	Orphaned OAB recovery scan has begun.
MSExchange OAB Maintenance 2005	Orphaned OAB Recovery	Information	No orphaned offline address books were found.
MSExchange OAB Maintenance 2006	Orphaned OAB Recovery	Information	%1 orphaned offline address books were found. The OAB Maintenance Servicelet will attempt to move these offline address books to functioning servers.
MSExchange OAB Maintenance 2007	Orphaned OAB Recovery	Information	The offline address book %1 was successfully moved to server %2.
MSExchange OAB Maintenance 2008	Orphaned OAB Recovery	Information	While attempting to move the offline address book %1, the OAB Maintenance Servicelet caught an exception of type %2: "%3". The offline address book was not moved.

1.8.7.15 Progress Manager Errors and Events

Progress Manager Errors and Events

Applies to: *Exchange Server 2010 SP3*

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates Process Manager events in Event Viewer so that you can troubleshoot and verify the Process Manager features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

Topic Last Modified: *2012-04-24*

Microsoft Exchange Server 2010 generates MSExchange Search Indexer events in Event Viewer so that you can troubleshoot and verify the Search Indexer features and services. Event Viewer tracks the following kinds of events in the given order, based on importance:

- Error events
- Warning events
- Informational events

MSExchange Search Indexer Errors and Events

The following table provides a list of MSExchange Search Indexer errors and events.

Event ID	Category	Event type	Value or description
MSExchange Search Indexer 122	General	Information	MS Search (Exchange) reached the memory cap, and now the memory is %1 Bytes. The cap is %2 Bytes.
MSExchange Search Indexer 115	General	Warning	Exchange Search Indexer failed to retreive local server object from AD (%1).

1.9 Unified Messaging

Unified Messaging

Exchange Server 2010 >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-16*

Unified Messaging combines voice messaging and e-mail into one Inbox, which can be accessed from the telephone and the computer. Unified Messaging integrates Exchange Server 2010 with the telephony network in your organization and brings the features found in Unified Messaging to the core of the Exchange Server product line.

The following topics are gateways to information about the Unified Messaging servers in Exchange 2010.

Understanding Unified Messaging

This topic is a collection of links to topics that provide detailed information about the Unified Messaging features in Exchange 2010. These topics will help you gain a better understanding of the Unified Messaging server role.

Planning Roadmap for New Deployments

This topic provides an overview of how to plan your Exchange 2010 deployment, including Unified Messaging features.

Deploy a New Exchange 2010 RTM UM Environment

This topic provides an overview of how to plan your Exchange 2010 Unified Messaging.

Upgrade from Exchange 2007 SP3 to Exchange 2010 RTM Unified Messaging

This topic describes the upgrade process from an existing Exchange Server 2007 Unified Messaging deployment to Exchange 2010 Unified Messaging.

Managing Unified Messaging

This topic is a collection of links that provide information about managing Unified Messaging features in your organization.

Securing Unified Messaging Servers

This topic is a collection of links that will help you manage the security of your Unified Messaging infrastructure.

Troubleshooting Reference for Unified Messaging Servers

This topic is a collection of links that provide troubleshooting information specific to

Unified Messaging.

Performance Counter Reference for Unified Messaging Servers

This topic is a collection of links that describe the various performance counters that are used by Unified Messaging.

Error and Event Reference for Unified Messaging Servers

This topic is a collection of links that provide explanations and suggested user actions for Unified Messaging errors and events you may encounter.

Virtualization of the Unified Messaging Role in Exchange 2010 SP1

1.9.1.1 Overview of Unified Messaging

Overview of Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-07-24*

Microsoft Exchange Server 2010 Unified Messaging (UM) combines voice messaging and e-mail messaging into a single messaging infrastructure. Unified Messaging puts all e-mail and voice messages into one Exchange 2010 mailbox that can be accessed from many different devices. After Unified Messaging servers have been deployed on a network, users can access their messages using Outlook Voice Access, from any telephone, from a mobile phone, or from the computer.

Today, people in organizations frequently manage their voice messages separately from their e-mail messages. Additionally, IT administrators frequently manage the voice mail or telephony networks and the e-mail systems or data networks as separate systems. In these situations, voice mail and e-mail are located in separate inboxes that are hosted on separate servers accessed through the desktop for e-mail and through the telephone for voice mail. Unified Messaging uses the Exchange 2010 store for all messages, including e-mail and voice messages.

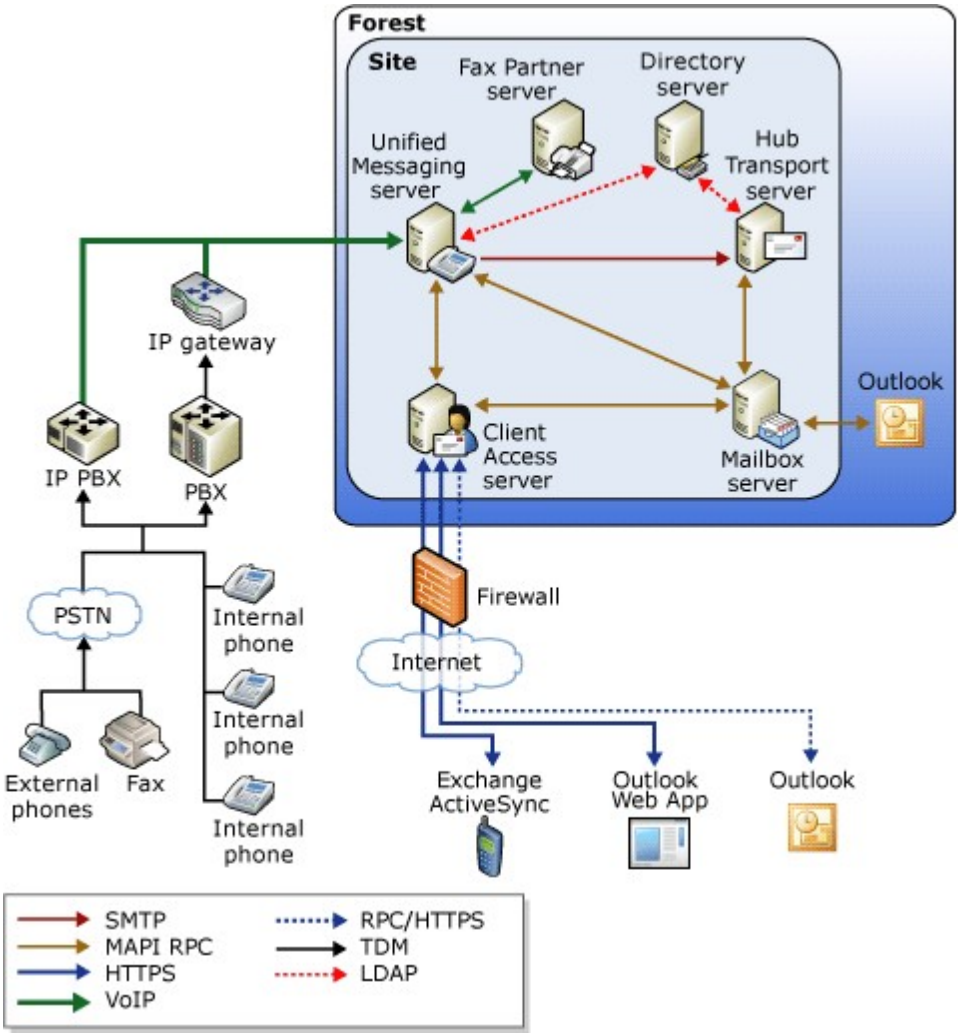
Looking for management tasks related to Unified Messaging? See Managing Unified Messaging.

Contents

Overview of Unified Messaging

In Microsoft Exchange 2010, the Unified Messaging server role is one of several server roles that you can install and then configure on a computer running Windows Server 2008. Unified Messaging is included with Exchange Server 2007 and Exchange 2010, and it brings with it new telephony concepts that may not be familiar to an Exchange administrator.

Unified Messaging combines voice messaging, fax messaging and e-mail messaging in the Exchange store. Unified Messaging integrates Microsoft Exchange with telephony networks and brings the UM features to the core of Exchange. The following figure shows the relationship between an organization's telephony network components and the UM system.



In the previous figure, the Unified Messaging solution provides access to telephony systems by using standard Voice over IP (VoIP) protocols. These protocols include Session Initiation Protocol (SIP), Realtime Transport Protocol (RTP), and the T.38 protocol. The IP gateways provide interoperability for legacy Private Branch eXchange (PBX) systems. For details, see Understanding Telephony Concepts and Components.

Note:
Installing and running the Unified Messaging server role in a virtualized environment is supported if you are running Microsoft Exchange Server 2010 Service Pack 1 (SP1) or a later version. The Unified Messaging server role is not supported in a virtualized environment that is running Exchange 2010 RTM.

Return to top

Benefits of Exchange 2010 Unified Messaging

The Exchange 2010 Unified Messaging solution offers benefits for the end user and also for the IT administrator.

User Benefits

When you deploy Exchange 2010 Unified Messaging, users can access voice mail, e-mail, and calendar information that's located in their Exchange 2010 mailbox from an e-mail client, for example, Outlook or Microsoft Office Outlook Web App, from a mobile phone with Microsoft Exchange ActiveSync set up, such as a Windows Mobile phone, or from a telephone. Additionally, users will be able to use the following features:

- **Access to Exchange information** UM-enabled users can access a full set of voice mail features from Internet-capable mobile phones, Microsoft Office Outlook 2007, Outlook 2010, and Outlook Web App. These features include many voice mail configuration options and the ability to play a voice message from either the Reading Pane, using an integrated Windows Media Player, or the message list, using computer speakers.
- **Play on Phone** The Play on Phone feature lets UM-enabled users play voice messages over a telephone. If the user works in an office cubicle, is using a public computer or a computer that isn't enabled for multimedia, or is listening to a voice message that's confidential, they might not want to or be able to listen to a voice message through computer speakers. They can play the voice message using any telephone, including a home, office, or mobile telephone.
- **Voice mail form** The Outlook 2007, Outlook Web App, and Outlook 2010 voice mail form resembles the default e-mail form. It gives users an interface for performing actions such as playing, stopping, or pausing voice messages, playing voice messages on a telephone, and adding and editing notes. The voice mail form includes the embedded Windows Media Player and an Audio notes field. The embedded Windows Media Player and notes field are displayed in either the Reading Pane when users preview a voice message or in a separate window when they open the voice message. If users aren't enabled for Unified Messaging, or if Outlook 2007 hasn't been installed on the client computer, they view voice messages as e-mail attachments, and the voice mail form isn't available.
- **User configuration** A user who's enabled for Unified Messaging can configure several voice mail options for Unified Messaging using Outlook Web App. For example, the user can configure telephone access numbers and the voice mail Play on Phone number, and can then reset a voice mail access PIN.
- **Call answering** Call answering includes answering incoming calls on behalf of users, playing their personal greetings, recording messages, and submitting them for delivery to their Inbox as an e-mail message.
- **Call Answering Rules** Call Answering Rules is a new feature in Exchange 2010. Using this feature, end users can dictate how their incoming call answering calls should be handled. The way call answering rules are applied to incoming calls is similar to the way Inbox rules are applied to incoming e-mail messages. By default, no call answering rules are configured. If an incoming call is answered by a Unified Messaging (UM) server, the caller is prompted to leave a voice message for the called party. Using call answering rules, a caller can:
  - Leave a voice message for the UM-enabled user.
  - Transfer to an alternate contact of the UM-enabled user.
  - Transfer to the alternate contact's voice mail.
  - Transfer to other phone numbers that the UM-enabled user has configured.
  - Use the Find-Me feature or locate the UM-enabled user via a supervised transfer.
- **Voice Mail Preview** In Exchange 2010, the Unified Messaging server role uses ASR on newly created voice mail messages. When users receive voice messages, the messages contain both a recording and text that's been created from the voice recording. Users see the voice message text displayed in an e-mail message from within Outlook Web App, Outlook 2007, or Outlook 2010.
- **Message Waiting Indicator** Message Waiting Indicator is a feature found in most legacy voice mail systems and can refer to any mechanism that indicates the existence of a new message. In Exchange 2007, this functionality was

provided by a third-party application, which indicated receipt of a new voice message by lighting the lamp on the desk phone. This feature has been added to Exchange 2010, and third-party software isn't needed. Enabling or disabling Message Waiting Indicator is done on the user's mailbox or on a UM mailbox policy.

- **Missed call and voice mail notifications using SMS** When users are members of a hosted or consumer dial plan, and they configure their voice mail settings with their mobile phone number and configure call forwarding, they can receive notifications about missed calls and new voice messages on their cell phones in a text message via the Short Messaging Service (SMS). However, to receive these types of notifications, the users must first configure text messaging and also enable **Notifications** on their account.
- **Protected Voice Mail** Protected Voice Mail is Unified Messaging functionality that enables users to send private mail. This mail is protected by Active Directory Rights Management Services (AD RMS), and users are restricted from forwarding, copying, or extracting the voice file from e-mail. Protected Voice Mail increases the confidentiality of Unified Messaging, and lets users rely on Unified Messaging if they want to limit the audience for voice messages. This functionality is similar to the way private e-mail messages were handled in Exchange 2007. In Exchange 2010, it also applies to voice mail messages.
- **Outlook Voice Access** There are two Unified Messaging user interfaces available to UM-enabled users: the telephone user interface (TUI) and the voice user interface (VUI). These two interfaces together are called Outlook Voice Access. Subscribers can use Outlook Voice Access when they access the Unified Messaging system from an external or internal telephone. UM-enabled users who dial in to the Unified Messaging system can access their mailbox using Outlook Voice Access. Using a telephone, a UM-enabled user can:
  - Access voice mail
  - Listen to, forward, or reply to e-mail messages
  - Listen to calendar information
  - Access or dial contacts who are stored in the global address list or a group in their Contacts
  - Accept or cancel meeting requests
  - Set a voice mail message to let callers know the called party is away
  - Set user security preferences and personal options
- **Group addressing using Outlook Voice Access** In Exchange 2007, users could use either the telephone user interface (TUI) or voice user interface (VUI) in Outlook Voice Access to send e-mail and voice messages when they logged on to their mailbox. However, users could only send a single e-mail message to a single user in their personal Contacts, to multiple recipients from the directory by adding each recipient individually, or by adding the name of a distribution list from the global address list. In Exchange 2010, when a user signs in to their mailbox using Outlook Voice Access, they can also send e-mail and voice messages to users in a group stored in their personal Contacts.

Return to top

Benefits for Administrators

Currently, most users and IT departments manage their voice mail separately from their e-mail. Voice mail and e-mail exist as separate inboxes hosted on separate servers accessed through the desktop for e-mail and through the telephone for voice mail. Unified Messaging offers an integrated store for all messages and access to content through the computer and the telephone.

Exchange administrators can manage Unified Messaging using the same interface they use to manage the rest of Exchange, using the Exchange Management Console and the Exchange Management Shell. They can:

- Manage voice mail and e-mail from a single platform
- Manage Unified Messaging using scriptable commands

- Build highly available and reliable Unified Messaging infrastructures

Exchange 2010 Unified Messaging offers administrators:

- **A complete unified messaging system** Exchange 2010 Unified Messaging offers a true unified messaging solution using a single store, transport, and directory infrastructure. The store is provided by the Exchange 2010 Mailbox server role. The transport is provided by the Exchange 2010 Hub Transport server role. All e-mail and voice mail messages can be managed from a single management point, using a single administration interface and tool set. This greatly reduces the overall cost of administration by consolidating infrastructure and training.
- **An Exchange 2010 deployment and administration model** Using the Exchange 2010 Unified Messaging solution, you can take advantage of the Exchange 2010 server design. You aren't required to purchase a new server to run the Unified Messaging server role. More important, you can reuse your Exchange knowledge, including training and troubleshooting methodology, and apply it to managing your voice mail infrastructure.
- **An Exchange 2010 security model** The Microsoft Exchange Unified Messaging service runs as an Exchange server account. This means that you don't have to create or manage a super user account for Exchange 2010 Unified Messaging.
- **Consolidation of voice mail systems** Currently, most voice messaging systems require that all the voice messaging system components be installed in every physical office location in an organization. In this kind of arrangement, the voice messaging systems in branch offices are located outside the central office and must be administered onsite. This frequently results in increased administration costs and complexity. Exchange 2010 Unified Messaging lets you manage your voice mail system from a central location. To create a centralized management system for Unified Messaging, you can place all Unified Messaging servers in a datacenter or location, and then deploy IP gateways in each of your branch offices that replace the voice messaging system for each branch office. Deploying a centralized voice messaging system in this manner can result in a significant savings in hardware and administrative costs.
- **Built-in Unified Messaging administrative roles** A set of roles for managing Unified Messaging and voice mail features has been defined within Exchange 2010. Administrative roles that included UM were available in Microsoft Exchange Server 2007. The following UM-specific administrative roles have been added for Exchange 2010:
  - UM Mailboxes
  - UM Prompts
  - Unified Messaging
- **Incoming fax support** Exchange 2007 provided built-in support for fax message creation through the Unified Messaging server role. A user with a UM-enabled mailbox could receive fax messages from calls placed to his or her phone number. There's no support in Exchange 2007 UM for inbound fax routing, or for outgoing fax.
  In Exchange 2010, direct support for fax has been removed from the Unified Messaging server role. Customers who require a fax solution that works with Exchange 2010 will have to deploy a fax partner solution. Fax partner solutions are available from several fax partners. The fax partner solutions are designed to be tightly integrated with Exchange 2010 and enable UM-enabled users to receive incoming fax messages.

Note:

If you're using the RTM version of Exchange 2010 Unified Messaging, you may have to enable inband fax tone detection for fax receiving to work correctly with some IP PBXs. You do this by changing the *EnableInbandFaxDetection* setting to True in the msexchangeum.config file. The msexchangeum.config file is located in the \Program Files\Microsoft\Exchange\V14\bin folder on an

Exchange 2010 Unified Messaging server. If you don't configure this setting, Unified Messaging servers must rely on IP gateways to perform inband fax tone detection.
Changing the *EnableInbandFaxDetection* setting to True in the msexchangeum.config file isn't required in Exchange 2010 Service Pack 1 (SP1). Enabling fax tone detection isn't necessary on a Unified Messaging server with Exchange 2010 SP1 installed because the Unified Communications Managed API v. 2.0 (UCMA) enables the Unified Messaging server to listen to both inband and out-of-band fax events.

- **Support for multiple languages** For Exchange 2010, all available language packs contain the Text-to-Speech (TTS) engine and the prerecorded prompts for a specified language and ASR support. However, only some language packs contain support for Voice Mail Preview. The US English (en-US) language pack is included on the Exchange 2010 DVD and additional UM language packs can be downloaded from the Microsoft Download Center.
- **Auto attendant** An auto attendant is a set of voice prompts that gives external and internal users access to the Exchange 2010 Unified Messaging system. The telephone keypad or speech inputs can be used to move through the auto attendant menu, place a call to a user, or locate a UM-enabled user and then place a call to them. An auto attendant gives the administrator the ability to:
  - Create a customized menu for external users.
  - Define informational greetings, business hours greetings, and non-business hours greetings.
  - Define holiday schedules.
  - Describe how to search the organization's directory.
  - Describe how to connect to a user's extension so external callers can call users by specifying their extension.
  - Describe how to search the organization's directory so external callers can search the organization's directory and call a specific user.
  - Enable external users to call the operator.

Return to top

Configuring a UM Server

During an installation of the Unified Messaging server role, a UM computer object is created in the Computers container in Active Directory. The UM computer object created in Active Directory is a representation of a physical server on which the Unified Messaging server role is installed. The UM Active Directory computer objects connect your organization's telephony infrastructure and the UM Active Directory networking environment.

Note:

For a new UM computer object to be created during installation, the UM server must be a member of a domain before the Unified Messaging server role is installed.

After the computer object is created, you can perform the procedures for deploying Unified Messaging on your network.

Server Operation

By default, the operational status of the UM server is set to Enabled after the Unified Messaging server role is installed. This lets the UM server process incoming and outgoing voice calls and route the messages to their intended recipients in your Exchange organization. A UM server won't process incoming calls unless the operational status is set to Enabled.

The operational status of the UM server can be controlled using the Enable and Disable commands in the EMC and the Shell. There are three status modes for UM servers:

- **Enabled** Process all incoming calls.
- **Disable immediately** Don't accept any new calls and drop all existing calls.
- **Disable after completing calls** Don't accept any new calls but process all existing calls.

When the UM server starts, it locates all UM IP gateways associated with the server and associated with the existing UM dial plan. To detect and determine any configuration changes on either UM dial plans or UM IP gateways, the UM server will either register a change notification or re-check the configuration every 10 minutes.

If the UM IP gateway list changes, the UM server will react accordingly and either start to use or stop using the IP gateways that are associated with the UM server's dial plan. After a UM server is working as an associated member of a UM dial plan and is communicating with an IP gateway or a PBX, you can run a set of diagnostic operations to verify that it's connected and operating correctly.

Return to top

Configuring UM Users

When you mailbox-enable a user, you're given the option to create a mailbox or to connect to an existing mailbox. After a user is connected to an existing mailbox or a mailbox is created for them, you must enable the mailbox so the user can use Unified Messaging. After the user is enabled for Unified Messaging, all e-mail and voice messages will be delivered to the user's mailbox. UM users can access their e-mail, voice messages, and calendaring information by using Outlook 2007, Outlook 2010, Outlook Web App, a mobile phone that's enabled for Exchange ActiveSync, or a regular or mobile phone.

Note:

To enable multiple UM users, use the **Enable-UMMailbox** cmdlet in the Shell.

User UM Properties

After a user is enabled for Unified Messaging, you can manage, modify, and configure the UM properties for the user.

There are two locations in which UM properties are stored for a user: the Mailbox object and the user's Active Directory object. When you enable a user for Unified Messaging, you set the UM property on the user's Mailbox object. After the Mailbox property is set to Enabled for Unified Messaging, the user can use the UM features found in Exchange 2010.

After a user is enabled for Unified Messaging, the user's UM properties, such as the user's extension number, spoken name, and other properties for the user, are stored in the user's properties in Active Directory and on the user's mailbox.

You can manage UM properties for an Active Directory user on the mailbox of the UM user by using the Shell or the EMC.

The Relationship of the UM User to a UM Mailbox Policy

When you enable a user for Unified Messaging, the user must be associated with or linked to an existing UM mailbox policy and you must provide the extension number for the user. You can associate a user with a UM mailbox policy by using the **Enable-UMMailbox** cmdlet or by selecting the UM mailbox policy when you create the user's Exchange mailbox.

A UM mailbox policy contains settings such as the dialing restrictions and PIN policies for a user. When a UM mailbox policy is created, the UM mailbox policy must be associated with only one UM dial plan. The UM dial plan is then automatically associated with at least one UM server. Any UM server that's associated with the UM dial plan can provide UM services for a UM-enabled user who uses the UM dial plan. Associating these Active Directory objects in this manner delivers the UM services by using Active Directory. After the user is enabled for Unified Messaging, the settings from a UM mailbox policy are applied to the UM-enabled user.

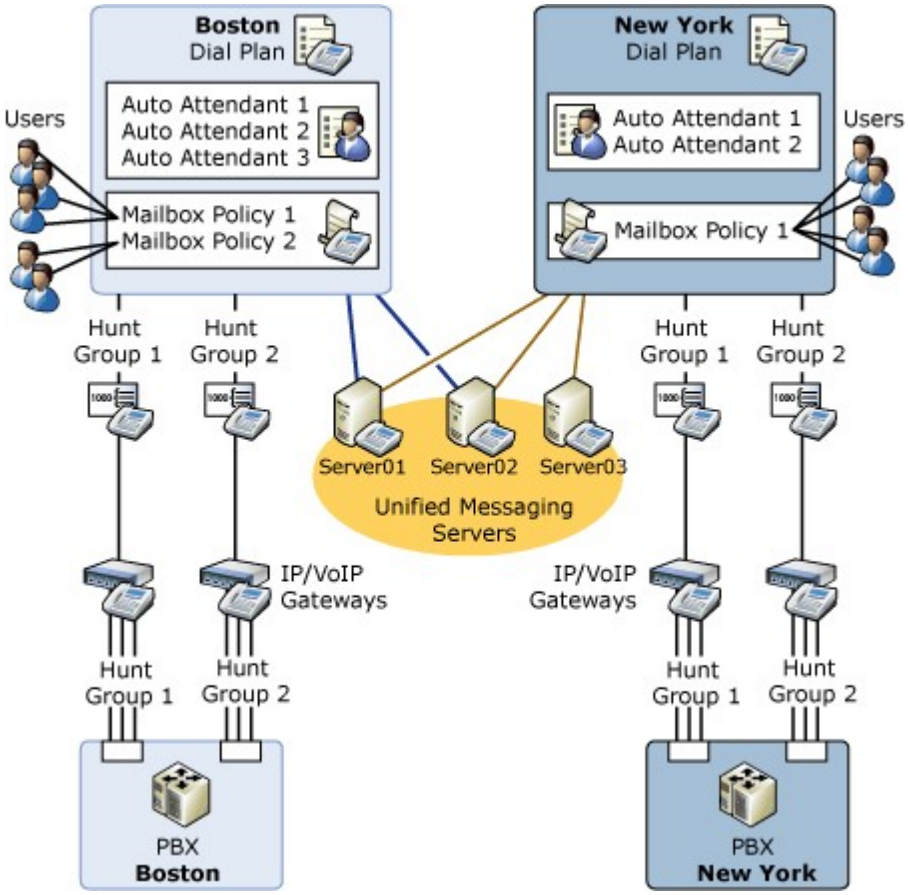
Configuring UM Components

Exchange 2010 Unified Messaging provides voice messaging services using objects that take advantage of your current Active Directory environment. UM Active Directory objects are created to support Unified Messaging. Active Directory acts as the container for all these UM objects and their configuration settings.

UM Active Directory objects make it possible for UM to interact with the telephony infrastructure. This physical infrastructure and the relationship between its components are mirrored in Active Directory. For details, see Understanding Unified Messaging Components.

Some UM Active Directory objects are created to represent each telephony hardware device, and other UM Active Directory objects are created to represent a telephony dial plan for an organization or to support a specific feature of Unified Messaging. For details, see Understanding Telephony Concepts and Components.

The following example and figure show the relationships between the UM objects found in Active Directory.



In the previous figure, the UM servers represented as Server01, Server02, and Server03 are located in the datacenter for a company. These servers are also represented as UM Server objects in Active Directory. Additionally, there are two UM dial plans, the Boston UM dial plan and the New York UM dial plan. There is a single PBX for each office. However, there are two IP gateways per PBX at each branch office to provide fault tolerance. Finally, Server01 and Server02 are members of the Boston UM dial plan, and Server01, Server02, and Server03 are all members of the New York UM dial plan.

When a call comes in to the PBX in the New York branch office and the call is forwarded to a UM server, any one of the three UM servers can answer the call and deliver the message to the user's mailbox because all the UM servers belong to the same dial plan. When a call is received in Boston for a user and the call is forwarded to a UM server, either Server01 or Server02 can answer calls for the users in the Boston dial plan.

There are several key Active Directory objects you need to create and manage. These objects are outlined in the following sections.

Return to top

UM Dial Plans

In a traditional telephony dial plan, users' extensions are configured on an IP PBX, PBX, or multiple PBXs and share a common numbering plan. This makes it possible for users to dial one another's telephone extensions without dialing a full telephone number.

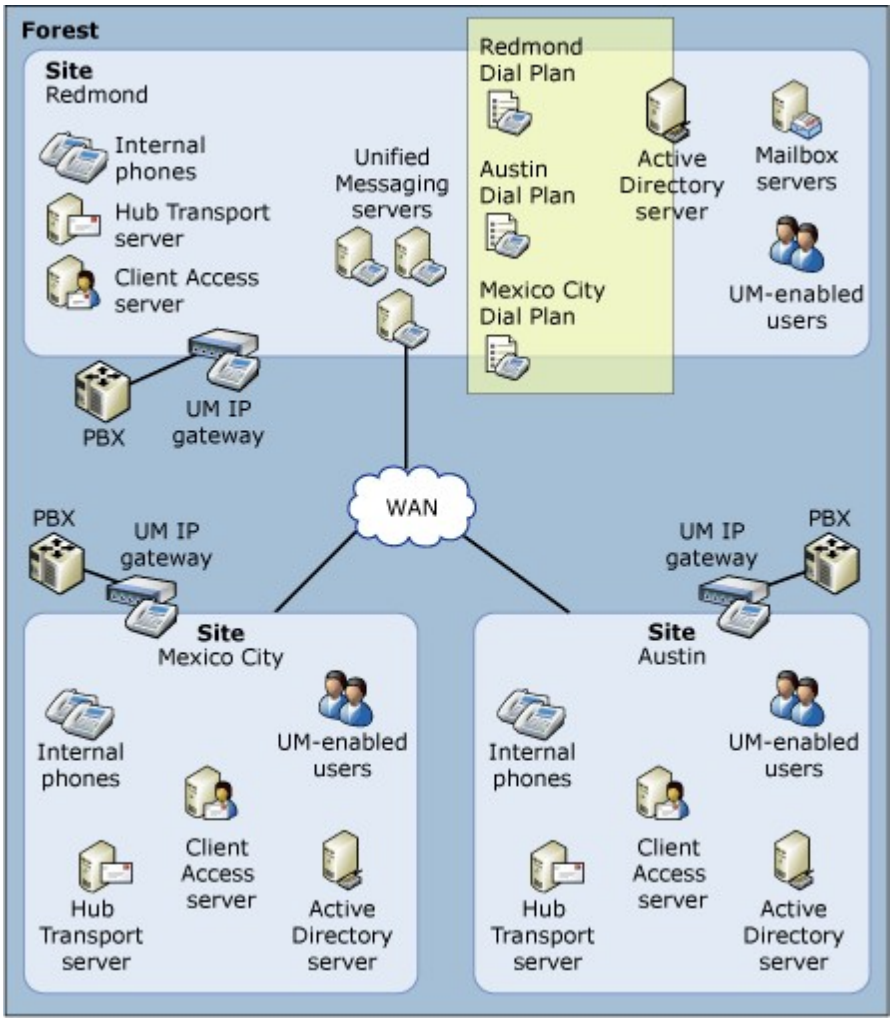
A UM dial plan mirrors a telephony dial plan. UM dial plans are required to successfully deploy Unified Messaging on your network.

A UM dial plan is an Active Directory object that represents sets or groupings of IP PBXs or

PBXs that share common user extension numbers. UM dial plans in Unified Messaging require that user telephone extension numbers be unique.

In some telephony networks, multiple PBXs and multiple dial plans exist. In these telephony networks, there can be two users who have identical telephone extensions if the two users who have the same extension number are placed in two separate UM dial plans. Putting the two users in separate dial plans makes their extension numbers unique for Unified Messaging purposes.

The following figure shows how UM dial plans can be used in an organization that has a single forest and multiple physical sites.



How Dial Plans Work

After you install the Unified Messaging server role on an Exchange 2010 computer, you must associate the UM server with at least one UM dial plan before it will answer calls. You can also associate a single UM server with multiple UM dial plans.

After the UM server is associated with a UM dial plan, you must create a UM IP gateway and associate it with the UM dial plan that was created.

Important:
Each time you create a UM dial plan by using the EMC, a UM mailbox policy will also be

created. The UM mailbox policy will be named *<DialPlanName>* Default Policy.

Creating and associating the UM dial plan and UM server objects in Active Directory enables the UM server to receive calls from the IP gateway or IP PBX and then process incoming calls for users who are associated with the UM dial plan. When a call comes in to the IP gateway or IP PBX, the IP gateway or IP PBX forwards the call to a UM server and the UM server tries to match the extension number of the user to the associated UM dial plan. The dial plan is identified from the pilot numbers that are sent by the IP gateway or IP PBX when an incoming call is received. The pilot numbers that are configured on a PBX or IP PBX may also be configured on a UM dial plan as a subscriber access number. For details, see Understanding Unified Messaging Dial Plans.

When you integrate a telephony network with Unified Messaging, there must be at least a single IP gateway or SIP-enabled IP PBX that connects your telephony network with your IP-based network. Each IP gateway or IP PBX in your organization is represented by a UM IP gateway object in Active Directory.

Return to top

UM Mailbox Policies

UM mailbox policies are required when you enable users for Unified Messaging. They're useful for applying and standardizing UM configuration settings for UM-enabled users. You create UM mailbox policies to apply a common set of policies or security settings to a collection of UM-enabled mailboxes. You use Unified Messaging mailbox policies to set UM settings for UM-enabled users, such as the following:

- PIN policies
- Dialing restrictions
- Other general UM mailbox policy properties

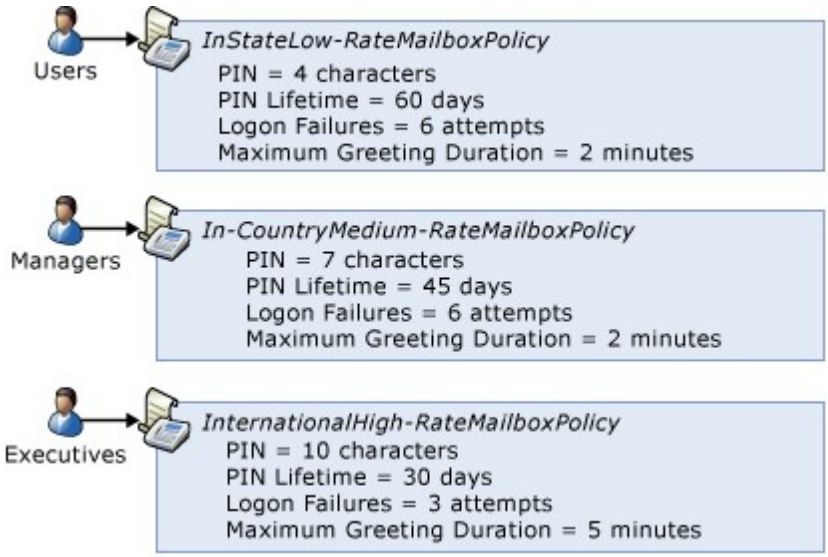
For example, you can create a UM mailbox policy to increase the level of PIN security by reducing the maximum number of logon failures before a user will be locked out for a specific group of UM-enabled users, such as executives.

UM mailbox policies are created in the **Configuration** container in Active Directory by using the Shell or the EMC. By default, a single UM mailbox policy is created every time you create a UM dial plan. The new UM mailbox policy is associated with the UM dial plan and part of the dial plan name is included in the display name of the UM mailbox policy. However, you can create additional UM mailbox policies based on the needs of your organization. Although a single UM mailbox policy is required to enable users for Unified Messaging, you can create additional UM mailbox policies and apply a common set of mailbox policy settings for other groups of users.

The mailbox of each UM-enabled user must be linked to a single UM mailbox policy when the mailbox is enabled for Unified Messaging. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of logon attempts for the UM-enabled users who are associated with the UM mailbox policy. If you prefer, you can also control message text settings or dialing restrictions for the same or a different group of UM-enabled mailboxes.

Multiple UM-enabled users can be linked to a single UM mailbox policy. However, a single user can be associated with only one UM mailbox policy. After you create a new UM mailbox policy and link it to a UM dial plan, the UM mailbox policy settings that are defined are applied to the UM-enabled users. The settings that are defined on a UM dial plan and a UM mailbox policy will be applied to all users who are associated with the UM mailbox policy.

The following figure shows how UM mailbox policies can be created to control dialing restrictions and PIN security settings for three different groups.



Return to top

UM IP Gateways

A UM IP gateway is an Active Directory object that represents a physical IP gateway hardware device, an IP PBX, or another SIP server that can interoperate with Unified Messaging. Before the physical IP gateway, IP PBX, or SIP server can be used to process UM calls, it must be represented in Active Directory by an UM IP gateway object.

Although there are many types and manufacturers of PBXs, IP gateways, and IP PBXs, there are basically two types of IP gateway component configurations:

- **IP PBX** A single device
- **PBX (legacy) and an IP gateway** Two separate components

To support Unified Messaging, one or both types of IP device configurations are used when connecting a telephony network with a data network.

The UM IP gateway can be associated with one or more Active Directory UM hunt groups. The combination of the UM IP gateway object and a UM hunt group object establishes a link between an IP gateway hardware device and a UM dial plan.

Enabling and Disabling UM IP Gateways

By default, UM IP gateways are left in an enabled state after they're created. However, the UM IP gateway can be enabled or disabled. If you disable a UM IP gateway, it can be in one of two disabled modes. The first disabled mode forces all associated UM servers to drop existing calls. The second disabled mode forces the UM server associated with the UM IP gateway to stop handling any new calls presented by the IP gateway.

Note:

Before an IP gateway can be used to process calls, a UM IP gateway must be associated with at least one UM dial plan. Also, at least one UM server must be associated with at least one UM dial plan. If a UM IP gateway is deleted, the UM servers associated with the UM IP gateway will no longer be able to accept or process new call requests from the IP gateway or IP PBX.

Return to top

UM Hunt Groups

In a telephony network, a hunt group is defined as a set of extension numbers that are

grouped as a single unit. When an incoming call is received, the PBX or IP PBX uses the hunt group to "hunt" for an available or open line, extension, or channel that can be used to receive the call.

Hunt groups are used to efficiently distribute calls into or out of a specific unit. For example, a PBX or IP PBX might be configured to have 10 extension numbers for a sales department. The 10 sales extension numbers would be configured as one hunt group.

Multiple algorithms or methods have been created for use by a PBX or IP PBX to define how the open line, extension, or channel will be located. These include the following:

- Round robin
- Most idle
- Start with lowest number

Creating and defining a hunt group in a PBX or IP PBX reduces the possibility that a caller who places an incoming call will receive a busy signal when the call is received.

Understanding UM Hunt Groups

UM hunt groups are used to define the PBX or IP PBX hunt group from which incoming calls will be received and are very important to the operation of the UM system. The UM hunt group represents an existing PBX or IP PBX hunt group. UM hunt groups act as a connection or link between the UM IP gateway and the UM dial plan. A single UM hunt group is associated with at least one UM IP gateway and one UM dial plan.

The pilot number defined for a hunt group in the physical PBX or IP PBX must also be defined for the UM hunt group. A pilot number is a telephone number that points to a hunt group and is the phone number for calls that are routed to Unified Messaging servers. The pilot number is used to match the information presented with incoming calls using the SIP header on the message. The pilot number enables the UM server to interpret the call together with the correct dial plan so that the voice message can be routed correctly. It's very important to configure UM hunt groups correctly, because incoming calls that don't correctly match the pilot number defined on the UM hunt group won't be answered and incoming call routing will fail.

When you create a UM hunt group, you're enabling all UM servers specified within the UM dial plan to communicate with an IP gateway. If you delete the UM hunt group, the associated IP gateway will no longer service calls by using the specified pilot number. If the IP gateway is left without remaining UM hunt groups, the IP gateway won't be able to handle incoming calls.

UM Auto Attendants

Unified Messaging enables you to create one or more UM auto attendants, depending on the needs of your organization. UM auto attendants can be used to create a voice menu system for an organization that lets external and internal callers move through the UM auto attendant menu system to locate and place or transfer calls to company users or departments in an organization.

When anonymous or unauthenticated users call an external business telephone number, or when internal callers call a defined extension number, they're presented with a series of voice prompts that help them place a call to a user or locate a user in the organization and then place a call to that user. The UM auto attendant is a series of voice prompts or .wav files callers hear instead of a human operator when they call an organization that has Unified Messaging. The UM auto attendant lets callers move through the menu system, place calls, or locate users by using DTMF or voice inputs. However, for automatic speech recognition (ASR) or voice inputs to be used, you must enable ASR on the UM auto attendant.

Important:

In some companies (especially in East Asia), office telephones may not have letters on

the keys of the telephone. This makes the spell-the-name feature that uses the DTMF interface almost impossible without a working knowledge of the key mappings. By default, Unified Messaging uses the E.161 key mapping. For example, 2=ABC, 3=DEF, 4=GHI, 5=JKL, 6=MNO, 7=PQRS, 8=TUV, and 9=WXYZ. When a combination of letters and numbers is inputted, for example "Mike1092", the numeric digits are mapped to themselves. For an e-mail alias of "Mike1092" to be entered correctly, the user must press the numbers 64531092. Also, there won't be a telephone key equivalent for characters other than A-Z and 0-9. Therefore, these characters shouldn't be entered. For example, the e-mail alias "mike.wilson" would be entered as 6453945766. Even though there are 11 characters to be input, only 10 digits are entered by the user because the period (.) doesn't have a digit equivalent.

The UM auto attendant:

- Provides corporate or informational greetings.
- Provides custom corporate menus so that you can link a menu option to another auto attendant to have more than one level.
- Provides a directory search function that enables a caller to search an organization's directory for a name.
- Enables a caller to connect to the telephone of, or leave a message for, members of the organization.

In Active Directory, each UM auto attendant created is represented as an object. There is no limit to the number of UM auto attendants you can create in Active Directory. Each auto attendant can support an unlimited number of extensions. A UM auto attendant is associated with one, and only one, UM dial plan. However, UM auto attendants can reference or link to other UM auto attendants.

An incoming call that is received from an external telephone number or an internal telephone extension is processed by a UM server and then sent to a UM auto attendant that has been created. The UM auto attendant is configured by the system administrator to use prerecorded voice (.wav) files that are then played over the telephone to the caller and that enable the caller to move through the UM menu system. When you configure a UM auto attendant, you can customize all the .wav files that are used to meet the needs of your organization. For more information about custom prompts in Unified Messaging, see Understanding Unified Messaging Audio Prompts.

For more information about message flow with UM auto attendants, see Unified Messaging Auto Attendant Call Processing.

Return to top

Auto Attendant with Multiple Languages

There are situations in which you may have to provide callers with auto attendants that have different languages. The language setting that's available on a UM auto attendant lets you configure the default prompt language on the auto attendant. When you're using the default system prompts for the auto attendant, the default prompt language is the language that the caller will hear when the auto attendant answers the incoming call. This language setting will affect only the default system prompts that are provided when the Unified Messaging server role is installed. This setting won't affect custom prompts that have been configured on an auto attendant. The language selected as the default for the auto attendant is based on the version of Exchange 2010 installed.

When you install the U.S.-English version of Exchange 2010, there will be only one language available to configure on UM auto attendants: U.S. English. However, if you install a localized version of Exchange 2010, for example, Japanese, you'll be able to configure the auto attendant you create to use Japanese or U.S. English as the default language. Additional UM language packs can be installed on a UM server to let you use other default language options on an auto attendant.

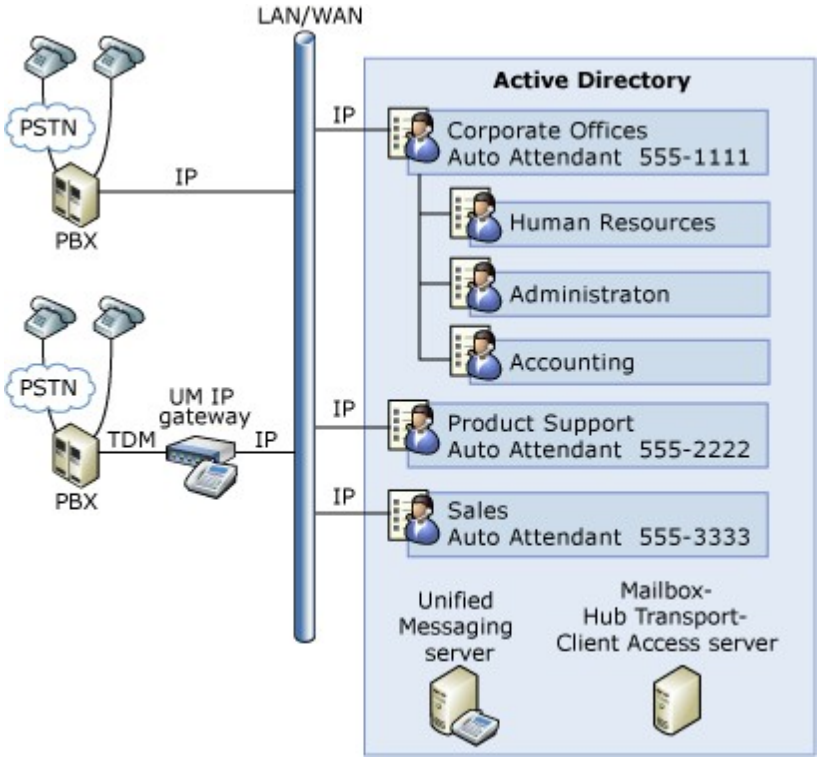
Caution:
You can't install UM language packs using the .msi file for the language.

For example, if you have a business that's based in the United States but requires a menu system that gives callers the options of moving through the system in U.S. English, Spanish, and French, you have to first install the UM language packs that you need. In this case, if you've installed the U.S.-English version of Exchange 2010, you'd install the UM language packs for Spanish and French. However, because a UM auto attendant can have only one language configured at a time, you'd create four auto attendants: a main auto attendant configured to use U.S. English and then one auto attendant for each language: U.S. English, Spanish, and French. You'd then configure the main auto attendant to have the appropriate key mappings to access the other auto attendants you've created for each language. In this example, the main auto attendant would answer the incoming call and the caller would hear, "Welcome to Contoso, Ltd. For English, press or say 1. For Spanish, press or say 2. For French, press or say 3."

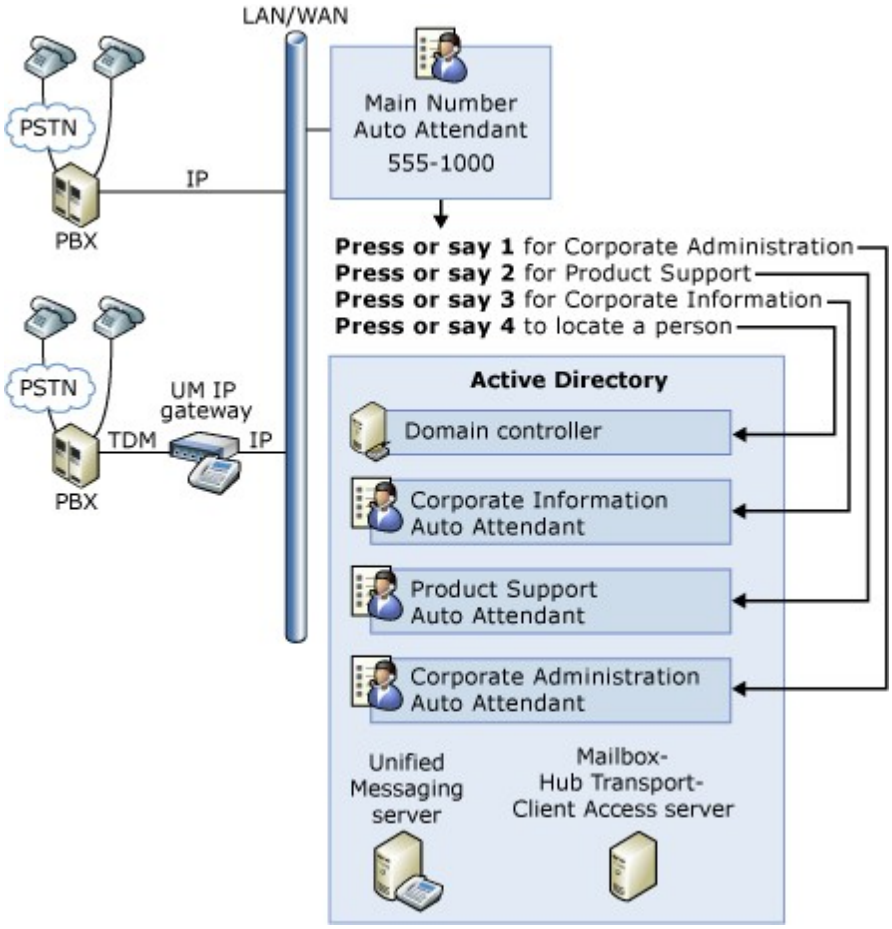
Auto Attendant Examples

The following examples demonstrate how you can use UM auto attendants together with Unified Messaging:

- **Example 1** At a company called Contoso, Ltd., external customers can use three external telephone numbers: 425-555-1111 (Corporate Offices), 425-555-2222 (Product Support), and 425-555-3333 (Sales). The Human Resources, Administration, and Accounting departments have internal telephone extensions and must be accessed from the Corporate Offices UM auto attendant.
  To create a UM auto attendant structure that supports this scenario, create and configure three UM auto attendants that have the appropriate external telephone numbers. Create three other UM auto attendants for each department in the Corporate Offices. Then you configure each UM auto attendant based on your requirements, such as the greeting type or other navigational information.
  The following figure is a graphical representation of how UM auto attendants can be used in Example 1.



- **Example 2** At a company called Contoso, Ltd., external customers call one main number for the business, 425-555-1000. When an external caller calls the main number, the UM auto attendant answers and prompts the caller by saying, "Welcome to Contoso, Ltd. Please press or say 'One' to be transferred to corporate administration. Please press or say 'Two' to be transferred to product support. Please press or say 'Three' to be transferred to corporate information. Please press or say 'Zero' to be transferred to the operator." To create a UM auto attendant structure that supports this scenario, you create a UM auto attendant that has customized extensions that route the call to the appropriate extension number.
  The following figure is a graphical representation of how UM auto attendants can be used in Example 2.



Return to top

UM Call Answering

This section describes how Unified Messaging handles message flow in different incoming call scenarios.

Unified Messaging handles the following types of incoming calls:

- Voice
- Outlook Voice Access
- Play on Phone
- Auto attendant

Unified Messaging depends on Active Directory to route incoming calls. For call answering to function correctly, each UM-enabled recipient must have a telephone extension number listed in Active Directory. The extension number for the recipient is listed in Active Directory and is mapped to the extension number that is configured on the user's UM-enabled Exchange mailbox. When a UM server answers a call, an Active Directory lookup is performed to locate the appropriate UM-enabled recipient, and then the message is routed to the recipient's mailbox.

Message Flow

Message flow in Unified Messaging is the process by which a message that's received by a UM server is routed in an Exchange 2010 organization.

Note:
In earlier versions of Microsoft Exchange, routing groups were used to route messages between bridgehead servers. In Exchange 2007 and Exchange 2010, bridgehead servers are known as Hub Transport servers. There are no routing groups in Exchange 2007 or Exchange 2010.

For example, in an incoming call scenario that includes incoming voice messages, a UM server uses the SMTP transport to submit the voice message to the Exchange 2010 server that has the Hub Transport server role installed. In a routing scenario that includes multiple Hub Transport servers, the incoming voice mail message is first submitted to the closest Hub Transport server and is then routed to the appropriate Mailbox server that contains the UM-enabled mailbox.

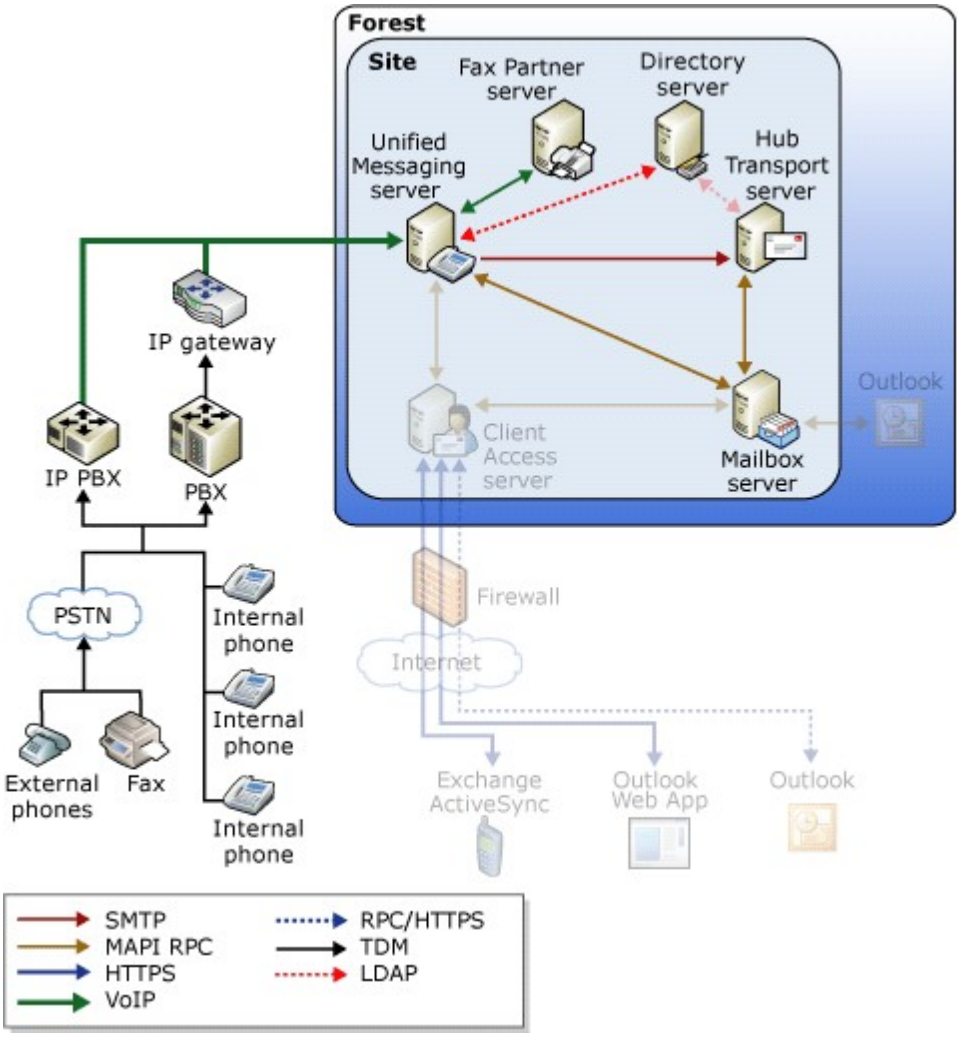
Note:
To make sure all incoming messages are transmitted and delivered to UM-enabled recipients, the UM servers use a spooling or retry algorithm. The UM servers try to connect to a Hub Transport server every 30 seconds to submit all messages that are stored on the UM server.

Return to top

Voice Call Processing

Voice calls that come in to an Exchange 2010 organization can be placed by callers who are inside or outside the organization. When a caller places a call to a UM-enabled user's telephone extension and the user isn't available to answer the call, the PBX forwards or routes the incoming call to an IP gateway and then to the UM server. In a UM system that uses an IP PBX, the IP PBX forwards the incoming message to the UM server. The IP gateway or the IP PBX translates or converts the incoming audio stream into RTP for incoming voice messages. The stream of IP data is then passed to the UM server. After the UM server receives the call, the UM server processes the message and determines how to route the message.

The following figure shows how incoming voice messages flow in an Exchange 2010 organization.



In this example, a call arrives at the PBX and is then forwarded to the UM pilot number. The pilot number is mapped to the hunt group that goes to the IP gateway. The IP gateway presents the call to the UM server. The UM server then receives SIP invitation header information such as who the call is for, who the caller is, and why the call was redirected. The UM server then looks up the number that was called and identifies which user was called and which dial plan the user belongs to. From there, the UM server looks in Active Directory to see whether the user is enabled for Unified Messaging. If the user is enabled for Unified Messaging, the caller receives a greeting for the user. Users' greetings are securely stored in their mailbox. This lets them manage their greetings. After callers reach the user's voice mail greeting, they can leave a voice message that will be sent to the user's mailbox. The UM server then records the message, locates a Hub Transport server, and submits the voice message to the Mailbox server that contains the UM-enabled user's mailbox.

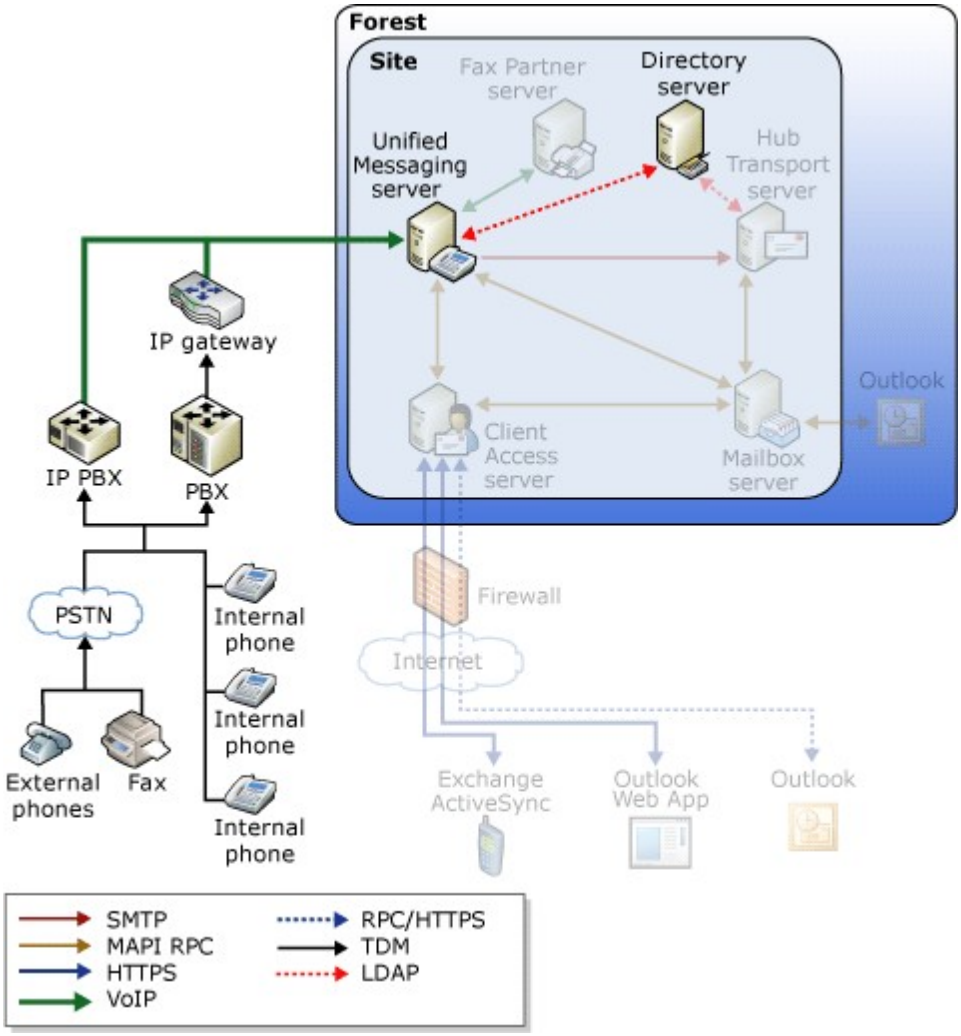
UM Auto Attendant Message Processing

When external or anonymous callers place a call by using an external business telephone number, or internal anonymous callers place a call to an internal extension number, they're presented with voice prompts to help them move through the UM menu system. The UM auto attendant is a set of voice prompts or .wav files that are played to callers instead of a human operator or receptionist when they call in to an organization that has Unified Messaging. Unified Messaging lets you create one or more auto attendants, depending on the needs of your organization.

Auto Attendant Message Flow

When a call is received by a UM server, the UM server performs a Lightweight Directory Access Protocol (LDAP) query to an Active Directory domain controller to determine how to handle the incoming call.

The following figure shows the message flow when UM auto attendants are used in an Exchange 2010 organization.



After you've created and enabled the auto attendant for your organization and associated it with a UM dial plan, the auto attendant can start to process calls. When a call for an auto attendant is received, it's first processed by the IP gateway and mapped to the appropriate hunt group. The call is then sent to the UM server. The UM server looks up the auto attendant object in Active Directory and then provides the correct auto attendant to handle the call.

Return to top

UM Outlook Voice Access Call Processing

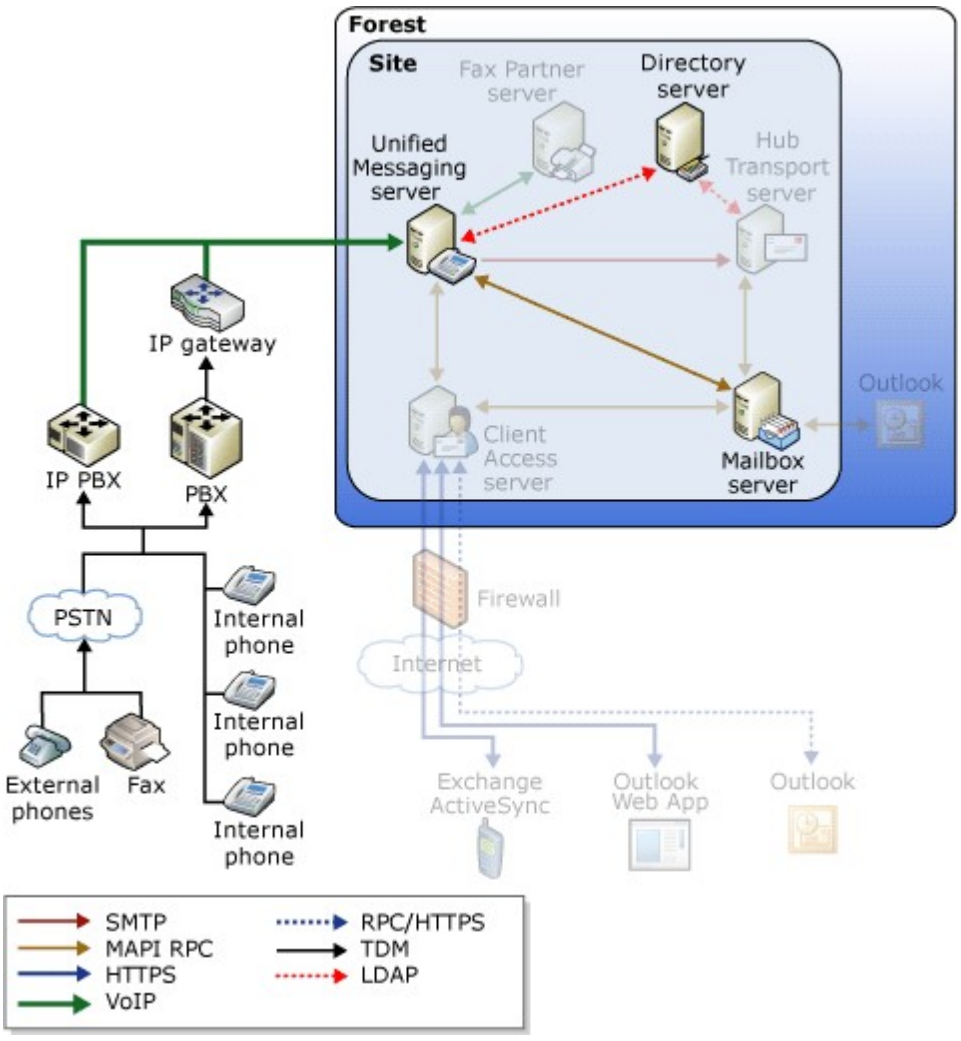
With Unified Messaging, UM-enabled users can access their e-mail, voice mail, contacts, and calendaring information using a standard analog, digital, or mobile telephone. Using Outlook Voice Access, a UM-enabled user can:

- Listen to new and saved e-mail and voice mail messages.
- Forward, reply to, save, and delete e-mail and voice mail messages.
- Interact with their calendar.
- Locate a person in the global address list or their personal Contacts.
- Send a voice message to a person.
- Change their PIN, spoken name, or greetings.

Outlook Voice Access Message Flow

Incoming calls that are received by a UM server from an Outlook Voice Access user are only routed to a Mailbox server to enable users to access their mailbox. However, if a message is submitted by using Outlook Voice Access, for example, a change in the schedule of a meeting, the message is first submitted to a Hub Transport server within the same Active Directory site as the UM server before it's routed to the recipient's mailbox.

The following figure shows how incoming calls and messages placed by subscribers or UM-enabled users flow in an Exchange 2010 organization.



When a user calls in to Outlook Voice Access, the PBX receives the call for the UM number and the IP gateway presents the call to the UM server. The UM server then looks up the user account information in Active Directory and collects information about the user. This

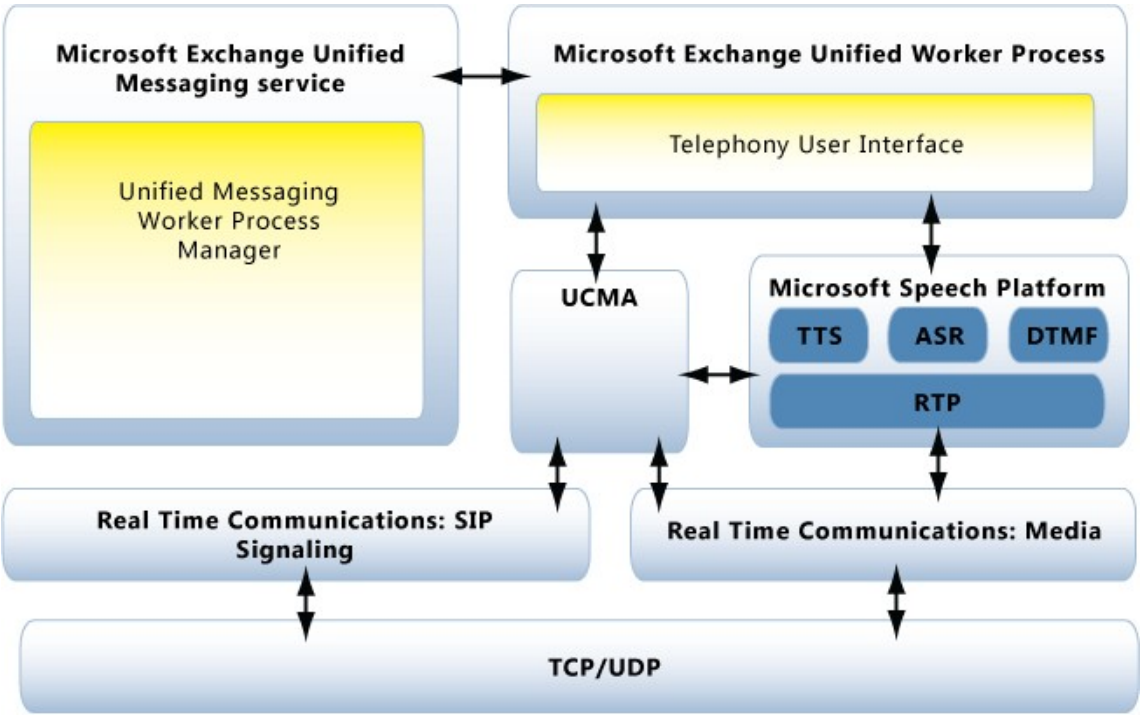
information includes dial plan information. If users place the call from their own extension, they're prompted for their PIN. The UM server contacts the Mailbox server and authenticates the user. From there, the UM server and the Mailbox server communicate information back to the user, as requested.

Overview of Unified Messaging Services and Components

When you install the Unified Messaging (UM) server role on a computer running Exchange 2010, several UM-specific components and services are installed. The Unified Messaging services and components installed by Setup enable a Unified Messaging server to answer and process incoming voice calls and enable users to interact with the Unified Messaging system by using Outlook Voice Access or by hearing a UM auto attendant when they call in to the Unified Messaging system.

Beginning with Exchange 2010 SP1, the UM server relies on Unified Communications Managed API v. 2.0 (UCMA) for its underlying SIP signaling and media, and speech processing. This dependency requires that the UCMA platform and prerequisites be installed on the UM server before Exchange 2010 UM SP1 installation or upgrade.

The following figure illustrates the relationships between Unified Messaging components.



Unified Messaging Services

The Microsoft Exchange Unified Messaging service is one of the two services that provide Unified Messaging services for your network. The Microsoft Exchange Unified Messaging service performs the following functions:

- Retrieves the dial plan configuration from Active Directory
- Loads the configuration information for monitoring UM worker processes from the Msexchangeum.config file

- Initializes the UM Worker Process Manager and the startup of a UM worker process
- Registers SIP endpoints

The Microsoft Exchange Unified Messaging service first accepts all incoming connections, and then reroutes those requests to a UM worker process that handles the incoming request. In addition, the Microsoft Exchange Unified Messaging service monitors any UM worker process that's created and ensures that the UM worker process is functioning correctly. If a UM worker process becomes unresponsive, the Microsoft Exchange Unified Messaging service stops the UM worker process and then creates a new UM worker process to replace it.

Note:

By default, each UM worker process will be recycled every seven days or 604,800 seconds. The setting can be found in the V14\bin\Msexchangeum.config file.

The Microsoft Exchange Unified Messaging service works with the Microsoft Exchange Speech Engine service to implement all the telephony features offered by Unified Messaging. The Microsoft Exchange Unified Messaging service handles call control and interacts with the Unified Communications Managed API 2.0 to handle the incoming media streams that are negotiated in the SIP signaling information between the Microsoft Exchange Unified Messaging service and a SIP-enabled telephony device such as an IP gateway or IP PBX. The following events happen when an incoming call is initiated by the Microsoft Exchange Unified Messaging service:

1. A call session is initiated by the Microsoft Exchange Unified Messaging service.
2. The Microsoft Exchange Unified Messaging service redirects the call to a UM worker process.
3. The UM worker process requests that a media session be established with Unified Communications Managed API 2.0, and then the UM worker process relays the media information back to the caller.
4. Unified Communications Managed API 2.0 provides a UDP port for the RTP stream.
5. The UM worker process uses the SIP signaling information to inform Unified Communications Managed API to end the call session when the RTP media stream is no longer needed.

UM Worker Process

A UM worker process is a process that's created during the startup of the Microsoft Exchange Unified Messaging service. UM worker processes interact with all incoming and outgoing requests received by the Microsoft Exchange Unified Messaging service.

The UM Worker Process Manager is also a component of the Microsoft Exchange Unified Messaging service. The UM Worker Process Manager handles the creation and monitoring of all the UM worker processes that are created. The UM Worker Process Manager creates new instances of a UM worker process based on the configuration settings located in the Msexchangeum.config file and also monitors the health of these processes. As a new incoming call arrives, the UM Worker Process Manager determines the appropriate instance of a UM worker process to redirect the call to. The UM worker process then interacts with the Unified Communications Managed API 2.0 components to correctly process incoming and outgoing requests. The UM worker process is responsible for the following startup tasks:

- Allocation of the runtime management objects
- Loading of the Unified Messaging configuration from Msexchangeum.config
- Registration of the process with Unified Communications Managed API 2.0
- Initialization of Simple Mail Transfer Protocol (SMTP) message submission

Unified Communications Managed API 2.0

Starting with Exchange 2010 SP1, the Unified Messaging server role relies on the Microsoft Unified Communications Managed API v. 2.0 (UCMA). UCMA simplifies the architecture of Unified Messaging and doesn't include any dependencies of other Windows-based or Exchange-based services. UCMA can be broken down into the following areas:

- **SIP Signaling** SIP signaling in UCMA v. 2.0 is very similar to SIP signaling in UCMA v. 1.0.
- **RTP Media** UCMA provides access to RTP media streams.
- **Collaboration** provides presence and conferencing support.

UCMA v. 2.0 is a managed-code platform that enables developers to build applications that provide access to and control over Enhanced Presence information, instant messaging, telephone and video calls, voice messaging, and audio/video conferencing. It enables both text-based and voice-based (speech technology-enabled) conversations and collaboration. UCMA v. 2.0 is intended to support the development of server side, middle-tier applications targeting Microsoft Office Communicator 2007 R2, Office Communications Server 2007 R2, or Microsoft Lync Server 2010 (the next generation of Office Communications Server) and Exchange 2010. It contains a SIP stack, a media stack, powerful speech engines for both Automatic Speech Recognition (ASR), as well as speech synthesis that's generated by Text-to-Speech (TTS).

UCMA v. 2.0 can be used to add communications capabilities to your business software and processes. It can also be used to create outbound applications such as alerts, notifications, or surveys, as well as inbound speech technology-enabled interactive voice response applications and automated agents. UCMA v.2.0 provides access to the presence information available in Communications Server 2007 R2 and can be used to build role agents that use Microsoft Enhanced Presence information to streamline communications between people.

UCMA v.2 makes more advanced developer scenarios possible, for applications such as automated call distributors, which perform skill-based routing; for conferencing services, such as conference access control; for custom client gateways that can interface with, for example, other communications networks, other Interactive Voice Response platforms, and with speech servers that are using the Microsoft ASR and TTS engines.

The UCMA platform replaces the Microsoft Exchange Speech Engine service and the Speech Engine service worker process (SESWorker.exe) and controls the following:

- The DTMF (touchtone) interface.
- ASR, which is used with the voice user interface (VUI) in Outlook Voice Access.
- The TTS engine that reads e-mail, voice mail, and calendar items and plays the menu prompts for callers.

UCMA v. 2.0 also supports the following features in Unified Messaging:

- ASR input recognition.
- DTMF (touchtone) input recognition.
- The TTS conversion process.
- Recording e-mail and voice mail messages.
- Playing e-mail and voice mail messages for users.

As a result of the integration of UCMA and Unified Messaging, you receive the following benefits when you integrate UM and Microsoft Lync Server 2010:

- Unified Messaging reports Quality of Experience (QoE) data to Lync Server 2010 Quality of Experience Monitoring or QMS servers. This is available in both on-premises and cross-premises integrated environments.
- UM doesn't drop the first incoming call if the first call to the UM server is being made from an Enterprise Voice user who's connected the Internet.

In earlier versions of Office Communications Server, the A/V Edge resources that were associated with the Office Communications Server pool didn't communicate with a specific UM server for a specific call. This led to less-than-optimal media quality in some scenarios.

With Exchange 2010 SP1, you can set, on a per UM-server basis, the Office Communications Server pool and associated A/V Edge server resources that should be used for all calls to and from that specific UM server.

Prerequisites for UCMA

The Unified Messaging server role in Exchange 2010 SP1 relies on the following, and requires that they be installed prior to installing SP1:

- Windows Server 2008 or Windows Server 2008 R2 - Installing Windows Server 2008 R2
- Microsoft .NET Framework 3.5 Service Pack 1 (SP1) - Microsoft .NET Framework 3.5 Service Pack 1
- Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64 updates - Microsoft .NET Framework 3.5 Family Update for Windows Vista x64, and Windows Server 2008 x64

Windows Remote Management (WinRM) 2.0 and Windows PowerShell V2 (Windows6.0-KB968930.msu) - Windows Management Framework Core package (Windows PowerShell 2.0 and WinRM 2.0)

- Microsoft Speech Platform - Server Runtime (Version 10.1) - (SpeechPlatformRuntime.msi).
- Unified Communications Managed API 2.0, Core Runtime (64-bit) (UcmaRuntimeWebDownloadX64.msi).

Note:

If you've already installed a version of the Unified Communications Managed API 2.0 on a Client Access server in your Exchange organization, you must also install a hotfix. For information about how to install the required hotfix, see OCS 2007 R2 Web Service Provider Hotfix KB 981256.

For more information about UCMA, see UCMA 2.0 Core Architecture.

For more information about the grammar files used in Unified Messaging, see Understanding Automatic Speech Recognition Directory Lookups.

Service Ports

The Microsoft Exchange Unified Messaging service and the UM worker process use multiple Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) service ports to communicate with IP gateways. The Microsoft Exchange Unified Messaging service and the UM worker process use Session Initiation Protocol (SIP) over TCP. By default, the Microsoft Exchange Unified Messaging service listens on both TCP port 5060 in Unsecured mode and TCP port 5061 when mutual Transport Layer Security (mutual TLS) is used. Each UM worker process that's created listens on port 5065 and 5067 (unsecured) and 5066 and 5068 (secured). But when an IP gateway or IP PBX sends Realtime Transport Protocol (RTP) traffic to the Speech Engine service worker process, the IP gateway or IP PBX will use a valid UDP port that ranges from 1024 through 65535.

A TCP control port is also used on a Unified Messaging server. When a UM worker process is created, the Microsoft Exchange Unified Messaging service passes the appropriate configuration options to the UM worker process. The configuration options sent include the parameters for the TCP control port number that's used for communication between the Microsoft Exchange Unified Messaging service and the UM worker process. The TCP control port that's chosen will be between TCP ports 16,000 to 17,000.

1.9.1.2 Understanding Unified Messaging Components

Understanding Unified Messaging Components

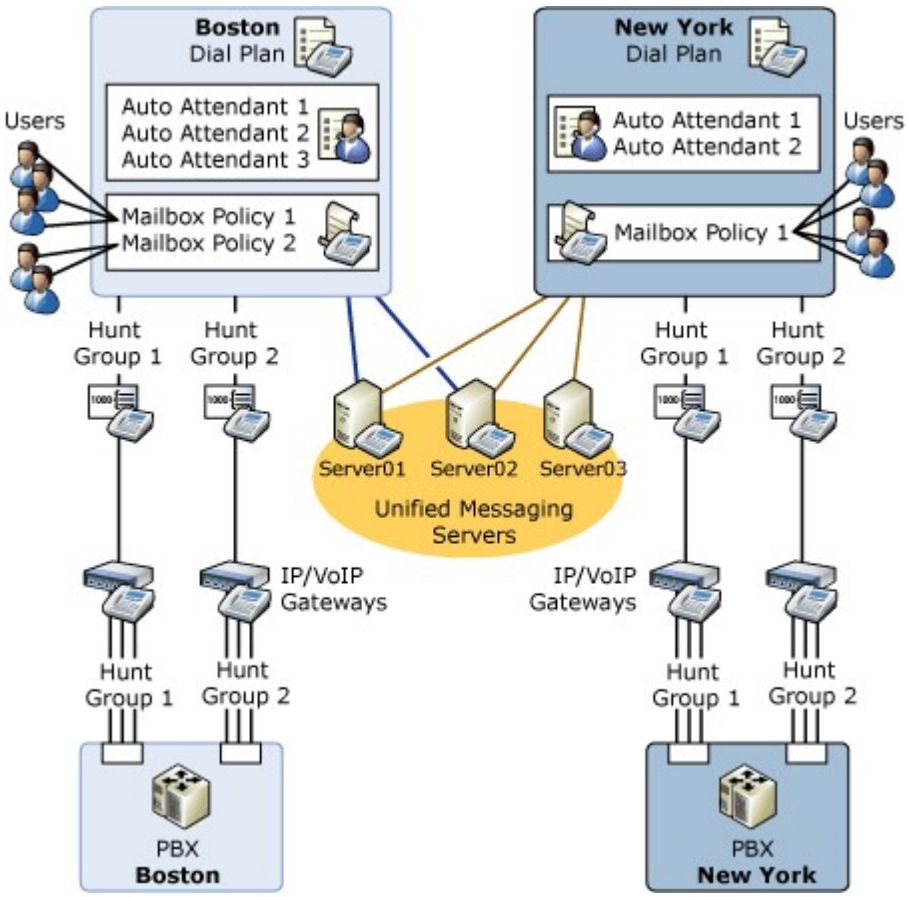
Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-03*

Active Directory objects are required for the deployment and operation of Microsoft Exchange Server 2010 Unified Messaging (UM). The UM Active Directory objects connect the telephony infrastructure and the Exchange 2010 UM Active Directory environment.

UM Active Directory Objects

The UM Active Directory objects enable the integration of Unified Messaging into Active Directory and the existing telephony infrastructure. Active Directory acts as a container for all the UM objects that are created and their configuration settings. Each UM object within Exchange 2010 is necessary to support Unified Messaging in an Active Directory environment. Some UM Active Directory objects are created to logically represent a telephony hardware device but others are created to represent a telephony dial plan for an organization or to support a specific feature of Unified Messaging. The following figure shows the relationships between the UM objects found in Active Directory.



There's a tightly integrated and interconnected relationship between the UM Active Directory objects and the features available in Unified Messaging. To successfully plan and deploy Unified Messaging in your organization, you need to fully understand this logical

relationship between each of the UM objects.

For more information about the UM Active Directory objects, see:

- Understanding Unified Messaging Dial Plans

1.9.1.2.1 Understanding Unified Messaging Dial Plans

Understanding Unified Messaging Dial Plans

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-12-10*

Unified Messaging (UM) dial plans are integral to the operation of Microsoft Exchange Server 2010 Unified Messaging and are required to successfully deploy Unified Messaging on your network. The following sections discuss UM dial plans and how UM dial plans are used when you deploy Exchange 2010 Unified Messaging on your network.

Overview of UM Dial Plans

Although Unified Messaging has many Active Directory objects that must be created and configured during deployment, UM dial plan objects are the central component of the Unified Messaging system. A UM dial plan object is an Exchange 2010 organization-wide object created in Active Directory. It represents sets or groupings of Private Branch eXchanges (PBXs) or IP PBXs that share common user extension numbers. In practical terms, all users' extensions hosted on PBXs or IP PBXs within a dial plan contain the same number of digits. Users can dial one another’s telephone extensions without appending a special number to the extension or dialing a full telephone number.

A UM dial plan mirrors a telephony dial plan. A telephony dial plan is configured on PBXs or IP PBXs.

For more information about telephony components, see Understanding Telephony Concepts and Components.

In Unified Messaging, the following UM dial plan topologies can exist:

- A single dial plan that represents a subset of extensions or all extensions for an organization with one PBX or IP PBX.
- A single dial plan that represents a subset of extensions or all extensions for an organization with multiple networked PBXs or IP PBXs.
- Multiple dial plans that represent a subset of extensions or all extensions for an organization with one PBX or IP PBX.
- Multiple dial plans that represent a subset of extensions or all extensions for an organization with multiple PBXs or IP PBXs.

Users who belong to the same dial plan have these characteristics:

- An extension number that uniquely identifies the user mailbox in the dial plan.
- The ability to call or send voice messages to other members in the dial plan using only the extension number.

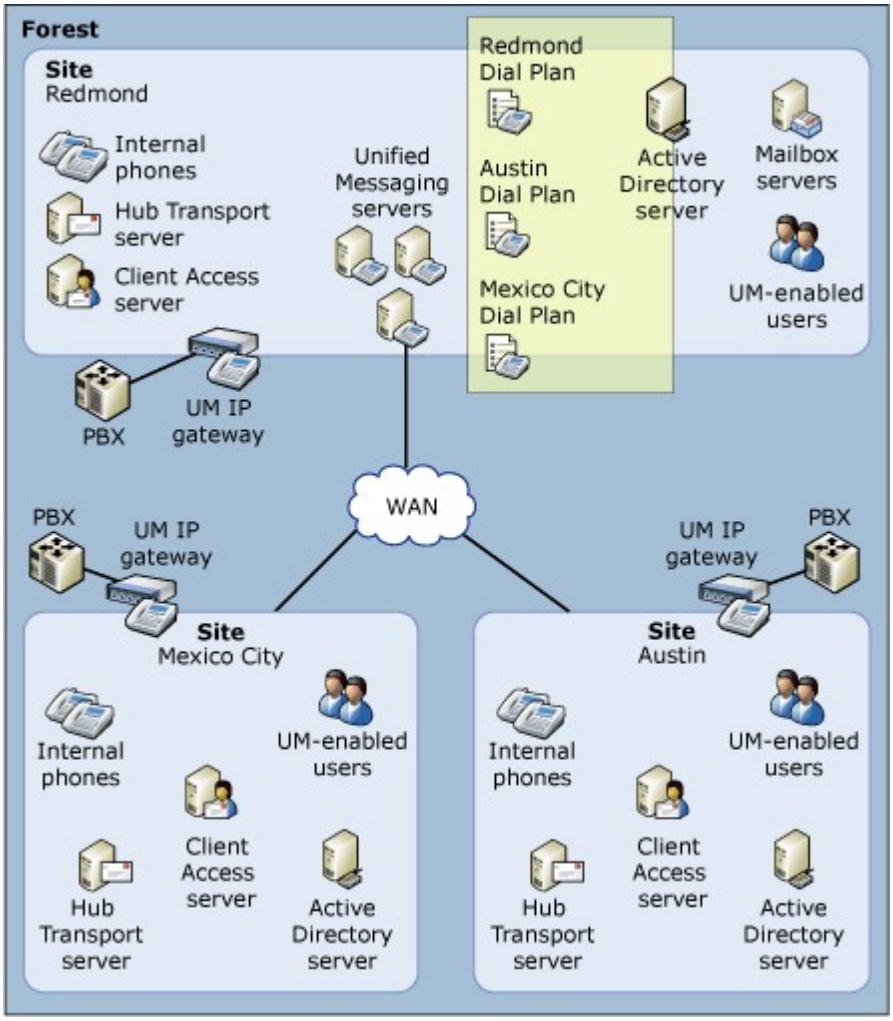
For more information about how to enable a user for Unified Messaging, see Enable a User for Unified Messaging.

UM dial plans are implemented in Exchange 2010 Unified Messaging to make sure that user telephone extensions are unique. In some telephony networks, multiple PBXs or IP PBXs can exist. In these telephony networks, there could be two users in Active Directory who have the same telephone extension number. UM dial plans resolve this situation. You can put the two users into two separate UM dial plans. This makes their extensions unique.

Note:

A user can be a member of only one UM dial plan. You can also use a UM dial plan to establish a common set of policies for a group of users. For example, you can enable different languages for different UM dial plans, or you can enable different features for different UM dial plans.

The following figure illustrates how UM dial plans can be used in an organization that has a single forest and multiple physical sites.



How Dial Plans Work

When you integrate a telephony network with Exchange 2010 Unified Messaging, there must be a hardware device called an IP gateway that connects your telephony network to your IP-based network. IP gateways convert circuit-switched protocols found in a telephony network to a data-switched protocol such as IP. Each IP gateway in your organization is represented by a UM IP gateway object in Active Directory. For more information about UM IP gateways, see Understanding Unified Messaging IP Gateways.

Exchange 2010 Unified Messaging requires that you create at least one UM dial plan and that the UM dial plan has a Unified Messaging server and a UM IP gateway associated with it. After you install the Unified Messaging server role on an Exchange 2010 computer, you must associate the Unified Messaging server with at least one UM dial plan before it will answer calls. You can also associate a single Unified Messaging server with multiple UM dial plans. After the Unified Messaging server is associated with a UM dial plan, you must create a UM IP gateway and associate it with the UM dial plan that was created.

Important:

Each time you create a UM dial plan, a UM mailbox policy will also be created. The UM mailbox policy will be named *<Dial Plan Name>* Default Policy.

When you create the first UM IP gateway and specify a UM dial plan at the time you create it, a default UM hunt group is also created. Creating and associating these objects

in Active Directory enables the Unified Messaging server to receive calls from the IP gateway and then process incoming calls for users who are associated with the UM dial plan. When a call comes in to the IP gateway, it forwards the call to a Unified Messaging server, and the Unified Messaging server tries to match the extension number of the user to the associated UM dial plan.

For more information about how to add a Unified Messaging server to a UM dial plan, see Add a UM Server to a Dial Plan.

Types of Dial Plans

A Uniform Resource Identifier (URI) is a string of characters that's used to identify or name a resource. In Unified Messaging, the main purpose of a URI is to enable Voice over IP (VoIP) devices to communicate with other devices using specific protocols. A URI defines the naming and numbering format or scheme used for the calling and called party information contained within a Session Initiation Protocol (SIP) header for an incoming or outgoing call.

The types of UM dial plans you create in Exchange 2010 Unified Messaging will depend on the URI types supported by the IP gateways, PBXs, or IP PBXs in your organization. When you create a dial plan, you should know the specific URI types supported by your PBXs or IP PBXs. There are three formats or URI types that can be configured on UM dial plans:

- Telephone Extension
- SIP URI
- E.164

In Unified Messaging, each time you create a dial plan, the dial plan will, by default, be created to use the telephone extension URI format type. However, you can configure the URI type when you create a dial plan using the New Dial Plan wizard or the **New-UMDialPlan** cmdlet. After you create a dial plan, you will be unable to change the URI type.

Telephone Extension

The Telephone Extension URI type is the most common type of UM dial plan and is used with PBXs and IP gateways. When you configure a telephone extension (TelExtn) dial plan, the IP gateways and IP PBXs must support the telephone extension (TelExtn) URI type. When the IP gateway or IP PBX communicates with a Unified Messaging server associated with a dial plan, the dial plan must then be configured to support the TelExtn URI type. Generally, most PBXs today support the telephone extension URI type. However, the IP gateway and the UM dial plan must also support the telephone extension URI type.

When a call is received by the PBX or IP PBX and the UM-enabled user isn't available to answer the call, the PBX or IP PBX will forward the call to the IP gateway. In the header for the SIP packet received by the Unified Messaging server from the IP gateway, the calling and called party information will be listed in one of the following formats:

- Tel:512345
- 512345@<*IP address*>

The telephone extension (TelExtn) format used is based on the configuration of the IP gateway or IP PBX.

SIP URI

Session Initiation Protocol (SIP) is a standard protocol for initiating interactive user sessions that involve multimedia elements such as video, voice, chat, and gaming. SIP is a request-to-response based protocol that answers requests from clients and responses from servers. Clients are identified by SIP URLs. Requests can be sent through any transport protocol, such as UDP or TCP. SIP determines the endpoint to be used for the

session by selecting the communication media and media parameters.

When you create a new dial plan, you have the option of creating a SIP URI dial plan that can be used in an environment that has Microsoft Office Communications Server 2007 deployed or in organizations that have IP PBXs. However, in organizations that have IP PBXs, the IP PBXs must also support SIP URIs and SIP routing.

A SIP URI is the SIP addressing scheme used to call another person using SIP. In other words, a SIP URI is a user's SIP phone number. The SIP URI resembles an e-mail address and is written in the following format: sip*:<user name>@<domain or IP address>*:*Port*. When a SIP-enabled IP PBX or an IP gateway is used to send the call to a Unified Messaging server, the device will send only the SIP URI for the calling and called party in the SIP header and will not include extension numbers.

E.164

E.164 is a standard numbering format that defines the international public telecommunication numbering plan used in the Public Switched Telephone Network (PSTN) and some data networks. E.164 defines the format of telephone numbers. E.164 numbers can have a maximum of 15 digits and are usually written with a plus sign (+) before the digits of the telephone number. To dial an E.164-formatted telephone number from a telephone, the appropriate international call prefix must be included in the number dialed. In an E.164 numbering plan for public telephone systems, each assigned number contains a country code (CC), a national destination code (NDC), and a subscriber number (SN).

When you create a new dial plan, you have the option to create an E.164 dial plan. However, if you create and configure an E.164 dial plan, the PBXs and IP PBXs must support E.164 routing. The SIP header received by the Unified Messaging server from an IP gateway associated with an E.164 dial plan will include the E.164-formatted telephone number for the calling and called party information and will be listed in the following format: Tel:+14255550123.

VoIP Security

Unified Messaging servers that have Exchange 2010 installed can communicate with IP gateways, IP PBXs, and other Exchange 2010 computers in either Unsecured, SIP secured, or secured mode, depending on how the UM dial plan is configured. A Unified Messaging server can operate in any mode configured on a dial plan because the Unified Messaging server is configured to listen on TCP port 5060 for unsecured requests and TCP port 5061 for secured requests at the same time. A Unified Messaging server can be associated with a single or multiple UM dial plans and can be associated with dial plans that have different VoIP security settings. A single Unified Messaging server can be associated with dial plans configured to use a combination of unsecured, SIP secured, and secured modes.

By default, when you create a UM dial plan, it will communicate in unsecured mode, and the Unified Messaging servers associated with the UM dial plan will send and receive data from IP gateways, IP PBXs, and other Exchange 2010 computers without using encryption. In unsecured mode, neither the Realtime Transport Protocol (RTP) media channel nor the SIP signaling information will be encrypted. You can use the **Get-UMDialPlan** cmdlet in the Exchange Management Shell to determine the security setting for a specific UM dial plan.

You can configure a Unified Messaging server to use mutual Transport Layer Security (TLS) to encrypt the SIP and RTP traffic sent and received from other devices and servers. When you add a Unified Messaging server to a UM dial plan and configure the dial plan to use SIP secured, only the SIP signaling traffic will be encrypted, and the RTP media channels will still use TCP, which is not encrypted. However, if you add a Unified Messaging server to a UM dial plan and configure the dial plan to use Secured mode, both the SIP signaling traffic and the RTP media channels are encrypted. An encrypted signaling media channel

that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data.

You can configure the VoIP security mode either when you're creating a new dial plan or after you create a dial plan using the EMC or the **Set-UMDialPlan** cmdlet in the Shell. When you configure the UM dial plan to use SIP secured or Secured mode, the Unified Messaging servers associated with the UM dial plan will encrypt the SIP signaling traffic or the RTP media channels or both. However, to be able to send encrypted data to and from a Unified Messaging server, you must correctly configure the UM dial plan, and devices such as IP gateways or IP PBXs must support mutual TLS.

For more information about VoIP security and UM dial plans, see Understanding Unified Messaging VoIP Security.

Outlook Voice Access

There are two types of callers who access the Unified Messaging system using the subscriber access number configured on a UM dial plan: unauthenticated callers and authenticated callers. When callers dial the subscriber access number configured on a dial plan, they are considered anonymous or unauthenticated until they input information including their voice mail extension and a PIN. However, the only option available to anonymous or unauthenticated callers is the directory search feature. After callers input their voice mail extension and their PIN, they will be authenticated and given access to their mailbox. After they gain access to the system, they are using the Outlook Voice Access feature. Outlook Voice Access is a series of voice prompts that give the caller access to e-mail, voice mail, calendar, and other information. Outlook Voice Access lets authenticated callers navigate their personal information in their mailbox, place calls, or locate users using dual tone multi-frequency (DTMF), also known as touchtone, inputs or voice inputs.

Important:

In some companies (especially in East Asia), office telephones may not have letters on the keys of the telephone. This makes the spell-the-name feature using the touchtone inputs almost impossible to use, without a working knowledge of the key mappings. By default, Exchange 2010 Unified Messaging uses the E.161 key mapping. For example, 2=ABC, 3=DEF, 4=GHI, 5=JKL, 6=MNO, 7=PQRS, 8=TUV, 9=WXYZ.
When inputting the combination of letters and numbers, for example, Jim1092, the numeric digits are mapped to themselves. For an e-mail alias of Jim1092 to be entered correctly, the user must press the numbers 5461092. Also, for characters other than A-Z and 0-9, there won't be a telephone key equivalent. Therefore, these characters shouldn't be entered. For example, the e-mail alias jim.wilson would be entered as 546945766. Even though there are 10 characters to be input, only 9 digits are entered by the user because the period (.) doesn't have a digit equivalent.

Subscriber Access Numbers

After you've created a UM dial plan, you need to add at least one subscriber access number. Subscriber access numbers are also called pilot numbers. This number is used by Outlook Voice Access users to access their mailboxes and lets them search the directory.

By default, when you create a UM dial plan, no subscriber access number is configured. To enable subscriber access, you must configure at least one telephone or extension number. The number of alphanumeric characters in the subscriber access number can't exceed 20. After you configure this number on the dial plan, this number will be displayed in the Microsoft Office Outlook 2007, Outlook 2010, and Outlook Web App voice mail options.

You can use the **Enter the telephone number to associate** field on the UM dial plan to add a telephone number or extension that a user will call to access the Unified Messaging system using Outlook Voice Access. In most cases, you'll enter an extension number or an

external telephone number. However, because this field accepts alphanumeric characters, a SIP URI can be used if you're using an IP PBX.

Depending on the needs of your organization, you may need one or more subscriber access numbers. You can have a single subscriber access number configured on a single UM dial plan or you can have multiple subscriber access number in a single UM dial plan, but you can't have a single subscriber access number that spans multiple UM dial plans.

1.9.1.2.2 Understanding Unified Messaging Mailbox Policies

Understanding Unified Messaging Mailbox Policies

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Components >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Unified Messaging (UM) Active Directory mailbox policies are required when you enable users for Exchange 2010 Unified Messaging. You create UM mailbox policies to apply a common set of policies or security settings to a collection of UM-enabled mailboxes. UM mailbox policies are used to set Unified Messaging settings for UM-enabled users, such as the following:

- PIN policies.
- Dialing restrictions.
- Other general UM mailbox policy properties.

For example, you can create a UM mailbox policy to increase the level of PIN security by reducing the maximum number of sign-in failures for a specific group of UM-enabled users, such as executives.

Looking for management tasks related to Unified Messaging mailbox policies? See Managing UM Mailbox Policies.

UM Mailbox Policies

UM mailbox policies are created in the Configuration container in the Active Directory directory service using the Exchange Management Shell or the Exchange Management Console. By default, a single UM mailbox policy is created every time you create a UM dial plan. The new UM mailbox policy is associated with the UM dial plan and part of the dial plan name is included in the display name of the UM mailbox policy. However, you can create additional UM mailbox policies based on the needs of your organization. Although a single UM mailbox policy is required to enable users for Unified Messaging, you can create additional UM mailbox policies and apply a common set of mailbox policy settings for other groups of users.

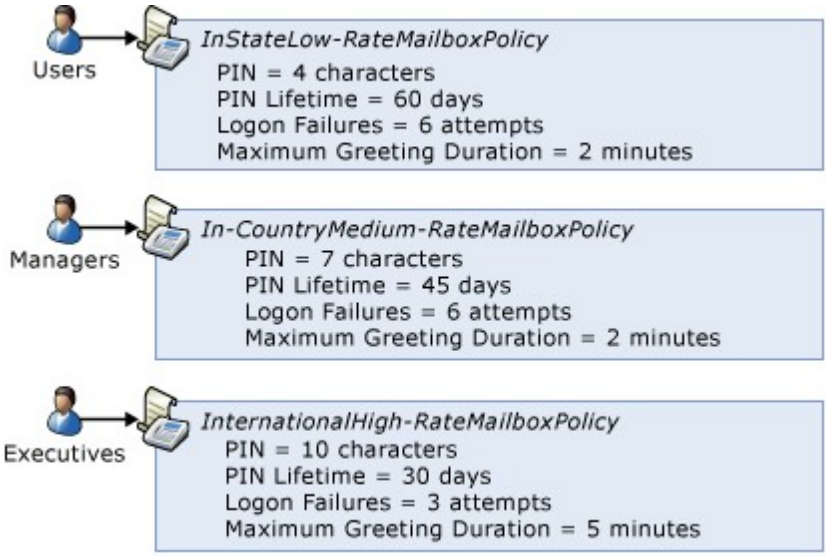
Each UM-enabled user's mailbox must be linked to a single UM mailbox policy. After you create a UM mailbox policy, you link one or more UM-enabled mailboxes to the UM mailbox policy. This lets you control PIN security settings such as the minimum number of digits in a PIN or the maximum number of logon attempts for the UM-enabled users who are associated with the UM mailbox policy. If you prefer, you can also control message text settings or dialing restrictions for the same or a different group of UM-enabled mailboxes.

Multiple UM-enabled users can be linked to a single UM mailbox policy. However, a single user can be associated with only one UM mailbox policy. When a user is enabled for

Unified Messaging, you must specify an existing UM mailbox policy to be linked to the UM-enabled user's mailbox. After you create a new UM mailbox policy and link it to a UM dial plan, the UM mailbox policy settings defined are then applied to the UM-enabled users. The settings defined on a UM mailbox policy apply only to UM-enabled users to which the UM dial plan is linked and the UM mailbox policy is associated.

Unified Messaging Policy Examples

The following figure illustrates how UM mailbox policies can be created to control dialing restrictions and PIN security settings for three different groups.



1.9.1.2.3 Understanding Unified Messaging IP Gateways

Understanding Unified Messaging IP Gateways

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Components >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-06-18*

The Unified Messaging (UM) IP gateway is a container object that logically represents a physical IP gateway hardware device. Before the IP gateway can be used to process Unified Messaging calls, the IP gateway must be represented by an object in the Active Directory directory service.

Contents

Overview of IP Gateways

Traditionally, *gateway* is a term that describes a physical device that connects two incompatible networks. With Microsoft Exchange Server 2010 Unified Messaging and other Unified Messaging solutions, the IP gateway is used to translate between the Public Switched Telephone Network (PSTN)/Time Division Multiplex (TDM) or circuit-switched based telephony network and an IP or packet-switched data network.

Note:

A packet-switched network is a network in which packets (messages or fragments of messages) are individually routed between nodes that may be shared by many other nodes. This contrasts with a circuit-switched network that sets up a dedicated connection between the two nodes for their exclusive use for the duration of the communication.

Exchange 2010 Unified Messaging relies on the ability of the IP gateway to translate TDM or telephony circuit-switched based protocols, such as Integrated Services Digital Network (ISDN) or QSIG, from a Private Branch eXchange (PBX) to protocols based on Voice over IP (VoIP) or IP, such as Session Initiation Protocol (SIP), Realtime Transport Protocol (RTP), or T.38 for real-time facsimile transport.

Types of IP Gateways

Although there are many types and manufacturers of PBXs, IP gateways, and IP PBXs, there are basically two types of IP gateway component configurations:

- **IP PBX** A single device
- **PBX (legacy) and an IP gateway** Two separate components

To support Exchange 2010 Unified Messaging, one or both types of IP/VoIP device configurations are used when connecting a telephony network infrastructure to a data network infrastructure.

IP Gateway Objects

The UM IP gateway is an Active Directory container object that contains one or more Active Directory UM hunt groups and other UM IP gateway configuration settings. UM IP gateways are created within Active Directory to logically represent a physical hardware device called an IP gateway. The UM IP gateway can represent either an IP gateway or an IP PBX. The combination of the UM IP Gateway object and a UM Hunt Group object establishes a logical link between an IP gateway hardware device and a UM dial plan.

After the UM IP gateway is created, the IP gateway can be linked to or associated with a single or multiple UM hunt groups and UM dial plans. The UM hunt group provides a link between the UM IP gateway and a UM dial plan. By creating multiple UM hunt groups, you can associate a single UM IP gateway with multiple UM dial plans.

After you create a UM IP Gateway object, the Unified Messaging server associated with the UM IP gateway will send a SIP OPTIONS request to the IP gateway to ensure that the IP gateway is responsive. If the IP gateway doesn't respond to the SIP OPTIONS request from the Unified Messaging server, the Unified Messaging server will log an event with ID 1400 stating that the request failed. To resolve this issue, ensure that the IP/VoIP is available and online and that the Unified Messaging configuration is correct.

A Unified Messaging server communicates only with IP gateways or IP PBXs listed as a trusted SIP peer. In some cases, if two IP gateways are configured to use the same IP address, an event with ID 1175 will be logged. Unified Messaging protects against unauthorized requests by retrieving the internal URL of the Unified Messaging Web services virtual directory located on the server that has the Client Access server role installed, and then uses the URL to build the list of FQDNs for the trusted SIP peers. When two FQDNs are resolved to the same IP address, this event will be logged.

Note:
Before an IP gateway can be used to process calls, a UM IP gateway must be associated with at least one UM dial plan. Also, at least one Unified Messaging server must be associated with at least one UM dial plan.

Enabling and Disabling UM IP Gateways

By default, IP gateways are left in an enabled state after they're created. However, the UM IP gateway can be enabled or disabled. If you disable a UM IP gateway, it can be in one of two disabled modes. The first disabled mode forces all associated Unified Messaging servers to drop existing calls. The second disabled mode forces the Unified Messaging server associated with the UM IP gateway to stop handling any new calls presented by the IP gateway.

Note:
If a UM IP gateway is deleted, the Unified Messaging servers associated with the IP gateway will no longer be able to accept or process new call requests from the IP gateway.

1.9.1.2.4 Understanding Unified Messaging Hunt Groups

Understanding Unified Messaging Hunt Groups

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-03*

This topic discusses Microsoft Exchange Server 2010 Unified Messaging (UM) hunt groups and how UM hunt groups must be implemented in your Exchange 2010 organization to support Unified Messaging.

Looking for management tasks related to Unified Messaging hunt groups? See Managing UM Hunt Groups.

Contents

What Is a Hunt Group?

Hunt group is a term used to describe a group of Private Branch eXchange (PBX) or IP PBX resources or extension numbers that are shared by users. Hunt groups are used to efficiently distribute calls into or out of a specific business unit. For example, a PBX or IP PBX might be configured to have 10 extension numbers for the sales department. The 10 sales extension numbers would be configured as one hunt group. In a PBX or IP PBX, hunt groups are used to efficiently locate an open line, extension, or channel when an incoming call is received.

In a telephony network, a hunt group is defined as a set of extension numbers grouped as a single logical unit. When an incoming call is received, the PBX or IP PBX uses the hunt group or group of extensions that are defined to *hunt* for an available or open line, extension, or channel that can be used to receive the call.

There are multiple algorithms or methods that have been created to be used by a PBX or IP PBX to define how the open line, extension, or channel will be located. These include:

- Round robin
- Most idle
- Start with lowest number

Creating and defining a hunt group in a PBX or IP PBX minimizes the chance that a caller who places an incoming call will receive a busy signal when the call is received.

Pilot Number

In a telephony network, a PBX or IP PBX can be configured to have a single hunt group or multiple hunt groups. Each hunt group created on a PBX or IP PBX must have an associated pilot number. The PBX or IP PBX uses the pilot number to locate the hunt group and in turn to locate the telephone extension number on which the incoming call was received. Without a defined pilot number, the PBX or IP PBX can't locate where the incoming call was received.

A pilot number is the address or location of the hunt group inside the PBX or IP PBX. A pilot number is generally defined as a blank extension number or one extension number from a hunt group of extension numbers that doesn't have a person or telephone associated with it. For example, you configure a hunt group on a PBX or IP PBX to contain extension numbers 4100, 4101, 4102, 4103, 4104, and 4105. The pilot number for the hunt group is configured as extension 4100. When a call is received on the extension number 4100, the PBX or IP PBX looks for the next available extension number to determine where to deliver the call. In this case, the PBX or IP PBX looks at the extension numbers 4101, 4102, 4103, 4104, and 4105.

Using a pilot number helps eliminate busy signals and helps route incoming calls to the circuits that are available. The PBX or IP PBX pilot number, when used with Exchange 2010 Unified Messaging, is used as the target. When an incoming call is unanswered or the line is busy, the call is correctly routed to an Exchange 2010 Unified Messaging server.

For more information about telephony concepts, see Understanding Telephony Concepts and Components.

Return to top

UM Hunt Groups

Unified Messaging hunt groups are critical to the operation of the Unified Messaging system. The UM hunt group is a logical representation of an existing PBX or IP PBX hunt group. UM hunt groups act as a connection or link between the UM IP gateway and the UM dial plan. Therefore, a single UM hunt group must be associated with at least one UM IP gateway and one UM dial plan.

Unified Messaging hunt groups are used to locate the PBX or IP PBX hunt group from which the incoming call was received. A pilot number defined for a hunt group in the PBX or IP PBX must also be defined within the UM hunt group. The pilot number is used to match the information presented for incoming calls through the Session Initiation Protocol (SIP) signaling message information on the message. The pilot number enables the Unified Messaging server to interpret the call together with the correct dial plan so that

the call can be routed correctly. The absence of a hunt group prevents the Unified Messaging server from knowing the origin or location of the incoming call. It is very important to configure the UM hunt groups correctly, because incoming calls that don't correctly match the pilot number defined on the UM hunt group will not be answered, and incoming call routing will fail.

When you create a Unified Messaging hunt group, you are enabling all Unified Messaging servers that are specified within the UM dial plan to communicate with an IP gateway. If you delete the UM hunt group, the associated IP gateway will no longer service calls with the specified pilot number. If the IP gateway is left without remaining UM hunt groups, the IP gateway will be unable to handle incoming calls.

For more information about IP gateways, see Understanding Unified Messaging IP Gateways.

1.9.1.2.5 Understanding Unified Messaging Auto Attendants

Understanding Unified Messaging Auto Attendants

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Components >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 Unified Messaging (UM) enables you to create a single or multiple UM auto attendants, depending on the needs of your organization. Unlike other Unified Messaging objects, such as UM dial plans and UM IP gateways, you aren't required to create UM auto attendants. However, auto attendants help internal and external callers locate users or departments that exist in an organization and transfer calls to them. This topic discusses the UM auto attendant feature found in Exchange 2010 Unified Messaging.

Looking for other management tasks related to UM auto attendants? Check out Managing UM Auto Attendants.

Contents

Auto Attendants

In telephony or Unified Messaging environments, an automated attendant or auto attendant menu system transfers callers to the extension of a user or department without the intervention of a receptionist or an operator. In many auto attendant systems, a receptionist or operator can be reached by pressing or saying zero. The automated attendant is a feature in most modern Private Branch eXchange (PBX) and Unified Messaging solutions.

Some auto attendant systems use message-only information menus and voice menus so an organization can provide business hours, directions to the premises, information about job opportunities, and answers to other frequently asked questions. After the message plays, callers are forwarded to the receptionist or operator, or they can return to the main menu.

In more complex auto attendant systems, the menu system can be used to search for other auto attendant menus, locate a user in the system, or transfer to another outside telephone line. The menu system can also be used to let the caller interact with the system in certain situations, such as when a student enrolls for a college class or checks a grade, or when you activate a credit card over the telephone.

Although auto attendants can be very useful, if they aren't designed and configured correctly, they can confuse and frustrate callers. For example, specifically in large organizations, when auto attendants aren't designed correctly, callers can be led through a lengthy series of questions and menu prompts before they are finally transferred to a person to answer their questions.

UM Auto Attendants

Exchange 2010 Unified Messaging enables you to create one or more UM auto attendants depending on the needs of your organization. UM auto attendants can be used to create a voice menu system for an organization that lets external and internal callers move through the UM auto attendant menu system to locate and place or transfer calls to company users or departments in an organization.

When anonymous or unauthenticated users call an external business telephone number, or when internal callers call a defined extension number, they are presented with a series of voice prompts that help them place a call to a user or locate a user in the organization and then place a call to that user. The UM auto attendant is a series of voice prompts or .wav files that callers hear instead of a human operator when they call an organization that has Exchange 2010 Unified Messaging. The UM auto attendant lets callers move through the menu system, place calls, or locate users by using dual tone multi-frequency (DTMF) or voice inputs. However, for Automatic Speech Recognition (ASR) or voice inputs to be used, you must enable ASR on the UM auto attendant.

Important:

In some companies (especially in East Asia), office telephones may not have letters on the keys of the telephone. This makes the spell-the-name feature that uses the DTMF interface almost impossible to use, without a working knowledge of the key mappings. By default, Exchange 2010 Unified Messaging uses the E.161 key mapping. For example, 2=ABC, 3=DEF, 4=GHI, 5=JKL, 6=MNO, 7=PQRS, 8=TUV, 9=WXYZ.
When inputting the combination of letters and numbers, for example Mike1092, the numeric digits are mapped to themselves. For an e-mail alias of Mike1092 to be entered correctly, the user must press the numbers 64531092. Also for characters other than A-Z and 0-9, there won't be a telephone key equivalent. Therefore, these characters shouldn't be entered. For example, the e-mail alias mike.wilson would be entered as 6453945766. Even though there are 11 characters to be input, only 10 digits are entered by the user because the period (.) doesn't have a digit equivalent.

A UM auto attendant has the following features:

- It provides corporate or informational greetings.

- It provides custom corporate menus. You can customize these menus to have more than one level.
- It provides a directory search function that enables a caller to search the organization's directory for a name.
- It enables a caller to connect to the telephone of, or leave a message for, members of the organization.

In the Active Directory directory service, each UM auto attendant created is represented as an object. There is no limit to the number of UM auto attendants you can create in Active Directory. Each Exchange 2010 Unified Messaging auto attendant can support an unlimited number of extensions. A UM auto attendant can reference one, and only one, UM dial plan. However, UM auto attendants can reference or link to other UM auto attendants.

An incoming call received from an external telephone number or an internal telephone extension is processed by a Unified Messaging server and then sent to a UM auto attendant that has been created. The UM auto attendant is configured by the system administrator to use prerecorded voice (.wav) files that are then played over the telephone to the caller and that enable the caller to move through the Unified Messaging menu system. You can customize all the .wav files used when you configure a UM auto attendant to meet the needs of your organization.

For more information about message flow with UM auto attendants, see Unified Messaging Auto Attendant Call Processing.

Return to top

Auto Attendant with Multiple Languages

There are situations in which you may have to provide callers with auto attendants that have different languages. The language setting available on a UM auto attendant enables you to configure the default prompt language on the auto attendant. When you are using the default system prompts for the auto attendant, this is the language that the caller will hear when the auto attendant answers the incoming call. This language setting affects only the default system prompts provided after the Unified Messaging server role is installed. This language setting doesn't affect custom prompts configured on an auto attendant. The language selected as the default for the auto attendant is based on the version of Exchange 2010 installed.

When you install the U.S. English version of Exchange 2010, U.S. English is the only language available to configure on UM auto attendants. If you install a localized version of Exchange 2010, for example, Japanese, you can configure the auto attendant that you create to use Japanese or U.S. English for the default language. Additional UM language packs can be installed on a Unified Messaging server to enable you to use other default languages on an auto attendant.

Caution:

You cannot install UM language packs using the .msi file for the language.

For example, if you have a business that's based in the United States but requires a menu system that gives callers the options of U.S. English, Spanish, and French, you must first install the UM language packs that you need. In this case, if you have installed the U.S. English version of Exchange 2010, you would install the UM language packs for Spanish and French. However, because a Unified Messaging auto attendant can have only one language configured at a time, you would create four auto attendants: a main auto attendant configured to use U.S. English and then one auto attendant for each language: U.S. English, Spanish, and French. You would then configure the main auto attendant to have the appropriate key mappings to access the other auto attendants that you created for each language. In this example, the main auto attendant would answer the incoming

call and the caller would hear, "Welcome to Contoso, Ltd. For English, press or say 1. For Spanish, press or say 2. For French, press or say 3."

Return to top

Non-Business and Business Hours Custom Greetings

After you create a UM auto attendant, a default system prompt will be used for the non-business hours main menu prompt greeting heard by callers after the non-business hours welcome greeting is played. Although the system prompts mustn't be replaced or changed, you probably want to customize the greetings and menu prompts used with UM auto attendants. Frequently, in addition to configuring a customized non-business hours welcome greeting, you also want to create and configure a custom non-business hours main menu prompt greeting. After you configure a custom non-business hours main menu prompt greeting, you must enable key mappings on the UM auto attendant for non-business hours.

A custom non-business hours main menu prompt greeting is a list of options callers hear during non-business hours. To let callers hear a non-business hours main menu prompt greeting, you first must configure the business and non-business hours schedule by using the **Times** tab available on the Properties for a UM auto attendant. For example, "You have reached Trey Research after normal business hours. If you are experiencing a medical emergency, please hang up and dial 911. To leave a message for one of our doctors, press 1. To leave a message for one of our physical therapists, press 2. To leave a general message for one of our front office coordinators, press 3. To be connected with an after hours operator, press 0."

By default, when you create a UM auto attendant, the business and non-business hours greetings or prompts aren't configured and no key mappings are defined for business or non-business hours main menu prompts. To correctly configure customized non-business hours main menu greetings and prompts, you must:

1. Configure business and non-business hours on the **Times** tab.
2. Create the greeting file that will be used for the non-business hours welcome greeting.
3. Configure the non-business hours welcome greeting on the **Greetings** tab.
4. Create the greeting file that will be used for the non-business hours main menu prompt greeting.
5. Configure the non-business hours main menu prompt greeting on the **Greetings** tab.
6. Enable and configure the non-business hours key mappings on the **Key Mapping** tab.

Return to top

Key Mappings

If you use the default main menu prompt greeting and define a key mapping or multiple key mappings, the UM Text-to-Speech (TTS) engine will synthesize a main menu prompt. However, the TTS engine will only synthesize a main menu prompt if the default greeting is configured and at least one key mapping has been defined. The TTS engine will not synthesize a main menu prompt if you're using a custom main menu prompt. For example, "For the sales department, press 1. For the support department, press 2." To create this main menu prompt, you must create two key mappings: one named "Sales Department" and another named "Support Department", and then configure the key mapping entry to play an audio file, transfer to an extension number, or send the caller to another auto

attendant.

When you configure key mappings, you define the options and the operations that will be performed if a caller speaks a phrase while they're using a speech-enabled auto attendant or the caller presses the key on the keypad of the telephone while they're using an auto attendant that isn't speech-enabled. To configure key mappings, you must add key mapping entries. When you configure the key mapping entries for an auto attendant, you must:

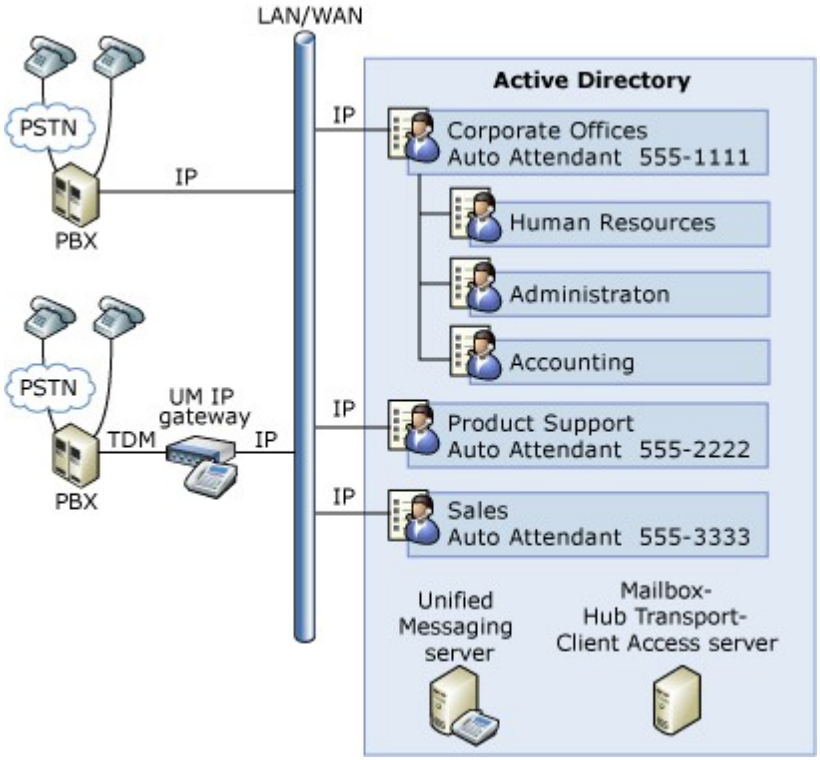
- Enable business hours key mapping.
- Add a key mapping entry.
- Type the name of the key mapping entry.
- Select **Presses this key** or **Presses no key (Time-out)** or type the phrase that the caller will say in the **Or the user says this phrase** field.
- Configure the action you want performed:
  - Play an audio file
  - Transfer to an extension number
  - Run an auto attendant

Return to top

Auto Attendant Examples

The following examples demonstrate how you can use UM auto attendants with Exchange 2010 Unified Messaging:

- **Example 1** At a company called Contoso, Ltd., external customers can use three external telephone numbers: 425-555-0111 (Corporate Offices), 425-555-0122 (Product Support), and 425-555-0133 (Sales). The Human Resources, Administration, and Accounting departments have internal telephone extensions and must be accessed from the Corporate Offices UM auto attendant.
  To create a UM auto attendant structure that supports this scenario, create and configure three UM auto attendants that have the appropriate external telephone numbers. Create three other UM auto attendants for each department in the Corporate Offices. You then configure each UM auto attendant based on your requirements, such as the greeting type or other navigational information.
  The following figure is a graphical representation of how UM auto attendants can be used in Example 1.



- **Example 2** At a company called Contoso, Ltd., external customers call one main number for the business, 425-555-0100. When an external caller calls the external number, the UM auto attendant answers and prompts the caller by saying, "Welcome to Contoso, Ltd. Please press or say 'One' to be transferred to corporate administration. Please press or say 'Two' to be transferred to product support. Please press or say 'Three' to be transferred to corporate information. Please press or say 'Zero' to be transferred to the operator." To create a UM auto attendant structure that supports this scenario, you create a UM auto attendant that has customized extensions that route the call to the appropriate extension number.
  The following figure is a graphical representation of how Unified Messaging auto attendants can be used in Example 2.

1.9.1.2.6 Understanding Unified Messaging Servers

Understanding Unified Messaging Servers

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Components >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

When you install the Unified Messaging (UM) server role on a computer running Microsoft Exchange Server 2010, a computer object is created in the Active Directory directory service. This topic discusses Unified Messaging server objects and Unified Messaging server operations that are included in Exchange 2010 Unified Messaging.

Looking for other management tasks related to UM servers? Check out Managing Unified Messaging Servers.

Computer Objects

Unified Messaging Active Directory computer objects are created in the Computers

container during the installation of the Unified Messaging server role. The Unified Messaging objects connect the telephony infrastructure of your organization and the Exchange 2010 Unified Messaging Active Directory networking environment and are a basic part of the Unified Messaging system. The Unified Messaging computer object created in Active Directory is a logical representation of a physical server on which the Unified Messaging server role is installed.

Important:

The Unified Messaging server must be a member of a domain before the Unified Messaging server role is installed so that a new Unified Messaging computer object can be created during the installation.

After the computer objects have been created, you can perform the procedures that are required to successfully deploy Unified Messaging on your network.

Note:

You can also apply Group Policy settings to the computer after the computer running Exchange 2010 is added to the domain.

Server Operation

A Unified Messaging server won't process incoming calls unless the operational state is set to enabled. By default, however, the operational status of the Unified Messaging server is set to enabled after installation. When its operational status is set to enabled, the Unified Messaging server can process incoming and outgoing voice calls and route the messages to the intended recipients in your Exchange organization.

Although the operational status of the Unified Messaging server is set to enabled after installation, the Unified Messaging server also maintains a status parameter that's used to control the operational status of the server. The status parameter lets you stop call processing so that the Unified Messaging server can be taken offline in a controlled way.

The operational status of the Unified Messaging server can be controlled by the enable and disable commands in the Exchange Management Console and the Exchange Management Shell. The following are the status modes for Unified Messaging servers:

- **Enable** Process all incoming calls.
- **Disable Immediately** Don't accept any new calls and drop all existing calls.
- **Disable After Completing Calls** Don't accept any new calls but process all existing calls.

For more information about how to enable and disable a Unified Messaging server, see Enable Unified Messaging on Exchange 2010 and Disable Unified Messaging on Exchange 2010.

Even though the operational status of the Unified Messaging server is set to enabled after the Unified Messaging server role is installed, the server can't correctly process and route incoming calls to UM-enabled users until it's associated with at least one UM dial plan, and the UM dial plan is associated with at least one UM IP gateway. For more information about how to add a Unified Messaging server to a UM dial plan, see Add a UM Server to a Dial Plan.

For more information about UM IP gateways, see Understanding Unified Messaging IP Gateways.

After the Unified Messaging server is started, it locates all IP gateways that are associated with the UM dial plans and with the Unified Messaging server. To detect and identify any configuration changes on either UM dial plans or UM IP gateways, the Unified Messaging server will either register a change notification or check the configuration every 10 minutes.

If the UM IP gateway identifies any changes to the configuration, the Unified Messaging server reacts accordingly, and either starts using or stops using the appropriate IP gateways. After a Unified Messaging server is associated with a UM dial plan and is communicating with an IP gateway or IP Private Branch eXchange (PBX), you can run a set of diagnostic operations to verify the correct operation and connectivity.

1.9.1.2.7 Understanding Unified Messaging Users

Understanding Unified Messaging Users

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

With Microsoft Exchange Server 2010 Unified Messaging (UM), users in an Exchange 2010 organization can receive all their e-mail and voice messages in one mailbox. The Unified Messaging functionality found in Exchange 2010 greatly increases user productivity and enables more flexible messaging throughout an organization.

When you're creating an Exchange 2010 recipient, you're given the option of creating a mailbox or connecting to an existing mailbox. After the mailbox is created for the user or the user is connected to an existing mailbox, you must enable the mailbox so that the user can use the Unified Messaging capabilities found in Exchange 2010. After the user is enabled for Unified Messaging, all e-mail and voice messages will be delivered to the user's Inbox. By using Microsoft Office Outlook 2007, Outlook Web App, a mobile phone enabled for Microsoft Exchange ActiveSync, or a regular or mobile telephone, users can access their e-mail, voice messages, and calendaring information.

Contents

UM User Properties

By default, a user who has an Exchange 2010 mailbox isn't enabled for Unified Messaging. You must create a mailbox for the Exchange 2010 user before they can be enabled for Unified Messaging. After the user is enabled for Unified Messaging, you can manage, modify, and configure the UM properties for them.

Note:

To enable multiple UM users, use the **Enable-UMMailbox** cmdlet in the Exchange Management Shell.

There are two locations in which UM properties are stored for a user: the Mailbox object and the user's Active Directory object. When you enable a user for Unified Messaging, you set the UM property on the user's Mailbox object. After the Mailbox property is set to

enabled for Unified Messaging, the user can use the Unified Messaging features found in Exchange 2010.

After a user is enabled for Unified Messaging, their UM properties are stored in their properties and their mailbox. The user's UM properties, including their extension number, spoken name, and other properties, are stored in their properties in the Active Directory directory service.

You can manage UM properties for a UM-enabled user on the mailbox of the Exchange 2010 Unified Messaging user by using the Shell or the Exchange Management Console.

Relationship Between the UM User and Other Active Directory Objects

When you enable a user for Unified Messaging, the user must be associated with or linked to an existing UM mailbox policy, and you must provide their extension number. You can associate a user with a UM mailbox policy by using the **Enable-UMMailbox** cmdlet or by selecting the UM mailbox policy when you create the user's Exchange mailbox.

A UM mailbox policy contains settings such as the dialing restrictions and PIN policies for a user. When a UM mailbox policy is created, the UM mailbox policy must be associated with only one UM dial plan. The UM dial plan is then associated with at least one Unified Messaging server. Any Unified Messaging server associated with the UM dial plan can provide Unified Messaging services for a UM-enabled user who uses the UM dial plan. Associating these Active Directory objects in this manner delivers the Unified Messaging services by using Active Directory. After the user is enabled for Unified Messaging, the settings from a UM mailbox policy object are applied to the UM-enabled user.

Note:
In a circuit-switched telephony environment, the user's telephone must be programmed in the Private Branch eXchange (PBX) to forward busy or unanswered calls to a UM IP gateway associated with the user's dial plan.

Extension Numbers and SIP Addresses

When you enable a user for Unified Messaging, you must define at least one extension number that Unified Messaging will use when voice mail is submitted to the user's Exchange 2010 mailbox. After you enable the user for Unified Messaging, you can add extension numbers to the user's mailbox, or modify or remove them by configuring the Exchange Unified Messaging proxy address (EUM proxy address) on the user's mailbox.

Note:
There's no limit to the number of secondary extension numbers that you can add for a UM-enabled user.

The mailbox of a UM-enabled user can be associated with only one UM dial plan. However, the mailbox of a UM-enabled user can be assigned the following:

- A single extension number, Session Initiation Protocol (SIP) address, or E.164 address on a single dial plan.
- Multiple extension numbers, SIP addresses, or E.164 addresses on a single dial plan.
- Multiple extension numbers, SIP addresses, or E.164 addresses on two separate dial plans.

Note:
Each extension number must be unique within a dial plan.

For example, a UM-enabled user travels frequently from New York to Tokyo. The user's mailbox is associated with the New York dial plan and a single extension number is configured on the user's mailbox. A second extension number is configured on the user's mailbox for the Tokyo dial plan. When callers dial either extension number and leave a voice message for the user, the voice message will be delivered to the same UM-enabled mailbox.

Return to top

Disabling UM for a User

When you disable Unified Messaging for a user, the user's account may still be listed when a caller performs a directory search using a UM auto attendant menu or using Outlook Voice Access. Callers may be able to locate a user in the directory, but when they try to contact the user, they're taken back to the main menu in Unified Messaging. This may cause callers to become frustrated with the system. You can prevent callers from using a directory search to contact a user who's been disabled for Unified Messaging by connecting the user to another voice mail system, removing the user from the UM auto attendant directory search, or removing the user's account from Active Directory.

After a UM-enabled user account is disabled for Unified Messaging, the user may still have access to the individual UM-enabled mailbox using Outlook Voice Access or Microsoft Outlook. This can occur when all domain controllers in Active Directory haven't fully replicated all changes to objects to the Active Directory database. To lessen the risk of a user gaining access to the mailbox even though the account has been disabled for Unified Messaging, you can manually force Active Directory replication to occur or remove all Unified Messaging information from the user's mailbox when the user is disabled for Unified Messaging.

1.9.1.3 Understanding Unified Messaging Features

Understanding Unified Messaging Features

Exchange Server 2010 > Unified Messaging > Understanding Unified Messaging >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

Microsoft Exchange Server 2010 Unified Messaging (UM) introduces new concepts in Exchange messaging. Exchange 2010 Unified Messaging provides a single storage location for e-mail and voice mail messages.

This overview of the new components, features, and concepts in Unified Messaging includes the following:

- Active Directory UM objects
- Auto attendants
- Subscriber access using Outlook Voice Access

Contents

Additional Components

Active Directory UM Objects

After you install and configure the Unified Messaging server, you can create Active Directory objects that enable the UM functionality found in Exchange 2010. You must create the following objects after you successfully install the Unified Messaging server role:

- Dial Plan objects
- IP Gateway objects
- Hunt Group objects
- Mailbox Policy objects
- Auto Attendant objects
- UM Server objects

The Active Directory UM objects provide the configuration information required to integrate Unified Messaging, Active Directory, and the existing telephony infrastructure. Each type of object created in Active Directory controls a feature set in Unified Messaging.

For example, when you create a UM Auto Attendant object, the settings on the Auto Attendant object control the features and settings for that auto attendant. When you configure or modify an Auto Attendant object, you control such settings as business hours, non-business hours, informational greetings, and whether to use dual tone multi-frequency (DTMF) inputs or enable speech recognition for the auto attendant.

For more information about UM objects, see Understanding Unified Messaging Components.

Auto Attendants

When internal or external callers call in to the UM system, a series of voice prompts helps them move through the menu system called an auto attendant. The auto attendant lets the caller connect to a person in an organization or locate a user in the organization so they can place a call without assistance from a human operator. Callers hear voice prompts instead of a human operator, such as, "Press 1 for technical support."

You can create multiple auto attendants in Unified Messaging. Within Active Directory, each auto attendant is represented as an object. Configuration settings for an auto attendant are made on the Active Directory object and can include language settings, customized menus, and other menu navigational settings. You can also configure each UM auto attendant so that when an external caller or an internal caller places a call, and it's answered by a UM auto attendant, the caller can use either DTMF inputs or voice inputs to move through the UM menu system.

Note:

When a caller uses the keypad on a telephone to move through the menu system, it is called DTMF input. If this is the case, the telephone user interface is used.

For more information about auto attendants, see Understanding Unified Messaging Auto Attendants.

Subscriber Access

Unified Messaging gives subscribers access to the UM system. A subscriber is an internal

business user or network user who has been enabled for Unified Messaging and has an Exchange 2010 mailbox. Subscriber access is used by the internal users to access their individual mailboxes to retrieve e-mail, voice messages, and contact and calendar information. Each Dial Plan object that's created contains at least one subscriber access number or extension number. Subscribers use this telephone or extension number to access their individual mailboxes.

For more information about subscriber access, see Understanding Unified Messaging Subscriber Access.

There are two Unified Messaging user interfaces available to UM-enabled subscribers: the telephone user interface and the voice user interface. In Exchange 2010, these two interfaces together are called Outlook Voice Access. Subscribers can use Outlook Voice Access when they access the UM system from an external or internal telephone. They can use Outlook Voice Access to access their Exchange 2010 mailbox, including their personal e-mail, voice messages, and calendar information.

Note:

For a copy of the Unified Messaging Outlook Voice Access Quick Reference Guide, see the Quick Start Guide for Outlook Voice Access 2010.

1.9.1.3.1 Understanding Unified Messaging Incoming Calls

Understanding Unified Messaging Incoming Calls

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

This topic provides an overview of the call handling features included with Microsoft Exchange Server 2010 Unified Messaging (UM). Each section in this topic gives you the information required to understand one or more of the call handling features included in Exchange 2010 Unified Messaging.

Contents

Overview

Call handling is a term that describes how incoming calls are answered and handled by a computer running Exchange 2010 Unified Messaging. The types of incoming calls handled by Exchange 2010 Unified Messaging include the following:

- Voice calls
- Outlook Voice Access
- Play on Phone feature
- UM auto attendants

For more information about Unified Messaging message flow and routing, see Understanding Unified Messaging Call Processing.

Voice Calls

Voice call handling is used when an internal or external user leaves a voice message for a subscriber on the Exchange 2010 Unified Messaging system. Incoming voice calls are created as MIME messages and then submitted using SMTP from the Exchange 2010 computer that has the Unified Messaging server role installed to an Exchange 2010 computer that has the Hub Transport server role installed. The two server roles must be installed in the same Active Directory site. The SMTP message transport for incoming voice calls is not only site aware, but all voice messages are submitted to the Hub Transport server using SMTP, even if the mailbox resides on the same computer that has the Mailbox server role installed.

For more information about voice calls and message routing, see Unified Messaging Voice Call Processing.

Outlook Voice Access

Unified Messaging servers also process and route incoming calls that are received by Outlook Voice Access users. When UM-enabled users or subscribers dial a subscriber access number that's set on a UM dial plan to access their Exchange 2010 mailbox, they are presented with a welcome message and a series of Telephone User Interface (TUI) voice prompts. The voice menu system presented to the user is called Outlook Voice Access. These voice prompts help the user navigate and interact with the Unified Messaging system using touchtone or speech inputs.

Note:

When an Outlook Voice Access caller uses touchtone inputs on a telephone keypad, the TUI is used. When the same caller uses speech inputs over the telephone, the Voice User Interface (VUI) is used.

For more information about the voice prompts found in Exchange 2010 Unified Messaging,

see Understanding Unified Messaging Audio Prompts.

Outlook Voice Access is the feature that enables UM-enabled users to access their Exchange 2010 mailbox using an analog, digital, or mobile telephone. By accessing their Exchange 2010 mailbox, they can perform the following tasks:

- Listen to new and saved e-mail and voice mail messages.
- Forward, reply, save, and delete e-mail and voice messages.
- Interact with their calendar, including:
  - Listening to daily calendar appointments and meeting details.
  - Accepting or declining e-mail and meeting requests.
  - Sending an "I'll be late" message to meeting participants.
  - Replying to a meeting request using voice inputs to send a message to meeting participants.
  - Declining or canceling meetings.
- Interact with global address list and personal contacts. These interactions may include:
  - Locating a person in the global address list or personal contacts.
  - Inputting a telephone extension number to leave a message for a person.
  - Sending a voice message to a person.
- Change their PIN, spoken name, or greetings.

For more information about how to navigate the Outlook Voice Access menus, see the Microsoft Exchange 2010 Unified Messaging Outlook Voice Access Quick Start Guide. For a copy of the Microsoft Exchange 2010 Unified Messaging Outlook Voice Access Quick Start Guide, see the Microsoft Download Center.

For more information about Outlook Voice Access message routing, see Unified Messaging Outlook Voice Access Call Processing.

Return to top

Play on Phone Feature

To enable the Play on Phone feature for UM-enabled users, the Unified Messaging server must first answer and then correctly route a call when it's placed by a user who is using Microsoft Office Outlook Web App or Office Outlook 2007. If UM-enabled users are in a location that's not private or the voice message is confidential, they will likely not want to play their voice message over their computer speakers. The Exchange 2010 Unified Messaging Play on Phone feature lets UM-enabled users listen to a voice message using a telephone instead of playing it over their computer speakers or headphones.

For more information about Play on Phone message flow, see Unified Messaging Play on Phone Call Processing.

UM Auto Attendants

To enable the UM auto attendant feature found in Exchange 2010 Unified Messaging, Unified Messaging servers must correctly answer and then route the incoming calls received from internal and external anonymous or unauthenticated users.

To enable a UM auto attendant to answer incoming calls, you must first create and configure a UM auto attendant. Creating and configuring UM auto attendants is an optional feature in Exchange 2010 Unified Messaging. However, auto attendants help internal and external callers locate and place calls to company users or departments that are in an organization.

A UM auto attendant is a set of voice prompts that callers hear instead of a human operator when they place a call to an organization that has Exchange 2010 Unified Messaging. A UM auto attendant helps callers navigate the organization's menu system using dual tone multi-frequency (DTMF) (also known as touchtone) inputs or voice-activated inputs that use Automatic Speech Recognition (ASR) so that they can locate a user or department in an organization and then place a call to that user or department.

- For more information about UM auto attendant message routing, see Unified Messaging Auto Attendant Call Processing.
- For more information about UM auto attendants, see Understanding Unified Messaging Auto Attendants.

1.9.1.3.2 Understanding Unified Messaging Audio Prompts

Understanding Unified Messaging Audio Prompts

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

When you install the Unified Messaging (UM) server role on a computer running Microsoft Exchange Server 2010, a common set of default audio files used for the Unified Messaging system and menu prompts, greetings, and informational announcements is copied to the Unified Messaging server. Although you can have a fully functional UM auto attendant or a dial plan that uses only the default audio prompts included in Exchange 2010, the audio files installed for greetings, informational announcements, and system and menu prompts are too generic to serve as an acceptable public interface for many companies. This topic discusses the system and menu prompts, greetings, and informational announcements used by UM dial plans and auto attendants and how they're used when callers access the Unified Messaging system.

Contents

Overview of Audio Prompts and Greetings

After the Unified Messaging server role is installed, audio files for UM dial plans and auto attendants are copied to the Unified Messaging server. By default, the installation program copies the audio files to the Program Files\Microsoft\Exchange Server\V14\Unified Messaging\Prompts\<*language*> folder. If you've installed the U.S. English version of Exchange 2010, a folder named \en is created during installation to hold the U.S. English versions of the system prompts. The UM server plays these system prompts to callers so

they can hear greetings, menu prompts, and informational announcements and so they can navigate the Unified Messaging menus.

These system audio files or prompts copied to the UM server should never be changed. However, Unified Messaging does enable you to customize UM dial plan and auto attendant welcome greetings, main menu prompts, and informational announcements.

The following table summarizes the prompts and greetings used with UM dial plans.

Audio prompts for UM dial plans

Prompts and greetings	Description
System prompts	Must not be modified.
Welcome greeting	The default welcome greeting is a system prompt that is played by default. However, you can use a customized greeting file that you create.
Informational announcement	By default, informational announcements are disabled. If you enable an informational announcement, you must specify a customized greeting file.

The following table summarizes the prompts and greetings used with UM auto attendants.

Audio prompts for UM auto attendants

Prompts and greetings	Description
System prompts	Must not be modified.
Business hours menu prompts	By default, business hours menu prompts are enabled and a system prompt is played. However, you can use a customized greeting file that you create.
Non-business hours menu prompts	By default, non-business hours prompts are enabled and a system prompt is played. However, you can use a customized greeting file that you create.
Business hours greeting	By default, a business hours greeting is enabled and a system prompt is played. However, you can use a customized greeting file that you create. This is also known as a welcome greeting.
Non-business hours greeting	By default, a non-business hours greeting is enabled and a system prompt is played. However, you can use a customized greeting file that you create. This is also known as a welcome greeting.
Informational announcement	By default, informational announcements are disabled. If you enable an informational announcement, you must specify a customized greeting file.

Caution:

Modifying the installed system prompts isn't supported.

Return to top

System Prompts

Unified Messaging is installed with a set of default audio prompts for use with Outlook Voice Access, dial plans, and auto attendants. Hundreds of system prompts for each language are installed on the Unified Messaging server. The UM server plays the audio files for these system prompts to callers when they access the Unified Messaging system. The following are some examples of these system prompts:

- "Please enter your PIN."
- "To access your mailbox, enter your extension."
- "To contact someone, press the # key."
- "Spell the name of the person you are calling, last name first."
- "To reach a specific person, just tell me the name."

Caution:

Modifying the installed system prompts isn't supported.

Note:

When the Unified Messaging service starts on the Unified Messaging server, it will verify that all the system prompts are available. If a system prompt can't be found, Unified Messaging will return an error. To fix the error that is returned, locate the event using Event Viewer and copy the file listed in the **Event Properties** window from the Exchange 2010 installation DVD into the appropriate folder on the UM server.

UM Dial Plan Greetings and Announcements

After you install the Unified Messaging server role and create a UM dial plan, you've the option to use the audio files for the default system prompts that are copied to the UM server during installation or to create customized audio files that can be used with UM dial plans.

UM dial plans have a welcome greeting and an optional informational announcement you can modify. The welcome greeting is used when Outlook Voice Access users or another caller calls the subscriber access number. The callers hear a default welcome greeting that says, "Welcome, you are connected to Microsoft Exchange." This audio file is the default greeting for a UM dial plan. However, you might want to change this greeting and provide an alternative welcome greeting specific to your company, for example, "Welcome to Outlook Voice Access for Woodgrove Bank." If you customize this greeting, you can record the customized greeting and save it as a .wav file, and then you can configure the dial plan to use this customized greeting.

Unified Messaging allows for an informational announcement to follow the welcome greeting. By default, there is no informational announcement configured. However, you may want to provide one for callers. You can use the informational announcement for general announcements that change more often than the welcome greeting or for announcements required by corporate compliance policies. When it's important that the whole informational announcement is heard, you can configure it to be uninterruptible. This prevents a caller from pressing a key or speaking a command to interrupt and stop the informational announcement.

The following table describes the UM dial plan greetings and informational

announcements.

UM dial plan greetings and informational announcements

Greeting	Default example	Customized example
Welcome greeting	"Welcome, you are connected to Microsoft Exchange."	"Welcome to Outlook Voice Access for Woodgrove Bank."
Informational announcement	By default, an informational announcement isn't configured.	"By using this system you agree to adhere to all corporate policies when you are accessing this system."

When you are customizing and configuring greetings and announcements, make sure the language setting configured on the UM dial plan is the same as the language of the custom prompts you create. If not, a caller may hear a message or greeting in one language and another message or greeting in a different language.

Return to top

UM Auto Attendant Greetings, Announcements, and Menu Prompts

As with UM dial plans, UM auto attendants have a welcome greeting, an optional informational announcement, and an optional custom menu prompt. There are different versions of the welcome greeting and menu prompt that you can configure for business hours and non-business hours. You can modify all of them.

The welcome greeting is the first thing a caller hears when a UM auto attendant answers the call. By default, this says, "Welcome to the Microsoft Exchange auto attendant." The audio file that is played for the call is the default system prompt for the UM auto attendant. However, you may want to provide an alternative greeting specific to your company, for example, "Thank you for calling Woodgrove Bank." To customize this welcome greeting, record the customized greeting and save it as a .wav file, and then configure the auto attendant to use this customized greeting. As with the welcome greetings, you can also customize the menu prompts.

Unified Messaging also allows for an informational announcement to follow a business hours greeting or a non-business hour greeting. By default, no informational announcement is configured, but you may want to provide one to callers. The informational announcement can announce your company's business hours, for example, "Our business hours are 8:00 A.M. to 5:00 P.M., Monday through Friday, and 8:30 A.M. to 1:00 P.M. on Saturday." The informational announcement can also provide information required for compliance with corporate policies, for example, "Calls may be monitored for training purposes." When it's important that the whole informational announcement is heard, you can configure it to be uninterruptible. This prevents the caller from pressing a key or speaking a command to interrupt and stop the informational announcement.

The following table describes the UM auto attendant greetings and informational announcements.

UM auto attendant greetings, informational announcement, and menu prompts

Greeting	Default example	Customized example

Business hours greeting	"Welcome to the Exchange auto attendant."	"Thank you for calling Woodgrove Bank."
Non-business hours greeting	No default non-business hours greeting is played until you configure the business hours for the auto attendant. However, the business hours greeting is played for callers during all times of the day.	"You have reached Woodgrove Bank after business hours. Our business hours are from 8:00 A.M. until 5:00 P.M., Monday through Friday."
Informational announcement	By default, informational announcements aren't configured.	"Calls may be monitored for training purposes."
Business hours main menu prompt	No default business hours main menu prompt will be played until you configure key mappings on the auto attendant.	"For technical support, press or say 1. For corporate offices and administration, press or say 2. For sales, press or say 3."
Non-business hours main menu prompt	No default non-business hours main menu prompt will be played until you configure key mappings and the business hours schedule on the auto attendant.	"Your call is very important to us. However, you have reached Woodgrove Bank after business hours. If you want to leave a message, please press or say 1, and we will return your call as soon as possible."

As with UM dial plans, make sure the language setting configured on the UM auto attendant is the same as the language of the custom greetings you create and is set to the same language as the UM dial plan. If not, a caller may hear a message or greeting in one language and another message or greeting in a different language.

Return to top

Customizing Greetings, Announcements, and Menu Prompts

Although the system prompts mustn't be replaced or changed, you'll probably want to customize the greetings, informational announcements, and menu prompts used with UM dial plans and auto attendants. After the Unified Messaging server role is installed, you can configure the UM dial plans and auto attendants to use these custom audio files (.wav). You must follow these steps before you can enable custom voice prompts for callers:

- Record the custom greeting and save it as a .wav file. The Linear PCM (16 bit/sample), 8 kilohertz (kHz) audio codec must be used to encode the .wav file. If you don't use this specific format for the .wav file, an error will be generated stating that the source file is in an unsupported format. Although an error is generated, the error won't appear in Event Viewer.
- Configure the UM dial plan or auto attendant to use the customized greeting. After you create a UM auto attendant, a default system prompt will be used for the non-business hours main menu prompt greeting heard by callers after the non-business hours welcome greeting is played. Although the system prompts mustn't be replaced or changed, you probably want to customize the greetings and menu prompts used with UM auto attendants. Frequently, in addition to configuring a customized non-business hours welcome greeting,

you also want to create and configure a custom non-business hours main menu prompt greeting. After you configure a custom non-business hours main menu prompt greeting, you must enable key mappings on the UM auto attendant for non-business hours.
A custom non-business hours main menu prompt greeting is a list of options callers hear during non-business hours. To let callers hear a non-business hours main menu prompt greeting, you first must configure the business and non-business hours schedule by using the **Times** tab available on the Properties for a UM auto attendant. For example, "You have reached Trey Research after normal business hours. If you are experiencing a medical emergency, please hang up and dial 911. To leave a message for one of our doctors, press 1. To leave a message for one of our physical therapists, press 2. To leave a general message for one of our front office coordinators, press 3. To be connected with an after hours operator, press 0."
By default, when you create a UM auto attendant, the business and non-business hours greetings or prompts aren't configured and no key mappings are defined for business or non-business hours main menu prompts. To correctly configure customized non-business hours main menu greetings and prompts, you must:

- Configure business and non-business hours on the **Times** tab.
- Create the greeting file that will be used for the non-business hours welcome greeting.
- Configure the non-business hours welcome greeting on the **Greetings** tab.
- Create the greeting file that will be used for the non-business hours main menu prompt greeting.
- Configure the non-business hours main menu prompt greeting on the **Greetings** tab.
- Enable and configure the non-business hours key mappings on the **Key Mapping** tab.

1.9.1.3.3 Understanding Unified Messaging Audio Codecs

Understanding Unified Messaging Audio Codecs

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-26*

In Microsoft Exchange Server 2010 Unified Messaging (UM), a codec is used to store voice mail messages. Another codec is used between an IP gateway or IP Private Branch eXchange (PBX) and the Unified Messaging server. Exchange 2010 Unified Messaging can use any of the following four audio codecs to create and store voice messages:

- MP3 (default)
- Windows Media Audio (WMA)
- Group System Mobile (GSM) 06.10
- G.711 Pulse Code Modulation (PCM) Linear

However, the G.711 (PCMA and PCMU) and the G.723.1 codecs are VoIP codecs used between an IP gateway and the Unified Messaging server.

Part of planning your Unified Messaging system involves selecting the correct audio codec based on the needs and requirements of your organization. This topic discusses the audio

codecs that Unified Messaging can use and will help you plan your UM deployment.

Codecs

Two types of codecs are used in Unified Messaging: the codec used between IP gateways and the Unified Messaging server or between a PBX and IP gateway, depending on the type of PBX, and the codec used to encode and store voice messages for users.

The term *codec* is a combination of the words "coding" and "decoding" and is used with digital audio data. A codec is a software program that transforms digital data into an audio file format or audio streaming format. Codecs are used to convert an analog voice signal to a digital version of the voice signal. Codecs can vary in their sound quality, the bandwidth required to use them, and the system requirements needed to do the encoding.

When you use an ordinary telephone over the Public Switched Telephone Network (PSTN) your voice is transported in an analog format over the telephone line. But with Voice over IP (VoIP), your voice must be converted into digital signals. This conversion process is known as encoding. Encoding is performed by a codec. After the digitized voice has reached its destination, it must then be decoded back to its original analog format so the person on the other end of the call can hear and understand the caller.

VoIP Codec

In Unified Messaging, three types of codecs can be used between IP gateways or IP PBXs and the Unified Messaging server. Unified Messaging servers can accept the following VoIP codecs from an IP gateway or IP PBX:

- G.711 µ-law
- G.711 A-law
- G.723.1

G.711 is a standard that was developed for use with audio codecs. There are two main algorithms defined in the standard for G.711: the µ-law algorithm that is used in North America and Japan and the A-law algorithm that is used in Europe and other countries. The G.723.1 audio codec is mostly used in VoIP applications and requires a license to be used. G.723.1 is a high quality, high compression type of codec.

Both a Unified Messaging server and a supported IP gateway or IP PBX can offer both the G.711 and G.723.1 codec. By default, the first codec to be used is G.723.1. If you want to use a different codec other than G.723.1 between the Unified Messaging server and the IP gateway or IP PBX, we recommend that you change the configuration on the IP gateway or IP PBX. The following table summarizes some common VoIP codecs.

VoIP codecs

VoIP codec	Bandwidth (Kbps)	Description
G.711	64	This codec requires very low processing. It needs a minimum of 128 kilobits per second (Kbps) for two-way communication.
G.723.1	5.3/6.3	This codec offers high compression with high quality audio. It requires more processing than the G.711 codec. The G.723.1 codec uses reduced bandwidth but offers poorer quality audio.

UM Voice Message Storage Codec

Unified Messaging dial plans are integral to the operation of Unified Messaging. By default, when you create a UM dial plan, the UM dial plan uses the WMA audio codec. However, after you create the UM dial plan, you can configure the UM dial plan to use GSM 06.10 or G.711 PCM Linear audio codecs.

Each audio codec has advantages and disadvantages. The WMA audio codec was selected as the default audio codec because of its sound quality and compression properties. GSM 06.10 and G.711 PCM Linear audio codecs were included as available options because of their ability to support other types of messaging systems.

When you plan for Unified Messaging, you must balance the size and the relative quality of the audio file that will be created for voice messages. Generally, the higher the bit rate for an audio file, the higher the quality. You must also consider whether the audio file is compressed. The sample bit rate (bit/sec) and compression properties for each audio codec used in Unified Messaging are as follows:

Default UM voice message storage codecs

Voice message storage codec	Bits	Compressed file?
MP3	16 bit	Yes
WMA	16 bit	Yes
G.711 PCM	16 bit	No
GSM 06.10	8-bit	Yes

In Unified Messaging, the MP3, WMA, G.711 PCM Linear, and GSM 06.10 audio codecs are used to create .mp3, .wma and .wav audio files for voice messages. However, the file type created depends on the audio codec that is used to create the voice message audio file. In Unified Messaging, the .mp3 audio codec creates .mp3 audio files, the .wma audio codec creates .wma audio files and the GSM 06.10 and G.711 PCM Linear audio codecs produce .wav audio files. Both kinds of audio files are sent together with the e-mail message to the recipient of the voice message.

Frequently, but not always, coding and decoding the digital data also involves compression or decompression. Audio compression is a form of data compression that reduces the size of audio data files. The audio compression algorithm used by the audio codec compresses the .wma or .wav audio files. In Unified Messaging, the type of audio compression algorithm that is used is based on the type of audio codec selected in the UM dial plan properties. After the audio file is created and compressed, it's attached to the voice message.

Sometimes information from the digital data is lost during compression and decompression. The higher the compression that is used to compress the audio file, the greater the loss of information during the conversion. However, less disk space is used because the size of the audio file is reduced. Conversely, the lower the compression, the lower the loss of the information. However, more disk space must be used because of the increased size of each audio file.

RTAudio wideband or high fidelity audio for recording voice messages is also available as an audio codec. However, high fidelity audio using RTAudio is available only after you have successfully integrated Exchange 2007 Unified Messaging with Office Communications Server 2007 R2 or Microsoft Lync Server 2010 (the next generation of Office Communications Server). To enable RTAudio, the UM dial plan must be configured as a Session Initiation Protocol (SIP) URI-type dial plan and you must set the call answering codec on the dial plan to WMA.

Important:
RTAudio is not available in environments where Office Communications Server 2007 or R2 or Lync Server 2010 is not deployed. This is because, in these environments, the dial plan is set to Telephone Extension and not SIP URI.

There are two media streams for each incoming call: inbound to a Unified Messaging server and outbound from a Unified Messaging server. When the dial plan type is set to SIP URI and the call-answering codec on the dial plan is set to WMA, a Unified Messaging server tries to select the RTAudio VoIP codec for the inbound media stream. If negotiation is successful, the RTAudio codec for the inbound stream will be used for call answering calls or calls that originate from Office Communicator 2007.

Note:
Calls placed by using the Play on Phone feature will not use the RTAudio codec. The inbound stream for calls placed by using Play on Phone will use the G.711 or G.723.1 codec.

When the RTAudio codec is used, the voice message that is recorded will be recorded in high fidelity and will be stored as an audio file that has a .wma extension. When the voice message is played back to the user in Office Outlook 2007 or Outlook Web Access, they will hear the voice message in high fidelity audio. If negotiation is unsuccessful, either the G.711 or G.723.1 codec will be used. Both the G.711 and the G.723.1 codecs are narrowband codecs. When they're used as the VoIP codec, the voice message is recorded and stored as a narrowband audio file that has a .wma extension.

The outbound media stream will always be negotiated by using either the G.711 or G.723.1 codec. This means that callers will always hear narrowband audio over the telephone. This also applies to situations when a call is placed by using Office Communicator.

The audio format and codec that Unified Messaging servers use to store the audio in voice messages depends not only on the audio codec that's configured on the dial plan but also on the bit rate of the audio that UM negotiates with a SIP peer. If your environment includes Office Communications Server 2007 R2, Lync Server 2010, or the SIP endpoints, a Unified Messaging server will also negotiate the audio codec to use with a SIP peer. For example, when wideband RTAudio is negotiated as the wire codec, a Unified Messaging server will then use either the 32 Kbps MP3 or WMA 9.2 format when creating voice messages, depending on the dial plan setting. The following table shows the relationship between the voice message storage audio codec and the VoIP or wire audio codec that's used.

Relationship between the storage audio codec and the VoIP or wire audio codec

Audio codec configured on a UM dial plan	VoIP or wire codec (narrowband) - G.723, G.711, or RTAudio (8KHz)	VoIP or wire codec (wideband) - RTAudio (16KHz)
G.711	G.711	Not applicable. A UM server doesn't negotiate wideband audio if the dial plan is set to G.711.
WMA	WMA 9 Voice	WMA 9.2
GSM	GSM 6.10	Not applicable. A UM server doesn't negotiate wideband audio if the dial plan is set to G.711.

MP3	MP3 (16 Kbps)	MP3 (32 Kbps)

Return to top

UM Message Sizing

You can configure Unified Messaging to use one of the four following audio codecs for creating voice messages: MP3, WMA, GSM 06.10, and G.711 PCM Linear. By default, the MP3 format is selected. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phones and devices and different computer operating systems.

The WMA audio codec is always stored in the Windows Media format, and the attachment is a file that has a .wma file name extension. Audio files encoded using the GSM or G.711 PCM Linear audio codecs are always stored in RIFF/WAV format, and the attachment is a file that has a .wav file name extension.

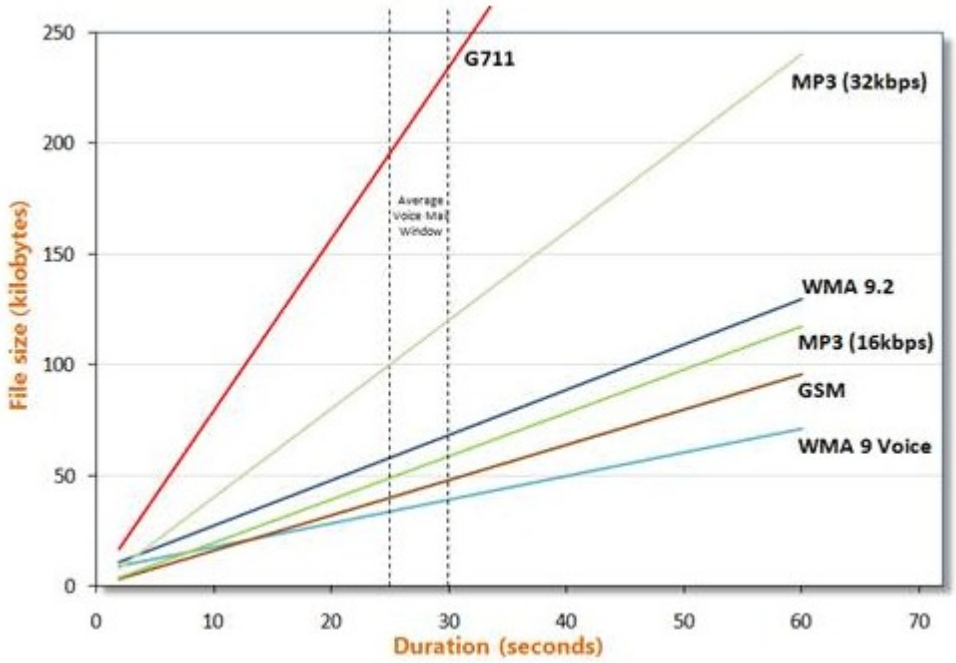
The size of Unified Messaging voice messages depends on the size of the attachment that holds the voice data. In turn, the size of the attachment depends on the following factors:

- The duration of the voice mail recording
- The audio codec that is used
- The audio file storage format

The following figure shows how the size of the audio file depends on the duration of the voice mail recording for the three audio codecs that you can use in UM.

Note:

In this figure, the average length of a call-answered voice message is approximately 30 seconds.



MP3

By default, the MP3 format is selected and is the default audio file format for voice mail messages. The MP3 format is a common audio file format that's used to greatly reduce the size of the audio file and is most commonly used by personal audio devices or MP3 players. MP3 is a cross-platform type of audio codec and is used for compatibility with many mobile phones and devices and different computer operating systems.

WMA

WMA is the most highly compressed audio codec of the three kinds of codecs. The compression is approximately 11,000 bytes for each 10 seconds of audio. However, the .wma file format has a much larger header section than the .wav file format. The .wma file header section is approximately 7 kilobytes (KB), whereas the header section for the .wav file is less than 100 bytes. Although WMA audio recordings are recorded for longer than 15 seconds, they become smaller than GSM audio recordings. Therefore, for the smallest but highest quality audio files, use the WMA audio codec.

G.711 PCM Linear

The G.711 PCM Linear audio codec creates .wav audio files that are not compressed. Therefore, G.711 PCM Linear .wav audio files occupy the most space for any given duration when they're compared to the GSM and WMA audio codecs. G.711 PCM Linear .wav audio files occupy just over 160,000 bytes for each 10 seconds of audio. G.711 PCM Linear .wav audio files have the highest audio quality of the three audio codecs used by Unified Messaging. However, the quality of comparable audio files created using the WMA and GSM audio codecs are acceptable to most users who listen to voice messages.

GSM

The GSM audio codec creates .wav audio files that are compressed. GSM .wav audio files are just over 16,000 bytes for each 10 seconds of audio. However, GSM creates an audio file larger than the audio file created by the WMA audio codec. Therefore, when you are balancing the quality of the voice message and the size, this may not be the best choice.

1.9.1.3.4 Understanding Unified Messaging Languages

Understanding Unified Messaging Languages

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-10-30*

You can install and configure language packs to support multiple languages in Microsoft Exchange Server 2010 Unified Messaging (UM) environments.

Exchange 2010 UM language packs let callers and Outlook Voice Access users interact with the Unified Messaging system in multiple languages. After you install an additional language on a Unified Messaging server, callers and Outlook Voice Access users can hear e-mail messages and interact with the Unified Messaging system in that language.

Several key components rely on UM language packs to enable users and callers to interact effectively with Exchange 2010 Unified Messaging in multiple languages. Each UM language pack includes a Text-to-Speech (TTS) engine, the pre-recorded prompts and support for Automatic Speech Recognition (ASR) and Voice Mail Preview for a specific language. This topic discusses UM language packs, the UM components that use the UM language packs, and how UM language packs, after they're installed, can be used to configure UM dial plans and UM auto attendants to use other languages.

Exchange Unified Messaging language packs are version-specific and platform-specific. Since Exchange Server 2007, there have been separate releases for UM language packs, including the RTM version of Exchange 2007, Exchange 2007 SP1, SP2, and SP3, the RTM version of Exchange Server 2010, and Exchange 2010 SP1 and SP2. For some of these versions, both 32-bit and 64-bit downloads are available, but for other releases only 64-bit downloads are available.

It's very important that you install the correct version and platform of the UM language packs on a UM server. Don't install UM language packs on a Unified Messaging server that's running an earlier version of Exchange or that's designed for a 32-bit platform.

Contents

Overview of UM Language Packs

Unified Messaging language packs allow an Exchange 2010 UM server to speak additional languages to callers and recognize other languages when callers use ASR or when voice messages are transcribed. UM language packs contain:

- Pre-recorded prompts in the language of the UM language pack. For example, "After the tone, please record your message. When you've finished recording, hang up, or press the # key for more options."
- Grammar files in the language of the UM language pack that are used by a UM server to look up the names of given users in the directory.
- Text-to-Speech (TTS) translation so that content (e-mail, calendar, contact information, etc.) can be read to callers in the language of the UM language pack.
- Support for Automatic Speech Recognition (ASR), which allows callers to interact with UM using the voice user interface (VUI) in the language of the UM language pack.
- Support for Voice Mail Preview, which allows users to read the transcript of voice mail messages in a specific language from within a supported e-mail client such as Outlook or Outlook Web App.

The UM language packs that are included with Exchange 2010 contain pre-recorded prompts, TTS conversion support for a specific language, and in some cases, support for ASR. In multiple-language environments, you may have to install additional UM language packs because some callers prefer to be prompted in a different language, or because they receive e-mail in more than one language. You must install multiple UM language packs to support the ability for the Unified Messaging server to read an e-mail message that contains more than one language, because the TTS conversion system must be instructed which language to select based on the text of the message that will be read. If the Unified Messaging language pack hasn't been installed, the e-mail message will be illogical and incoherent when it's read back to the user. Installing the appropriate language pack enables the TTS engine to read e-mail and calendar items to the Outlook Voice Access user by using the correct language and also provides the language-specific pre-recorded prompts for Unified Messaging. In some cases, they may also provide support for ASR.

Note:

The TTS engine converts text to speech but doesn't convert from speech to text. UM-

enabled users can send an e-mail message that has a voice file attached to another user. However, they can't create and send a text-based e-mail message to another user.

When you install a language pack, the installation program does the following:

1. Copies the language prompts that will be used to configure UM dial plans and auto attendants.
2. Allows the TTS engine to read messages when Outlook Voice Access users access their Inbox.
3. Enables ASR for speech-enabled UM dial plans and auto attendants for the language installed.
4. Enables Voice Mail Preview for clients in other languages.

You can add UM language packs using the **Setup.com** command or run the *<UMLanguagePack>*.exe installation program after you've downloaded the UM language pack from Exchange Server 2010 SP2 UM Language Packs. However, you can remove a UM language pack only by using the Setup.com command. There's no Exchange Management Shell cmdlet that you can use to add or remove languages from a Unified Messaging server. For more information about how to install a UM language pack, see Install a Unified Messaging Language Pack on a UM Server. For more information about how to remove a UM language pack, see Remove a Unified Messaging Language Pack from a UM Server.

Note:
By default, when you install Exchange 2010, the U.S. English language (en-US) will be installed and can't be removed unless you remove the Unified Messaging server role from the computer.

Return to top

The following table lists the Unified Messaging language packs that are currently available. It also lists the installation file name for each UM language pack and the culture ID for the UM language.

UM language pack installation file names and culture IDs

Language	Country/Region	Culture ID	Installation file name	Availability
Catalan	Spain	ca-ES	UMLanguagePack. ca-ES	Download available
Chinese (Hong Kong)	China	zh-HK	UMLanguagePack. zh-HK	Download available
Chinese (Simplified)	China	zh-CHS	UMLanguagePack.zh-CN	Download available

Return to top

UM Language Components and Features

There are several key components and features in Exchange 2010 Unified Messaging that enable users and callers to interact with a multiple-language Unified Messaging system. For these components and features to work correctly and enable callers to interact with the system in multiple languages, the UM language packs must be installed correctly on a Unified Messaging server.

Pre-recorded Prompts

The Exchange 2010 Unified Messaging server role is installed with a set of default audio prompt files. These audio files contain the recordings for Outlook Voice Access menus, voice mail greetings, and numbers that are used by Exchange Unified Messaging. The audio files are played by a Unified Messaging server to incoming callers, both internal and external. Many of the audio files are default prompts that provide the users of the Telephone User Interface (TUI) and Outlook Voice Access the information that they need to move through the TUI and the Voice User Interface (VUI). The prompts are located in *<Program Files>*\Microsoft\Exchange Server\V14\UnifiedMessaging\Prompts\<language>. The prompts used by the Unified Messaging server to help callers move through the menus shouldn't be replaced or changed.

When an additional UM language pack is installed, the pre-recorded prompts for that language will also be installed. After a UM language pack is installed, the pre-recorded prompts for that language can be used by UM dial plans and auto attendants.

TTS Languages

Unified Messaging relies on the Text-to-Speech (TTS) engine. TTS functionality is provided by the Microsoft Speech Server service. The TTS engine reads and converts written text into audible output that can be heard by a caller. The TTS engine reads and converts the following items in a user's mailbox:

- E-mail and voice mail message bodies, subjects, and names
- Calendar item bodies, subjects, locations, and names
- Personal contact names
- Users' default voice mail greetings

Note:

After a user has recorded personalized voice mail greetings, the TTS version of the voice greetings are no longer used.

Automatic Speech Recognition

In addition to TTS, Automatic Speech Recognition (ASR) support is included in Exchange 2010 Unified Messaging. ASR functionality is provided by the Microsoft Speech Server service. ASR enables callers to use voice commands to interact with the Unified Messaging

system. Using ASR, callers can move through menus and interact with items from their individual mailboxes, including messages, personal contacts, and calendar. ASR support is included with each language pack.

Return to top

Voice Mail Preview

In addition, UM language packs provide support for Voice Mail Preview, which allows users to quickly triage their voice messages by reading their transcripts from within a supported e-mail client such as Outlook or Outlook Web App.

When a caller leaves a voice message for a UM-enabled user, the voice message file and a transcript of the voice message are placed in the body of the voice mail message that's sent to the user's mailbox.

All UM language packs are single files that can be downloaded. These language packs include the pre-recorded prompts, grammar files, Text-to-Speech (TTS) translation, and ASR. However, not all the UM language packs contain support for Voice Mail Preview.

The following UM language packs contain support for all the components and features, including Voice Mail Preview:

1. English (US) - (en-US)
2. English (Canada) (en-CA)
3. French (France) - (fr-FR)
4. Italian - (it-IT)
5. Polish (pl-PL)
6. Portuguese (Portugal) (pt-PT)
7. Spanish (Spain) (es-ES)

For more information about Voice Mail Preview, see Voice Mail Preview for End Users.

By default, when you install the Exchange 2010 Unified Messaging server role, the server will send voice mail previews to UM-enabled users if a supported UM language pack is installed.

There are Exchange 2010 Unified Messaging Voice Mail Preview partners that offer enhanced transcription support for the Voice Mail Preview feature. These partners employ people to correct voice mail transcriptions that were created using Automatic Speech Recognition (ASR). Each Voice Mail Preview partner must meet a set of requirements to be certified to interoperate with Exchange 2010 Unified Messaging.

If you determine that the voice mail previews sent to your users aren't accurate enough, you can contact one of the certified Voice Mail Preview partners listed on the Microsoft PinPoint web page and sign up with them at an additional cost. For more information, see Voice Mail Preview Advisor for Exchange 2010.

You can download the Exchange 2010 UM language packs for SP1 from the Microsoft Download Center. For details, see Install a Unified Messaging Language Pack on a UM Server.

Unified Messaging Languages

To enable callers to use the multiple language features found in Exchange 2010 Unified Messaging, you must first install a UM language pack, as described below. Then you have the option to configure other UM components.

- Install the UM language pack on the Unified Messaging server.
- If required, configure the default language for a UM dial plan. This lets Outlook

Voice Access users associated with the UM dial plan use the new language when they access their mailbox. However, users can still configure their language setting in the options that are available in Outlook Web App.

- If required, configure the language setting on a UM auto attendant. By default, a UM auto attendant uses the UM dial plan language. However, you can change this setting and enable unauthenticated callers to connect to your organization and move through the auto attendant menus in the language that you've specified on the UM auto attendant.

Unified Messaging Server Languages

You install a UM language pack on the Unified Messaging server using Setup.com. After you install the new language pack on the Unified Messaging server, the language associated with the language pack will be added to the list of available languages that you can use. You can view the languages that have been installed using the **UM Settings** tab in the Unified Messaging server properties in the Exchange Management Console or using the Get-UMServer cmdlet in the Exchange Management Shell.

When you install the UM language pack, the files that are used by the TTS engine and the pre-recorded prompts for the chosen language are copied and made available for users who connect to the Unified Messaging system.

UM Dial Plan Languages

Each UM dial plan that's created contains a default language setting. The UM dial plan language setting is needed because Unified Messaging may have to use TTS conversion or play a standard audio prompt for Outlook Voice Access users when they access their Exchange 2010 mailbox. You don't have to select a default dial plan language.

When you first install Exchange 2010, U.S. English will be the default language, and the only available language option for your dial plan. After you install a UM language pack on a Unified Messaging server, the language associated with the language pack will be listed as an available option when you configure the default language for the dial plan.

The default language is important to callers. When an Outlook Voice Access user calls in to the Unified Messaging system, the language setting chosen is based on the language setting configured in Outlook Web App that was set when the user first signed in to the mailbox using Outlook Web App. Unified Messaging then compares the language set in Outlook Web App to the list of available languages on the dial plan with which the user is associated. If there is no suitable match for the language, the default UM dial plan language will be used. Sometimes, you may have to set this language as the default language. For example, if you have a dial plan that contains only users from France, you may want to change the default language setting on the dial plan to French. For more information about how to change the default language for a UM dial plan, see Configure the Default Language on a UM Dial Plan.

UM Auto Attendant Languages

By default, because UM auto attendants are associated with a UM dial plan when they are created, they use the default language setting of the associated UM dial plan. However, this setting can be changed after the UM auto attendant is created.

The UM auto attendant language setting is needed because Unified Messaging may have to use TTS conversion or play a standard audio prompt to a caller. Unified Messaging doesn't check whether the language of custom prompts for the auto attendant matches the language setting on the auto attendant. However, as a best practice, make sure that the language setting of the auto attendant matches the language of the custom prompts. Otherwise, the caller may hear the system shift from one language to another.

Being able to change the UM auto attendant language setting is also useful if you need several different language-specific auto attendants for callers. For more information about how to configure language settings on a UM auto attendant, see Configure the Language Setting on a UM Auto Attendant.

Important:
To ensure that all Unified Messaging features are available in the UM language packs you install, you must install the Exchange 2010 Client and Server Language Pack on each UM server in the dial plan. If you don't install the Client and Server Language Pack, some features may not work as expected. Some features, like Voice Mail Preview, will work in the language that is configured on the dial plan but when only the UM language pack is installed. However, features like Outlook Voice Access and user interface text won't work in the language by the user without having both the UM language pack and the Client and Server Language Pack installed. To download and install additional client and server language packs on servers in your organization, see the Microsoft Exchange Server 2010 SP1 Language Pack Bundle.

1.9.1.3.5 Understanding Storage Quotas and Voice Mail

Understanding Storage Quotas and Voice Mail

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2011-04-28*

When a caller leaves a voice message for a Unified Messaging (UM)-enabled user, the storage quotas or limits configured on the user's mailbox may prevent voice messages from being delivered correctly. This topic discusses the relationship between the configuration of the Microsoft Exchange Server 2010 Unified Messaging server and the storage quotas that could potentially prevent a caller from recording a voice message.

Looking for management tasks related to storage groups? See Managing Mailbox Servers.

Contents

UM Dial Plans

Although there are many Active Directory objects that must be created and configured when Exchange 2010 Unified Messaging is deployed, UM dial plan objects are the central component of the Unified Messaging system. A UM dial plan object is an Exchange 2010 organization-wide object created in the Active Directory directory service.

After you install the Unified Messaging server role, you must associate the Unified Messaging server with at least one UM dial plan. You can also associate a single Unified Messaging server with multiple UM dial plans. For more information about how to create a new UM dial plan, see Create a UM Dial Plan.

There are many configuration settings that you can change after you create a UM dial plan to meet the needs of your organization. After you create a UM dial plan, you can configure

subscriber access numbers, greetings, message properties, and other UM dial plan features. Although there are many settings that can be changed to control your Unified Messaging environment, one of the more important mailbox settings is storage quotas. If you don't set the storage quotas for users correctly, you might unintentionally prevent voice messages from being recorded for Exchange users in your organization.

Because Windows Media Audio (.wma) and .wav files are attached to each voice message, voice messages may be larger than e-mail messages. This may cause problems for users by filling their mailbox more quickly than e-mail messages that don't include attachments. When you plan your storage quotas for users, you should consider the maximum length of a voice message that a caller will leave. Very long voice messages create large files. However, you can control the size of the voice files by reducing the length of time that callers have to leave a voice message.

The **Maximum recording duration (minutes)** setting controls the maximum length for the recorded messages from callers. This setting can range from 5 through 100 minutes, but the default setting is 20 minutes. You can change this setting using the Exchange Management Console or using the **Set-UMDialPlan** cmdlet in the Exchange Management Shell. For more information about how to configure settings on a UM dial plan, see View or Configure the Properties of a UM Dial Plan.

In some Exchange environments, the default setting of 20 minutes may be too high or too low. If the storage quota is set too high, you may risk using too much storage space on your Exchange servers or users may exceed their storage quotas too quickly. If the storage quota is set too low, it may frustrate callers by not giving them enough time to leave a whole message. Callers may then have to call back to leave another voice message for the user.

Storage Quotas

Users may store too many e-mail and voice messages in their mailbox, in addition to attached files. If users in your organization store numerous e-mail messages, voice messages, and attached files, you may have to limit the storage space allocated to each user's mailbox to reduce the storage demands on your computers running Exchange 2010. Frequently, large mailbox stores lead to long backup and restore times. Large mailbox stores may also affect the availability and reliability of your Exchange environment. Therefore, we recommend that you control the size of users' mailboxes to avoid running out of storage space on your Exchange servers. When users don't have a storage quota configured or they have a large storage quota configured, they could possibly fill the disk drives on an Exchange server. To prevent this, enable and configure storage quotas on users' mailboxes. By default, and starting with the first installation, each new mailbox database includes the following default limits:

- **Warning** 1991680 kilobytes (KB)
- **Prohibit Send** 2097152 KB
- **Prohibit Send/Receive** 2411520 KB

After you configure storage quotas, if a storage limit is exceeded, the mailbox-enabled user is warned or prohibited from sending or receiving e-mail. You can use the default storage limits, or you can set your own storage limits to control the amount of data that can be stored in a user's mailbox. For more information about how to manage recipient storage quotas, see Managing User Mailboxes.

Because storage quotas are implemented in most Exchange environments, there may be times when a caller can't leave a voice message for a user. Make sure that you understand the effect that setting storage quotas can have on your Unified Messaging environment and correctly plan your storage quotas for users so that voice messages are recorded correctly.

Return to top

Voice Mail Delivery

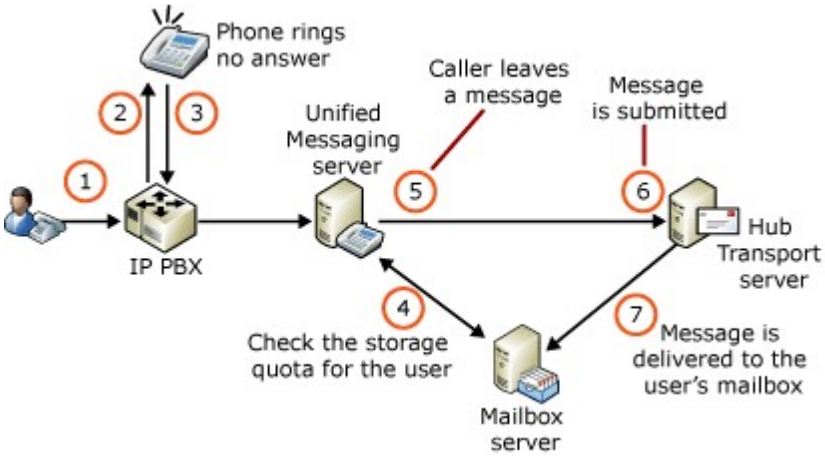
The following three scenarios describe what can occur when a voice message is delivered to a user's mailbox in different circumstances:

- The voice message fits into the user's mailbox.
- The voice message can't fit into the user's mailbox, and it fills the remaining storage space in the user's mailbox.
- The user's mailbox has already reached its storage capacity.

In the first scenario, the telephone rings and there's no answer. The call is transferred to the Private Branch eXchange (PBX) and then to the Unified Messaging server. The Unified Messaging server checks the user's mailbox storage quota. If the user's mailbox hasn't reached its storage limit and a voice message is created by the Unified Messaging server for the caller, the voice message is submitted to a computer that has the Hub Transport server role installed. The Hub Transport server then routes and submits the voice message to the appropriate Mailbox server. Because the voice message doesn't exceed the storage quota set for the user's mailbox and the storage quota hasn't already been reached, the voice message is delivered to the mailbox of the intended recipient.

In the second scenario, the Unified Messaging server checks the user's mailbox storage quota. If the user's mailbox hasn't reached the storage limit, the voice mail message is submitted to a Hub Transport server. The Hub Transport server routes the voice mail message to the appropriate Mailbox server. The voice message is submitted to the Mailbox server, but the voice message fills the remaining storage space and exceeds the set storage quota for the user. When this occurs, the voice message is still delivered. Even though the storage quota is exceeded when the voice message is delivered, the voice message is still delivered the same way a non-delivery report (NDR) is delivered to a user even though the mailbox has reached its capacity.

The following figure illustrates how a voice message is submitted when the user's storage quota hasn't been reached and how a message is submitted when a voice message causes the storage quota to be reached for the user's mailbox.



In the third scenario, the Unified Messaging server checks the user's mailbox storage quota. Because the user's mailbox has already reached its storage capacity, the Unified Messaging server won't record a voice message and informs the caller that the recipient's mailbox is full. The user must delete or archive messages to reduce the size of the mailbox to be lower than the storage quota to be able to receive voice messages again.

The following figure illustrates how a call is handled when a user's mailbox storage quota has been reached.

1.9.1.3.6 Understanding Unified Messaging VoIP Security

Understanding Unified Messaging VoIP Security

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2010-08-16*

An important aspect of your network security is the ability to protect your Unified Messaging (UM) infrastructure. There are components within your Unified Messaging environment that you must correctly configure to help protect the data sent and received from Unified Messaging servers on your network. These include components such as Unified Messaging servers and dial plans. This topic discusses how you can increase protection for the Unified Messaging network data and servers in your organization. You must follow these steps to help secure your Unified Messaging environment and enable Voice over IP (VoIP) security:

1. Install the Unified Messaging server role.
2. Create a new self signed or public certificate that you can use for mutual TLS.
3. Associate a certificate with the UM server.
4. Configure the UM dial plan as SIP Secured or Secured.
5. Configure the startup mode on the UM server.
6. Associate the Unified Messaging servers with the UM dial plan.
7. Configure the UM IP gateways used to have a fully qualified domain name (FQDN) and to use TCP port 5061.
8. Export and import the required certificates to enable the Unified Messaging servers, IP gateways, IP Private Branch eXchanges (IP PBXs), and other servers running Microsoft Exchange Server 2010 to use mutual Transport Layer Security (mutual TLS).

Types of Certificates

Configuring Mutual TLS

IPsec

UM Dial Plans and VoIP Security

How Unified Messaging Determines Security Mode and Selects Certificates

Protecting Unified Messaging

There are several security methods that can help you protect your Unified Messaging servers and the network traffic sent between your IP gateways and Unified Messaging servers and between your Unified Messaging servers and other Exchange 2010 servers in your organization. The following table lists some possible threats to your Unified Messaging infrastructure and the security methods that can be implemented to help protect it.

Protecting Unified Messaging

What am I protecting against?	How can I protect it?
Monitoring voice traffic	• Use Internet Protocol security (IPsec). The IP gateway or IP PBX must support IPsec. • Use Secure Realtime Transport Protocol (SRTP).
An attack against an IP gateway or IP PBX	• Use strong authentication methods. • Use strong administrative passwords. • Use Secure Sockets Layer (SSL) to protect administrative credentials. The IP gateway or IP PBX must support SSL. • Use Secure Shell (SSH) instead of Telnet.
Unauthorized long distance calls	• Use UM dial plan rules and dialing restrictions. These can be configured on the UM dial plan and UM mailbox policies. • Optionally, you may be able to enforce other dialing restrictions by configuring your PBX.
A denial of service attack	• The Unified Messaging server communicates only with UM IP gateways or IP PBXs included in the list of trusted VoIP devices or servers. This list of trusted VoIP devices or servers is created when a UM IP gateway is created in the Active Directory directory service. • Use mutual TLS.
A Session Initiation Protocol (SIP) proxy impersonation	• Use mutual TLS. • Use IPsec. The IP gateway or IP PBX must support IPsec. • Configure trusted LANs, such as virtual LANs (VLANs), dedicated WAN circuits,

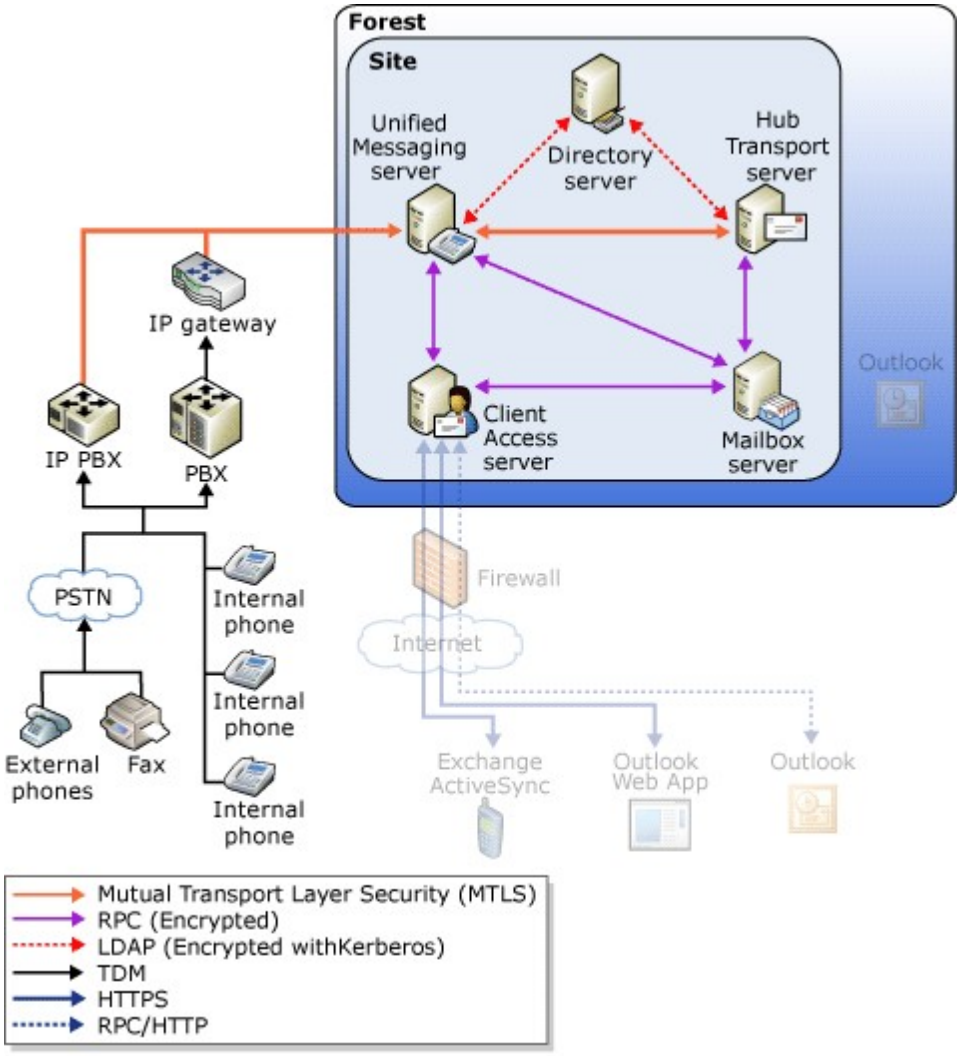
	or virtual private networks (VPNs).
Eavesdropping and session hijacking	• Use mutual TLS to reduce signal eavesdropping. • Use IPsec. The IP gateway or IP PBX must support IPsec. • Configure trusted LANs, such as VLANs, dedicated WAN circuits, or VPNs.

There are several security methods listed in the previous table that you can use to protect your Unified Messaging environment. One of the most important mechanisms for protecting your Unified Messaging infrastructure and the network traffic generated by Unified Messaging is mutual TLS.

You can use mutual TLS to encrypt Voice over IP (VoIP) traffic passed between IP gateways, IP PBXs, and other Exchange 2010 servers and the Unified Messaging servers on your network. The best choice for protecting this data is to use mutual TLS to encrypt the VoIP data.

However, depending on the security threat, you can also configure IPsec policies to enable data encryption between IP gateways or IP PBXs and a Unified Messaging server or between a Unified Messaging server and other Exchange 2010 servers on your network. In some environments, you might be unable to use IPsec because IPsec may be unavailable or may not be supported on the IP gateways or IP PBXs. Additionally, IPsec puts an additional processing load on system resources on Unified Messaging servers. Considering these two factors, mutual TLS is a better choice for protecting the VoIP network traffic in your Unified Messaging environment.

After you correctly implement and configure mutual TLS, the VoIP traffic between the IP gateways, IP PBXs, and from other Exchange servers to the Unified Messaging servers is encrypted. However, when mutual TLS cannot be used to help secure the traffic sent or received from a Unified Messaging server, such as when a Unified Messaging server communicates with another server on your network, such as an Active Directory domain controller or an Exchange 2010 Mailbox server, other types of encryption are used to protect the data. The following figure shows the methods of encryption that you can use to protect Unified Messaging.



Return to top

Types of Certificates

Digital certificates are electronic files that work like an online passport to verify the identity of a user or computer and are used to create an encrypted channel to protect data. A certificate is basically a digital statement issued by a certification authority (CA) that vouches for the identity of the certificate holder and enables the parties to communicate in a secure manner using encryption. They can be issued by a trusted third-party CA, such as Certificate Services, or be self-signed. Each type of certificate has its advantages and disadvantages. However, certificates are always tamperproof and cannot be forged. Certificates can be issued for a variety of functions, such as Web user authentication, Web server authentication, S/MIME, IPsec, TLS, and code signing.

A certificate binds a public key to the identity of the person, computer, or service that holds the corresponding private key. The public and private keys are used by both the client and the server to encrypt the data before it's transmitted across the wire. Certificates are used by a variety of public key security services and applications that provide authentication, data integrity, and secure communications across networks such as the Internet. For Windows-based users, computers, and services, trust in a CA is

established when there's a copy of the root certificate in the trusted root store and the certificate contains a valid certification path. This means that no certificates in the certification path have been revoked or have had the validity period expire.

Digital certificates do the following:

- They authenticate that their holders—people, Web sites, and even network resources such as routers—are truly who or what they claim to be.
- They protect data exchanged online from theft or tampering.

There are traditionally three options or kinds of certificates that Unified Messaging and IP gateways or IP PBXs can use. In all three approaches or options, the public key of the certificate owner is part of the certificate so that the server, user, Web site, or other resource on the other end can decrypt the messages. The private key is known only to the signer of the certificate. Each certificate has an **EnhancedKeyUsage** attribute set on it to dictate the specific usage for the certificate. For example, usage could be specified only for server authentication or for use with the encrypting file system. Unified Messaging uses the certificate for server authentication and data encryption.

Self-Signed Certificates

A self-signed certificate is a certificate signed by its own creator. The subject and the name of the certificate match. On self-signed certificates, the issuer and subject are defined on the certificate. Self-signed certificates don't require the presence of a CA from your organization or from a third party. You must configure these certificates explicitly and copy them to the trusted root certificate store on each IP gateway, IP PBX, other Unified Messaging servers, and other Exchange 2010 computers if they're to be trusted by the Unified Messaging server that has issued the certificate.

If a public key infrastructure (PKI)-based or third-party certificate is unavailable, the Unified Messaging server will search for a self-signed certificate in the local certificate store. If it cannot find a PKI or third-party certificate, it will generate a self-signed certificate for mutual TLS. However, because it's a self-signed certificate, it won't be trusted by the IP gateways, IP PBXs on the network, or other servers on the network. To make sure that the self-signed certificate is trusted by IP gateways, IP PBXs, or other servers, you must import the self-signed certificate into the local trusted root certificate store for the devices and servers. After you do this, when the Unified Messaging server presents this self-signed certificate to the IP gateway, IP PBX, or server, it will be able to verify that the certificate was issued by a trusted authority because the issuer will equal the subject defined on the self-signed certificate.

If you're using only self-signed certificates, you must import a single self-signed certificate for each IP gateway, IP PBX, or server. In large network environments that have multiple devices or computers, this may not be the best choice for implementing mutual TLS. Using self-signed certificates in a large enterprise network doesn't scale well because of the additional administrative overhead. However, administrative overhead isn't a problem if you have multiple devices and you're using a PKI or commercial third-party certificate. This is because each device has a certificate that has been issued by the same trusted root authority. Having a certificate from the same trusted root authority guarantees that all IP gateways, IP PBXs, and other servers trust the Unified Messaging server.

For mutual TLS to work using self-signed certificates:

1. Take the Unified Messaging server's self-signed certificate and import it into the trusted root certificate store on each IP gateway and IP PBX and on other servers that the Unified Messaging server will communicate with using mutual TLS.
2. Take the self-signed certificate from each IP gateway, IP PBX, and other server and import it into the Unified Messing server's trusted root certificate store. If you're using a PKI or third-party certificate, you will import the certification authority's certificate into the trusted root certificate store on all devices and servers.

Self-signed certificates are frequently not the best certificate option when you deploy mutual TLS or certificate-based authentication. However, smaller organizations with a limited number of devices or computers may decide to use the self-signed certificate method because it's the most easy to configure and the least expensive method to use when you implement mutual TLS. Frequently, smaller organizations decide not to use a third-party certificate or to install their own PKI to issue their own certificates because of the expense, because their administrators lack the experience and knowledge to create their own certificate hierarchy, or for both reasons. The cost is minimal and the setup is simple when you're using self-signed certificates. However, establishing an infrastructure for certificate life-cycle management, renewal, trust management, and revocation is much more difficult with self-signed certificates. For more information about how to create a certificate for TLS, see Understanding TLS Certificates.

Return to top

Public Key Infrastructure

A PKI is a system of digital certificates, CAs, and registration authorities (RAs) that verify and authenticate the validity of each party involved in an electronic transaction using public key cryptography. When you implement a CA in an organization that uses Active Directory, you provide an infrastructure for certificate life-cycle management, renewal, trust management, and revocation. These qualities provide a solid infrastructure for all the certificates in your organization. However, there's some cost involved in deploying additional servers and infrastructure to create and manage these types of certificates.

You can install Certificate Services on any server in the domain. If you obtain certificates from a domain Windows-based CA, you can use the CA to request or sign certificates to issue to your own servers or computers on your network. This enables you to use a PKI that resembles using a third-party certificate vendor but is less expensive. Although these PKIs cannot be deployed publicly, as other types of certificates can be, when a PKI is used, a CA signs the requestor's certificate using the private key, and the requestor is verified. The public key of this CA is included with the certificate issued by the CA. Anyone who has this CAs certificate as a root certificate can use that public key to decrypt the requestor's certificate and authenticate the requestor.

When you use a PKI certificate to implement mutual TLS, you must copy the required certificates to the IP gateways or IP PBXs. Then you must copy the certificates on the IP gateways or IP PBXs to the Unified Messaging servers associated with the UM dial plan that has been configured in secured mode.

The setup and configuration for using PKI certificates and third-party certificates resemble the procedures that you perform when importing and exporting the self-signed certificates. However, you mustn't only install the computer certificate into the trusted root certificate store. You must also import or copy the trusted root certificate for the PKI into the trusted root certificate store on the Unified Messaging servers and the IP gateways and IP PBXs on your network.

To deploy mutual TLS when you've already deployed a PKI infrastructure, follow these steps:

1. Generate a certificate request on each IP gateway or PBX.
2. Copy the certificate request to use when requesting the certificate from a certification authority.
3. Request a certificate from the certification authority using the certificate request. Save the certificate.
4. Import the certificate that you saved onto each device or computer.
5. Download the trusted root certificate for your PKI.
6. Import the trusted root certificate from your PKI on each device. If you're importing the trusted root certificate on an Exchange 2010 computer running the Unified Messaging server role, you can also use Group Policy to import the trusted root certificate into the trusted root certificate store on the

Unified Messaging server or other Exchange 2010 servers. However, this process is also used when you're configuring a server running the Unified Messaging server role.

Note:
You will use the same steps if you're using a commercial third-party certificate to implement mutual TLS.

For more information about certificates and PKIs, see the following topics:

- For more information about certificates, see Public Key Infrastructure for Windows Server 2003.
- For more information about best practices for implementing a Windows Server 2003 public key infrastructure, see Best Practices for Implementing a Microsoft Windows Server 2003 Public Key Infrastructure.
- For more information about how to deploy a Windows Server 2008-based PKI, see the Step-By-Step Example Deployment of the PKI Certificates Required for Configuration Manager Native Mode: Windows Server 2008 Certification Authority.
- For more information about Windows Server 2008 Certificate Services for a Windows Server 2008-based PKI, see Active Directory Certificate Services Overview.

Third-Party Certification Authorities

Third-party or commercial certificates are certificates generated by a third-party or commercial CA and then purchased for you to use on your network servers. One problem with self-signed and PKI-based certificates is that, because the certificate isn't trusted, you must make sure that you import the certificate into the trusted root certificate store on client computers, servers, and other devices. Third-party or commercial certificates don't have this problem. Most commercial CA certificates are already trusted because the certificate already resides in the trusted root certificate store. Because the issuer is trusted, the certificate is also trusted. Using third-party certificates greatly simplifies deployment.

For larger organizations or organizations that must publicly deploy certificates, it's best to use a third-party or commercial certificate, even though there's a cost associated with the certificate. Commercial certificates may not be the best solution for smaller and medium-size organizations, and you might decide to use one of the other certificate options available.

Depending on the configuration of the IP gateway or IP PBX, you might still have to import the third-party or commercial certificate into the trusted certificate store on the IP gateways and IP PBXs to be able to use the third-party certificate for mutual TLS. However, in some cases, the third-party certificate will be included in the trusted root certificate store on your Unified Messaging server and other Exchange 2010 computers in your organization.

The procedures that you perform to use a commercial third-party certificate for enabling mutual TLS are the same procedures that you perform when you use a PKI certificate. The only difference is that you won't have to generate a PKI certificate because you've purchased a certificate from a commercial third-party certificate vendor that will be imported into the trusted root certificate store on the servers and devices on your network.

Return to top

Configuring Mutual TLS

By default, when an incoming call is received from an IP gateway, the VoIP traffic isn't encrypted and doesn't use mutual TLS. However, the security setting for a Unified

Messaging server is configured on the UM dial plan associated with the Unified Messaging server. To enable the Unified Messaging server to communicate securely with IP gateways, IP PBXs, and other Exchange 2010 servers, you must use the **Set-UMDialPlan** cmdlet to configure VoIP security on the UM dial plan, and then enable mutual TLS for the Unified Messaging servers associated with the UM dial plan.

After you've enabled VoIP security on the UM dial plan, all Unified Messaging servers associated with the UM dial plan can communicate in a secure manner. However, depending on the type of certificate that you use for enabling mutual TLS, you must first import and export the required certificates both on the Unified Messaging servers and the IP gateways and PBXs. After the required certificate or certificates have been imported on the Unified Messaging server, you must restart the Microsoft Exchange Unified Messaging service to be able to use the certificate that was imported to establish an encrypted connection with the IP gateways or IP PBXs. For more information about how to import and export certificates, see Import and Export Certificates.

After you successfully import and export the required trusted certificates, the IP gateway will request a certificate from the Unified Messaging server, and then it will request a certificate from the IP gateway. Exchanging the trusted certificates between the IP gateway and the Unified Messaging server enables the IP gateway and Unified Messaging server to communicate over an encrypted connection using mutual TLS. When an incoming call is received by an IP gateway or IP PBX, it will initiate a certificate exchange and negotiate security using mutual TLS with the Unified Messaging server. The Microsoft Exchange Unified Messaging service isn't involved in the certificate exchange process or in determining whether the certificate is valid. However, if a trusted certificate cannot be located on a Unified Messaging server, a trusted certificate is found but isn't valid, or a call is rejected because of a mutual TLS negotiation failure, the Unified Messaging server will receive a notification from the Microsoft Exchange Unified Messaging service.

Although the Microsoft Exchange Unified Messaging service doesn't participate in the certificate exchange between the Unified Messaging server and the IP gateways, the Microsoft Exchange Unified Messaging service does the following:

- Provides a list of FQDNs to the Microsoft Exchange Speech service so that calls from only the IP gateways or IP PBXs included on the list are accepted.
- Passes the **issuerName** and **SerialNumber** attributes of a certificate to the Microsoft Exchange Speech service. These attributes uniquely identify the certificate that the Unified Messaging server will use when an IP gateway or IP PBX requests a certificate.

After the Unified Messaging server and the IP gateways or IP PBXs have performed the key exchange to establish an encrypted connection using mutual TLS, the Unified Messaging servers will communicate with the IP gateways and IP PBXs using an encrypted connection. The Unified Messaging servers will also communicate with other Exchange 2010 servers, such as Client Access servers and Hub Transport servers, using an encrypted connection that uses mutual TLS. However, mutual TLS will only be used to encrypt the traffic or messages submitted from the Unified Messaging server to a Hub Transport server.

Important:

To be able to enable mutual TLS between a UM IP gateway and a dial plan operating in secured mode, you must first configure the UM IP gateway with an FQDN and configure the UM IP gateway to listen on port 5061. To configure a UM IP gateway, run the following command: `Set-UMIPGateway -Identity MyUMIPGateway -Port 5061`.

Return to top

IPsec

IPsec also uses certificates to encrypt data. It provides a key line of defense against private network and Internet attacks.

IPsec has the following goals:

- To protect the contents of IP packets.
- To defend against network attacks through packet filtering and the enforcement of trusted communication.

IPsec is a framework of open standards that helps ensure private, secure communications over IP networks using cryptographic security services.

IPsec uses cryptography-based protection services, security protocols, and dynamic key management. It provides the strength and flexibility to protect communications between private network computers, domains, sites, remote sites, extranets, and dial-up clients. It can even be used to block receipt or transmission of specific types of traffic.

IPsec is based on an end-to-end security model that establishes trust and security from a source IP address to a destination IP address. The IP address itself doesn't have to be considered an identity. Instead, the system behind the IP address has an identity validated through an authentication process. The only computers that must know about the traffic being secured are the sending and receiving computers. Each computer handles security at its respective end and operates under the assumption that the medium over which the communication occurs isn't secure. Computers that route data only from source to destination aren't required to support IPsec unless firewall-type packet filtering or network address translation is being done between the two computers. This enables IPsec to be deployed successfully for the following organizational scenarios:

- **LAN** Client-to-server, server-to-server, and server-to-VoIP device
- **WAN** Router-to-router and gateway-to-gateway
- **Remote access** Dial-up clients and Internet access from private networks

Typically, both sides require IPsec configuration to set options and security settings that allow two systems to agree on how to help secure traffic between them. This is known as an IPsec policy. The Microsoft Windows 2000 Server, Windows XP, Windows Server 2003, and the Windows Server 2008 operating system implementations of IPsec are based on industry standards that were developed by the Internet Engineering Task Force (IETF) IPsec working group. Parts of IPsec-related services were jointly developed by Microsoft and Cisco Systems, Inc. For more information about how to configure IPsec policies, see Creating, modifying, and assigning IPSec policies.

For more information about IPsec, see IPSec Concepts.

Caution:

If you currently have IPsec policies implemented on your network, you must exclude the IP gateways and IP PBXs from the IPsec policy. If you don't, for every 3 seconds of a voice mail, there will be a 1 second drop of the voice transmission. This is a known issue and there's a hotfix for Windows Server 2003. For more information about this hotfix, see How to simplify the creation and maintenance of Internet Protocol (IPsec) security filters in Windows Server 2003 and Windows XP.

UM Dial Plans and VoIP Security

Unified Messaging servers can communicate with IP gateways, IP PBXs, and other Exchange 2010 computers in either unsecured, SIP secured, or secured mode depending on how the UM dial plan is configured. A Unified Messaging server can operate in any mode configured on a dial plan because the Unified Messaging server is configured to listen on TCP port 5060 for unsecured requests and TCP port 5061 for secured requests at the same time. A Unified Messaging server can be associated with a single or multiple UM dial plans and can be associated with dial plans that have different VoIP security settings. A single Unified Messaging server can be associated with dial plans configured to

use a combination of unsecured, SIP secured, or secured mode.

By default, when you create a UM dial plan, it will communicate in an unsecured mode, and the Unified Messaging servers associated with the UM dial plan will send and receive data from IP gateways, IP PBXs, and other Exchange 2010 computers using no encryption. In unsecured mode, both the Realtime Transport Protocol (RTP) media channel and SIP signaling information won't be encrypted.

You can configure a Unified Messaging server to use mutual TLS to encrypt the SIP and RTP traffic sent and received from other devices and servers. When you add a Unified Messaging server to a UM dial plan and configure the dial plan to use SIP secured mode, only the SIP signaling traffic will be encrypted, and the RTP media channels will still use TCP. TCP isn't encrypted. However, if you add a Unified Messaging server to a UM dial plan and configure the dial plan to use secured mode, both the SIP signaling traffic and the RTP media channels are encrypted. A secure signaling media channel that uses Secure Realtime Transport Protocol (SRTP) also uses mutual TLS to encrypt the VoIP data.

You can configure the VoIP security mode either when you're creating a new dial plan or after you create a dial plan using the Exchange Management Console or the **Set-UMDialPlan** cmdlet. When you configure the UM dial plan to use SIP secured or secured mode, the Unified Messaging servers associated with the UM dial plan will encrypt the SIP signaling traffic or the RTP media channels, or both. However, to be able to send encrypted data to and from a Unified Messaging server, you must correctly configure the UM dial plan, and devices such as IP gateways or IP PBXs must support mutual TLS.

You can use the **Get-UMDialPlan** cmdlet in the Exchange Management Shell to determine the security setting for a specific UM dial plan. If the VoIP security parameter has been enabled, you can verify that the Microsoft Exchange Unified Messaging service has started in secured mode by checking the application event log to see whether information events numbered 1114 and 1112 have been logged.

Important:

If you're configuring mutual TLS to encrypt data exchanged between a Dialogic model 2000 or 4000 IP gateway, you must use the Computer V3 certificate template that supports both server and client authentication. The Web Server certificate template that supports server authentication will only work correctly with Dialogic 1000 and 3000 IP gateways, AudioCodes IP gateways, and Microsoft Office Communications Server 2007.

Return to top

How Unified Messaging Determines Security Mode and Selects Certificates

When the Microsoft Exchange Unified Messaging service starts, it checks the associated UM dial plan and the *VoipSecurity* parameter setting and identifies whether it should start in a secured or an unsecured mode. If it determines that it must start in a secured mode, it then determines whether it has access to the required certificates. If the Unified Messaging server isn't associated with any UM dial plans, it determines which mode to start in by looking at the *StartSecured* parameter in the Msexchangeum.config file. This parameter can be set with a value of 0 or 1. A value of 1 starts the Unified Messaging server using encryption to protect the VoIP traffic. A value of 0 starts the server, but encryption won't be used to protect the VoIP traffic. If you want to change the startup behavior of the Unified Messaging server from secured to unsecured or from unsecured to secured, you can associate the server with the appropriate UM dial plans and then restart the Unified Messaging server. You can also change the configuration setting in the Msexchangeum.config configuration file and the restart the Microsoft Exchange Unified Messaging service.

If the Microsoft Exchange Unified Messaging service is started in unsecured mode, it will start correctly. However, make sure that you verify that the IP gateways and IP PBXs are also running in unsecured mode. Also, if you're testing the Unified Messaging server's connectivity in unsecured mode, use the **Test-UMConnectivity** cmdlet with the -*Secured:false* parameter.

If the Microsoft Exchange Unified Messaging service is started in secured mode, it queries the local certificate store to find a valid certificate to use for mutual TLS to enable encryption. The service first looks for a valid PKI or commercial certificate and then, if an appropriate certificate isn't found, it looks for a self-signed certificate to use. If no PKI, commercial, or self-signed certificate is found, the Microsoft Exchange Unified Messaging service creates a self-signed certificate to use to start in secured mode. If the Unified Messaging server is starting in unsecured mode, a certificate isn't needed.

All the details of the certificate used to start in secured mode will be logged whenever a certificate is used or if the certificate has changed. Some details logged include the following:

- Issuer Name
- Serial Number
- Thumbprint

The thumbprint is the Secure Hash Algorithm (SHA1) hash and can be used to uniquely identify the certificate used. You can then export the certificate used by the Microsoft Exchange Unified Messaging service to start in secured mode from the local certificate store and then import this certificate on the IP gateways and IP PBXs on your network into the trusted certificate store.

After an appropriate certificate has been found and is used, and no additional changes have occurred, the Microsoft Exchange Unified Messaging service will log an event one month before the certificate being used expires. If you don't make any changes to the certificate during this time, the Microsoft Exchange Unified Messaging service will log an event each day until the certificate expires and each day after the certificate has expired.

When the Unified Messaging server is looking for a certificate to use for mutual TLS to establish an encrypted channel, it will look in the trusted root certificate store. If there are multiple certificates that are valid and are from different issuers, the Unified Messaging server will choose the valid certificate that has the longest time before the certificate will expire. If multiple certificates exist, the Unified Messaging server will choose the certificates based on the issuer and the date that the certificate will expire. The Unified Messaging server will look for a valid certificate in this order:

1. PKI or commercial certificate with the longest expiration period.
2. PKI or commercial certificate with the shortest expiration period.
3. Self-signed certificate with the longest expiration period.
4. Self-signed certificate with the shortest expiration period. A valid commercial, PKI, or self-signed certificate is required. If a valid certificate isn't found, the Unified Messaging server will generate a self-signed certificate. The Unified Messaging server needs a valid certificate to encrypt the VoIP traffic when it's operating in SIP secured or secured mode.

Important:

When a new certificate is installed on a Client Access server used to encrypt Play on Phone data between the Client Access server and a Unified Messaging server, you must run the **IISreset** command from a command prompt to load the correct certificate.

Return to top

Understanding Operator Transfers in Unified Messaging

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-11-14*

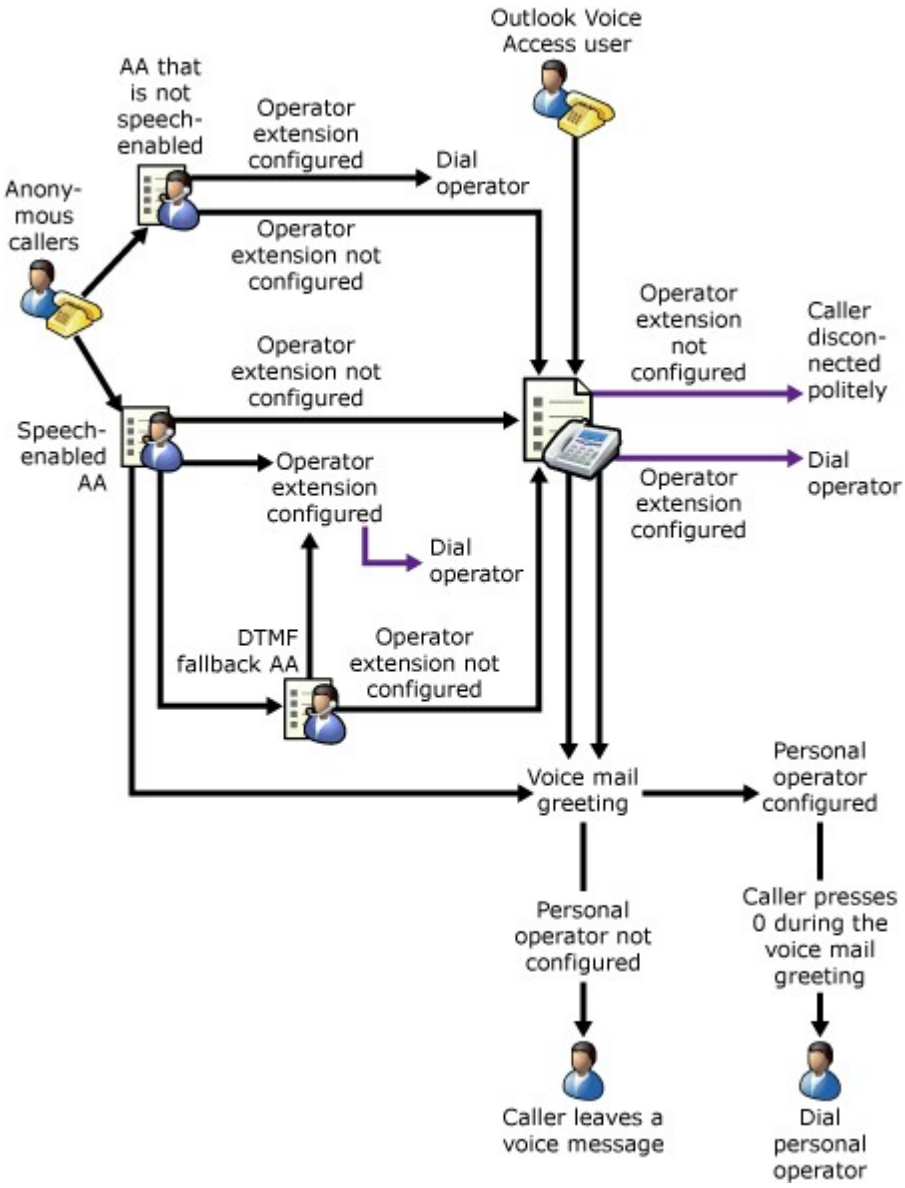
Microsoft Exchange Server 2010 Unified Messaging (UM) includes functionality that enables callers to be transferred to an operator if the caller isn't able to correctly navigate the system or must speak to a human operator. There are several types of operators that you can configure. These operators allow callers to be forwarded to the extension number of a receptionist, administrative assistant, operator, or in some cases, to another auto attendant. This topic discusses the different types of operators that you can configure in Exchange 2010 Unified Messaging and how incoming calls can be transferred to each type of operator, depending on how the caller dials in to the Unified Messaging system.

Overview of Operators in Unified Messaging

In Exchange 2010 Unified Messaging, you can configure one or all of the following types of operators:

- Dial plan
- Auto attendant
- Personal

The following figure illustrates the different types of operators found in Exchange 2010 Unified Messaging.



With Exchange 2010 Unified Messaging, you have the option to configure an operator extension on UM dial plans, UM auto attendants, and on UM-enabled users' mailboxes. If you configure an operator extension number on a UM dial plan or on a UM auto attendant that's not speech-enabled, the caller will hear a voice prompt that says, "To reach an operator, press 0." When a caller calls in to a speech-enabled UM auto attendant and an operator extension number is configured, the caller will have the option to press 0 or say "operator" or "reception" and be transferred to an operator extension number.

When you configure an operator extension number for a UM dial plan, auto attendant, or to another UM-enabled user (called a *personal operator*), you can configure the extension number using one of the following:

- **An internal telephone extension number** This can be an extension number for a specific person within the organization such as a receptionist, administrative assistant, or another person who's available to answer the call. Generally, this is an extension number where a person is always available to answer an incoming call.
- **The extension number for a UM auto attendant** This can be used when you

want to allow callers additional menu options before they're transferred to a human operator or when your organization doesn't have a human operator. In this case, you can configure an extension number that transfers the incoming call to the extension number associated with a UM auto attendant. The auto attendant can be either speech-enabled or not speech-enabled.

- **An external telephone number** This can be used when a vendor or external answering service is used to answer incoming calls for your organization. If you choose to configure an operator extension number with a telephone number external to your organization, you must verify that you've correctly configured your outdialing rules on the UM dial plans and Private Branch eXchanges (PBXs) so that the calls are transferred successfully.

At a minimum, we recommend that you configure either the UM dial plan or a UM auto attendant associated with the dial plan to have an operator extension number to help callers find the person they're trying to reach or to navigate the menu system. For more information about how to configure an operator extension on a UM auto attendant, see Configure an Operator Extension on a UM Auto Attendant. For more information about how to configure an operator extension number on a UM dial plan, see Configure an Operator Extension on a UM Dial Plan.

Dial Plan Operators

Although Exchange 2010 Unified Messaging has many Active Directory objects that must be created and configured during deployment, a UM dial plan is a central component of the Unified Messaging system. A UM dial plan is an Exchange 2010 organization-wide object created in the Active Directory directory service.

The UM dial plan is an Active Directory object that represents sets or groupings of PBXs that share common user extension numbers. In practical terms, user extensions hosted on PBXs share a common extension numbering format. Users in the same dial plan can dial one another's telephone extensions without appending a special number to the extension or dialing a full telephone number. Therefore, a UM dial plan is a representation of a telephony dial plan created on a PBX or IP PBX.

There are two types of callers who access the Unified Messaging system using the subscriber access number configured on a UM dial plan: unauthenticated callers and authenticated callers. When callers dial the subscriber access number configured on a dial plan, they're considered anonymous (unauthenticated) until they input information. This information includes their voice mail extension and a PIN. The only option available to anonymous (unauthenticated) callers is the directory search feature. However, if an operator extension number is configured on the dial plan, unauthenticated users can use the directory search feature and can also press 0 to be transferred to the operator extension number configured on the dial plan.

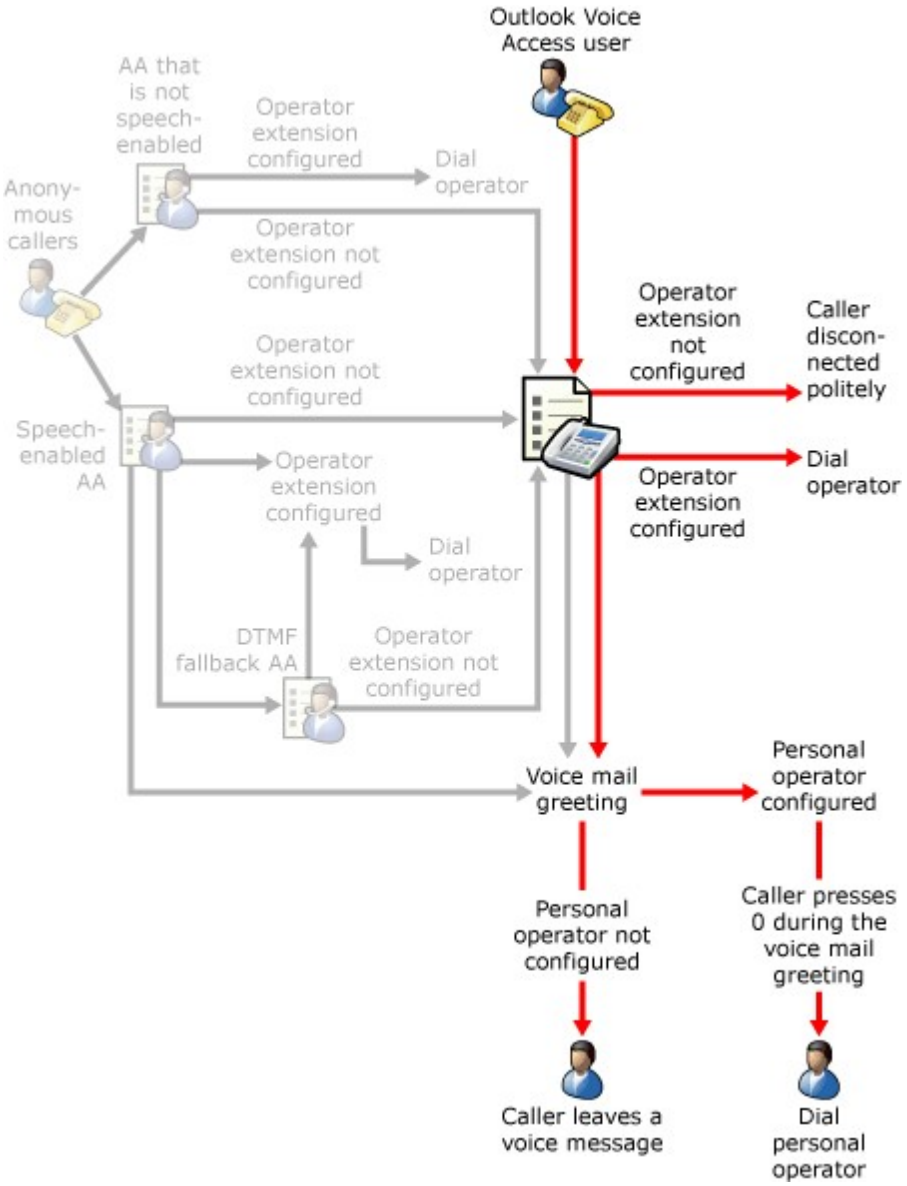
After callers input their extension number and their PIN, they're authenticated and given access to their Exchange 2010 mailbox. After they gain access to their mailbox, they use Outlook Voice Access. Outlook Voice Access is a series of voice prompts that allows authenticated callers to access their e-mail, voice mail, calendar, and contact information using a standard analog, digital, or mobile phone. Outlook Voice Access also enables authenticated callers to navigate their personal information in their mailbox, place calls, locate users, and navigate the system prompts and menus using dual tone multi-frequency (DTMF), also known as touchtone, inputs or voice inputs.

When UM-enabled users use Outlook Voice Access, they can perform the following tasks:

- Listen to new and saved e-mail and voice mail messages.
- Forward, reply, save, and delete e-mail and voice mail messages.
- Interact with their calendar.
- Locate a person in the global address list or personal contacts.
- Send a voice message to a person.

- Change their PIN, spoken name, or greetings.

When an Outlook Voice Access user dials the subscriber access number configured on a UM dial plan, and an operator extension has been configured on the dial plan, and the user presses the 0 key or says "operator" or "reception," the user will be transferred to the telephone number that you configured on the UM dial plan. If no telephone number has been configured for an operator extension on the dial plan, users won't be given the option to reach an operator and will be politely disconnected from the Unified Messaging system. The following figure illustrates the operator transfer options available to Outlook Voice Access users when they dial in to a subscriber access number.



For more information about subscriber access in Exchange 2010 Unified Messaging, see Understanding Unified Messaging Subscriber Access.

For a printable copy of the menus and options available with Outlook Voice Access, see the Microsoft Download Center for a copy of the Outlook Voice Access Quick Start Guide.

Auto Attendant Operators

In Exchange 2010 Unified Messaging, many Active Directory objects must be created and configured during and after deployment. UM auto attendants aren't required objects; they're optional. UM auto attendant objects are Exchange 2010 organization-wide objects created in Active Directory.

Exchange 2010 Unified Messaging enables you to create one or more UM auto attendants, depending on the needs of your organization. UM auto attendants can be used to create a voice menu system for an organization. This voice menu system lets external and internal callers locate users in an organization and place or transfer calls to users, departments, or to an operator extension number configured on the UM auto attendant.

There are three types of UM auto attendants that you can configure to use an operator extension number:

- Auto attendants that aren't speech-enabled
- Speech-enabled auto attendants that don't have a DTMF fallback auto attendant
- Speech-enabled auto attendant that have a DTMF fallback auto attendant

You can configure the operator extension number on a UM auto attendant to be the extension number of a human operator, another auto attendant, a UM-enabled mailbox, or a telephone number external to an organization. The internal or external telephone number you enter for the operator's extension number can be from 1 through 20 digits.

You can configure an operator extension number on UM auto attendants that are speech-enabled and on auto attendants that aren't speech-enabled. Configuring an operator extension number on a UM auto attendant allows callers to press 0 or say "operator" or "receptionist" to transfer to a human operator or another auto attendant if they can't navigate the auto attendant menu.

If you use an external telephone number, you must verify that you've correctly configured the appropriate outdialing rule groups and entries to enable this functionality. For more information about how to configure outdialing entries, see Create a Dialing Rule Entry on a UM Dial Plan.

If you create a speech-enabled auto attendant and configure an operator extension on the speech-enabled auto attendant, when the caller says "operator," the auto attendant will forward the call to the number configured on the speech-enabled auto attendant. If the speech-enabled auto attendant is configured to have a DTMF fallback auto attendant but not to have an operator extension number, and the DTMF auto attendant is configured to have an operator extension number, the operator extension number on the DTMF fallback auto attendant will be dialed. If no extension number is configured on the speech-enabled auto attendant or the DTMF fallback auto attendant, and the caller says "operator," the system will call the operator extension configured on the dial plan associated with the auto attendant. If neither of the auto attendants or the dial plan is configured to have an operator extension, the system will respond by saying "Sorry. Neither the operator or the touchtone service are available."

Note:

At a minimum, we recommend that you configure either the auto attendant or the dial plan associated with the auto attendant to have an operator extension number to help callers.

Operator Transfers for Business and Non-business Hours

For UM auto attendants, you can configure business hours operator transfers on the properties for the UM auto attendant. By default, business hours transfers are enabled. You can also configure non-business hours operator transfers on the UM auto attendant.

However, by default, the business hours for a UM auto attendant are 24 hours a day, so non-business hours or after hours operator transfers aren't available. To configure operator transfers after business hours, you must first configure the business hours schedule on the UM auto attendant properties and then enable or disable operator transfers during business or non-business hours.

By default, operator transfers are disabled for non-business hours. However, you can enable operator transfers for non-business hours to allow callers to be transferred to an operator. Operator transfers for non-business hours happen according to the business hours you've defined on the **Times** tab on the properties of the UM auto attendant.

- For more information about how to configure business and non-business hours for your organization, see Configure Business Hours for a UM Auto Attendant.
- For more information about how to configure the business hours for a UM auto attendant, see Configure Business Hours for a UM Auto Attendant
- For more information about how to enable or disable operator transfers during business hours, see Enable or Disable Operator Transfers During Business Hours on a UM Auto Attendant.

When you configure an operator extension number on a UM auto attendant and enable non-business hours operator transfers, a caller can connect to the auto attendant operator by doing one of the following:

- Pressing the zero (0) key
- Saying "Reception"
- Saying "Operator"

Note:

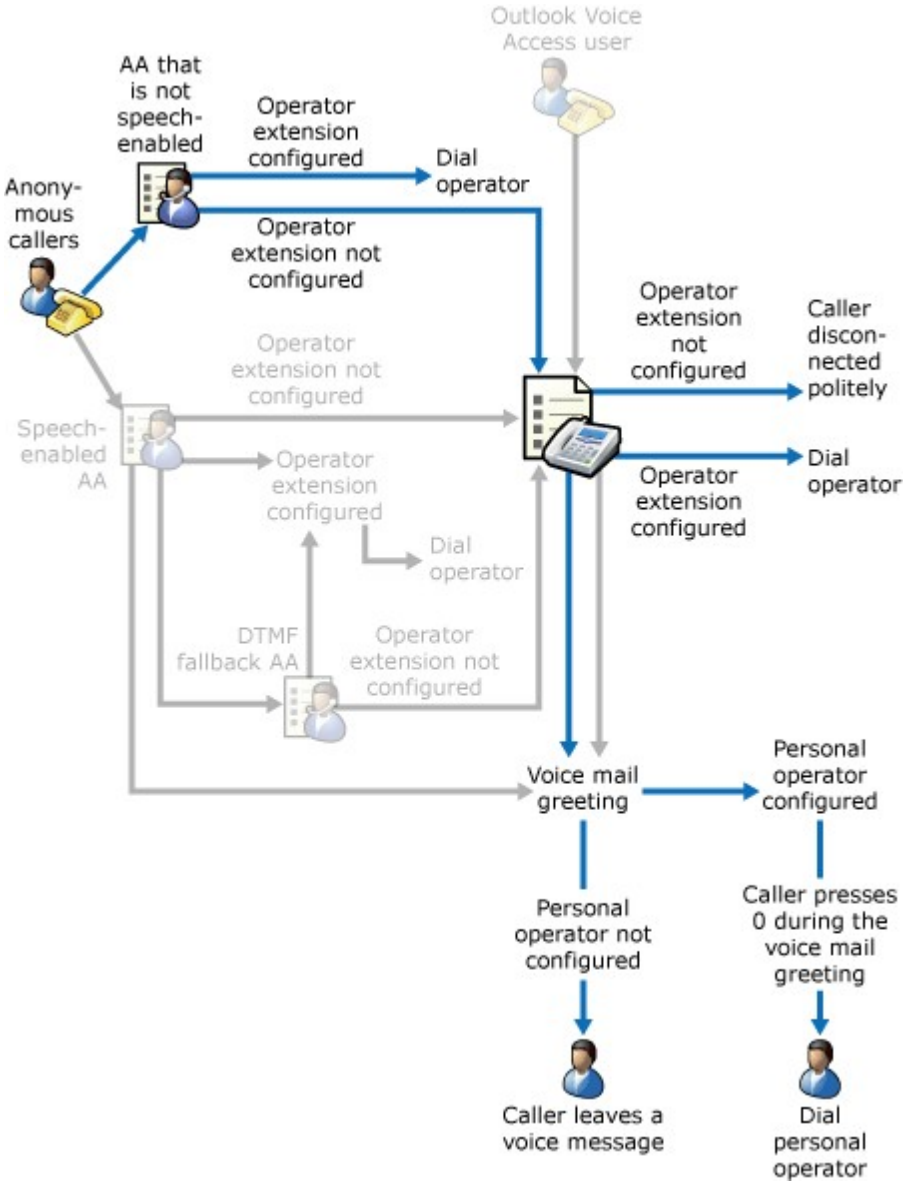
If callers exceed the maximum number of touchtone or voice input retries, they're also transferred to the operator extension number, if you've defined an operator extension number and enabled non-business hours operator transfers.

If no operator extension number is configured on a speech-enabled auto attendant, an auto attendant that isn't speech-enabled, or a DTMF fallback auto attendant, and the caller says "Operator" or "Reception" or presses the zero (0) key, the system will call the operator extension that's configured on the dial plan associated with the auto attendant. If neither of the auto attendants or the dial plan is configured to have an operator extension, the system will respond by saying, "Sorry. Neither the operator or the touchtone service are available." The caller will be politely disconnected. By default, an operator extension number isn't configured on a dial plan.

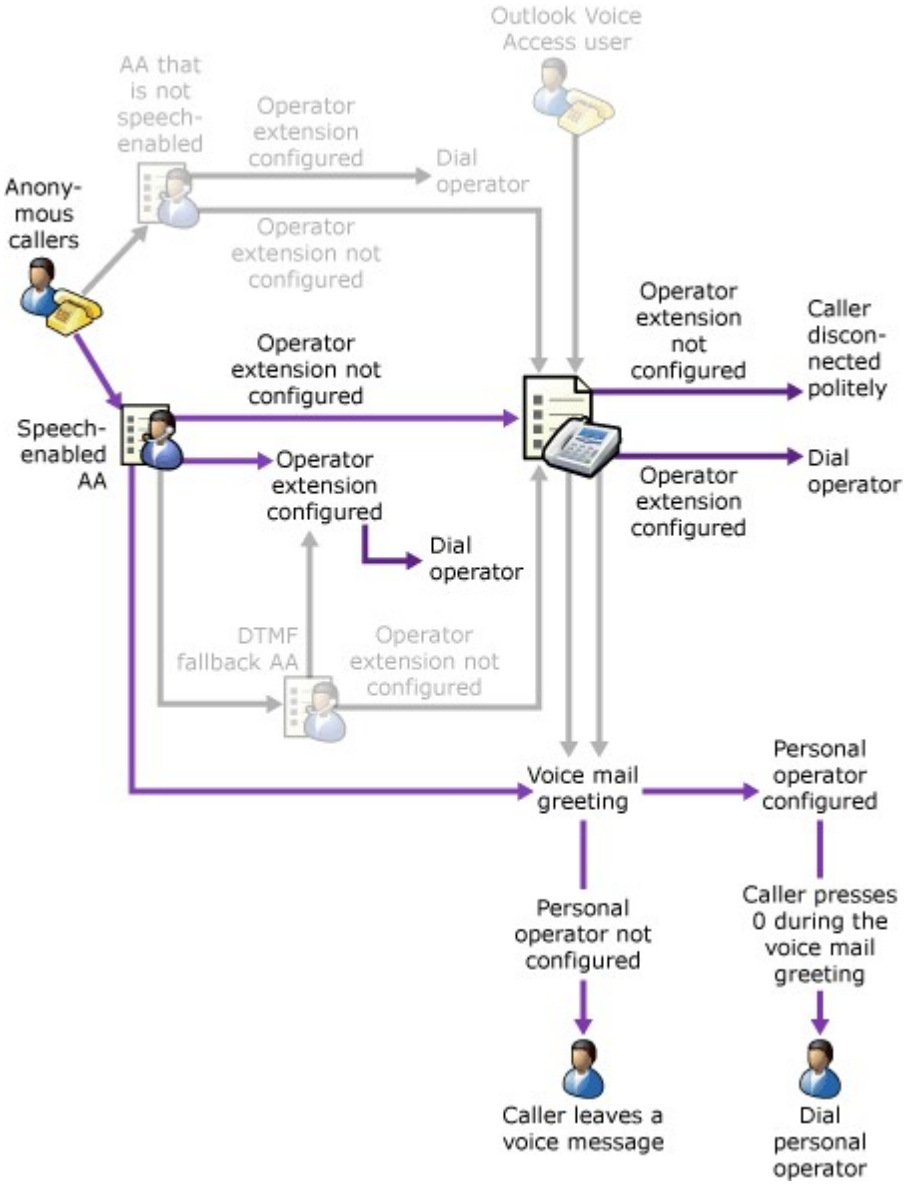
- At a minimum, we recommend that you configure either the UM auto attendant or the UM dial plan associated with the auto attendant to have an operator extension number. This will help callers find the user they're trying to reach or navigate the menu system.
- For more information about how to configure an operator extension on a UM auto attendant, see Configure an Operator Extension on a UM Auto Attendant.
- For more information about how to enable or disable operator transfers after business hours, see Enable or Disable Operator Transfers After Business Hours on a UM Auto Attendant.

Auto Attendant Operator Transfers

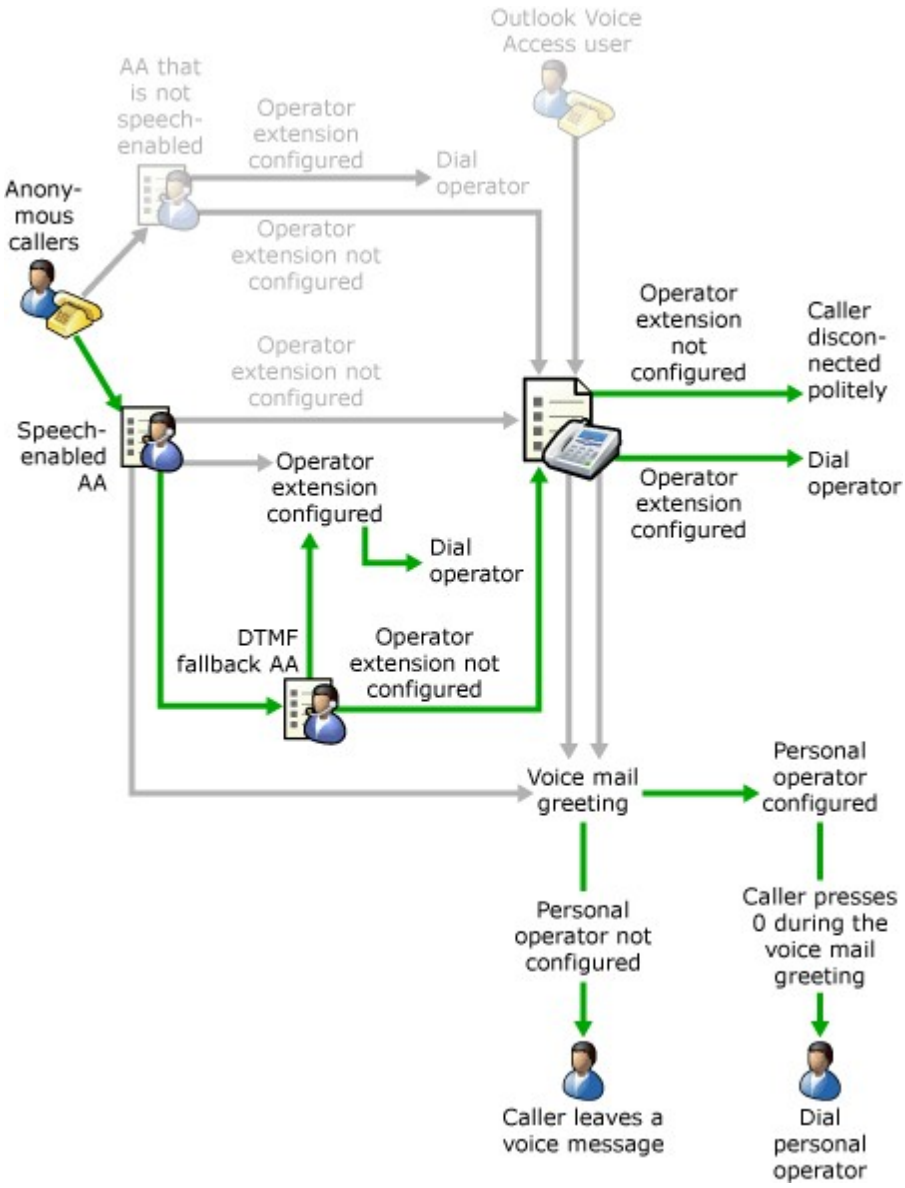
- The following figure illustrates the operator transfer options available to callers when they dial in to a UM auto attendant that's not speech-enabled. For more information about how to create a UM auto attendant, see Create a UM Auto Attendant.



The following figure illustrates the operator transfer options available to callers when they dial in to a UM auto attendant that's speech-enabled but doesn't have a DTMF fallback auto attendant configured. For more information about how to speech-enable a UM auto attendant, see Enable or Disable Automatic Speech Recognition on a UM Auto Attendant.



The following figure illustrates the operator transfer options available to callers when they dial in to a UM auto attendant that's speech-enabled and also has a DTMF fallback auto attendant configured. For more information about how to configure a UM auto attendant that has a DTMF fallback auto attendant, see Configure a UM Auto Attendant with a DTMF Fallback Auto Attendant.



Although UM auto attendants are an optional feature that can be created and configured when you're deploying Unified Messaging, we recommend that if you make the choice to create and configure a single UM auto attendant or multiple auto attendants, you take the time to plan them carefully. One of the most important factors when planning for auto attendants is to make sure that callers can contact a human operator or another auto attendant to correctly direct their calls. If you don't plan and implement the auto attendants for your organization correctly, the system could frustrate callers so that they won't call in to the system again.

Personal Operators

Exchange 2010 Unified Messaging enables you, as the administrator, to configure a personal operator extension number on a user's UM-enabled mailbox. However, the UM-enabled user won't be able to configure this setting. If UM-enabled users were able to configure this setting, they could potentially forward all their calls to another UM-enabled user or to an internal extension number that isn't valid. This could be very frustrating for

both the user to whom the calls were being forwarded and the callers. A caller wouldn't be able to leave a voice message for the person they were trying to contact and could lose their place in the menu system, and might eventually give up without reaching the person they were trying to contact.

The personal operator extension setting on a UM-enabled user's mailbox can be used when an administrative assistant or personal assistant answers incoming calls for a specific user instead of voice mail being generated for the user. By default, a personal operator extension number isn't defined.

For a caller to be transferred to a personal operator, the caller must press zero (0) on the telephone keypad when the user's custom voice mail message greeting is being played. Therefore, we recommend that, if users are going to use a personal operator, they include information in their custom voice mail greeting to give the caller instructions about how to access their personal operator.

However, if the user hasn't configured a customized voice mail greeting, the default system greeting will be used and the system will add the operator prompt automatically. For example, "Please leave a message for Tony Smith. To speak to an administrative assistant and leave a message, press 0." If the caller doesn't press 0 during the voice mail greeting, the caller will be able to leave a voice message for the user.

If you haven't configured a personal operator extension for a UM-enabled user's mailbox, the Unified Messaging server uses the operator extension number configured on the UM auto attendant or UM dial plan, depending on which number the caller has called. If callers have called an auto attendant telephone extension number, they're forwarded to the operator, if one has been configured on the UM auto attendant. If they've called the subscriber access number configured on a UM dial plan, they're forwarded to the operator extension number configured on the UM dial plan. If an operator extension hasn't been configured, callers are politely disconnected from the system. For more information about how to configure a personal operator, see Enable or Disable a Personal Operator for a UM-Enabled User.

In most cases, an internal extension number for an administrative assistant, receptionist, or operator will be configured as a personal operator. A personal operator extension number can be configured as an internal or external telephone number that ranges from 1 through 20 digits. However, if you use an external telephone number, you must verify that you've correctly configured the appropriate outdialing rule groups and entries to enable this functionality. For more information about how to configure outdialing entries, see Create a Dialing Rule Entry on a UM Dial Plan.

1.9.1.3.8 Understanding Outdialing

Understanding Outdialing

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-03*

There are many outdialing settings used on a Microsoft Exchange Server 2010 Unified Messaging (UM) server to dial internal and external calls for users. To configure outdialing, you must configure dialing rule groups, dialing rule entries, and dialing restrictions on UM dial plans and UM mailbox policies. Additionally, you can also configure UM dial plans to have dialing or access codes, a national number prefix, and in-country/region or international number formats that enable you to control outdialing in your organization.

This topic discusses dialing rule groups, dialing rule entries, and dialing restrictions and how they are used to control outdialing for your organization.

Contents

Overview

Outdialing is the process used by users when they call in to a UM dial plan or UM auto attendant and place or transfer a call to an internal or external telephone number. When a user calls in to a UM dial plan or a UM auto attendant and places a call, a Unified Messaging server will use the settings configured on the dial plan, auto attendant, and if appropriate, the UM mailbox policy to place the call. The outdialing process happens when:

- A Unified Messaging server places a call to an external telephone number for a caller.
- A Unified Messaging server transfers a call to an auto attendant.
- A Unified Messaging server transfers a call to a user in your organization who is UM-enabled or not UM-enabled.
- A UM-enabled user uses the Play on Phone feature found in Microsoft Office Outlook 2007 or Outlook Web App in Exchange 2010.

For outdialing to work correctly, the following settings must be configured correctly:

- **Dialing group rules** Dialing group rules determine the types of calls users within a dial group can make.
- **Dialing rule entries** Dialing rule entries define the number that is dialed by the UM-enabled user and the actual number that will be dialed by the Private Branch eXchange (PBX) or IP PBX.
- **Dialing restrictions** Dialing restrictions determine the restrictions that will be applied to prevent users from incurring unnecessary telephone charges or from dialing long distance calls.

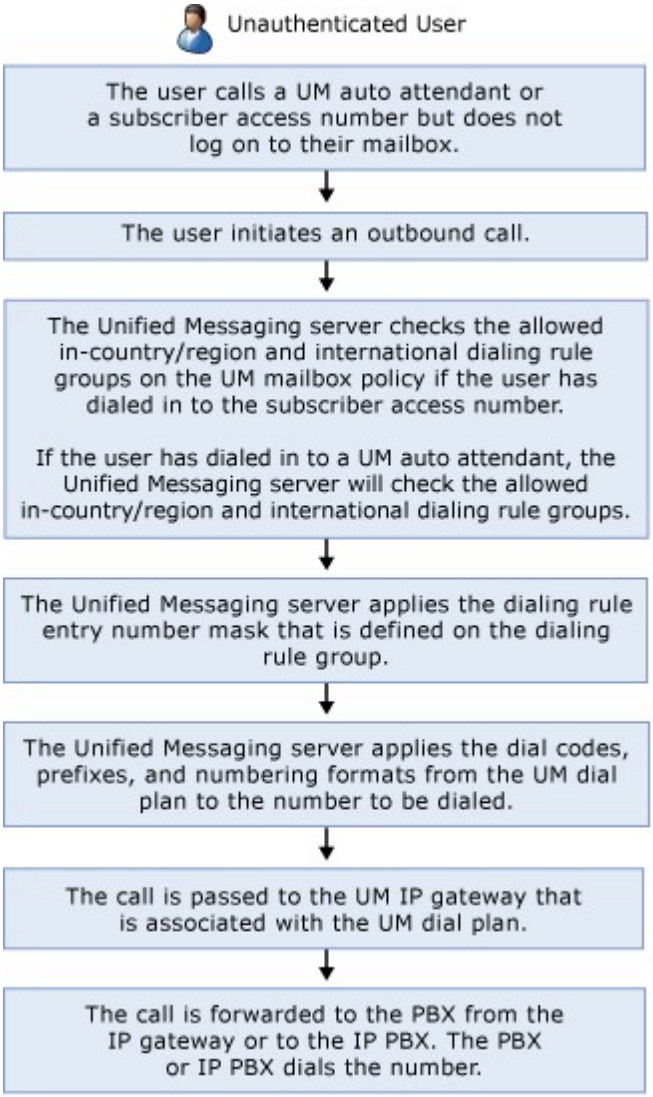
To enable outdialing for users who call into a dial plan or auto attendant, you must:

- Make sure the UM IP gateway or IP gateways associated with the dial plan will allow outgoing calls.
- Create dialing rule groups by creating dialing rule entries on the UM dial plan.
- Create dialing restrictions on the UM dial plan or auto attendant associated with the same dial plan as the UM IP gateway.

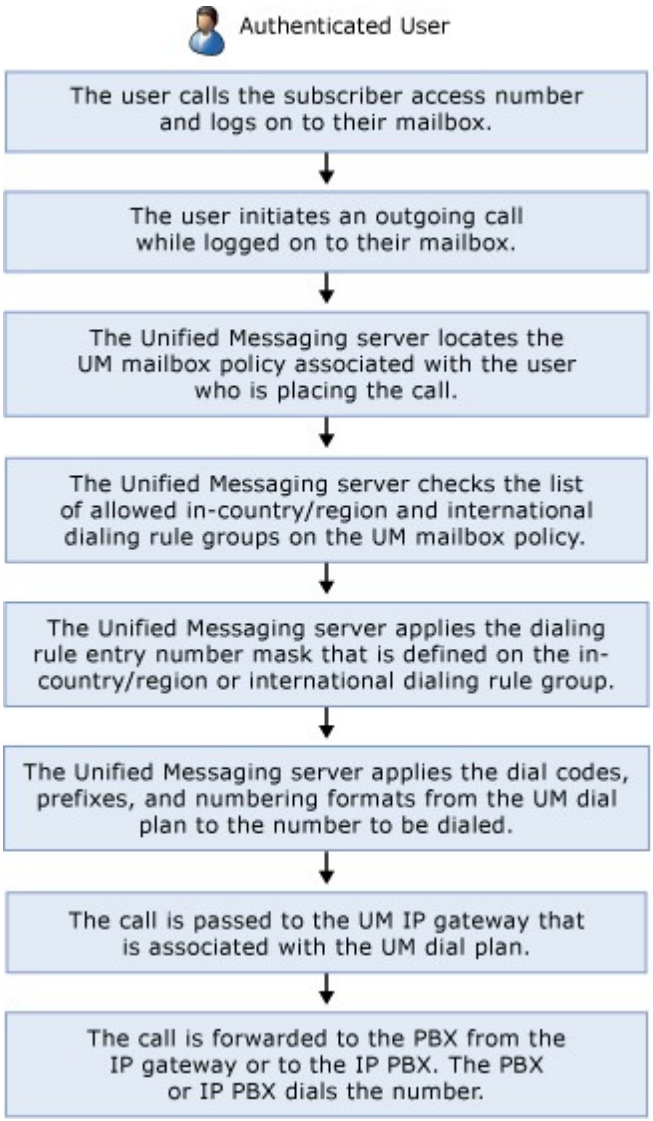
UM-Enabled Users

There are two types of users who can use the outdialing feature in Unified Messaging: authenticated and unauthenticated. The users who call in to a subscriber access number configured on a UM dial plan are unauthenticated at first. All users who call in to a UM

auto attendant are unauthenticated. When users call in to a subscriber access number, they are considered unauthenticated because they haven't provided their extension number and PIN and signed in on to their Exchange 2010 mailbox. The following figure illustrates the outdialing process for an unauthenticated user.



Users are authenticated after they provide their extension number and PIN and successfully sign in to their Exchange 2010 mailbox. The following figure illustrates the outdialing process for a user who has been authenticated.



When users call in to a subscriber access number configured on a UM dial plan and try to place or transfer a call without signing in to their Exchange 2010 mailbox, only the UM dial plan outdialing settings will apply to the call. Users are unauthenticated because they didn't sign in to their mailbox. However, when anonymous or unauthenticated users call in to a UM auto attendant, both the outdialing settings configured on the auto attendant and the outdialing settings configured on the dial plan associated with the auto attendant are applied to the call.

When users call in to the subscriber access number configured on a dial plan and successfully sign in to their Exchange 2010 mailbox, they become authenticated users. The configuration settings from the UM dial plan and the UM mailbox policy associated with the authenticated user are both applied to any outdialing calls the user makes.

Return to top

Outdialing Settings

There are several settings that you must configure to apply outdialing rules for your organization. To control outdialing, you must configure the UM dial plans, UM auto

attendants, and UM mailbox policies that you have created. The following outdialing settings are configured on dial plans, auto attendants, and UM mailbox policies:

- Outside line, country/region, and international access codes
- National number prefixes
- In-country/region and international number formats
- Configured in-country/region and international dialing rule groups
- Allowed in-country/region and international dialing rule groups
- Dialing rule entries
- Dialing restrictions

For you to successfully configure outdialing for your Exchange 2010 organization, you must first understand how each component can be used with outdialing and how the component must be configured. The following table introduces each component that must be configured on UM dial plans, UM auto attendants, and UM mailbox policies to enable outdialing to function correctly.

Outdialing components

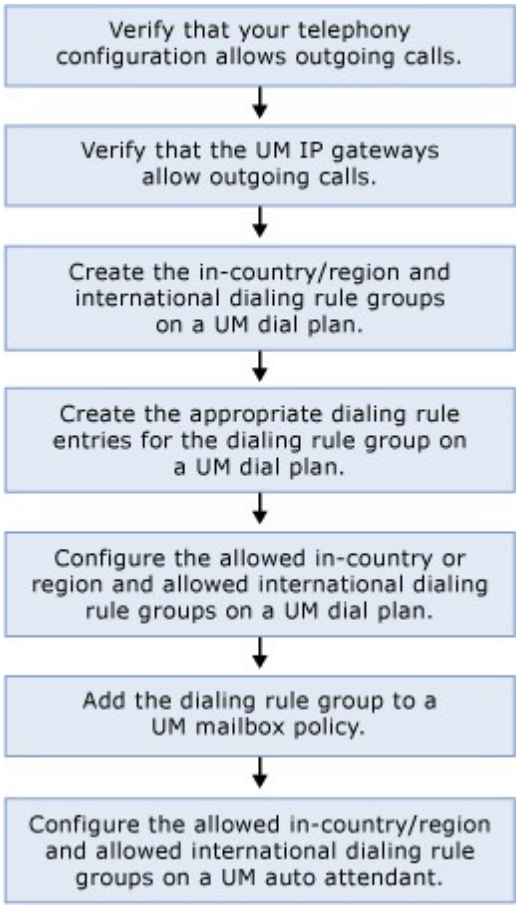
Component	Description
Dial codes, number prefixes, and number formats	Dial codes, number prefixes, and number formats are used by a Unified Messaging server to determine the correct number to dial when placing an outgoing call. You can configure dial codes, number prefixes, and number formats to restrict outgoing calls for users who dial in to a UM auto attendant associated with a UM dial plan or for users who dial in to the subscriber access number configured on the dial plan. For more information about dial codes, number prefixes, and number formats, see Understanding Dial Codes, Number Prefixes, and Number Formats.
Dialing rule groups	Dialing rule groups are created to enable telephone numbers to be modified before they are sent to the Private Branch eXchange (PBX) for outgoing calls. Dialing rule groups remove numbers from or add numbers to telephone numbers being placed by a Unified Messaging server. For example, you can create a dialing rule group that automatically adds a 9 as a prefix to a 7-digit telephone number to provide access to an outside line. In this example, users who place outgoing calls don't have to dial the 9 before the telephone number to reach someone external to the organization. Each dialing rule group contains dialing rule entries that determine the types of in-country/region and international calls that users within a dialing rule group can make. Dialing rule groups apply to the users who are associated with a UM dial plan or UM auto attendants and UM mailbox policies associated with the UM dial plan. Each dialing rule group must contain at least one dialing rule entry.

Dialing rule entries	A dialing rule entry is used to determine the types of calls that users within a dialing rule group can make. When you create a dialing rule group, you configure one or more dialing rule entries. When you configure each dialing rule entry, you must enter the name, number mask, and dialed number. You can also enter a comment. Comments can be used to describe how the dialing rule entry will be used or to describe a group of users to whom the dialing rule entry will apply. When you add a number mask and the dialed number to a dialing rule entry, you can substitute the letter x to replace a digit in a telephone number, for example, 91425xxxxxxx. You can also use an asterisk (*) symbol as a wildcard character, for example, 91425*.
Dialing restrictions	A dialing restriction uses dialing rule groups to apply dialing restrictions for users who are associated with a specific UM mailbox policy. They can also be used when you want to let users place calls to in-country/region or international telephone numbers. After you create a dialing rule group on a UM dial plan, you add the dialing rule group to a UM mailbox policy. After the dialing rule group is added to a UM mailbox policy, all settings or rules defined will apply to UM-enabled users who are associated with the UM mailbox policy.

Return to top

We recommend that you follow the steps in the following figure when you configure outdialing on your dial plans, auto attendants, and UM mailbox policies, to ensure that outdialing functions correctly.

Configuring outdialing



Configuring Outdialing

A dialing rule group is a collection of one or more dialing rule entries configured on a UM dial plan. There are two types of dialing rule groups that can be configured on a UM dial plan: in-country/region and international. In-country/region dialing rule groups apply to telephone numbers dialed within the same country or region. International dialing rule groups apply to international telephone numbers dialed from one country or region to another country or region.

Each UM dial plan can contain one or more dialing rule groups. However, to apply a dialing rule group to a set of users, after you create the dialing rule group, you must add the configured dialing rule group to the list of allowed dialing rule groups on the UM dial plan and on the UM auto attendants and UM mailbox policies associated with the UM dial plan.

Dialing rule groups enable you to specify dialing rule entries that you want to apply to a group of UM-enabled users who fall into a specific category. For example, you can use dialing rule groups to specify which group of users can place international calls and which group can only make in-state or local calls. You can create a dialing rule group using the Exchange Management Console or the **Set-UMDialPlan** cmdlet in the Exchange Management Shell. When you create a dialing rule group, you must define at least one dialing rule entry for the dialing rule group.

When a number is dialed by a user, the Unified Messaging server takes the telephone number and looks for a match in the dialing rule entries. If a match is found, the dialing rule entry configured on the dialing rule group is applied. The Unified Messaging server looks at the dialing rule entry to determine the number to dial by looking at the telephone number or digits listed in the DialedNumber section of the dialing rule entry. The number

listed in the DialedNumber section of the dialing rule entry will be dialed by the Unified Messaging server.

The following table shows an example of dialing rule groups and dialing rule entries. In this example, Local-Calls-Only and Low-Rate are the dialing rule groups that have been created. The dialing rule group Local-Calls-Only has two dialing rule entries: 91425* and 91206*, and the dialing rule group Low-Rate also has two dialing rule entries: 91509* and 91360*.

Dialing rule groups and dialing rule entries

Name	NumberMask	DialedNumber	Comment
Local-Calls-Only	91425*	91*	Local calls
Local-Calls-Only	91206*	91*	Local calls
Low-Rate	91509*	9*	In-state calls
Low-Rate	91360*	9*	In-state calls

For example, when a user dials 9-1-425-555-1234, the telephone number that the Unified Messaging server dials is 4255551234. The Unified Messaging server will remove any nonnumeric characters (in this example, the hyphens) and apply the number mask from the dialing rule entry. In this example, the Unified Messaging server will apply the number mask 91*. This tells the Unified Messaging server not to dial the 9 or the 1, but to dial all the other numbers in the telephone number that appear to the right of the number 1. This includes all the numbers represented by the asterisk (*).

You can use the EMC or the Shell to create and configure single or multiple in-country/region and international dialing rule groups and dialing rule entries. However, if you're creating many or complex dialing rule groups and dialing rule entries, you can use a comma-separated value (.csv) file in the Exchange Management Shell. You can import or export a list of dialing rule groups and dialing rule entries.

To import a list of dialing rule groups and dialing rule entries that you've defined in a .csv file, run the **Set-UMDialPlan** cmdlet, as follows.

```
Set-UMDialPlan "MyUMDialPlan" -ConfiguredInCountryOrRegionGroups $(IMPORT-CSV c:\
```

To retrieve a list of the dialing rule groups configured on a UM dial plan, run the **Get-UMDialPlan** cmdlet, as follows.

```
(Get-UMDialPlan -id "MyUMDialPlan").ConfiguredInCountryOrRegionGroups | EXPORT-CS
```

The .csv file must be created and saved in the correct format for the file to be used. Each line in the .csv file represents one dialing rule entry. However, each dialing rule entry is configured on the same dialing rule group. Each entry in the file will have four sections separated by commas. These sections are name, number mask, dialed number, and comment. Each section is required, and you must enter the correct information in each section except for the comment section. There should be no spaces between the text entry and the comma for the next section, nor should there be any blank lines in between entries or at the end. The following is an example of a .csv file that can be used to create in-country/region dialing rule groups and dialing rule entries.

Name,NumberMask,DialedNumber,Comment

Low-rate,91425xxxxxxx,9xxxxxxx,Local call

Low-rate,9425xxxxxxx,9xxxxxxx,Local call

Low-rate,9xxxxxxx,9xxxxxxx,Local call

Any,91*,91*,Open access to in-country/region numbers

Long-distance,91408*,91408*,long distance

The following is an example of a .csv file that can be used to create international dialing rule groups and dialing rule entries.

Name,NumberMask,DialedNumber,Comment

International, 901144*, 901144*, international call

International, 901133*, 901133*, international call

Return to top

Applying Configured Dialing Rule Groups

Dialing rule groups are created on a UM dial plan. You can create in-country/region or international dialing rule groups using the EMC or the **Set-UMDialPlan** cmdlet in the Shell. After you create the appropriate dialing rule groups on a UM dial plan and define the dialing rule entries, you can apply the dialing rule groups that you created to a UM dial plan, a UM auto attendant, or to users who are associated with a UM mailbox policy, depending on how the user accesses the Unified Messaging system.

You can apply the dialing rule groups that you created on a UM dial plan to the following:

- **Same dial plan** The settings will apply to all users who call in to the subscriber access number but don't sign in to their Exchange 2010 mailbox. To apply an in-country/region dialing rule group named MyAllowedDialRuleGroup to the same dial plan, use the Exchange Management Shell **Set-UMDialPlan** cmdlet, as follows.

```
Set-UMDialPlan -Identity MyUMDialPlan -AllowedInCountryOrRegionGroups M
```

- **Single or multiple UM mailbox policies** The settings configured on a UM mailbox policy will apply to all users who are associated with a specific UM mailbox policy. The settings configured on a UM mailbox policy apply to users who call in to a subscriber access number and sign in to their Exchange 2010 mailbox. To apply an in-country/region dialing rule group named MyAllowedDialRuleGroup to a single UM mailbox policy, use the **Dialing Restrictions** tab in the EMC or use the **Set-UMMailboxPolicy** cmdlet in the Shell, as follows.

```
Set-UMMailboxPolicy -Identity MyUMMailboxPolicy -AllowedInCountryOrRegi
```

- **Single or multiple auto attendants associated with the UM dial plan** This will apply to all users who call in to a UM auto attendant. To apply the in-country/region dialing rule group named MyAllowedDialRuleGroup to a single UM auto attendant, use the Exchange Management Shell **Set-UMAutoAttendant** cmdlet, as follows.

```
Set-UMAutoAttendant -Identity MyUMAutoAttendant -AllowedInCountryOrRegi
```

Return to top

The following table summarizes the way that dialing rule groups are applied in Unified

Messaging.

Applying outdialing rules

Caller type	Scope	Outdialing settings applied
Subscriber access or Outlook Voice Access	User calls a dial plan subscriber access number and signs in to the mailbox	UM mailbox policy
Anonymous caller	User calls a dial plan subscriber access number	UM dial plan
Anonymous caller	User calls an auto attendant pilot number	UM auto attendant
Caller from inside the organization	User calls the Play on Phone number	UM mailbox policy

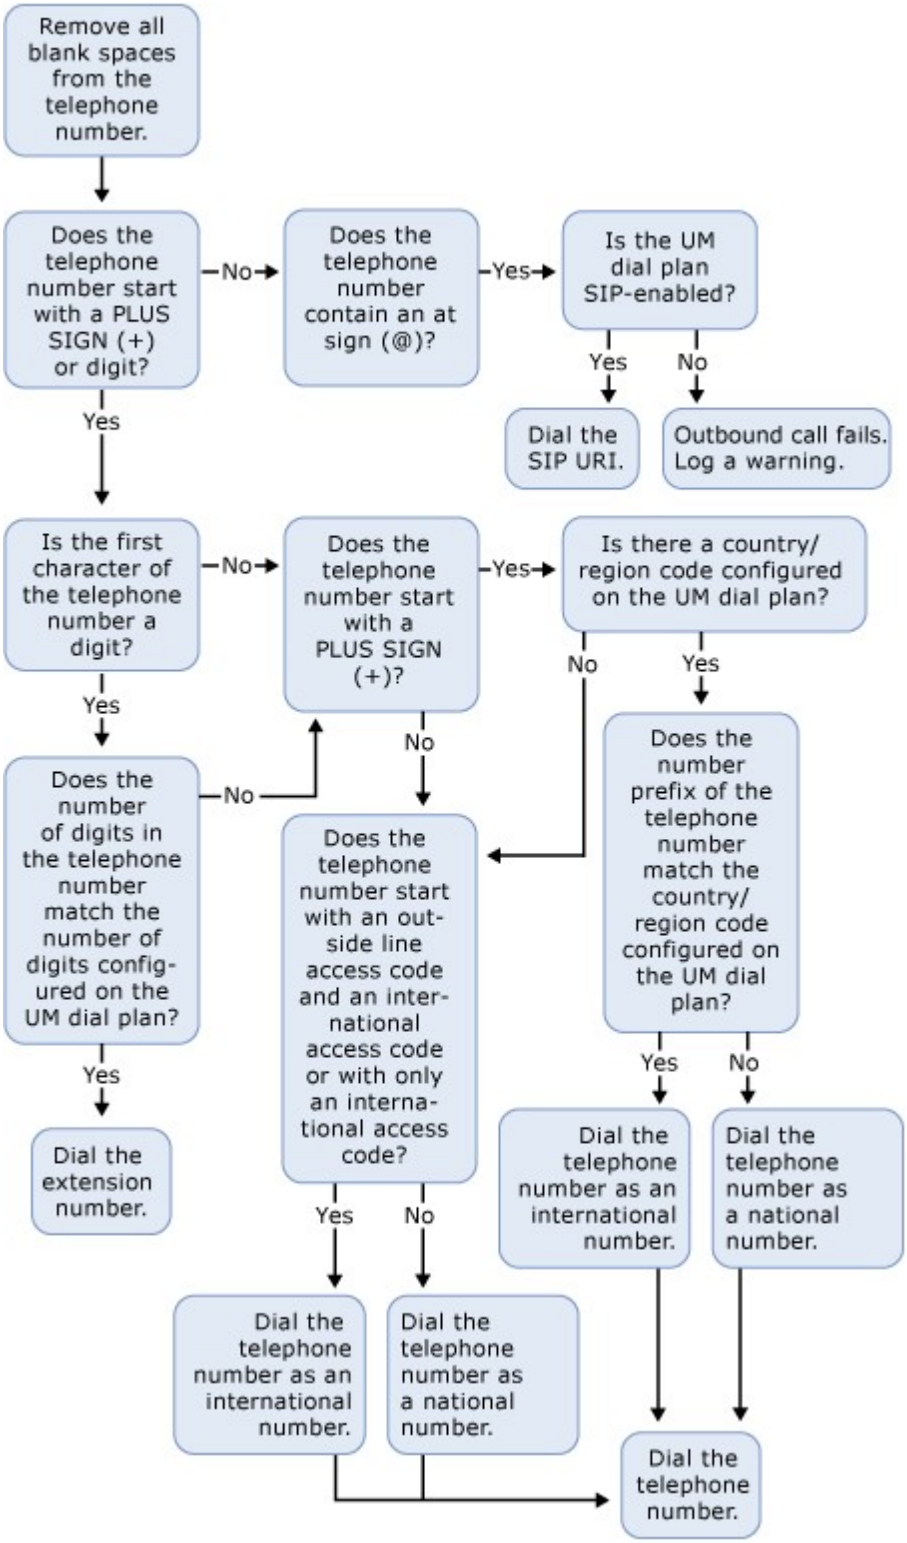
Applying Dialing Rules

The outdialing process happens when:

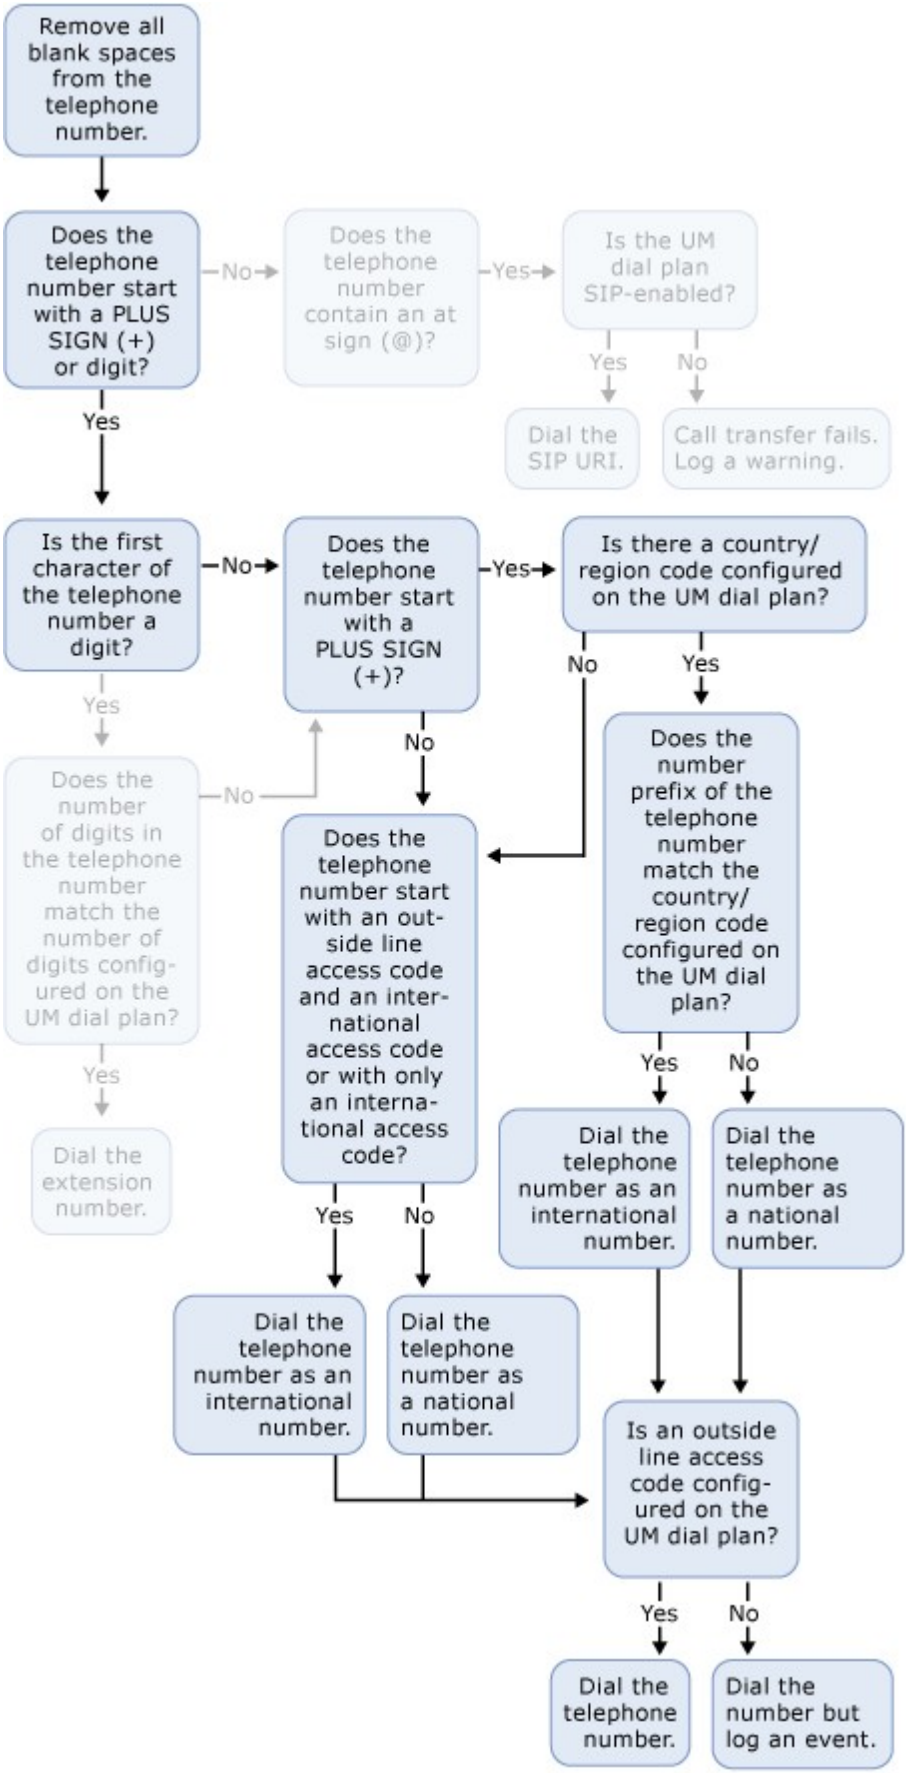
- A Unified Messaging server places a call to an external telephone number for a caller.
- A Unified Messaging server transfers a call to an auto attendant.
- A Unified Messaging server transfers a call to a user in your organization who is UM-enabled or not UM-enabled.
- A UM-enabled user uses the Play on Phone feature found in Outlook 2007 or Outlook Web App in Exchange 2010.

In each outdialing scenario, a Unified Messaging server will apply the outdialing rules that have been configured, and then place the call for the user. However, depending on the scenario and how the call is initiated by the user, a Unified Messaging server may apply only some of the outdialing rules to the telephone number being dialed. In other outdialing scenarios, the Unified Messaging server may apply all the outdialing rules configured to the telephone number being dialed. The outdialing rules applied are based on how the call was initiated and are illustrated in the following figures.

The following figure illustrates how outdialing rules are applied when a user uses the Play on Phone feature to place a call.



The following figure illustrates how outdialing rules are applied when a user places a call to a personal contact.



Remove all blank spaces from the telephone number.

1.9.1.3.9 Understanding Dial Codes, Number Prefixes, and Number Formats

Understanding Dial Codes, Number Prefixes, and Number Formats

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2009-10-10*

You can configure several dialing codes used by a Unified Messaging (UM) server to dial internal and external calls for UM-enabled users. Frequently, you want to configure a dial plan together with the dialing or access codes, a national number prefix, or the in-country/region or international number formats so that you can control outdialing for users in your organization. This topic discusses dial codes, number prefixes, and number formats and how you can use them to control outdialing for your organization.

Contents

Overview

Outdialing is the process used by users when they call in to a UM dial plan or UM auto attendant and then place a call to an internal or external telephone number. When a user calls in to a UM dial plan or a UM auto attendant and then places a call, a Unified Messaging server uses the settings configured on the dial plan, auto attendant, and UM mailbox policies to place the call. A Unified Messaging server places an outgoing call in the following situations:

- When it places a call to an external telephone number for a caller.
- When it transfers a call to an auto attendant.
- When it transfers a call to a user (either UM-enabled or not) in your organization.
- When a UM-enabled user uses the Play on Phone feature in Microsoft Office Outlook 2007 or the version of Outlook Web App that released with Microsoft Exchange Server 2010.

There are two types of users who use outdialing: authenticated and unauthenticated. Unauthenticated users call in to a subscriber access number configured on a UM dial plan but don't sign in to their mailbox. Unauthenticated users also call in to a number

configured on a UM auto attendant. Authenticated users call in to a subscriber access number and successfully sign in to their Exchange 2010 mailbox. When users call in to a subscriber access number, they are considered unauthenticated because they haven't provided their extension number and PIN and logged on to their mailbox. They are authenticated after they provide their extension number and PIN and successfully sign in to their Exchange 2010 mailbox.

When an unauthenticated user calls in to a UM auto attendant and places a call using outdialing, the outdialing settings configured on the UM dial plan and the auto attendant are used. When an unauthenticated user calls in to a subscriber access number configured on a dial plan, the settings configured on the dial plan are the only settings that are used. However, when users have successfully signed in to their Exchange 2010 mailbox, configuration settings from the dial plan and the UM mailbox policy associated with the authenticated users are applied to the authenticated users.

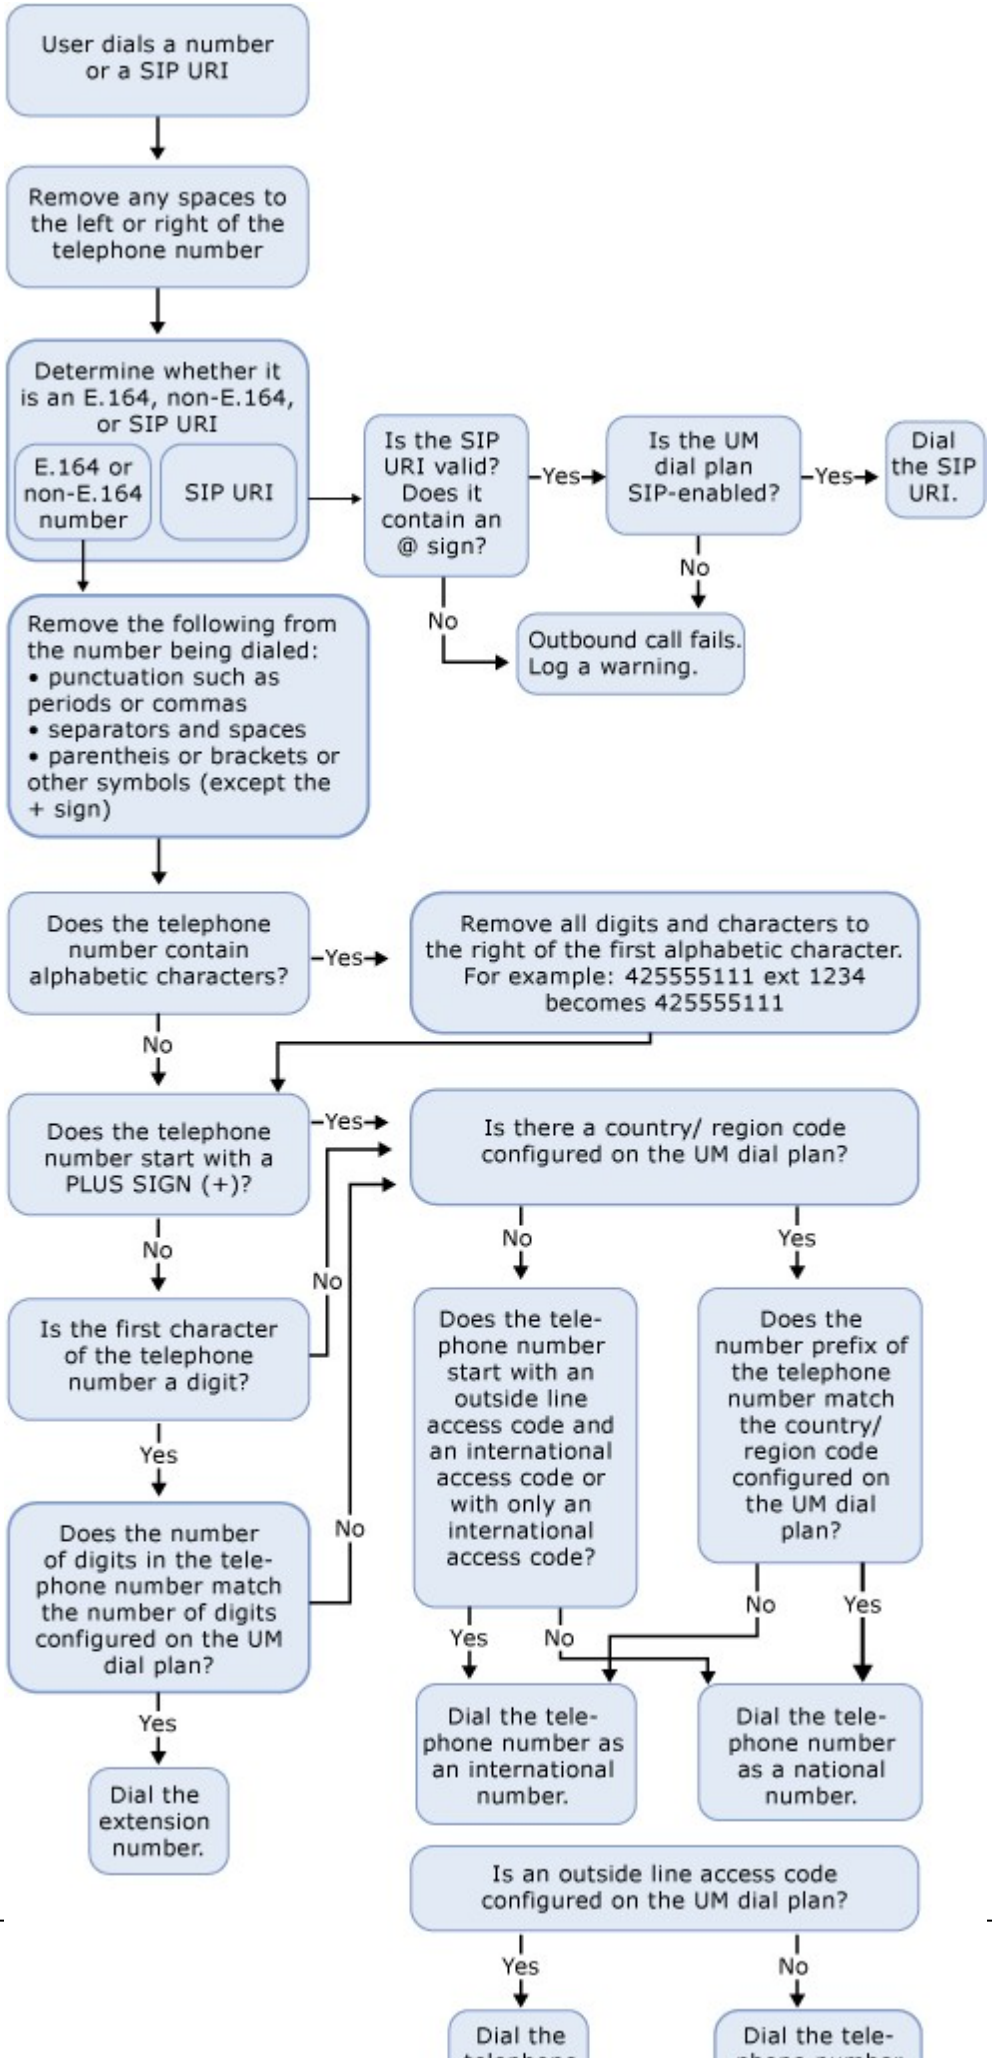
There are several settings that you must configure to control outdialing for your organization. To control outdialing, you must configure the UM dial plans, auto attendants, and UM mailbox policies in Exchange 2010 Unified Messaging. The following settings can be configured on UM dial plans, auto attendants, and UM mailbox policies to control outdialing:

- Outside line, country/region, and international access codes
- National number prefixes
- In-country/region and international number formats
- In-country/region and international dialing rule groups
- Allowed in-country/region and international dialing rule groups
- Dialing rule entries

You configure access codes, number prefixes, and number formats on a UM dial plan on the **Dial Codes** tab in the Exchange Management Console. You can also configure the settings using the **Set-UMDialPlan** cmdlet. You can choose to configure all the settings, none of the settings, or only some of the settings. However, each setting controls a specific part of the outdialing process.

Access codes, number prefixes, and number formats are used by a Unified Messaging server to determine the correct number to dial and can be configured to restrict outgoing calls for users who dial in to a UM auto attendant associated with a UM dial plan or when users dial in to the subscriber access number configured on the dial plan. The following figure illustrates the outdialing process and how access codes can be used to control outdialing.

Outdialing overview



User dials a number or a SIP URI
Remove any spaces to the left or right of the telephone number
Determine whether it is an E.164, non-E.164, or SIP URI
E.164 or non-E.164 number
SIP URI
Is the SIP URI valid? Does it contain an @ sign?
Yes
Is the UM dial plan SIP-enabled?
Yes
Dial the SIP URI.
No
Outbound call fails. Log a warning.
No
Remove the following from the number being dialed:
• punctuation such as periods or commas
• separators and spaces
• parentheis or brackets or other symbols (except the + sign)
Does the telephone number contain alphabetic characters?
Yes
Remove all digits and characters to the right of the first alphabetic character. For example: 425555111 ext 1234 becomes 425555111
No
Does the telephone number start with a PLUS SIGN (+)?
Yes
Is there a country/ region code configured on the UM dial plan?
No

Return to top

Outside Line Access Code

An outside line access code should be configured on each dial plan that you create. However, this depends on the type of telephony network that you have and how it's configured. You can configure an outside line access code, also known as a *trunk access code*, on each dial plan that you create. This is the number used to gain access to an outside telephone line. This number is also configured on the Private Branch eXchanges (PBXs) or IP PBXs in your organization. In most telephony networks, users dial the number 9 to gain access to an outside line and place a call to an external telephone number.

If you don't configure the outgoing dial codes on a dial plan, when a Unified Messaging server associated with the dial plan dials an outgoing call, the PBX or IP PBX may not be able to recognize the number string that's sent. If this happens, the PBX or IP PBX can't complete the outgoing call for the user. For example, as stated earlier, in many organizations, the access code that users dial to gain access to an outside line is 9, and this is configured on a PBX or IP PBX. The Unified Messaging server must add the outside line access code (9) before the telephone number string for the PBX or IP PBX to correctly dial the outgoing number. If you configure the dialing code so that the Unified Messaging server will add the outside line access code, the Unified Messaging server will be able to use the outside line access code to access an outside line before it dials the external telephone number string. The dialing code that you configure will apply to all users who are associated with a UM mailbox policy associated with the UM dial plan.

National Number Prefix

The national number prefix and the country/region code can also be configured on a UM dial plan. The number you enter is used by the Unified Messaging server to dial the correct national number prefix or country/region code when a user dials an outgoing call destined within the same country/region or an international call. For example, when a user from North America places an outgoing international call to Europe, the Unified Messaging server will add the national number prefix before the number string that it sends to the PBX to place the outgoing call. The Unified Messaging server will add the number 0 for Europe to the telephone number string. The number 1 is used as the national number prefix for North America.

Country/Region Access Code

A country/region access code can be configured on a UM dial plan. The country/region access code consists of the digits associated with a specific country or region. The country/region access code is used by the Unified Messaging server to dial the correct telephone number when a call is placed to a telephone number from inside the same country or region. The Unified Messaging server will add this number before the number string that it sends to the PBX or IP PBX when it places the outgoing call. For example, the Unified Messaging server will add the number 1 to a call placed from the United States and destined for the United States. For the United Kingdom, the country/region code is 44.

International Access Code

An international access code can be configured on a UM dial plan. The international access code consists of the digits used to access international telephone numbers. The international access code is used by the Unified Messaging server to dial the correct international access code when a call is placed from a telephone number within a country/region but the number being dialed is located in another country/region. The Unified Messaging server will add this number before the number string that it sends to the PBX or IP PBX when it places the outgoing call. For example, the Unified Messaging server will use 011 as the international access code for the United States. For Europe, the international access code is 00.

Return to top

In-Country/Region and International Number Formats

You can configure the incoming call configuration for in-country/region and international number formats on a UM dial plan. After you configure these settings, the Unified Messaging server will be able to recognize incoming calls from inside a country/region and internationally from other UM dial plans within the same Exchange 2010 organization. Configuring these options also enables your organization to save money by preventing outgoing calls that shouldn't be made by users from inside your organization and helps prevent toll fraud. The Unified Messaging server will use the information that you configure to match the number format of the incoming call and verify that the number pattern matches before it accepts the call. For example, you may have multiple dial plans inside an organization that exist within the same Active Directory forest. If you have one dial plan for the United States and another for the United Kingdom, you may want to let users in the United States dial plan have Unified Messaging servers place calls to users who are located in the United Kingdom dial plan but not let the users in the United States dial plan place calls directly to other country/regions or internationally.

1.9.1.3.10 Understanding Name Lookups from a Caller ID

Understanding Name Lookups from a Caller ID

Unified Messaging > Understanding Unified Messaging > Understanding Unified Messaging Features >

Applies to: *Exchange Server 2010 SP3, Exchange Server 2010 SP2*

Topic Last Modified: *2012-02-24*

Unified Messaging (UM) uses information about the calling and called parties to perform a name lookup. This lookup enables a caller's name to be included in the following situations:

- In a missed call notification
- When a caller leaves a voice message for a UM-enabled user if the calling party's name is located in Active Directory or in the called party's personal contacts

Contents

Equivalent Dial Plan Groups

Caller ID

Caller ID is a service that's provided by telephone companies. It can tell a person who's receiving a call the telephone number, and sometimes the name, of the person who's calling and other information about the call. This information is sent over a serial cable by using call signaling. When a call is received by a PBX or IP PBX from a telephone company, the call includes calling identification information such as the following:

- The calling party's number
- The called party's number
- Status codes that indicate such things as the following:
  - Ring-no-answer (The phone rang, but the called party didn't answer.)
  - The state or condition of the telephone line
  - Line busy (The call connected, but the line is busy.)
  - Call forward always (The incoming call is always forwarded to another number.)
- The line or port number that's being used for the call

Name Lookup Process

Unified Messaging uses two data sources to receive information about the calling party and to map it to the name of the caller: Active Directory and personal Contacts. When the name lookup process is successful, the name of the calling party will be inserted into voice mail messages and missed call notifications if they've been enabled for the called party. When an incoming call is received, the calling party information is passed to a Unified Messaging server. The caller can be calling from inside or outside your organization.

In Microsoft Exchange Server 2007 Unified Messaging, a call that was diverted to a Unified Messaging server because of a ring-no-answer or busy condition is answered and a voice message is taken. After the call is answered, Exchange 2007 Unified Messaging tries to resolve the caller ID. It does this so that it can insert a name, rather than a number, into the sender information.

In Exchange 2007, name lookups for voice mail messages are done by using information about a caller who's in the same dial plan as the user being called in one of the following ways:

- Using an EUM proxy address.
- From the personal Contacts of the user receiving the call.
